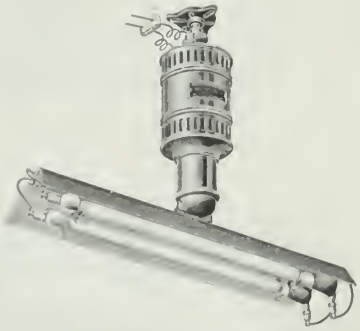
it swivels on two discs. By this means rivet connections are eliminated and it is possible to remove the drawbar without taking down the draft gear.

AUTOMATIC TILTING LAMP.

The automatic, self-tilting lamp, which is shown in the illustration, is manufactured by the Cooper Hewitt Electric Company, Hoboken, N. J., and is similar in most respects to

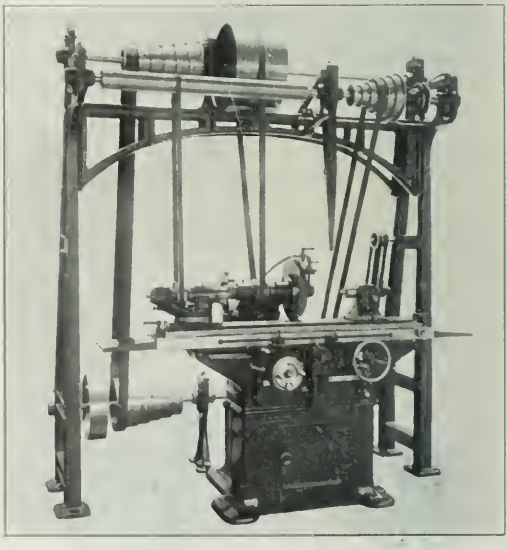


Cooper-Hewitt Automatic Tilting Lamp.

the other mercury vapor lamps manufactured by that company. It has, however, a small solenoid or magnet between the cylinder and the auxiliary and when the circuit is closed, the current flows through the solenoid which tilts the tube for lighting. This makes the automatic lamp particularly desirable for use in places where it would be difficult to reach the lamp to tilt it by hand. The automatic operation insures the relighting of the lamp should there be a momentary interruption of the current supply. In places where the bluish-green light given out by the mercury vapor lamp is not desired, this company is now prepared to fit their lamps with a device known as a light transforming reflector. This is a parabolic rhodomain reflector which takes the place of the standard white glazed reflector and is based on the phenomenon of florescence. This reflector transforms the light to a white with a slight rosy tint.

UNIVERSAL GRINDING MACHINE.

The Morse Twist Drill & Machine Company, New Bedford, Mass., is exhibiting a universal grinding machine with automatic feed and arranged for motor drive, as shown in the illustration. This machine will take wheels 12 in. in diameter and 3/8 to 3/4 in. thick, and 7 in. in diameter and 3/8 in. thick. The wheel spindle is hardened and ground and runs in phosphor bronze boxes, which are arranged for adjustment for wear. The wheel slide is graduated in degrees and is adjusted by a hand wheel and dial, the latter having graduations to express thousandths of an inch on the diameter of the work. The travel of the table is automatic and the reversing is controlled by dogs; the table can be



Universal Grinder Equipped for Motor Drive.

stopped at any point by a lever on the front of the machine, leaving it free to be moved by a hand wheel. A feed box, arranged conveniently on the machine, provides a means, through a lever, of instantly changing the traverse feed from a roughing to a finishing feed. The usual pump and piping are provided for wet grinding, the pump tank is hung on pivots to provide a ready method of cleaning. The overhead apparatus is provided with two shipper arms, one of which controls the drive for the wheel and the feed, and the other the work and the pump. The wheel feeds range from 1,025 to 3,333 r. p. m. in six changes. The weight of the machine is 3,750 lbs., and the floor space occupied is 50 in. by 119 in.

Subscriptions, including 52 regular weekly issues and special daily editions published from time to time in New York, or in places other than New York, payable in advance and postage free:

United States and Mexico	$5.00
Canada	6.00
Foreign Countries (excepting daily editions)	8.00
Single Copies	15 cents each

Engineering and Maintenance of Way Edition and four Maintenance of Way Convention Daily issues, North America, $1.00; foreign, $2.00.

Entered at the Post Office at New York, N. Y., as mail matter of the second class.

WE GUARANTEE that of this issue more than 9,200 copies were printed; that of those more than 9,200 copies, 7,048 were mailed to regular paid subscribers, 200 were provided for counter and news companies' sales; and 1,700 were printed for distribution at Atlantic City and for use as sample copies.

AT the recent convention of the Air Brake Association the operation of triple valves was thoroughly discussed. The undesired quick action of the brakes has been carefully investigated by the Duluth, Missabe & Northern and it was found that the triple valve was the chief cause of this difficulty. That road is now using a high grade of fine dry graphite for the triple valve slide valve, which has practically done away with the trouble. It was also found necessary to use a brake cylinder lubricant that would remain at the same consistency in hot and cold weather; some lubricants become lighter and more penetrating in warm weather, working back on the slide valve feed valve and destroying the beneficial effects of the dry graphite. That road now finds its greatest trouble with foreign cars whose triple valves are not so carefully maintained. If some standard practice was adopted in this matter and strictly adhered to, a very material reduction could be made in the number of break-in-twos, thus reducing the maintenance cost of cars.

IN looking over the machine tool exhibit in Machinery Hall, which is larger this year than most of the railway machine shops of this country, with its whirring wheels and big cuts with high speed tools, one's mind instinctively wanders back a few years to the time when machine tools were few and far between. When the conventions were held at Saratoga power was not available for operating machine tools, and it was only occasionally that such a tool was shown, and then not in operation. The first time that the machine tools were a feature of any convention of railway officers was at the International Railway Congress meeting at Washington in 1905. At that time, owing to the efforts of J. Alexander Brown, the secretary and director of the exhibit, a considerable number of tools was shown in operation. The machine tool builders were so pleased with the result that a number of tools were shown at the next meeting of the M. M. and M. C. B. conventions which was held on the steel pier. Because of the weight carrying limitations of the steel pier the larger machine tools could not be accommodated, but in spite of this a considerable number of such tools was shown during the two years the conventions were held there. The Million Dollar Pier afforded such good facilities for this purpose that the exhibit has grown steadily ever since. This year practically all the space in Machinery Hall, 360 ft. long by 45 ft. wide, is given over to machine tools and one need only to stroll through it at any time during the day to be convinced of its popularity with the convention attendants.

THE young railway men and supply men attending these conventions can do themselves great and permanent good by looking about them, and taking careful note of certain very important developments that are occurring in the railway and supply business. The developments in question are all closely associated with a very marked moral awakening that is taking place throughout the entire business world. It has not been many years since personal conduct and business methods prevailed generally, and were generally tolerated, which to-day are avoided, repudiated and condemned by every man who has any real self-respect or desire for the respect of others. There are a few here and there, some of them in very high places in the railway and supply business, who are so lacking in moral sense, or so incapable of observing the trend of the times, or have so much contempt for public opinion, that they do not, and perhaps cannot, come up to modern standards in their manners and conduct. Some of them have been able up to the present time, in spite of this, to maintain their positions in the railway and supply business. But hardly a day passes without some event ocurring which shows there is no man in the railway or supply business who is too big to be reached and disgraced, if not actually ruined, if he persists in the use of methods that defy public opinion and fall below a high standard of decency and honor. The railway and supply history of this country in recent years is strewn with the wreckage of little men and big men who have had the notion, equally reprehensible and stupid, that they could persistently over-ride and defeat the opinions of their fellows, and the dictates of law and of morals. The young men attending these conventions will profit greatly if they will learn *now* that they are living in a new era; that the old ways are not the new ways; that certain methods that formerly were condoned and sometimes spelled success are now condemned and denounced and spell certain failure; and that not only the future, but the immediate present, belongs to the decent man, to the square man, to the man who helps to make the right kind of public opinion and who then respects and heeds the kind of public opinion that he knows to be right.

THE problem of increasing the efficiency of common labor in railroad shops and repair yards is a most difficult one and must be given more attention, as suggested by President Crawford in his address on Wednesday morning. The need of employing interpreters, or of having foremen who can understand foreign languages and thus direct the men to the best advantage, has not been as apparent in the motive power and car department as in maintenance of way work. Mr. Crawford's idea, however, is that as the demand for common labor increases, more and more of the foreign element will find employment in the mechanical department and that conditions will be much improved if the foremen, and particularly those in charge of unskilled and semi-skilled labor, become proficient in a foreign language, thus avoiding the necessity of using interpreters, which is usually a more or less unsatisfactory arrangement. Mr. Crawford's suggestion that more attention be given this phase of the problem is, therefore, an excellent one. There is another problem which involves the skilled, as well as the unskilled employes, and should be given immediate atten-

tion. It is the more careful selection and assignment of workmen for the different classes of work. The necessity of this has been realized in the railway shops of several of the European countries, and more particularly in the Hungarian State Railways. The practice of that railway system in the shops at Buda Pesth was described in a series of articles on Impressions of Foreign Railway Practice by H. W. Jacobs, which appeared in the *Railway Age Gazette* during the past few months. The personality and characteristics of each man are carefully studied during his apprenticeship, and he is later assigned to the particular kind of work for which he is best fitted. In this country comparatively little attention has been given to this matter, except in a few isolated cases, none of which, as far as we can find, are on railroads. Of course, a good executive intuitively selects the men who are best qualified for work in his department, but in these days of large organizations, more scientific methods must be used in order that the efficiency of the organization as a whole shall not unnecessarily suffer. Possibly the most advanced exponent of this theory is Dr. Katherine Blackford. She has had unusual success and has discovered and outlined certain principles which should govern the selection of employes. These include not only a study of the physical characteristic and character of the workman and the class of work for which it is proposed to use him, but also the personality of the man he is to work for, or the boss, as she calls him. While her methods and views are so advanced as to be beyond the comprehension of many of those in charge of forces of workmen, there can be no question as to the value of a more scientific study of this problem, and the Master Mechanics' Association can well afford to give it more attention.

GEARING IN MACHINE TOOLS.

AMONG the most important features of the extensive improvements in machine tools in recent years is the full appreciation, by some of the builders, of the value of proper material, properly treated, for the gearing. In the earlier stages of machine tool building, cast iron was exclusively used for gears and pinions, and it has a number of advantages for this use. Because of the large percentage of uncombined carbon in it, it is practically self-lubricating and will run without serious wear with the minimum of oil, or even with no oil at all. Furthermore, its cheapness and ease of machining, and the convenience of obtaining the rough stock in case of an emergency, make it attractive. Its structural weakness and inability to withstand shocks, however, make it unsuitable for use on many of the modern, high power, machine tools, except for a few unimportant gears.

With the advent of steel gears came the necessity of more thorough lubrication, as this material is in no degree self-lubricating and wears rapidly when run dry. It has been found, however, that, even with what would ordinarily be considered good lubrication, the quality of material used makes a surprising difference in the wearing qualities and strength of the teeth. One of the large machine tool manufacturers has exhaustively investigated this subject during the past four or five years and developed some valuable information. The first steel gears were made from ordinary spindle steel having a carbon content of about 40 points. A gear was made from this material without further treatment and was run under working conditions with a pinion of similar material case-hardened. Grease was used for lubrication. The gear wore rapidly, and it was clearly shown that this material was not suitable in that form. Trials with the same combination running in oil gave better results, but by no means satisfactory service. A pair of gears of the same steel both case-hardened, was then tried running in oil. The wearing qualities were practically perfect, but it was found that the process of case-hardening had apparently affected seriously the interior structure of the teeth and they were not able to properly withstand a shock or even a heavy strain.

Trials were next made with two gears of a high carbon alloy steel, case-hardened. These showed practically the same structural weakness and were discarded. The experience thus far indicatd that case-hardening, while excellent to produce the desired wearing qualities, apparently weakened the best material to a serious extent. Oil tempered manganese steel with a low carbon content was then tried. This gave much better results, but still the wear was more than it was believed should take place. The strength was found to be satisfactory. An investigation of the practice of some of the leading automobile manufacturers was then made, and the next tests were with a material that had been found suitable for that purpose. This is a heat treated, oil hardened, nickel-chromium steel. These gears fulfilled all requirements both as to wear and strength when the treatment and composition were exactly right. A great variation was found in the result by an error even as low as 25 deg. in the temperature at which it is hardened. Furthermore, the exact proportions of the alloys are found to be of equal importance. Experiments with steel of this kind made from ores having the desired elements in natural combination were not successful, and all the later experiments point to the vital importance of exactness in the composition and treatment. In the case of this manufacturer, this feature is believed to be of so great importance that a complete chemical and physical laboratory for testing steels is being installed.

This is but one example of the way in which the problems of producing a high grade, modern machine tool are being solved. It is becoming better understood that the present demands for output from machine tools of all kinds require the employment of the highest grade of engineering skill and the use of materials which were practically unknown a few years ago. It is comparatively easy to build a lathe, shaper or drill press which will take a very heavy cut, but to produce such a machine which will continue to do it accurately and without failure of parts is a problem of considerable magnitude. That many are doing it speaks well for the continued progress of the industry.

A CRITICISM, AND AN ANSWER.

Atlantic City, June 13, 1913.

To the Editor of The Railway Age Gazette:

These conventions are really a post graduate course for railroad men, who come here to exchange ideas and match experience with the keenest intellects in their line of endeavor. Here they discuss problems, adjust differences, acquire knowledge and deal in facts, born of actual experience, all with a view to formulating rules for the safety, advancement and betterment of railroad operations.

Most professions offering a post graduate course to their members supplement the work of the lecture room and the convention hall with a *practical clinic* and this world-wide, every-day working university of railroad mechanical construction and operation has a valuable clinic, supplied by men whose interests dove-tail very closely with that of their railroad customers.

This clinic each year increases its scope and aims to extend its usefulness, but each year there is a growing feeling on the part of those who provide this feature of the convention that the exhibits are not receiving their share of attention.

Is the clinical feature of this convention being neglected and are its possibilities as factors in the progress and development, so earnestly desired by all, being underestimated to an extent that will lead the manufacturers to conclude that their efforts to contribute their mite in the form of this educational work are not appreciated?

There is a serious thought back of this question, involving as it does the consideration of the futility of coöperation that is apparently one-sided. In the joy of fellowship the serious business feature of these occasions should not be neglected, and the fact that the exhibits offer educational advantages, second only to the benefits of the meetings themselves, cannot be overlooked without serious injustice to both interests involved.

Tom Lehon.

The *Railway Age Gazette* gladly publishes Mr. Lehon's letter. But, while it agrees fully with what he says as to the merits of the exhibitions, it does not believe that the railway men attending the conventions fail, as he seems to imply, to take full advantage of it. Doubtless many of them might give more attention to it; but most of them do give a great deal of attention to it. Furthermore, the amount of time railway men give to the exhibits has been increasing year by year. They are of great mutual benefit to the supply men and the railway men, and never in our opinion, has this been more true than it is this year.

PROGRAM OF THE WEEK.

MASTER CAR BUILDERS' CONVENTION.

MONDAY, JUNE 16.

9.30 A. M. to 1.30 P. M

Address by the president	9.30 A. M. to 10.30 A. M.
Reading of the minutes of the last meeting	10.30 A. M. to 10.35 A. M.
Report of secretary and treasurer	10.35 A. M. to 10.50 A. M.
Assessment and announcement of annual dues; appointment of committees on correspondence, resolutions, obituaries, etc	10.50 A. M. to 11.00 A. M
Election of auditing committee	11.00 A. M. to 11.05 A. M.
Unfinished business	11.05 A. M. to 11.10 A. M.
New business	11.10 A. M. to 11.20 A M
Discussion of reports on:	
Nominations	11.20 A. M. to 11.30 A. M.
Revision of standards and recommended practice	11.30 A. M. to 11.45 A. M.
Train brake and signal equipment	11.45 A. M. to 12.00 M.
Brake shoe and brake beam equipment	12.00 M. to 12.30 P. M.
Coupler and draft equipment	12.30 P. M. to 1.00 P. M.
Car wheels	1.00 P. M. to 1.30 P. M.

3.00 O'CLOCK P. M.

The executive committee decided that it would be best to have a session devoted exclusively to a discussion of the revision of the rules of interchange. Heretofore it has been the custom to hold an informal discussion on the report of the arbitration committee on the revision of these rules, and no record made of the meeting except that possibly the arbitration committte might make some changes in its recommendations. The record of this meeting will now be a part of the proceedings.

At this session the following reports of committees will be considered:

1. Arbitration committee.
2. Conference with Association of American Railway Accounting Officers.
3. Revision of Prices for Labor and Material.

TUESDAY, JUNE 17.

9.30 TO 1.30 P. M.

Discussion of Reports on:	
Safety Appliances	9.30 A. M. to 9.45 A. M.
Rules for Loading Materials	9.45 A. M. to 10.00 A. M.
Overhead Inspection	10.00 A. M. to 10.15 A. M.
Car Trucks	10.15 A. M. to 10.45 A. M.
Train Lighting and Equipment	10.45 A. M. to 11.30 A. M.
Train Pipe and Connection for Steam Heat	11.00 A. M. to 11.15 A. M.
Tank Cars	11.15 A. M to 11.45 A. M.
Specifications for Tests of Steel Truck Sides and Bolsters for Cars of 80,000, 100,000 and 150,000 Pounds Capacity	11.45 A. M. to 12.00 M.
Topical Discussion:	
Retirement from Interchange Service of Cars of 40,000 and 50,000 Pounds Capacity	12.00 M. to 12.30 P. M.
Discussion of Reports on:	
Capacity Marking of Cars	12.30 P. M. to 1.00 P. M.
Lettering Cars	1.00 P. M. to 1.30 P. M.

WEDNESDAY, JUNE 18.

9.30 A. M. TO 1.30 P. M.

Discussion of Reports on:	
Damage to Freight by Unloading Machines	9.30 A. M. to 10.00 A. M.
Air-brake Hose Specifications	10.00 A. M. to 10.30 A. M.
Revision of Present Specifications	10.30 A. M. to 11.30 A. M.
Car Construction	11.00 A. M. to 11.30 A. M.
Unfinished business; Reports of Committees on Correspondence, Resolutions, and such other committees as may be named during the convention	11.30 A. M. to 11.45 A. M.
Election of Officers	11.45 A. M. to 1.30 P. M.

Adjournment.

ENTERTAINMENTS.

MONDAY, JUNE 16.

Orchestra Concert, 10.30 A. M.—Entrance Hall, Million Dollar Pier.

Orchestra Concert, 3.30 P. M.—Entrance Hall, Million Dollar Pier.

Social Gathering and Informal Dance, 9.00 P. M.—Blenheim Exchange, Marlborough-Blenheim Hotel.

TUESDAY, JUNE 17.

Orchestra Concert, 10.30 A. M.—Entrance Hall, Million Dollar Pier.

Orchestra Concert, 3.30 P. M.—Entrance Hall, Million Dollar Pier.

Informal Dance, 9.30 P. M.—Entrance Hall, Million Dollar Pier.

B. & O. CLUB.

The annual meeting of the B. & O. Club will be held in the Park Place Hall of the Marlborough-Blenheim hotel at 3.30 this afternoon.

LOST.

Supply men's badge No. 2563. Please return to the enrollment booth.

Badge No. 3448 was lost Friday evening, probably on the pier. Finder please return to Secretary Conway's office.

A card case containing personal cards and a railroad ticket to Washington, D. C. Finder please return to T. G. Smallwood, Room 555, Dennis Hotel.

SUPPLY MANUFACTURERS' ANNUAL MEETING.

The annual meeting of the Railway Supply Manufacturers' Association was held in Convention Hall Saturday morning. The attendance was large. President Allen's annual report consisted simply of brief remarks to the effect that the affairs of the association were in excellent shape.

Officers for the ensuing year were chosen as follows:

President, Benjamin A. Hegeman, Jr.

Vice-president, J. Will Johnson.

Members of the executive committee, C. B. Yardley, Jr., J. C. Currie, C. F. Elliott and Joseph H. Kuhns.

In retiring from the chair in favor of the new president Mr. Allen received a rousing vote of thanks.

VISIT THE COUPLER EXHIBIT.

The coupler committee's report will be received and discussed at about noon to-day and if possible every member should visit the committee's exhibit, if only for a few minutes, before the report is presented. The exhibit is just beyond the Convention Hall and consists of nine special designs which have been submitted by different manufacturers, from which it is expected that it will be possible to select one standard design.

In 1911 the coupler committee was authorized to prepare a standard design. Since that time it has given considerable attention to studying the weak points of couplers on roads

where the service is exceptionally severe, and has worked jointly with the coupler manufacturers in outlining the requirements and specifications for a standard design.

Six companies have designed couplers, which according to their experience will best fill these requirements, and they are on exhibition so that the members may examine them carefully and come to some conclusion as to the most satisfactory design. The companies are the Buckeye Steel Castings Company, American Steel Foundries, Gould Coupler Company, The McConway & Torley Company, National Malleable Castings Company and Monarch Steel Castings Company. It is also proposed to change the contour in order to strengthen the coupler, and templates are on exhibition showing the changes which are recommended for consideration.

VALUATION BOARD NEEDS MECHANICAL EXPERTS.

The Interstate Commerce Commission has issued applications for the examinations of men acquainted with railroad operation and construction who desire to enter the government service in connection with the work of appraising the physical property of the railroads. The commission wants a large staff of structural, electrical, mechanical, railway signal, and civil engineers, inspectors of car equipment and motive power, and architects. The salaries will range from $1,080 to $4,800, but as the work mainly takes them away from Washington expenses will be allowed while on duty. July 21 has been fixed as the closing date for the filing of applications.

M. C. B. ASSOCIATION OFFICERS 1911-1912.

President, C. E. Fuller, A. G. M., Union Pacific Ry.

Vice-presidents, M. K. Barnum, G. S. M. P., Illinois Central R. R.; D. F. Crawford, G. S. M. P., Penna. Lines; D. R. MacBain, S. M. P., L. S. & M. S. Ry.

Treasurer, Jno. S. Lentz, M. C. B., Lehigh Valley Ry.

Secretary, Jos. W. Taylor, 390 Old Colony Building.

Executive members, Henry LaRue, M. C. B., C., R. I. & P. Ry.; R. E. Smith, G. S. M. P., Atlantic Coast Line R. R.; C. E. Chambers, S. M. P., Central R. R. of N. J.; F. W. Brazier, S. R. S., N. Y. C. & H. R. R. R.; C. A. Schroyer, S. C. D., C. & N. W. Ry.; Alex. Kearney, A. S. M. P., Norfolk & Western Ry.

M. C. B. ASSOCIATION COMMITTEES.

STANDING COMMITTEES.

Arbitration:—J. J. Hennessey (Chairman), M. C. B., C. M. & St. P. Ry.; T. W. Demarest, S. M. P., Penna. Lines; J. S. Lentz, M. C. B., Lehigh Valley R. R., So. Bethlehem, Pa.; M. K. Barnum, Chicago, F. W. Brazier, S. R. S., N. Y. C. & H. R. R. R.

Revision of Standards and Recommended Practice:—T. H. Goodnow (Chairman), A. S. C. D., C. & N. W. Ry.; W. E. Dunham, Supervisor M. P., C. & N. W. Ry.; W. H. V. Rosing, Asst. to V. P., St. L. & S. F. R. R.; C. E. Fuller, A. G. M., Union Pacific R. R.; T. M. Ramsdell, M. C. B., Ches. & Ohio Ry.; O. C. Cromwell, M. E., Balto. & Ohio R. R.; O. J. Parker, G. C. I., Penna Lines.

Train Brake and Signal Equipment:—R. B. Kendig (Chairman), G. M. E., N. Y. C. Lines; B. D. Flory, S. M. P., N. Y. O. & W. Ry.; F. W. Pratt, A. S. M. P., C. & N. W. Ry.; R. K. Reading, S. M. P., Penna. R. R.; L. P. Streeter, Air Brake Engr., Ill. Cent. R. R.

Brake Shoe and Brake Beam Equipment:—Chas. H. Benjamin (Chairman), Purdue University; C. D. Young, Eng. Tests, Penna. R. R.; R. B. Kendig, G. M. E., N. Y. C. Lines.

Coupler and Draft Equipment:—R. L. Kleine (Chairman), C. C. I., Penna. R. R.; G. W. Wildin, M. S., N. Y. N. H. & H. R. R.; F. W. Brazier, S. R. S., N. Y. C. & H. R. R. R.; I. H. Stark, Supt. Pittsburgh Coal Co.; J. F. DeVoy, A. S. M. P., C. M. & St. P. Ry.; H. L. Trimyer, M. C. B., S. A. L. R. R.; B. Julien, G. F. C. D., Union Pacific R. R.

Rules for Loading Materials:—A. Kearney (Chairman), A. S. M. P., N. & W. Ry.; R. E. Smith, G. S. M. P., A. C. L. R. R.; L. H. Turner, S. M. P., P. & L. E. R. R.; W. F. Kiesel, Asst. Mech. Engr., Penna. R. R.; J. M. Borrowdale, S. C. D., Ill. Cent. R. R.; C. N. Swanson, S. C. S., A. T. & S. F. Ry.; G. H. Gilman, M. C. B., Northern Pac. Ry.

Car Wheels:—Wm. Garstang (Chairman), S. M. P., C. C. C., & St. L. R. R.; W. C. A. Henry, S. M. P., Penna. Lines; A. E. Manchester, S. M. P., C. M. & St. P. Ry.; R. W. Burnett, G. M. C. B., Can. Pac. Ry.; R. L. Ettenger, C. M. E., Southern Ry.; J. A. Pilcher, M. E., N. & W. Ry.; O. C. Cromwell, M. E., B. & O. R. R.

Safety Appliances:—C. E. Fuller (Chairman), A. G. M., Union Pac. Ry.; A. Stewart, G. S. M. P. & E., Southern Ry.; A. LaMar, M. M., Penna. Lines; C. B. Young, M. E., C. B. & Q. R. R.; H. Bartlett, G. S. M. P., B. & M. R. R.; M. K. Barnum, Chicago; W. O. Thompson, M. C. B., N. Y. C. & H. R. R. R.

SPECIAL COMMITTEES.

1. Car Trucks.—J. T. Wallis (Chairman), G. S. M. P., Penna. R. R.; J. R. Gould, G. S. M. P., Ches. & Ohio Ry.; E. W. Pratt, A. S. M. P., C. & N. W. Ry.; R. W. Burnett, G. M. C. B., Can. Pac. Ry.; Jas. Coleman, S. C. D., Grand Trunk Ry.; J. J. Tatum, S. F. C. D., B. & O. R. R.; G. A. Hancock, G. S. M. P., St. L. & S. F. R. R.

2. Prices for Labor and Material.—F. H. Clark (Chairman), G. S. M. P., B. & O. R. R.; G. E. Carson, D. M. C. B., N. Y. C. & H. R. R. R.; C. F. Thiele, G. C. I., P. C. C. & St. L. Ry.; Ira Everett, G. F. C. R., Lehigh Valley Ry.; S. T. Park; H. E. Passmore, M. M., T. & O. C. Ry.; J. F. Dunn, A. G. M., Oregon Short Line R. R.

3. Train Lighting and Equipment.—T. R. Cook (Chairman), A. E. M. P., Penna. Lines; C. A. Brandt, M. E., C. C. C. & St. L. Ry.; Ward Barnum, Elec. Engr., L. & N. R. R.; J. H. Davis, Elec. Engr., B. & O. R. R.; C. H. Quinn, A. E. M. P., N. & W. Ry.; D. J. Cartwright, Elec. Engr., Lehigh Valley R. R.; E. W. Jansen, Elec. Engr., Illinois Central R. R.

4. Train Pipe and Connections for Steam Heat.—I. S. Downing (Chairman), M. C. B., L. S. & M. S. Ry.; C. A. Schroyer, S. C. D., C. & N. W. Ry.; T. H. Russum, S. P. C. D., B. & O. R. R.; J. J. Ewing, M. E., C. & O. Ry.; W. C. Arp, S. M. P., Vandalia R. R.

5. Nominations:—F. W. Brazier (Chairman), S. R. S., N.Y. C. & H. R. R. R.; A. W. Gibbs, C. M. E., Penna. Lines; C. A. Seley, Chicago, Ill.; C. A. Schroyer, S. C. D., C. & N. W. Ry.; F. H. Clark, G. S. M. P., B. & O. R. R.

6. Arrangements:—C. E. Fuller, A. G. M., Union Pacific Ry.

7. Tank Cars:—A. W. Gibbs (Chairman), C. M. E., Penna Lines; Thos. Beaghan, Jr., M. C. B., Union Tank Line; J. W. Fogg, M. M., B. & O., Chgo. Ter. Ry.; S. K. Dickerson, S. M. P., L. S. & M. S. Ry.; C. E. Chambers, S. M. P., C. R. R. of N. J.; E. J. Searles, S. M. P., B. & O. R. R.; Wm. Schlafge, G. M. S., Erie R. R.; C. A. Shoemaker, G. S. German-American Car Lines.

8. Specifications for Tests of Steel Truck Sides and Bolsters for Cars of 80,000, 100,000, and 150,000 Pounds Capacity:—E. C. Schmidt (Chairman), University of Illinois; J. S. Sheafe, Engr. Tests, Illinois Central R. R.; C. D. Young, Engr. Tests, Penna. R. R.

9. Capacity Marking of Cars:—C. E. Fuller (Chairman), A. G. M., Union Pacific R. R.; M. K. Barnum, Chicago; A. W. Gibbs, C. M. E., Penna. Lines; F. H. Clark, G. S. M. P., B. & O. R. R.; D. R. MacBain, S. M. P., L. S. & M. S. Ry.

10. Lettering Cars:—D. F. Crawford (Chairman), G. S. M. P., Penna. Lines; F. H. Clark, G. S. M. P., B. & O. R. R.; F. A. Torrey, G. S. M. P., C. B. & Q. R. R.; D. R. MacBain, S. M. P., L. S. & M. S. Ry.

11. Damage to Freight Equipment by Unloading Machines:—

P. F. Smith, Jr. (Chairman), S. M. P., Penna. Lines; J. J. Tatum, S. C. D., Balto. & Ohio R. R.; E. A. Westcott, S. C. D., Erie R. R.; I. S. Downing, M. C. B., L. S. & M. S. Ry.; J. J. Birch, D. C. I., Norfolk & Western Ry.; C. S. Morse, M. C. B., Wheeling & Lake Erie R. R.

11. Air-brake Hose Specifications—M. K. Barnum (Chairman); J. R. Onderdonk, Engr. Tests, B. & O. R. R.; J. J. Birch, D. C. I., N. & W. Ry.; C. D. Young, Engr. Tests, Penna. R. R.; A. J. Cota, M. M., C. B. & Q. Ry.; I. S. Downing, M. C. B., L. S. & M. S. Ry.; T. H. Goodnow, A. S. C. D., C. & N. W. Ry.

13. Conference with the Association of American Railway Accounting Officers:—D. F. Crawford, G. S. M. P., Penna Lines; C. E. Fuller, A. G. M., Union Pacific R. R.; M. K. Barnum.

14. Revision of Present Specifications:—C. D. Young (Chairman), Engineer Tests, Penna. R. R.; J. S. Sheafer, Engineer Tests, Ill. Cent. R. R.; J. W. Taylor, Secretary.

15.—Car Construction.—W. F. Kiesel, Jr., (Chairman), A. M. E., Penna. R. R.; C. A. Seley, American Flexible Bolt Co.; A. R. Ayres, G. M. E., L. S. & M. S. Ry.; S. G. Thomson, S. M. P. & R. E., Phila. & Reading Ry.; C. E. Fuller, A. G. M., Union Pacific R. R.

THE TRACK EXHIBIT.

A most interesting feature of this year's track exhibit is the inspection locomotive of the Philadelphia & Reading. This locomotive was built at the Reading shops of the company and is of the Atlantic (4-4-2) type, with screw reverse gear and piston valves. It is electrically lighted throughout, has nickel plated cab fittings and is very handsomely finished. Beside the steel postal car built for the Chicago, Milwaukee & St. Paul by the American Car & Foundry Company, there are included in this exhibit a Southern Pacific box car equipped with the Van Dorn steel end, a gondola car with the Ditchfield door operating gear and the Standard Car Truck Company's four-point bearing flat car. There is also a flat car containing the Jacobs-Shupert and radial stay fireboxes which were used in the Coatesville tests last year, and an electric locomotive built by the General Electric Company and the American Locomotive Company for the Butte, Anaconda & Pacific.

CORNELL DINNER.

Thirty-one alumni of Cornell University and two guests met for their eighth annual dinner in Atlantic City on Friday evening at the Marlborough-Blenheim. B. P. Flory, '95, superintendent of motive power, New York, Ontario & Western, presided as president. Songs, stories and a discussion of educational policies in connection with training for a railroad career enlivened the meeting. It was decided to invite a representative of the faculty of Sibley college to address the meeting in 1914. C. P. Storrs, '95, Storrs Mica Company, was elected president for the next year. The success of the meeting was largely due to the activity of A. S. Lewis, Cleveland-Chicago Car Roofing Company.

The following were present: B. P. Flory, '95, president, superintendent of motive power, New York, Ontario and Western; F. F. Gaines, '95, superintendent of motive power, Central Railroad of Georgia; R. L. Gorden, '95, Standard Steel Car Company; F. M. Whyte, '89, Hutchins Car Roofing Company; A. S. Lewis, '02, Chicago-Cleveland Car Roofing Company; R. S. Cooper, '03, Independent Pneumatic Tool Company; H. A. Rogers, '03, Woven Steel Hose and Rubber Company; G. W. Ristine, Jr., '01, Pressed Steel Car Company; H. H. Gilbert, '07, Pressed Steel Car Company; F. L. Siryer, '03, North Western Malleable Iron Company; F. H. Park, '92, Westinghouse Air Brake Company; J. N. Mowery, '99, Keystone Lubricating Company; C. D. Young, '02, Engineer of Tests, Pennsylvania; C. B. Goodspeed, '08, Buckeye Steel Castings Company; J. H. Mitchell, '95, Pressed Steel Car Company; E. A. Averill, '00, *Railway Age Gazette;* G. T. Johnson, '06, Buckeye Steel Castings Company; L. B. Jones, '04, assistant engineer of motive power, Pennsylvania Lines West, F. N. Bard, '04, Barco Brass and Joint Company; E. B. Clark, '94, Celfor Tool Company; J. H. Wynne, '98, American Locomotive Company; L. H. Snyder, '00, Dixon Graphite Company; W. E. Dunham, '95, supervisor motive power and machinery, Chicago & North Western; A. R. Ayres, '00, General mechanical engineer, New York Central Lines; G. S. Goodwin, '99, mechanical engineer, Chicago, Rock Island & Pacific; C. P. Storrs, '95, Storrs Mica Company; R. R. Harrison, '08, Watson Stillman Company; Walter Smith, '08, Delaware & Hudson; A. C. Morgan, '90, Chicago Varnish Company; J. F. DeVoy, '93, assistant superintendent of motive power, Chicago, Milwaukee & St. Paul; W. G. Ransome, '99, The Bettendorf Company. The guests were T. R. Cook, Wisconsin, '00, assistant engineer of motive power, Pennsylvania Lines West, and J. H. Thomas, Standard Paint Company.

PAST PRESIDENTS, M. C. B. ASSOCIATION.

I. W. Van Houten	1867-68-69, 1873
F. D. Adams	1870-1871
M. C. Andrews	1872
Leander Garey	1874-1885
B. K. Verbryck	1885-1887
Wm. McWood	1887-1890
Jno. Kirby	1891-1893
E. W. Grieves	1893-1895
J. S. Lentz	1895-1897

F. H. Clark	1909-1910
T. H. Curtis	1910-1911
Alexander Stewart	1911-1912

DEATH OF ANDREW S. CROZIER.

Andrew S. Crozier, attached to the New York office of the American Steel Foundries as salesman, died suddenly of heart failure in the room of his hotel at Atlantic City Saturday evening. Mr. Crozier seemed to be in his usual good health during the day. He retired to his room in the early evening to dress for a dinner engagement, but did not appear at the appointed time. He was found lying on his bed and a hastily summoned physician pronounced him dead.

Mr. Crozier had been associated with the American Steel Castings Company and its successor, the American Steel Foundries, for the past sixteen years. He came from a fine Philadelphia family and was always highly regarded in business and social circles. He had never married. He was born at Rockdale, Pa., March 16, 1863. He was a member of several societies. He was a Mason, a Shriner, a member of the Camp Bradbury Sons of Veterans, a member of the Machinery Club, the Railroad Club in New York and the New England Railway Club. His brothers, William M. and H. D. Crozier, took the body to Ridley Park, Pa., where the funeral services were held.

PENNSYLVANIA SHOPMEN GIVE BAND CONCERT.

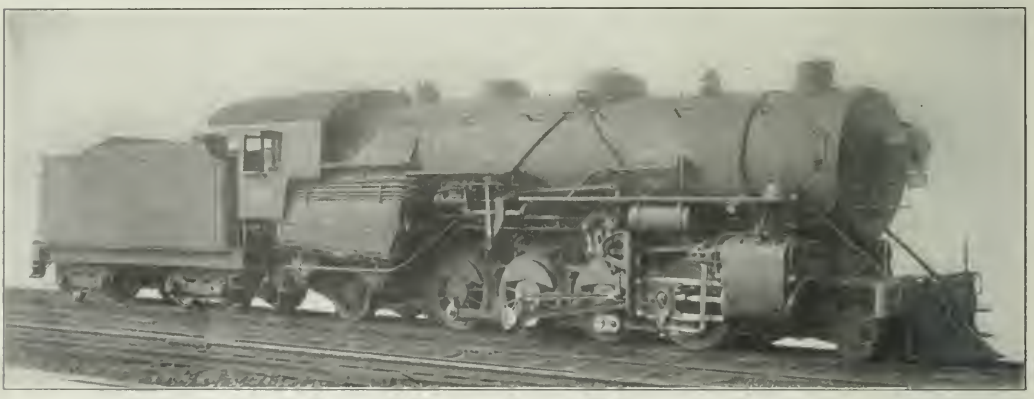
A band concert was given yesterday morning and afternoon in the entrance hall of the Million Dollar Pier by the Enola Pennsylvania Railroad Y. M. C. A. band, composed

entirely of shopmen employed by the Pennsylvania Railroad at the Enola shops.

The band was organized about four years ago with 15 pieces and has since been increased to 45 pieces. It has played every year at the principal conventions in the state of Pennsylvania and has given many special concerts. Supported by the Y. M. C. A. at Enola, it is now almost self sustaining, receiving no assistance from the railroad company except free transportation. The band was organized by H. G. Hassler, now president and general manager of the band, who is foreman of the car shops at Enola and much of its success is due to his efforts. Enola is a town of 1500 inhabitants and no other town of its size in the state has a band of its size and quality. The band is directed by George F. Tyrrell, a retired army officer.

MIKADOS FOR THE LEHIGH VALLEY.

The first Mikado locomotives built by the Baldwin Locomotive Works for the Lehigh Valley were put in service in 1903. These engines were equipped with balanced slide valves and Stephenson link motion, and used saturated steam. The road has recently received, from the same builders, 17 locomotives of the same type which use superheated steam, and are equipped with piston valves, and Walschaert gear. They are large engines of their type, and represent a decided increase in capacity over the previous ones.



Powerful Slow Speed Freight Locomotives; Lehigh Valley.

The total equivalent heating surface of the new locomotives, according to the usual method of calculation, is 6472 sq. ft. For an increase in total weight of 38 per cent., there is an increase in tractive effort of 33 per cent and of total heating surface of 81 per cent. The ratio of tractive effort to total heating surface is 12.2 for the design of 1903, and 8.95 for the new engines. This represents an increase in relative steaming capacity of 36 per cent.

The locomotives illustrated have a ratio of adhesion of 4.02 and with driving wheels 56 in. in diameter they are especially suitable for heavy, slow speed service. As previously indicated, however the boiler power is relatively high, and the design is suitable for long hard runs where there is a constant demand for steam.

The boiler has an extended wagon top, and the firebox is of the modified Wootten type without a combustion chamber. It is exceptionally large, as the depth, in front, is 87½ in., while the grate area is 100 sq. ft., and the firebox heating surface 274 sq. ft. In the design of 1903, the front end of the firebox was immediately over the rear pair of driving wheels; but in the new locomotives the box is back of the wheels, and full advantage has been taken of the opportunity to gain depth. The sides and crown are of 5-16 in. plate, in one piece. The sides and roof of the outside box are also in one piece, the thickness being ½ in. The fuel used is a mixture of bituminous coal and fine anthracite, and it is fired through two circular doors which are placed 38 in. apart transversely. The grate is composed of table bars, arranged in three groups, supported at the sides of the firebox and on two intermediate longitudinal bearers. The bars of each group rock in three sections. No drop plates or water bars are used with this arrangement.

The front end of the firebox crown is supported from two T-bars hung on expansion links. All the staybolts in the throat, with the exception of those in the bottom horizontal row, are flexible; no flexible bolts are used in the sides or back. The small boiler tubes are spaced with ¾ in. bridges. The superheater is unusually large, is of the Schmidt top-header type, with 43 elements, and provides 1101 sq. ft. of superheating surface. Steam is conveyed to the steam chests through outside pipes.

The cylinders are bushed and are fitted with circulating and vacuum relief valves. The steam distribution is controlled by 14-in. piston valves; these are driven by the Walschaert gear, and are set with a lead of 5-16 in. The link and reverse shaft bearings, on each side of the locomotive, are combined in a steel casting which is bolted to the guide yoke. The Ragonnet power gear is applied, the cylinder being bolted to the boiler barrel forward of the firebox. Contrary to the usual practice in locomotives with Wootten fireboxes, the cab is placed at the rear end. The furnace is of such width that it would be difficult to locate a hand reverse lever in a convenient position, but by employing the Ragonnet gear the lever can be mounted on a bracket bolted to the back head of the boiler. Such an arrangement is convenient for the engineman, while it leaves room for a satisfactory grouping of cab fittings.

The frames are of .40 carbon steel, 5½ in. wide, with single front extensions measuring 11 in. deep under the cylinders. The equalization system divides between the second and third pairs of driving-wheels. The spring hangers at this point are pinned to lugs which are cast on a wide frame brace. Strong transverse bracing is also placed at the second and third pairs of driving-pedestals, and under the front end of the firebox, where the rear frames are spliced to the main frames. The brace here carries the radius-bar pin for the back engine truck, and also supports the expansion plate for the mud-ring. The rear truck is of the Rushton type, with inside journals. The spring rigging is arranged with six leaf springs on each side, one being over each driving-box, and one in front and one in the rear of the trailing truck. This provides ample spring support at the rear end, and should insure easy riding.

These locomotives were built in accordance with specifications and drawings prepared by the Railroad company. They have been specially designed to meet conditions existing on the heavy grade sections of the line, and, where practicable, use details

interchangeable with those of locomotives previously built. They constitute an interesting step in the development of eight-coupled anthracite burning locomotives.

Some of the principal dimensions are given in the following table:

Cylinders, diameter and stroke	27 in. x 30 in.
Driving wheels, diameter	56 in.
Driving journals	9 in. x 14 in.
Steam pressure	175 lbs.
Boiler, diameter	83¾ in.
Tubes, number and diameter	264—2¼ in.
Flues, number and diameter	43—5½ in.
Length of tubes and flues	21 ft.
Heating surface, tubes and flues	4,547 sq. ft.
Heating surface, total	4,821 sq. ft.
Grate area	100 sq. ft.
Weight, total	321,800 lbs.
Weight on drivers	232,300 lbs.

NEW VICE-PRESIDENTS OF M. M. ASSOCIATION.

Two new vice-presidents were elected at the closing session of the Master Mechanics' Association, both of whom had previously served upon the executive committee. These were E. W. Pratt, the second vice-president, who is assistant superintendent of motive power and machinery of the Chicago & North Western, and William Schlafge, the third vice-president, who is general mechanical superintendent of the Erie.

E. W. PRATT.
Newly-Elected Second Vice-President, M. M. Association.

WILLIAM SCHLAFGE,
Newly Elected Third Vice-President, M. M. Association.

Mr. Pratt was born at Fort Atkinson, Wis., on June 2, 1869. He is a graduate of the mechanical engineering department of Lehigh University. Before attending college and during his vacations he was engaged with the Chicago & North Western on field work in civil engineering and with the Elgin, Joliet & Eastern during its construction. For a short time after leaving college he was engaged in the manufacture of varnish and lubricating oils at San Francisco, Cal., and during 1890-1 was a designing engineer of the Western Electric Company at Chicago. Following this he was general superintendent of the Chicago Hardware Company for about a year, and from 1892 to 1899 was general air brake inspector of the Chicago & North Western. He has been connected with that road ever since and in the following capacities: 1899-1901, engine house foreman at Chicago; 1901-2, general foreman at Ashland, Wis.; 1903, master mechanic at Mason City, Iowa; from 1903 to January, 1909, master mechanic of the lines west of the Missouri River, with headquarters at Missouri Valley, Iowa. In January, 1909, he was made assistant superintendent of motive power and machinery, which position he now holds. Mr. Pratt became a member of the association in 1903.

William Schlafge, the new third vice-president, was born in Berlin, Germany, October 11, 1868, and after receiving a common school education continued it by attending night school. He first entered the railway service in the machine shops of the Lehigh Valley, at Packerton, Pa., and remained with that company until 1887, when he went to the Minneapolis, St. Paul & Sault Ste. Marie shops at Minneapolis as an apprentice. After finishing his apprenticeship he was engaged as a mechanic and foreman in several railway and contract shops, and in 1893 returned to the service of the Soo as an engine house foreman at Gladstone, Mich. He resigned this position in 1898 to go with the Escanaba & Lake Superior as a locomotive fireman; later he was made an engineman, and was then promoted to the position of master mechanic. He next went with the Baltimore & Ohio at Newark, Ohio, as an engine house foreman, and three years later was promoted to general foreman in charge of the locomotive and car departments, with headquarters at Chicago Junction, Ohio, remaining in that position until 1893. In March

of that year he was made general foreman of the Erie at Port Jervis, N. Y., and in 1894 was made master mechanic at Jersey City, N. J. In December, 1906, he was made master car builder with headquarters at Meadville, Pa., and a few months later was promoted to the position of general master mechanic, and then to that of assistant mechanical superintendent. In October, 1907, he was made mechanical superintendent of the Erie Grand division and the New York, Susquehanna & Western, with office at Jersey City. When Mr. Rumney left the Erie early in 1912 to go with the Rock Island, Mr. Schlafge was promoted to the position of mechanical superintendent. Mr. Schlafge became a member of the Master Mechanics' Association in 1904.

STEEL POSTAL CAR.

The American Car & Foundry Company, New York, is exhibiting an all-steel postal car, built for the Chicago, Milwaukee & St. Paul. It conforms to the latest specifications of the United States post office department in construction, floor plan and interior fixtures and was among the first cars built under the specifications and approved by the post office committee. It is designed with trussed side frames to carry the load, the truss consisting of a 6 in. x 4 in. x 3/8 in. angle side sill, a 5 in. x 3 in. x 5/16 in. angle side plate, 3 in x 2 in. x 5/16 in. angle side posts and 3 in. x 2 in. x 1/4 in. angle and 4 in. 5.25 lb. channel side braces with suitable reinforcements at the side door openings.

The center sills are of the fish belly type and are designed to absorb the end shock and carry the center sill loads between the bolsters and cross-bearers, from which points it is transferred to the side trusses. The center sills are 26 1/2 in. deep at the center and consist of two 5/16 in. web plates 25 1/2 in. deep, spaced 18 in. apart and reinforced by four bottom flange angles 3 in. x 3 in. x 3/8 in., two top flange angles 4 in. x 3 in. x 5/8 in. and a top cover plate 30 in. x 1/2 in. The cross-bearers are located 18 ft. 2 in. apart, and consist of a 1/4 in. web plate with a 3 in. flange at the top, a 3 in. x 3 in. x 1/4 in. angle reinforcement and a 16 in. x 1/4 in. cover plate. The bottom flange is reinforced by two 3 in. x 3 in. x 1/4 in. angles which are continuous between the side sills and pass below the center sill flange angles. The combined body bolster and platform is of steel and was furnished by the Commonwealth Steel Company. The floor beams are 3 in. 4 lb. channels riveted to the center and side sills, and the floor supports are channels of the same size and are covered with No. 14 gage steel upon which is secured 1 in. hair felt insulation; between this insulation and the floor is 15/16 in. air space. The floor consists of two courses of 13/16 in. floor boards nailed to stringers which are bolted to the floor supports and center sill cover plate.

The end framing is designed especially strong to prevent telescoping and consists of 12 in. 31.5 lb. I-beam vestibule posts reinforced by 4 in. 5.25 lb. channels, end door post stiffeners and a 3/16 in. pressed steel door post cover, which is screwed to wood furring. The intermediate end posts and corner posts are 4 in. 10.3 lb. Z bars and the corner post cover is a 3/16 in. pressed plate; the end sheathing is 1/8 in. plate which is riveted to all the posts. The end framing members are securely riveted in pockets cast in the combined end sill and double body bolster at the bottom, which takes care of the bottom reactions and distributes any shock throughout the longitudinal members of the underframe. At the top they are secured to a built-up end plate consisting of 1/4 in. plates and a 4 1/2 in. x 3 in. x 5/16 in. angle ramp carline which is further reinforced by a 3/8 in. anti-telescoping plate 21 13/16 in. wide, flanged at the outer side and extending from side plate to side plate to distribute the

Interior of Chicago, Milwaukee & St. Paul Steel Postal Car.

top reactions from the end posts through the longitudinal roof members.

The side sheathing consists of 1/8 in. plate, spliced at the belt rail which is a 1/4 in. x 4 in. plate in a continuous length between the door openings and a 4 in. 5.25 lb. channel which is framed between the posts. The letter board is 1/8 in. plate reinforced at the bottom by a 2 in. x 2 in. x 3/16 in. angle and at the top is riveted to the side plate, the same rivets fastening a U-shaped eaves moulding to which the roof sheets are riveted. The roof is of the clere-story type and has 3 in. x 3 in. x 1/4 in. angle deck sills running the full length of the car and riveted to the carlines. The carlines are 1 3/4 in. x 1 1/4 in. x 3/16 in. angles extending from side plate to side plate in one piece

Steel Postal Car for the Chicago, Milwaukee & St. Paul.

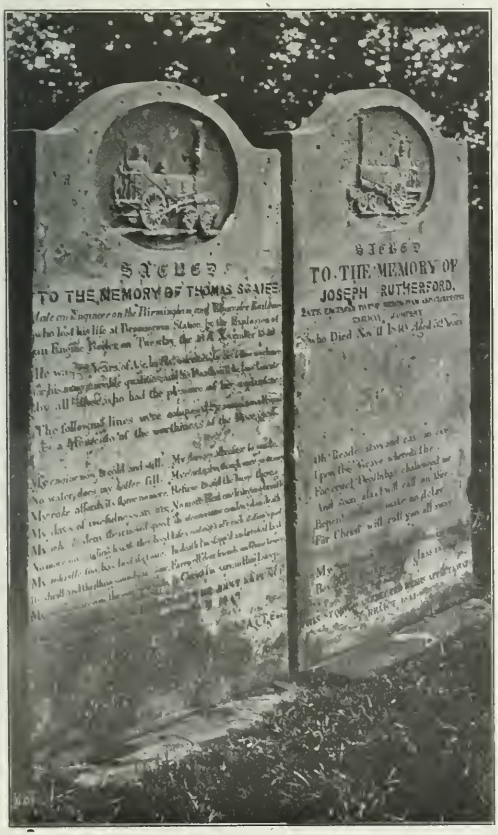
and arranged in pairs. The upper deck roof sheets are No. 14 steel, and the lower deck sheets No. 16 steel insulated with three-ply salamander which is secured by wood furring.

The interior finish of the car is entirely of steel, the sides being lined with corrugated iron. The outer window sash are removable and all sash are made of wood and provided with screens as required by the railway mail service standards; the sliding side doors are of wood, and the H. W. Johns-Manville Company's three-ply salamander insulation is applied to the inner side of all outside sheets; there is a dead air space between the sheathing and inside finish. Ventilation is obtained by 6 in. Utility ventilators. The car is lighted by electricity, the head end system of current supply being used and is also equipped with two battery boxes of 16 cells each. The principal dimensions as follows:

Length over end posts	60-ft. 10⅝ in.
Length inside	60-ft. 1 in.
Width over side sills	10-ft. ¾ in.
Width inside	9 ft. 3¾ in.
Weight of car body	80,580 lbs.
Weight of trucks	38,080 lbs.
Weight, total	118,660 lbs.

AN EARLY LOCOMOTIVE BOILER EXPLOSION.

In 1840 one of the small railways, which a few years later were combined to form the beginning of the present Midland Railway of England, purchased eight locomotives from Norris of Philadelphia. The works of Norris later became the Baldwin Locomotive Works. These engines were used on an incline between Bromsgrove and Blackwell, which had a 2.65 per cent. grade and pulled a train of 53¼ tons weight at a speed of 8½ miles an hour. They were of the single driver, inclined cylinder type with a four wheel truck.



Headstones of Engineer and Fireman Killed in a Locomotive Boiler Explosion in 1840.

Shortly after they were put in service, the boiler of one of these exploded, killing the engineer and fireman. These men were probably the first enginemen to be killed by a locomotive boiler explosion. They were buried side by side in a church yard in Bromsgrove, and the friends of the engineer erected a suitable headstone at his grave, on which was carved a reproduction of the locomotive he was driving when killed. This action aroused the friends of the firemen to a similar action.

A short time ago Mr. Fowler, chief mechanical engineer of the Midland, heard that these stones were showing signs of disintegration and he hastened to have photographs of them made. He brought copies of these pictures with him to the convention and the accompanying reproduction is made with his permission.

The inscription on the engineer's headstone reads as follows:

"Sacred to the memory of Thomas Scaife, late engineer on the Birmingham & Gloucester Railway, who lost his life at Bromsgrove Station by the explosion of an engine boiler on Tuesday, November 10, 1840. He was 28 years of age, highly esteemed by his fellow workmen for his many amiable qualities, and his death will be long lamented by all those who had the pleasure of his acquaintance. The following lines were composed by an unknown friend as a memento of the worthiness of the deceased:

"My *engine* now is cold and still,
No water does my *boiler* fill,
My *coke* affords its flame no more,
My days of usefulness are o'er.
My *wheels* deny their noted speed,
No more my guiding hand they heed.
My *whistle* too has lost its tone,
Its shrill and thrilling sounds are gone,
My *valves* are now thrown open wide,
My *flanges* all refuse to guide.
My *clacks*, also, though once so strong,
Refuse to aid the busy throng.
No more I feel each urging breath,
My *steam* is now condensed in death.
Life's *railways* o'er each *station's* past,
In death I'm stopp'd and rest at last,
Farewell dear friends and cease to weep,
In Christ I'm safe, in Him I sleep."

"This stone was erected at the joint expense of his fellow workmen in 1842."

The inscription on the other stone reads:

"Sacred to the memory of Joseph Rutherford, late engineer to the Birmingham & Gloucester Railway Company, who died November 11, 1840; age 52 years.

"Oh! reader stay and cast an eye
Upon this grave wherein I lie,
For cruel death has challenged me.
And soon, alas! will call on thee.
Repent in time, make no delay,
For Christ will call you all away.
My time was spent like days in sun,
Beyond all cure my glass is run.

"This stone was erected by his affectionate relict, 1841."

Military Railway in Mongolia.—Russia has constructed a military railway from Harkatu to Urga and the whole line is divided into four sections, on each of which a barrack has been erected.

New Railway in China.—The railway built by Chinese engineers, and financed by the Chinese themselves, which will connect Pak Kaai, province of Kwangtung, the port on one of the largest branches of the Canton river with Hong-Kong is now opened for traffic as far as the city of Kongmun, which is only three miles from Pak Kaai.

LITTLE INTERVIEWS.

"Compounding has not been entirely discarded, although its use is not being noticeably extended. The railways already having large numbers of compounds are finding them satisfactory. One of the most interesting developments in this connection is the application of a superheater to a three-cylinder, four-coupled locomotive by Mr. Fowler, of the Midland. While this engine is not yet in service the general opinion of locomotive engineers in England is that it will be a very successful combination."

"I hope to see the time," said M. Waitt the other day, "when the railways of the United States will to some extent follow the example of those of Europe in the interior arrangement of their day coaches and sleeping cars. The day coaches in Europe are divided into compartments seating four or more persons, instead of being simply one large compartment, as ours are. This makes far much greater privacy. It promotes more satisfactory ventilation, because it is easier to ventilate a compartment satisfactorily to a few people than a big car satisfactorily to a large number of people. It also enables one to choose his company. The argument for the division of sleeping cars into compartments is much stronger still. European travelers regard our large, open sleeping cars as little short of indecent. The man who travels much in Europe soon gets to sympathizing with their point of view."

"I think the exhibits in connection with these conventions have an educational value beyond what most people realize," said James Ogilvie, assistant chief operating officer of the Board of Railway Commissioners of Canada, on Saturday. Mr. Ogilvie is attending the conventions and is staying at the Traymore. "I have been attending the meetings of the mechanical associations for many years," he continued, "and it seems to me that the usefulness both of their sessions and of the exhibition increases steadily year by year. I believe it would pay the railways to bear the expenses of their mechanical men, if that were necessary to get them to come here, and should then make it their duty carefully to inspect every new or improved theory shown. Any mechanical officer who comes here and does not carefully inspect the exhibit makes a great mistake."

Mr. Ogilvie was for twenty-three years superintendent of motive power of the Canada Atlantic, now a part of the Grand Trunk. Following the acquisition of the Canada Atlantic by the Grand Trunk he was master mechanic of the latter road at Port Huron. E. J. Chamberlin, now president of the Grand Trunk, was then its general manager. Mr. Ogilvie was at one time connected with the Canadian Pacific, and had charge of equipping its first shops at Montreal. In his present position he deals for the Canadian Commission, with the regulation of safety appliances, boiler inspection, etc. He has been with the Commission since 1907.

The dinner to be given the Brazilian Minister of Foreign Affairs in New York on June 17 by the American Manufacturers' Export Association which is composed largely of railway supply manufacturers, calls attention forcibly to the opportunities that exist for increasing the foreign market for railway equipment and supplies made in this country. Among the supply men attending the conventions who recently have been abroad trying to broaden the foreign market for their companies is J. Will Johnson general manager of the Pyle-National Electric Headlight Company. Mr. Johnson spent two months in the late summer of 1912 in Norway and Sweden.

"I don't think we fully appreciate in this country how much, with a reasonable amount of effort and expenditure, we could increase our foreign sales of supplies," said Mr Johnson this week. "The managements of the railways of Norway and Sweden could gain by introducing the kind of automatic couplers used in this country. Other things, it occurred to me, they could well afford to borrow from us, are some of our types of derails and curtain fixtures. On the other hand, it would be a mistake to assume that we have nothing to learn from the manufacturers and railway managers of other countries. The American visitor in Europe is impressed with the fact that the Europeans avail themselves of many refinements of design and practice which we might profitably imitate. In many respects our railways are superior to those of Norway and Sweden; but I rode 66 miles in 44 minutes on a locomotive on the Swedish State Railways near Stockholm, which shows that they can 'go some' over there."

Lawford H. Fry, the European representative of the Baldwin Locomotive Works, who is visiting the conventions for the first time since 1906, has been particularly interested in the reports and discussion in connection with superheated steam.

"The railways in England," Mr. Fry says, "are all showing much activity in the investigation of this subject, and all of the larger systems are applying superheaters. The fire tube type is being universally used, but several of the roads are trying designs originated by their own engineers. These differ principally in the arrangement of the headers and the method of fastening the pipes. The advantage of the higher degrees of superheat is generally admitted, and most of the designs closely follow the general plan of the Schmidt type, universally used here.

"There is still but one Pacific type locomotive in Great Britain, the 'Great Bear' of the Great Western, and there is but little demand for this type in that country, although there is a constant tendency for the weight of passenger trains to increase. The ten-wheeler is the most popular type for heavy passenger traffic, and probably will be able to meet the demands for some time to come. The very large locomotive will always be forbidden in England because of the small size of the loading gage.

"In freight service there appears no tendency toward larger cars except in exceptional instances. The ten-ton, four-wheel car seems to suit the traffic requirements perfectly. Nearly all freight traffic is high speed, and the heavy, slow "drags" so common here are found in only a few instances. In view of this condition the eight-coupled locomotive is the most suitable, and is generally designed without a front truck, although there are a few examples of the consolidation type in use.

"The Interstate Commerce Commission heartily approves these meetings," said George B. McGinty, secretary of the commission, who has been an interested visitor at the convention throughout the week with several of the locomotive boiler inspectors of the commission. "The railroads have in their hands right now in these meetings the power of preventing further legislation along the lines of standardization. If the Master Mechanics' and Master Car Builders' associations adopt standards wherever they see plainly they are needed, and if the managements of the roads will adhere to the standards adopted, they will prevent public agitation and preclude the people from demanding legislation by Congress which will place additional burdens on the Interstate Commerce Commission to enforce. There is no reason why the commission should be made to bring about standardization when the carriers have it in their own power to do it, and if the roads will only back up the work that is done here by the associations by adopting their conclusions they can forestall legislation on the subject.

"We are gratified to find that the railroad men themselves are giving our inspectors such coöperation. It is rare to meet a master mechanic or a superintendent of motive power who does not give us all the assistance in his power.

"Occasionally we find one who fails to understand our intentions and methods and who objects if one of our inspectors calls his attention to some defect which is outside of our authority. We try to make them understand that we are not anxious to order engines out of service, but that it is our

purpose, so far as possible, to call attention in an informal way to matters that can be remedied so that they may be cared for before they have a chance to make trouble. If we call attention to a defect, even if it is outside of our authority, and if it is not remedied and an accident ensues, it is, of course, our duty to report that we had called attention to it in advance. When the railroad men understand us we are sure of their coöperation. But they should remember that the commission does not make the laws. It is only required to enforce them and if the carriers had adopted proper standards themselves the laws would not be there for us to enforce them."

A REMARKABLE CAREER AS LOCOMOTIVE ENGINEER.

Among the special guests at the convention is A. Chambers, who retired from the service of the Pennsylvania Railroad on a pension two years ago, at the age of 68, after 51 years of continuous service. For the last 46 years of that time Mr. Chambers was a locomotive engineer and ran his engines over almost the entire system of the Pennsylvania as well as over a number of other roads on special trips. During most of his service he has been assigned to the duty of handling the locomotive on special and inspection trips of the presidents and general managers. He has hauled six Pennsylvania presidents, J. Edgar Thomson, Thomas A. Scott, George B. Roberts, Frank Thomson, A. J.

Left to right—A. Chambers, Retired Pennsylvania Engineer, and W. H. Bennett, Master Mechanic, Juniata Shops, Pennsylvania.

Cassatt and James McCrea, as well as the present president, Samuel Rea, before he was elected to that office, and has attended the funerals of the six former presidents. He also for 39 years presided at the throttle for eight general managers on inspection trips, A. J. Cassatt, Frank Thomson, C. E. Pugh, S. M. Prevost, J. B. Hutchison, W. W. Atterbury, W. H. Myers and S. C. Long.

Mr. Chambers ran the locomotive on the special trains of Presidents Grant, Hayes, Cleveland, McKinley and Roosevelt, and also the Duke of Sutherland, as well as the special train of the Centennial Commissioners in 1876. In that year he was the engineer on the first division of a run made by a special train from Jersey City to San Francisco in 83 hours, his part of the run being from Jersey City to Pittsburgh without stops.

In his entire career as an engineman Mr. Chambers never had an accident and never lost a day through sickness.

He now has two sons in the Pennsylvania service and his father before him was a track supervisor for the same road. Mr. Chambers entered the service in 1861, carrying water for the track gangs when he was 16, and later was made fireman on a wood-burning engine. He was promoted to engineman in 1868 and in 1871 to a passenger run. He continued as a passenger engineer until his retirement on January 1, 1912. For many years his regular run was on the Cincinnati Express from Philadelphia to Harrisburg, except when he was assigned to special trains. Later he ran locals on the Philadelphia division.

Mr. Chambers made his fortieth trip on the general manager's inspection last year in a private car by special invitation from General Manager Long. He has been personally acquainted with all of the presidents and general managers during his period of service as well as the directors who went on the inspection trips and always had a good word for him. A. J. Cassatt was general manager when he entered service, and he remembers James McCrea as a supervisor. One of his first special trips was in 1876 with Col. Scott from Philadelphia to St. Louis.

Mr. Chambers has witnessed some wonderful changes in railroading in his time. He thinks the work is much safer now, with signals and other modern appliances, but that it is also more of a strain on a man on account of the higher speed and the greater volume of traffic. His first engine was type "G," with 15 in. x 22 in. cylinders, and 54-in. drive wheels. His last had 18 in. x 26 in. cylinders and 68-in. wheels. He claims to have had the "cleanest engine in the United States," all nickel work, with a cab as neat as a Pullman. It was kept in a special house to be used only on special trips. He wore out four engines in this special service, retaining the same number "937" throughout. The last "937" was new in 1906.

Mr. Chambers is now living at Atlantic City, taking it easy on his liberal pension. He does not look his age and walks for at least an hour every day on the Boardwalk for exercise. He has been bringing officers to the conventions for many years and since his retirement has been a daily visitor to the exhibits where he meets many old friends.

Tokaido Line, Japan.—The construction of the iron bridge with the double line over the Kiso river having been completed the section will be put into active use for traffic immediately. Now the only single track section of the Tokaido line left is the iron bridge over the river Tenryu.

The Amur Railway, Siberia.—The Czar of Russia has addressed to the Governor-General of the Amur Region a message of congratulation on the progress of construction of the Amur Railway, and has expressed his thanks to all Russians engaged on the works. Credits amounting to over $375,000,000 have been voted for this enterprise during the last five years. The railway is expected to be completed in 1915, or, at latest, in 1916. The section as far as Blagoveshchensk will probably be opened for traffic in the course of this year.

Arisan Line, Formosa.—The Arisan railway is one of the most interesting lines in Formosa, and it might almost be said in the Far East. The line was undertaken by the Arisan Works Department of the government of Formosa, and a well-informed critic observes that this mountain railway will elicit favorable remark from the engineering fraternity in many countries. The construction involved steep gradients, sharp curves, a picturesque spiral, and many tunnels and bridges. The entire railway will cover 41 miles, from Kagi to Mount Ari Station—the latter point being 7,000 ft. above sea level. From Kagi to Chikutoki, 9 miles, the grade is two per cent. From Chikutoki, Nimandaira is reached after a 32-mile zigzag climb up the mountains to 7,000 ft., the gradient being five per cent. Nearly the entire line is sinuous, the sharpest curve being 35 degrees. To reach Nimandaira the railway must circle a peak spiral fashion. The spiral construction begins at 1,824 ft. and ends at an elevation of 2,500 ft. Between Kagi and Mount Ari there are 70 bridges, 73 tunnels, and almost innumerable cuts. The Rinnai or forest railway is 18 miles long, is tortuous, and has a gradient of six per cent. This railroad is called the Mount Arisan line, Mount Ari lending its name to the railway as well as to the giant forests that are the objective point of the undertaking.

Conventionalities.

The "movies" on the Pier are mighty popular all day.

The superheater white pants have plenty of company now.

O. C. Gayley, vice-president of the Pressed Steel Car Company, arrived Friday evening. He is staying at the Marlborough-Blenheim.

News of the death in Chicago on Friday of Mrs. A. E. Buffum, mother of Mrs. Mark A. Ross, was received by Mr. Ross late Friday evening.

J. French Miller, secretary of the Galena Signal Oil Company, dropped in Saturday, but found it necessary to return to Franklin Sunday.

Vernon Job, manager of the Pacific Coast territory of the Independent Pneumatic Tool Company, is paying his first visit to the M. M. and M. C. B. conventions.

F. H. Clark, general superintendent of motive power of the Baltimore & Ohio, was here a short time for the M. M. Convention, and has returned for the M. C. B. Convention. He is at the Marlborough-Blenheim.

When the *Daily* said in its issue of June 14 that Mrs. J. M. Hopkins and J. M., Jr., were traveling it meant to tell also where they were traveling, but failed to do so. They have been in Europe for some months.

"Votes for Women"—Convention Ladies who on Wednesday Last Rejoiced in the News of the Passage of the Illinois Suffrage Bill.

Top row, left to right—Mrs. Charles D. Jenks, Mrs. Burton W. Mudge, Mrs. W. J. Tollerton, Mrs. L. A. Richardson, Mrs. J. S. Sneafe.

Bottom row, left to right—Mrs. B. A. Clements, Mrs. F. O. Bunnell, Mrs. J. P. Landreth.

On Saturday morning Chairman Yardley, of the enrollment committee, was presented by the members of his committee with a handsome stickpin—a sapphire surrounded by four diamonds. E. T. Sawyer, a member of the committee, made the presentation.

Blake C. Howard, who has attended the conventions during the past three or four years with his father George E. of the Commonwealth Steel Company arrived Sunday afternoon. This year he comes as the St. Louis representative of Mudge & Company.

"Votes for Women"—Compelled to Smile when the News was Received from Illinois.

Left to righ—J. S. Sheafe, Eng. of Tests, Illinois Central; J. P. Landreth, Chicago Manager Garloch Packing Company; E. A. Park, Supt. Motive Power & Equipment, Peoria & Pekin Union.

T. H. Goodnow at the time of the Conventions last year was with the Armour Car Lines. This year he comes as superintendent of the Car department of the Chicago & Northwestern. Mr. Goodnow was last year's president of the Western Railway Club.

David J. Champion, vice-president and general manager of the Champion Rivet Company, more familiarly known as "Dave" Champion, is unable to get to the convention this year. He is compelled to stick close to the new plant of the company at East Chicago, soon to be put in operation.

J. F. Muhlfield, formerly general superintendent of motive power of the Baltimore & Ohio, and later vice-president of the Kansas City Southern, is attending the conventions this year. He is now located in New York City and is engaged in special and consulting work.

R. A. Bachman, vice-president and general manager of the Edison Storage Battery Co., motored down from New York the latter part of the week and is stopping at the Dennis. Mr. Bachman has just bought a new National and is taking considerable pleasure in feeling its pulse.

George Durham, master mechanic of the Delaware, Lackawanna & Hudson at Scranton, Pa., is among the Lackawanna representatives at Atlantic City this year. The superheater slide valve locomotive which is giving such successful service on that road is operating on his division.

We miss the smiling face—and box of cigars—of our friend Stephen C. Mason, secretary of The McConway & Torley Company. In writing about his inability to be here because of press-

W. C. Arp, Superintendent Motive Power, Vandalia.

ing business engagements, Mr. Mason says, "It goes without saying that I hope the conventions will be fully up to their previous mark."

Maham H. Haig, mechanical engineer of the Santa Fe, has the reputation this year of giving more earnest and conscientious attention to the exhibits on the pier than any other railroad representative present. If there is anything

W. J. Tollerton, General Mechanical Superintendent, Rock Island Lines, and Mrs. Tollerton.

that he does not know about it when he returns home it will not be his fault.

Among the Rock Island men in attendance at the convention is W. J. Hartman, general air brake instructor. He is especially interested just at this time in the application of high speed brakes to the passenger equipment and in the inspection of a number of new locomotives which are being built for his company.

Left to right—T. Rumney and A. B. Appler, Mechanical Engineers, Delaware & Hudson Company

Left to right—John E. Davis, M. M., Hocking Valley; H. F. Staley, M. M., Carolina, Clinchfield & Ohio.

Another Good Railway Man Gone Wrong—W. H. Foster (on the Left) Until Recently Master Mechanic of the N. Y. C. & H. R. R. R., Now With the Ashton Valve Company, and N. A. Campbell.

A. M. Darlow is probably the youngest superintendent of motive power in attendance at the conventions. During the past year he was promoted to that position on the Buffalo & Susquehanna. Previously he had been mechanical engineer and general storekeeper of that road. He was graduated from Cornell in 1906.

W. S. Butler, master mechanic, and H. M. Brown, shop superintendent of the Chesapeake and Ohio at Huntington, W. Va.,

George B. McGinty, Secretary Interstate Commerce Commission.

are taking in the conventions together. During the recent floods on the Ohio river, the water reached a height of several feet in the Huntington shops, and Mr. Brown had a staff of men engaged in building boats for use in getting about the plant.

C. B. Smith, mechanical engineer of the Boston & Maine, found it necessary to return to Boston Saturday evening. He was accompanied by Mrs. Smith. Mr. Smith has had an exceptionally interesting piece of work during the past

Left to right—H. W. Coddington, Engineer of Tests, and John A. Pilcher, Mechanical Engineer, Norfolk & Western.

year in connection with the building and equipment of the new shops at Billerica, Mass.

William Smith, formerly foreman of the North Western at Boone, Iowa, and now with the Delaware & Hudson at Watervliet, N. Y., spent a couple of days at Atlantic City, going home Saturday evening. He has just completed a report on Engine House Efficiency which is to be presented at the annual meeting of the International Railway General Foreman's Association at Chicago in July.

In Chicago the street sweepers wear small lamps on their hats so that drivers of carriages and automobiles will not run them down. It was suggested Saturday morning that George Bourne might have made himself still more conspicuous in his superheater suit if he had arranged with Ostby for an acetylene headlight.

J. S. Turner, of the Pressed Steel Car Company, packed his trunk, locked it, and put the key somewhere. The trunk got here all right; but the key didn't. Now Jack isn't given to swearing. He is, however, characteristically original in his expressions; and "they" say that the amusement he afforded pending the arrival of a locksmith put Barnum & Bailey's clowns in the shade.

R. W. Burnett, general master car builder of the Canadian Pacific, arrived with Mrs. Burnett on Saturday morning. The developing and building of steel passenger cars, improvements in box car construction and extensive additions to the car building plant at Angus are among the more important features of the work in the car department of the Canadian Pacific during the past year.

James Powell, chief draughtsman of the Grand Trunk and

F. O. Bunnell, Engineer of Tests, Rock Island Lines.

secretary of the Canadian Railway Club, is attending the conventions. The Grand Trunk has been noted for its use of two-cylinder compound locomotives, and a number of the consolidation type have been replaced by single-expansion Mikados equipped with superheaters. The Mikados are reported to be giving excellent service in heavy freight service.

Daniel Royse, assistant to W. V. S. Thorne, vice-president and director of purchases of the Union Pacific system, arrived yesterday and began early a tour of inspection of the exhibits. To those who know him, it is almost needless to say that he and John C. Whitridge of the Buckeye Steel Castings Company were together. Messrs. Royse and Whitridge formerly were associated when both were in technical newspaper work.

J. F. Prendergast, master mechanic of the East Broad Top Railroad & Coal Co., is stopping at Haddon Hall. He is quite enthusiastic about the service which is being given by the Mikado locomotives which his road recently received from the Baldwin Locomotive Works, and the all-steel hopper cars which were built by the Pressed Steel Car Co. The East Broad Top is a narrow gage road and undoubtedly the only one with as modern and up-to-date equipment as that which has lately been put in service.

Lawford H. Fry, European representative of the Baldwin Locomotive Works, is attending the convention for the first time since 1900. Mr Fry has, during the past few years, published in the *Engineer* and *Engineering* of London some exceptionally valuable articles on locomotive proportions and ratios which have attracted much favorable comment. He will return to his headquarters in London in a couple of weeks.

The Michigan Central is represented this year by W. H. Flynn, superintendent of motive power, and J. A. McRae, mechanical engineer. They are about to place in service a new lot of Mikados which are the first of that type to be used on the M. C.; also some new heavy passenger powers which is similar to the standard New York Central Lines K 3 engines and is considerably heavier than any passenger power which has yet been used on that road.

George Duffey, master mechanic of the Lake Shore & Western, has complete charge of the locomotive and car departments on that road, and is especially interested in the progress of the apprenticeship work at Lima, Ohio. The apprentice school there, which is under the general direction of C. W. Cross, superintendent of apprentices of the New York Central Lines

G. I. Evans, Superintendent Angus Locomotive Shops, C. P. R.

west of Buffalo, is giving instruction to a large number of apprentices with gratifying results.

C. A. Brandt, mechanical engineer of the Big Four, has been pretty busy during the year in supervising the extensions to the freight and passenger car shops at Beech Grove, Ind., and also some additions which have been made to the locomotive shops. He is splendidly equipped for this class of work, as he was in charge of all of the shop engineer's work on the Lake Shore for several years, and is one of the few railroad men who may be classed as experts in this line.

J. Leonard Replogle, vice-president of the Cambria Steel Company, and C. B. McElhany, assistant manager of sales, drove here from Johnstown, Pa., in the automobile of a friend, Mr. Stineman. Mr. Replogle had ordered a new $5,000 Stearns silent Knight touring car which he had intended to bring to Atlantic City. While still in the hands of an expert from the factory, who was testing the car, it upset on a curve and was badly damaged. Fortunately neither the expert nor Mr. Replogle's chauffeur was injured.

I. J. Justice, special inspector on the staff of F. W. Brazier, superintendent of rolling stock of the New York Central & Hudson River, is one of the two men in charge of the exhibit which is being made by the coupler committee near the end of the pier beyond the Convention Hall. He has devoted the greater part of the last six months to the work of this committee. The other representative at the exhibit is T. J. Boring, of the Pennsylvania Railroad. The courteous way in which these two gentlemen are assisting the convention attendants in getting a good idea of the features of the exhibit has been commented on by many of those who have visited it.

J. C. Currie, one of the two new members of the Executive Committee of the Railway Supply Manufacturers' Association

J. H. Manning, Superintendent of Motive Power, Delaware & Hudson Company.

from the Second District, has been with the Nathan Manufacturing Company for the last 22 years. Born in Scotland in 1851, he came over here when 19 years old and got a job in the then famous seed store of B. K. Bliss & Sons, on Park Row, New York City. Having no particular fondness for seeds, he found employment in a confectionery store. When he had got his fill of sweets, he decided to become a locomotive engineer; and in 1872 was put to work nights on a switch engine on the Pennsyl-

C. Phillips, Master Mechanic, Queen & Crescent, Meridian, Miss., and Son.

vania R. R. In 1877 he reached his goal and was given charge of a freight engine. At the time he left the Pennsylvania to go with the Nathan Manufacturing Company he had been pulling the Congressional Limited between Washington and New York for some four years. Committee work at these conventions is not new to Mr. Currie. This is his seventeenth consecutive meeting; and up to a few years ago he did a lot of active work on various committees. During one convention he was treasurer of the Finance Committee.

George F. Laughlin, General Superintendent, Armour Car Lines.

A. Buchanan, Jr., Supervisor of Equipment, New York Public Service Commission.

L. L. Yates, Superintendent Car Department, Pacific Fruit Express.

MASTER CAR BUILDERS' REGISTRATION.

Beattie, J. H., Supt., Sea Side House.
Beaumont, H. A., Gen. For. Car Shops, B. & O., Dennis.

New Line for Manchuria.—Governor Chang-hsi-lan is said to have been authorized to build a light rail line for military use between Hsinmintun and Fakumen. Engineers have been sent out to start a survey of the proposed line.

Straits Settlements Railways.—Beginning on January 1, 1912, the railways of the Straits Settlements came under the management of the Federated Malay States Government. The terms called for a lease of 21 years at an annual rental of $95,200, subject to septennial revision. It is proposed to sell the railways to the Federated Malay States Government, and a joint committee has been considering the question of the price to be paid.

Railway Construction in Korea.—Sixty-one miles of the railway to Cholwon, a station on the new line between Seoul and Gensan have been completed and opened to traffic. At the Gensan end of this line about 10 or 15 miles of road are now being operated, and vigorous work is being prosecuted on the intervening route. It is expected that through communication between Seoul and Gensan will be available for trains by November, 1913.

Northern Railway, Siam.—The sum allotted for new construction on this railway during 1913 is more than twice as large as that for 1912. The explanation of this is that it has now been decided to push on with the construction of the line as far as Chiengmai, the chief town of Northern Siam. In previous reports it was stated that, owing to the difficult and less-paying nature of the country which the railway had then reached, it had been arranged for construction to be temporarily suspended when the line had advanced to a place called Dene Chai, about 139 miles southeast of Chiengmai. This was done in the interests of railway finance, in order to prevent any serious diminution in the dividend paid by the line; for a rapid and continuous extension through the less thickly populated parts of the country must, unless time is allowed to develop traffic, adversely affect the dividend-paying capacity of the whole railway. The necessary period for this purpose having now elapsed, it has been deemed opportune to continue the work of construction northwards: hence the increased allotment this year, which is made out of the unexpended balance of the last loan of $15,000,000 taken in January, 1907.

ELECTRIC LIGHTING FIXTURE FOR VESTIBULES.

Much of the expense involved in the inspection of electric light wiring on modern steel railway cars is unnecessary and is frequently the result of insufficient consideration of small details. With a steel ceiling it is often difficult to obtain access to electric wiring without involving the labor of removing the entire lighting fixture. This is particularly true as regards electric vestibule lighting fixtures and aside from the time and labor involved, the fixtures may be injured and the finish on the vestibule ceiling marred. The Safety Car Heating & Lighting Company, New York, has recently brought out an electric vestibule lighting fixture which has been designed particularly to give easy access to the electric wiring and also to provide for the most improved method of conduit construction. The illustration shows a section of this unit and it will be noted that a junction box is employed, having a terminal block for making connections to the circuit on which the fixture is located. When it is desired to inspect the wiring, the electric socket and flange are easily removed, giving free access to the terminal block connections without disturbing the balance of the fixture in any way. In this

Electric Fixture for Lighting Car Vestibules.

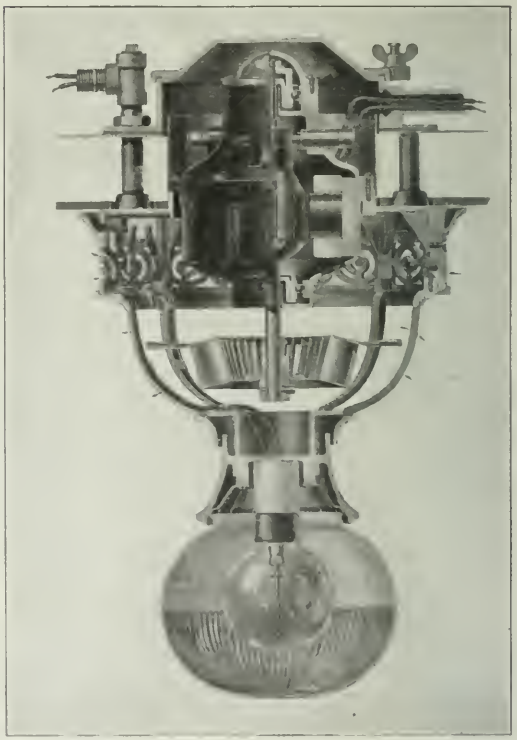
manner the fixture becomes actually a permanent part of the car, which is a very important consideration in steel car construction. The reflector, which also remains permanently in the car, is of white enamel and easily cleaned; it is securely fastened to the junction box at the top and to the ceiling of the vestibule at the bottom. A similar type of fixture employing the same method of wiring is made by this company for use as a pendant for saloons, dining car kitchens and other locations where glass reflectors are not required.

Efficient Broaching Machine. At the exhibit of Manning, Maxwell & Moore is shown a broaching machine made by J. N. Lapointe Company, New London, Conn. It is used for cutting internal gears; keyways, square or multiple spline holes for sliding gears as well as a considerable range of external work. It will cut keyways from the smallest to the largest size at the rate of 40 to 100 per hour. They can be either straight or tapered, or of the dove tail type. Internal gears up to 6 in. in diameter can be broached at the rate of 25 to 50 per hour.

COMBINED ELECTRIC FAN AND LIGHTING FIXTURE.

The use of fans for cooling and ventilating railway cars is a problem which has, up to the present, never been satisfactorily solved. The usual method employed is the installation of one or more bracket fans at each end of the car, which subject the passengers to drafts and do not produce effective ventilation, as the breeze is unequally distributed throughout the car. Large paddle fans are also used in many cases, particularly in dining cars, and while the results obtained with this type of fan are better than with the bracket fans, their appearance is unsightly and the mechanism requires considerable attention for its proper maintenance.

The Safety Car Heating & Lighting Company, New York, has developed a type of ceiling fan which may be used alone



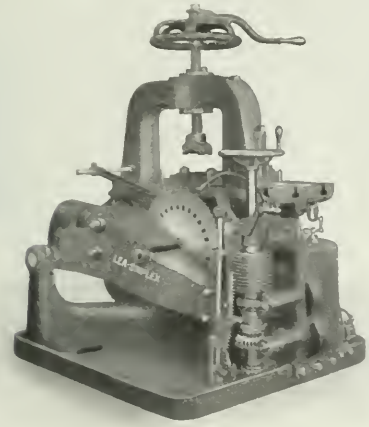
Combined Electric Lighting Fixture and Fan.

or in combination with a lighting fixture as shown in the illustration.

The design of the fan portion of the fixture is the result of very careful study and experiments to control the direction of the air which is circulated. As the fan is located in the top portion of the fixture it is partially concealed by the ornamental work and does not detract from the appearance of the lighting fixture. The air is drawn in along the ceiling and thrown out at an angle of 45 deg., as shown by the arrows. The fan is driven by a ball bearing electric motor mounted in the ceiling in such a way as to be accessible from the roof and lubrication, renewal of brushes, etc., can be accomplished by opening the cover from the outside of the car.

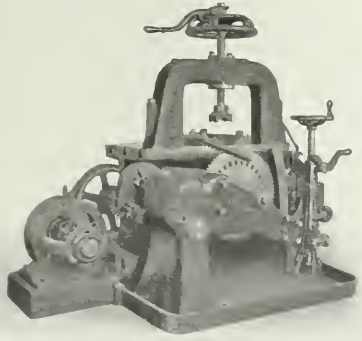
COLD CUT-OFF SAW.

The Lea Equipment Company, Philadelphia, Pa., has made a number of improvements in its cold cut-off saws, which are embodied in the 1913 model. A large tank is provided in the frame to accommodate the lubricating compound and is so designed that none of the lubricant will find its way to the floor. The swing arm is equipped with a new style of wearing plate to facilitate the removal of the



Lea-Simplex Cold Cut-off Saw.

saw blades. The spiral gear drive which was a feature of former models has been replaced with a bevel gear drive and the drive shaft is also provided with an additional outboard bearing. The 1913 model is designed for either the use of standard blades or inserted tooth blades; the force pump is of a new pattern with a positive action, is driven from the feed box, and is so located as to prevent chips from getting into it. The control rod is provided with an additional



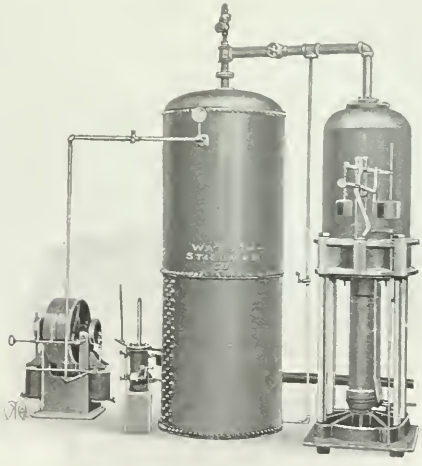
Lea-Simplex Saw Showing Motor Application.

steady bearing and the feed mechanism has automatic, as well as manual, control. The indicator dial formerly used has been replaced with an indicator rod which permits the operator to know at any time how much feed he is using. The yoke is of a heavier design than formerly and is provided with a large slot which permits movement of the screw in a direction parallel to the saw blade, thus providing a better adjustment of the blade to the stock. The V-blocks are now made in two parts and are separate from the table; they are intended for use in fastening either round, square or structural shape

HYDRO-PNEUMATIC ACCUMULATOR.

With an increase in the number and size of tools operated by hydraulic pressure, the weighted type of accumulator used in connection with this service has grown to a very large and cumbersome size. The problem becomes especially complicated if it is necessary to locate the accumulator on the upper floors of a building.

An accumulator which is designed to contend with conditions that make the weighted type undesirable, is being exhibited by the Watson-Stillman Company, New York. This design has no heavy weights, and operates without shock; while occupying little space it is claimed it will do everything that a weighted accumulator will do. Furthermore, it provides two pressures. A low pressure is used for effecting that part of the stroke made against no resistance, which is a large percentage of the stroke of almost any hydraulic press tool. The high pressure is arranged to automatically come in action for effecting the final squeeze.



Hydro-Pneumatic Accumulator.

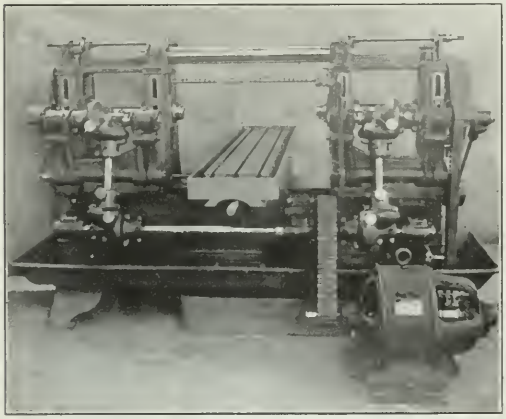
This combination of pressures is obtainable without complications in the operating valve or gear, and is entirely automatic in its action.

This type of accumulator is shown in the illustration. In the center is a large tank which is partially filled with water by means of a low pressure pump, the operation of which is controlled by a hydraulic governor which starts the pump and keeps it running until the water reaches a predetermined level, at which point it stops the pump, starting it again as soon as this level is lowered. Above the water is an air pressure of from 180 lbs. to 200 lbs., which is maintained by a special compressor forming part of the equipment. A low pressure feed main is run from the bottom of this tank and carried to the hydraulic tool. Alongside of this tank is the accumulator proper which has two cylinders, a large one at the top for pneumatic pressure and a small one at the bottom for hydraulic pressure. The areas of the pistons are made proportional to the pressures desired and available. There is a high pressure hydraulic pump connected with the

bottom of the accumulator, which is automatic in its action, and is controlled by a governor in the same manner as the low pressure pump. It is thus seen that both pumps are in operation only when a supply is required, and that there is no waste of power or efficiency since a high pressure is not used when a low pressure is sufficient. These accumulators are made in any size for pressures from 300 lbs. to 6000 lbs. per sq. in.

DOUBLE HEAD MILLING MACHINE.

A Lincoln type milling machine, manufactured by the Hendey Machine Company, Torrington, Conn., is shown in the exhibit of Manning, Maxwell & Moore. It is especially adapted to plain milling. As will be seen, the two heads are mounted on a long bed and there is an overhead arm connecting them and providing a rigid support above as well as below the spindles. The cutter spindles are driven through reduction gears from countershafts in hinged



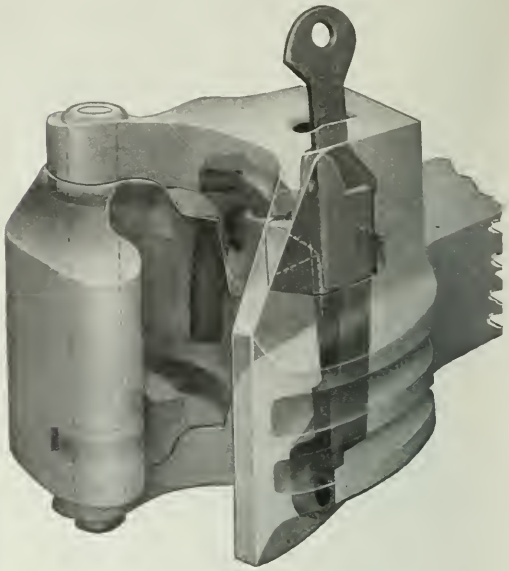
Double Head Milling Machine.

frames. The countershafts in turn are driven by bevel geared connections from a main shaft running along the back of the bed. This shaft is connected to the motor by a silent chain. One of the heads is arranged to slide along the bed. Provision is made for all desirable adjustments in each direction. The design is simple, compact and powerful.

PENN FREIGHT COUPLER.

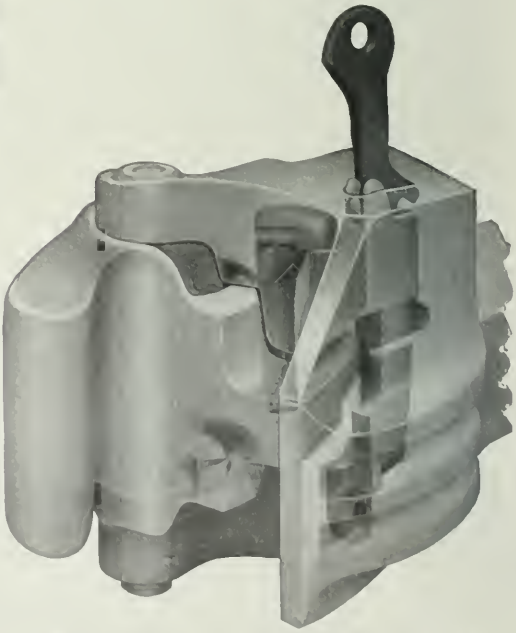
The McConway & Torley Company, Pittsburgh, Pa., is showing in its exhibit, spaces 501, 503 and 505, a new development of the Penn freight coupler which has been redesigned to meet the present severe service conditions. The weight of the coupler has been increased over the average M. C. B. coupler from 30 to 40 per cent, depending on the size of the shank, the metal being carefully distributed to produce the best results. The coupler also embodies features of design, which not only contribute toward greater strength, but also tend to prolong the length of service and increase the efficiency in mechanical operation.

The knuckle is so designed that it has ribs engaging shoulders within the coupler head, which relieve the knuckle pin from draft strains, and when the coupler is under a pulling strain of 200,000 lbs. the knuckle pin can readily be removed. The vertical depth of the knuckle hub has been increased from 6 in. to 9 in. and the guard arm has been reinforced to correspond with the general dimensions. The knuckle opener is of the bell crank type with direct mechanical action, and pushes the knuckle open to its fullest range of movement from either a fully closed or a partially open position; the lock adapted for



Penn Freight Coupler in Lock-set Position.

use with either an overhead or an underneath attachment of the uncoupling lever and has "lock-to-the-lock" and "lock-set



Penn Freight Coupler with Knuckle Wide Open.

features, while another important feature is the large bearing area between the contact surfaces of the locking block and the knuckle. One of the illustrations shows the head of the coupler

with the locking block raised to the "lock set" position and the lock held in the uncoupled position by resting on a seat within the coupler head, from which it is dislodged by the closing movement of the knuckle in coupling. The second illustration shows the coupler with the locking block raised to its highest range of movement, bringing into operation the "knuckle-opener," which has pushed the knuckle completely open.

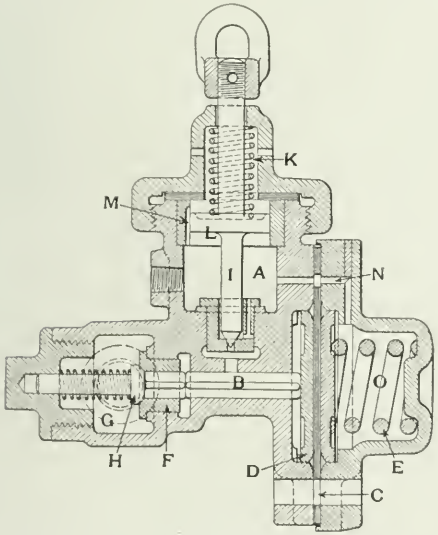
The coupler shown in the exhibit has a slight modification of the present M. C. B. lines. This company is also showing one of these couplers in connection with the exhibit of the M. C. B. Coupler Committee, and also another similar coupler with wide or open lines.

THE SAUVAGE AIR BRAKE SAFETY ATTACHMENTS.

John C. Knight, Inc., has an interesting exhibit of a number of safety devices for air brake work that have been designed by W. H. Sauvage. They do not in any way interfere with the regular operation of the air brake apparatus, nor do they require any changes in the methods of piping and attaching of that apparatus other than the mere connections involved in their application to the system.

They consist of a train line sustaining valve whose object is to automatically sustain the train line pressure at any point high or low at which it has been set, thus giving the engineer control of that pressure at all times ,independent of the position of the engineer's valve, preventing an unnaturally quick action of the triple valve, of an application of the brakes due to the leaking off of the train line pressure.

This may be supplemented by a discharge valve, which serves to accelerate the discharge of air from the train pipe



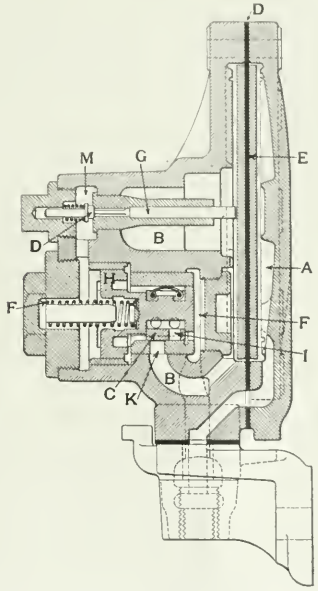
Sauvage Automatic Light and Load Brake Valve.

when the brakes are being applied on long trains only. It consists of a diaphragm to the top of which air from the equalizing reservoir is admitted while the connection to the train pipe comes in beneath. When the two pressures are the same the connection to the valve itself at the diaphragm makes a differential that holds this valve shut. But when the pressure in the equalizing reservoir drops below that of the train pipe, the latter pushes up the diaphragm and opens the valve that allows the air from the train pipe to escape to the atmosphere.

There is also a new form of retaining valve in which a spring is used to hold the valve to its seat instead of the usual weight. It is intended that this shall be attached, either to the triple valve or in the usual position. There is also a gage that is intended to be attached to the brake cylinder showing the pressure of air that exists in it. This is for the convenience of the inspectors and repair men to enable them to determine as to whether the brakes are acting properly or not.

In connection with the brake apparatus under the car there is also a brake cylinder accelerating and sustaining valve, the object of which is to hold a constant pressure in the brake cylinder and prevent leakage from lowering the braking power.

On the engine is an automatic warning and stop valve whose function is to blow a whistle in the cab when the



Sauvage Automatic Locomotive Train Line Sustaining Valve.

train line pressure falls below a predetermined amount which may be considered a danger point. The whistle continues to blow for a number of minutes and meanwhile it is gradually lowering the train line pressure and, unless the engineer takes measures to restore it and stop the whistle, it will continue to lower it to a point where the brakes will be applied and a stop will be necessitated.

One of the most interesting of the exhibits is a valve for varying the braking pressure according to the condition of the car as to whether it is loaded or empty.

There is also a signal valve by means of which the signal pipe is fed from the rear of the train instead of from the front so that when the engineer sees a pressure indicated in the signal pipe gage he knows that the pipes are open for the full length of the train.

Finally there is shown an ingenious angle cock by means of which no cock can be closed throughout the train without applying the brakes, except that on the last car. There are also a number of brake slack adjusters.

The automatic locomotive train line sustaining valve is shown in section in one of the drawings. There are three connections made to the piping of the air brake system. One to the main reservoir, a second to the equalizing reservoir and a third to the train line. The connection to the equal-

izing reservoir admits air to the right hand side of the diaphragm *D* to the space marked *A*. Air from the train line *B* and air from the main reservoir is admitted to the space marked *M* at the left and also to the backs of the two valves *C* and *D* and also surrounds the slide valve *C* and fills the space to the right of it marked *F*.

When a train line reduction is made and the pressures in the equalizing reservoir and train line have equalized the diaphragm *E* is balanced by the equal pressures on each side of it. If there is any leakage reducing the train line pressure, after that, the diaphragm moves to the left and, through the stem *G*, unseats the valve *D* permitting air to pass directly from the main reservoir to the space *B* thus raising the train line pressure. This holds so long as the valve *D* has a capacity sufficient to supply the leak when this is all that happens.

In the connection to the main reservoir from the space *F* the opening is large and free. From this space to the space *M* the air has to pass through the restricted area left by the clearance or play of the piston *H* in its cylinder. Hence when the draft by the train pipe is more than can leak through this restricted passage the pressure in *M* is lowered and the full main reservoir pressure in *F* moves the piston *H* to the left, carrying with it the slide valve *C*, causing the port *I* in the valve to open the passage *K* to *B*. Thus admitting air direct from the main reservoir to the train pipe. As soon as the pressures on the two sides of the diaphragm are again equalized, the latter moves back into its normal position and all flow of air from the main reservoir to the train pipe is cut off. In this manner a constant train pipe pressure is maintained.

LIGHT AND LOAD BRAKE.

The light and load brake is a simple arrangement by means of which the brake pressure on the wheels can be varied according to the total weight of the car. That is to say, for its light and loaded condition.

The principle of the operation is to use a brake cylinder much larger than would be suited for an empty car of the given weight if the full pressures that are ordinarily used in such a cylinder were employed. The auxilliary reservoir, however, is of the dimensions that would be used for a brake cylinder of the usual size. The result is that for the ordinary service reductions the pressure in the brake cylinder is much less than it would be with the full size reservoir, but the push on the brake road is about what is proper for the light weight of the car. Connected with the main auxilliary reservoir is another one which, by supplementing the first, is capable of raising the brake cylinder pressure up to the proper amount to secure full braking pressure on the loaded car. The method by which this second reservoir is thrown into action is controlled by the valve that is shown in the exhibit.

It is shown in section in one of the illustrations. In the charging of the regular reservoir, air is admitted through the triple valve in the usual manner and from this reservoir there is a connection leading to the point *B* of the light and load valve. Here it comes into contact with the left hand face of the diaphragm whose stiffening plate *D* is held against the seat to the left by the spring *E*. When in this position, it pushes the check valve *F* open and thus makes a free communication between the regular auxilliary and the supplementary reservoir which is connected to the chamber *G*. When the pressure in the reservoirs has reached 22 lbs. the air pressure against the left hand side of the diaphragm *C* presses it against its stop to the right, but the increasing air pressure at *B* still holds the check valve *H* open and the two reservoirs are charged together. As soon, however as a train pipe reduction is made and air is drawn off from the reservoir to the brake cylinder, the pressure at *B* falls below that at *G* and the regular reservoir alone serves to charge the brake cylinder and the extra supply in the second reservoir is held back by the check valve *H*. This is the method of operation when the car is light.

When the brake is to be applied to a loaded car the stem *I* whose end is in the form of a valve is drawn back and with it the piston *L*. Until this is done the spring *K* holds the valve against its seat and any air pressure that may have leaked into the chamber *A* passes through the leakage groove *M* to the other side of the piston to the atmosphere. But when the piston is drawn back so as to cover the leakage groove, the full air pressure from the reservoir is admitted into the chamber *A* and this holds the piston *L* back against its seat. At the same time the air passes through the passage *N* to the chamber *O* and equalizes the air pressure on the two sides of the diaphragm. The spring *E* then presses the diaphragm to the left and holds the check valve *H* open. This puts the two reservoirs in communication with each other and they serve to increase the brake cylinder pressure accordingly. This continues as long as the piston *L* is held back against its seat. The pulling out of the stem is done by hand whenever it is desired to use the brake for a loaded car.

In order to prevent the application of the load brake to an empty car, the cutting out is made automatically. When the car has been set aside and the pressure in the system has fallen, the spring *K* forces the piston to the right again and by closing the needle valve automatically puts the brake back into the condition for use with the empty car.

SUPPLEMENTAL LIST OF EXHIBITORS.

Automatic Drill Chuck Company, New York, N. Y.—Automatic drill chuck. Represented by G. W. Emrick, Space 541.

Barcalo Manufacturing Company, Buffalo, N. Y.—Non-binding pipe wrench. Represented by K. R. Shadek. Space 307.

Donath Valve Gear Company, Windsor, Mo.—Locomotive valve gear. Represented by Otto A. Donath and Holmes Hall. Space 381.

Grinden Art Metal Company, Brooklyn, N. Y.—Steel interior trim for steel passenger coaches. Space 300.

Kerr, Henry C., Roanoke, Va.—Model of car coupler. Represented by Henry C. Kerr. Space 194.

Remy Electric Company, Anderson, Ind.—American electric headlight—turbine generator and lamp. Represented by Joseph R. Arnold and Thos. B. Arnold. Space 631.

Siemund-Wenzel Electric Welding Company, New York, N. Y.—One 400 ampere welding machine in operation. Represented by G. S. Stuart, T. Rumney and W. D. Fowler. Space back of 188.

Stark & Company, Jas. P., Toledo, Ohio.—The Carpenter flush door. Represented by Jas. P. Stark and F. T. Carpenter. Space 13.

Wine Railway Appliance Company, Toledo, Ohio.—Locomotive and car specialties. Represented by C. J. Pilliod, Jr. Space 13.

KEY-CONNECTED CAST STEEL YOKES FOR NEW CARS.—During the past two years, a large number of cast steel drawbar yokes have been applied to new cars. These usually weigh from 155 to 195 pounds, depending on the type of drift gear used. With key-connected cast steel yokes it is possible to change the couplers without disturbing the draft gear or yoke, thus avoiding much of the handling in the shop and repair yards which is necessary with the old riveted type of yoke. The rivets which have for years been a source of heavy maintenance expense are entirely eliminated. As regards strength, yokes now manufactured are required to pull not less than 350,000 to 360,000 lbs. ultimate and have an elastic limit of 200,000 lbs. The Buckeye Steel Castings company, Columbus, Ohio, is exhibiting several types of these yokes

PERMISSION has been granted the committee on brake shoes and brake beam equipment to continue the series of tests on brake shoes which was begun at Purdue University several years ago. These tests have already given results of great value to the association, and the decision to continue them was to be expected. Tests will now be made at a speed corresponding to 65 miles an hour with pressures ranging from 9,000 to 18,000 lbs. These will be with the same types of shoes which were tested at 80 miles an hour in 1910. It is believed that the data to be obtained will allow specifications to be prepared covering shoes for heavy passenger equipment. In the section of the report on brake beams the most important action was the decision to refer to letter ballot for adoption as a standard, the recommendation that the spacing of the brake shoes should be 60 in. with allowable variations of ⅛ in. either way. The request of the committee that it be instructed to prepare a specification for a brake beam for passenger cars to be submitted for action next year, was referred to letter ballot.

A NUMBER of years ago when the subject of the lighting of the cars of the elevated railways of New York was under discussion and it was proposed to substitute Pintsch gas for oil lamps, Russell Sage asked: "And what shall I do with all the good oil lamps that we have?" There was no reply but, "Throw them away." The feelings of the millionaire at this iconoclastic suggestion are not a matter of record, but may be imagined. It looks very much as though a similar reply would have to be made to Mr. Schroyer's parallel question as to what should be done with all the good 8-inch brake cylinders if the 10-inch is substituted as suggested in the committee's report on train brake and signal equipment. Equipment has been increasing in capacity for twenty-five years, and the end is not yet. If the retirement of cars of 20 and 25 tons capacity from service is brought about, the 8-inch brake cylinder will have to go, even though it may be as good as new. It will simply add one more to the long list of perfectly good appliances that have gone to the scrap heap because they are obsolete and not because of old age or deterioration. As it stands an increase of brake shoe pressure is imperative and that the 8-inch cylinder cannot provide.

THE following sentence appears in President Fuller's address: "Let us consider carefully all the various recommendations which are placed before us for approval, and let us not lend the prestige of this association to anything that will mean increase in maintenance and operation which cannot be satisfactorily defended before the bar of public opinion on the ground of safety and economic progress." This is good advice for the mechanical association and, indeed, for all railway associations. It is still better advice for law-making bodies and railway commissions, because they need it a great deal worse. If the word "commission" were substituted for the word "association" the sentence might appropriately and profitably be framed and hung up on the wall in the office of every commission regulating public utilities in this country. The principle involved is constantly disregarded. It is easy enough to impose requirements on railways in the nominal interest of safety. It is very difficult to adopt only requirements which actually will be beneficial and which will at the same time accomplish the desired end with the minimum cost. In the long run, the public pays in passenger and freight rates the expense caused by every requirement imposed on the railways; and the commissions should take more care to see that the expenses caused are not out of proportion to the results that probably will be secured.

WITH the tendency in recent years toward more refinement and permanency in American locomotive design has come the increasing use of flange joints in pipe connections. It is probable that the reason for the infrequent use in this country in the past of this type of connection has been the need for easy accessibility for repair purpose; but flange joints have long been in general use in Europe and are practically standard in stationary power plant work, and the change has come with the development of the locomotive into a highly efficient power plant and the consequent necessity for more permanency in construction. In the past few years there has also been a surprising increase in the use of non-lifting injectors, due at least in part to the lack of room available in the modern locomotive cab. With the perfecting of the lifting injector and the increase in the size of locomotives, the earlier non-lifting injectors, which were very often difficult to prime and the cause of much waste of water, were discarded by many roads; but the non-lifting injector of to-day is of necessity a great improvement on the early types. Non-lifting injectors are in every day use on a large number of high-power locomotives throughout the country, in many cases providing the entire water supply, and it will be interesting to watch their future development.

IT is interesting to note that President Fuller, in his address, reports that reliable information from several large interchange points indicates that the number of defect cards issued at interchange points has been reduced approximately one-half as a result of two changes in the interchange rules adopted by letter ballot last fall. The first change referred to abrogated the rules which formerly penalized a delivering line for certain defects in cars which, although primarily owning line defects, became "handling line's responsibility" as soon as the cars were offered in interchange. The second change was to add 10 per cent. to the prevailing M. C. B. repair allowances for labor and material charges in order to make it more attractive to repair

cars while on foreign roads. The delays incident to the enforcement of the carding rule had become unbearable to some companies, while the fact that the existing allowances for repairs were so low as to virtually penalize the repairing road had a most important effect on the number of bad order cars. Both changes in the rules, which were adopted by an almost unanimous vote, but which only became effective on November 1 after strong pressure had been brought to bear against the increased repair allowances by the private car lines, were in the interest of promoting a freer interchange of cars during a time of acute shortage. President Fuller's statement that carding has been reduced by one-half and that the conditions which had caused unnecessary delays were almost immediately relieved, fully bears out the predictions made by the executive and arbitration committees in their resolutions proposing the changes.

IT looks very much as if we were not far advanced from the days of thirty years ago, when the Master Car Builders' Association and the railroad clubs were discussing the relation of the wheel to the rail; when everybody was guessing and nobody knew. Before the first standard contour of wheel tread and flange was adopted there was much talk, much conjecture and high hopes. Then there was more, but not of the same intensity and wide variations of opinion when it was changed as it was done with comparative quiet. But now comes Dr. Dudley, who thinks the present contour is bad for the rail heads and the wheel committee is asked to see what had best be done—stick to the one in twenty taper or go back to the one in thirty-eight, or something else? The mutual effect on wheel and rail has never been studied in minute detail. Cylindrical treads have been used with and without satisfaction, but it does seem as though, had conditions been the same, results must have been identical. The rail effect on the taper and the straight treads is a matter of conjecture and there is little data to support any conjecture that may be made. It is stated and denied that the rail causes a greater tread deformation on the cylindrical tread than on the taper, but no one knows what work has been done seems to indicate that, under the ordinary loads, it is the rail that suffers the greater part of the deformation and that there is little or none of a permanent character impressed on the wheel. We do know, however, that the area of contact between the wheel and the rail is a spot of considerable size; that the load per square inch of area of that contact is well up to and beyond the limit of elasticity of the metal of either the wheel or the rail; that the shape of that area is subject to constant variation as the wheel and rail wear; that the size of the area itself varies with the load, the metal composing wheel and rail, the wear of wheel or rail, and that its point of application runs from one side of the rail head to the other and performs all manner of gyrations around and across the tread, and finally, that every possible cause of variation is subject to change with the weight of the rail, the kind of ballast and the condition of track maintenance. So to the outsider it looks as though the committee had been assigned somewhat of a task when it was asked to determine what had best be done in the matter of wheel tread and do it in a year. But, perhaps, after all, the old assertion that taper is of no moment on a wheel because it so soon disappears and the natural running contour is developed, will hold.

LEAKY CAR ROOFS.

NO problem of car design has attracted more attention in the past few years than that of box car roofs; the result has been a marked improvement in them, and yet not a few railway officers are to be found who feel that there is still much to be desired in this direction. The number of cars now in service which have roofs that will fail under a water test is surprisingly large. One important system on this continent is having a minimum amount of trouble with its box car roofs because it has certain regulations in force which make it necessary to give the roofs frequent attention and thus prevent the development of slight and comparatively important defects. That particular road is fortunate because its cars are not so generally interchanged as those of other roads. If it is not possible to give the roofs systematic and frequent attention in order to keep them in first-class condition, then it is not only desirable, but necessary, that a type of roof be used which will not need such attention.

One of the larger systems has a solid riveted roof, with air spaces at the sides to provide for ventilation, which was applied to about 110 cars a year and a half or two years ago, and has given splendid satisfaction—so great satisfaction, in fact, that cars in service or under order to the number of 10,000, either have or are being equipped with it. The argument is constantly being advanced that it is necessary to have a flexible roof on all box cars to provide against the various stresses to which the superstructure is subjected. The designers of the solid riveted roof under consideration argue that it has been found necessary to develop rigid underframes and that it is just as necessary to have a rigid roof, the former stiffening the box at its lower end and the latter at the top.

If further observation of these cars in service proves as satisfactory as it has on the first cars so equipped, and those in charge must have little doubt as to whether it will or they would not have specified it so freely, then why not go one step further and make an all-steel box car? With a steel underframe, rigid steel roof, and steel members in the side and end frames, it is only a short step further to substitute metal for wooden sheathing. All of which is suggested by the comment in President Fuller's address directing attention to the necessity of giving more attention to the problem of leaky roofs.

STANDARD COUPLER.

MOST encouraging progress toward a standard coupler is shown by the report of the committee on Couplers and Draft Equipment presented at yesterday's session. In keeping with the importance of the subject, the report is one of the most detailed and thorough ever presented to the association. It contained 153 pages, including 148 illustrations and many tables, and gave the essential parts of the discussion at the several joint meetings of the committee and the representatives of the manufacturers.

The development of a new contour which, after further experiment in the laboratory, will probably be recommended for experimental service by all the members, is the most important single feature of the report. This has been termed the Krakau or straight line contour. It provides for a parallel coupler face and face of the knuckle, both perpendicular to the center line of the shank. The advantages claimed for it are that it provides greatly increased strength through the hub of the knuckle and in the front face of the coupler head, and it shortens the average length of the lever arm from pivot to buffing face and will practically stop the bending of the knuckle under buffing shocks. Furthermore, owing to the increase in the longitudinal clearance to 7/8 in. when in the coupled position, provision is made for the vertical angling between couplers when passing over humps without putting a strain on the couplers, and, in buffing on curves, as well as on a straight track, the wedging due to the knuckle engaging the face of coupler head and the face of the guard arm of the mating coupler is avoided. The proposed contour will couple at a greater angle than the present coupler.

There seem to be but three disadvantages in the minds of the committee. These are a lesser maximum angle through which the new contour will swing when coupled; the amount of slack in the heads when coupled together; and the fact that the last portion of knuckle closure is accomplished by momentum when coupling on curves. On large radius curves, however, the last objection does not hold as the new couplers will adjust themselves to straight track conditions up to the limit of the side clearance. The fact that the proposed contour gives an initial slack of 7/8 in. was the subject of considerable discussion in the

committee, and to ascertain how serious an objection this might be in regular service, an investigation was made of the amount of slack existing in the present standard couplers which were in service and in good condition. The test of a train of 61 cars on the Pennsylvania showed an average initial slack per coupler of 1.66 in., and a train of 68 cars on the New York Central gave an average slack of 1.39 in. It thus appeared that the proposed 7/8 in. is considerably under the present everyday condition. The report also anticipates the perfection of a wedge type of lock and, with this, it is pointed out that the slack will not increase in service as the present coupler heads were shown to do. In view of the important advantage of the elimination of the distinctive strains set up in the present couplers in hump yards and on tipple tracks, it seems that the 7/8 in. clearance is a strong point in favor of the new lines.

Tests of a proposed wedge lock in a jiggling machine showed it to have a slight tendency to creep, but it was felt that this could be overcome and, therefore, since the adoption of the new contour hinges so much on this feature, the committee has requested that none of the new designs be put in experimental service, which will eventually settle the question of any trouble that may appear in connection with coupling on curves, until it has made further experiments. It will notify the members which couplers are recommended for trial purposes at a later date.

The result of the general investigation of the subject has convinced the committee that the present couplers are entirely inadequate in strength. It is satisfied, however, that the desired increase in strength can be obtained, but that it will necessitate an increase of from 30 to 40 per cent. in the weight.

TO-DAY'S PROGRAM.

M. C. B. ASSOCIATION.
9.30 TO 1.30 P. M.

Discussion of reports on:	
Safety Appliances	9.30 A. M. to 9.45 A. M.
Rules for Loading Materials	9.45 A. M. to 10.00 A. M.
Overhead Inspection	10.00 A. M. to 10.15 A. M.
Car Trucks	10.15 A. M. to 10.45 A. M.
Train Lighting and Equipment	10.45 A. M. to 11.30 A. M.
Train Pipe and Connection for Steam Heat	11.00 A. M. to 11.15 A. M.
Tank Cars	11.15 A. M. to 11.45 A. M.
Specifications for Tests of Steel Truck Sides and Bolsters for Cars of 80,000, 100,000 and 150,000 Pounds Capacity	11.45 A. M. to 12.00 M.
Topical discussion:	
Retirement from Interchange Service of Cars of 40,000 and 50,000 Pounds Capacity	12.00 M. to 12.30 P. M.
Discussion of reports on:	
Capacity Marking of Cars	12.30 P. M. to 1.00 P. M.
Lettering Cars	1.00 P. M. to 1.30 P. M.

ENTERTAINMENT.

Orchestra Concert, 10.30 A. M.—Entrance Hall, Million Dollar Pier.

Orchestra Concert, 3.30 P. M.—Entrance Hall, Million Dollar Pier.

Informal Dance, 9.30 P. M.—Entrance Hall, Million Dollar Pier.

M. C. B. ASSOCIATION RAISES DUES.

At the meeting yesterday morning it was announced that the executive committee at its conference last Saturday had decided to recommend increasing the annual dues from $4 to $5 per vote. The rate of $4 a vote does not cover the necessary expenses of the association. The recommendation of the committee was approved by the association.

LOST.

Badge No. 2701 has been lost. Finder please return to Secretary Conway's office.

Black belt, with jet buckle, lost on the pier. Return to Secretary's office.

FUNERAL OF ANDREW S. CROZIER.

The funeral services for Andrew S. Crozier will be held in the Calvary Church, at Glen Riddle, Pa., on Wednesday, June 18, at 3 o'clock P. M. Those who desire to attend should leave from the Broad Street Station of the Pennsylvania R. R., Philadelphia, taking the 1.28 P. M. train on the West Chester Branch, via Media.

M. C. B. SOCIAL GATHERING AND DANCE.

The M. C. B. social gathering and informal dance was held last evening at the Marlborough-Blenheim, under the charge of the following committee: Messrs. Hammond (chairman), Hibbard, Furry, Faure, McClintock, Wardell, Caton and Crowe. Like the previous dances held during this convention it was informal and was very well attended.

ELECTRICAL ENGINEERS INVITED TO VIEW EXHIBITS.

The Railway Supply Manufacturers' Association extended an invitation to the members of the Association of Railway Electrical Engineers attending their semi-annual convention to examine the exhibits on the pier.

The A. R. E. E. badge will entitle each member to admission.

RETURN TRANSPORTATION.

The Pennsylvania has notified members of the M. C. B. Association that transportation home over its lines will be furnished to those entitled to it. The Central of New Jersey offers the same courtesy to members who wish to return over its lines or the Reading, application to be made to C. E. Chambers. A special train of parlor cars for New York will leave Atlantic City on Wednesday afternoon at 2.30 over the Central of New Jersey.

Special provision will also be made on the 2.10 train of the Central of New Jersey for members wishing to return to New York at that time.

LOST BADGES.

The convention badges bearing the following numbers have been lost and they have therefore been cancelled. Admission will be denied to any one attempting to use these numbers: 3635, 2536, 4331, 1145, 2941, 3448, 4361, 2563, 2425, 4336, 3580, 2836.

THE PURDUE DINNER.

The annual dinner of the Purdue men in attendance at the M. M. and M. C. B. conventions was held at the Shelburne on Saturday evening, June 14. The following men were present: Dean C. H. Benjamin and Professor L. E. Endsley, Purdue University; F. B. Ernst, American Steel Foundries; J. P. Neff, American Arch Co.; Garland Robison, Interstate Commerce Commission; W. L. Robinson and C. B. Woodworth, Baltimore & Ohio; W. H. Winterrowd, Canadian Pacific; E. E. Silk, Bettendorf Axle Co.; Fred Schaff, Locomotive Superheater Co.; W. S. Humes, General Railway Supply Co.; J. R. Mitchell, W. H. Miner, Chicago; Percy Hauser, W. B. Leet, O. D. A. Pease and B. B. Milner, Pennsylvania R. R.; R. J. Himmelright, Locomotive Stoker Co.; B. F. Bilsland, General Electric Co.; and H. A.

Smith, J. E. Sample and J. M. Lammedee, Railway & Engineering Review, Chicago. The committee, consisting of E. E. Silk, J. P. Neff, L. E. Endsley, W. H. Winterrowd and J. M. Lammedee, having this year's dinner in charge, will arrange for a similar gathering at the time of next year's convention.

COMMITTEE ASSIGNMENTS.

Secretary Taylor announced at the meeting yesterday morning that in accordance with Article VI, Section 4, of the consituation, the executive committee suggested the following names for the committee on nominations: F. W. Brazier, A. W. Gibbs, F. H. Clark, F. H. Goodnow, F. F. Gaines, J. T. Wallis, W. H. Lewis, C. E. Fuller, G. W. Wildin, J. J. Hennessey.

T. M. Ramsdell, R. D. Smith and T. H. Goodnow were appointed a committee on correspondence and resolutions.

The president named the following committees on obituaries: For W. H. Taylor, J. W. Taylor; for H. Schlacks, C. A. Schroyer; for C. F. Gossett, M. W. Seidel; for J. J. Ryan, J. R. Cade; for Harry Coulter, R. L. Kleine.

ANOTHER LETTER FROM MR. LEHON

Atlantic City, N. J., June 16, 1913.

To the Editor of The Railway Age Gazette:

In view of my personal interview and understanding with you in connection with my letter of June 13. I am somewhat surprised at the caption employed by you of "A Criticism, and an Answer."

You know that my letter was an expression of opinion and in no way offered or intended as a criticism; accordingly it was not fair to preface the letter with the suggestion that it was intended as a criticism, although such an interpretation was possible.

Here is one of the greatest conventions held in the country, so creditable and remarkable that both interests contributing thereto have just reason to be proud of it, and while it may be expedient from your standpoint to minimize whatever apathy and inattention actually exists in regard to exhibits, such a policy is not calculated to remedy the situation, neither will it promote further growth and development.

Everyone who has the courage of his convictions expects to be made "the goat" occasionally and for the opportunity offered me by you to serve in that capacity, I thank you.

Tom Lehon.

[It appears that the editorial comments made by us on Mr. Lehon's letter in the *Daily* of Monday misinterpreted its intent and spirit, and we gladly give space to the above further communication from him.—Editor.]

REGISTRATION IN 1911-'12-'13.

The following table giving comparative figures of registration of the M. M. and M. C. B. Association for the years 1911, 1912 and 1913 will be of interest. The figures are based on official Registration Book No. 4, containing all registrations for the 1913 conventions up to 3.40 o'clock Sunday afternoon:

	1911	1912	1913
Members of M. M. and M. C. B. Assns.	712	647	577
Special Guests	757	453	499
R. R. Ladies	699	330	427
Supply Ladies	399	224	281
Supply Men	1684	1465	1611
Totals	4251	3119	3395

Two hundred and forty-five members of the M. C. B. Association registered before noon Monday morning.

Lo-tung Railway, China.—The first section of the Lo-tung Railway from Lo-yang to Tieh-men has been completed, and daily passengers and freight trains between these two stations are now being run.

MEETING OF RAILWAY ELECTRICAL ENGINEERS.

The semi-annual convention of the Association of Railway Electrical Engineers was held at the Hotel Dennis, June 16, Vice-President H. C. Meloy, chief electrician, Lake Shore & Michigan Southern, presiding. President D. J. Cartwright commented on the growth of the association and the constantly widening field for its activities. Much of the work done by it has proved of considerable importance to the M. C. B. Association. The purpose of the association is to study problems that come under its special jurisdiction so that standards may be established that will represent the best practices. While the original work of the association was in connection with car lighting, its opportunities for considering other electrical subjects have greatly increased because of the extended use of electricity in shops and other places on railroads. Secretary J. A. Andreucetti reported an approximate cash balance of $1400 in the treasury and a total membership, including associate members, of 532. There were about 50 members in attendance at the meeting.

A report of progress was offered by the following committees: Data and Information; Dynamo Suspension; Headlight; Illumination; Incandescent Lamp Specifications; Head End Equipment; Organization and Yard Force; Outside Construction and Yard Lighting; Standard Operating Reports; Standards; Rubber Belt Specifications; Shop Practice; Wire Specifications; and Installation of Wiring. The committee on charging of passenger car storage batteries, of which J. R. Sloan, Pennsylvania Lines East, is chairman, presented a full report. Six methods of charging batteries for straight storage were described. The system known as the constant potential system was preferred by the committee and was covered in the report as follows:

A definite fixed resistance is placed in series with the battery and a definite constant voltage is maintained across both battery and resistance.

With this method the ampere hour input is determined by an ampere hour meter operating a circuit breaker to cut the battery off charge. Care must be exercised in determining the proper resistance and voltage to use, and especially must the voltage be held very closely approximating the predetermined value chosen. It may be said in general that the higher the voltage chosen (which conditions the use of the greater charging resistance) the greater will be the permissible fluctuation of voltage. Increased voltage will, however, increase the amount of energy consumed and reduce the amount of the "taper" effect.

The reasons for favoring this system are: The minimum amount of attention is required from the operator who has only to connect the batteries to the charging plant.

The resistance and voltage are taken at such values as to permit using the highest current rate that will not injure the battery, which will be fully charged in a minimum time, while the current being reduced to normal at the end of the charge, excessive evolution of gas at this portion of the charge is avoided, thus maintaining the efficiency of the charge and minimizing the depreciation of the battery.

The elimination of overcharging the battery and so wasting power, as current is automatically cut off on completion of charge.

The results obtained will depend upon the accuracy of the meter and the constancy of the voltage.

This method has the disadvantage that the rate of current flow is affected by the physical condition of the battery, i. e., whether the cells are short-circuited or sulphated by the temperature, level and specific gravity of the electrolyte, age of battery and on whether antimony and certain impurities are present in the cells.

It has the further disadvantage that for the best results it is probable that different terminal voltages and resistance will probably be required for each of the three different types of batteries, viz., Faure, Planté and Edison, although it is believed that very good results will be obtained if the initial charging rate (neglecting the first momentary rush of

current) does not greatly exceed the three-hour or double normal rate and the final charging rate does not greatly exceed the normal or eight-hour rate of the Plante battery.

Four methods of charging the batteries used with the head end system were considered, the following method being considered the best: A definite fixed resistance on each car is placed in series with the battery and a definite constant voltage is maintained across both battery and resistance. The ampere hour input is determined by an ampere hour meter compensated for battery ampere hour efficiency, and when the battery is fully charged opens the charging circuit by completing the circuit through the trip coil of a circuit breaker.

The comments under the method mentioned in straight storage apply equally well here.

With the axle generator system the committee recommended a constant battery current with a voltage control, together with an ampere hour meter on each car to indicate the charge condition of the battery and show whether terminal charging is necessary.

R. Norberg of the Willard Storage Battery Company, and also a member of the committee, presented a minority report not agreeing with the method for charging straight storage batteries. He said: "I believe that a great percentage of the batteries that are actually operated are far from normal and batteries of this class would stand a great chance of getting damaged if charged according to your recommended method for straight storage.

"I have no objection to the recommendation theoretically; but I do believe that in practice it is liable to do more damage than good. I would, therefore, suggest that the recommendation be modified to such an extent as to recommend this method as theoretically the best method, where the voltage of the battery is normal and absolutely known. For practical purposes under general service conditions, method E should be recommended."

Method E is as follows: Charging current held approximately constant by manipulation of the rheostat and ampere input determined by ampere hour meter. This meter so designed as to compensate for the ampere hour efficiency of the battery when the battery is fully charged, acting to complete a circuit through the trip coil of a circuit breaker. This breaker when opened cuts the battery off charge.

Other members of the convention agreed with Mr. Norberg. The discussion brought out the importance of the subject, as there are about 8,000,000 batteries in service which represents considerable capital. It was also mentioned that the specific gravity of the battery solution should be carefully watched.

In the report of the committee on illumination was mentioned a series of tests to be made on the Lake Shore & Michigan Southern at Collinwood, Ohio, on all types of reflectors with gas and electric lights. The tests will be very complete and will be in charge of an illuminating engineer. The manufacturers of reflectors will aid the committee in the tests.

In the afternoon S. T. Dodd, General Electric Company, gave an interesting illustrated lecture on gas-electric cars, in which he mentioned the various types of self-propelled cars. A brief historical sketch was given of these cars and a somewhat detailed description of the operation of the latest types. In regard to the fuel or distillate used for the engines he pointed out that the specific gravity specification for such fuel was not reliable, it being only an average of all the mixed distillates. A more accurate specification should be a certain percentage of distillate at one temperature, another certain percentage at another temperature, and so on until the desired blend had been obtained.

G. H. Stickney, of the lamp department, General Electric Company, and also a member of the Illuminating Engineering Society, presented a paper on illuminating engineering co-operation, whereby both the Illuminating Engineering Society and the A. R. E. E. may be greatly benefited. This may be done by joint meetings; representation by papers presented before each association; by the establishment of joint committees on co-operation and a representation of one society in the committees of the other. This scheme has been worked out with other associations with good results.

PROPOSED LINE FOR MANCHURIA.—It is proposed to build a railway from Kirin, Manchuria, to Hailungcheng via Panshihhsien. Chinese capitalists have subscribed to two-thirds of the required capital. All that is left to be done is to raise the remaining third locally, and when this sum is raised, which is, however, considered no easy task in view of the prevailing stringency in the money market, the promoters intend to start work without delay.

ENTERTAINMENT COMMITTEE.

Left to right, top row—Roger J. Faure, W. C. Wardell, H. A. Neally, J. D. Purcell, P. M. Brotherhood, J. M. Crowe, C. D. Eaton, C. J Donahue, W. S. Furry, and W. J. Caton.

Bottom row—Harry S. Hammond, L. B. Sherman, J. P. Landreth, Leonard J. Hibbard, W. K. Krepps, John D. McClintock, Gilbert E. Ryder, and Edward P. Chaffee.

MASTER CAR BUILDERS' ASSOCIATION PROCEEDINGS.

Includes President's Address, Reports on Standards, Brakes, Brake Shoes, Couplers, Wheels, Interchange Prices, etc.

The first session of the forty-seventh annual meeting of the Master Car Builders' Association was held in the Greek Temple, on Young's Million Dollar Pier, Atlantic City, N. J., on Monday, June 16, 1913.

The president, C. E. Fuller (Union Pacific) called the meeting to order at 9.30 A. M., the Rev. Dr. Newton W. Cadwell invoked the Divine blessing.

ADDRESS OF PRESIDENT FULLER

It affords me pleasure to welcome you to the forty-seventh annual convention of the Master Car Builders' Association. The Master Car Builders' Association from a small beginning has grown to be a great international institution, which is being regarded more and more as the medium upon which this whole country must rely to solve the questions of safety and permanency in methods of car construction and maintenance, and to a greater or less degree those of car operation. To hold its prestige the association must of necessity keep pace with the constant changes in affairs, and boldly step forward in the line of progress.

While we have been lending our best efforts to car construction and to the promulgation of rules which have for their purpose the minimizing of restrictions and delays in the interchange of cars, have we as an association always kept before us the necessity for taking into consideration also the question of reducing the cost of maintenance and operation of equipment? This is essential, you will agree, and it is of paramount importance that the association as a whole, and each of its committees, should weigh the cost and consider carefully the benefits attainable by their adoption before approving or advancing any changes, and especially those that will entail large expenditures.

A number of reports will be presented by standing and special committees for your consideration, and it is hoped they will be afforded careful scrutiny and be given a full and impartial discussion. Let us consider carefully all the various recommendations which are placed before us for approval, and let us not lend the prestige of this association to anything that will mean increase in maintenance and operation, which cannot be satisfactorily defended before the bar of public opinion on the grounds of safety and economic progress. While it may be true that we are surrounded by flattering conditions of prosperity, it is nevertheless true that the expenditures which our companies have been called upon to make, by reason of changes in car construction, have in recent years been enormously increased. Our watchword, therefore, should be "Economy."

C. E. FULLER,
President, M. C. B. Association.

The committee on Standards and Recommended Practices has given very careful and exacting consideration to the problems submitted to it, and has presented a report which will be found both interesting and instructive.

The committee on Car Construction has presented an interesting report, with appropriate recommendations to be submitted for the consideration of the members. A salient feature of this report is the determining of a limit for minimum strength of underframes. This limit is based on the minimum cross-sectional area of center sills, and, when approved, will serve as a basis to define the handling line's responsibility for combination of damages under ordinary usage to such cars as fall below the minimum strength so established. I feel that this committee should be continued, and that it should undertake to consider seriously the building of heavier capacity cars—say of 70 tons capacity—so as to increase the tonnage and enable us to reap

the benefit of reduced grades and heavier tonnage without increasing the length of our trains.

In freight car construction there has been a decided trend within the last year or so towards single-sheathed box and other house cars, indicating that this type of car is growing in favor. It has the advantage of light weight combined with strength of superstructure, comprising rolled or pressed steel shapes riveted to the underframe, but the problems of the end construction and providing for the shrinkage of lumber in the side and end lining still confront us and must receive our further attention. In view of this it seems questionable whether the solution of the entire proposition is not steel construction for freight car equipment. Speaking of steel construction, in going from wood to steel in passenger car construction probably the most important feature is that of proper insulation, which was largely neglected in the beginning, due principally to a lack of appreciation of the enormous difference between heat conductivity of steel and wood construction. Some types of early steel cars were unsuccessful from a heating standpoint; others have been made comfortable only by the addition of an unusual amount of heating surface, and the question of insulation of steel passenger cars at the present time merits our earnest study.

M. K. BARNUM,
Vice-President, M. C. B. Association.

J. S. LENTZ,
Treasurer, M. C. B. Association.

The Coupler committee has made a report which we believe is worthy of your full consideration, and especially should the question of contour lines be considered, to enable flexibility in passing around sharp curves, consequently reducing undue strains on the underframe of the car, as well as reducing the flange friction. I feel that this committee should be encouraged, and that early action should be taken to adopt a standard M. C. B. coupler.

While this association by letted ballot has adopted wheel tolerances for solid steel wheels as recommended practice, under the head of "Specification Covering Dimensions and Tolerances for Solid Wrought-Steel Wheels for Freight and Passenger Car Service," there is a possibility that this specification should go further and show the desired chemical analysis, together with the methods of test and inspection. In this connection I wish to remark that the Master Car Builders' Association is fully qualified from every standpoint to formulate its own standards and specifications, and I would recommend that a committee be appointed for the ensuing year to take this subject under consideration and make a complete report at the next convention.

With reference to the matter of light weight and maximum weight capacity stenciling of freight cars; the railroads have been rather loath to follow out the original recommendation of the association regarding this method of stenciling. The committee has been confronted with the danger that the universal adoption of the plan would possibly transfer the responsibility for failure of cars of weak construction to the handling line. At the same time it feels the necessity for recognizing the right of companies to adopt this method of stenciling for such cars as are of proper design and physical strength, to enable them to increase the carrying capacity of a very considerable number of cars without any untoward results. It is, therefore, recommended for your consideration that this stenciling be confined to steel and steel-underframe cars with a proper factor of safety in the body structure and trucks.

In the last few years the abuse of the repair card has had considerable attention at the hands of the association, and the executive committee has given this subject consideration during the past year. It is recognized that honesty cannot be legislated into the human race; however, it is believed that if the officials of the various companies will give it out plainly to their subordinates that sharp practices will not be tolerated, the complaint that some companies are making "pencil repairs" to cars will be done away with.

During the past year the American Railway Association through its committee on Car Efficiency reported to the executive committee a serious condition at several large interchange points, brought about by the enforcement of that part of M. C. B. Rule Number 2, which requires that defect cards must be attached to cars at the time of interchange. The delays incident to the enforcement of this rule became unbearable to some companies. Cars were set back for defect cards by

both sides, and the situation became critical at some locations. It was up to the executive committee to act. It was clearly not possible to rescind that part of the rule requiring that defect cards be placed on cars. The executive committee, after due deliberation, agreed that it was absolutely necessary to reduce the number of defect cards issued. It was the opinion that this could be brought about by making some provision or arrangement, whereby the necessary repairs would be made to the cars by the handling line, so that defect cards would not be required by the receiving line; and by eliminating the carding of owner's defects. Defect cards were being issued for defects which, although primarily "owner's responsibility" became "handling line's responsibility" as soon as the car crossed an imaginary line at the time of interchange. The committee felt that there could be no possible objection raised, nor any injustice done any car owners, by placing the responsibility where it primarily belonged. Again it was a well-known fact that the prices allowed in the rules for both labor and material were not increased in recent years to meet the advances in wage schedules and the increases in cost of materials, nor did the prices in the car interchange rules include any percentage to cover facilities, supervision, or use of tools. To meet the emergency that existed the executive committee, by virtue of the authority given it by the constitution, caused circular number 8, "Result of Special Letter Ballot on Change in the Rules of Interchange" to be issued by the arbitration committee, effective November 1, 1912, by which the existing condition was almost immediately relieved. We have reliable information from several large interchange points indicating that the number of defect cards has been reduced approximately one-half.

It is a well-known fact that tht executive committee, through the arbitration committee, is called upon at times to interpret certain parts of the Interchange Rules, also to meet emergencies and to remove misunderstandings that are shown to actually exist to the detriment of prompt interchange of cars, and it has been necessary to instruct the arbitration committee to issue certain circulars to the members to meet such emergencies. Should there be any doubt in the minds of the members as to whether the reading of article six of the constitution invests the executive committee with authority to so instruct the arbitration committee, I would suggest that a committee be appointed to revise this article and remove the uncertainty.

The past year has been a particularly strenuous one for the members of the arbitration committee; their duties have been arduous and they have had some hard problems to face. I feel they are entitled to much credit and that the Association is greatly indebted to them for the work they have accomplished. I believe we can do much to lighten the labors of this committee. It has had to contend, especially in the last year or so, with cases which were based on the most trivial and technical objections; also in some instances with matters of a nature that should be settled by the contestants themselves, instead of placing the burden on the committee. It is, therefore, hoped that railroads and private car companies will refrain from placing themselves in a position where it would seem they are trying to evade payment of bills on technicalities. Another thing which I might mention under this heading is the method practiced by some roads of delaying payment of bills on technical objections. To remedy this trouble the arbitration committee will submit for your consideration a revision of interchange rule number 91 which we hope will meet with your approval.

The subject of "Salt Water Drippings from Refrigerator Cars" has been discussed for a great many years; we now have a recommended practice. At the present time the damage to track and bridges due to the dripping of brine from refrigerator cars warrants advancing this to standard, and the arbitration committee in its report this year has recommended a time after which no car carrying products which require for their refrigeration the use of ice and salt, will be accepted in interchange unless equipped with suitable devices for retaining the brine between icing stations. This subject is of such importance to the railroads that it is hoped the arbitration committee's recommendation will be adopted by the association and incorporated in the interchange rules.

There is another subject that has been receiving considerable attention of late, particularly by western roads—the retirement of cars of 50,000 lbs. and less. capacity. A great number of these cars are equipped with old style triple valves, and their physical condition as a rule is not such as to make them desirable equipment to be handled in heavy trains over steep grades. This subject will come up at the noonday discussion of topical subjects, and it is to be hoped that this matter will be fully discussed with a view to having each road confine its light equipment to local business.

The necessity of putting car roofs in proper condition is another matter, which I believe should have the attention of the association with a view to taking action that will overcome the trouble being experienced by the roads and the expense incidental to claims being paid on account of leaky roofs.

It is with regret we recall that death has taken during the past year honored members of our association as follows: W. H. Taylor, Henry Schlacks, C. E. Gossett and J. J. Ryan. A committee will be apointed to draw up suitable resolutions for record in our proceedings.

At these annual gatherings, in addition to the opportunity for exchange of ideas and absorption of knowledge, we are afforded further mental treat through the elaborate and up-to-date display of modern railroad machinery and tools which the manufacturers place before us, and I feel they are entitled to our thanks and appreciation. I would urge the members to take full advantage of the opportunity.

In conclusion I wish to express to you my sincere appreciation of the confidence you have placed in me, and assure you I feel it is a great honor to be permitted to preside over these meetings. I wish to express my deep gratitude for the assistance given me by the officers, committees and individuals during the year in conducting the affairs of the association.

ASSOCIATION BUSINESS.

Secretary Taylor then presented his report which showed the membership to be as follows: Active members, 433; representative members, 414; associate members, 11; life members, 21. The number of cars represented in the association is 2,713,650 as compared with 2,593,397 in June, 1912. Thirty-nine railroads and private car lines gave notice during the year of their desire to become subscribers to the rules of interchange governing freight cars, and three railroads advised of their acceptance of the code of rules governing the interchange of passenger equipment. The report of the treasurer, John S. Lentz, showed a balance in the treasury of $627.91. The reports of the secretary and treasurer were referred to an auditing committee consisting of T. M. Ramsdell (C. & A.), T. J. Burns (M. C.), and E. W. Pratt (C. & N. W.).

Secretary Taylor said that on October 30, 1912, the executive committee sent the following communication to the members: In accordance with article 12, section 1, of the constitution, relating to amendments to the constitution, it is proposed that article 6, section 1, be amended as follows:

Section 1. First paragraph. No change; second paragraph, a new paragraph as follows: "The executive committee may exercise such supervision over the standards, recommended practice or rules of this association as may be necessary to meet any emergency that may arise during the year in the conduct of the affairs of the association, such action to be taken only on the unanimous vote of the members of the executive committee."

Third paragraph, revised: "It shall make a report at each convention, which shall cover the action it has taken on such general or emergent supervision and make such recommendations as it may deem necessary on questions of importance to the association."

F. W. Brazier (N. Y. C.): I move that the proposed amendment as read be approved and become part of the constitution. The motion was seconded and carried.

REPORT OF THE COMMITTEE ON NOMINATIONS.

The committee suggested the following: For President, M. K Barnum, G. S. M. P., Illinois Central; for First Vice-President, D. F. Crawford, G. S. M. P., Penna. Lines West; for Second Vice-President, D. R. MacBain, S. M. P., L. S. & M. S.; for Third Vice-President, R. W. Burnett, G. M. C. B., Canadian Pacific; for Treasurer, J. S. Lentz, M. C. B., Lehigh Valley; for Executive Members, C. E. Fuller, A. G. M., U. P.; T. M. Ramsdell, M. C. B., C. & A.; and C. F. Giles, S. M., L. & N.

The ballot will take place on Wednesday and the tellers will be named on Wednesday morning.

REVISION OF STANDARDS AND RECOMMENDED PRACTICE.

After due consideration of present standards and recommended practice of the association, together with replies from members to the circular of inquiry, and in connection with which we wish to say that very few of same were received; also requests involving standards presented by the secretary your committee desires to report as follows:

AXLE "A." (Standard.)

With journals 3¼ in. by 7 in. Page 681. Sheet M. C. B. 15.

A member calls attention to investigation of a number of axle failures which have caused derailment on their system, and in which it has been found that they were almost entirely caused by 3¼-in. journals, worn close to the M. C. B condemning limits. This, of course, referring only to jour-

nals with "cold breaks," as contrasted with journals "burned off."

From the foregoing it is safe to assume that the M. C. B. condemning limits for the 3¾ in. by 7 in. journals do not provide for the same margin of safety as in the larger sizes, due probably in part to the very heavy mileage that the small journal makes before reaching its condemning limits contrasted by the fact that in the case of the 5½ in. by 10 in. and to a lesser degree the 5 in. by 9 in. journals, are generally condemned by collar wear or journal length before they reach the minimum diameter.

"If this is correct, which I believe investigation on other lines will prove, the M. C. B. Association should increase the condemning limit for the 3¾ in. by 7 in. journals to give a greater margin of safety which I believe is required particularly in winter weather in the northern climates, into which district any of the cars of the southern lines are apt to pass."

The committee does not concur in this recommendation.

AXLES "C" AND "D." (Standard.)
With journals 5 in. by 9 in. and 5½ in. by 10 in. Sheet M. C. B. 15.

A member calls attention as follows:

"There are quite a number of cases of cars of relatively heavy tare weight using 5 in. by 9 in. and in some cases 5½ in. by 10 in journals. From information we have received, I believe particularly in the case of the 5½ in. by 10 in. that the journals seldom reach their condemning limits unless frequently in the 5 in. by 9 in. If it can be shown that the

T. H. GOODNOW,

Chairman, Committee on Revision of Standards and Recommended Practice.

larger condemning limit for journal diameter could be put into force without shortening the present life of these axles and that their freedom from failures even under overload has shown them to have a very considerable margin of safety, is there any reason why the permissible load carried might not be slightly increased—I believe less than five per cent. increase would be sufficient—to enable some existing equipment to carry ten per cent. overload, which is becoming generally customary, without an overload on the journal, particularly as the tendency is to increase the weight of the underframe to meet service conditions which makes it difficult to build stiff cars to carry their nominal capacity with ten per cent. overload and not overrun the journal capacity.

The committee does not concur in this recommendation.

AXLES. (Standard.)
Pages 681 to 684. Sheets M. C. B. 15 and "B."

Through a member, the following communication from Mr. George R. Henderson, consulting engineer of The Baldwin Locomotive Works, was received:

"I desire to call your attention to some investigations which I have recently made regarding the standard M. M. and M. C. B. axles in connection with the operations of the quick action ET brake under emergency application.

"There have been cases of axle failures under tenders and also there have been cases where there seems to be a tendency of the journal to roll out of the bearing or under the edge of the bearing when a severe application of the brake is made.

"Referring to the question of the strength of the axle, would say that I have investigated the combined action of the brake taken in connection with the worst strains that can occur from the natural loading and wind or centrifugal pressure, which horizontal force has been assumed at 40 per cent. or just sufficient to relieve the rail on the windward side of pressure and throw the whole load on the outer or leeward side rail. Of course this is the worst case that could occur, as any further horizontal strains would cause the car to roll entirely off the track. I find that under these conditions the greatest strains occur at the point just inside of the collar at the inner point of the wheel hub and that this strain amounts to from 22,500 to 23,000 lbs. on the 5 in. by 9 in. and 5½ in. by 10 in. axles. Of course, I see the logic in making the weakest point at this section where a crack could be discovered, which would not be the case if it occurred the other side of the collar next to the wheel hub; however, the stress seems rather high, but the action of the brake shoe coming at right angles to these stresses does not materially affect the outer strains in the axle.

"It is possible with an emergency application of the ET brake, when the brake-shoe pressure is based on 80 per cent. of the light weight of the tender with 50 pounds of air in the cylinder, in accordance with the recommendations of the Westinghouse Air Brake Co., to obtain a shoe pressure equal to about one-third of the normal axle load or maximum load for which the axle is intended. Thus, for the 5 in. by 9 in. axle the pressure horizontally of each brake shoe may amount to 10,000 lbs. under the conditions above stated and, if the tank should be practically empty, there would be very nearly enough side pressure, taken in connection with the journal friction, to roll the axle out of the bearing. In other words for the 5 in. by 9 in. axle there is a moment of 26,700 pounds disturbing force against a static moment of 30,000 pounds tending to maintain it in the bearing, and the 5½ in by 10 in. axle gives a disturbing moment of 36,700 lbs. as opposed to 40,000 lbs. of stability.

"The subject of axles rolling out of the bearings has been considered by the Westinghouse Air Brake Co., and I was recently told by W. V. Turner, the chief engineer of that company, that they were recommending double or clamp brakes on passenger equipment to take care of this trouble. This would be almost prohibitive on freight cars and tenders equipped with freight trucks and it is possible that for these conditions it would be desirable to alter the depth of the standard bearing in order to reduce this tendency of the axle to roll out of the bearing."

The committee refers this to the Committee on Car Trucks.

AXLE "E." (Recommended Practice.)
Page 683. Sheet M. C. B. "B."

A member suggests advancing axle with 6 by 11 journal, designed to carry 50,000 pounds, to standard.

The committee concurs in this recommendation.

SIGNAL LAMP SOCKET. (Standard.)
Page 802. Sheet M. C. B. 26.

In accordance with action of this Association, 1912 Convention, with respect to location of signal lamp socket in relation to exposure of Marker Lamp. The committee, after further consideration of the matter, recommends this as indicated in sketch accompanying, which is at a fixed angle of 45 degrees, and, as well, at a specified distance from the side of car to the center of socket.

MARKING ON FREIGHT EQUIPMENT CARS. (Recommended Practice.)
Page 804. Sheet M. C. B. "G."

A member suggests that this be advanced to standard, and sheet M. C. B. *G* corrected as to location for marking United States Safety Appliances Standard.

The committee concurs in this recommendation.

MARKING ON FREIGHT EQUIPMENT CARS. (Recommended Practice.)
Page 805. Sheet M. C. B. "G."

The attention of your committee was called to American Railway Association Car Service Rule No. 11, as revised November 20, 1912, which has reference to the weighing of freight equipment, and omits the star indication, with recommendation that the Recommended Practice of this Association be changed to conform.

The committee concurs in this recommendation.

MARKING ON FREIGHT EQUIPMENT CARS. (Recommended Practice.)
Pages 804-805. Sheet M. C. B. "G."

Through the secretary of the association was referred the suggestion of a representative of the American Railway As-

sociation for a standard for stenciling on cars of date of building, on account of the requirements in regard to the re-weighing of cars.

The committee concurs in this recommendation, and suggests that the word "new" be stenciled preceding the word "weight," in accordance with the American Railway Association Car Service Rule No. 11, as amended November 20, 1912.

SPRINGS AND SPRING CAPS FOR FREIGHT CAR TRUCKS. (Recommended Practice.)

Page 903. Sheet M. C. B. "H."

A member suggests adding a spring for the 140,000-capacity freight car truck.

The committee concurs with the recommendation, and refers same to the Committee on Car Trucks.

CLASSIFICATION OF CARS. (Recommended Practice.)

Pages 906-913.

Through the Secretary, request from Mr. G. P. Conard, Secretary of the Association of Transportation and Car Accounting Officers, for assignment of designating symbols for equipment, was received, as follows:

"BM"—MILK CAR.—Exclusively for the transportation of milk, being a car for this purpose and fully equipped for handling in passenger trains.

"ES"—ELECTRIC PASSENGER CAR.—For long hauls or suburban service; multiple unit, and fitted with automatic couplings and air brakes. Operating power, storage battery.

"GB"—GONDOLA CAR.—A car with solid bottom, sides and ends, and open on top; suitable for mill trade.

NOTE TO FOLLOW CLASS "H."

If any of these hopper cars are provided with roof or cover for protection of contents, the letter "R" should be affixed to the regular symbol to designate its special class of service.

"MPE"—COMBINATION, BAGGAGE, MAIL AND EXPRESS CAR. A car having three compartments, each entirely separate from the other for handling its individual class of business.

"MPB"—COMBINATION, BAGGAGE, MAIL AND EXPRESS CAR. A car having an individual compartment, each entirely separate, one suitable for mail, one suitable for baggage, and one suitable for passengers.

"XI"—BOX CAR, INSULATED.—A box car having walls, floor and roof insulated, not equipped with ice bunkers or baskets. This car ordinarily used for transporting vegetables, freight, etc.

"MWX"—BOARDING OUTFIT CARS.—This includes cars used for boarding' sleeping, or cooking purposes in construction and similar work.

The committee concurs and assigns symbols as indicated.

A member suggests assigning designating symbols to the following class of equipment:

Symbol.	Kind of Car.	Description.
"MWE"	Ballast Spreader and Trimmer.	A car with blades or wings for spreading or trimming ballast.
"MWJ"	Ballast Unloader.	A car equipped with machinery for pulling a plow through cars loaded with ballast.
"MWP"	Pile Driver.	A car equipped with machinery for pile-driving.
"MWK"	Snow Removing Cars.	Cars equipped with any special device for removing snow from between or along side of rails.
"MWM"	Store Supply Car.	A car equipped for handling material to be distributed for railway use.

Following the heading of "General Service Freight Equipment Cars," note to be added, as follows:

Any of the following classes of equipment having special heating appliances for the protection of commodity against freezing, to be covered by affixing the letter "H" to the designating symbol.

"SH"	Horse Car.	A car specially fitted for the transportation of horses in freight service.

The committee concurs in the recommendation, so far as designating symbols are assigned.

NEW SUBJECTS.

The committee has further considered the establishment of a maximum standard or limiting height for the running board of a standard dimension box car, and in view of the variance found, brought about to meet traffic requirements, we do not feel warranted in recommending a standard height for running board in view of the other conditions which enter in connection with this.

A member suggests the necessity for a journal box, brass and wedge for axle with 6 in. by 11 in. journals, so as to complete the Association's approval of the use of an axle with 6 in. by 11 in. journal in freight service.

The committee concurs and refers this to the Committee on Freight Car Trucks.

A member calls attention to difficulty experienced with cars with arch bar trucks, or trucks with rigid side frames, and having side bearings located outside gauge of track, and suggests establishing a standard spacing for side bearings.

The committee concurs in this recommendation, with the suggestion that the maximum side bearing spacing should not exceed the rail gage, with a minimum of 44-inch centers, and a minimum clearance between side bearings of 5/16 inch.

A member calls attention to the necessity of end doors on account of difficulty experienced in having yard clerks obtain seal records of same, due to the inconvenient location and risk of personal injury. Claims are now being paid on account of no end door seal record, and cars are being pilfered by theft through the end doors, which can be entered with the least chance for detection. Is an end door in a standard box car essential? If so, could it not be placed near the side of car where seals could be read from the side ladder?

The committee refers this to the Committee on Car Construction.

The committee, at this time, wishes to submit for consideration, separating the proceedings of the association as at present, published, taking out the standards and recommended practice, and have same published as a separate volume.

The report is signed by:—T. H. Goodnow (C. & N. W.), chairman; C. E. Fuller (U. P.); W. H. V. Rosing (St. L. & S. F.; W. E. Dunham (C. & N. W.); O. C. Cromwell (B. & A.); T. M. Ramsdell (C. & A.), and O. J. Parks (Penna.).

During the presentation of the report the chairman stated that the committee wished to withdraw the article referring to Signal Lamp Socket.

T. H. Goodnow (C. & N. W.): Since this report was drawn up, the committee has received several other suggestions, which we could not handle on account of the report having been completed and sent in to the secretary for printing, but at a meeting of the committee held this morning, it was decided that there would be included and presented now, as a supplemental report to the convention, the suggestion made by the arbitration committee that the recommended practice on the Collection of Salt Water Drippings be advanced to standard.

DISCUSSION.

D. F. Crawford (Penna. Lines): I would like to ask the chairman of the committee a question. On page 9, in reference to the marking of freight equipment cars, recommended practice, page 804, sheet M. C. B. G, the suggestion was made that on account of the numerous markings which we are compelled to put on the cars a badge plate with small letters be permitted and used as the recommended practice of the association. I notice that a number of railroads, as well as our lines, are building house cars with considerable outside framing. It is a single sheet car with steel frame. This steel frame makes it extremely difficult to put on the car all the markings which are required, in the comparatively large letters required by the recommended practice of the association, and I would like to know what the objection is to putting on a badge plate.

T. H. Goodnow: I believe it was considered that the present markings were practically established in connection with the meeting which was held with the Interstate Commerce Commission inspectors; that it was thought that on account of that they ought to stand at present as included in the proceedings. The Committee did not feel there would be an objection to using the other, but at the same time, on account of the situation it brought about with the present standard in the proceedings, it had better be left as it is.

D. F. Crawford: The marking of the government is United States Safety Appliance Standard, and they permit the use of the badge plate. The other markings, such as the size of the shank of the coupler and the character of the triple-valve, I do not think the government is particularly interested in.

W. E. Dunham (C. & N. W.): I would suggest that the recommendation indicated that all the markings were to be taken care of by a badge plate. We did not feel that was advisable; the general marks on the car we do not think should be reduced to badge plate sizes.

T. H. Goodnow: In connection with Mr. Dunham's remarks, if I recollect rightly, the only samples submitted were United States stenciling.

D. F. Crawford: That is all covered by page 105, which reads that a badge plate 3½ in. x 10 in., with proper marking, may be used instead of penciled stenciling. The technical point may be raised that a great many cars now turned out with the information regarding the air-brake, coupler and brake-beams and other information of that kind, are all turned out with badge plates. I would suggest a modification of that section of the report.

D. R. MacBain (L. S. & M. S.): It seems to be a good thing to concur in Mr. Crawford's remarks.

M. K. Barnum: It seems to me it would be a good thing to request this committee to consider the markings now placed on the outside of the cars with a view to separating them into two classes, one to be put on a badge plate and the other class to be stenciled on the car in a suitable manner. I would make that as a motion, that the committee be requested to revise that part of their report under those instructions; and that they separate the different items that

now are placed on the outside of the cars, making two lists, one of which may be placed on a badge plate and the other stenciled on the cars in the proper manner.

C. A. Schroyer (C. & N. W.): Why is it necessary to incorporate that in the recommended practices of the association when it is now permissible, and nobody will be able to tell as to whether it goes on with a badge plate or is stenciled on.

M. K. Barnum: I think it is necessary in order to have uniform practice.

C. A. Schroyer: It seems to me that there would be no uniform way if the matter is left permissible; "may be" does not make it a uniform practice, because we would not like to pay sixty or seventy cents for a badge plate when we can put it on with one cent's worth of paint. If we want to do it, we have the privilege under existing conditions.

D. F. Crawford: If this particular paragraph had not been entered and had been ignored by the committee, I would not have raised the point; the committee raised that point.

T. H. Goodnow: This was submitted to the committee to be considered, they had to consider it, and for that reason it was incorporated in our report.

President Fuller: The point submitted was the safety plates; they only refer to that.

D. F. Crawford: That is already covered and is a standard of the association.

C. A. Schroyer: I want to make a motion, as an amendment to this amendment, that that portion of the committee's report be stricken out entirely, and the standards and recommended practice will then remain as they are now, which will permit a railroad to use the badge plate if desired, or to put the lettering on with paint if desired.

President Fuller ruled that the motion was not in order at the time.

C. A. Schroyer: When will my motion be entertained?

President Fuller: If the motion made by Mr. Barnum is defeated, your motion will be in order.

C. A. Schroyer: Then there will be no occasion for my motion.

T. H. Goodnow: Yes there will, because that will allow the report to stand as at present.

President Fuller: The question is on Mr. Barnum's motion. The motion was lost.

President Fuller: The motion made by Mr. Schroyer is now in order.

C. A. Schroyer: I make that as an original motion and not as an amendment.

E. W. Pratt: It occurs to me there is no provision in our rules for badge plates except for the words "Safety Appliances," or "Safety Appliances Standard." On the contrary, it tells us the letters for all dimensions of cars and capacities, and everything else, and therefore the standards of the association apply to nothing but that one particular item. We have not anything if we carry this motion, because it will not apply to the matter which we have in hand.

W. F. Kiesel, Jr. (Penna.): I would like to suggest as an amendment to that motion that the committee be requested to make standard plans for badge plates which can be used as a substitute for the stencil for such parts, if the badge plates are available.

President Fuller: Mr. Schroyer, will you accept that amendment?

C. A. Schroyer: No, I am not inclined to accept that amendment.

T. H. Goodnow: It seems to me this committee cannot handle Mr. Kiesel's recommendation, as we simply handle the standards. The standards are established as to the style and size of letter and their location, and it is not within the province of this committee to take up the work that Mr. Kiesel proposes; that is for some other or some special committee to handle.

W. F. Kiesel, Jr.: Your committee can refer the matter to some other committee for consideration.

T. H. Goodnow: That will delay the matter another year.

W. F. Kiesel, Jr.: Let it be delayed another year.

E. W. Pratt: You can make one amendment to an amendment, and I amend Mr. Kiesel's motion to the effect that this suggestion be made by the convention to the executive committee, and that the executive committee put this matter into the hands of such committee as they deem proper. That will save a year's delay.

C. A. Schroyer: I accept the amendment.

The amendment was carried.

President Fuller: By the action just taken, it is understood that this report will go to letter ballot for adoption as recommended practice, and the amendment just made by Mr. Pratt will be considered by the executive committee.

TRAIN BRAKE AND SIGNAL EQUIPMENT.

The committee recommends that hereafter all freight cars weighing between 37,000 and 58,000 lbs. be equipped with 10-in. brake cylinders. The committee also believes that the braking power for freight equipment should be made 60 per cent. of the light weight of the car, based on fifty pounds per square inch cylinder pressure. With 10-in. brake cylinders applied to cars coming under the weight limits given, and using the braking power recommended, a total leverage ratio of 9 to 1 need never be exceeded.

The committee corresponded with the air brake companies for the purpose of ascertaining what triple they would recommend for all freight car equipment to be considered as standard. The replies received stated that they would suggest K-1

R. B. KENDIG,
Chairman, Committee on Train Brake and Signal Equipment.

for 8-in. and K-2 for 10-in. equipments as the one to choose for a standard. The advantage to be derived from the adoption of a standard triple valve for all freight equipment and the elimination from service of several different types are so obvious that the committee does not hesitate to recommend that the K-1 and K-2 triples be made the standard for freight cars.

On account of the increased weight and length of passenger trains, the highest degree of perfection in the operation to obtain uniform application and to avoid annoyance from sticking brakes in releasing is more necessary now than ever before. The committee having before it a report of the results of tests made by the Westinghouse Air Brake Company to de-

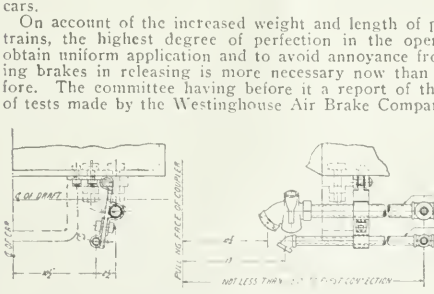

Fig. 1.—Proposed Swing Hanger for Air Brake and Air Signal Pipes at End of Passenger Train Cars.

termine the effect on brake operation of various internal diameters of brake pipe, recommends that no pipe having an internal diameter less than that of 1-in. standard weight be used on passenger cars, and that for all new equipment 1¼-in. extra-heavy pipe be used.

In the case of modern passenger cars, the committee believes that the ends of the brake pipe should be supported by swinging clamps and hangers, so that no trouble from hose parting while train is passing through crossovers will be experienced. Fig. No. 1 illustrates a swinging brake and signal pipe end hanger that has given good service for over two years.

The action of acids and salt water drippings from coal and refrigerator cars falling onto the brake pipe and its fittings causes them to deteriorate rapidly, and it has been suggested

to this committee that the brake pipe on such cars should be galvanized to protect them. This practice is recommended.

There appears to be a lack of uniformity upon the various railroads in the use of a standard socket or pipe coupling, located 10 in. back of the angle cock in the brake pipe. These sleeves or sockets are furnished in various weights and lengths by different manufacturers, and where short ones are used there is more likelihood of leakage. The committee recommends that Sheet No. 18, showing location of brake pipe, be revised or amplified so as to show a pipe nipple, extra strong, 11½ in. in total length, and a line pipe coupling, extra heavy, 2⅞ in. long, the distance between the angle cock and pipe coupling to remain the same as at present—10 in.

The position of bolting lugs of hose clamps as shown on Sheet Q interfere with the operator's hand when operating the angle cock, and at the coupling end with the steam hose where cars are equipped with both the air and the steam lines. In Fig. 2 is shown the locations of the clamps as the committee believes they should be. The committee believes an M. C. B. specification, providing for the proper application of the clamps to the hose, should be prepared and the drawings on Sheet Q be changed to conform to it.

On account of not carrying out the recommendation made by the committee last year for the adoption of a distinctive hose label, the rearrangement shown on Sheet Q costs more to apply, and, therefore, the committee recommends the design of hose label shown on Fig. 2 for adoption.

There are also many other important brake matters that should be investigated and reported upon, such as Foundation Brake and Gear and Clasp Brakes for Heavy Passenger Equipment, Proper Location of Ends of Brake Pipe with Reference to Pulling Face of Coupler, Distance of Brake Pipe

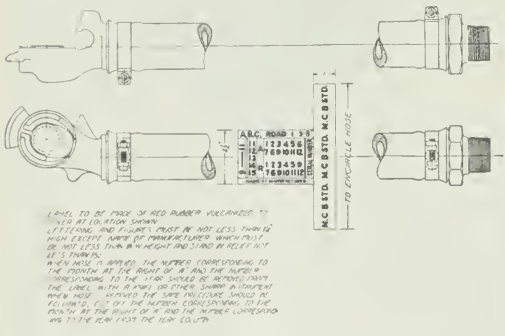

Fig. 2.

from Center of Car Coupler and Height from Rail. The members of the association are earnestly requested to submit to the committee at as early a date as possible matters such as they consider deserving of attention that pertain to the work of the Train Brake and Signal Committee, so that ample time may be had to deal thoroughly with them.

The report is signed by:—R. B. Kendig (N. Y. C.), chairman; R. K. Reading (Penna.); B. P. Flory (N. Y. O. & W.); E. W. Pratt (C. & N. W.) and L. P. Streeter (Ill. Cent.).

B. P. Flory, N. Y., O & W., presented the report in the absence of the chairman, R. B. Kendig, and in connection with Section Eight, under the heading "The M. C. B. Hose Label," said: Since this report was printed and distributed, we have received a report from the committee on Air-Brake Hose Specifications, showing another label, and it was thought by our committee that the discussion on this particular part would be better left out until the time when the committee on Air-Brake Hose Specifications comes up, as the two labels are quite different.

DISCUSSION.

W. E. Dunham (C. & N. W.): I do not quite appreciate why the committee has recommended item Number 3, to the effect that 11½ in. extra heavy pipe be used. It seems to me standard 1¼ in. pipe would answer all purposes and certainly would not be as expensive.

D. C. Young (Penna.): In regard to section 2, I would like to ask the committee or submitting this question by letter ballot when it would become operative as a standard of the association. If it was passed it would seem to me a great many triple valves would have to be removed from freight cars, that would be perfectly good for service. Therefore, it seems to me, the committee should name some date when this standard would become effective in reference to the question of the application of the valves.

C. A. Schroyer (C. & N. W.): I would say in that connection, it is only in the past few years that we have had a 10 in. cylinder for freight cars. We have a great many hundred freight and refrigerator cars now equipped with an 8 in. cylinder, and this recommendation would knock the whole thing right out. The trouble is, if this association goes on establishing standards, they will cut out our cars; in interchange, this would all have to be cut out, or spend $40. or $50 in brakes. In this, they allow a latitude of 37,000 to 58,000 lbs. on a 10 in. and it cuts down the 8 in. to everything below 37,000; and a large majority of the cars we have in service for freight are between 28,000 and 36,000 lbs.; so now we only have 8,000 limit for 8 in. brakes and 21,000 limit for the 10 in. brakes. It seems to me we should be very careful about this.

E. W. Pratt (C. & N. W.): These have been the recommended appliances of the air-brake companies for several years, and most of the railroads, all the up-to-date railroads, have been adopting these recommendations of the air-brake companies; and this was simply to emphasize that. If it is a recommended practice, it would apply to new equipment for some years to come, and yet be a standard for the association.

C. D. Young: We are one of the up-to-date railroads using the 10 in. cylinder and the K-2 triple valves; but this would apply to all the existing cars with 8 in. cylinders and plain triple-valves; therefore the triple-valves would have to be removed and K-2 triple-valves substituted for them, and I think if the committee would let it apply to new cars built after January 1, there would hardly be any objection to their recommendation. I make such a motion.

C. A. Schroyer: The loss comes in in this respect—the law compelled us to fit up these cars, commencing in 1893. We, as an association, recognized that there is no deterioration in an air-brake, and we allow none when we settle for one. All the cars we are destroying to-day have 8 in. air-brake cylinders on them, all of which are good and usable hereafter; and we have to throw them away and scrap those brakes.

B. P. Flory (N. Y., O. & W.): The committee says K-1 and K-2 standard. I think the word "standard" was hardly the intention of our committee, and it should be "Recommended Practice," and that this matter should be referred to as recommended practice, and for that only. That would, I think, cover all the objections raised.

The motion was seconded and carried.

O. C. Cromwell (B. & O.): I notice in number 5, the last paragraph, that the length of the nipple has been changed from 10 in. to 11½ in. A-1, the M. C. B. cuts specify the 10 in. nipple. Why should we make that change?

E. W. Pratt: The chairman of the committee gives me that information, and asks me to explain it. The M. C. B. cut shows from shoulder to shoulder; this refers to the length of the nipple, including threads, so they are practically identical.

O. C. Cromwell: It simply specifies the 10 in. nipple and shows no points between which the length extends.

President Fuller: On M. C. B. sheet 18 it says 10 in., and the arrow-points show between the fittings.

C. A. Schroyer: Then it would mean an 11½ in. nipple. I think it is all right.

O. C. Cromwell: If you order a 10 in. nipple, you won't get it between the collars. You put in a requisition for a 10 in. nipple; it would be the total length and that is the way it was intended to be in these proceedings.

President Fuller: It does not show it.

O. C. Cromwell: It specifies a 10 in. nipple; and that means full length.

F. F. Gaines (C. of Ga.): We have been at some trouble at getting at a standard nipple, and I think we should stick to what we have.

President Fuller: Does anybody know what they are using?

O. C. Cromwell: We use a piece of pipe 10 in. long.

F. W. Brazier (N. Y. C.): A 10 in. nipple is but 10 in. and not 11. If it is an error in the drawing, would it not be easier to correct that?

O. C. Cromwell: If the drawing shows 10 in. from shoulder to shoulder, it does not show a 10 in. nipple.

W. E. Dunham (C. & N. W.): I make the motion that the cut be corrected to show a 10 in. nipple.

President Fuller: Ten inches in length?

W. E. Dunham: Yes, sir, a ten inch nipple.

O. C. Cromwell: You will have to show how many threads will go into the nipple.

The motion was carried.

T. H. Goodnow: As I understand it now, the nipple is taken out of this report, is it not?

President Fuller: The plate will be corrected to show a 10 in. nipple instead of 10 in. between shoulders.

M. K. Barnum (Illinois Central): I move that this report

be adopted as revised, with the exception of paragraph 8, referring to the Hose Label which shall be omitted and deferred for discussion until the report of the committee on Air-brake and Hose Specifications is taken up.

The motion was seconded and carried.

BRAKE SHOE AND BRAKE EQUIPMENT.

BRAKE SHOES.

The committee would repeat the recommendation of last year, namely:

"That some further work be undertaken by the association for the purpose of connecting the results obtained under high brake-shoe pressure with those upon which the association's specifications are based."

Previous to 1911 the tests on brake shoes had been confined to pressures of 2,808, 4,152, 6,840 and 12,000 lbs., and to speeds of 20, 40 and 65 m. p. h.

The tests made by the committee in 1910 at a speed of 80 m. p. h., and at pressures of 9,000 12,000, 14,000, 16,000, 18,000 and 20,000 lbs., established new standards for high-pressure and high-speed service.

In order to complete the series and to furnish data for high-pressure specifications, it is desirable that some further tests of an intermediate character should be made on the shoes tested in 1910.

The committee accordingly recommends for this year's program tests on these same shoes at a speed of 65 m. p. h. and at pressures of 9,000, 12,000, 14,000, 16,000 and 18,000 lbs.

The pressure of 20,000 lbs. is not included, since the results obtained in 1910 show that no practical advantage attends the use of pressures higher than 18,000 lbs.

The committee further recommends that from the data thus obtained specifications should be prepared covering the use of shoes in heavy passenger work.

In view of what has been said above, the committee feels that further tests should be made to complete the series and render available for the purposes of the Association the high-pressure work already done.

The committee presented an Appendix showing results of tests made by the New York Central Lines at the laboratory of the American Brake Shoe & Foundry Company, Mahwah, New Jersey.

BRAKE-BEAM EQUIPMENT.

Standard Brake Beam.—The recommendation of the committee in regard to the adoption of standard No. 2 brake beam was rejected. In order to ascertain the reasons for this rejection, and to get further information, the committee addressed a circular letter of inquiry to the members. The replies to this letter as received by the committee have led the committee to make certain changes in Sheet 17-B, as follows:

The hole at the lower end of strut member in Sheet 17-B is drawn dotted as being optional. It will be noted that the hole in the upper end of the head is also dotted. The committee has found by investigation that it will be difficult to reduce the weight of the beam shown in Sheet 17-B enough to make any appreciable saving without the probability of stresses in the compression member, which would be unsafe for commercial open-hearth steel. The committee would indicate that the new brake-beam gage shown in Sheet 17-A was accepted for trial, with a view to adoption as recommended practice by letter ballot. The committee would accordingly recommend Sheet 17-A to be accepted as showing the details of the gages under trial.

The committee would also recommend the beam as shown on M. C. B. Association Sheet 17-B for consideration and trial by members of the Association, with a view of adopting such beam as recommended practice for No. 2 M. C. B. brake beam.

Brake Beams for Passenger Equipment Cars.—In the circular letter the committee asked whether it was desirable to prepare specifications for the test and inspection of brake beams to be used on passenger train cars. The vote on this question was indeterminate. The committee would ask of the Association, therefore, an expression of opinion as to the advisability of preparing a specification for a brake beam for passenger train cars.

Spacing of Brake-beam Heads.—In the opinion of the committee, the spacing of 60¼ in. between the brake beam heads is unnecessarily large and allows the brake beam to shift to one side or the other and to bring the brake shoe on one side beyond the tread of the wheel so as to bear on the outside edge and wear to a shoulder. This can easily be demonstrated by comparing the maximum and minimum distances for brake heads with the standard maximum and minimum gages of wheels. The committee would accordingly recommend that an average spacing of 60 in. be adopted in place of 60¼ in., with a maximum spacing of 60⅛ in. and a minimum of 59⅞ in.

The report is signed by:—Prof. Chas. H. Benjamin (Purdue Univ.), chairman; C. D. Young (Penna.), and R. B. Kendig (N. Y. C.).

In connection with the matter of further tests to be made, Prof. Benjamin in presenting the report, said: "I will say in explanation, that the association, for the past two years, has authorized these tests but unfortunately we have not been able to obtain the money with which to complete them. I hope that the association will continue this recommendation and that we may be able this year to make the tests. This will practically complete the work on the tests of brake-shoes for this purpose, and will make our specifications complete."

DISCUSSION.

President Fuller: It is considered best to take up the discussion on the brakeshoes first, and go to the brakebeam equipment afterwards.

F. F. Gaines (C. of Ga.): I would move that the recommendation of the committee be adopted, that is, that further tests be made according to the sections on brakeshoes which have been outlined.

The motion was seconded and carried.

Prof. Benjamin then presented the portion of the report relating to brakebeam equipment, and after reference to the beam, as shown on M. C. B. sheet 17-B, for consideration and trial by members of the association with a view to adopting such a beam as recommended practice for a No. 2, M. C. B. brake-beam, he said: "Another question which was raised was that of making the head stronger; that is, re-enforcing the back of the head, for the reason that the steel-back brakeshoe sometimes breaks in the middle, and brings the pressure on the head in such a way as to subject it to more stress than it was intended for. The committee has considered this point, and would prefer to reduce the clearance which now exists from 1/16 in. to 1/32 in., which would perhaps remedy the difficulty without any change in the size of the head."

After the paragraph headed Brakebeams for Passenger Equipment Cars, Prof. Benjamin said: "The reason for asking this was that the answers to the circular of inquiry were so few and indefinite that the committee got no information, and we would like to have the matter referred to the association for an expression of opinion. In this connection, the Buckeye Steel Castings Company, whose exhibit is located at Booths 603-605 of the annex, has kindly consented to exhibit a brakeshoe with the wheels and brakebeams, so that members can make these comparisons directly on a wheel. The brake is so arranged that the wheels on one end have a maximum spacing and maximum thickness of flange, while on the other end they have a minimum spacing and minimum thickness of flange. There are three brakebeams available, one averaging 59¾, one 60, and one 60¼. These will enable all members who are interested in this to see what the tolerances are and satisfy themselves as to the position which the brakeshoe is liable to have, and as to how much motion it has one way or the other."

After the paragraph on Spacing of Brake-Beam Heads, Prof. Benjamin said: "In supporting this last recommendation, I would say that the increasing accuracy in standardization of the wheels and axles themselves makes it more practicable to limit the spacing of the brake-heads in this way than five or ten years ago."

President Fuller: Some action should be taken on the recommendations of the committee under section 3 reading "That the question of preparing a specification for a brake beam for passenger train cars be submitted to the membership of the association for letter ballot." The committee would like the views of the members on this proposition.

O. C. Cromwell (B. & O.): I move that the committee be instructed to prepare such specifications and present them to the association.

(Motion seconded and carried.)

F. F. Gaines (C. of Ga.): I would like to move that recommendation Number four as to its spacing of 60 inches for brake beam heads be adopted as standard and referred to letter ballot.

O. C. Cromwell: I do not think that our present standard should be changed. If you investigate this matter, you will find that you have, with 60 inches at the centre of the head, a 3/8 in. clearance between the shoe and fillet of the flange. It is a much more serious matter wearing out the throat of the flanges than wearing the shoes on the outside of the trend. You have established a centre now of 60-¼ in., you have a gage for it, and the suspension on the trucks is arranged for that; you have the hangers for it, and why go away from it? I cannot see any great necessity for it. We have no trouble with the

shoes sliding off from the outside treads where we run 60-½ in.

F. F. Gaines: I want to say that our experience has been with the wider gages, 60-½ and 60-⅓. We find more throat wear due to the wide gage where the shoe will loop over the face of the opposite side and bring the other shoe tread up into the throat of the wheel, and that will wear the shoe out much more quickly. I would like to see the matter go to letter ballot this time.

The motion of Mr. Gaines was put to a vote and carried.

F. F. Gaines: In reference to recommendation No. 1, this motion we have just put involves a change of sheet 17-A, in regard to the spacing of 60¼ in. there, and I just call the attention of the committee to it. With that in view, I move that the recommendation of the committee be submitted for adoption as standard. It says 60¼ and will have to be changed to 60, if section 4 is adopted according to the recommendation of the committee.

President Fuller: Your motion carries with it a change of the standard, and the matter is before the association for vote by letter ballot for adoption as standard. If section 4 is adopted, it will be necessary to make some changes in other sections to agree therewith.

F. F. Gaines: I move that we adopt recommendation Number 1 as standard, with the change to 60 in., as called for by the other motion.

The motion was adopted.

R. L. Kleine (Penna.): I move that recommendation number two be submitted to letter ballot for adoption as recommended practice.

A. W. Gibbs (Penna.): As I understand the matter, we are not clear on the subject of patents in connection with that brake gearing.

President Fuller: This matter which we are discussing relates to brake beams.

A. W. Gibbs: Recommendation number two says "That No. 2 brake beam, shown in sheet 17-B of this report, receive consideration and trial by members of the association, with a view of adopting such beam as recommended practice for No. 2. M. C. B. brake beam." In that sheet is shown the brake head. The brake head, I find out from reports from one of the legal associations, is covered by two patents, both of which are controlled by the same company, and that the important one is described as follows: "The Harrison patent is the more important one, and covers a brake head having broad attaching lugs with chambered legs, the lugs being cored transversely of the keyway, giving the advantage of strength and uniformity of casting, besides certain alleged incidental advantages in manufacture. The important thing is that this patent contains a claim (No. 6) reading 'A brake head having a shoe attaching lug, extending from side to side of the brake head, said lug having a broad bearing face of substantially rectangular shape and uniform width, the leg portions of said lug being chambered at each side of the key-hole of the lug.'"

President Fuller: Can you enlighten us on this matter, Prof. Benjamin?

Prof. Charles H. Benjamin: This matter regarding the patent was called to my attention subsequent to the preparation of the report by Mr. Gibbs, and I wrote to the person who owns this patent, asking what his attitude would be, and received simply a non-committal letter as to the attitude with regard to making this public property. If it is the pleasure of the association, I will read the letter.

Prof. Benjamin: The committee had not intended to precipitate this discussion before the association, but as long as it is before the house, the committee feels bound to give the association all the information in its power.

R. L. Kleine: Inasmuch as the subject before us involves a patent, I suggest that it be referred to the executive committee, in accordance with the constitution, rather than that the matter shall be discussed here on the floor.

President Fuller: That will delay the action on the report of the committee unless you cut out the head entirely.

R. L. Kleine: I would have to withdraw my motion, under those conditions.

F. W. Pratt: It seems to me that the angle this discussion has reached is something like our standard coupler discussion, and if it would be agreeable to the ideas of the committee, it would seem to me to be a good thing if this association would refer this standard brake beam back to the committee, and the committee be requested to confer with the manufacturers, as well as the coupler committee, and report at the next convention.

C. D. Young (Penna.): I believe that by a slight addition to sheet 17-B which was prepared in my office, any question of [illegible] can be easily handled by the executive committee. I believe the matter can then be voted on as recommended practice. I am of the opinion that by a slight change in the drawing, which will not affect in any way the interchangeability of the head with the channel or the head with the tie member, that the whole thing can be settled this year, and I would make an amendment to Mr. Kleine's motion that this question of the patent situation, agreeable to the executive committee, be disposed of before this matter is submitted to letter ballot.

Mr. Kleine accepted the amendment and the motion was carried.

COUPLER AND DRAFT EQUIPMENT.

COUPLER TESTS—STATIC AND DYNAMIC.

The tests outlined in report of last year were conducted by the Pennsylvania Railroad under the direct supervision of C. D. Young, engineer of tests and the chairman of the committee. These tests were started April 3, 1912, and carried along continuously, using Pennsylvania Railroad testing facilities, as well as those of the Baltimore & Ohio, the Baldwin Locomotive Works and the Pressed Steel Car Company to expedite the work, and were completed April 24, 1913. A total of 481 tests were made.

The couplers used in these tests comprised those in general use to-day, as well as some reinforced or strengthened couplers which were in course of development, as follows: Pitt, Major, Latrobe, Major Special 103, Gould "Z," Janney "X," Sharon, Krakau, Alliance, Bazeley and Simplex.

With a view of increasing the elastic limit and ultimate strength of the material, experiments were made with heat

R. L. KLEINE,
Chairman, Committee on Coupler and Draft Equipment.

treatment and varying chemistry. All designs of couplers tested were divided in four groups, each group being subjected to the full list of tests. The four groups comprise the following:

A. Couplers of the regular commercial product.

B. Couplers with the best heat treatment and chemistry which coupler manufacturers could recommend in light of their present experience.

C. Couplers unannealed by the manufacturers with 0.35 per cent. carbon low-phosphorus steel, heat treated by the Pennsylvania Railroad.

D. Couplers unannealed by the manufacturers and made of steel in accordance with their present foundry practice and chemistry, and heat-treated by the Pennsylvania Railroad.

All testing of couplers and separate knuckles has heretofore been made by measuring the ultimate distortion after the final blow as prescribed by the M. C. B. Specifications, but in the tests conducted by this committee, the distortions were measured after each drop or pull and tabulated by so much plus or minus from the original dimensions, the idea being to establish the point at which permanent set takes place and study design therefrom. Fig. 1 shows the location of points, etc.

The results of all the individual tests were plotted graphically as well as summaries of the important dimensions, illustrating permanent set at the various blows or increments of load in each test (jerk, strike, pulling, etc.) for all

types of couplers under each grade of material. The four grades of material in each coupler were also compared by summary plots for the various tests.

ANALYSIS OF RESULTS OF TESTS.

The following comparisons are based upon the "A" material or the present commercial material used in couplers, and are only of a general nature without going into detail.

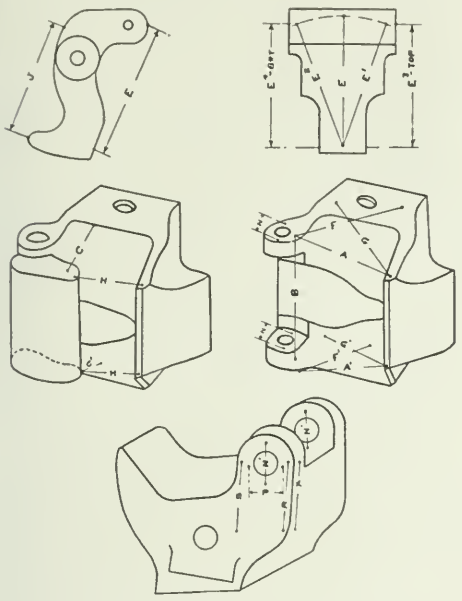

Fig. 1—Location of Points for Testing.

All couplers were given letter designations to represent the names of the couplers tested. Couplers Ta, Ua, Wa, Xa, Xb, Ya and Yc represent couplers of the latest types in general service; couplers Tb, Ub, Yb and Yd represent couplers of increased weight and strength in the development stage, a number of which are in service experimentally.

Pulling Test of Complete Couplers.—Standard M. C. B.

AVERAGE RESULTS OF PULLING TESTS.

test, 150,000 lbs. pull with limit knuckle opening of 5/8 in. ("C" dimension).

Static Guard-arm Tests (Pulling).—This test was developed on account of the present face test being unsatisfactory from the standpoint of not giving uniform results, mainly due to the variation between the minimum and maximum contour lines, allowing the block to seat higher or lower in the head, thus increasing or decreasing the wedging action. It consists of holding down the guard arm and shank and pulling on the coupler lugs.

Static Tensile Tests of Coupler Lugs.—This test was made to ascertain the strength of the coupler lugs in pulling, each lug being pulled separately on a standard diameter pin placed in the knuckle pivot pin hole.

Tensile Test of Material.—This was a regular tensile test of the material in the couplers, using a piece sawed from shank of each coupler. Microscopic photographs (100 diameters) were taken of a section from both the shank and knuckle of each coupler.

Static Knuckle Tests, Pulling, Separate Knuckles.—This test was made to determine the elastic limit and ultimate strength of the separate knuckles. The knuckles were held in a forging by a standard diameter pin through pivot hole, the knuckle tail blocked on lock-bearing area and dummy engaging pulling face.

Dynamic Strike Tests, Complete Coupler.—Standard M. C. B. test, three blows of 1,640 pounds falling 5 feet, and three blows falling 10 feet.

Limit of knuckle closure "C" is ¾ in. on bottom after third blow at 5 feet.

Limit of axial distortion is 1⅞ in. on bottom after third blow at 10 feet.

Dynamic Guard-arm Tests, Coupler Body.—Formerly an M.

varying chemistry and special annealing or heat treatment, showed, in general, much higher tests, both static and dynamic, as compared with the "A" material or the commercial product of the manufacturers. The following comparison on the pull test will serve as an indication of the results of this special treatment, although the dynamic tests are not as uniform as the pulling tests. It is thought to design the standard coupler on the basis of the present commercial steel, reserving the advantages to be gained by heat treatment for future strengthening of the coupler or detail parts.

"A" = annealed by manufacturers.

"B" = heat-treated by manufacturers.

"C" = approximate .35 per cent. carbon, heated to 1,600 deg. F., quenched in water, annealed at 1,100 deg. F.

"D" = approximate .25 per cent. carbon, heated to 1,600 deg. F., quenched in water, annealed at 900 deg. F.

Pulling Test of Complete Coupler.—Standard M. C. B. test, 150,000 lbs. pull with limit knuckle opening of 5/8 in. ("C" dimension).

ROAD TESTS.

Road-service tests were conducted with couplers of present type on freight cars and with couplers of both present and the experimental design on freight locomotive tenders on the Pennsylvania. The freight car couplers were applied to 100,000 pounds capacity steel hopper cars in the coal trade between the bituminous mines in western Pennsylvania and tide water, a service comprising grade and flat country as well as hump-yard classification. The tender couplers were

nently by referring to the logs of these tests.—[Not reproduced.—Editor.] It is surprising to note the short life of couplers of the present type in this service, as well as the relatively longer life that is being obtained from the experimental couplers.

Summary—Freight Car Couplers.—Summary of measurements, showing deflections at "C," "H" and "E" of the twelve couplers of present type in freight car service at last reading. All these couplers were in service at the last reading.

CONFERENCES WITH MANUFACTURERS.

While the committee was engaged in conducting the foregoing tests, as well as gathering data on the breakage of couplers in service, the gage of couplers, efficiency of knuckle

throwers and lock-sets, slack in couplers, etc., the coupler manufacturers were experimenting along the lines of tentative specifications bearing on the important and fundamental principles involving the detail design of coupler and parts which the committee had previously decided should be incorporated, as far as practicable, in the standard coupler. These tentative specifications had been submitted to the coupler manufacturers for their consideration at the first joint meeting, held March 4, 1912, and were as follows:

Knuckle.—No strain on the knuckle pin. A minimum of 6 sq. in. knuckle-bearing area on the lock, to be central with the knuckle face. That the back thrust should be taken on the shoulders of the knuckle hub and on the back of the knuckle shank. That lost motion between the knuckle and lock (¼ to ⅜ in. now allowed by M. C. B. specifications) be eliminated if possible. That a smaller knuckle pin than the present standard be used as a pivot pin only, thus making it possible to increase the section through the knuckle hub and coupler lugs.

Lock.—Wedge type, to take up wear. One piece, if possible. Lock-bearing area on wall of coupler to be 6 sq. in. minimum. Top and bottom unlocking arrangement.

Knuckle Throw.—Bell crank type, which will throw the knuckle from any position and follow it out to the full open position.

Lock Set.—Preferably on some stationary part of the coupler head instead of on a movable part.

Coupler Head.—To be designed to conform to the above details.

Subsequent to the conference of March 4, 1912, joint meetings were held at Altoona, Pa., with the coupler manufacturers on April 26 and May 15, 1912, the results of which were recorded in the report to the last convention.

At a meeting of the Coupler Committee, held at Altoona, October 22, 1912, it was decided that sufficient data were at hand taken from couplers in service, as well as from the tests being conducted, to enable the committee to proceed with the coupler manufacturers in designing the proposed standard coupler.

The joint committee of representatives of coupler manufacturers and the committee accordingly held meetings to discuss and decide upon details and fundamentals of design, such as operation, contour lines, strength of the various parts, dimensions of knuckle hub and knuckle pin hole, location of knuckle pin hole and lock set, and type of knuckle thrower, etc. Much discussion ensued on these points which are pertinent to design, each one influencing the other to such an extent that full development of any one will handicap the other.

The harmonizing of ideas between the committee and the mechanical representatives of the coupler manufacturers, who have practically devoted their whole life to coupler design, and each previously working along different lines, was gradually accomplished in many of the details.

At a meeting on November 19, 1912, at the suggestion of Mr. Bush, the fundamentals to be used in the design of the coupler or couplers were discussed, taking the Coupler Committee's recommendations as a basis, and the following decided upon:

Knuckle:

1. The knuckle should be of uniform strength throughout and should provide for a pull of 200,000 lbs., not exceeding the elastic limit.
2. That the greatest dimension possible through hub is most efficient and desirable.
3. That the point of fulcrum should be as far forward as possible.
4. The center of pivot should not be far from the neutral axis at the hub and toward the back of knuckle
5. The knuckle should be so designed in connection with other parts as to permit of relieving stresses on pivot pin under pull of 200,000 lbs., without permanent set.
6. Knuckle should be so designed that back thrust should be taken on shoulders of hub and back of shank of knuckle
7. Bearing areas for locking, pulling and buffing should be sufficient to avoid distortion of the surface
8. The center line of vertical dimension of knuckle tail at lock bearing surface should coincide approximately with the center line of vertical dimension of head and knuckle face

Lock:

1. A. Wedge type, to take up wear
   B. Straight lock
2. One piece, if possible
3. There shall be no portion of the lock or lock lifter which may be possible to kink in operation
4. Lock to be adaptable for top or bottom uncoupling arrangement
5. Lock must not be cored within the knuckle-bearing area in order that crushing will not take place.
6. Lock must be so designed as not to twist or roll under tension.
7. Lock which requires a reversal of motion in locking is undesirable.
8. Bearing areas for the knuckle and coupler wall should be sufficient to avoid distortion of the surfaces.
9. Lift of lock to be kept as small as possible.
10. Lock must be so designed as to avoid creeping from the locked position.

Lock-set:

1. Preferably on some stationary part of the head rather than on any movable part.
2. Lock-set must be so designed that the lock will not be dislodged by jarring, due to uncoupling or switching.
3. Lock-set should preferably be arranged so that the lock can be dislodged by hand.
4. Lock-set should be dislodged at about 60 per cent. of the total swing of nose of knuckle.

Knuckle Throw:

1. Bell crank type, which will throw the knuckle from any position and follow it out to the full open position.

Mr. Bush was of the opinion that if a much stronger coupler is designed, having a wedge lock and resultant closer fitting, and decreasing dimensions between nose of knuckle and guard arm, more clearance between the face of knuckle and the contour line of head should be allowed by taking a little off of nose of knuckle and putting it on the hub.

At a meeting on December 16 and 17, 1912, the question of determining beforehand the length of head of the standard coupler was brought up and it was decided that this should remain as hitherto, between 9¼ in. and 12¼ in., keeping as near the former as possible.

The question of height of coupler head and total lift was also brought up, and it was decided that this should be investigated on locomotives, passenger and freight cars, with a view of establishing a limit.

The subject of contour lines was taken up. The National Malleable Casting company went into the proposition very thoroughly and Mr. Krakau presented the subject in a very able manner, distributing to each member present a set of 38 blue-prints, each of which was discussed in detail.

The data on coupling and curving was obtained on a special machine built for this purpose by the National Malleable Casting company, whose representatives also brought to the meeting an extensive set of adjustable wooden templates to illustrate the contour lines. The coupling and curve tests were all made without having any side clearance in the carrier iron, in order that they would be strictly comparative. Among the advantages claimed for this straight-line contour are:

1. Ideal for buffing forces in having the coupler face and front face of knuckle parallel to each other and both perpendicular to the centre line of the coupler shank. Elimination of buffing forces of the nose of the knuckle against the coupler face of mating coupler, distributing it along the whole of the face of both couplers and eliminating the wedging condition of the knuckles bearing at the same time on both the guard arm and the face of the mating coupler, which causes the splitting of the coupler faces.
2. Greater diameter of knuckle hub, wherein lies the limitation of knuckle strength.
3. The total number of degrees in the following series of coupling tests was 77 for two straight-line contours, 68 for two M. C. B. contours, and 67 for the combination of an M. C. B. contour coupling with a straight-line contour.

a. Both knuckles open	When machine is angled toward knuckle side of moving coupler.
b. Moving knuckle open	
c. Stationary knuckle open	
d. Both knuckles open	When machine is angled toward guard arm side of moving coupler.
e. Moving knuckle open	
f. Stationary knuckle open	

4. The clearance between the coupler face of one and the front of the knuckle of mating one of two straight-line contours is about ⅞ in., which represents initial slack. This initial slack in a coupler having a wedge lock would not increase in service as the present M. C. B. couplers do, and most of it is required for vertical angling. This would eliminate the destructive strains set up by vertical angling in the M. C. B. contour lines in hump and tipple operations.

The proposed contour line will provide about ⅞ in. initial slack between two such contour couplers, whereas the slack between two M. C. B. standard contours of mean contour lines is ⅞ in.

At a meeting on February 18, 1913, several members feared this increase in initial slack as being destructive to the coupler in starting trains, but the advocates of the pro-

posed contour explained that the initial slack in this proposed contour would not be materially increased by service when accompanied by a wedge type of lock in the coupler.

It was also claimed that most of this initial slack of 7/8 in. is required for vertical angling of couplers in going over summit of yard humps and coal wharfs, and that couplers of present M. C. B. contour lines are being greatly distorted and damaged in operations of this nature.

Most of the members favored the proposed contour lines, providing this initial slack would not prove detrimental; therefore, to accurately ascertain the slack per coupling in couplers in present service the following test was decided upon and carried out: A mixed train of 61 empty cars and an engine was taken in "WJ" west-bound empty receiving yard, Altoona, Pa., and cars separated a distance of about 6 feet, the following data being taken for each end of the car:

Car.—Initials, number and type.

Coupler.—Name, age—old or new, and size of shank

With the coupler locked the dimensions "C" and "H" were taken both with the knuckle pulled out by hand against lock and pushed back by hand, also the distance from guard arm to nose of knuckle with knuckle in full open position. The

* Gauge of couplers in this coupling, 5 inches and 5 3/8 inches.

cars were then coupled and bunched, setting brakes on several cars on both ends to insure the bunching, and each coupler was centrally punched on top of head just back of face and on longitudinal centre line of coupler; that is, one coupler of each coupling was centre-punched on its centre line and with a pair of dividers set at 6½ in., and with the centre-punch-hole on one coupler as a centre, an arc was described on the other coupler and then centre-punched thereon at that coupler's centre line, thus getting a uniform distance of 6½ in. between these two points. The train was then stretched by a locomotive and brakes set on several cars on both ends to insure the stretching, then the distance between the centre-punched marks of each coupling above referred to was trammed and the difference between this distance and the original 6½ in. as laid off with cars bunched is the slack per coupling.

The accompanying table shows the information obtained, as well as similar data taken by the N. Y. C. & H. R. R. R. and the C. M. & St. P. Ry.

These tests showed that slack per coupling in couplers in service greatly exceeds the slack per coupling as given in the proposed straight-line contour.

Vertical Angling.—Vertical angling on humps and the slack available and its location in the contour lines was illustrated by T. J. Boring, who also showed that the most severe hump on the P. R. R. is one having a 4.46 per cent. grade on one side of apex and a 3.07 per cent. grade on other side (equalling a 7.53 per cent. grade adjacent to a level), which with 9-in face knuckles would require 21-32 in. slack in contour lines neglecting the ever variable vertical curve at the apex which the overhang of the cars would often span. Considerable argument ensued concerning the amount of slack available in M. C. B. contour lines for vertical angling as to whether the slack proper in the lines should be counted once or twice. It was demonstrated and finally agreed that 7-32 in., the clearance in the mean M. C. B. lines, is all that is available for vertical angling, with the understanding that the couplers are in tension at the time when the top of the pulling face of both knuckles are in contact with each other, which would be at the vertex of any hump having same grade on both sides and couplers of the same height. When the latter conditions are not present the knuckles will assume the mentioned position a short distance either side of the summit of the hump. It was also demonstrated and agreed that the slack per coupling with couplers in bunched position available for starting trains is 7 32 in., which is clearance in the mean M. C. B. contour lines, plus an equal amount, 7-32 in., taken from back lash of couplers plus the very small amount which may be developed by the knuckles rotating on the coupling point after the second 7-32 in. just mentioned is taken up.

At this meeting a compromise was made in the location of the knuckle pivot pin hole and ½ in. back of coupling line was decided on for the present.

It was also decided that the height of the coupler head above the centre line of the shank be set at 8¼ in. tentatively and to be further investigated.

The subject of the depth of the knuckle hub brought forth considerable discussion, especially relative to using the eventual one-standard head and particularly the knuckle for both passenger and freight, which Mr. Brazier strongly contended for. With a knuckle hub depth of 10 in. the height above centre line of shank would be 5 in. of the knuckle hub depth plus 2 in. for coupler lug, totaling 7 in., allowing that knuckle pivot pin would be applied from below; this 7 in. would curve under the buffer plate of passenger cars and 3 in. should also be allowed there for clearance, to allow for variation in coupler height. The making of an unsymmetrical head such as offsetting head below centre line of shank, etc., was mentioned, but finally it was decided to design the standard freight car coupler and later design a passenger head to take same knuckle if possible.

The depth of knuckle hub was set at 10 in., not counting pivot pin protector lugs, should any be used. To do this it will probably be necessary to reduce the 200,000 lbs. elastic limit previously decided upon as desirable. (This was subsequently reduced to 9 in.)

Depth of Coupler Shank:—It was decided that the Coupler Committee would thresh this out among themselves. In the meantime we will consider 6 by 8 in. shank for new cars and 5 by 7 in. shank **for existing cars.**

When Lock-set Is Dislodged:—The tripping of lock-set at 6¼ in. measured perpendicularly from guard arm to nearest point of knuckle nose was decided tentatively at the December, 1912, meeting. Adopted at 6¼ in.

Full Opening of Knuckle:—It was suggested that this be in line with coupler lug parallel to centre line of coupler, but was finally decided at 9 in., with ⅛ in. variation either way measured perpendicularly from guard arm to nearest point of knuckle nose. The question was brought up that the end of guard arm only takes half of the guard-arm movable point of the M. C. B. contour gage. It was stated that this was intentional, but no change was decided at this time.

Lift of Locking Pin:—It was decided that the maximum total lift, should be same as present M. C. B. maximum lift, 6 in., operated either top or bottom.

COUPLING TESTS, COMPARING PRESENT M. C. B. STANDARD AND PROPOSED STRAIGHT-LINE CONTOUR

Full-size steel couplers having the various contour lines were used, and the tests were made on a machine specially built for determining the greatest possible degree of horizontal angling between two couplers and for testing coupling operations between them when in line or at an angle.

The end of the machine supporting one coupler is sta-

tionary, and the other coupler is mounted on a carriage arranged to move longitudinally by means of compressed air on a short track, supported in a frame which is pivoted at the inner end, and capable of swinging laterally at the outer end, the pivot being in vertical alignment with the pulling

placed in alignment with both knuckles open and coupled three times; then the knuckle on the moving carriage was opened, the other closed, and three couplings made; then the knuckle on the moving carriage was closed and the other opened and three couplings made; then nine similar coup-

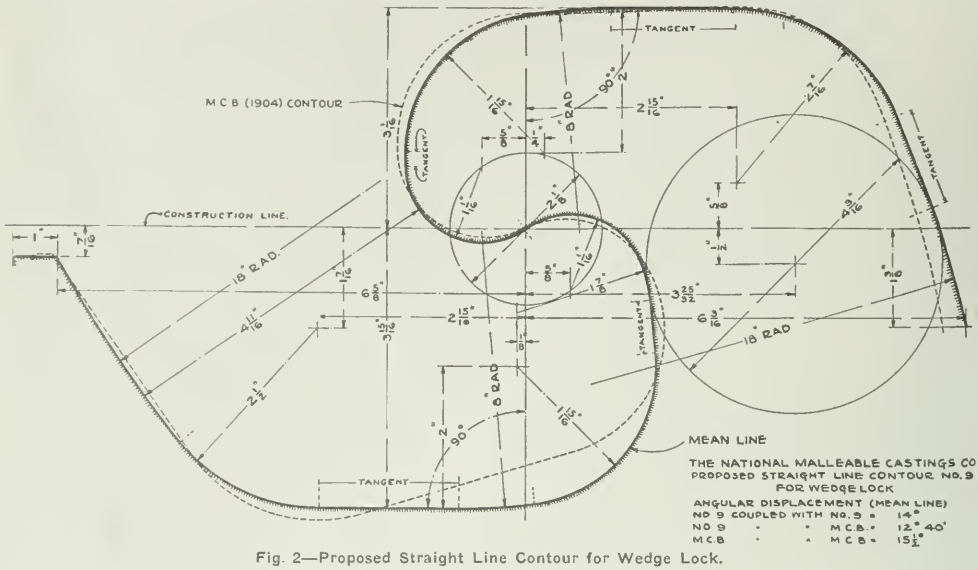

Fig. 2—Proposed Straight Line Contour for Wedge Lock.

faces of the two knuckles when coupled. Thus the couplers can be angled relatively, and coupled and uncoupled in various positions. Each degree of angularity is shown by an indicator at the outer end of the swinging frame. The couplers are designated hereafter as being on the "moving carriage" or on the "stationary" end of the machine, as the case may be, and the sheets also indicate whether they were held rigidly in the carry irons, or were given the M. C. B clearance of 1¼ in. on each side.

lings were made after swinging the moving carriage one degree to one side; the carriage was swung one degree further each time and similar couplings made at each degree, until a degree was reached at which couplings could no longer be made; then the moving carriage was swung one degree on

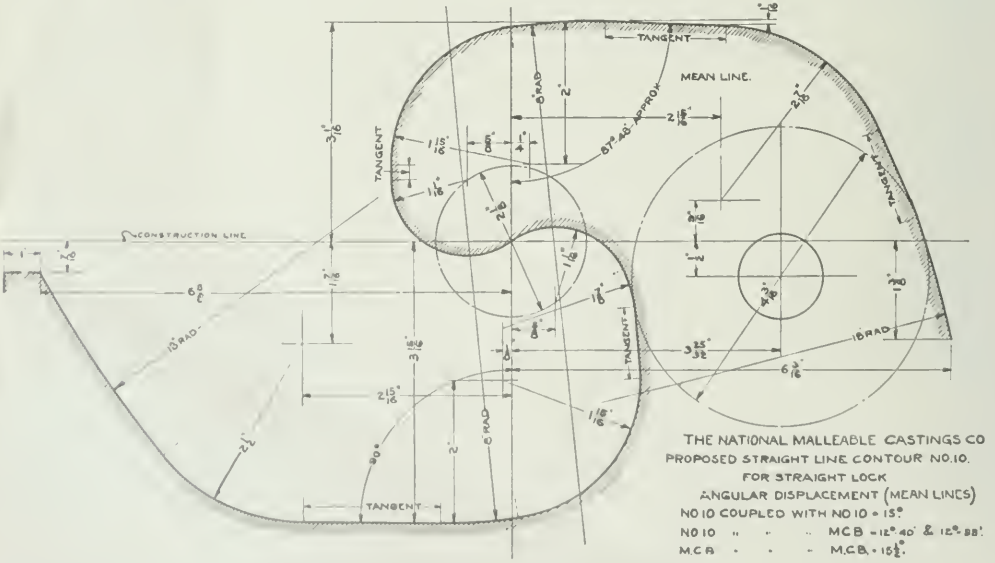

Fig. 3—Proposed Straight Line Contour for Straight Lock.

Each test was conducted as follows: Two couplers were the other of the center and similar couplings made at each degree on that side.

This test was made with two couplers having the M. C. B. contour operating together, with two having the proposed straight-line contour and also with two couplings, one hav-

ing one contour and the other the other contour, and in the case of two different contours, first with one contour on the moving carriage and then with the other thereon, so as to test all the different combinations in precisely the same manner and avoid any variations in results. After each test was made with the couplers held rigidly in the carry irons, so as to determine what could be accomplished with the lines alone, a similar test was made after giving the couplers the total side clearance of 2½ in. When side clearance was provided, couplings were considered to have failed if they could not be made without moving the couplers laterally in the carry irons by hand.

The speed of the moving carriage was regulated so that it was uniform throughout the test, and from two to three miles per hour.

Figs. 2 and 3 show the proposed straight-line contours, the former for a coupler with wedge lock, the latter for a coupler with straight lock. The difference between the two is entirely on the outer buffing face of the knuckle, and is due to the fact that the wedge lock holds the knuckle tightly when in locked position so that the knuckle tail cannot be pushed back away from the lock, and the outer face of the knuckle then has only one position, whereas the tail of the other knuckle has movement back of the straight lock when in

made for the vertical angling between couplers when passing over humps, etc., without putting any strain upon the couplers; at present there is not nearly enough clearance for this purpose, and strains are put upon all the parts when the knuckles are stretched in passing over humps and dips. The proposed straight-line contour with ⅞ in. longitudinal clearance will permit couplers having a 9-in. depth knuckle face to angle 5 degrees 35 minutes, which will permit them to pass freely over a change in grade of 9.7 per cent.

Fourth: In buffing on curves, as well as on a straight track, there is never any wedging action due to knuckle engaging face of coupler head and face of guard arm of mating coupler. With the present M. C. B. line, couplers are distorted and broken on this account.

Fifth: The proposed straight-line contours gave a higher total number of degrees at which couplings could be made as compared with M. C. B. contour.

Some of the Disadvantages are:

First: Lesser maximum angle which straight-line contours will swing when coupled together.

Second: Last portion of knuckle closure is accomplished by momentum when coupling on curves, instead of by contact of knuckle with face of mating coupler, but on the larger radius curves the couplers will adjust themselves to

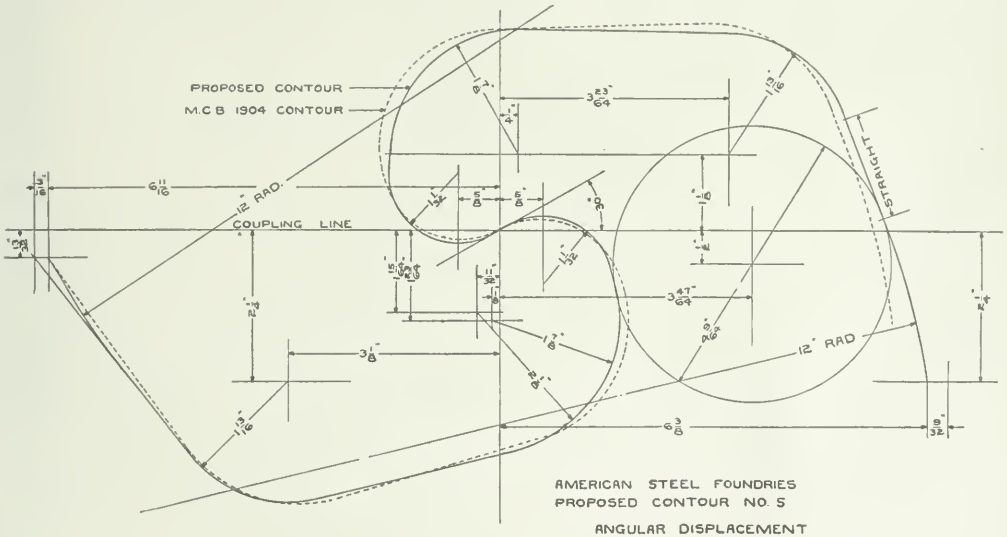

Fig. 4—Proposed Straight Line Contour; American Steel Foundries No. 5.

locked position and when the knuckle is buffed back as far as possible its outer face, which should then be at right angles with the longitudinal axis of the coupler, is not in the same position as when the knuckle is pulled out against the lock, which latter position is the one gaged and the one which must be considered in a diagram of the line. Therefore, slightly different lines are necessary for the two kinds of coupler. In the exhibits illustrating contour lines the proposed lines as well as the present M. C. B. lines are the "mean" lines. All the couplers tested had the mean line.

There are several advantages in the proposed straight-line contour as compared with the present M. C. B. contour.

First: There is provision for greatly increased strength through the hub of knuckle, and also in the front face of coupler head.

Second: The outer face of knuckle has a continuous buffing bearing across face of coupler head at right angles to longitudinal axis of coupler, thus making the average length of lever arm from pivot to buffing face much shorter than that in the M. C. B. coupler, and by means of the continuous bearing and the short lever arm practically stopping the bending of the knuckle under buffing strains.

Third: By increasing the longitudinal clearance between two couplers when coupled together to ⅞ in. provision is straight-line conditions to the amount of side clearance for coupler shank.

Third: Amount of slack in starting trains.

The proposed straight contour line was approved by all members of the M. C. B. Coupler committee and three of the coupler manufacturers, while two of the latter had not replied and the American Steel Foundries criticised same and submitted their No. 6 contour as one which would give better results, it being a compromise of straight-line face and M. C. B. face with other modifications over present M. C. B. contour.

Since the contour lines are so vastly important and the earnest desire of all is to arrive at the best contour possible, the chairman decided to give the American Steel Foundries No. 6 contour a try-out, hence the meeting at Cleveland was called to try out and test the various contours and decide upon one as our unanimous recommendation to the M. C. B. Association. The American Steel Foundries agreed to ship to the National Malleable Castings Company at Cleveland two couplers having the No. 6 contour and two couplers having present M. C. B. contour, all with recommended location of knuckle pivot pin.

The first day of the meeting two couplers with proposed straight-line contours and two couplers with present M. C.

B. contours were tried out in the machine, mating with themselves and with each other; and during the second day of the meeting two couplers having the American Steel Foundries No. 6 contour were tried out with themselves and with couplers having present M. C. B. contour, both for angling and coupling.

The trials were very closely observed and all points previously brought out and those appearing during the trials were freely and very generally discussed. The American Steel Foundries No. 6 contour gave the greatest range of horizontal angling and coupling, but was not considered satisfactory when compared with the straight lines for taking care of the buffing shocks, and R. E. Janney, representative of the American Steel Foundries, withdrew his No. 6 contour in favor of his No. 5, (Fig. 4), which does not take metal off face of present M. C. B. contour, though it embodies the other modifications for increased strength across knuckle hub and increased angling. It was agreed and proven by tests that with any contour departing from present M. C. B. by taking metal off coupler face, when coupling with present M. C. B. on straight track and the M. C. B. knuckle open, there will not be contact between nose of M. C. B. knuckle and face of mating coupler throughout the act of coupling, but will require momentum during the last ¼ inch (depending upon design) of locking of M. C. B. knuckle (this does not apply when the knuckle of the straight-line contour is open and the M. C. B. knuckle closed); also that contours with incline of coupler face reduced over present M. C. B. mating with its kind, will require this momentum in closing when couplers are angled.

In summing up the trials, each representative present voiced his views, and it was decided that the proposed straight-line contour and a contour not reducing incline of coupler face but embodying enlargement in diameter of knuckle hub and other slight changes over present M. C. B. contour as represented by the American Steel Foundries No. 5 contour, should be given a large and thorough trial in service, with the feeling that if the proposed straight-line contour couplers gave no general trouble in coupling it should be adopted, otherwise we should hold to a contour having incline of coupler face not reduced over present M. C. B. contour and make the best of it in buffing, even though it was not designed for sustaining the enormous shocks imposed in buffing in service.

STRENGTH OF COUPLERS.

The general investigation of coupler conditions and the result of tests—static, dynamic and road—conducted by the committee, as well as the great number of couplers and parts requiring renewal, demonstrates beyond a doubt that the present coupler is inadequate in strength to meet the increased demands placed upon it, consequently considerably curtailing its life, which is aside from the desirability of reducing the number of designs to a minimum. The investigations and developments made during the past year have satisfied your committee that this required increase in strength can be accomplished, but the weight of the coupler will necessarily have to be increased from 30 to 40 per cent.

EXHIBIT OF COUPLERS.

Immediately back of Convention Hall, at the north side of the Pier, the committee has on exhibition various designs of couplers embodying the specifications jointly agreed upon between the coupler manufacturers and the committee, the manufacturers having designed the working parts according to their ideas to meet these specifications. It is now essential to select from these couplers several designs to be tried out in service during the coming year to definitely determine the best contour lines, efficiency of operation and strength of the various parts, with a view of harmonizing the designs and eliminating the details that prove unsatisfactory, to the end of establishing the standard coupler. The committee desires the members of the Association to make a critical examination of the couplers in this exhibit and give to the coupler committee the benefit of their criticisms and recommendations.

EXPERIMENTAL COUPLERS.

After the committee has selected the couplers to be placed in service to be tried out experimentally, and the service tests show that no serious defects exist, the members will be notified which couplers can be recommended for trial purposes, so that a general trial, in limited quantities, can be made by the railroads to ascertain their suitability for general service, this trial to be preferably conducted on locomotives. Until this announcement is made, the committee must earnestly request the railroad representatives not to apply any new or experimental types of couplers on freight cars which involve new designs unless the parts are interchangeable with present couplers in service, as by so doing it will forestall the work of the committee and, for various reasons, possibly prevent the Association from arriving at a successful issue of the one-standard coupler.

The report is signed by.—R. L. Kleine (P. R. R.), Chairman; G. W. Wildin (N. Y., N. H. & H.); F. W. Brazier (N. Y. C.); J. F. De Voy (C. M. & St. P.); F. H. Stark (Pitts. Coal Co.); H. L. Trimyer (S. A. L.), and B. Julien (U. P.).

After reading the report Mr. R. L. Kleine said: The tests of the couplers are not of those couplers shown in the exhibit; but they were the early stages in the development of which these couplers are the refinement. Now, if you will refer to the report I will indicate a few of the important dimensions used throughout these tests. The important dimensions are the C dimension, from the coupling face to the knuckle face of the coupler, and the H dimension, known as the gage dimension; and in the knuckle-stretch, the E dimension, which is from the nose of the knuckle to the lock of the knuckle.

Referring back you will find two curves, the present grouping and the earlier experimental. We had an average permanent set of .3 in.; and in the experimental set an average of .1, or a decrease of 61.3 per cent. In the ultimate average load of the present couplers, we have 261,000 lbs. and in the experimental couplers, 373,000 lbs. an increase of 42.6 per cent. The static guard-arm test, which is a new one, was developed because of the unsatisfactory state of the present face test from the standpoint of not giving uniform results, mainly due to variations between the minimum and maximum contour lines, allowing the block to seat higher or lower in the head, thus increasing or decreasing the wedging action. It consists of holding down the guard-arm and shank and pulling on the coupler lugs. The average ultimate load is 295,000 lbs. for the present couplers and 333,000 lbs. for the experimental couplers.

DISCUSSION.

F. W. Brazier (N. Y. C.): Although a member of the coupler committee, I want to say that perhaps you do not realize the amount of work and the care and attention, as well as the expense that the Pennsylvania Railroad has gone to in connection with this report. I have not the least doubt that that company has spent over $30,000 and each one of the committee has had a substitute on the committee, and each of these persons have worked for a period of at least six months on the report. There are lers. Is it not time that we got down to a standard coupler? Mr. Kleine and Mr. Wallis of the Pennsylvania have been so energetic and earnest in this work that they are deserving of more than ordinary praise. Mr. Kleine has given his time and thought to it night and day. We must come down to one standard form of knuckle which will fit into any coupler.

J. F. DeVoy (C. M. & St. P.): While I do not care to discuss the report at all, as a member of the Coupler Committee, it appears to me that after the representatives of the railroads have gone through this report and seen the amount of work that has been done, they should at least give their moral support to one of the greatest works that has been done in this association. I do not want to claim any credit whatever; I do not know that I have ever seen a man who has so tenaciously stuck to a subject as the chairman of the Coupler Committee, Mr. Kleine. He has been ably assisted by Mr. Young and Mr. Wallis, who have given their thought and attention to the matter and furnished every appliance that could be given to facilitate the work of the committee. Nothing has been said in the report which is contrary to the interests of the manufacturers. There has been nothing suggested in any way that the manufacturers cannot live up to. I believe every member of this association should go home, and insofar as he is able, get the support of his company in the purchase of a coupler which will conform to the recommendations of this committee.

J. J. Hennessey (C. M. & St. P.): I move that the recommendation that no railroad shall purchase or put into service any of these experimental couplers until they have received the final recommendations from the coupler committee, be carried out.

C. A. Schroyer (C. & N. W.): Does that mean experimental couplers which may be brought forward? Does it mean not to exclude the couplers we are now using, but to exclude experimental couplers that are not in line with what our committee is going to recommend?

R. L. Kline: The purpose of that suggestion is that we do not want at this time to place in service strengthened couplers which take other knuckles and other detailed parts, and thus increase the number of couplers we already have on the market; and furthermore, not to place any of these experimental couplers in service until the committee has had an opportunity to go over them and make an examination

and investigation of them, and say to the members which one they should try.

Mr. Hennessey's motion was put to vote and carried.

President Fuller: We will be glad to hear from any of the coupler manufacturers, if they will confine their remarks to the mechanical features of the couplers and not refer to the name of the manufacturers.

F. F. Gaines (C. of Ga.): I would like to ask the chairman of the committee one question regarding the new contours proposed. The report does not remark very largely on the fact that if you are going to couple with the present M. C. B. knuckle, and the present M. C. B. knuckle has to be opened, you must depend on the impetus given it to close. Some of the present M. C. B. knuckles are gravity knuckles and have a spring in them. There are a lot of them in the country. It looks now as if we would get into trouble on that point.

R. L. Kleine: The committee absolutely taboos springs in couplers. There are some passenger couplers with spring locks, and in that case it would be a decided detriment to use the straight lines with a spring-lock arrangement, but the committee does not recommend a spring-lock arrangement. These contour lines, of course, will be for the new couplers, and also for the couplers we are now using. However, if the new coupler is adopted, it will be the standard, and you will not have to apply that contour line to the passenger car coupler, as we believe the passenger car coupler can be developed from the freight car coupler and possibly use the same lock and knuckle.

F. F. Gaines: I had no reference to passenger car couplers, but to freight car couplers. There are many which I do not believe will couple unless you have an impact all the way home. I do not want to decry the coupler at all, but I want to call attention to the one fact, because if we have to go in to close the knuckle by hand, we will be in the wrong place.

R. L. Kleine: We do not contemplate any closing by hand. We believe the ordinary coming together of the two couplers, with the slowest speed at which you can move the two cars, will close the coupler by impact, and after we have experimented with the coupler further, if we find that it does not, we will not recommend it to the association. For that reason we ask for a tryout, rather than suggesting it for recommended practice; and it can be tried out, irrespective of the adoption of a standard coupler, as the same coupler can be made with the two contour lines, that is, a coupler with the contour lines suggested in the report, and also with the present contour lines.

C. A. Schroyer (C. & N. W.): I have gone through that thing for so many years that I feel a little fearful in undertaking to interfere with our present contour lines. The contour line as adopted and used today, was shaped in such a way as to obtain the closing of the knuckles without having any slack between the drawbacks or as little as foundry practice would permit. In this report they show that there is a large amount of slack existing in the cars in operation today. That is due to the bending of the guard-arm of the knuckle, the wearing of the wearing-faces of the knuckle, and the wearing face of the pin. In the new knuckle, it is proposed to do away with that slack; but it is proposed to give slack by other means. The tight drawbar was used as a result of tests made at Burlington, where it was found there was a destructive shock and breaking in two of a train, which was a very dangerous thing. I am afraid of this today under the conditions we propose to adopt in the new coupler, which are practically the conditions which exist in the old coupler. I want to caution the committee to go carefully in the matter of changing the contour lines in any perceptible degree; the question of changing the lines to the extent of changing the buffing places is very important. We took out wedge lugs twenty years ago because we could not keep them in position. Many methods were tried to prevent it, but none were successful, and while you may have an anti-creeping device on these, they are not so positive in their action as to prevent it.

Col. Ralph W. Pope: The whole subject has been so admirably presented by the chairman of the committee, that we manufacturers have nothing to add; but we stand in the position of your servants, doing what we can to help the good work on.

Mr. Janney: I do not think there is anything we can add to the report. There is a great deal to be discussed which is not included in the report, but it is not material. We are all working as hard as we can and probably when the next convention comes around, we will have one coupler to submit.

R. L. Kleine: Mr. President, I move the recommendations for the changes in standard be submitted to letter ballot.

The motion was seconded and carried.

CAR WHEELS.

The committee submitted last year a proposed specification governing dimensions and tolerances for solid wrought-steel wheels for freight and passenger service, which specifications have been since adopted as recommended practice. As explained in last year's report, these specifications did not include rules governing the process of manufacturing the chemical and physical properties of the material, or analysis and tests. The determination of these questions has constituted the major part of the committee's work this year.

The specification has been revised to include all additions and changes and copy of the complete specifications are attached. It will be noted that no specification is given for physical test of steel wheels as the committee has been unable to determine a proper physical test for solid wrought-steel wheels. A number of experimental tests have been made but sufficient data have not been obtained to decide upon this question. The committee expects to continue its investigations on this subject and report to the next convention.

Specifications.

Specification for solid wrought carbon steel wheels for freight and passenger car service.

MANUFACTURE.

1a. *Process.*—The steel shall be made by the open-hearth process.

1b. *Discard.*—A sufficient discard shall be made from the top of each ingot from which the blanks are made, to insure freedom from injurious piping and undue segregation.

CHEMICAL PROPERTIES AND TESTS.

2a. *Chemical Composition.*—The steel shall conform to the following requirements as to chemical composition.

	ACID.		BASIC.	
Carbon	0.60 —0.80		0.05 —0.55	per cent.
Manganese	0.55 —0.80		0.55 —0.80	per cent.
Silicon	0.15 —0.35		0.10 —0.30	per cent.
Phosphorus	not over	0.05	not over	0.05 per cent.
Sulphur	not over	0.05	not over	0.05 per cent.

2b. *Ladle Analyses.*—To determine whether the material conforms to the requirements specified in Section II, an analysis shall be made by the manufacturer from a test ingot taken during the pouring of each melt. A copy of this analysis shall be given to the purchaser or his representative.

2c. *Check Analyses.*—A check analysis may be made by the purchaser from any one or more wheels representing each melt and this analysis shall conform to the requirements specified in Section II. A sample may be taken from any one point in the plate; or two samples may be taken, in which case they shall be on radii at right angles to each other. Samples shall not be taken in such a way as to impair the usefulness of the wheel. Drillings for analysis shall be taken by boring entirely through the sample parallel to the axis of the wheel; they shall be clean from scale, oil, and other foreign substances. All drillings from any one wheel shall be thoroughly mixed together.

2d. *Limits of Segregation.*—The segregation of either element of carbon, manganese, and phosphorous must not exceed 6 per cent. of the ladle test of the same melt or any part forming the thickness of the plate and tread and rim of the wheel.

TOLERANCES.

3. Wheels should be furnished rough bored and with faced hubs and have a contour of tread and flange as rolled or machined according to recommended practice Sheet M. C. B. *C.* They should conform to dimensions specified within the following tolerances:

3a. *Height of Flange.*—The height of flanges should not be more than 1/8 in. over and must not be under that specified or 1 in.

3b. *Thickness of Flange.*—Thickness of flange shall not vary more than 1/8 in. over or under that specified.

3c. *Throat Radius.*—The radius of the throat shall not vary more than 1/8 in. over or under that specified.

3d. *Thickness of Rim.*—The thickness of rim to be measured between the limit of wear groove and the top of the tread at the point where it joins the fillet at throat of flange. The average thickness of service metal of all wheels in any shipment must not be less than 1 3/4 in. measured from the limit of wear groove to top tread. The thickness of rim should in no case be less than 7/8 in. under that specified.

3e. *Width of Rim.*—The width of rim shall not be more than 1/8 in. less nor more than 1/8 in. over that specified.

3f. *Thickness of Plate.*—The thickness of the plate of the wheel shall not be less than 3/4 in. at the point where the plate joins the fillet at the rim and not less than one in. at the point where the plate joins the fillet at the hub. Intermediate minimum thickness to be proportional.

3g. *Limit of Wear Groove.*—The limit of wear groove to

be located as shown in Sheet M. C. B. C. recommended practice.

3h. *Diameter of Bore.*—The diameter of rough bore shall not vary more than 1/16 in. above or below that specified. When not specified the rough bore shall be 1/4 in. less in diameter than the finished bore subject to the above limitations.

3i. *Hub Diameter.*—The hub diameter may be either 10 in. or 11 in. in diameter as specified with a maximum variation of 1/8 in. below. The thickness of the wall of the finished bored hub shall not vary more than 3/8 in. at any two points on the same wheel.

3j. *Hub Length.*—The length of hub shall not vary more than 1/8 in. over or under that specified.

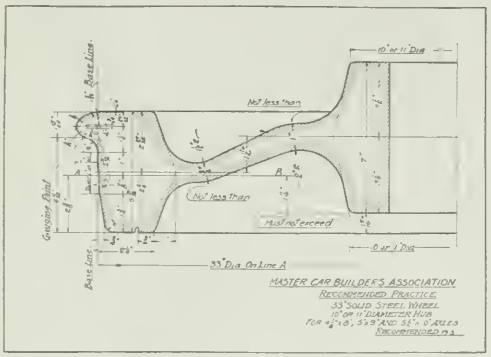

Fig. 1.—Recommended Practice for 33 in. Solid Steel Wheels For 5 1-2 in. x 10 in. Axles and Under.

(The 36 in. and 38 in. wheels have the same dimensions except for the diameter.)

3k. *Depression of Hub.*—The depression of the hub must be made so that the distance from the outside face of the hub to the line *AB* shall not exceed 1 1/16 in. for wheels used on 5½-in. axles and under and 1 1/16 in. for wheels used on 6 in. by 11 in. axles.

3l. *Black Spots in Hub.*—Black spots will be allowed within 2 in. of the face of the hub, but must not be of such depth

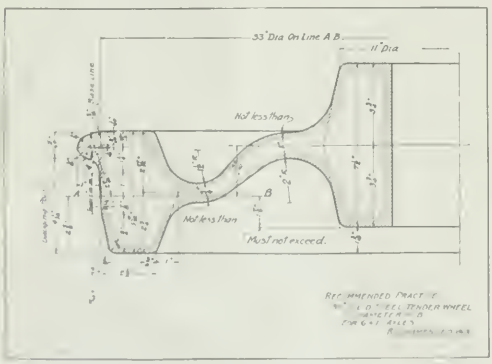

Fig. 2.—Recommended Practice for 33 in. Solid Steel Wheels for 6 in. x 11 in. Axles.

(The 36 in. and 38 in. wheels have the same dimensions except for the diameter.)

that they will not break out and give clear metal at finished [illegible] of bore.

3m. *Eccentricity of Bore.*—The eccentricity between the tread at its center line and the rough bore shall not exceed [illegible] in.

3n. *Block Marks on Tread.*—The maximum height of block marks must not be greater than 1/32 in.

3o. *Roundness.*—All wheels shall be gaged with a ring gage and the variation between the gage and tread at any one point shall not exceed [illegible] in.

3p. *Flatness.*—Wheel shall be gaged with a ring gage placed concentric and perpendicular to the axis of the wheel. All points on the back of the rim equidistant from the center shall not differ in a variation of [illegible] from the plane of the same gage when so placed.

3q. *Tape Sizes.*—Wheels shall not vary more than five tapes under nor nine tapes over the size called for.

3r. *Mating.*—The tape sizes shall be marked in plain figures on each wheel. Wheels must be mated to tape sizes and shipped in pairs.

3s. *Gage.*—Gages and tape used shall be M. C. B. Standard or Recommended Practice as follows: Wheel circumference measure, M. C. B. Standard, Sheet 16-A Maximum flange thickness gage, M. C. B. Standard, Sheet 16. Minimum flange thickness gage, M. C. B. Standard, Sheet 16. Rotundity gage, M. C. B. Recommended Practice, Sheet C. Plane Gage, M. C. B. Recommended Practice, Sheet C. Gage for measuring service metal, M. C. B. Recommended Practice, Sheet C-1.

BRANDING.

The name or brand of the manufacturer, date, and serial number shall be legibly stamped on each wheel in such a way

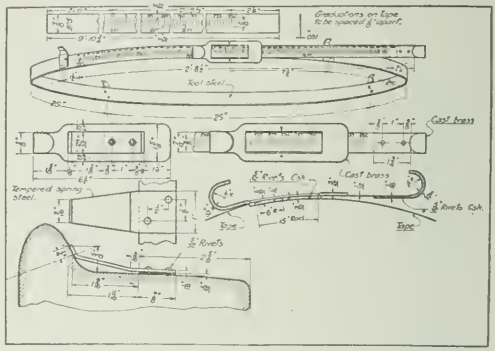

Fig. 3.—Circumference Gage for Steel and Steel Tired Wheels.

that the wheel may be readily identified. The tape size shall be legibly marked on each wheel. Sheet M. C. B. C-2.

FINISH.

5. The wheel shall be free from injurious defects, and shall have a workmanlike finish.

5a. Wheels shall not be offered for inspection if covered with paint, rust, or any other substance to such an extent as to hide defects.

INSPECTION.

6. Inspector representing the purchaser shall have free entry at all times while work on the contract of the purchaser is being performed, to all parts of the manufacturers' work which concern the manufacturer of the material ordered.

6a. The manufacturer shall afford the inspector, free of cost, all reasonable facilities and necessary gages to satisfy him that the wheels are being furnished in accordance with these

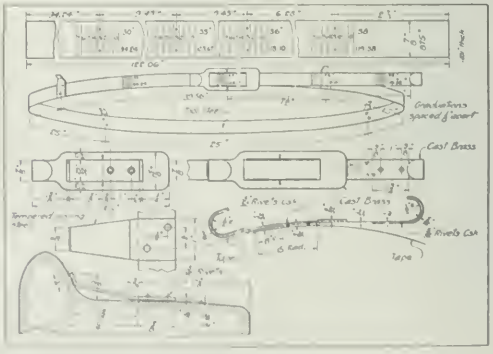

Fig. 4.—Circumference Gage for Cast Iron Wheels.

specifications. Tests and inspection at the place of manufacture shall be made prior to shipment, and free of cost to the purchaser.

6b. The purchaser may make the tests to govern the acceptance or rejection of material in his own laboratory or else-

where as may be decided by the purchaser. Such tests, however, shall be made at the expense of the purchaser.

6c. All tests and inspection shall be so conducted as not to interfere unnecessarily with the operation of the works.

6d. Wheels showing injurious defects while being finished by the purchaser shall be rejected, and manufacturer properly notified.

6e. Samples of rejected material must be preserved at the laboratory of the purchaser for one month from date of test report. In case of dissatisfaction with the results of the test, manufacturer may make claim for a re-hearing in that time.

On account of dimension of plates being added to the designs of steel wheels shown in 1912 report, it is recommended that new cuts be made to show the following wheels:—33 in.; 36 in., and 38 in. solid steel wheels for 5½ in. by 10 in. axles and under. (See Fig. 1). Thirty-three in., 36 in., and 38 in. solid steel wheels for 6 in. by 11 in. axles. (See Fig. 2).

The present M. C. B. circumference measure for cast-iron wheels has been found unsatisfactory for using with steel or steel-tired wheels, and a new circumference measure as used by most railroads and manufacturers, for taping steel wheels is recommended, as shown in Fig. 3.

It is also recommended that the present standard wheel circumference measure for cast-iron wheels, which has been found unsatisfactory, be discarded and a new design adopted, as shown in Fig. 4.

In last year's report the committee mentioned the question of establishing a maximum gross load for each design of wheel. This had particular reference to failures of cast-iron wheels used on heavy tare weight, such as refrigerator cars. The committee has given this matter further consideration and recommends that the titles of the chilled cast-iron wheels shown on M. C. B. Sheets N, O, and P, be changed as follows:

M. C. B. Sheet N, title to be changed from "M. C. B. Recommended Practice for Cast-iron Wheels for 60,000-pound Cars" to "M. C. B. Association Recommended Practice for 33-inch Cast-iron Wheels for Cars of Maximum Gross Weight, Not to Exceed 112,000 Pounds."

M. C. B. Sheet O, title to be changed from "M. C. B. Recommended Practice for Cast-iron Wheels for 80,000-pound Cars" to "M. C. B. Recommended Practice for 33-inch Cast-iron Wheels for Cars of Maximum Gross Weight, Not to Exceed 132,000 Pounds."

M. C. B. Sheet P, title to be changed from "M. C. B. Recommended Practice for Cast-iron Wheels for 100,000-pound Cars" to "M. C. B. Recommended Practice for 33-inch Cast-iron Wheels for Cars of Maximum Gross weight, Not to Exceed 161,000 Pounds."

The chairman of the committee has received a letter from G. W. Lyndon, secretary of the Association of Chilled Car Wheel Manufacturers, dated January 31, in regard to the question of guarantees of cast-iron wheels. A copy of letter is attached as an appendix to this report.

The report is signed by:—Wm. Garstang (C. C. C. & St. L.), chairman; W. C. A. Henry (Penna.); A. E. Manchester (C. M. & St. P.); R. W. Burnett (C. P.); R. L. Ettenger (So. Ry.); J. A. Pilcher (N. & W.), and O. C. Cromwell (B. & O.).

APPENDIX.

January 31, 1913.

William Garstang, Chairman, Master Car Builders' Standing Committee on Car Wheels, Indianapolis, Indiana.

DEAR SIR,—Our association has been endeavoring to uniformize the guarantee on car wheels with particular reference to the relative guarantee to be carried for wheels serving under cars of 30, 40 and 50-ton capacities. The increases in the loads carried by cars which have been put in service in the last twenty years present new conditions of guarantee, and the relative guarantees have never been figured on a scientific basis.

The six-year guarantee under 30-ton cars for 625-lb. wheels has been found satisfactory to maker and user, and this is because the wheel carries relatively a small load per pound of its own weight. When the cars are increased from 30 to 50-tons capacity, or 66⅔ per cent., the conditions of service are 625 to 725 lbs., or 16 per cent., the conditions of service are materially changed, because the tread or running surface of the three classes of wheels, which are your standards, are identically the same, and we contend that it is manifestly unfair to exact the same guarantee for each wheel, particularly by reason of the fact that the cars run relatively the same distance per year, but the tonnage carried by a 50-ton car exceeds that of a 30-ton car by 66⅔ per cent.

One or two railroads have insisted that the wheels under the three classes of cars should carry the same guarantee of six years.

I am attaching you herewith, a statement which will show that a guarantee of 6 years for 30-ton cars, 5 years for 40-ton cars and 4 years for 50-ton cars is a reasonable adjustment of the guarantee question on all classes of wheels. It really figures out 4½ years for 40-ton cars and 3½ years for 50-ton cars.

All we are trying to arrive at is a uniform basis by which we can present this matter to the railroads and arrive at a mutual understanding, and what we are striving for is a fair and reasonable basis of guarantee for the chilled iron car wheel.

I would be very much obliged if you would give me your answer at your earliest convenience.

Weight of car.	Weight of load.	Total weight	Average mileage per year.	Ton Miles.
30-ton car ..15 tons	30 tons	45 tons	8000	360,000
40-ton car ..20 tons	40 tons	60 tons	8000	480,000
50-ton car ..25 tons	50 tons	75 tons	8000	600,000

30-ton car, 360,000 ton miles, 6 years — 2,160,000 ton miles guarantee.
40-ton car, 480,000 ton miles, 4½ years — 2,160,000 ton miles guarantee.
50-ton car, 600,000 ton miles, 3½ years — 2,160,000 ton miles guarantee.

We ask for guarantee:
6 years — 625-pound wheel.
5 years — 675-pound wheel,
4 years — 725-pound wheel.

Yours truly,
Association of Manufacturers of Chilled Car Wheels,
By G. W. Lyndon, Special Secretary.

William Garstang (C. C. C. & St. L.) after reading the report said: I would like to mention that Mr. Dudley, consulting engineer on rails and wheels and structural materials for the New York Central Lines, in his research for defects in rails, has come to the conclusion that our present contour of the wheel is not a correct one; that the one and twenty contour throws the greater part of the load on the inside of the rail, and on account of this, that the rails are wearing much more rapidly than he thinks they would if we went back to our old contour of one in thirty-eight. In view of the fact that this matter has been brought before the wheel committee, I wish the association would consider that feature while considering the balance of the report.

DISCUSSION.

J. R. Onderdonk (B. & O.): Regarding "Limits of Segregation," the report states that the segregation of either element of carbon, manganese, and phosphorus must not exceed 6 per cent. of the ladle test. I would like to see steel as good as that made by the manufacturers, but I am afraid if we had a 6 per cent. variation, it would be difficult to live up to it. Take the element of phosphorus ,and you have .043; six per cent. would be .0026, with a variation of only 3 per cent. in phosphorus, the probability is that the chemist would not come any closer than that. I would also like to ask, in selecting the elements of carbon manganese and phosphorus, why the element of sulphur was left out?

C. A. Brandt (C. C. C. & St. L.): The sulphur should have been included in connection with phosphorus. In regard to the .06, it was considered that a limit of segregation of .06 per cent, would be a good thing. It is included in some of the railroads' specifications to-day, although the manufacturers will probably claim that they cannot make a good rail as low as that, but it is a thing we desire to get at.

C. D. Young (Penna.): I question the advisability of putting in a limit on segregation at the present time in our rolled steel wheel specifications. There are two reasons; in the first place, I am quite confident that the limit of .06 per cent. is too close for sulphur and phosphorus, with the present methods of determining commercially, phosphorus and sulphur in the laboratory. Sometimes the error in chemistry would be almost .06 per cent., and that would stand then as a rejection on a lot of wheels. There is another reason from the inspection standpoint, which makes it difficult. At the present time we are accepting our wheels on a .05 phosphorus and sulphur rejection, and we simply say that if the sulphur and phosphorus comes within that rejection limit, the wheels are acceptable and we do not carry the analyses any further. If it is within the limits, the material is accepted. We have been getting very satisfactory use from our wheels. A clause of this kind will require the railroads to have their chemistry carried on accurately in order to find whether the melt as determined by the manufacturer agrees with the railroad company's chemistry.

The practice in most of the mills, in getting chemical analyses, is to take the shortest methods possible, and I believe there will be a good deal of confusion in the checking of the heat analysis with the analysis from the borings of the wheels. I would like to make a motion that recommendation No. 1 be submitted to the association for letter ballot as recommended practice, as printed, leaving out these limits for segregation. I believe we should have some data from people who have had this entire specification in use, showing that they have gotten better service from it than those who have not had it in their specification, before we make it an M. C. B. requirement.

William Garstang: In order that we might vote on the report as a whole, would it not be well for someone who has had considerable experience in this matter to suggest

what would be a reasonable limit to be used in place of .00 per cent?

J. R. Onderdonk: I do not think that is a good way to get the segregation. The segregation which gives trouble in the wheel is the variation in the wheel itself, and not a variation of one part of the wheel with another, within small limits. If we put a limit of 10 per cent. on it I do not believe that we would arrive at what we are trying to accomplish. If we want to ascertain the segregation, the better way, I should judge, would be to make an analysis of two different parts of the same wheel, and then put in a limit of possibly 10 per cent. I think we shall have to go as high as that.

C. A. Brandt: According to the specifications, the limits of carbon are .00 to .08 per cent.; and of course the ideal method is to limit the variation of carbon to .00 to .08 in the same wheel. I think possibly a good many wheels are manufactured where the carbon might vary to that extent and yet the wheel be desirable; .00 per cent. is pretty close to what is desirable, and one of the important railroads in this country has that clause in its specifications now.

George L. Fowler: I think the suggestion to make the point of segregation two points in three might be very well, if you could pick out those two points, because in a wheel that was made from a slab that was rolled lengthwise of the ingot the line of segregation would be quite different from the segregation of a wheel that was made from a slab cut across the ingot; so I do not see how it would be possible to put in any kind of a specification a rule for picking out the place where the analysis should be made in order to determine the average segregation.

D. F. Crawford (Penna.): In seconding Mr. Young's motion, I had in mind the practical application of this particular point. I happened to know of some rails that gave rather excellent service, and they were examined chemically and very carefully, and it was found that they were quite badly segregated. I do not feel at this time we should put in a limit of segregation until we find out what effect it will have on the service results of the wheels.

President Fuller: The motion before the house is that recommendation No. 1 be approved and submitted to letter ballot, eliminating the limit of segregation.

The motion was put to vote and carried.

E. W. Pratt (C. & N. W.): I move that the balance of the recommendations be approved and submitted to letter ballot.

The motion was seconded and carried.

William Garstang: Before we close on the wheel question, there is a point in connection with the chilled cast-iron wheels which is not touched on in the committee's report, and that is a thickness of the flange of greater dimensions than that described to this association. The wheel manufacturers have asked repeatedly to be allowed to increase the thickness of the flange 1/8 in., an increase of 1/16 in. of metal back of the flange and below the tread line, or between the tread line and the centre of the wheel; but the committee has not considerd this request seriously, from the fact that such an increase would interfere with the road conditions in regard to clearances, frogs, switches and crossings.

There are samples of the thick-flanged wheel to which I refer, on exhibition on the pier, and as nearly as I can learn there are several thousand of these wheels in service today. I have been written to on two or three occasions asking what we would recommend be done with such wheels when they are offered in interchange? Personally I think the wheel can be run with safety; in fact, I know it is run with safety. We feel that with the additional 1/8 in. added to the flanges of these wheels we would have a cast-iron wheel of sufficient strength to use under the heaviest cars contemplated at the present time, and in view of the fact that there are a large number of these wheels in service, I would suggest that the question of opening up the clearances in frogs and crossings and guard-rails be taken up by this association, either through its executive committee or a committee appointed especially for that purpose, with the American Railway Association, with a view of having that association appoint a committee to work with this association, to see whether or not we can get the clearances increased.

I believe that with 1/8 in. more clearance in our frogs and switches, the manufacturers of chilled cast-iron wheels can produce a wheel that is perfectly safe and one which will yield more economical service than any wheel we have on the market; and I would recommend that the matter be taken up by this association with the American Railway Association with regard to getting increased clearances in the frogs and crossings. I mean that as a motion.

The motion was seconded and carried.

President Fuller: Mr. Garstang, you spoke of one other subject, the taper, which I overlooked. Will you bring that up now?

William Garstang: I thought it would be well for the members to consider that feature in discussing that paper. I have taken it up with the Wheel committee, and the committee as a whole did not think that we should change the contour. I have explained to you just what has been discovered by Dr. Dudley, and it is for this association to instruct the committee on that point.

D. R. MacBain (L. S. & M. S.): I believe it would be well for the association to consider this matter of changing the contour from one in 20 to one in 38 very seriously before any decided action is taken. About fifteen months ago, as we were coming out of the winter of 1912, during which time we had a great deal of trouble with shelled-out wheels, and various other ailments of wheels, we made a radical step on the Lake Shore. We took two big club cars and went from the standard cone of 1 in 20 to a cylindrical tread, with a view of getting a more uniform or wider bearing on the top of the rail, and thought we would improve conditions that way. We ran the cars about four months, and during the time they were running, we probably changed all the wheels on the cars, and some of them were probably changed two or three times. It is due to flangeway. It is a question if you can take on more flange area, which you will do if you increase the taper, and stand for the additional wear which the present contour gives on the rail.

A. E. Manchester (C. M. & St. P.): We manufactured several thousand wheels which were straight, and we felt that we were getting the proper results in relation to flange way. When we did go, finally, to the coning, while we did it not to be odd, and not to be doing something different from anybody else, we did not do it for the purpose of improving the wheel as we did not feel that way at the time and do not feel so to-day.

A. R. Ayers (N. Y. C. Lines): This question might be illustrated by a report which Dr. Dudley compiled. A few years ago, before the new contour was adopted, they had in service on the Boston and Albany some wide, flat-topped 95 lb. rails. These rails carried about 350 million tons before they were worn out, and the wear was noticeably flat across the top of the tread. After the one in 20 contour was adopted, there was put into service in some parts of the New York Central & Hudson River some 100 lb. rails which only carried from 24 million to 32 million tons, possibly one-tenth of what the other rails carried, and the wear on such rails was noticeably deeper. In my opinion, the one in 38 taper will flatten until it has the proper area for carrying its load with much less actual flattening of the wheel or distortion of the metal than the one in 20, for the reason that in the one in 20, most of the flattening is one way towards the throat, and the taper is such that that portion of the tread outside of the axial theoretical line of contact does not come in contact with the rail to nearly such an extent as if we used the one in 38 taper.

When heavy wheel loads are used, the question is different from what it is with lighter wheel loads, because the wheel must flatten, as your finger flattens if you press it out on the table. If the loads are very heavy, the flattening is greater than with light wheel loads, and while I do not think that Dr. Dudley was at all hopeful that any definite action could be taken at this time, he wanted to have the matter presented before the convention in its full importance. As Mr. MacBain says, it is largely a question of how much rail expense we are willing to put up with in order to save wheel expense, but the difference in wear with the two treads was so noticeable that it is worthy of a great deal of consideration.

William Garstang: I think there is something besides how much rail wear and how much wheel wear we can stand. I think the contour of the wheel does its best service in starting the wheel running right. It is a question whether a contour of one in 20 or one in 38 will do it best.

J. A. Pilcher (N. & W.): We recently had some wheels put under test with varying tapers, and after the first wear the examination seemed to indicate that they had all reached very nearly the same shape. Of course, the wheel that is nearest to the cylindrical form will probably reach that shape earlier than the others, but they quickly come to the shape of the rail. While in the transitory period they are bound to have an influence on the rail in localizing the load on one side, but the indications are that they quickly conform themselves to the shape of the rail where the taper is not too excessive.

President Fuller: Could not your committee take this subject up during the coming year and give it a little more attention before the next convention?

William Garstang: There is no reason why it should not be done. The committee is a standing committee and our object in bringing this matter before the association was that perhaps some of the members might have had similar experiences with Dr. Dudley and we might get something from them.

A. W. Gibbs (Penna.): The inception of this one in 20

taper should not be lost sight of. Up to about 1904, the one in 38 taper was the general one, and the breakage of flanges from seams was advancing in leaps and bounds; it scared us very much. The contour in England and on the continent was 1 to 20. Comment was made by many foreigners coming over here as to the great increase in the side wear of rails, which was one-third greater as compared with their own. The study we made indicated that the formation of the seams was due to excessive loads at certain points. The wheels which were cylindrical or nearly so usually ran with one flange against the rail and the other away from it. The idea of introducing the tapered contour was that the wheels should oscillate, as Mr MacBain stated, and spread the wear over the whole contour. The results obtained, which were shown by the monthly and annual records of wheel failures, indicated that we did accomplish the result, to a large extent, of preventing flange breakages. It was not only to reduce the flange wear, but to reduce the failure from seamy flanges. I think it has done it, and I believe the wrecks and damages from broken flanges will far outweigh any other consideration, and those we have eliminated, to a considerable extent.

O. C Cromwell (B. & O.): The remarks of Mr. Gibbs simply bear out the experiences we have had. At one time we operated a large number of wheels of the M C. B. contour tread and the failure of flanges became very pronounced, and we went to a full coned taper of the tread with a very beneficial result.

D. R. MacBain: I move that the Association instruct the Standing Committee on Car Wheels to investigate the subject further and report at the next convention and find out what the different railroads think about the matter.

The motion was seconded and carried.

AFTERNOON SESSION.

Vice-president M. K. Barnum called the meeting to order at 3.05 P. M. in the afternoon session, June 16.

REVISION OF THE RULES OF INTERCHANGE.

Arbitration Cases 881 to 917 have been decided and distributed to the members during the year and are herewith submitted as a part of this report for approval.

RULES OF INTERCHANGE.

At the suggestion of the Arbitration Committee, a committee from each of the railway clubs was appointed to consider jointly the proposed changes. A meeting of this joint committee was held in Chicago on April 14, at which meeting representatives from the New England, Central, Pittsburgh, Canadian, Western, St. Louis and Southern and Southwestern Railway Clubs were present.

At the request of several members of the Association, representing cars of private ownership, a hearing was given by the committee on May 6, 1913, at which representatives of the following companies were present: Armour Car Lines, Morris & Co. Refrigerator Line, Swift Refrigerator Transportation Co., Cold Blast Transportation Co., Street's Western Stable Car Line, Mather Stock Car Co., Western Live Stock Express, Missouri River Despatch.

Rule 1.—F. C. Schultz, chief interchange inspector, Chicago, and Chief Interchange Inspectors' Association suggest change:

"Each railway company must give to foreign cars while on its line the same care as to inspection, oiling, packing, adjusting brakes and repairs that it gives to its own cars."

The Joint Club Committee concurs in the first suggestion, with the exception that the word "running" precede the word repairs. The Arbitration Committee also approves.

Rule 2.—The committee would recommend that the second paragraph be changed to read as follows:

"Empty cars offered in interchange must be accepted if in safe and serviccable condition, the receiving road to be the judge. Owners must receive their own cars when offered home for repairs at any point on their lines, subject to the provisions of these rules."

The committee recommends Section (b) of Rule 2 be changed to read as follows:

"Cars loaded with explosives shall be handled in accordance with the regulations of the I. C. C.

"Leaking tank cars containing inflammable liquid must be repaired or transferred without any unnecessary movement, or at nearest available point, with least possible risk.

"Tank cars (empty or loaded) shall be rejected if the safety valve is not stenciled to show it adjusted, etc., within the time limit required by paragraphs 5, 6 and 7 of the M. C. B. specifications for tank cars."

The committee suggests that section *C* read as follows:

"Cars improperly loaded, when not complying with the Rules for Loading Material, or when transfer or rearrangement of lading is necessary."

Rule 5.—W. H. Lewis suggests changing the word "shall" to "must" and "should" to "must." The committee approves.

Rule 7.—The Western Railway Club Car Foremen's Association, Chicago, and Chief Interchange Inspectors' Association suggest change as follows:

"When repairs of any kind are made to foreign cars a billing repair card must be made out. This card must specify fully the repairs made and reason for same, the date and place where made and name of road making repairs; also show location of parts repaired or renewed, as per Rule 14.

"If no bill is to be rendered the billing repair card must be attached to the monthly bill, with the words "No bill" written across the face of the card."

The Joint Club Committee does not approve. The Arbitration Committee approves recommendations with the modification that the word "billing" shall precede word "repair" in the first line.

Rule 8.—The committee would recommend that Rule 8 be changed to read as follows:

"The billing repair card shall be made in duplicate, the original to be known as billing repair card and the duplicate to be known as record repair card, and to be on forms shown on pages 103 and 104, the items of repairs to be in handwriting."

J. J. HENNESSEY,
Chairman, Committee on Arbitration.

Rule 9.—The committee recommends that the rule be changed to read as follows:

M. C. B. Couplers, or Parts Thereof, R and R:
- New or secondhand.
- Size of shank.
  - (Where 1 2¼-in. head coupler is applied or removed it must be so stated.)
- Yoke, stem or key attachment.

Wheels and Axles, R and R:
- Cast-iron, cast-steel, rolled or forged-steel or steel-tired wheels.
- New or secondhand.
- Cause of removal (see Rule 10).

Journal Bearings:
- Solid, filled, or other kind, R and R.
- Length of journal.
- Box number (see Rule 14).

Metal Brake Beams or Parts Thereof, R and R:
- Make or name of beam.
- New or secondhand.
- Complete, or part or parts.
- Cause of renewal.
- Part or parts scrapped.

Brake Shoes Applied:
- Cast or reinforced back.

Triple Valve, R and R:
- Make and type.
  - (Need not be shown when cleaned only.)

Rule 10.—The committee recommends that after word "groove"

add "or preferably by gage shown on M. C. B. Sheet *C1* of the Recommended Practice."

Rule 13.—The committee recommends changing the rule to read as follows:

"Joint evidence card showing copy of billing repair card, covering wrong repairs, when wrong repairs have been corrected, shall be sent to the company issuing such billing repair card, and it shall issue M. C. B. defect card."

Rule 14.—The committee recommends eliminating from this rule any reference to repair card to conform to action on previous rules. In connection with the recommendation to permit the use of a cardholder, the committee believes that eventually a cardholder will be developed which will satisfactorily answer all purposes, but such cardholder should be a standard of the Association, and the property of the Association for the sake of uniformity. The committee does not agree to the introduction of a diagram for locating defects, as it does not feel that the accurate location and extra work entailed therewith is justified.

Rule 15.—The committee recommends that words "repair card" be changed to read "billing repair card."

Rule 17.—F. C. Schultz, C. I. I., suggests that a pamphlet be issued by the Committee on Standards showing brake beams which meet the M. C. B. requirements.

The Pittsburgh Railway Club suggests adding after the fifth paragraph the following: "Cars built after September 1, 1913, not equipped with either No. 1 or No. 2 brake beams will not be accepted in interchange."

The committee concurs in the suggestion of Mr. Schultz that a pamphlet be issued by the Committee on Standards showing brake beams which meet the M. C. B. requirements, these brake beams to be used on all new cars built after September 1, 1914. The recommendation of the Pittsburgh Railway Club is approved, except that the committee would recommend that the date be changed from September 1, 1913, to September 1, 1914.

Rule 20.—Twin City Club; J. E. Keegan; Central Railway Club; Pittsburgh Railway Club, and Western Railway Club suggest in first paragraph, last portion, eliminate the words:

"Any company finding cars not within the limits of standard height for couplers may repair and charge the owners."

The committee concurs in these recommendations.

Rule 21.—F. C. Shultz, C. I. I.; Car Foremen's Association; Chief Interchange Inspectors' Association, and Western Railway Club suggest adding to rule:

"When repairs are chargeable to car owners."

The committee approves the suggestion, but would recommend that the wording be changed to read, "when owners are responsible for the defective condition of the roof."

Rule 28.—J. E. Keegan, S. M. P., G. R. & I. Ry.; Pittsburgh Railway Club, and Central Railway Club suggest: Change last two lines to read:

"Not stenciled showing the capacity or maximum weight, or limit weight I or limit weight II."

The committee recommends that the suggestion be adopted.

Rule 29.—The committee recommends amending this rule by striking out the words following "applied" as follows: "under conditions which make them chargeable to the owners"; also to amend that portion of rule reading "diameter of journal must be ⅛ in. greater" to "diameter of the journal must be at least ⅛ in. greater," in order to prevent, under any conditions, the application of axles which may be practically worn to the limit.

Rule 33.—The committee suggests that the rule be made vacant, because a car with missing coupler can not be offered in interchange. The charge which may be made for missing coupler, etc., is provided for in Rule 95.

Rule 36.—Canadian Railway Club: New rule, under delivering companies' defects:

"No car to be accepted in interchange with journal bearings other than M. C. B., standard on cars built after September 1, 1914."

The committee approves of this suggestion.

The committee also recommends a new rule as follows:

After September 1, 1915, cars not having stenciled on them the date when built new, will not be accepted in interchange.

The committee at the request of the General Managers' Association would recommend a new rule as follows:

After September 1, 1914, no car carrying products which require for its refrigeration the use of ice and salt will be accepted in interchange unless equipped with suitable device for retaining the brine between icing stations.

Rule 37 to 42 incl. In regard to various recommendations made to eliminate the combination under Rules 37 to 42, inclusive, the committee feels that this change would be too radical to be effected at the present time.

It, however, recommends the elimination entirely of Rule 38, because there are very few cases in which the damaged pocket is a factor, except when due to local weak design or inferior material. Similarly, the reference to the pocket in Rule 39 should be omitted. The committee also suggests the omission of the reference to the coupler attachment in the second note at bottom of page 30, following Rule 42.

Rule 43.—The committee suggests the following change:

Owner's Responsibility

"Any damage to the underframe of all-steel or steel underframe cars, unless such damage occurred in wreck, derailment, cornering or side-wiping, and except unconcealed fire damage."

Rule 44.—The committee recommends that Rule 44 be made vacant for the reason that under Rule 2 such cars should be rejected in interchange.

Rule 49.—The committee recommends the omission of reference to repair card and the addition of joint evidence cards in this rule.

Rule 50.—W. H. Lewis suggests that this rule be eliminated, as it is covered by Rule 20. The committee approves the suggestion.

Rule 51.—W. H. Lewis suggests that this be eliminated, as rule 18 covers it.

The committee suggests that the rule be made vacant.

Rule 52.—The committee suggests changing the first paragraph to read:

"Running boards in bad order or insecurely fastened. Bolts, rivets or screws be used on parts repaired.

Also, change third paragraph to read:

"Handholds or grabirons must be of wrought iron or steel. In applying on repairs they must be secured by bolts or rivets.

Rule 53.—The committee suggests that the last line of this rule read: "Also quick-action triple valve, pressure-retaining valve and an efficient hand brake."

Rule 54.—The committee recommends that this rule be eliminated, for the reasons given under Rule 33.

Rule 56.—J. E. Keegan, S. M. P., G. R. & I. Ry.; Central Railway Club, and Western Railway Club suggest substituting Rule 66 in order to place it in its proper place.

The committee approves the suggestion, namely, placing the rule under Rule 56, now vacant, thus putting the rule in its proper place.

Rule 57.—The committee suggests that this rule be changed to Rule 58, and be changed to read as follows:

Delivering Company Responsible

Rule 58. Missing air-brake hose; missing or damaged cylinders, reservoirs, triple valves, angle cocks, cut-out cocks, brake pipe strainers or dirt collectors, pressure-retaining valves, release valves, pipe, pipe fittings, or any parts of these items, except as specified in Rule 59.

Rule 58.—The committee recommends that Rule 58 be changed to Rule 57 and that the first note following the rule be omitted.

The committee recommends that second note following present Rule 58 be amended as follows:

The committee on air-brake hose specifications will submit to the association recommendations for new air-brake hose label, and if the association adopts this label the arbitration committee recommends that after September 1, 1914, no new hose should be purchased or applied unless it bears the revised label, it being understood that the adoption of this recommendation will not penalize any hose now in service or in stock at this time.

Rule 59.—The committee would suggest a revision of this rule as follows:

Owners Responsible

Rule 59. Air hose burst, torn or worn out; air hose labels illegible or missing from wear; air-hose couplings that become defective in fair usage; release valve rods defective or missing; leaky pipe or pipe fittings account rust or seams; broken pipe or pipe fittings account insecure fastenings; defective interior parts of cylinder or triple valve; failure or loss under fair usage of other parts of brakes.

Rule 62.—The committee recommends the elimination of the words "and so labeled" and to allow the balance of the rule to remain as it is.

Rule 65.—The committee recommends change in Rule 65 as follows:

"Journal bearings (regardless of previous condition) and journal-box bolts which require renewal, when delivering company is responsible for change in wheels and axles."

Rule 68.—The committee recommends changing this rule as follows:

"Fast sliding, cast-iron or cast-steel wheels, if spot is 2½ in. or over in length, or if there are two or more adjoining spots, each 2 in. or over in length, the same responsibility to apply to mate wheel, regardless of length of slid spot."

Rule 86.—The Pittsburgh Railway Club suggests adding the 6 in. by 11 in. axle to this rule:

Capacity.	Journal.	Wheel Seat.	Center.
"FOR CARS MARKED WITH CAPACITY:			
140,000	5½	7⅜	6⅞
FOR CARS MARKED MAXIMUM WEIGHT:			
210,000	5½	7⅜	6⅞
FOR TANK CARS MARKED LIMIT WEIGHT I.			
210,000	5½	7⅜	6⅞
FOR TANK CARS MARKED LIMIT WEIGHT II.			
210,000	5½	7⅜	6⅞

This is approved by the committee.

Rule 89.—The committee recommends the elimination of Rule 89, for the reason that amended Rule 13 covers this rule.

Rule 90.—The committee recommends the elimination of the first paragraph of Rule 90, as it is already provided for in Rule 13, and would also recommend eliminating the third paragraph of Rule 90 on account of the abolition of the repair card.

Rule 93.—The committee on conference with the association of american railway accounting officers suggests changing rule to read:

"Separate bills must be rendered for cars destroyed. All charges for repairs made to cars account of owner's defects, defect cards and rebuttal authorities must be consolidated against any one company into one bill.

"Separate statements to be made:

"1. For owner's defects for each calendar month.

"2. For all charges based on defect cards, including rebuttal charges.

"NOTE.—Totals only of these statements to be shown on the recapitulation."

The committee recommends that present Rule 93 be abrogated, and recommends in its place that new Rule 93, as proposed by the joint committee from the M. C. B. Association and the Association of American Railway Accounting Officers, be adopted.

Rule 95.—The committee recommends the restoration of the third paragraph of this rule shown on page 56 reading:

"Brake levers, lever guides, top and bottom brake rods, whether or not they are lost with the brake beam" to comply with changes made in previous rules and because it is only consistent to feel that if the brake beam when lost is in good condition, the further details as stated above should also be in good condition.

Rule 99.—The committee recommends that this rule read as follows, in order to make it plainer and to conform to Rule 86:

"If car owner elects on account of improper repairs to remove M. C. B. standard axles suitable to the marking of the car, he shall make charge for secondhand axles, and allow credit for secondhand axles if they are in good order. If M. C. B. standard axles unsuitable to the marking of the car are removed, they should be credited as scrap regardless of their condition. Axles removed below the journal limits for cars marked capacity, limit weight or maximum weight, as per Rule 86, should be credited as scrap when removed."

Rule 104.—The committee recommends changing Rule 104 to read as follows:

"Secondhand M. C. B. coupler or parts, or secondhand metal brake beam, may be used in repairs, but must be charged at 75 per cent. of value new.

"Secondhand M. C. B. coupler or parts removed, must be credited at 75 per cent. of value new. Credits shall be confined to the body, lock, knuckle and knuckle pin, whether secondhand or scrap.

"Secondhand parts of metal brake beams removed must be credited at 50 per cent. of value new.

"In applying new M. C. B. coupler or new metal brake beam it shall be so charged, whether or not it be of same make as that removed."

Rule 106.—The committee suggests the elimination of revised Rule 106 as shown on Circular No. 8 giving result of letter ballot on changes in the rules, and restoration of old Rule 106. (See page 66 of the 1912 code) reading as follows:

"No percentage to be added to either labor or material."

Rule 111.—The committee recommends the following change at the bottom of page 86 and top of page 87:

The following basic units must not be used in rendering bills in the foregoing schedule but may only be used in determining cost of other combinations of air-brake repairs not mentioned, for the reason that the present wording is misunderstood.

Rule 113.—The committee recommends rewording this rule, as follows:

"The company on whose line the bodies or trucks are destroyed shall report the fact to the owner immediately after their destruction, and shall have the option of rebuilding or setting for the same."

Rule 115.—The committee approves the recommendation eliminating word "axles" in the second paragraph and concurs in the recommendation changing word "designate" to "nearest," for the reason that such change is in accordance with conference ruling No. 224 of the Interstate Commerce Commission.

The committee suggests changing the last paragraph to read:

The underframe of damaged steel and steel underframe cars, when intact and in serviceable condition, may be forwarded to the owner on defect card, in which case it must be accepted by the owner.

Rule 120.—The committee recommends that wording of the first paragraph of this rule be changed to read as follows:

"A car unsafe to load account of general worn-out condition due to age, decay or corrosion, shall be jointly inspected by the handling line and a representative of owner or a disinterested line whichever can be most conveniently obtained by handling line. If inspectors agree that home route cards are justifiable, joint inspection statement shall be sent to owner, showing in detail all defects found on car, also an estimate of cost of temporary or partial repairs necessary to make car safe to move. Upon receipt of this information, owner shall either furnish two home route cards or authorize destruction of car. When issuing home route cards, car shall be short-routed per Car Service Rule 3, paragraph (f), at owners' expense, and owner shall be responsible for necessary repairs to make car safe to move. If owner elects to have car destroyed, the handling line shall allow credit for all material at M. C. B. scrap prices, less labor cost of destruction.

"The joint inspection and home route cards will apply in cases of direct or indirect connection except where car is already at junction point with car owner's line, in which case owner must accept car per Rule 2."

Rule 121.—The committee recommends that rule 119 be consolidated with Rule 121, and that the consolidated rule read as follows:

"When the body or trucks of a foreign car are destroyed in wreck or accident, the owner shall, upon request, furnish statement of depreciated value of body and trucks separately.

"If the car is not destroyed, and the owner elects upon request, to furnish home route cards for its movement it shall be short-routed as per Car Service Rule 3, paragraph (f) to point designated by owner, at the expense of the company on whose line the car was damaged. A joint inspection should be made at said designated point, and settlement made on the basis of the M. C. B. rules."

Rule 131.—The committee suggests that the new rules go into effect October 1, 1913, for the reason that under the operation of the rules from January 1, only about three months' experience would be had with them prior to having recommendations made for changes in the rules.

PASSENGER CAR RULES.

Appendix—Rule 3.—The committee recommends that icing and lubrication be stricken from the items forming line expenses, for the reason that each line interested should be individually responsible for lubrication and icing while the car is on its line. Terminal cleaning is accepted because cleaning of this character is only done at the point where the car starts.

Appendix—Rule 6.—The committee suggests changing rule to read:

"Each operating line at interest may charge one journal bearing only per journal per trip. The following information must be specified on billing repair card or on the bill itself:

"Whether solid, filled, or any other kind, removed and replaced.

"Length of journal.

"Box number."

Appendix—Rule 12.—The committee on train lighting suggests that the following instructions covering repairs to electric-lighting equipment on passenger cars be added to Rule 12, page 129:

"For repairs to electric-lighting equipment on cars in interchange or leased cars, the instructions issued by the manufacturer of the apparatus should be strictly adhered to. In the absence of any agreement, the material furnished and applied must be of the manufacturer's make."

The committee approves the above suggestion.

The report is signed by:—Jos. W. Taylor, *Secretary*.

Chairman Barnum: This special session is called to take the place of the conference that has hitherto been held in the Marlborough-Blenheim Hotel on the afternoon or evening of the first day, to canvass the Arbitration committee's report prior to its presentation by that committee at the regular session of the second day. This action is in accordance with a suggestion made last year for the purpose of obtaining a record of the discussion on the changes in the rules.

The Arbitration committee has had an unusually arduous series of meetings during the past year, not only for the purpose of considering the arbitration of cases, but especially on account of the large number of changes that were suggested in the rules. There were, I believe, 280 changes in

the freight car rules, which number 131. These changes applied to about 95 of the 131 rules, and while the suggestions have in many cases not been adopted, they have, we believe —I say that as a member of the Arbitration committee— been very carefully considered.

To show this I wish to state that at one time the Arbitration committee met for seven days ,and altogether did nine days' work in actual sessions on this report, in addition to the time spent traveling by those members who live outside of Chicago, and some extra work that was done outside of the meeting. You can, therefore, understand the problem that was presented to them, and if there are some changes recommended which have been disapproved, or some changes which have been approved that did not meet with your ideas, you will appreciate that it is not surprising.

In order to give the utmost consideration to all suggestions, the Arbitration committee held two separate meetings to discuss propositions made by the private car line representatives for some changes in the rules as they were in effect last year, and for some objections to changes that were proposed in the rules as covered by this report; as the result of these conferences, considerable modifications were made in the original form of the report.

It has been the object of the Arbitration committee in revising the rules this year, to make as few changes as seemed necessary to bring them up to date, and at the same time keep them as simple as possible to avoid any unnecessary complications. One suggestion, which may not be understood, was that the rules be changed to go into effect October 1, instead of November 1, as heretofore. The object of that was to give the secretary more time to get the rules printed and distributed, and also to give the railroads more opportunity to post the inspectors on the changes in the rules. September 1 has left insufficient time to get the rules out and have them well discussed before they went into effect. That will be one of the recommendations which you will be asked to pass upon.

The first part of the Arbitration Committee's report covers the cases arbitrated during the year. Arbitration cases 881-917 have been decided and distributed to the members during the year, and are submitted as part of this report.

I. S. Downing: (L. S. & M. S.): I move they be accepted. The motion was seconded and carried.

Chairman Barnum: The secretary has a communication which he will read to you. The Arbitration committee has been advised that Rule 30 has been acted upon by the American Railway Association and if you will turn to the report, the committee wishes a change there, recommending the adoption of American Railway Association Rule 11. That is the rule in regard to weighing cars, and when our report was made, we did not understand that that rule had been finally settled upon.

I have already said that the Arbitration committee had met the representatives of the private car lines on two occasions and discussed some changes which were made in the rules, and as they still feel that there are certain rules which affect them seriously, and which are not in the form at present shown in the report, they are not altogether satisfactory. The Arbitration committee, with your approval, will follow the plan that the private car line representatives be given a hearing at the beginning of this meeting on those rules which are especially applicable to them, and the secretary will read the communication which they have sent.

Secretary Taylor then read the following communication:

To the Members of the M. C. B. Association:

The undersigned companies, after representing to the various committees who have had charge of the changes in the M. C. B. rules of interchange, find that certain recommendations will be made to this convention which will affect most materially the operation of the cars we represent.

By reason of the non-reciprocal arrangement as between cars of individual ownership and railroad companies, these changes discriminate against the individually owned cars in favor of the railroads. We recognize the fact that it is not in our province to dictate or interfere with any code of rules covering the handling of railroad companies' cars; we only ask that where the reciprocal feature does not exist that exceptions be made for our relief.

The various changes which have been made in the rules in recent years have increased the expenses to such an extent that we are now frankly stating to the association that the recommended changes will prevent the continued operation of cars of individual ownership except at a loss. We do not believe that it is the desire of the association to legislate out of existence this special equipment and we request your earnest consideration of the question involved. Therefore, we present herewith a list of our objections and ask the association to give us the relief which we must have:

Rule 1.—Do not omit reference to rules 33 and 55.

Rules 33-55.—Do not eliminate these rules.

Rule 64.—Reinstate as in effect previous to Nov. 1, 1912.

Reason.—So far as the railroads are concerned, the elimination of these rules as proposed is reciprocal, but on cars of individual ownership such arrangement does not exist and therefore protection should be given. This can be accomplished by continuing the reference to rules 33 and 55 in rule 4, by retaining rules 33 and 55, and restoring rule 64 as in effect prior to November 1, 1912, making such provision as will restrict the application to cars of individual ownership if so desired.

Rule 36.—Referring to application of brine retaining tanks, time allowance is entirely too short. The perfecting and application of a device satisfactory for the safe handling of lading cannot be accomplished in the alloted time.

Rule 94.—Change the last sentence to read—"but no bill shall be rendered unless repairs are made or car withdrawn from service." The reason is this. In view of the growing sentiment to withdraw light capacity cars it is unjust and inconsistent to require that they be repaired before owners can recover on defect card covering badly damaged cars.

Rule 98.—Restore price of second-hand wheels and make no change in labor charge for application.

Reason: It is unfair to car owners to allow scrap value only for second-hand wheels removed. The present labor allowance is ample to cover cost.

Rule 117.—Add to proposed changes on depreciation of wooden car bodies (first paragraph), "except cars covered by rule 118." Make no change in seventh paragraph of 1912 rules.

Reason: Cars designed for special purposes must be frequently rebuilt to protect their lading and consideration should be given this rebuilding in figuring their depreciation which at most does not exceed six per cent. yearly or 60 per cent. of their total value.

The communication is signed by Armour Car Lines, Swift Refrigerator Transp. Company, Morris & Company, Cold Blast Transportation Company, Kingan Refr. Line, St. Louis Refr. Car Company, American Cotton Oil Company, Street's Western Stable Car Line, Pacific Fruit Express and German American Car Company.

Chairman Barnum: In order to make definite progress in this work, I think we better take action as we proceed, on each recommendation separately. I think it will not be necessary to make separate motions on these rules; it is agreed that the business of the meeting is to consider them in order. We might first hear from the representatives of the private car lines as to their reasons for making the recommendations.

DISCUSSION.

H. L. Osmond (Morris & Co.): The members of the private car lines represented here and at the meeting before the Arbitration committee, were given every consideration by that committee, but at the same time there has been enormous pressure brought to bear by railroad companies with the idea eventually of making everything an owner's defect, wrecks and derailments, perhaps, excepted.

I want to repeat what we said in our communication to you. We realize it is not our business what rules you make as to the handling of your affairs, but we at the same time are compelled to furnish a special equipment for the handling of our business, and when we offer you a car, it is subject to your, and only your inspection, and everything must be on that car before you will accept it. If there is anything missing, or any defect which you feel makes a car unsafe to run, you refuse to accept the car. We are absolutely powerless, but it seems to us that it is no more than fair to return that car after it is unloaded at its destination, in as good conditions as you take it from us, ordinary wear to be excepted.

F. F. Laughlin (Armour & Co.): We appreciate the conditions and circumstances under which the Arbitration committee has worked in making rules that will take care of the interchange of cars as between railroad companies, and it is somewhat unfortunate that we have to have our cars in this interchange; but it is a necessary condition.

These suggestions have been made to take care of the cars of individual ownership, the idea being that this missing material can be taken care of at our expense while it is on your line. Its waste does not benefit anybody and it is a very large item of expense to us. It means that we have to accept the cars home with this material missing or lost when, by a little care, probably, on the part of the handling line, you would be able to preserve and restore the car to us in good condition, and at our expense.

If I. Osmond: There is one thing I omitted to say, and that is with relation to the financial question. I do not know whether you gentlemen realize the position we are in. To start with, we are forced to build this special equipment. There has been absolutely no change in our compensation for the use of these cars for years past; on

the other hand, our average haul and in consequence, our earnings, are decreasing every year. We earn nothing like as much on these cars as we used to; one of th reasons is that America has lost the English dressed beef trade. We have been driven out of the market by the Argentine; they can raise cattle cheaper than we can in America. We have had to hunt up a market in this country to take care of our output. We have established branch houses at nearby points through our packing centres. In the year 1912, we shipped over 3,000 carloads of beef to branch houses in Chicago, on which we derived not one cent of revenue. In addition to that, we shipped over 6,000 carloads of dressed beef to nearby points in so-called refrigerator cars. These cars average a haul of 74.7 miles each. In addition to our earnings going down all the time, you all will admit that the changes which have been made in these M. C. B. rules, under which we have to live, have increased our expenses until today, the points of shipment being so near together, we are literally struggling for existence.

We have had to make reports to the Interstate Commerce Commission, and I showed for the year 1912 earnings of 4.71 per cent. on the money invested in our car lines. So far this year, covering the first five months, the average bills against us have increased 80 per cent. over the first five months of 1912. We have got to the point this year where I doubt very much whether we will be able to show 2½ per cent. I believe you will admit we are entitled to a fair return on the money invested in these cars.

J. J. Hennessey (C. M. & St. P.): In the Arbitration committee's report, we gave the reasons why we did not concur in the various arguments which came to us, and I feel that it is up to the convention now to talk. We put in an enormous amount of labor trying to get these rules to harmonize and we tried to be as just as possible.

F. W. Brazier (N. Y. C. & H. R. R.): The gentleman who last spoke must admit that the equipment is in bad shape, as the bills coming in are so heavy. Since we have been here we have had four cars out of one of our trains for defective arch bars; that will go in as repairs against owner of these cars.

A. LaMar (Penna.): I would like to answer Mr. Brazier on that point. You all know our labor is costing more than it did a year ago, and so is material, and I will leave it with Mr. Brazier to say if our equipment is not in better shape than it was a year ago.

J. J. Hennessey: That is what I wanted to bring out—whether you thought these were real repairs, or whether you thought we were making "pencil repairs" as someone has designated them.

T. W. Demarest (Penna. Lines): If I understand the proposition of the car lines in reference to rule 4, it is the re-establishment of rules 33 and 55. If you will consider the reasons given for the omission of these rules, I think you will be in a position to answer as to rule 4. As to rule 33, it covers the missing couplers, and you cannot offer an interchange of a car with a missing coupler; they also understand that you cannot offer an interchange of a car with a defective brake attachment, and for that reason they have asked for the omission of rule 55. If their understanding is correct on those two details, you must omit the rules; those reasons are given in their report.

I. S. Downing (L. S. & M. S. Ry.): Where?

T. W Demarest: Under rules 33 and 55.

I. S. Downing: There are just two reasons, one is improper workmanship and the other is lack of care. I do not see why the private line people should not stand for a missing hook or a missing brake hanger or shoe. If the private line is responsible 40 miles away from a point where interchange takes place, they are responsible there; I think the Arbitration committee's recommendation should be adopted.

M. F. Covert (Swift & Company): The cars could not be offered in interchange; I do not know what was meant by interchange movement. We have a considerable number of cars returned to us with brake beams and shoes missing, which were torn off, no doubt, by some obstructions on the track. I do not see why the private car line should not be re-embursed for that when the car is returned; and if the railroads repair and replace that material at their own expense, instead of sending the car home to us, there would probably be no objection.

T. W. Demarest: Mr. Covert, you are talking about the rule as it is at present. If you omit that rule, you will not get your car home with a brake beam missing. The handling company will repair that and charge you under rule 95.

E. Chamberlain (N. Y. C. Lines): The gentleman has made a statement representing the private car line. I am in doubt as to whether the 80 per cent. of equipment controlled by this company has had steel underframes and betterments of that character, and as to the increase of M. C. B. bills. Perhaps the gentleman can throw some light upon the character of the bills that accumulated. The natural sequence would be when you placed a steel underframe under the car and made other betterments, that your M. C. B. bills would be less. I cannot quite assimilate the reasons.

M. F. Covert: As I understand, Mr. Demarest, rule 95 has gone back, and you make the handling line responsible for the missing brake material?

T. W. Demarest: The present rule 33 reads as follows:

"Material missing from bodies of cars offered in interchange, except grain doors, water troughs and attachments, all inside parts or concealed parts of cars; also nuts, body truss-rod, saddles on bolsters, roof boards, side and end fascia, wooden door caps, hatch covers, vent slides and ventilated side and end doors, unless the car is stenciled for such door." Now, if that rule is omitted, the delivering company cannot give you your car home with that material missing, but they must supply the material and bill you under rule 95 for the labor only. So you only get your car home in the condition provided for in rule 33 for the reason that the Arbitration committee believes it is not the intent of the rule to deliver the car home with defective material. That is in reference to rule 55, but in rule 33 it is the missing coupler. If that is understood, rules 33 and 55 should be omitted and private car lines would be benefited.

T. H. Godnow (C. & N. Y.): The only injustice done the private car lines is in the question of credit. If you tear their brake beam or other parts from the car, you will have that in your possession. It is true you can make the repairs and deliver the car and they have to stand for the bill. As I understand it, they want to get a defect card when the car is delivered. It seems to me that if an individual car owner got some credit for the parts in the possession of the railroad company, it doesn't make any difference whether the railroad makes the repairs and bills for it, or the owner takes the car himself and makes the repairs.

T. W. Demarest: I would again like to call attention to the fact that the discussion does not pertain to whether rules 33 or 55 should be omitted from rule 4. If the Arbitration committee's reasons are good, the rules must be omitted; and it seems to me there should be no further discussion.

Chairman Barnum: I think it is for the benefit of all concerned to have as thorough a discussion as possible; if there are misunderstandings, this is the time to clear them up.

T. H. Goodnow: There is a lot of material which has not been charged when missing, but has been credited as interchange. The question of the missing roof is accepted as a defect, and the coupler we cannot deliver unless under special arrangements we go to our own shops.

F. H. Stark (Montour Railroad): I appreciate that we are a little out of order in talking on this rule; but the private car interests are after some redress in some manner. I appreciate that the Master Car Builders themselves are not in position to correct matters so as to make the ownership of private cars break even. We have heard here to-day regarding the earnings on refrigerating cars, in which they state that they doubt whether they can make 2-½ per cent. There was a time when the railroads failed to provide equipment for carrying coal, and the coal operators were induced to purchase cars. Later on, the Interstate Commerce Commission wiped out all the special consideration accorded to the private car owners, and today any company that owns coal cars will lose.

We might say "Missing material is owner's responsibility, except when offered to the owner." That will not do because it will put the burden on the delivering line, and I do not see how this association can correct the trouble. I would suggest that the matter be referred to a committee for their consideration.

The Interstate Commerce Commission is getting data on the purchase, cost of maintenance and revenue from private cars, and as a matter of fact, people owning coal cars cannot help but sustain the loss anywhere from $30 to $50 a car per year under the present conditions. They do not get their own proportion of the railroad company's equipment; they have to take all classes of cars, including cars owned by other private lines. They are the victims of circumstances, and I do not see how you can correct the trouble without having it go before the American Railway Association as to the matter of increased compensation.

The cars are sometimes held two months in a switching district, which in some cases includes 40 miles, and the owner does not get any compensation whatever, and has to pay for all the necessary repairs to the cars while they are in the switching district.

Chairman Barnum: I will state on the part of the Arbitration committee that it was suggested at some of the conferences

we had that an exception be made in the case of the private car lines, and that we make a rule covering the interchange of cars between the railroads, especially covering the missing material, and where these cars belong to private car lines make an exception when the car was returned to the owner. That matter was considered carefully, and discussed thoroughly, and the Arbitration committee felt that it would be inconsistent. This is a very important subject, and the Arbitration committee has been, theoretically, lying awake nights over it, and we should have a full discussion, because everyone here is interested as well as private car lines. It is a matter that is worthy of very careful consideration, and I think we should take plenty of time to thresh it out.

T. W. Demarest: In reference to the point brought out by Mr. Barnum, as to the feasibility of making one set of rules to cover private line cars, and another set to cover railroad owned cars, I think every member of the Arbitration committee consulted with the legal department of his road before giving that thought up. As a result of such consultation we did not feel it advisable to make any difference between the treatment of a private car line car and a railroad owned car, in interchange.

H. L. Osmond: I fail to see why an exception cannot be made in favor of the private car lines. You start out and take our cars on a mileage basis, which is certainly different from the basis on which you settle among yourselves for the use of railroad cars. In settling for a destroyed car, while it is settled for according to M. C. B. rules, it is a different method of settlement than for a destroyed railroad car.

Chairman Barnum: I think you are mistaken. It makes no difference whether a refrigerator car is owned by a railroad company or a private car line, it is settled for on the same basis.

H. L. Osmond. The fact is you settle for the use of the car on a different basis.

E. Chamberlain: Will the gentlemen give us a concise idea on the cause of the increase in his bills? Why has there been an increase in the M. C. B. bills, and for what defects were these bills incurred?

H. L. Osmond: We do not claim that our equipment is in an ideal condition. I do not think anyone has equipment he thinks is in an ideal state.

E. Chamberlain: You do not claim the highest degree of efficiency; you say that 80 per cent. has been equipped with steel underframes.

H. L. Osmond: Yes, 80 per cent. has been equipped with steel underframes.

E. Chamberlain: Why, then, the enormous increase and accumulation of bills?

H. L. Osmond: The traffic is heavier.

J. J. Tatum (B. & O.): I have always had a great deal of confidence in the consideration which the Arbitration committee has given to matters of this sort. It has been said that the enormous accumulation of bills is due to the present M. C. B. rules, and it has also been said that 80 per cent. of certain equipment has been improved by applying steel underframes and side truck frames, and that the cost to maintain the equipment has come almost within five per cent. on the investment. May I ask if the cost of maintaining this equipment has actually resulted in but a five per cent return on the investment? It may be that the application of these steel underframes and side truck frames and other betterments applied to the cars has added to the cost and reduced the earnings on the investment; but later on, the advantages to be obtained from these betterments will reduce the expense of maintenance.

I am inclined to believe that the right course to take is to refer the matter to a committee. We should find what is the real cost of maintaining private line cars under the M. C. B. rules in effect, in accordance with the billing for repairs and with these renewals, and we should find what these betterments are costing, we can then tell what the earnings are on the money invested.

H. L. Osmond. I want to make it clear to you, gentlemen, and especially to Mr. Chamberlain, that we have not increased 80 per cent in our total expenses the first five months of this year as compared with the same period of last year, but it is an increase in the railroad bills against us.

I will answer the last speaker by saying that we do not charge to car repairs, the cost of steel truck sides or steel underframes. That is charged to equipment account.

M. F. Covert: Five years ago, the cost of maintaining our cars, not including any betterments, steel underframes or steel truck sides, was around $75, and now it is $115 per car.

H. L. Osmond: Mr. Stark suggested a committee to investigate this private line question. I do not believe you gentlemen realize what we are up against, but we are trying to make it plain to you. We said to the Arbitration committee, when we gave them figures, that we would be glad to have them go over our books. We are entitled to consideration, and I, for one, will be glad to see a committee appointed.

W. T. Demarest: The rules as proposed by the Arbitration committee this year are more in favor of the private car owners than the rules they are working under. Whatever changes have been made, have been made in their favor.

W. T. Demarest: When you gentlemen appeared before us in Chicago, you made one strong point about brake material which was missing from trucks. That point was particularly emphasized, and we have covered that in rule 95, by restoring it to what it was before November 1 last.

M. F. Covert: There is a point I do not understand, as to what is to be done with cars delivered with this material missing. How will you get it? The rules, I think, prevent those deliveries.

W. T. Demarest: We are talking about the proposed changes and not the present rule.

M. F. Covert: There are a lot of railroads delivering to us in Chicago, and the cars have to go eight or ten miles. If they tear off a couple of brake beams in our yards, then that material is missing. Are we to send the car back? They have no inspectors.

J. J. Hennessey: This expression of "tearing off material" is worth while making an answer to. Tearing off a brake beam is unfair usage, and a railroad is responsible for anything in the way of unfair usage, and if the private lines do not protect themselves, they are responsible.

C. R. Ord (C. P.): It is not clear just what the private car lines are suggesting in reference to the particular rule of interchange under discussion. It will appear that the discussion on the matter is unnecessary if they take the necessary steps to protect themselves. It would be my understanding that they have the right to refuse to accept a car with that material missing, to comply with the interchange rules in the two cases referred to. If there is any necessity for further discussion I would like to know just what definite recommendation they have to make regarding the rule.

H. Boutet, (Cincinnati Rys.): A good deal of reference has been made to missing brake material. One of the speakers referred to three or four cars being cut off on his line since he was here. I kept a record of brake beams falling on one division and I find that two brake beams have fallen. Upon investigating these cases, I found that the rods were of malleable iron, and all the outer casting of the iron was eaten off; they failed to keep the car in proper condition, the draw-bars fell down, and we had to break up the car. If the private car owners would take better care of the cars, they would not have so much missing material, and we would not be called upon to make repairs as often as we are.

M. F. Covert: That brings us back to the point where the railroads have the benefit of making the inspection. If it is not safe to return the car, you can make repairs and charge the owner.

T. H. Goodnow (C. & N. W.): I would like to see any railroad or private car line in Chicago start in and refuse to receive cars because a brakebeam is missing. If the car is left at the repair point, the receiving road has the right to take it and put the brakebeam on, whether it is a private car line or not.

F. W. Brazier: I think we are satisfied with the explanation made, that there is no great hardship in adopting the recommendation of the Arbitration committee.

H. L. Osmond: I have not been convinced in any way, and to bring this matter to a focus, will move that the president appoint a committee to investigate this entire question, and that in the meantime, we continue on the present code of rules.

D. F. Crawford: If I understand this situation, this book of interchange rules assumes to legislate for cars and not for the earnings of cars. The gentlemen have very properly stated that their earnings are insufficient to meet their expenses, and therefore they need some increase in rating. The M. C. B. A. has no authority whatever over the situation, as representatives of the railway companies, to appoint any committee to look into the question of the difference between the earnings and the expenses of the private car companies. The American Railway Association is the only association that I know of that can take up that subject. As I see it, the question before us is, is this a proper code of rules, to interchange cars, to keep them moving in interchange and in safe condition to haul a load? Each company owning the cars bears its share of the burden in keeping them in a safe condition.

As to the appointment of this committee, or to any investigation, I am heartily in favor of any investigation that will bring

out the facts, but as I see it, a motion cannot be entertained by the chairman to give consideration to the difference between expenses and earnings of the private car lines.

Chairman Barnum: I think Mr. Crawford is absolutely right in his point of view, and in regard to the matter of missing material, the idea all the way through has been that that material will not be missing under fair usage from cars that are well built and properly maintained. That principle has been growing in the development of the interchange rules during the last few years, and many of the members of the M. C. B. Association with whom I have talked, feel that they should be carried even further than they have been up to this time; but in the application of the principle, it has been modified to some extent in this report in order to make such concessions as seem possible and consistent to the private lines where there was a question as to whether they would suffer more than the railroads would in extending that principle.

D. R MacBain (L. S. & M. S.): While the gentlemen from the privately owned car lines are speaking of their increasing expenses, I wish to mention the increasing expense of betterments and the providing of facilities for the movement of cars that the railroad companies are standing up under. I think the provisions and suggestions made by the Arbitration committee are absolutely just, and would move that the recommendation of the Arbitration committee as regards rule four be approved.

M. F. Covert: So far as this association is concerned, it might disregard the financial side of the thing, but I would like to appeal to the members to consider what it means. Is it right or wrong to take my car and lose material off it and bring the car back to me without giving me a cent for the lost material? That is the proposition, so long as the financial end is not to be considered by this association.

Chairman Barnum: I do not feel authorized to answer the question, but from what I have gathered from the discussion, it is not the intention or proposition to do that.

Mr. MacBain's motion to adopt a report of the committee on Arbitration with reference to rule four was put to a vote and adopted.

Secretary Taylor: The next suggestion is: Rule 4; do not omit reference to rules 33 and 55; rules 33 and 35 do not eliminate these rules.

Chairman Barnum: Unless there is some objection, I make the ruling that this matter is involved in the motion of rule 4.

Secretary Taylor: They also ask rule 64 to be reinstated as in effect previous to November 1, 1912.

Chairman Barnum: I think this calls for separate action.

J. L. Hodson (Grand Trunk): Does not action on rule 4 cover that? It says "Any missing material." It does not specify what material.

Chairman Barnum: There was a question in my mind as to whether it did or not.

J. L. Hodgson: I move that the action on rule four be taken as covering the recommendation for rule 64.

The motion was seconded and carried.

Secretary Taylor: The private car lines state as follows Rule 36: referring to application of brine retaining tanks. Time allowance entirely too short; the perfecting and application of a device satisfactory for the safe handling of lading can not be accomplished in the allotted time.

Chairman Barnum: Will the Arbitration committee explain their action in regard to that?

J. J. Hennessey: We have made our recommendation.

Chairman Barnum: You have the recommendation of the Arbitration committee, and the request of the representatives of the private lines. What do you wish to do about this rule?

H. L. Osmond: In explanation of our request, you gentlemen know what kind of stuff we ship; it is perishable freight. We have got to protect that freight. We give you a carload and you do not touch it. You simply hook an engine to the carload, and away you go with it. It is up to us not only to load the car at our own expense, but ice it, and see that our refrigerating plant in the car is in proper shape to take care of the load. I want to assure you that we have been working hard on that question and we have not tried to dodge this issue at all. We were willing to go ahead and equip these cars with brine retaining tanks, but we cannot do it in the time you have given us.

Chairman Barnum: How long have the packing companies been working on this proposition already?

H. L. Osmond: Morris & Co. have worked on it for over two years. We had to get some kind of a device that is fool-proof and could not be tinkered with from the outside, and our brine allowed to escape. We have been applying this device to every car that we have put through our shops, and that means, that we have to throw away half the ice tanks that are in these cars, because when you couple up two tanks with this valve, unless your tanks are in good condition, they will not stand the connection. If we put the new ice tanks in our cars, it means an expense of $64, and these rods and valves that we are putting in cost $18 a car; that is an expense of over $80 on every car. We have got to pay for that out of our earnings and the camel's back is pretty nearly ready to break.

Chairman Barnum: About what per cent. of your company's cars have been equipped with this arrangement?

H. L. Osmond: On our beef cars we have equipped less than 10 per cent. We first had to find the device. You must get something that will not freeze up, to start with you have to test a device for a year before you know that it will serve your purpose.

M. F. Covert: We have 788 cars fixed up to date.

Chairman Barnum: What per cent. is that of the total?

M. F. Covert: About 3 per cent. of the beef cars and about 8 per cent. of the total number of cars. It is only recently that we have been able to get anything that was satisfactory. There are several different design of valves but they would leak, and that is a thing we must guard against. We are equipping the cars with the valves just as fast as we change the tanks.

Chairman Barnum: How long do you think it will take to complete that work?

M. F. Covert: At least three years. That valve cannot be applied to any tank; it also takes a different design of hatchway.

G. F. Laughlin: As to brine tanks, you can appreciate our position when I say we are now testing our fifth device. We experimented with different devices, some outside, and some inside the tanks. We found the valves inside the tanks were prone to close up with accumulations of salt, etc. The tamping of the ice destroyed the mechanism of the valves, and the valves located on the outside are subject to freezing from condensation.

We have in our storeroom 1,600 valves which were purchased for application to our cars, and after some 250 were applied, we found they only ran about 3 per cent. perfect. It is of no use to put in a valve that will not do the work. It is a source of expense to the company that puts it in, and it does not help the railroad company. The valve which is put in must be one which operates readily from the top, and can be understood by any class of labor, positive in its closing, and equally positive in its opening to allow all of the water to flow out. During the winter months the cars return with from 2,000 to 3,000 lbs. of ice in them which it will be necessary to handle in order to apply these valves. You can imagine what that means with a daily receipt of from 150 to 250 cars. We want to put these valves on, but we want to put them on in the right way, and the time allotted is not sufficient.

Chairman Barnum: Our Arbitration committee have extended the time from September 1 to October 1 next year.

G. F. Laughlin: We are thankful for that, but any extension in the winter months does not help us.

I. S. Downing: I believe the Association has recommended practice for taking care of brine. If our recommended practice is not any good it should be thrown out.

Chairman Barnum: The recommendation simply gave general rules, and did not attempt to present anything in the way of a specific device. The private car line representatives are correct in their statement that they have had to work out the details, and I believe that they are also fair in the statements of the difficulties they have met in finding something entirely satisfactory.

E. W. Pratt: We all appreciate the assistance which the private refrigerator car owners gave the committee on refrigerator cars. Without their aid, we would have been a long time in getting results. To further show that appreciation, I make a motion that the date be extended to September 1, 1915, and if the other rule carries, that will be until October 1, 1915.

H. L. Osmond: I want to emphasize Mr. Laughlin's statement, that we can only do this work in the summer. This summer is half gone, practically, and if you extend that time only until September 1, 1915, we have a portion of this year and the summers of 1914 and 1915 in which to do the work. I do not believe we can accomplish it in that time. I am fair in this, and I think the gentlemen should be fair to us, and I offer an amendment that the date be made September 1, 1916.

G. F. Laughlin: That does not mean we will wait until September 1, 1916, before we start on this work, but we do not want to harness ourselves up to a proposition that we cannot pull. The general managers association has expressed a feeling that little or no progress has been made toward controlling the salt water drippings. They are not fully advised, possibly, of the difficulties which we were encountering or they would not have drawn that conclusion. It was at their request that this matter was taken up and the date set for September 1, 1914.

Chairman Barnum: The Arbitration committee felt that could it be, if necessary, deferred next year, before the time arrives,

the same as has been done in similar cases. The time has been advanced, and I think that Mr. Pratt's motion making the time September 1, 1915, should be carried, and the private car lines will not be hurt at all; in the meantime they can make such progress as is possible in the work.

H. L. Osmond: To show my good will, I will withdraw my motion with the understanding that we be given two years from now to show that we have made progress and that having made satisfactory progress, we may make application for a further extension of time.

Mr. Pratt's motion was stated and carried.

Secretary Taylor: The next is rule 94, changing the last sentence to read: "But no bill shall be rendered unless repairs are made, or car withdrawn from service." That is the report of the Arbitration committee.

M. F. Covert: It has been no light capacity car which was returned to us in bad condition, but we have had two cars returned recently with the bodies right down to the floor, and all that was returned to us was the steel underframe. Under this rule, we could get a defect card which the railroads could insist upon giving. If we tore the car down, it would mean that we would have to build it all the way up.

Chairman Barnum: Mr. Hennessey, what was the intention of the Arbitration committee in covering such cases.

J. J. Hennessey: In such a case, it seems to me that if the steel underirame of the car was returned in good condition and it was covered by a defect card, that there was no reason why it should be destroyed, but it should be repaired under the defect card. On the other hand, if the car was beyond repair, then it should be settled for under the rules.

G. F. Laughlin: Under the proposed change, 119 takes the place of that rule. There is no provision for the apportionment under that condition. Does the Committee understand that we must rebuild that car under the same number? In building a car, it is necessary to handle it under "equipment," to put it under a new number.

J. J. Hennessey: I think the private lines would have a first right to build that car and use any number they wish to. If two private lines consolidated, the Master Car Builders could not consistently say that your cars must all maintain the old number; but if I had a car practically worn out and you accepted it home, under a defect card, then you could not. It also provides for joint inspection in those cases.

I. S Downing: If the private car people wanted to put in a better underframe and a better upper structure, I do not see anything to prevent them putting in a whole new truck or an underframe and billing for the upper structure, as far as the card called for.

G F. Laughlin: With the new style underframe and new style truck and new number on the truck, we are not returning the same car; then there is an objection to our bill remaining on the defect card. Our light capacity cars could not be operated.

J. L Hodgson (G. T.): Is it not the general understanding that where a defect card is given and the owner elects to make some changes, he is entitled to bill for the part that the defect card calls for if he reconstructs a car?

J. J. Hennessey: Yes.

F. W. Brazier, (N. Y. C. & H. R. R.): The difference between the value of the car we destroyed and one you wanted to put in, you and I could settle that between ourselves. I would like to ask if you have had any trouble so far with any railroad in such matters?

M F Covert: No, sir, we have not.

G. F. Laughlin: The defect card calls for just the items that were destroyed. The point we wanted to bring out was that the railroad company was responsible for that amount of repairs, and if we put that amount of repairs in, we were entitled to bill on the defect card construction; and you could bill on the cash value. We all of us, private car lines as well as railroads, have some light-capacity cars. There is a general sentiment to withdraw these. If we had a car come in with a broken end post or side post and so forth, and if we get that in the shop, we prepare a defect card for all damage and we decide that we shall dismantle that car. It is not a case of the car with a body destroyed. If we elect to tear that down instead of repairing it, we feel we are entitled to the bill on that defect card.

J. J. Tatum (B. & O.): As I understand our friend's question, if a car comes in damaged and he destroys that car, he can build the car by dismantling.

H T Bentley (C. & N. W.): Mr. Hennessey made the point clear. If the gentleman wants to tear the car down, he can have a joint inspection, an appraisement, and then bill according to the agreement and on the basis of the M. C. B. rule.

G. F. Laughlin: Can we?

Mr. Bentley: The proposed rules give that.

A. Sternberg (Wabash): No, rule 94. I understand that the gentleman gets a car from the Wabash, and the upper structure of the car is in such condition that they elect to tear it down. If that originally was a 30 ft. car and he makes it into a 34 or a 40 ft. car to bring it up to date, he has no right to claim on that defect card.

J. J. Hennessey: I stated very clearly that you should build as originally constructed—that would not permit the taking of a 30 ft. car and making a 40 ft. car out of it.

T. H. Goodnow: It is a fact that you cannot get a defect card on some cars, and it is up to the point practically where you would naturally condemn the car. The repairs are made, and that class of cars is perpetuated; while on the other hand if it was something you were responsible for, rather than put the $100 or $125 in that car, you would tear the car down and put it in a new car. It seems to me to be possible to reimburse the car owner to some extent for possibly twelve or fourteen months' service which he has lost out of that car; but at the same time it would be a saving to the road which did the damage to have some basis of settlement for the months of service the car owner is out.

E. Chamberlain: Does the gentleman expect this association to extend its paternal authority to the private car owners and to have this rule operated as by a corporation? If that is his logic, in what position would it place this organization? There has been some talk about rebates, and that might work in that category.

T. H. Goodnow: I have made several such settlements as that in the last year. Some roads will do it and some will not.

R. E. Smith (A. C. L.): As I understand the purpose of the defect card, it is to reimburse the car owner for damage. Now, what is the difference between a car coming home for damage done on another road and the same kind of car coming home without that damage, if in both cases the car owner elects to tear it down?

T. H. Goodnow: The car that comes home in that condition is probably a sixty thousand pounds capacity car, seventeen or eighteen years old, and it may have had an old roof replaced; it comes home and some company is kind enough to give you a defect car for all the sills, and you have a car after repairing that you can get eighteen months more service out of.

F. H. Stark: I would like to second the remarks of Mr. Goodnow. At the Pittsburgh Railway Club we discussed that feature and the consensus of opinion was that the car owner should not be reimbursed to the full amount of the damage estimated on the defect card, but that the car owner might be authorized to render a bill for fifty per cent. of the damage. In that case the car owner would no doubt dismantle the car, owing to its light capacity.

Chairman Barnum: Mr. Hennessey, if you, as Chairman of the Arbitration committee would explain the general principle which has been followed in cases of this sort it might clear up this matter.

J. J. Hennessey: It has been a ruling principle, ever since the rules were first inaugurated, that unless the repairs were made a bill should not be rendered. One of our old cars came home, just as one of the speakers said, in such a condition that we were practically going to destroy it. We simply repair it, because part of that damage is covered by a defect card. Are we not perpetuating a class of cars that is not very desirable. You will either repair the car and charge it to the man that damaged it, or destroy it and let it go.

J. J. Tatum (B. & O.): Suppose we start out with this proposition—we have a damaged car and we will settle in accordance with the M. C. B. rules to the extent of that damage. The car may be one of 40,000, 50,000 or 60,000 capacity. The record value of that car may be $200, and the cost to repair may be $300. Is it fair that you would expect any railroad company to give you $300, for a car which you say yourself is only worth $200?

C. F. Fuller (U. P.): I think the discussion illustrates that it is a good thing to keep the old 30,000, 40,000 and 50,000 lbs. capacity cars at home and if you do it, you will not have trouble of this kind. It costs money to tear a car down.

D. R MacBain: As I view this matter, the railroads have entered into a contract, one with the other, that they would restore any damage occurring, up to the complete destruction of the car, and that is not changed in the proposed change by the Arbitration committee.

As regards any betterment of the old standard we would have to consider that in an entirely different light, if we want to retire any class of cars we have. I think it is fair that the rule should stand as recommended.

R. L. Kleine (Penna.): I second that motion.

Chairman Barnum: The question is as to whether the rec-

on recommendation of the Arbitration committee in regard to rule 94 shall be modified or shall be approved.

The recommendation was adopted.

Secretary Taylor: The next suggestion is in reference to rule 98.

T. W. Demarest: Does not that come in with the report of the committee on Prices?

Secretary Taylor: We have the report of the committee on Prices to cover this afternoon.

T. W. Demarest: This is part of the Price committee's report.

Chairman Barnum: If there is no objection, we will discuss this rule 98 in its order at the present time, and let it apply on the other report. We are talking about the communication from the private car lines. It has been decided to close up this communication completely.

R. L. Kleine: The recommendation of the change in the rule by the Price committee seems advisable that is that we have an average graded price, instead of a second-hand price, and a scrap price for the wheels. It is difficult to determine just what a second-hand, and a scrap wheel is. That is between the man on the repair tracks and the man at the wheel mounting press, and for that reason, the average graded price for each wheel removed was suggested, and I would move you, that the recommendation of the Price committee be adopted.

G. F. Laughlin: In the event of that not being adopted, what would have been the allowance?

J. J. Tatum: The matter has been gone into very thoroughly, and we decided the scrap value of that wheel would have been reduced. In order to avoid that, that in the case of such wheels as were worth while using, that we place a value on the wheel as between the scrap value and the second-hand value.

Chairman Barnum: All in favor of approving the Price committee's recommendation say aye, contrary-minded, no. (The motion was carried).

Secretary Taylor: The next recommendation of the private car lines is Rule 117.

G. F. Laughlin: That is one point that has always affected us. I presume it has affected anyone who has rebuilt to the extent we have. We have torn out cars after spending $400 or $500 on them. If they were damaged or destroyed the next day, there was no consideration given to the extent of the repairs made. In other words, that $500 was lost as far as that company was concerned. On account of the lading the cars carry we cannot allow them to depreciate to the extent shown in the report. We have to rebuild them at frequent intervals and keep them in shape for carrying fresh meat products, and in view of the fact that this rebuilding is necessary we think the depreciation value of 60 should stand as it always has.

J. J. Tatum: The price committee has made recommendations in regard to this depreciation. We feel that the depreciation recommended is a fair one, but the committee does not feel it has convinced the railroad and the private car owners that it is a fair depreciation, for the reason that we have not had an opportunity to study this recommendation carefully; and we feel that full consideration should be given to that portion of the recommendation of the committee in regard to the depreciation.

J. J. Hennessey: I am inclined to feel that as far as refrigerator cars are concerned that the depreciation is too much; and as it has come before this association it says, "Private line cars." Now, refrigerator cars are not the only cars—there are stock cars, coal cars and other cars that are not carrying perishable goods; and it could be arranged with the price committee to keep the depreciation at the old figure on refrigerator cars.

Mr. F. H. Clark (B. & O.): It might be important to consider the recommendations of the Price Committee on the subject of depreciation. We arrived at certain conclusions which are embodied in the report. Our recommendation would be, as far as wooden refrigerator car bodies are concerned, to fix the depreciation at 7 per cent. unless steel sills were built, in which case it would be made 6 per cent. for depreciation. But on the other hand some of our friends say the steel sills are not being built on some of the cars. But I would suggest that a vote be taken upon the recommendation of the Price Committee as to the case of wooden car bodies without steel centre sills; and wooden car bodies with steel centre sills, and depreciation of trucks, we recommend 7 per cent. depreciation. For all metal trucks, a 6 per cent. depreciation.

President Fuller: The past two questions are really Price-Committee questions, and as this last question of depreciation is one which has been covered by the Price Committee, I think it might be well to defer action on that until the other questions are taken up, and then take them all up together.

C. E. Fuller: I move that the report of the arbitration committee be accepted with the exception of the Weighing Rule which is changed. (The motion was carried.)

PRICES FOR LABOR AND MATERIAL.

The committee decided it proper to submit two propositions to be voted upon for Rule No. 98:

First: It is proposed that wheels be settled for, when removed for renewal, on a flat credit rate, in place of having secondhand and scrap prices as heretofore. Flat rate proposed is:

One 36-in. cast-iron wheel.....$5.25
One 33-in. cast-iron wheel..... 4.75

Voting against this proposition will indicate that the present rule will remain without change, except regarding change in price for rolled-steel wheels being reduced from $21 new to $19.50.

Second: It is proposed that cast-steel wheels be settled for when removed for renewal on a flat credit basis, as follows:

One 33-in. cast-steel wheel.....$4.75

A vote against the proposition means that there will be no rate for secondhand or scrap cast-steel wheels.

The committee also recommends that Rule No. 116 be changed as regards to settlement price for all steel freight-car bodies in place of settling as heretofore on a price per car body, that the car body be settled for on a pound basis, using the builder's weight of the car when built new. The price recommended is $0.0325 per pound, and the value of car so placed be subject to yearly depreciation as per Rule No. 117.

Rule 98.—Bills rendered for wheels and axles shall

F. H. CLARK,

Chairman, Committee on Prices for Labor and Material.

be in accordance with the following schedule of prices for material, with the proper debits and credits:

One 36 in. cast-iron wheel....	$10.50	$ 7.75	$5.25	$10.50		$5.25
One 33 in. cast-iron wheel....	9.00	7.00	4.75	9.00		4.75
One 33 in. cast steel wheel.....				19.50		4.75
One 33 in. forged or rolled steel wheel	21.00	.....	4 50	19.50	.....	$4.50
One axle 140,000 lbs. (New... Item)				25.50	$15.25	9.00
One axle 100,000 lbs.....	20.00	12.00	7.50	19.50	11.75	6.75
One axle 80,000 lbs.....	16.00	10.00	6.50	16.50	10.00	5.75
One axle 60,000 lbs.....	14.00	7.75	5 25	13.00	7.75	4.50
One axle 50,000 lbs. (or under)	10.00	5.00	3.00	10.00	5.00	3.50
And with an additional charge for all labor for each pair of wheels and axles removed from all types of trucks.....				2.25	.....	
Removing, turning and replacing a pair of forged or rolled steel or steel tired wheels for all types of trucks.....				3.25	.....	

Rule 101.—The committee suggests that item for labor in this rule be changed from 24 cents per hour to 28 cents per hour. If the recommendation of committee in regard to this change is not accepted, the report should be returned for revision, for the reason that all prices in Rule No. 107 have been arranged on the 28-cent hourly basis. On account of the increased labor rate providing for overhead charges and use of facilities, the committee would recommend the elimination of the ten per cent. additional charge to net total of bills authorized last year.

The following changes are recommended by the committee: Under repairs of steel or steel parts or composite cars;

change "All rivets ½-in. diameter or over, 12 cents net per rivet, which covers, etc.," to read "All rivets ½-in. diameter or over, 14 cents net per rivet, which covers, etc."

Change—"All ¼-in. rivets and less than ½-in. diameter, 7 cents net per rivet, etc.," to read: "All rivets ¼-in. diameter and less than ½-in. diameter, 8 cents net per rivet, etc."

Change—"Straightening or repairing parts in place on damaged cars, also any part that requires straightening, repairing or renewing, not included on rivet basis, 24 cents per hour," to "Straightening or repairing parts in place on damaged cars, also any part that requires straightening, repairing or renewing, not included on rivet basis, 28 cents per hour."

NEW ITEMS.

REPAIRS TO STEEL TANKS OF TANK CARS.

Labor for repairing and testing, per hour	$0.40
Steaming, per tank	0 75
Water for testing, per 1,000 gallons	0.06

In making repairs to cars on a rivet basis the cost of removing and replacing fixtures not secured by rivet but necessarily removed in order to repair or renew adjacent defective parts, should be in addition to the rivet basis, rules covering wood car repairs to govern.

Rule 109.—The committee suggested that this rule be changed to read: "When it is necessary to apply any M. C. B. coupler complete, on account of a broken or missing knuckle or lock, the usual labor charge for replacing a coupler can be made.

"When one or more carrier iron bolts over 6 in. long are replaced and pocket coupler at same end of car is removed and replaced, the regular charge for applying carrier iron bolts should be reduced one-fourth hour for each bolt."

Rule 116.—The settlement prices of new eight-wheel cars shall be as follows, with an addition of $27.50 for each car equipped with 8-in. air-brake equipment and $35.00 for 10-in. air-brake equipment. The road destroying a car with air brakes may elect to return the air-brake apparatus, including such attachments as are usually furnished by the air-brake manufacturers, complete and in good condition. The following new items have been added:

Self-clearing hopper, 30 tons, but not less than 40 tons	$295.00
Self-Clearing hopper, 40 tons, but not less than 50 tons	315.00
Self-clearing hopper, 50 tons capacity and over	400.00

The lengths of the cars above mentioned refer to lengths over the end sills. In the case of double-deck stock cars, $25 may be added to the prices given above for stock cars.

The paragraph reading: "Where the capacity of any car other than gondola is 60,000 lbs. or over, 10 per cent. should be added to the above prices for the car bodies" should be eliminated.

Change paragraph reading: "When cars of 60,000 lbs. capacity or over, and so stenciled, have trucks with journals 4 in. or over, etc.," to read: "When cars of 60,000 lbs. capacity or over, and so stenciled, have trucks with journals 4¼-in. or over, etc."

Change the last two lines of the paragraph reading: "When cars are equipped with metal center sills, the following prices shall be added to the values of bodies for cost of such metal sills:

10 in. or less	$60
Over 10 in.	80"

To read:

10 in. or more	$80
Less than 10 in.	60

The committee also recommends that Rule 116 be changed in regard to the settlement price for all-steel freight car bodies, and in place of settling as heretofore on a price per car body, that the car body be settled for on a pound basis, using the builder's weight of the car when new. The price recommended is $0.0325 per lb., and the value of car so fixed subject to yearly depreciation, as per Rule No. 117.

To the prices for box or stock cars with metal underframe and steel framed composite superstructure, add $50 if built with sheathing boards on outside, or $100 if built with sheathing boards on inside only.

Trucks.	Present Prices.	Proposed Prices
80,000 lbs. capacity, but under 100,000 lbs., all metal, per pair, but under 140,000 lbs.	$400 00	$350.00
100,000 lbs capacity or over, but under 140,000 lbs, all metal per pair	425 00	375.00
140,000 lbs. capacity or over, all metal, per pair		600 00

Prices include brake beam complete, truck levers, dead lever guides and bottom connection rods. For trucks with steel or steel-tired wheels, an additional allowance of $112 per car shall be made All trucks in service of 60,000 lbs. capacity or over, which consist entirely of metal with the exception of the spring plank, shall be known hereafter as all-metal trucks.

The following changes in depreciation rates were proposed:

In the case of wooden car bodies the depreciation due to age shall be figured at 7 per cent. per annum upon the yearly depreciated value.

In the case of wooden car bodies with steel center sills the depreciation due to age shall be figured at 6 per cent. per annum upon the yearly depreciated value.

In case of all steel car bodies the depreciation shall be figured at 5 per cent. per annum upon the yearly depreciated value.

The depreciation on the tanks or tank cars for handling non-corrosive substances shall be 4 per cent. per annum. For tanks of tank cars handling corrosive substances, the depreciation shall be 5 per cent. per annum upon the yearly depreciated value.

The depreciation of trucks other than all metal shall be figured at 7 per cent. per annum upon the yearly depreciated value.

The depreciation on all metal trucks shall be figured at 5 per cent. per annum upon the yearly depreciated value.

The allowance for depreciation on wooden car bodies shall in no case exceed 80 per cent. of the value when new. The allowance for depreciation on steel underframe or all steel car bodies shall in no case exceed 60 per cent. of the value when new. The allowance for depreciation on trucks other than all metal shall in no case exceed 70 per cent. of the value when new. The allowance for depreciation on all metal trucks shall in no case exceed 60 per cent. of the value when new. The allowance for depreciation of wooden car bodies with steel center sills shall in no case exceed 70 per cent. of the value when new.

PASSENGER EQUIPMENT.

Rule 7.—Change to read: "No labor charge shall be made for applying brake shoes, incandescent bulbs, gas domes, gas globes, gas bulbs, gas bowls, gas pillars, journal bearings, hose (air, steam or signal), mantles, tips, filling lamps, charging batteries, gasing tanks, icing or coaling cars."

The report is signed by:—F. H. Clark (B. & O.), chairman; G. E. Carson (N. Y. C. & H. R.); Ira Everett (L. V.); J. F. Dunn (O. S. L.); S. T. Park; H. E. Passmore (T. & O. C.), and C. F. Thiele (P. C. C. & St. L.).

F. H. Clark read the following after presenting the report: I would like to include in the report of the Committee a communication from the General Secretary of the American Railway Association as follows:

"At the session of the American Railway Ass'n held on May 21, the following resolution was adopted:

'Resolved, that in view of the increase in the per diem rate and the cost of cleaning and switching freight cars, this Association recommends to the Master Car Builders' Association that the charge for re-weighing and re-marking foreign freight cars should not be less than $1 for other than stock cars and not less than $1.25 for stock cars.'"

That we want to include as a change in Rule 107. The present corresponding prices being 75c to $1, we propose to increase them to $1 and $1.25.

DISCUSSION.

A motion was adopted to accept the report with the exception of the recommendations as to depreciation which is to remain the same as last year; and to incorporate it in the rules of interchange.

FREIGHT CAR REPAIR BILLS.

The committee appointed to confer with the subcommittee of the Association of American Railway Accounting Officers regarding freight car repair bills, recommends that the following rules of that association be observed when rendering or correcting bills:

A. Bills should not be rendered for amounts less than 25 cents in aggregate, but charges for items less than 25 cents may be held until they amount to that sum, provided the aggregate is rendered within 60 days.

B. No bills should be returned for correction on account of incorrect car numbers, but shall be passed for payment at once and the alleged errors in car numbers brought to the attention of the company rendering same within 60 days from date of receipt of bill.

The billing company shall furnish correct car reference, or shall issue within 30 days counter charge authority, as per Form 1 attached.

C. No bills shall be returned for correction on account of other error or questionable charges unless the net amount involved exceeds 10 per cent. of the total amount of the bill, but shall be passed for payment at once and the alleged error brought to the attention of the billing company within 60 days from the date of receipt of the bill. The billing road must

furnish proper explanation or shall issue, within 30 days, counter charge authority on Form 1.

D. Undercharges shall be similarly adjusted on regular authority of the company against which the bill has been rendered.

E. When bills are returned for correction, all defect cards and billing repair cards, except those in question, must be retained by the company against which the bill has been rendered.

FORM 1.

M. C. B. ASSOCIATION—COUNTERBILLING AUTHORITY.

(NAME OF RAILROAD)

Place.....191..

This will Authorize the.....Railroad Company to counterbill the.....Railroad Company, ... Dollars to offset overcharge in our bill No.....Amount, $..... $..... .....

This authority must be attached to bill. Signature of person issuing.

This report is signed by:—D. F. Crawford (Penna. Lines), chairman; C. E. Fuller (U. P.), and M. K. Barnum.

This report was adopted.

ABUSE OF THE REPAIR CARD.

A committee, representing the Association of American Railway Accounting Officers and Master Car Builders' Association, met at the LaSalle Hotel, Chicago, April 8, 1913, to consider the subject, particularly as to alleged irregularities practiced by some railroads in rendering bills for repairs to cars. A letter from F. A. Delano, receiver of the Wabash, was read carefully, and his suggestions were given due consideration. It was the unanimous opinion of the joint committee that the handling company should not be expected to assume the expense in connection with the application of M. C. B. knuckles, air hose, brasses, etc., as the committee felt that this plan would not furnish the desired relief, but on the other hand would place a burden on those railroads which aim to keep their cars in first-class condition for service by imposing additional expense of partially maintaining the cars of other railroads who do not maintain their own cars in a serviceable condition.

It is believed that in some instances the price for labor and material established by the Master Car Builders' Association are less than cost, if supervision, the use of facilities and tools and other shop expenses are taken into consideration. This has a tendency to cause some car owners to encourage the making of repairs to cars by the handling company. Therefore it is suggested that the Master Car Builders' Association make such changes in the allowances for labor and material as will more nearly represent the actual cost of repairs. To enable the car owners to make a check of the car repair bills on the basis of car days, it is recommended that Rule 93 be changed to read as follows:

"Separate bills must be rendered for cars destroyed."

All charges for repairs made to cars account of owners' defects, defect cards and rebuttal authorities must be consolidated against any one company into one bill.

Separate statements to be made: First, For owners' defects for each calendar month; second, For all charges based on defect cards, including rebuttal charges.

NOTE.—Totals only of these statements to be shown on the recapitulation.

If the above rule, as amended, is complied with, it will, it is believed, enable a car owner to readily ascertain from time to time the exact amount charged his company for car repairs per car day on any line in any given period. The joint committee is of the opinion that no practical method can be devised to check car repair bills, by which dishonest practices can be positively detected, and, further, is unwilling to believe that dishonest methods are being employed, excepting in isolated cases.

It is the opinion of the joint committee that the interchange rules of the Master Car Builders' Association as now formulated, if honestly followed, are perfectly fair and equitable to all car owners, and it is further believed that the enforcing of honest methods in connection with repairing of cars and making repair bills is something which is to a very large extent under the control of the ranking officials of each company. The recommendation of the joint committee therefore is that the officer in charge of the mechanical department of each railroad and company look into the practice of making repairs to foreign cars and rendering bills for such cars repaired on his own line, with a view of seeing that the work is honestly performed, and also that the bills are rendered only for defects for which the car owner is responsible.

The committee approves the foregoing report and recommendations of the joint committee, and recommends that rule 93 be changed in accordance therewith at this convention, and recommends further that the attention of all members be again called to the resolution passed in 1909, with the request that where any evidence of improper use of the repair card is available that it be submitted to the executive committee for appropriate action.

The report is signed by:—D. F. Crawford, (Penna. Lines), chairman, C. E. Fuller, (U. P.), and M. K. Barnum.

Discussion was deferred to a later session.

Conventionalities.

John F. Snyder, chief clerk to the vice-president of the Norfolk & Western, came in on Sunday morning.

A. B. Lacy, purchasing agent of the Virginian railway, accompanied by Mrs. Lacy, who is visiting the conventions for the first time, are stopping at Haddon Hall.

William G. Phelps, assistant purchasing agent of the Pennsylvania Lines west of Pittsburgh, is making his first visit to the conventions.

N. D. Maher, vice-president in charge of operation on the Norfolk & Western, arrived Friday evening, and spent Saturday and Sunday in Atlantic City.

Mrs. Walter E. Coffin came from Cleveland to join Mr. Coffin in Atlantic City Sunday night. She will spend several weeks in visiting relatives in Pennsylvania before returning home.

Grant W. Spear, vice-president of the Dearborn Chemical Company, accompanied by Mrs. Spear and their daughter, Miss Emily Spear, will sail July 1 for a visit of three months in Europe.

Thomas J. Burns, master car builder of the Michigan Central, arrived yesterday afternoon and is stopping at the Traymore. This is his first trip to Atlantic City. He is accompanied by Mrs. Burns.

H. B. Henry, Assistant to Director of Purchases, Southern Pacific.

H. C. Van Buskirk, formerly superintendent motive power of the Colorado & Southern, is missed by his friends this year. He is now basking in the sunshine at Oceanside, Cal., and is reported to have fully recovered his health.

Arthur Hale, general agent of the American Railway Association, and chairman of the committee on Relations between Railroads, was a visitor yesterday and was especially interested in the report on Car Interchange Rules. He was at the Dennis.

John McKinnon, president of the Kalamazoo Railway Supply Company, and an honorary director and ex-president of the National Railway Appliances Association, has been an interested visitor to the conventions this week. He is stopping at the Wiltshire.

T. F. Barton, master mechanic of the Lackawanna at Kingsland, N. J., who is attending the convention, has in his charge some of the new fast freight Pacific type locomotives which are being used in manifest service on that road. Another interesting feature on his division is the use of brick arches in the hard coal burning Pacific type locomotives.

Rodney Evans, who retired several years ago as purchasing agent of the Pittsburgh & Lake Erie, has been quite ill during the past year and came to Atlantic City several weeks ago to benefit from the change in air. He is stopping at the Chalfonte.

B. B. Milner, assistant master mechanic of the P., B. & W. at Wilmington, Del., says that the division with which he is connected had a lively time during the week of the inauguration. In spite of the heavy pressure under which it was working everything went off in fine shape.

J. S. Stringham, Capt. Charles Gifford and Neil MacDonald, of the Monarch Steel Castings Company, are quartered at the Marlborough-Blenheim. The ferocious looking lion in their exhibit is not a real, live lion, though it looks the part and though it has frightened small children.

S. K. Dickerson, superintendent of motive power of the Big Four, had some interesting experiences in the recent flood. Several of the engine houses were badly flooded but in all cases, except for a few unimportant locomotives, the power was placed so that the flood could not injure it.

J. T. Carroll, assistant general superintendent of motive power of the Baltimore & Ohio, and Mrs. Carroll, are at the Marlborough-Blenheim. They are accompanied this year by little golden-haired Virginia Carroll and Master Carroll. The little ones are great favorites among the guests at the hotel.

L. A. Richardson, Mechanical Superintendent, Rock Island Lines.

E. Beyer, brother of O. S. Beyer, Jr., of the Rock Island Lines, spent two or three days looking over the exhibits and seeing Atlantic City. He is in steamship service and had some interesting stories to tell of conditions in the ports of Mexico at which his steamer stopped and of the refugees that they brought away with them.

F. H. Stark, superintendent of the Montour Railroad, will soon be an officer of a real railroad. The Montour is now being extended so as to connect with all the railroads entering Pittsburgh, and when it does it will be the only railroad which can boast of this accomplishment. Over 1000 men are now employed on the construction work. The railroad will be operated entirely independently of the Pittsburgh Coal Company, of which it has always been a part.

In discussing the untimely end of Andrew S. Crozier, of the American Steel Foundries, Bert Waycott and Harry Frost, two old timers, remarked that insofar as they could recall, the death of Mr. Crozier was the first, at least in more than 20 years, to have occurred at one of these meetings. In a way this is remarkable. There are several thousands of us; and what with the

chances for accident on one hand, and the danger of unusual and unseasonable viands on the other, an occasional death would not have been contrary to the law of average.

W. J. Press, mechanical engineer, National Transcontinental of Canada, is a visitor at the conventions. The National Transcontinental is the portion of the Grand Trunk Pacific between Winnipeg and the Atlantic Coast, which is being constructed by the Canadian government, and Mr. Press has charge of the shop, engine house and other mechanical matters over the entire distance. A part of the Winnipeg end of the line has been in operation by the company for some time and it is expected that additional sections will be turned over for operation during the year.

Among the convention visitors who arrived on Sunday is Samuel T. Fulton, vice-president of the Railway Steel Spring Company, a man who has left the railway service and risen rapidly in the supply business. Mr. Fulton was for several years assistant to President B. L. Winchell, of the Rock Island. At the time of the separation of the Rock Island and Frisco he became connected with the Railway Steel Spring Company as western manager, and on March 1, 1912, was made general sales agent at New York, from which position he has just been promoted to vice-president. He is staying at the Strand.

Robert P. Lamont, president of the American Steel Foundries, attended the conventions most of last week. He attended the M. M. meetings and made a careful examination of the exhibits. In leaving for New York Mr. Lamont expressed the opinion that in points of interest and educational benefit the convention and exhibits surpassed the record over all previous years. George E. Scott, vice-president of the American Steel Foundries, motored to Atlantic City from Chicago. Rumor says all existing automobile records between Chicago and Atlantic City received a shattering when Mr. Scott stopped his machine in front of the Marlborough-Blenheim.

Mr. and Mrs. W. A. Blanchard are, as usual, at the conventions and are stopping at the Marlborough-Blenheim. Mr. Blanchard

Left to right—Mrs. C. H. Terrell, C. H. Terrell, Assistant Superintendent of Motive Power, Chesapeake & Ohio, and T. Kilcoin, Foreman Boilermaker, A. C. & I.

spoke enthusiastically about the exhibits and contrasted the present splendid display, occupying some 90,000 square feet, with the showing made by the supply men some twenty years ago when most of the manufacturers were accustomed to take their exhibits with them to the conventions. Mr. Blanchard, for the American Steel Castings Company, exhibited for the first time at Old Point Comfort a locomotive frame. It was the heaviest exhibit ever taken to the conventions, and Mr. Blanchard had considerable difficulty in installing it. The negro helpers were afraid the casting would fall on them and absolutely refused to touch it. It was then that some of the master car builders and master mechanics came to Mr. Blanchard's assistance, took off their coats and in a short time the exhibit was in its proper place.

Among the special guests of the M. M. and M. C. B. Associations attending the convention is Dwight C. Morgan, vice-president and general manager of the Pittsburg & Shawmut. As chief engineer of the Minnesota Railroad Commission Mr. Morgan a few years ago made the valuation of the Minnesota railways which was so conspicuously involved in the Minnesota rate case decided last week by the Supreme Court of the United

C. H. Kenzel, Purchasing Agent, Elgin, Joliet & Eastern.

States. Mr. Morgan's attitude in that case has commanded respect in all quarters as being eminently fair throughout as he declined to accept the theories either of the commission or of the railways alone but was guided entirely by his ideas of justice to both sides. Since completing the valuation work for that commission four years ago Mr. Morgan has been working 16 hours a day developing and rehabilitating the property of the Pittsburg & Shawmut and the Pittsburg, Shawmut & Northern, the underlying securities of which are owned by the P. & S. This has included the building of about 100 miles of extensions, now completed with the exception of 17 miles. The property serves a rapidly developing bituminous coal region and the roads will this year handle from 3½ to 4 million tons of coal. Mr. Morgan is accompanied by Mrs. Morgan.

Among the arrivals Sunday morning were Sam Lynn, master car builder, and Harry W. Ferree, general foreman of the car department of the Pittsburgh & Lake Erie. A considerable amount of equipment has been added to the steel car shop at McKees Rocks, Pa., during the year, including a new flange press, three punches and a shear. Just now the old 50,000 lb. capacity steel cars are being rebuilt at the rate of eight a month. This rebuilding includes the application of new floor and hopper sheets, and in some cases the reinforcement of the center sills. It is expected that the old side sheets will wear as long, if not longer, than the new floor sheets. During the summer the building for steel car work will be extended, practically doubling its capacity. When the shop was first put in operation several years ago only a small part of it was required for steel car repairs, but the increased number of these cars in use and the fact that the older cars are now needing heavy repairs have not only made it necessary to do the heavy repairs on the wooden equipment elsewhere, but have required the above mentioned increase in capacity. Heavy repairs to wooden equipment are now being made north of McKees Rocks, near the works of the Pressed Steel Car Company. A new shop is also being built at Struthers, Pa., to make repairs to wooden coal cars as they are received from other roads and before they are sent to the mines for loading.

VARIABLE LOAD BRAKE.

A brake of this type that permits of a variation in brake shoe pressure according to the load on the car to which it is applied has been developed by the Bettendorf Company, Bettendorf, Iowa. The advantages claimed for it as compared to the present brake arrangement are: Increased braking power when the car is loaded and a corresponding decrease when not loaded, thereby reducing the tendency to slide the wheels; increased braking power of one truck if that truck is loaded heavier than the other; ease of maintenance and renewal of its parts; automatic in action, and the less likelihood of pulling mixed trains in two on an emergency application of the air brakes.

The device is based on the idea of applying the brake

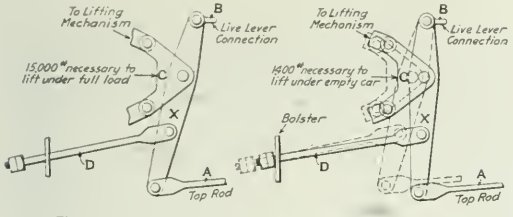

Fig. 1—Car Loaded. Fig. 2—Car Unloaded

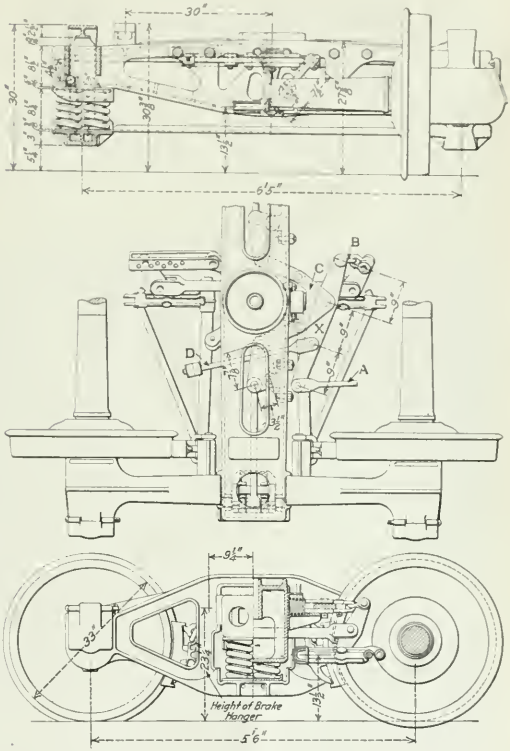
Arrangement of Levers for Light and Loaded Car.

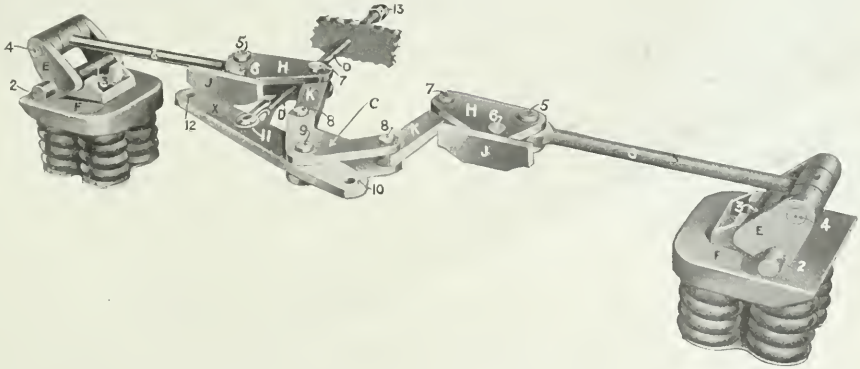
cylinder and lever proportions for the desired load weight brake power and utilizing a series of parts (which are capable of lifting the car body) as a fulcrum for one of the levers. This fulcrum will not move unless the brake cylinder force becomes equal to some predetermined percentage of the downward force due to the weight of the car body and the load thereon, but when the brake cylinder force does not exceed the predetermined amount the car body will be lifted and the before mentioned lever through the movement of its primary fulcrum assumes a new position in which a supplementary fulcrum comes into play.

The action of the parts is clearly shown in the accompanying illustrations. Lever X has four connections; A is is the brake cylinder rod, B is the live lever connection, C is the connection to that series of parts capable of lifting the car body, and D is a connection that anchors the lever X when C moves, causing the lever to fulcrum at the pin connection between D and X. When the car is loaded to its capacity the arrangement, shown in Fig. 1, will apply. Connection C will not move and will act as the fulcrum for lever X, and there will be a greater force applied at B, the live lever connection, than when the fulcrum is at the D connection. When the car is not loaded there will be sufficient force at C, when the brakes are applied, to lift the car—and C will move to the position shown in Fig. 2—allowing the



Bettendorf Variable Load Brake as Applied to Truck of 50-Ton Capacity Car.

nuts on the end of the rod D to bear against the back of the bolster causing the lever X to fulcrum at its pin connection, with the rod D.



Isometric View of Bettendorf Variable Load Brake.

Assuming that it takes a force of 1,400 lbs. at C to lift the empty car, we will have, with a 3,000 lb. pull on the rod A and the length of lever as shown on the general drawing,

a pull at C sufficient to lift the car and a resultant pull at B of $\frac{3{,}000 \times 9 - 1{,}400 \times 9}{18} = 2{,}200$ lbs.

With the loaded car it will take 15,000 lbs. at C to raise the car, which is not available under the above conditions. C will then act as the fulcrum giving a resultant pull at B of $\frac{3{,}000 \times 18}{9} = 6{,}000$ lbs.

By means of this scheme the load of the car body plays a part in determining the effective force at the brake shoes, and both the amount of brake cylinder force and weight of the car body and the load thereon is necessary for the determination of the brake shoe force.

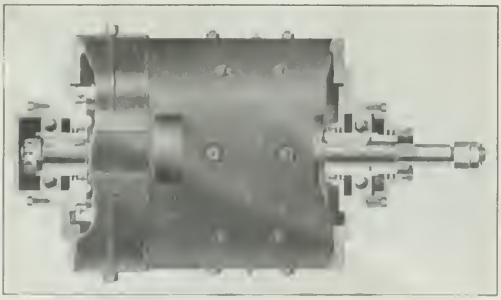
If 1,400 lbs. is the resistance offered by the empty car body when the car is lightly loaded the resistance will increase as the load increases. Hence the 1400# effective at C with an empty car will gradually increase as the load increases, and in so doing effects the resultant force at the top of the live lever so long as the brake cylinder force is sufficient to lift the car body and load thereon.

This lever combination with its many variations, makes it possible to secure almost any desired range of empty and load weight brake power for any constant air brake cylinder force, and especially so when a spring is interposed to partially balance the lifting force at C for the empty car body.

The system of levers, operating from C, for lifting the car is shown in the general drawing. This device is being exhibited at the Bettendorf booth (200) and although somewhat similar to that shown last year contains several improvements.

BALL BEARINGS ON AXLE LIGHTING GENERATORS.

The Safety Car Heating & Lighting Company, New York, has made measurements recently of the ball bearings of an axle lighting generator used constantly on a car that made a total of 137,933 miles up to March 7, 1913. These measurements show a radial wear, or wear at right angles to the axis of the shaft, of only .0005 in. on the pulley end bearings, and only .0008 in. on the commutator end bearings. The endwise or axial wear was .0005 in. on the pulley end and .0008 in.

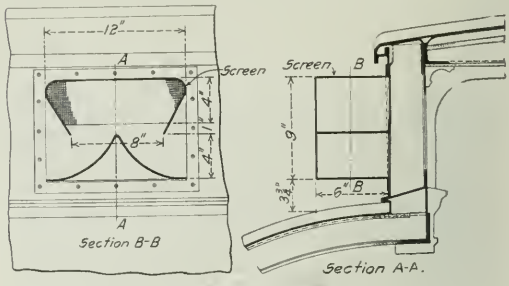


Axle Lighting Generator Equipped with Ball Bearings.

on the commutator end. The eccentricity of the pulley end bearings was .0002 in. and the commutator end bearings showed no eccentricity. Considering the severe service and exceptional conditions under which axle generators operate this is a remarkable showing and this company states that all their ball bearing generators are ivin equally satisfactory service. It is also claimed that the saving in the cost of lubrication and labor by the use of ball bearing generators soon absorbs the extra expense involved in their application.

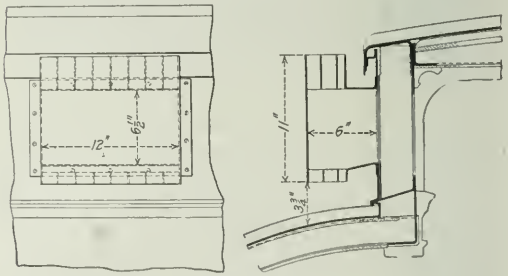
UTILITY VENTILATORS.

The Railway Utility Company, Chicago, is exhibiting a new type of intake ventilator which can be applied to either arched or clere-story car roofs, as shown in the illustrations. Whichever direction the car may be running the air



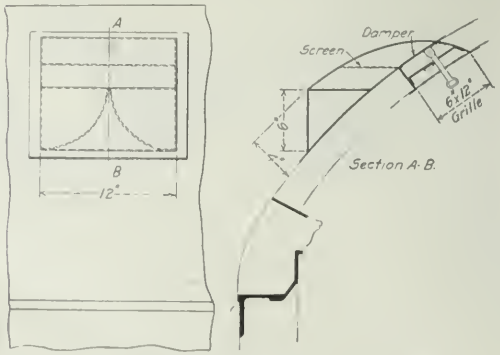
Utility Intake Ventilator Applied to a Postal Car with Clere-story Roof.

striking the chute is thrown upward and creates a pressure in the chamber in the upper part of the ventilator. It then passes into the car through a screen, but cinders, rain, snow, etc, are dropped and carried out at the other side,



Utility Exhaust Ventilator Applied to Clere-story Roof.

as there is no place for them to lodge; the air loses its velocity in the pressure chamber and the heavy particles are dropped in much the same way that sand is deposited by a river at certain points, or that snow is drifted. There is



Utility Intake Ventilator Applied to a Postal Car with Arched Roof.

a certain amount of leakage of air down the chute of the ventilator, and a suction caused by this also helps to remove the foreign substances. The incoming air is passed

into the car in such a manner that it does not cause drafts or currents. The usual deck sash may be used on the inside as a means for controlling the admission of air over, if desired, a pressed steel register is furnished. The exhaust ventilators are removed a considerable distance from the intake ventilators so that there will be no tendency to take the air directly from one ventilator to the other without passing it through the car. The improved Utility exhaust ventilator is shown in one of the illustrations.

TANDEM GASOLENE DRIVEN AIR COMPRESSOR

The Chicago Pneumatic Tool Company, Chicago, is furnishing compressed air for the exhibitors, as is the usual custom, but this year the equipment consists of a pair of its latest type of tandem gasolene driven compressors. The illustration shows the pair installed on the shore end of the Pier.

Air Compressor Plant for M. M. and M. C. B. EXHIBIT.

The gas cylinder is on the rear end and the air cylinder is just ahead of it, the gas piston being direct connected to the air piston. The gas and air cylinders are bolted together by outside tie rods which make possible a simple gasket arrangement between the two cylinder joints and reduces the leakage troubles.

The lubricating system is of the self-oiling type. The air intake valves are of the Corliss type, being mechanically operated and designed to give ample openings for the entering air. The compressor is provided with a combination speed and pressure regulator and the choking type of air control. With this arrangement the gas consumption is controlled by the pressure and speed, and the amount of air to be drawn in is regulated according to the presure.

The compressors installed here have a capacity of 150 cu. ft. of free air per minute. They are rated at 30. I. h. p. and have 11½ in. gas cylinders, 8 in. air cylinders and a 12 in. stroke. The machine occupies a floor space of 11 ft. x 3 ft. 8 in. and has an approximate weight of 5,000 lbs. These machines are adapted for small capacity plants and have given splendid results in construction work. They may be mounted on a truck and be used as a portable machine, as well as a stationary plant.

STEEL CAR SEATS.

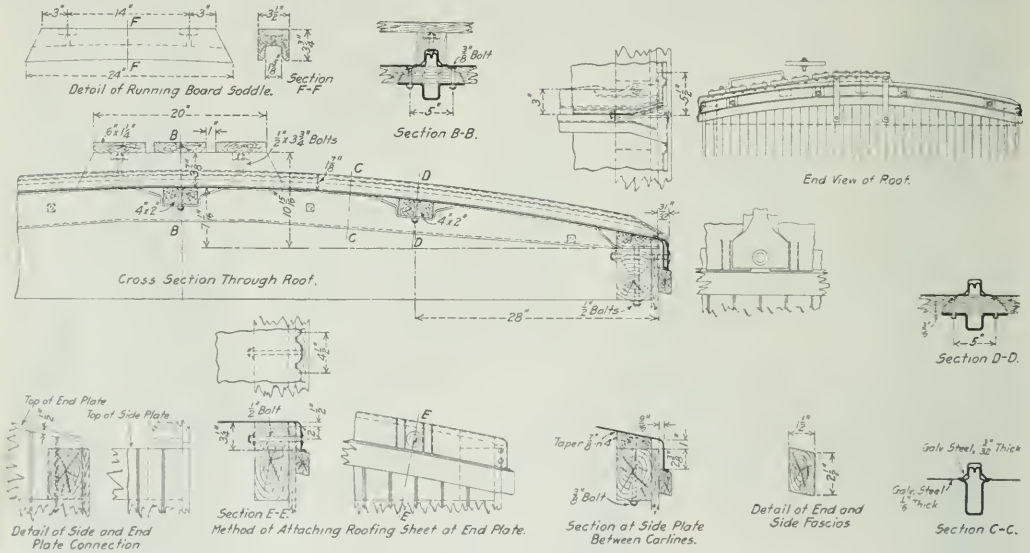
Among the exhibits of the Heywood Brothers & Wakefield Company, Wakefield, Mass., is a sample of the seat recently adopted by the New York, New Haven & Hartford for its latest steel passenger cars. This seat is made with pressed steel cushion, and back frame, and has pressed steel back corner sockets. The pedestal base and aisle end are also of pressed steel, the arm fitting the seat frame with an interlocking arrangement on which patents are pending. A similar arrangement gives a rigid fastening of the wall end of the seat frame to a pressed steel wall fixture which is permanently attached to the side of the car. The seat is attached to the monolith floor by means of a plate and binding ring on which patents are also pending. A distinctive feature of this seat is the wide arm cap which materially adds to the comfort of the passenger. The backs are upholstered plain without headroll and are sufficiently high to afford a rest for the head if desired.

NON-BINDING WRENCH.

The Barcalo Manufacturing Company, of Buffalo, N. Y., is exhibiting a pipe wrench possessing several new and interesting features. It is of simple construction, and contains but five parts, any one of which can be instantly replaced should occasion so require. It has no springs or rivets, and is so constructed as to absolutely prevent binding.

FLEXIBLE ARCHED METALLIC ROOF.

The Franklin Railway Supply Company, New York, has recently developed a new form of its flexible metallic car roof, known as the arched type. The carlines are made of 3/16 in. steel plate pressed to a U section and tapering in depth from the center of the car to the side plates. The carlines are attached to the side plate in such a manner as to give the minimum width of fascia and thus provide maximum clearance at the eaves. The roofing sheets are arched and continuous between the side plates; they are made of No. 16 gage galvanized steel and the edges adjacent to the carlines are turned up and then down. The upturned edges of the roof sheets are covered by galvanized steel carline caps, made from No. 13 gage steel and arched to the contour of the roof. Their ends are turned down over the ends of the carlines, at which point they are attached by horizontal bolts. It is claimed that with this construction any water which may get under the caps and work its way up and over the turned up edges of the roofing sheets will enter the carline and be carried to the side of the car by gravity, the carline extending beyond the side plates for this purpose. The down-turned portions of the roofing sheets extending over the side plates are spaced a distance from the plates in order to allow the sheets to move independently of the car frame; this movement occurs when the car is in service, due to the twisting action. The ridge pole and purlines are continuous from end to end and it is recommended by the manufacturers that these members be made of wood where wooden side plates are used, but that a steel ridge pole and purlines be used when steel side plates are applied.



Franklin Arched Type Flexible Metallic Roof.

ACETYLENE MANTLE LAMP.

An acetylene mantle lamp, which is just being introduced in this country, is being exhibited by the Commercial Acetylene Railway Light & Signal Company, of New York. It was invented by G. Dalen, of Stockholm, Sweden, who was also the inventor of the sun dial and flasher that was awarded the Noble prize last year. A mixer used in connection with the light, and which may be installed either under or on top of the car body, provides a mixture of air and acetylene in proper proportions according to a predetermined formula. A pilot flame which uses one-third of a cubic foot of gas in 24 hours is used for lighting the lamps. No electric spark is required, and all of the lights may be lighted at one time by means of a push button in the saloon.

The lamp gives off very little heat, and the mantle will not carbonize when the gas is turned off slowly. A 90 candle power light requires about ½ cubic foot of gas per hour.

AUTOMATIC TRAIN-LINE ACCELERATING AND BRAKE CYLINDER SUSTAINING VALVE.

This valve, which is being shown by John C. Knight, Inc., New York, serves to accelerate the reduction of pressure in the train line when the brakes are applied and to maintain a uniform pressure in the brake cylinder. The method of connecting it to the brake system and its operation is as follows:

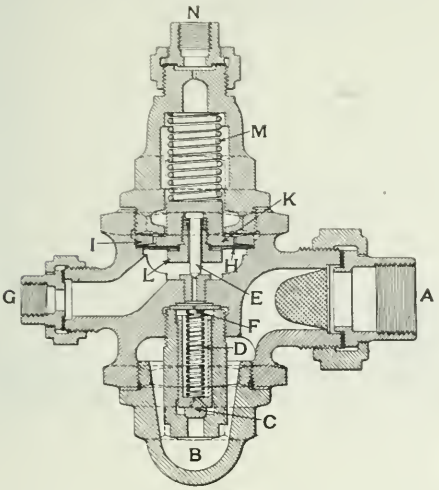
Connection is made with the train pipe at the point *A*. The air, under train-pipe pressure, then flows down to the bottom of the cap at *B* and presses upward against the valve *C* tending to unseat it. The spring *D* exerts a pressure upon the top of this valve equal to an air pressure of 40 lbs. per sq. in. so that the valve becomes a differential valve, closing when the difference between the pressure above and below the valve is less than 40 lbs. per sq. in. Hence, when there is 70 lbs. of air in the train pipe the valve *C* will be held open ntil the chamber occupied by the spring *D*, up to the needle valve *E* is filled with air at a pressure of 30 lbs.. The flow of the air to the needle valve is checked by a choke bore *F* placed above or below the spring *D*. The object of this will be explained later.

Again direct connection is made to the brake cylinder at *G*. When the brake cylinder is under atmospheric pressure only, there is no movement of any of the parts except as already stated. But, when the train pipe pressure has been reduced and the triple valve has admitted air to the brake cylinder, the air, under pressure from the latter, enters at the connection *G*, and presses up against the diaphragm *H*. This diaphragm is held in place by the ring *I* and is stiffened by the plate *K*, which is drawn down to it by the bolt *L*. This diaphragm has a lift of about 1/32 in. and, as it lifts, it must compress the spring *M* and, in doing so, it raises the needle valve *E* from its seat, thus per-

mitting the air to flow from the train line into the brake cylinder. This reduces the train line pressure and in consequence causes the triple valve to move and admit more air to the brake cylinder, until the differential of 40 lbs. between the train line and brake cylinder has been reached, when the valve *C* is again closed and the draft of air from the train pipe is stopped.

The valve acts, then, only to maintain the brake cylinder pressure until a ten pound reduction has been made in the train pipe, holding a pressure of from 20 to 23 lbs. in the brake cylinder, beyond which it is inoperative. Of course, it is understood that these figures in service are dependent upon the amount of differential at which the valve is set as well as the highest train line pressure that is used, and when once put in place it cannot be tampered with or changed.

The opening *N* at the top of the valve is connected to the exhaust pipe from the triple valve. If, then, the retaining valve is open, the action of the valve is as stated. But when the retaining valve is closed the pressure in the exhaust pipe below, it enters at *N*, passes down through the choke and supplements the pressure of the spring *M* to force the diaphragm *H* down and close the needle valve *E* so that there is no flow from the train



Sauvage Car Valve.

line to the brake cylinder. This continues so long as the triple valve is in the exhaust position. But, when another train line reduction is made, or the engineer's valve is put in lap position, the triple valve moves so as to close the exhaust and the accelerating valve is, at once, thrown into action.

Reverting for a moment to the choke bore *F*, the purpose of its restricting the flow of air to the needle valve is this: As it has a sectional area less than the feed valve port in the triple valve it will not allow enough air to pass to affect the recharging of the train when brakes are in use on grades. It also prevents a sudden flow of air to the brake cylinder and consequent erratic action: When the leakage is in excess of the capacity of the choke to supply, the needle valve automatically closes and so prevents an excessive drain on the train pipe, as would be the case if any part of the brake equipment were to be ruptured. In case of an emergency application, the valve *C* acts as a check valve to prevent the flow of air from the brake cylinder to the train pipe, which is then reduced to atmospheric pressure.

At any differential that this valve may be holding in the brake cylinder, whether it be high or low, the question may be raised as to whether, with a constant brake cylinder leakage, which this valve is automatically maintaining by means of air taken from the train line, it would not tend to set the brakes still harder until equalization took place. This would occur were it not for the locomotive "sustaining" valve, whose functions and operations are described elsewhere.

When the regular 15 lbs. retaining valves are used the connection of *N* to the exhaust pipe is necessary; but, when special retaining valves holding 25, 30 or 50 lbs. are used this connection is omitted and *N* is left open direct to the atmosphere.

Finally when all conditions are normal and a ten pound reduction is made there is no action of this valve; but if, on any car, there is an excessive piston travel so that the pressure does not come up at once, then the valve comes into play and builds the pressure up immediately to what it should be.

The value of this valve lies in its ability, when a train is descending a long grade, to hold the brake cylinder pressure in what amounts to a straight air condition of application, with a uniform pressure, making it possible for the engineer to leave his brake valve handle in running position, charging the auxiliary reservoirs, and, at the same time holding up any leaks that there may be in the brake cylinders or their connections, and preventing the speed of the train from becoming excessive, while recharging. This, in conjunction with the locomotive trainline sustaining valve allows the engine driver to raise or lower the brake cylinder pressure according to the conditions of the grade permitting him to know the cylinder pressure that he is maintaining at all times, either in application or release position when the retaining valves are in use.

EXPANSION BORING TOOL.

Among the tools which are being exhibited by the Davis Boring Tool Company, St. Louis, Mo., is an expansion car wheel boring tool that is intended for car building or other large shops that have great numbers of wheels to bore to standard gages or to fit axles. This tool has the cutters so placed that when the roughing cutters pass through, the finishing cutters enter immediately, so that the boring of the wheel is accomplished

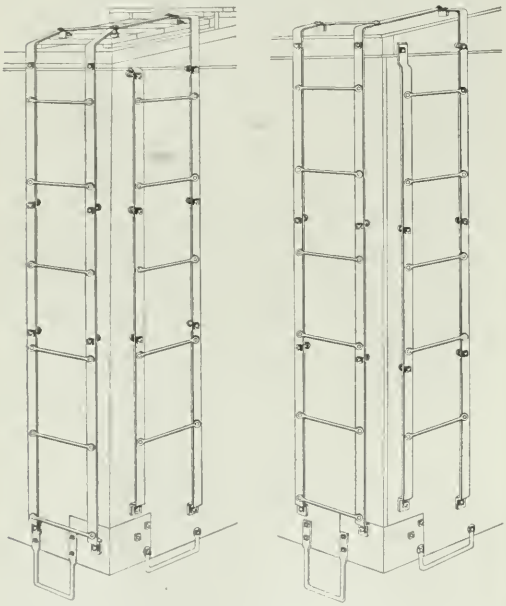
Davis Special Expansion Tool for Boring Car Wheels.

in two separate cuts, but with one continuous feed. As soon as the finishing cutters have passed through the wheel, it is chamferred to prevent it from cutting the axle while being pressed on. It is claimed for this tool that it has bored twenty cast iron wheels per hour, for 5½ in. by 10 in. axles, in two separate cuts. In addition to boring tools for general service, this company is also exhibiting a tool for boring driving wheel centers and tools for use on turret lathes and boring machines.

SAFETY BOX CAR LADDER.

The Safety Steel Ladder Company, St. Louis, Mo., is exhibiting a full sized end of a box car equipped with a safety steel ladder, as shown in the illustration. This ladder was designed to facilitate the bringing of the ladder equipment of box cars within the requirements of the United States Safety Appliance Law. The rungs are riveted to stiles made from bar steel, and those parts of the ladder on the body of the car are spaced to a convenient position by putting cast iron furring spools back of the stiles on the intermediate bolts and by bending the stiles outward from the bottom bolts where necessary. Spacing on top of the car roof is effected by bending the projecting stiles parallel with the

roof, and by further bending the stile ends downward. The top construction differs somewhat for wood and metal roofs, but in both instances the roof grab irons are a solid part of the main ladders and require no holes in the roof. On wooden roofed cars the stile ends of the side ladder bear squarely on the roof and the stile end of the end ladder



All-steel Safety Box Car Ladder.

is bolted to the side ladder stile, thus leaving no part on which trainmen would be apt to catch their feet or clothing. On metal-roofed cars, an equally safe arrangement is effected by bolting the side ladder stile ends to the brakeman's platform.

SMALL STEEL CASTINGS.

The Standard Steel Castings Company, Cleveland, Ohio, has recently been formed for the production of steel castings, weighing from one pound to 1,000 lbs. Special care is used in making the models to provide a finished casting

Steel Castings Made by the Standard Steel Castings Company.

free from sand holes, thereby making a casting that may be easily machined. The illustration shows a group of castings just as they were taken from the molds. The casting at the right was bent cold and was unannealed no cracks developing into the casting. No sand blast is required to clean these castings. The converter process is used in making the steel and the company makes a specialty of blank gearing and small parts. The foundry is in charge of John H. Davis, formerly superintendent of the foundry for the Otis Steel Company. The new plan is provided throughout with new equipment and has a capacity of 15 tons per day. The company has produced successfully castings 3-16 in. thick.

HEAVY DUTY BACK GEARED SHAPER.

Among the machine tools in the exhibit of the Cincinnati Shaper Company, Cincinnati, Ohio, is a 32 in. back geared shaper adapted for round house work, and especially locomotive driving boxes. It is equipped with a draw cut head and, in addition, has an extended circular feeding head for driving box work, which also works on the draw cut prin-

Back Geared Shaper for Driving Box Work.

ciple. The table is provided with a tilting top, and the machine is equipped with a crane of 1,000 lbs. capacity for lighting the work in and out. A constant speed motor is used, and is belt-connected to the shaper, which is driven through a gear box. A planing attachment for rod brasses is also provided. The weight of this machine is 9,200 lbs.

Burglar-Proof Devices.—A burglar-proof stop, lock and hasp arrangement, as well as a burglar-proof bracket for car doors, is being exhibited by the Camel Company, Chicago. The former arrangement prevents the splitting out of the door stop at the front edge of the door and has a burglar-proof sealing arrangement. The bracket is so designed that it is impossible to remove it while the door is in the bracket.

Major Couplers.—At the Buckeye Steel Castings Company's exhibit, Booths 603-605, a comparison is made between the experimental coupler developed by this company, as its part of the work of the M. C. B. Coupler committee, and its present Major top-lift and under-lift couplers. The Major couplers are probably as heavy as any of the couplers now in use. But in the experimental design, much greater strength and weight are provided and special attention has been given to the further development of the under-lift or side operation and the possibility of doing away entirely with the over head operating rods and chains.

Entered at the Post Office at New York, N. Y., as mail matter of the second class.

In the abstract, every railroad should build good cars and keep them in good repair, and the Master Car Builders' Association apparently proposes to do all it can to see that they do it. All the members that have investigated the subject carefully seem to find that it is costing them decidedly more to have their cars repaired away from home, although the prices allowed are, in some case, claimed to be below the actual cost. The extension of the list of owner's defects each year makes the total continually increase and the great advantage of having the highest class of equipment, properly maintained, is beginning to be more thoroughly appreciated. The eliminattion of the requirement of applying a repair card will also tend to increase the tendency toward better repairs.

At the closing session of the Master Mechanics' convention last week a letter was read from a committee of the International Railroad Master Blacksmiths' Association asking the members of the M. M. Association to send their blacksmith foremen to the convention which meets at Richmond, Va., August 18. F. F. Gaines spoke in favor of the idea and asked for a closer co-operation with the smaller and more highly specialized mechanics' association. He had found that such of his foremen as attended the different conventions returned home with a supply of good ideas, which, when put into practice, saved more money than it cost to send the delegates to the conventions. There can be little question on the part of those who are accustomed to attending the meetings of these associations, but that Mr. Gaines is right and that the railroads generally should adopt the policy of their progressive roads which not only allow their men to attend such conventions, but encourage them to do so, there can be no question. It might be a good idea to require a report from each foreman on those features that had interested him and which he believed could be adopted by his road with good results—this report to be either in written form to his superior or to be presented at one of the foremen's meetings which are now held at regular intervals on many roads. A survey of the situation six months after the convention, with the idea of finding just what results could be credited to the information and inspiration gained from attendance at the convention might reveal some interesting facts.

There have been two or three additions made to the official list of enrollment this year that have contributed materially to the value of the list and which have been the subject of much commendation. First in value stands the classification of railway officials by the roads with which they are connected. This has made it possible for those seeking a representative of any road to ascertain who is here, and if the particular man whom it is desired to see is about, to pick the next best from those present. Then the list of exhibitors with their space numbers, and a plan of the pier, and the list of the member companies of the Railway Supply Association have contributed their own quota to the convenience of the list.

The discussion on the overhead inspection of freight cars yesterday morning was interesting as showing the difficulty of advance inspection whereby one road should attempt to inspect and choose cars for service on a connecting line. The unavailability of the statistics of one road as a means of checking efficiency on another is a matter of common acceptance, and so it is not surprising that the association should balk at the idea of adopting a card that would imply that the standards of one road could be made to guide in the acceptance, by another line, of cars intended for loading with flour or grain. The American Railway Association asked for a report on the subject and a most able one has been presented. Further action will depend on the wishes of that association as the question is largely one of operation. The M. C. B. Association stands ready to co-operate in any way it can.

In the report on Car Trucks the committee states that the distance of the side bearings from the center line on various types of cars will receive consideration in connection with the design of the standard holster. In view of the fact that this distance is recognized as having great influence on the riding qualities of tenders, as well as on their liability to a freedom from derailment, it seems that it cannot fail to be of vital importance in the designing of freight cars as well. There is no apparent reason why a box car with a lading of high center of gravity should not have its rail holding qualities influenced in identically the same manner as a tender. To be sure, the distance between truck centers is greater and there are other modifying conditions that may lessen the influence of side-bearing location as a cause of derailment. But the influence or tendency must exist just the same, and it seems as if these could hardly be any subject more worth a careful and thorough investigation than this one of side-bearing location.

The experiment of keeping the exhibits open at night was tried Monday. It was not a success. Unfortunately, however, the experiment was tried under extremely unfavorable conditions. The M. C. B. Association on that day had both morning and afternoon sessions. The afternoon session lasted until 7 o'clock. The members naturally were very tired after this long day's work; and by the time they had got their dinner it was pretty late. But for these circumstances, doubtless a larger number of railway men would have visited the exhibits on Monday evening. One plan which has been suggested to give the railway men a better oppor-

tunity to visit the exhibits is that of having on each day one session from 10 to 12 a. m. and another from 2 to 4 p. m. It is reasoned that they would then have some time before the morning session began, and also some between the morning session and lunch time, and that as they would be on the Pier attending the afternoon session, they would naturally find it convenient to spend some time among the exhibits following the afternoon session. This is an interesting plan which merits consideration.

MANY prophesies have been made as to the possible length of life of all-steel freight cars, and its estimates have varied over a wide range. Steel freight cars in considerable numbers have now been in service since 1896, and from the observations which have been made of their condition it can safely be said that the life of the floor and hopper sheets will vary from fifteen to twenty years, and that the life of the rest of the car will be double that of the floor sheets, or from thirty to forty years. New floors and hopper sheets can be put in a hopper car at an expenditure of roughly $75 for material and $50 for labor—a total of about $125. When this is done the cars are said to be in practically as good condition as when new. The mistake was made in many of the cars which were designed in the earlier stages of steel freight car development—and in some of the later stages as well—of making the center sill constructions too light and in not using a cover plate or heavy box girder construction. When new floor sheets are applied it is therefore necessary in some cases to reinforce the center sills, but this is not generally the case. Naturally, as the steel cars in service have grown older, and more and more have been built, it has become necessary for roads to provide more extensive facilities for making repairs to them. The steel car shop of the Pennsylvania at Altoona has been doubled in size within the last two years; only about one-quarter of it, however, is used for repairs to old cars, the rest of it being used for the building of new equipment. The Pittsburgh & Lake Erie expects to double the size of its steel car repair shop during the coming summer.

FALSE ECONOMY IN FREIGHT CAR CONSTRUCTION.

IN discussing the proposed retirement from use in interchange service of freight cars of 50,000 lbs. capacity and less, F. W. Brazier stated in a resolution which he introduced that the railroads should start with a good car and then maintain it; and D. F. Crawford later gave it as his belief that if cars are properly repaired there will be little trouble experienced in the abuse of the repair card. There are freight cars of large capacity in service today that are a disgrace to the designers and owners and yet the policy of cutting the first cost down to the last dollar continues on many roads. When cars are intended for operation in long trains and hump yard service, with the heavy locomotives now in general use, they should be given the benefit of the best possible engineering skill and experience; much has been said on this subject, but there are still many railroad managers who will not listen to a proposal to spend even a very few dollars extra per car when they must realize, if they have studied their repair bills and have any confidence in the judgment of their car department officers, that those few dollars would be returned many times over in the reduction of maintenance costs.

It is this false economy employed in first cost that is responsible for a very large percentage of the cases of leaky roofs, broken doors, pulled out drawbars and racked superstructures and broken trucks that are daily causing train delays, overtime and increased car maintenance expenditures. Some cars of this type are known among repair men the country over; these men know that the cars are poorly built and that it is impossible to make repairs on them that will put them in satisfactory condition, and they consequently make only what repairs are absolutely essential, hoping that the cars will then run to their destination. In most cases they do not, but are again marked bad order at the next terminal—if indeed they are not set out along the road—and so it goes on in a succession of delays and temporary repairs.

Every car department man should miss no opportunity to bring home where they are most needed the facts concerning this policy. No opportunity should be neglected, in the Master Car Builders' Association conventions and elsewhere, to overturn this idea of false economy to which some of our railroad officers cling so tenaciously and which is the greatest cause of the enormously increased cost of car maintenance. Cases are not lacking where railroads buy the best locomotives available, and reduce to the last possible cent the expenditure for new cars to be handled by those locomotives, a policy as inconsistent as it later proves expensive.

LOW CAPACITY CARS IN INTERCHANGE.

WHAT the members arguing in favor of the suggestion to retire from interchange service all cars of 40,000 and 50,000 lb. capacity really desire is a reduction in the accidents and delays due to weak equipment in heavy tonnage trains. There is no doubt that this trouble is serious, and immediate steps should be taken to correct it, but it hardly seems that the selection of certain capacity cars for execution is the fair way of doing it. No one objects particularly to their capacity; it is their weakness that is criticised. Certain classes of traffic require cars of 40,000 lb. and 50,000 lb. capacity, and in any case there would have to be exceptions made to any rule of interchange based on capacity. The first motion suggested excepted cars with metal underframes and metal trucks and it was later suggested that refrigerator cars also be excepted. This is but an example of what exceptions would continue to arise when the rule was put in force. It is comparatively simple to build a wooden underframe on short cars of any reasonable strength and simply because it is wood is no indication of weakness. There have been a number of instances where 60,000 lb. and 80,000 lb. steel underframes have been too weak to withstand the shocks received in service. In some cases certain railroads are now refusing to accept some cars in interchange which are marked 60,000 lb. and 80,000 lb. capacity and make it a practice to transfer the loads and send the cars back.

It thus seems that a rule based on capacity when wooden underframes are used does not answer the requirements any better than a rule with no exception. What is really needed is a car that will stand up to the requirements of modern traffic conditions, be its capacity 30,000 lb. or 140,000 lb. This brings up the question of determining a standard minimum strength for freight cars and this in turn largely hinges on the draft gear and its attachments. If such a minimum strength can be specified, cars of the lower capacities can be stenciled and the rules could allow the refusal to accept all cars below 60,000 lb. capacity which are not stenciled as being of the required strength. Improper stenciling would not be difficult to discover and the Arbitration committee could quickly settle the matter.

Metal trucks should be required under all cars offered in interchange and a rule to this effect would cause no great inconvenience or expense to anyone.

The decision of the convention was to refer the whole subject to a committee for investigation and to then refer it, with recommendations, to the American Railway Association. While cars are, of course, built of a capacity and size to suit the requirements of the traffic department, their strength and form of construction are entirely within the control of the mechanical department. If no attempt is made to legislate certain capacities out of existence it would seem impossible to settle the question within the Master Car Builders' Association.

TO-DAY'S PROGRAM.

M. C. B. Association

9.30 A. M. to 1.30 P. M.

Discussion of Reports on:	
Damage to Freight by Unloading Machines	9.30 A. M. to 10.00 A. M.
Air-brake Hose Specifications	10.00 A. M. to 10.30 A. M.
Revision of Present Specifications	10.30 A. M. to 11.30 A. M.
Car Construction	11.00 A. M. to 11.30 A. M.
Unfinished business; Reports of Committees on Correspondence, Resolutions, and such other committees as may be named during the convention	11.30 A. M. to 11.45 A. M.
Election of officers	11.45 A. M. to 1.30 P. M.

Adjournment.

LOST.

A 4 by 5 Premo B camera with film pack has been lost in the Hotel Dennis or on the pier. Five dollars reward will be given if the finder will return to Edward Wray, Advertising Building, Chicago.

CORRECTIONS IN THE DISCUSSION OF THE REVISION OF THE RULES OF INTERCHANGE.

In discussing the letter from the private car lines in connection with the report of the Arbitration committee on the Revision of Rules of Interchange, Monday afternoon, the remarks ascribed to H. Boutet, of the Cincinnati Railways, on page 1456, should have been credited to F. W. Brazier, superintendent of rolling stock of the New York Central & Hudson River.

The final motion in connection with the report of the Arbitration committee on the revision of the rules of interchange was not reported quite accurately yesterday. It was made by C. E. Fuller and should read: "I move that the report of the Arbitration committee be accepted, including the modification of the recommendation of the committee in rule 30 referring to the reweighing and relettering of cars." The motion was carried.

M. C. B. DANCE.

The M. C. B. dance was held last evening in the entrance hall of the Million Dollar Pier, with the following committee in charge: Messrs. Landreth, (chairman), Brotherhood, Ryder, Purcell, Eaton, Donahue, Chaffee, Sheridan and Sherman.

B. & O. CLUB MEETING.

Because of the afternoon session of the Monday meeting of the M. C. B. Association it was necessary to postpone the B. & O. Club meeting from 3.30 to 5.30 P. M., and even then the late session of the association prevented a large attendance at the club meeting. Because of this no action was taken on the report of the committee on constitution and by-laws and it was continued until next year. C. F. Giles was re-elected president and C. L. Sullivan was re-elected secretary.

MR. BRAZIER MISQUOTED ON COUPLERS.

In the discussion of the report on Coupler and Draft Equipment, page 1446 of the June 17 *Daily*, a line was dropped in the print shop from the remarks of F. W. Brazier, making one of the sentences incomplete. In commenting upon the fact that it was about time to adopt a standard coupler, Mr. Brazier stated that there were now 433 different patents of couplers in use on the railways of this country, and asked, "Is it not time that we got down to a standard coupler?"

PENNSYLVANIA RAILROAD Y. M. C. A. BAND, OF ENOLA, PA., COMPOSED ENTIRELY OF SHOPMEN OF THE P.R.R.

PRESENTS FOR ENTERTAINMENT CHAIRMAN KREPPS.

Shortly after the regular morning meeting of the entertainment committee Tuesday, Chairman Krepps was summoned to appear in the executive committee room on the steel pier. There he found assembled the members of his own committee, who presented him with a slight token of appreciation of his able leadership during the conventions. The gift consisted of a gold mounted cane and umbrella on both of which appeared the following inscription:

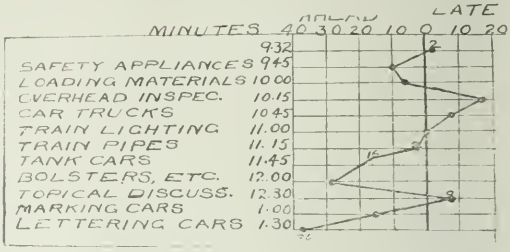
> Presented to Chairman W. K. Krepps by the members of the Enrollment Committee. M. M. and M. C. B. Conventions, Atlantic City, New Jersey, 1913.

Mr. Krepps was surprised and delighted with the beautiful remembrance.

REGISTRATION AS SHOWN BY BOOK No. 5.

Official registration book No. 5, containing all three associations up to 5.20 P. M. Monday, told an interesting story. It showed that there were registered 362 members of the M. M. Association, 325 Master car builders, a total of 687; 690 special guests, 508 railway ladies, 309 supply ladies and 1704 supply men, a total of 3,898. The totals in book No. 5, therefore, show that at the time of its going to press there were 140 more members of the railway associations and special guests present this year than in 1912, and a total increase in registration of 385.

KOWLOON-CANTON RAILWAY, CHINA.—No special development has been made on the Kowloon-Canton Railway, with the exception that Great Britain bought a tract of land comprising about 340,000 sq. ft. last June at the cost of $1,762,615 to prepare for the expansion of Kowloon station when the Canton-Hankow line is completed.



Joe Taylor's Time Study of the Performance at Yesterday's Session.
(Not an Agricultural Report!)

TRANSPORTATION COMMITTEE.

Top row, left to right—Walter Greenwood, Texas Co.; J. T. Anthony, American Arch Co.; A. W. Brown, United & Globe Rubber Mfg. Co.; H. N. Turner, Kay & Ess Co.; Wm. T. Hawley, U. S. Light & Heating Co.; M. F. Ryan, Pittsburgh Spring & Steel Co; F. S. Hiland, Patton Paint Co; J. F. Schurch, Railways Materials Co.; J. J. Toomey, Ball Chemical Co.

Bottom row, left to right—C. F. Elliott, Acme White Lead & Color Works; C. R. King, Pittsburgh Steel Products Co.; J. H. Kuhns (Chairman), The Republic Rubber Co.; George Hull Porter, Western Electric Co.; G. P. Berger, Gould Coupler Co.; Geo. A. Nicol, H. W. Johns-Manville Co.

MASTER CAR BUILDERS' ASSOCIATION PROCEEDINGS.

Includes Reports on Loading Materials, Overhead Inspection, Trucks, Train Lighting, Retiring 20- and 25-Ton Cars, etc.

The Tuesday morning session was called to order at 9.30 A. M., by President Fuller.

SAFETY APPLIANCES.

Owing to the magnitude of the safety appliance work and the many complications entering into it, the committee does not feel that at this time it can render any report other than a general statement of the conditions. Investigation develops that the roads are making diligent effort to equip their cars with safety appliances to meet the requirements of the law. The committee earnestly recommends that the importance of this matter be kept before the members.

In some instances it was found that the stenciling "United States Safety Appliances" on the cars was not being done in accordance with M. C. B. Sheet G, and for the benefit of all concerned the committee recommended to the arbitration committee that a note be added after Rule 52, on page 34 of the M. C. B. Code, which will indicate the location and manner of stenciling cars equipped with United States safety appliances.

The committee recommends that no further changes be made for the present in the interchange rules so far as safety appliances are concerned.

The report is signed by:—C. E. Fuller (U. P.), chairman; A. Stewart (So. Ry.); A. La Mar (Penna.); H. Bartlett (B. & M.); M. K. Barnum; W. O. Thompson (N. Y. C. & H. R.), and C. B. Young (C. B. & Q.).

DISCUSSION

F. F. Gaines, (Cent. of Ga.):—I move that the committee be continued and instructed to look into the question of whether it is going to be possible or not—in case we do not all come under the rule in time—of getting an extension. I think this committee should look into the question of getting an extension or continuation on some points—the coupler question particularly.

President Fuller:—That suggestion will be referred to the executive committee.

RULES FOR LOADING MATERIALS.

The committee recommends change in the title of the code of rules, from "Rules for Loading Materials." to "M. C. B. Loading Rules."

Rule 7.—This rule should be changed to read: "Lading will not be accepted if placed on top of box or stock cars. If lading is placed on top of wooden cars having sides not more than 30 in. high, and not less than 3 in. thick," and so on.

Rule 10.—(Second paragraph) Change the word "should" to "must," which would make this paragraph read as follows: "If the idler is a flat car of wooden construction its capacity *must* not be less than that of the carrying cars."

Rule 17.—Add "and must conform to Rule 51." to the end of the rule.

Rule 18.—In order to make this rule agree with the Safety Appliance Laws it should be made to read as follows:

"A group of cars must have at least one accessible and operative hand brake for two or three cars; or two hand brakes for more than three cars.

Rule 30.—This rule should be changed to read as follows:

"Material in open cars requiring special staking or clamping and all material carried on two or three cars, must always be examined by a competent inspector before the cars are moved from the loading point. If an inspector is not stationed at the loading point, the agent must give notice to the proper authority when the cars are loaded, so proper inspection may be arranged for. The object of such inspection is to see that these regulations have been complied with."

Rule 67.—Rule changed to read:

"Flat cars loaded with cross ties, fence posts or similar short material, will not be accepted for shipment, unless otherwise agreed."

Rules 69, 70, 71.—These rules are changed to read as follows:

"Rule 69.—If the load extends more than 12 in. above end or end gate at center, each pile must be tied across by at least 2 binders. Each binder is to be fastened to each tie in passing over the load (see Rules 70 and 71 for manner of securing binders)."

"Rule 70.—When wire is used it must not be less than good ⅛ in. diameter and but one strand may be used, the wire to be secured to the side of car at least three nails or staples, or to stake pockets, or through holes in top of flange on side of steel cars, or fastened to outside edge of first tie projecting above car side."

"Rule 71.—When sapling is used it must be of green timber, split, and not less than 1½ in. wide on the split or flat side. The ends of the sapling must extend at least 12 in. below car side and be securely fastened to each tie with nails in passing over the load."

Rule 74A.—The following new rule has been added:

"Rule 74A.—Small steel plates and similar material loaded in box, stock or gondola cars—the load should be uniformly distributed over the floor of the car. In no case should the amount of load placed between the body bolsters and either end of car exceed 15 per cent. of the capacity of cars with wood underframing, and 20 per cent. of the capacity of cars with steel underframing."

Rule 81-D.—To make this rule conform to Fig. 33-B, after the word "car" in fourth line should be inserted "On the same side of car two (2) straight-grain hardwood pieces 4 in. by 6 in. to be securely fastened to car side; the other side supported by three (3) vertical straight-grain hardwood posts 6 in. by 8 in. in section and of sufficient height that when plates are placed diagonally across the car they will extend from one side across to full width of upright posts."

Rule 83.—Add to the end of this rule the following:

"Where the weight of overhang is not excessive and material very flexible, a 6 in. by 8 in post of sufficient length may be bolted to inside of end of car to support overhang in lieu of sliding pieces placed on adjacent car."

Rule 85.—This rule should be changed to read as follows:

"The method of loading as shown by Figs. 34, 35, and 36 may be made use of to load long lattice girders, box girders, columns, one-half roof trusses and similar material, in lengts not to exceed 65 ft., overhang not to exceed 15 ft.—height and width to conform to Rule 25, if the material would be injured if loaded on more than one car. From a point of safety in transit, it is a very undesirable method and should be used only when absolutely necessary."

Rule 91.—Change side clearances from 18 in. to 22 in. to conform to changes in Rule 51.

Rule 93.—In order to cover triple loads of long flexible material, this rule should be changed to read as follows:

"Long flexible material like plates, etc., which can not be loaded as shown in Fig. 24, must be loaded on two (2) bearing pieces and two (2) or more sliding pieces as in Figs. 41, 42, 43, 43-A and 43-B. The sliding pieces must be 4 in. lower than the bearing pieces and must have flat iron ½ in. by 6 in. secured to the upper side, either with spikes or lag screws at each end. These iron pieces which are intended to facilitate curving must extend at least 22 in. beyond each side of the lading and must be coated with grease before the lading is placed upon them. The bearing pieces must be secured to the car and the material clamped together in the same manner as described in Rules 72 and 80 to prevent it from shifting."

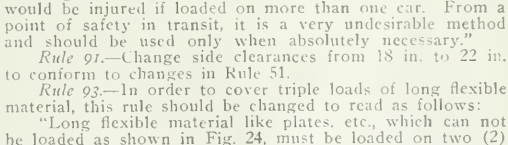


Fig. 1—Loading of Long Flexible Material on Flat Cars and Gondola Cars.

Rule 98.—The last sentence should be changed to read: "Rolling freight must be loaded longitudinally with car and must be chocked to prevent end and side motion."

Rule 103.—"All structural material and plates more than 60 ft. long, also," should be eliminated, as this class of lading is covered by Rule 93.

Rule 112.—The following should be added to this rule:

"Pipe 8 ft., or less in length, side and end protection must be provided."

Rule 112-A.—On account of the difficulty experienced handling pipe where small sizes have been placed inside of larger pipe, a rule prohibiting the practice has been sug-

gested to read as follows, and shown as second and third paragraphs of Rule 112-A:

"Wrought-iron pipe of the smaller sizes, approximately 1½ in. in diameter and less, should not be loaded inside of larger sizes of pipe, unless below the ends or end gates of cars."

"Wrought-iron pipe of the smaller sizes, approximately 1½ in. in diameter and less, should not be loaded on top of the larger sizes of pipe, unless the load is below the ends or end gates of cars, except where the smaller pipe is securely tied in bundles."

Rule 112-B and 115.—Omit the last sentence in brackets, reading: "(See Rule 112 for wiring and staking)."

Rule 115-A.—Add after the word "Pipe" the last word on page 105 the following: "Provided that blocking more than 10 in. in height will not be required."

Rule 116.—This rule has been revised to conform to the present method of loading as follows:

"Blocking of more than 10 in. in height will not be required, but on loads of pipe 3 ft., or over in diameter the blocking must be stayed by suitable chocking."

Rule 117-A.—This rule should read as follows:

"Gondola cars. Galvanized iron culvert pipe of all sizes, for size and number of stakes to be used see Rule 12 and 112. When mixed sizes are loaded on the same car, the small size pipe when possible, should be placed inside the large size. In loading galvanized pipe Rule 9 must be complied with."

Rule 117-C.—This rule should read as follows:

"Mining cars and similar vehicles; the length of cars being equal to or greater than twice the height of car side, if loaded in gondola cars on ends, the broad side or bottom must be loaded parallel with car side and securely blocked against side of car, the other ends brought together in a cone shape. Each pair of cars or vehicles must be securely fastened together on each side with a board not less than one by 6 in. bolted to each car or vehicle with one ⅝-in. bolt, the entire load to be tied together with four strands, two wrappings of good ⅛-in. diameter wire. The blocking

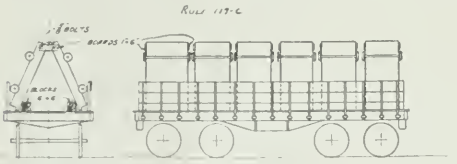

Fig 2—Manner of Loading Mining Cars and Similar Vehicles in Gondola Cars.

must be of sound timber not less than 6 in. by 6 in. square. Fig. 61-A shows substantially how the load is to be secured."

On page 108, first line under the heading "End Protection," should be changed to read as follows:

"Cars not provided with end stake pockets the necessary, etc." and after "or" in first line on page 109, the word "two" should be inserted.

Rule 121.—Last sentence in second paragraph should be changed to read as follows:

"End blocking to be not less than 6 in. in height, bolted to car floor and securely cleated." Fig. 64-B should be changed to conform to the above change in the rule. Four inch blocking is not sufficient to hold boilers and tanks over 8 ft. in diameter on flat cars.

Rule 121-A.—Should be added to the code to cover shipment of smoke stacks on same car with boiler. This rule to read as follows:

"When smoke stacks are shipped on same car with boiler, not less than 4 in. by 4 in. stakes should be applied to each side of car, and each pair of stakes tied together with one inch by 5 in. cross braces, nailed to each side of stakes with 3 tenpenny nails. The smoke stacks should be loaded on top of cross braces and securely wired to them with ⅛-in. diameter wire. The projection of stakes above cross brace should not be less than one half the diameter of smoke stack."

Rule 121-B.—This rule should read as follows:

"Engines, machinery and vehicles shipped on their own wheels, should have wheels securely chocked fore and aft and longitudinal sills placed on the inside of wheels and securely fastened to floor of car. Struts should be used to prevent the heavy parts of the engine shifting endwise. One end of the strut should be placed against some strong protection on engine machine or vehicle, the other end securely fastened to floor of car."

Rule 122.—Fig. 64 shows three horizontal tie braces, instead of one.

Rule 122-A.—The 2 in. by 4 in. diagonal braces to axel journals now shown in Fig. 66-B and 66-C, should be eliminated and angular chocks 8 in. in height against wheel tread, spiked to car floor, should be substituted.

Rules 127 and 127-A.—These rules should read as follows:

"*Rule 127.*—Hewed ties 8 ft. or more in length, or sawed ties of lengths 8 ft. to 12 ft. or similar material which does not conform to Rule 126, may be loaded longitudinally in four tiers, as per Fig. 71, in which case the ends of the tiers next to the end of car and end of ties projecting into the doorways must rest on bearing pieces not less than 6 in. thick laid crosswise on floor of car. If the length of car is such that ties can not be piled in four tiers, three tiers may be used as shown in Fig. 72, in which case the spaces between the ties must be blocked to prevent any shifting of the middle tier. When loaded in three or four tiers as indicated the door protection strips need not be applied.

"*Rule 127-A.*—Sawed ties more than 12 ft. in length (see rules for loading lumber)."

Rule 132.—A paragraph should be added as follows:

"To protect the ends of cars loaded with greased shaftings, boards 2½ in. thick, full width of car and to height of lading, should be securely nailed to end of car."

Rule 133.—This rule to read as follows:

"If box cars are used for loading heavy machinery, such as lathes, planers, boring machines, etc., each machine should be blocked by securely nailing to floor of car 2 in. by 4 in. hardwood strips fore and aft, to prevent shifting endwise."

New Rule 134.—Automobiles should have gasoline and water tanks emptied and batteries disconnected. If electric automobiles, remove batteries. Place automobile in car parallel with sides of car. See that front wheels are in line with back wheels. Set brakes. The lower third of tires should be wrapped with at least two thicknesses of good burlap to prevent chafing. Secure each wheel with bands of good strong material (canvas preferred) fastened with 2 in. by 4 in. by 12 in. sound wood blocks, placed on each side parallel with wheel, and securely nailed to car floor to prevent bands from pulling loose. Each wheel should be chocked fore and aft with angular chocking one-third the height and 2 in. wider than wheel. The chocking of each wheel should be tied together with a board on each side of wheel, securely nailed to the chocks. To preserve alignment of the front wheels small ropes tightly drawn should be fastened from the top of one wheel to the bottom of the other. Burlap should be placed around wheels under rope to protect paint. When shipped without tires, no part of the wheel except center of rim should come in contact with the chocking. In addition to chocking referred to, an iron band not less than 1¼ in. wide and not less than 18 gage in thickness should be passed over top of wheel and securely fastened to chocking.

The report is signed by:—A. Kearney, (N. & W.), chairman; R. E. Smith, (A. C. L.); L. H. Turner, (P. & L. E.); W. F. Kiesel, (Penna.); C. N. Swanson, (A. T. & S. F.); G. H. Gilman, (No. Pac.), and J. M. Barrowdale, (Ill. Cent.).

In presenting the report, Mr. Kearny said: "Rule No. 93 is to be modified to the extent that we will allow a uniform plate of 1¼ in. Under Rule No. 117-A, there should be added to the code to cover shipment of galvanized "corrugated sheet" iron culvert pipe."

The committee had a meeting yesterday, and received some other suggestions relating to changes in the M. C. B. Loading Rules. The committee would like to embody the following changes in its report:

Rule 12.—Add to first sentence fourth line, "or rolled or built up steel sections of equal strength."

Rules 15-A, B and C.—Make reference to the use of "sliding pieces" as well as "bearing pieces."

Rule 15 I.—Make reference to 15-C.

Rule 15 F.—In order to make the rule correspond to the figures, it should be changed as follows:

"For twin or triple loads of long flexible material, such as plates or similar lading, requiring two or more sliding pieces in addition to the bearing pieces, the weight of lading must not exceed one half the capacity of car, and must conform to Figs. 41, 42, 43, 43-*A* and 43-*B*.

"For material of less flexibility such as heavy channels and I beams, see rules 15-*A*, *B* and *C*, and Figs. 39 and 40.

"For Tee and girder rails 60 to 65 ft. long, loaded on flat cars having four or more stress rods or on gondolas with deep ends, the lading may equal the marked capacity of car."

Rule 22.—Add to end of second section: "Or rolled or built up steel construction."

Rule 24.—Change to read: "The preferable distance between bearing pieces under lading on two or more cars is 7/10 the total length of lading, with allowable variation from 6/10 to 8/10."

Fig. 12.—Add to the heading, "Rule 91."

Fig. 29.—Omit the words "in bundles" in notes.

Add Fig. 33-A to second line of heading to table covering maximum weight of load.

Fig. 43. Add the word "flexible" to heading, after the word "material."

Rule 71.—Reference to Fig. 29 should be omitted.

Rule 76.—Reading should refer to Fig. 33-A as well as Fig. 24.

Rule 78.—Change the words "bearing pieces" in the second line to "clamping pieces."

Rule 93.—Page 83 first line, change to 1¼ in. x 6 in.

Rule 94.—Change words "bearing piece" in sixth line to "clamping piece."

Rule 100.—Add "See rule 93 for sliding pieces and sliding irons."

Rule 101.—Omit

Fig. 59.—Change cut to show 3 instead of 4 pairs of stakes to illustrate the rule rather than the exception.

Rule 81-B.—Add words "structural bars and shapes," after "plates" in first line.

Fig. 46—Change heading to read: "Structural material loaded on flat cars or top of sides of gondola cars."

DISCUSSION

I. S. Downing, (L. S. & M. S.): Under Rule 121-B it says: "Engines, machinery and vehicles shipped on their own wheels should have wheels securely chocked fore and aft, and longitudinal sills placed on the inside of wheels and securely fastened to floor of car." A little further down, it says "securely fastened to floor of car." Inspectors generally understand when you say "shipped on their own wheels," that the thing will run on the way like a crane. We had a serious accident on account of a crane loaded on a flat car, the wheels of which were securely locked, but the machinery of the crane was not locked. It was only covered by canvas, and in going around the curve, the machinery of the crane became free, and a serious accident was caused, and I think we should specify that the gearing of these cranes should be blocked.

A. Kearney: It is the intention to cover that point by an illustration which will show how that class of shipment is to be handled.

M. K. Barnum: I suggest that in Rule 121-B the word "shipped" be changed to "loaded";—"Engines, machinery and vehicles loaded on their own wheels."

A. Kearney: That is acceptable to the committee. (The report was referred to Letter Ballot).

OVERHEAD INSPECTION OF BOX CARS.

The committee on Rules for Loading Materials, to whom was last year assigned the formulation of rules for the overhead inspection of box cars for loading, was forced to present a report of progress at the last convention on account of its inability to satisfactorily cover the field a subject of so much importance seemed to warrant. With the assistance of the American Railway Association, the General Managers' Association of the Southeast, and others, a great deal of data showing in a general way what was taking place, and what claims were resulting from damaged and defective equipment, were secured; however, the statistics submitted at that time and those subsequently obtained seem to be much the same, except perhaps in quantity, rate of increase and losses sustained.

On account of the many damage claims presented, with the attendant difficulties in adjustment, often by reason of uncertainty in some instances as to the proportion of the claim that might belong to the condition of the car at the initial point of loading, and how much originated on the line of the road, its treatment, etc., it seemed proper to mention at the outset that the solution of the problem evidently narrows itself down to the important factor of inspection, selection and proper preparation of the car at the loading station. The committee found itself confronted with innumerable difficulties and objections offered by railroads explaining that latitude must be allowed on account of possible unwarranted interference to movement where unnecessary time might be consumed selecting and preparing equipment, especially where the supply and opportunity to obtain equipment is of considerable moment. It is still further argued that such a procedure might result in embarrassment if any specific and more stringent rules are established for the crating and inspection of equipment, even though the work be confined to cars for shipment of only certain commodities readily damaged by water, or leakage losses. At all events, it seems to be the general opinion, at least in certain localities, that steps might be profitably taken working to the standardization of rules and requirements for the selection and inspection of equipment required for certain shipments, and it is the opinion of the committee that if it is going to be possible to secure improved conditions along this line, they are most likely to be obtained by confining attention to shipments readily damaged by moisture, eliminating for the present the consideration of other commodities, at least until some systematic rule can be established and gotten under way.

It has been the idea of the committee that a composite card acceptable to the roads now following the practice of securing certificate of inspection cards will be the first solid ground reached in working to a uniform practice and if the interest of such roads can be secured in this direction, the proposition will be readily given the necessary impetus to carry it as far as it can be employed with profit and without danger of being used beyond the point of economy. Working to this end the committee has secured what is supposed to be a complete list of roads using certificates of inspection cards. They are as follows: Great Northern; Chicago, Burlington & Quincy; Chicago Great Western; Chicago, Milwaukee & St. Paul; Minneapolis, St. Paul and Sault Ste. Marie; Illinois Central; Atchison, Topeka & Santa Fe and St. Louis & San Francisco.

The Great Northern, Chicago Great Western, and Chicago, Milwaukee & St. Paul use only one form of card and the card used by each road is practically the same, and is given below:

C. M. & St. P. Ry.
This car
No..... Initial.....
FOR FLOUR.
Inspected by.....
Date....., 191.....

There have been no special instructions issued by these roads as to the inspection to be made, a specially trained man being selected for the work.

The C. B. & Q. are using four different forms of inspection cards, one being for flour, cement, grain, rough freight; one for flour, one for cars fit for grain and one for cars not fit for grain. There are no specific instructions for inspection issued. The master mechanics are instructed to have the empty cars inspected and carded according to their condition and the requirements of traffic.

The M. St. P. & S. S. M. is using two inspection cards, one for cars suitable for flour loading, and one for cars not suitable for flour, grain or merchandise. The instructions relative to the use of these cards are that the cars are to be given a special interior and exterior inspection to see that sheathing, lining, flooring, roofing, doors and fastenings are in good condition; any small holes found in the floor are to be cleated over, care being taken to bevel the edges of the cleats to prevent damage to flour sacks. Cars with a bad odor, due to carrying hides, oil, etc., are not to be used for flour. Cars otherwise O. K.'d with the exception of having small oil spots on the floor are to be painted over with quick-drying paint. All projecting nails, spikes or bolts to be removed or driven in to prevent damage to flour sacks, and all cars are to be swept out thoroughly clean. Cars fit for flour loading are to be carded O K., and the numbers and initial of such cars are to be turned in to the agent.

The Santa Fe is using two inspection cards, one for flour and one for grain loading. There is no difference in the make-up of the cards, except that one is printed in red and the other in green. The Santa Fe instructions relative to the use of the inspection cards are as follows:

Where car inspectors are located, cards will be furnished the inspectors, and at the stations where there are no car inspectors, the local agents, or their representatives, will inspect all cars for grain and flour loading. If after proper inspection cars are found to be in suitable condition for grain and flour loading, a card is to be attached to the car door, three feet from the bottom of the door. Switchmen or local crews should be prohibited from placing at loading docks, platforms, or elevators, an empty car which does not have one of these cards attached. When a car has been inspected and card placed thereon and placed at loading dock, and when shipper or his representative has inspected the car and accepted same for loading, the card will be detached and returned to the representative of the company, and shall be attached to and filed by the agent with duplicate bill of lading or shipping instructions. Shippers must be notified when a car is made empty at their plant that the car must not be loaded until it has been inspected and necessary card attached. The Santa Fe is now contemplating the use of another form of inspection card, which is made up in manifest form so that shippers can have a copy for their use.

The Frisco Lines are using three forms of inspection cards, and an abstract of the instructions follows: The roofs must be carefully inspected to ascertain if waterproof, the doors to see that they fit tight, and are in good condition. The doors should be pulled shut and inspected for leakage. The doors of all cars loaded on Frisco rails and on foreign line rails for movement via Frisco, must be wedged, papered and striped in the following manner: Drive one wedge

between each door shoe and the door, which will force the door up against side of car. After the wedges have been applied, a strip of odorless asphalt paper, 11 in. wide, must be applied over the openings of the car door, that is, one strip on each side of the door and one on the top of the door, the paper to be held in place with narrow wooden strips. A standard grain door section is seven ft. long and 20 in. wide. Usually three or more sections are used for each door. They should be placed in position and nailed to the door posts with 8-penny nails. Large nails or spikes must not be used. Care should be exercised to see that the doors fit closely, and that there are no holes in them. Nails protruding from door posts must be pulled out so that the grain doors will fit closely. Grain doors made of light material must not be used for the bottom or middle section, account pressure being greater on these sections. Doors made of good strong lumber should be used. Burlap will be furnished by the store department upon receipt of proper requisition, cut in strips eight ft. long and 40 in. wide for the doors, and 3 ft. long and 40 in. wide to cover the draft bolts. Two strips 8 ft. long should be used to cover the grain doors. This leaves 6 in. over each end of the grain door for tacking to the side of the car. The lower strip should be allowed to lap on the car floor 8 to 10 in. in order to make a leak-proof joint. It must not be tacked to the car floor. The top strip should lap over the lower strip from 4 to 6 in., and should not be tacked to the grain door. Wooden strips will be furnished with the burlap to tack the ends to the side of the car. The short pieces of burlap are to be tacked over the draft bolts and held in place by short strips of wood tacked around the edges. Burlap should be applied loosely and not stretched tight across the boards, so that it can give and not tear from the bulging of the doors.

While the general practice seems to be to use cards bearing printing in large letters showing a specific commodity, or in some cases one or two products, the committee did not seem to be able to readily get away from a card on which provisions are made for the designation of the shipment for which the car is inspected and made suitable without introducing more than one card, which is not wanted unless it cannot be avoided. A sample of such a card, representing the result of a combination of all the cards, with their instructions, is as follows:

A. B. & C. Ry.
This car
No. ...... Initial..........
O. K. FOR SHIPMENT OF COMMODITIES.
Under ....Classification
Inspected by.......................
Date ...... 191.. Station ....
(Size of card, 6 by 8 inches.)

The committee points out the three apparent classifications of lading for which the box car is on some roads and in some localities receiving special attention before loading. The three following classifications were given as covering the situation at least until improvement can be suggested and worked out.

Classification *A*.—Flour and sugar.

Classification B.—Bulk grain.

Classification C.—Lime, cement, plaster; boxed, sacked and crated packages of seeds, coffee and merchandise; hay, dry goods and notions; high grades of finished lumber; tobacco, furniture, household goods and certain grades of tin and galvanized iron.

In the arrangement of the above classification, the items shown under *A* have been grouped together in order to secure cars which might be necessary for such shipments, i. e., those free from soiled floors and interiors carrying odors liable to damage the goods; whereas cars selected for classification *B*, intended for bulk grain, clearly indicate by their character what might be suitable for their safe transportation; likewise classification C, covering the commodities mentioned, could be safely transported in a car which, while it should be tight, need not necessarily be as carefully selected as to other conditions as a car for classification *A*.

On the back of the cards, inspection instructions should be printed as follows:

[illegible]

Classification *A*.	Classification *B*.	Classification C.
Leaky roof.	Leaky [illegible]	Leaky roof.
Leaky siding.	Leaky [illegible]	Leaky siding.
Loose roof [illegible]	Loose roof [illegible]	Loose roof boards.
Shifted roof sheets.	Shifted roof sheets.	Shifted roof sheets.
Broken door stops.	Broken door stops.	Broken door stops.
Leaky doors, [illegible]	Leaky [illegible]	Leaky doors, [illegible] and sides.
Broken [illegible] posts.	[illegible]	Broken end posts.
Broken or loose [illegible]	[illegible]	Broken or loose [illegible]
Protruding nails in floor and lining.	[illegible]	[illegible]
Floors soiled by oil, [illegible]	[illegible]	Protruding nails in floor and [illegible]

METHOD OF INSPECTION BEFORE LOADING.

(A) Inspection to be made at point of loading whenever practicable.

(B) At point of distribution from which car is forwarded to loading station, and again by Agent.

(C) Cars received and unloaded at station where no inspectors are located, should be inspected by the Agent.

Aside from the Master Car Builders' inspection of car, including roof, running boards, air brakes, safety appliances, and running gear, as well as the external inspection of sides, ends, doors, ventilators and windows an internal inspection must be made of the roof and siding, with doors, ventilators and windows in closed position.

1. Search for light indicating openings and cracks which might produce leaks.

2. For loose, damaged and broken boards, loose knots, knot holes, bad joints, etc.

3. For all nails and bolts extending above surface of floor and lining and nails protruding through roofing.

4. Search for water stains indicating cracks and air spaces.

5. Search for cracks sufficient to admit storm water beating through opening, also for openings and bad joints around window and doors.

6. Examine for metal sheets out of position along edge of subcarlins or down from edge of ridge pole.

7. Search for small holes in metal roofs due to rust or small openings in roof from other causes.

8. Doors must open and close properly.

The floors should be clean, dry and free from defects sufficient to admit moisture, and any fouling by previous shipments, such as fertilizer, oils, and other freight which would damage more perishable commodities. If the centerpin is uncovered, it might be necessary to cover it with a piece of board, depending entirely upon the character of freight to be loaded. Inspect closely for defects in framing which might, by reason of their weakness, allow the sheathing to be readily broken or damaged.

After a car is thoroughly inspected and known to be in good condition and suitable for the transportation of the commodities in the classifications, the inspector or agent, as provided for, making such inspection or able to certify to the condition of the car, must make out the prescribed certificate of inspection card and tack it to the car just under the car number. After the car is placed and accepted for loading, the certificate of inspection card must be detached from the car and delivered to the Agent before bill of lading is issued. The card must finally be attached to the agent's office copy of bill of lading or shipping ticket, for future reference in case of question arising as to the condition of car before loading.

Inspection of car bodies, doors, and the placarding of bad roofs, etc., as well as making notation of the extent of damage, is at present given attention; but it is also true that the general results seem to indicate that improvements can be made and higher efficiency obtained, since it seems to be generally accepted that any observation, inspection, and amount of prevention can be more economically directed at the time of selection and preparation of the car than through repeated repairs and attention to cars en route, only to find the car arriving at its destination offering opportunities for criticism and possibly heavy damage claims. Hence the fact remains that the successful launching of any systematic and uniform practice hinges upon a closer inspection of equipment as to the physical condition of the superstructure for the loading of certain commodities, and such inspection should be made in the best possible manner, to meet local conditions.

SUPPLEMENTARY REPORT.

The foregoing report was forwarded to the eight railroads now using a certificate of inspection card, inviting from them criticism and suggestions as to what might be further offered in the committee's report. The real object, as explained to them, was to obtain their views upon the conclusions reached by the committee, and to further ascertain if in their judgment a uniform plan and the uniform card, as suggested by the committee will meet the requirements; furthermore, if they would be willing in the interest of uniformity to use it in lieu of what might now be their practice.

The committee failed to secure unanimous approval of the inspection card recommended. While the majority of the roads agree to the arrangement of the card, and the plan covering its use as suggested, others think that better results can be obtained by using separate cards for each classification, either printing on the card the commodity to be handled, or by using cards of different colors. The main objection raised against a single card for the three classifications is on account of requiring the inspector to write the letter *A*, *B*, or *C*, indicating the classification; and there is still another objection raised, as it contemplates requiring the switchmen or trainmen to read the card and ascertain from the information written thereon the class of commodity the car is suitable for handling.

The committee found that a schedule for such an inspection was feasible, as has been shown in the report, and that the requirements can be made to very readily fit in with whatever final form and plan of handling the card is adopted; but has not been so successful in working out a card satisfactory to all railroads. The use of colored cards would seem to be perfectly practicable, and would not necessarily disturb the fundamental inspection plan proposed, provided it would be considered better to relieve the inspection force from writing the classification *A*, *B*, and *C* on the card (which as a matter of fact is practically nothing); and requiring as a substitute the carrying of a larger number of cards so as to designate the classification by color. It would seem that even such an arrangement could be worked out and still obtain a uniform practice; but it is the opinion of the committee that since it has gone about as far as it can in the consideration of this subject from a mechanical point of view, that the subject should be referred to the American Railway Association, or that a committee be instructed to handle it in conjunction with that Association. The report is signed by:—A. Kearney (N. & W.), Chairman; R. E. Smith (A. C. L.); L. H. Turner (P. & L. E.); W. F. Kiesel, Jr. (Penna.); J. M. Borrowdale (Ill. Cent.); C. N. Swanson, (A. T. & S. F.); G. H. Gilman (N. P.).

DISCUSSION

C. N. Swanson, (A. T. & S. F.): As a member of this commitee, I would say that we have received communications from our operators and transportation officials. I will read one of them:

"Your letter of May 12, addressed to Mr. Raymond as chairman of the cooperage committee, enclosing a copy of your letter of April 21, to Messrs. Lehman and Purcell regarding overhead inspection, and the adoption of a uniform inspection card."

Uniformity of action, if well directed on the part of all railroads in the matter concerning car maintenance, is commendatory because:

First: It serves to develop a more general understanding of car defects, their nature, and what to the ordinary inspector to-day may seem trivial is indeed responsible for the payment of thousands of dollars in claims for damage done when loaded with certain commodities under certain conditions. A Santa Fe car inspector today may be the inspector of another railroad tomorrow. If he learns to do his work right on the Santa Fe, he will be more valuable to the other railroad he is employed by, if they work along the same line as we, and to the same end.

Second.—It is one more step in the ultimate direction of co-operative endeavor along which road railroads must travel if they are to attain maximum results in the operation of their properties. There is no more reason why the railroads whose interests otherwise are foreign, should not work together for the common good of all, when the upholding of a common economic principle rests in the balance, than there is of two divisions of the same railroad.

Third.—Aside from this, I am in favor of the uniform card, because it is designed to meet all conditions and will do so far better than our present individual grain and flour inspection card. The use of such a card by all railroads would develop into a great good, and in the event it is adopted by the M. C. B. Association, I trust its adoption by the various railroads who are members of that Association may be forthcoming at an early date.

F. F. Gaines. I move that the committee be continued, and the matter referred to the American Railway Association, with the understanding that this committee stands ready to co-operate with them in everything they can. (Motion seconded).

T. H. Goodnow, (C. & N. W.): Is the proposed card supposed to carry any empties in the way of exchange; that is, by delivering cars to other roads on orders. If this card is intended to protect the line receiving those empties in moving the cars into the train-loading territories to ensure good cars? Or is it simply intended to be used by the road in selecting their individual cars and forwarding them to train-loading points? If it is the latter, it will not accomplish much more than their present arrangement for such selections.

C. N. Swanson.—We believe in a card of the character; that when Road *A* asks for a number of cars from Road *B*, the cars will be so thoroughly inspected that they will be delivered to Road *A* fit for the commodity for which they were sent over, whether it is wheat, flour, cement, or whatever it may be. When an agent calls for cars, there is a thorough inspection made for grain or flour loading, and that is the intent of this uniform inspection card.

T. H. Goodnow: If the committee has not considered that, I suggest that they do so for the reason that it is becoming more and more the practice to deliver cars on orders, already coopered with the train doors boarded up, and it is difficult for the receiving roads to make an interior inspection of the cars without providing their inspectors with ladders; and if it could be carried out and accomplish that particular effect, it would serve a good purpose.

C. N. Swanson: It should not be necessary for the receiving road to make such an inspection if the car has been thoroughly inspected and coopered, and the card placed on the car. The card on the car would indicate that the car was fit for the commodity intended.

A. Kearney: Mr. Hale of the American Railway Association suggested that it might be well to have this item returned to that Association with a definite recommendation.

D. F. Crawford (Penna.): There are only a total of 8 roads, out of all those in the United States, apparently, that are using this card, and I do not feel that the association itself is prepared to send this to the American Railway Association with its endorsement.

F. F. Gaines: I would not favor the proposition that the association is to go on record as favoring this as standard practice, by any means whatever, at this time, but we have got to the point, if you want to go any further with it, and it does seem desirable that we should go further with it, that it be recommended only as Recommended Practice. The operating end wants it, it is purely an operating proposition.

President Fuller: Mr. Crawford is correct in his position. There are very few of the members present who know very much about the subject, and they have not had much time to consider it. It seems to me that the Committee's recommendation in the last part of the report is about as far as you can consistently go, or about as far as this Convention can consistently go.

I. S. Downing: I do not think that these different classes of lading should be put up to the car inspector, for the reason that they do not know how many cars are wanted for grain, etc., except on special order, and if this rule is adopted in big yards, it will compel the inspecting forces to inspect 5,000 or 6,000 cars and card them and classify them, and maybe they only want 50. I think the agents' men know as much about grease-spots on the floor of the cars, and such things, as our inspectors do. We have to put on special men to do this work on our road. I think as Mr. Goodnow says, this is to be an individual lading proposition, each road handling their cars and inspecting their cars. I do not think we should try to inspect cars three or four hundred miles away from the point where they are to be used, for another road.

W. E. Dunham, (C. & N. W.): I have had considerable experience in the past few years in inspecting cars for grain lading, and we do not depend even upon the neighboring divisions of our own road for inspection. We inspect the cars again, and inspect them where they are loaded, and that is the only way in which we can absolutely cut out the use of improper cars.

A. Kearney: I simply wish to say a few words in the way of explanation. This report was handed to us by the American Railway Association. A committee of that association presented a report to the executive committee of the M. C. B. Association, showing them what had been lost, or what was being lost, by reason of the poor inspection of cars, and asking the executive committee of the M. C. B. Association if they thought they could work out a code of inspection rules for such equipment. That has been the work of this committee, and now I should say we are ready to report back to the American Railway Association and hand them this recommendation for the inspection of such equipment.

T. H. Goodnow: I believe that if the report is confined to the question of inspection, a system of inspection of the cars, that will be all right, but the introduction of these cards is another matter. If, as Mr. Kearney stated, that will be left solely to the loading road, to use the cards for their own protection, they carry no significance with them, and I do not see why it is not as well for the road to handle the inspection under the system of chalking the cars or whatever other means the roads prefer to use. The big grain-loading roads in the West have to haul cars empty hundreds of miles, and you cannot depend on the inspection in big cities where the cars accumulate, to have the cars O. K. when they arrive out in Dakota, for example.

F. F. Gaines: I believe our managements, as a whole, are looking to us to do something, not so much as an interchange proposition, but in the way of a more thorough inspection of box cars to prevent damage to lading. It is not my idea that this thing is being presented for adoption

as standard to concur with the recommendations started by the American Railway Association. We have done all we can, and now it is our province, I believe, to turn it back and see how far they want to go with it.

I. S. Downing: I do not feel like some car men, that we are entirely responsible for this equipment. Our assistant superintendent of motive power and myself made an inspection of 27 cars last week, and out of the 27 cars, we found 7 brand new cars unfit for grain loading, due to the fact that the cars had been loaded with hides and oil. The transportation department will not switch out good box cars, and take them for grain, if they need them at the nearby freight house. The American Railway Association can help the mechanical department by getting at these fellows a little and stopping that sort of thing. It costs the freight department a considerable amount of money to switch cars not fit for grain, to the rough loading station and hold the good cars for grain and a good load.

C. E. Chambers, (C. of N. J.): Mr. Downing struck the nail on the head. How many of the roads here have absolute control over the conditions at the points to which their cars go? Many times the cars are put in as fit for a certain class of freight, and the roads do not have an opportunity to inspect for that class of freight. The transportation department orders the cars where they want them, and uses them as they want them.

J. J. Tatum, (B. & O.): I believe there should be some standard method of inspecting cars for special lading. The necessity for such a method is brought about by the car supply. If you have not a sufficient number of cars of a certain class to supply for a certain shipment, you have to resort to means to supply the cars from what equipment you have then to select from. You may start your car after an inspection by an ordinary inspector at your own yard, and at an interchange point the inspector may hold out the car, and he may decide the car to be unfit for grain and flour. He may possibly lay out for rough freight a greater number of cars than the equipment in hand would justify him in doing.

A short time ago, a large number of cars were selected in Chicago for the transportation of grain. In the train which was dispatched, there were so many for grain and so many for flour and so many for rough freight. When they were delivered to the loading road, the cars which were chosen by our inspector as being fit for grain, were considered by the inspector of the loading road to be fit only for merchandise freight, and it resulted in many of these cars being cut out for the lading they were intended for. So it seems to me almost impracticable to think that one road can inspect for another road, because they are along different lines as regards the class of cars they will use for different lading.

(Mr. Gaines' motion was then put and carried.)

CAR TRUCKS.

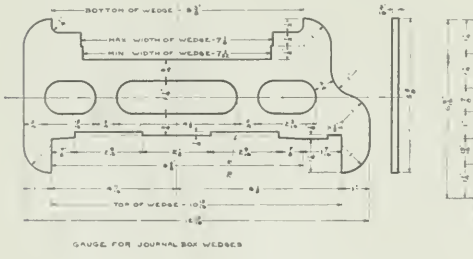
The following subjects were assigned by the executive committee to the committee on car trucks and the committee reports as follows:

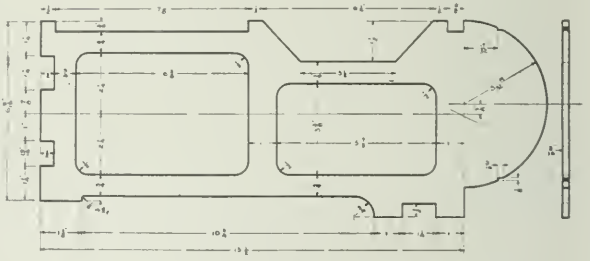
DESIGN OF CAST-STEEL TRUCK SIDES AND BOLSTERS FOR FREIGHT CARS.

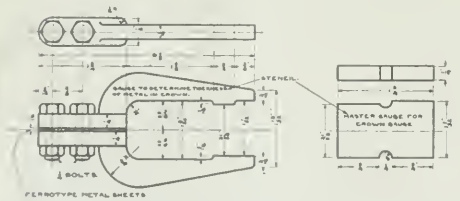
Cast-steel Truck Sides.—The various designs of cast-steel truck sides were considered, but as a number of them are covered by letters patent it was decided to prepare diagrams showing the limiting dimensions for truck sides for 80,000, 100,000 and 140,000 lbs. capacity cars, so as to provide for interchangeability of truck sides of the same capacities but different design, instead of proposing any definite design. The truck sides which come within these proposed limiting dimensions are to be subject to the specifications and tests contained in M. C. B. Recommended Practice adopted last year, which are being revised, and will include a proof load test for deflection without permanent set as well as limiting weights. This will provide truck sides which will be safe and interchangeable for the given capacities of cars for which they are intended and eliminates those of weaker designs.

The manufacturers have submitted drawings of the different truck sides manufactured by them, which are being tabulated with a view of arriving at the limiting dimensions. Results of tests of various truck sides made by individual railroads as well as manufacturers have been considered and tests are now being conducted by the committee, but the latter are not completed, which prevents submitting definite recommendations to the Association this year.

Cast-steel Truck Bolsters.—Tests of various types of cast-steel bolsters have been made and it is confidently expected that the committee will be able to recommend a standard design for Recommended Practice next year which will be applicable to truck sides represented by the contemplated limiting dimensions. It is intended to make provision for adjustable side bearings; and the question of center plates, whether they should be cast integral or be of the removable type, is receiving consideration.







Journal Bearing and Wedge Gages for 6 In. x 11 In. Journal.

The bolsters conforming to the design which will be proposed are to be subject to the specifications and tests contained in M. C. B. recommended practice adopted last year, which will be revised and also include a proof load test for deflection without permanent set, as well as limiting weights.

LIMITING STRAINS PER SQUARE INCH FOR ARCH BAR TRUCKS.

It is the opinion of the committee that little would be accomplished in endeavoring to harmonize the different formulæ used for figuring the limiting strains for arch bar trucks, with a view of establishing a standard along these lines. The association has adopted standard arch bars, column and journal box bolts for 80,000 and 100,000 lbs. capacity cars. These standards are not being adhered to generally by the different railroads, changes being made in the truss dimensions to accommodate car construction and for design reasons. Different sections of arch bars are also used by some railroads on account of the standard section failing to meet the service conditions imposed. The committee is making a series of tests of the M. C. B. arch bar side frames, as well as of a number of individual designs, to determine their relative strength, and this data will be available for comparison with the tests of the cast-steel side frames when completed.

AXLE FAILURES UNDER TENDERS AND TENDENCY OF THE JOURNALS TO ROLL OUT OF THE BEARING.

George R. Henderson, Consulting Engineer of the Baldwin Locomotive Works, raises two questions concerning the standard *C* and *D* axles, with 5 in. by 9 in. and 5½ in. by 10

in. journals, respectively, when used under tenders in connection with the operation of the quick-action E. T. brake under emergency application as follows: Axle failures. Tendency of the journal of the axle to roll out of the bearing or under the edge of the bearing.

In reply to the first question, the committee would refer to the report of the Committee on Axles to the 1896 convention. The committee has not heard of any failures on these axles purchased according to specifications under the conditions mentioned by Mr. Henderson.

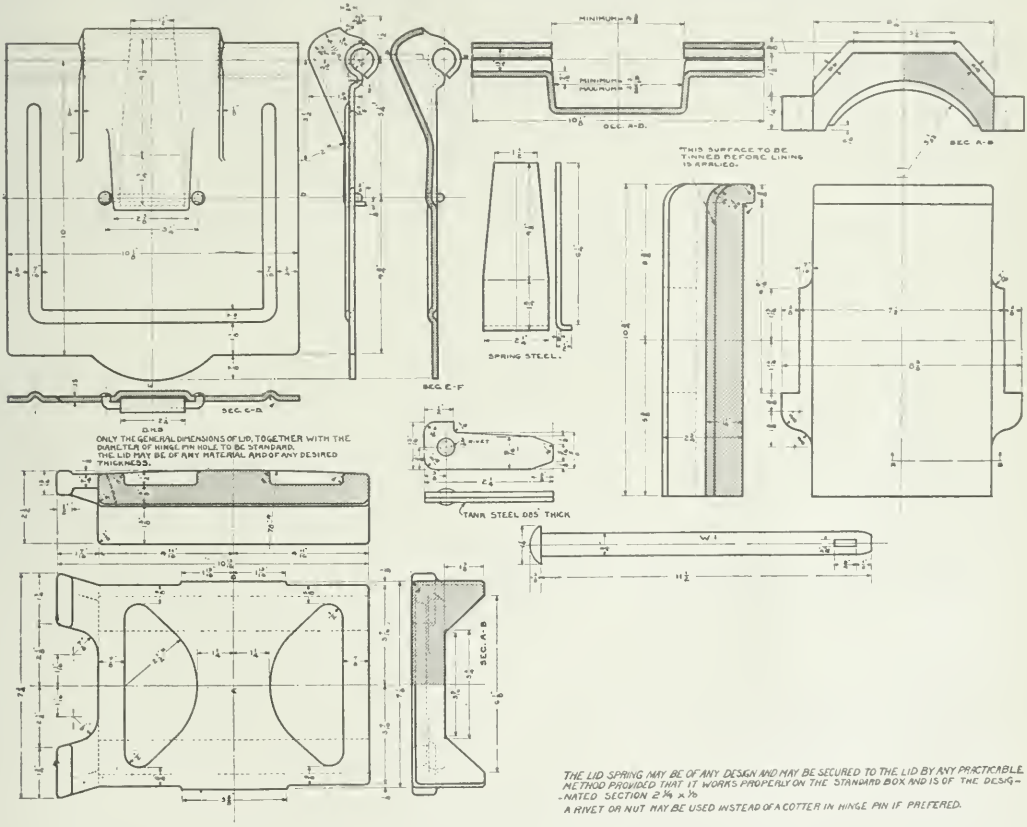
Referring to the tendency of the journal to roll out of the bearing, the committee would state that while it has no knowledge of this condition existing on tenders or freight cars, it was found on passenger cars equipped with standard M. C. B. bearings and high-hung single brake. Lowering the position of the brake shoe prevented the journal from rolling out from under the bearing. This tendency to roll out does not exist with clasp brakes. This subject was considered by the committee which conducted the Lake Shore Emergency Brake Tests, and their recommendations are recorded on page 89 of the 1910 M. C. B. Proceedings.

alloy steel springs. If alloy steel springs, which will stand about 35 per cent more stress when solid, can be furnished, it will be possible to adopt springs with sufficient flexibility for trucks having 5½ in. by 10 in. journals without any change whatever in the space now allotted for springs. For trucks having 6 in. by 11 in. journals it would then be advisable to use five springs, of exactly the same details as the four springs used for the 5½ in. by 10 in. journals, which will require the same height and about 40 per cent more width for spring space. It would then be advisable to make the bolster for the 140,000 lbs. capacity truck somewhat wider, in order to avoid, to some extent, increasing the depth.

CONSTRUCTION OF CENTER PLATES FOR STANDARD FREIGHT CARS.

This subject originated in a communication from W. J. Tollerton, General Mechanical Superintendent of the Rock Island Lines, in which he suggests for investigation "The construction of center plates, for standard freight cars, bringing present practice as shown in the M. C. B. Proceedings up to date. Center plate shown is some ten years old and not suitable for steel-constructed cars."

This center plate has been generally adopted on 100,000 lbs. capacity cars, and we have not heard of any serious objections to them. This subject will be given further consideration by the committee in connection with the design of the standard truck details.



Journal Bearing, Wedge and Lid for 6 in. x 11 in. Journal.

SPRINGS.

The committee on springs for freight car trucks at the last convention submitted a tentative design of spring for 140,000 lbs. capacity cars with arch bar trucks, recommending that the various railroad companies furnish dimensions of available space, or preferably prints of springs which have been designed or used for trucks with 6 in. by 11 in. axles. As far as has been ascertained, the Baltimore & Ohio and the Pennsylvania Railroad are the only roads who have placed such trucks in service.

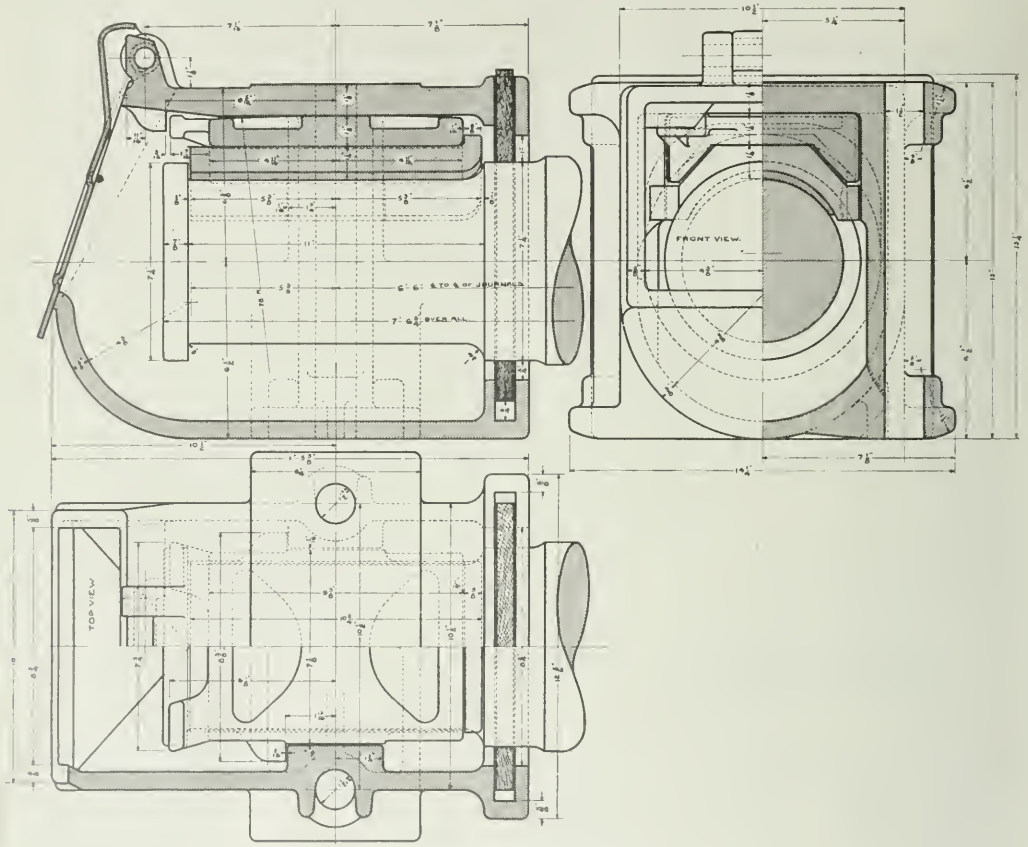
The line of investigation thus far made covers the use of

JOURNAL BOX, BEARING AND WEDGE FOR 6 IN. BY 11 IN. AXLE USED IN FREIGHT SERVICE.

D. F. Crawford, general superintendent motive power, Penna. Lines West of Pittsburgh, recommends that standards be adopted for journal box, wedge and bearings for

standard axle with 6 in. by 11 in. journal. The committee presented designs and recommended that they be submitted to letter ballot for adoption as Recommended Practice.

The report is signed by:—J. T. Wallis (Penna.), chairman; J. R. Gould (C. & O.); J. J. Tatum (B. & O.); E. W. Pratt (C. & N. W.); R. W. Burnett (C. P.); James Coleman (G. T.), and C. A. Hancock (St. L. & S. F.).



Box and Contained Parts for 6 in. x 11 in. Journal for Freight Cars.

DISCUSSION.

W. F. Dunham (C. & N. W.): I note the exhibits A and C, that the detail of the wedge indicated is not according to the latest practice of the Association. The face has been increased, and I think this should be changed in the same way before it is submitted to letter ballot.

C. A. Schroyer (C. & N. W.): I do not entirely agree with Mr. Henderson's second question included in the report insofar as the experience of our line is concerned. We have had much trouble caused by shocks in the yard while switching. This was brought very forcibly and costly to our attention, from the fact that we used cast iron oil boxes at one time, and under the 40-ton carrying-capacity cars, were having the sides of the boxes knocked out constantly. I have seen the sides of five oil boxes broken out of one car at one shock; as the result of which we substituted iron, and since then have had no trouble from that cause. I am not in favor of the shape of the wedge shown, insofar as the recesses on the top of the wedge are concerned which are put in for the purpose of saving metal in the manufacture of that wedge. You can see that the line on which the wedge carries the greatest strain there is the least amount of metal. That wedge wears into the top plate of the oil box, and we have there as much metal as it is possible for us to obtain.

E. A. Millar, (B. & M.): In line with what the last speaker said, and in connection with the report of the Committee, I would say that one of these cars is on the line I am connected with, with a journal bearing split in two. It only traveled 15 miles after it was loaded. This was not strong enough to carry the load.

C. A. Schroyer: Was it the bearing or the wedge.

E. A. Millar: They both failed.

F. F. Games, (C. of Ga.): I move that the committee be continued for another year, as they promise additional work on the lines involved, that the last item be submitted to letter ballot, and that the committee, before sending this letter out to ballot, take into consideration the remarks made about the wedge this morning.

T. M. Ramsdell, (C. & A.): Our experience with a wedge of this design is that the bearing face at the end is not sufficiently strong to stand the underthrust of the journal, that the metal should extend clear across the face of the wedge, instead of being cut out.

R. L. Kleine: I cannot understand Mr. Millar in regard to his split of the journal-bearing. Why did it split? There are upwards of 1,000 cars running with a bearing and wedges as herein shown, and we have had no trouble whatever, and there must have been some abnormal condition in his case. However, speaking for Mr. Wallis of the committee, the Committee has taken into consideration the question brought out by this wedge, and about changing the design of this wedge to conform to the outline of the present 5½ in. x 10 in. wedge.

E. A. Millar: There was no abnormal condition. The

journal had not run hot. It had a solid bearing and was on a 100,000 lb. car with 5½ in. x 11 in. journal.

J. J. Tatum, (B. & O.): We have had over a thousand of those, and we have never had such a failure. I believe the Penna and the B. & O. are operating a greater number of that class of equipment, and our experience has been that the recommended practice as herein shown and suggested, has given satisfaction.

I. S. Downing: As this seems to be on coal cars that are dumped in a coal-dumping machine, we have found on investigation, that in dumping the car upside down, the waste gets under the bearings ,and when you run again, you get a hot box. I thought it might be possible to cast a lug on the side of the box to tend to hold that waste down on coal cars. We had the same trouble with the 80,000 and 100,000 lb. capacity car, that are put through the coal dumpers.

(Mr. Gaine's motion was put and carried).

TRAIN LIGHTING.

The committee makes the following suggestions for recommended practices:

AXLES FOR AXLE DYNAMOS.

Axles for application of axle pulleys should be in accordance with the following three designs: First, axle in accordance with M. C. B. standard, rough-turned; second, axle straight between the wheel-fit collars, rough-turned; and third, axle with straight pulley fit. In any of these designs the axle pulley as recommended in paragraph 18 of recommended practices can be applied with the proper bushing.

NOTE.—The committee feels that the question of design of axles should be left to the mechanical men of the individual railroads in question.

STANDARD DESIGN OF AXLE-DYNAMO SUSPENSION.

Axle-dynamo suspension must be designed so that with full diameter wheels and truck on straight, level track, any part of the dynamo or suspension must have a clearance not less than 6 in. above top of rail, and a clearance of at least 3½ in. between any part of the mechanism attached to the car body.

In axle-dynamo suspension the metal carrying the weight of the dynamo must not be subjected to wear.

In axle-dynamo suspension, if side arms are used, the end to be secured to the truck frame must extend under transom and be bolted to the side frame near the transom, and if carried through or over end sill, must be held securely to end sill by a hooked bolt not less than ¾ in. in diameter.

When possible, the belt should go over the end sill and under the brake beam with belt clearances of at least one inch.

A typical design covering the above recommendations is shown herewith and recommended where applicable.

NOTE.—On account of the variety of trucks and car designs, it is impossible for the committee to recommend a standard suspension which will meet all conditions.

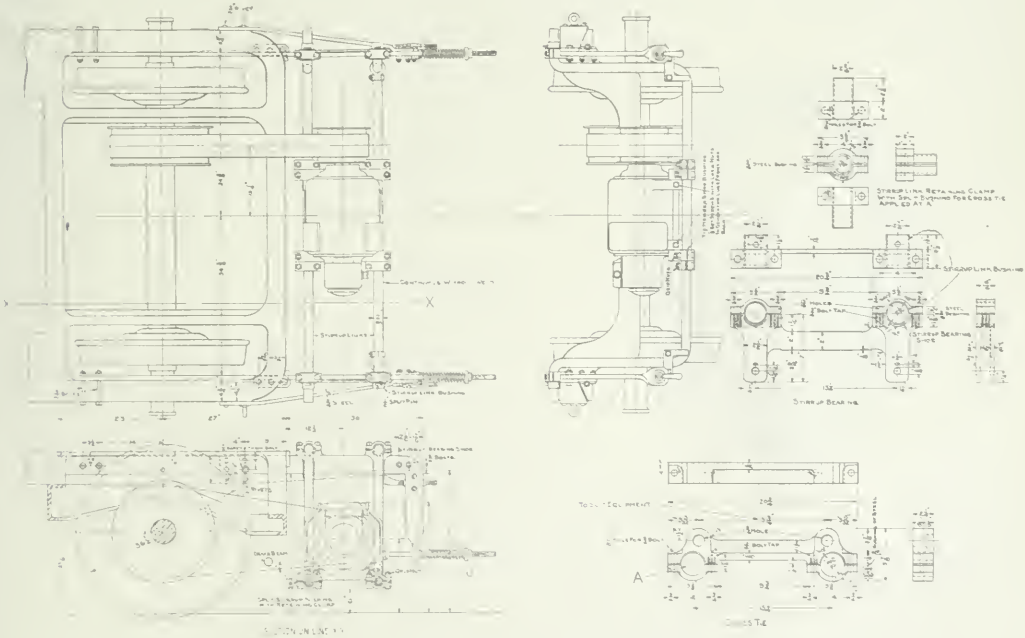
STANDARD DESIGN OF BATTERY BOX.

The inside clear dimension of battery boxes should be as follows:

Depth, front to back, 2 ft. 4 in.
Height in clear, not less than 21½ in.
Length of compartment for two standard compartment tanks or equivalent, 22⅝ in.
Length of compartment for four standard compartment tanks or equivalent, 3 ft. 9¼ in.

Battery boxes with two compartments each 22⅝ in. long, or with one compartment 3 ft. 9¼ in., must be designed to safely carry a battery weight of 1,600 lbs. Battery boxes with four compartments each 22⅝ in. long, or two compartments each 3 ft. 9¼ in. long, must be designed to safely carry a battery weight of 3,200 lbs.

That in all battery-box designs, two angle irons or straps shall extend longitudinally under the battery box in such a loca-



Dynamo Suspension, Link Type Belt Drive.

tion that in case of a defective battery-box floor the battery trays will be supported by these angle irons or straps; the angle irons or straps shall be supported to the car body independent of the battery box proper and shall be of sufficient strength in all parts to safely support the battery in accordance with the weight shown in the previous paragraph and the additional weight of the battery box proper, and the angle irons or straps and the supports for same shall be so installed that they can be readily inspected for corrosion.

MAINTENANCE AND REPAIRS OF BATTERIES.

The following repair instructions were forwarded to the Secretary, to be referred to the Arbitration Committee for insertion in the Code of Rules:

"For repairs to electric lighting equipment on cars in interchange or leased cars, the instructions issued by the manufacturers of the apparatus should be strictly adhered to. In the absence of any agreement, the material furnished and applied must be of the manufacturer's make."

In addition to the above, the Committee beg to make the following recommendations:

Under the caption of axle dynamo, the following should be added to paragraph 18:

"Diameter of axle pulleys should preferably be 17 in. or 21 in.; the diameter of generator pulley should preferably be 8 in. or 11 in."

Under the caption "Axle Dynamo," following paragraph 19, should be added the following:

"The electric connector between dynamo leads and permanent wiring on the car should be made with non-reversing self-locking receptacle and plug."

The report is signed by:—T. R. Cook (Penna.), chairman; C. A. Brandt (C. C. C. & St. L.); Ward Barnum (L. & N.); D. J. Cartwright (L. V.); E. W. Jansen (Ill. Cent.); J. H. Davis (B. & O.), and C. H. Quinn (N. & W.).

Mr. Cook presented the report and continued as follows:

In order to facilitate the handling of this report, I move that the items be referred to the Association by letter ballot by paragraphs. (The motion was carried.)

TRAIN PIPE AND CONNECTIONS FOR STEAM HEAT.

Proposed Specification for Steam Heat Hose.

The committee was continued to give consideration to this subject. It has gone into the matter very thoroughly and from previous tests, which have been reported to the Association, finds that there is so little difference between the opening in the medium-size coupler and what is known as the large coupler that it does not affect the passage of steam through the train

I. S. DOWNING,

Chairman, Committee on Train Pipe and Connections for Steam Heat.

line sufficient to warrant the large coupling. The adoption of what is known as the medium-size coupling is recommended. It also recommends a two-piece coupler, with the nipple separate, and a clamp which holds the hose on the nipple by friction.

A proposed specification for the steam-heat hose and steam-hose couplings for passenger cars is given below. Inside diameter 1⅝ inches as adopted as recommended practice in 1903.

1—MANUFACTURE.

Steam-heat hose must be composed of a tube of rubber, wrapped with five ply cotton fabric and the whole covered with rubber.

2—PHYSICAL PROPERTIES AND TESTS.

The railway company's inspector will select for test one piece at random from each lot of 200 pieces. When this hose is received at the test laboratory, a section 2½ in. long will be cut from one end in order to determine the friction, tensile strength and elongation. The remaining portion will then be subjected to steam heat in the drier. After this section has been heated another section 2½ in. long will be cut from it and used to ascertain the friction, tensile strength and elongation, in order to show the change in these characteristics due to the action of heat.

Friction Test Before Steaming.—A section 1 in. long will be cut from the hose and supported in such a manner that it will turn freely on its axis. A twenty-pound weight will be suspended from the separated end of the fabric. The latter must unwind uniformly, if at all, and not faster than 6 in. in ten minutes.

Tensile Test Before Steaming.—A strip cut from the tube with a die or other suitable means to the dimensions shown in Fig. 1 will be marked at points 2 in. apart, and the width and thickness will be accurately measured. It will then be slowly

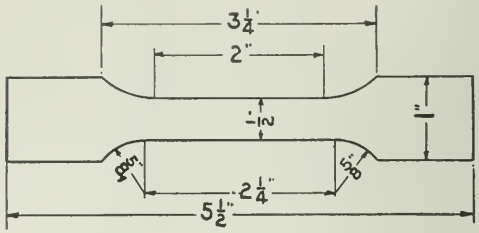


Fig. 1—Tensile Specimen.

stretched in a suitable tensile-testing machine until it breaks. The ultimate tensile strength must not be less than 600 lbs. per square inch and the elongation of the 2-in. section at the time of fracture must not be less than 6 in.

Friction Test After Steaming.—A section 1 in. long will be supported in such a manner that it will turn freely on its axis. A fifteen-pound weight will be suspended from the separated end of the fabric. The latter must unwind uniformly, if at all, and not faster than 6 in. in ten minutes.

Tensile Test After Steaming.—A strip cut from the tube with a die or other suitable means to the dimensions shown in Fig. 1 will be marked at points 2 in. apart, and the width and thickness will be accurately measured. It will then be slowly stretched in a suitable tensile-testing machine until it breaks. The ultimate tensile strength must not be less than 450 lbs. per square inch, and the elongation of the 2-in. section at the time of fracture must not be more than 8 in. or less than 4 in.

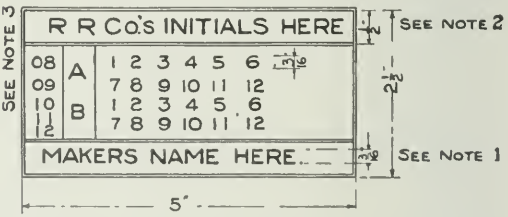
3—SIZE AND DIMENSIONS.

	Maximum, Inches.	Minimum, Inches.
Length	24¾	23¾
Inner diameter	....	....
Outer diameter	....	....
Thickness of tube	....	⅛
Thickness of cover	....	1/16

4—WORKMANSHIP.

Tube.—The tube should be composed of at least two calenders of rubber. It must be free from holes, bits of wood, bark, sand and other foreign matter, and from other imperfections. It must be so firmly joined to the fabric that it can not be pulled off without tearing it.

Fabric.—The fabric must be of duck, with the warp containing



NOTE:—
No.1- MANUFACTURERS NAME TO BE PLACED IN THIS SPACE IN 3/16" LETTERS.
No.2- RAILROAD CO.'S INITIALS WILL BE FURNISHED WITH INDIVIDUAL ORDERS.
No.3- THE FIRST FIGURE IS TO BE THE YEAR WHEN HOSE IS MADE. FOLLOWING FIGURES ARE TO BE SUCCESIVE YEARS.

Fig. 2.

not less than 27 strands, 3 threads per strand, and the filler 18 strands and 4 threads per strand. It must be frictioned on both sides and have, in addition, a distinct layer of rubber on one side, readily visible between the plys when the finished hose is cut open.

Cover.—The material of the cover should be a rubber compound which has good weather-resisting qualities, as firmly

attached to the fabric as is the tube, and to be equally free from defects. The end of the hose should be cut off true to length, but shall not be capped.

5—MARKING.

Serial Number.—Each lot of 200 hose or less must bear the manufacturer's serial number, beginning with one on the first of each year and continuing consecutively until the end of the year. Serial numbers of hose which are rejected must not be used again. With each lot of 200 hose or less, one extra piece of hose must be furnished free of cost.

Label.—Each piece of hose must have securely vulcanized to it a label of white or red rubber, as shown on Fig 2. The letters and figures in the badge plate must be 3/16 in. high and 1/32 in. in relief, except in serial number, which must be 1/2 in. in height and 1/32 in. in relief.

6—INSPECTION.

Rejection.—If the sample fails to pass the above tests, the lot represented by it will be rejected, and the same serial number must not be applied to any other steam hose during the same calendar year.

Inspection.—If the sample passes all the tests, all pieces

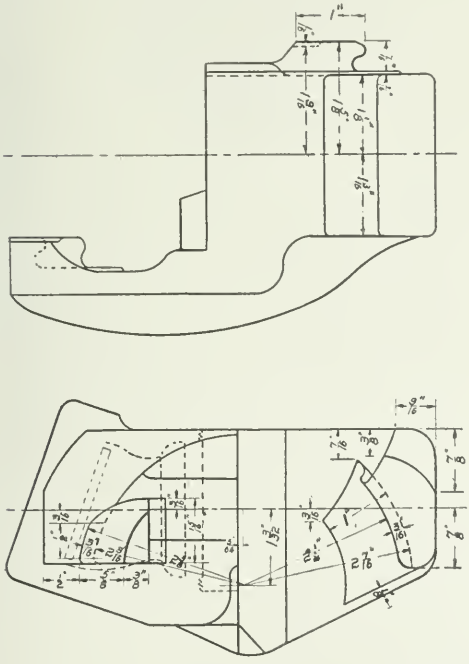


Fig. 3.

represented by it will be accepted if free from injurious mechanical defects.

Rejected hose will be returned at the expense of the manufacturer.

You will note, paragraph 3, dimensions—the committee has not recommended inner or outer diameter. It does not feel that the adoption of the specification need be delayed on account of this and hopes the association will approve of the recommendations. If this is done, the committee has in mind the running of tests of hose made under these specifications, with inside diameter 1¼ in. with six-ply, 1⅝ in. with five-ply, 1½ in. with ends expanded five-ply.

The committee recommends that these tests be conducted by the Committee on Specifications for Air Hose and that this committee be discharged.

STEAM HOSE COUPLINGS.

1. Coupling contour to be such that coupling will interchange with the coupler as shown on Fig. 3.

2. Coupler must have a locking attachment which will securely lock the two couplers together without depending on the hose in any way.

3. The angle of the nipple to a line perpendicular to the coupling face of the coupling should not be less than 20 degrees.

4. The coupler should be of the two-piece type, having the nipple separate and, screwed into the coupler head with 1½-in. pipe thread. The nipple shall be of the type having a shoulder to engage clamp-nipple shown on Fig. 4.

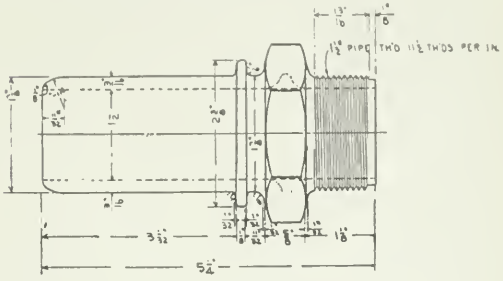

Fig. 4.

5. The clamp shall be of the two-piece type, as shown on Fig. 5.

6. The minimum diameter of hose through the gasket to be 1 7/16 in.

7. Gasket shall be flat face, securely held in place in coupler head, but so designed that they can be removed and replaced without removing the hose or coupler head from the car.

The report is signed by:—I. S. Downing (L. S. & M. S.),

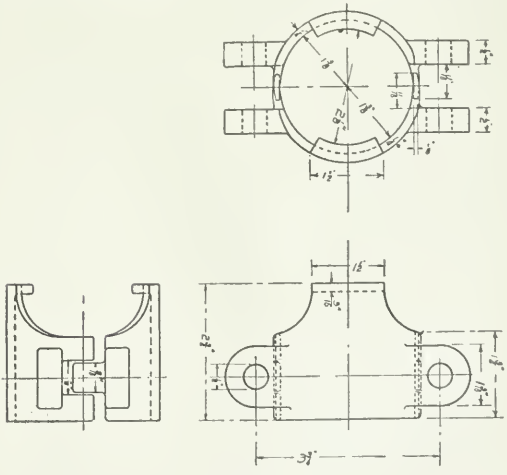

Fig. 5.

chairman; C. A. Schroyer (C. & N. W.); T. H. Russum (B. & O.); J. J. Ewing (C. & O.), and W. C. Arp (Vandalia).

DISCUSSION.

F. F. Gaines, (C. of Georgia): I think this is one of the things we need to get down to standard, especially the coupler and the specifications for steam hose. The report of the committee is thorough, and I move that the two recommendations, one for standard specification for steam hose and the other for coupler, be referred to letter ballot for recommended practice.

I. S. Downing: There is another recommendation I failed to mention—we did not give the inner or the outer dimension of the hose. We find some are using 1¾ in., others 1½ in. and others 1⅝ in. Now, either of those diameters can be used with this nipple; and we recommend that they be turned over to the air-hose committee to be followed up, and this committee discharged.

President Fuller: Is the outside diameter mentioned?

I. S. Downing: The roads using 6-ply outside diameter claim that they get away with kinking absolutely; while with the others there is a lot of kinking. We feel that this other committee on

air hose could test out those three sizes to determine whether we should get 5-ply, 1½ in., or 6-ply, 1¾ in.

C. A. Schroyer (C. & N. W.): In connection with the steam-hose specifications I am afraid they will put us through the same course of sprouts as the air-brake hose specifications did, and if the adoption of this as a recommended practice, which will be followed by having it for a standard practice, is going to cause the rejection of the cars because they have not the same kind or brand on the hose that the specifications call for, it will put us in the position of the air-brake matter, where simply because a brand does not comply with the regulations of the association, it could not be received; and that cost the railroads of the country thousands and thousands of dollars.

I. S. Downing: As far as Mr. Schroyer is concerned, that will not affect matters until we get it into the M. C. B. rules. There is no reason why we should force roads to do this. It is a guide for roads not having chemists and engineers' tests for such matters; and then it is well for them to have the M. C. B. back of them.

C. A. Schroyer: The Committee is not recommending any given inside diameter of hose. Now, the Northwestern Railroad, in the use of air-brake hose, always purchased 1¼ in. inside diameter for freight car use, with the expanded end sufficiently expanded to meet the requirements of the nipples used by us. After that was changed and we bought an air-brake hose 1½ in. or 1⅝ in. straight through, which the manufacturers claim would not cost us any more money than the 1¼ in. hose with expanded end. We have found we have paid ¾ of a cent to a cent and a half more because of that increased inside diameter of the hose.

F. F. Gaines: I think Mr. Schroyer is unduly worried about this thing. We are not going beyond recommended practice.

(Mr. Gaines' motion was put and carried.)

TANK CARS.

Since the 1912 report, the tank car committee has approved, as meeting the requirements of the Master Car Builders' specifications for "Special" tank cars:

Design and specification for lagged tank car for the transportation of liquefied chlorin gas, submitted by the Goldschmidt Detinning Company, New York City.

Design and specification for lagged tank car for the transportation of liquefied petroleum gas, submitted by the Pennsylvania Tank Car Company, Pittsburgh, Pa.

The committee also approved a design of cast-steel vent with frangible lead disk, for sulphuric acid tank cars, submitted by the Crescent Tank Line, New York City.

The committee also considered the question of the handling in tank cars of bisulphide of carbon, which is highly inflammable, and gives off vapors under tension. As, however, the vapor tension came within the requirements for "Ordinary" tank cars, and as the chief inspector of the Bureau of Explosives saw no objection to the handling of this product in ordinary cars, the committee advised the Taylor Chemical Company, Penn Yan, N. Y., that there was nothing in the rules governing the transportation of materials in tank cars to prevent the handling of bisulphide of carbon in tank cars which meet the requirements of the M. C. B. specification for "Ordinary" tank cars.

The committee has still pending:

Design for tank car for casing head gasoline submitted by the German American Car Company, which has not been approved by the committee, pending revision of the drawings.

Also, question as to the use of existing tank cars for the transportation of ammonia solutions. In the case of this product it develops that the vapor tension at 100 degs. F., may be as high as 22 lbs. per sq. in., and that the variation in the bursting pressure of lead disks nominally intended to rupture at 25 lbs. is that such a disk might rupture at 22 lbs. Consequently, after consultation with the chief inspector of the Bureau of Explosives, it has been decided that the lead disk should be made for a nominal bursting pressure of 30 lbs. This pressure would not in any way injure the tank, whereas the rupture of the disk would permit the loss of the most valuable constituent of the solution, viz., the ammonia gas. In view of the information that the life of tanks carrying ammonia liquors is much shorter than that of petroleum-carrying cars, the committee thinks it wise, for the present, to require retests at intervals of not over five years. These changes have been covered in the revision of the Tank Car Specifications.

As regards the tests of tanks and safety valves now provided for by the tank car specifications, the committee feels that some improvement should be made on the present practice, by requiring that a certified record of the tests shall be available in some one office. Heretofore the rule has been that the railroad on whose line a car is at home shall exercise supervision. The importance of these tests will be very great in the event of law suits following damage, and your committee believes that the office of the chief inspector of the Bureau of Explosives would be the proper place for the filing of these certificates. Considering the fact that the Interstate Commerce Commission requires that tank cars shall conform to the rules of the Master Car Builders' Association, it is highly probable that a ruling will be made by the commission, fixing the procedure to be followed in reporting the tests of both cars and valves.

Nothing has transpired during the past year to call for any radical changes in the tank car specifications. The changes which the committee recommends are principally with a view to removing ambiguities.

The report is signed by:—A. W. Gibbs, (Penna.), chairman; C. E. Chambers, (C. of N. J.); S. K. Dickerson, (L. S. & M. S.); J. W. Fogg, (B. & O.); E. J. Searles, (B. & O.); Wm. Schlafge, (Erie); Thos. Beaghen, Jr., (Union Tank Line), and C. A. Shoemaker, (Ger.-Am. Car Lines).

DISCUSSION.

Mr. Hartley, of the Summit Solvay Company, was given the privilege of the floor.

Mr. Hartley: There is one thing we would hesitate to follow in the tank car specifications and that is the recommendation which you have put in simply as a preference, as to how you shall anchor a tank on the underframe. We continued to hold our tank in place with head blocks instead of anchoring the tank to the underframe with saddle riveted to the underframe. Our belief is that in the tanks as we ship those products, that very often the rivets in the saddles anchoring the tank would simply be tight under the heads, and not fill the holes.

After the rows of nuts had been eaten away under the head of the rivet, we would have a very annoying leak which is a very expensive one to stop. It was suggested that the end sills were being distorted by the movement of the loaded tank. We tried to overcome that by getting 55 lb. channels in our centre sills, and we are greatly increasing the sectional area of the central sills over the requirements, and also have the head block reinforced and have two heavy steel castings.

We test all our tanks every 3 years instead of every 5 years. We test some of our tanks every trip before they are loaded, purely as a matter of operating policy. We think it is better to do so in some cases. I understand that the requirements in the case of tanks to be built from now on is that they shall stand a bursting pressure of 240 lb., and be subject to a test pressure of 160 lb. We believe if a factor of safety was introduced, there would be no evading the design or the strengthening of that tank.

It is possible that the tanks could be made safe to sustain the bursting pressure of 240 lbs. by butt strapping and the use of a high tensile strength material, and the use of lighter plates, which however, would not make as good a tank to stand corrosion. The lighter shell plate would undoubtedly corrode somewhat more quickly, and perhaps the tank would not be good for 5 year service. However, in the majority of cases we believe the test once every 5 years ought to be sufficient for the larger number of tank car users, but a factor of safety introduced into your requirements would actually insist that the tanks should be made of certain materials, and perhaps even the thickness of the materials should be specified, that would carry with it automatically its high bursting pressure.

(The recommendations were referred to letter ballot and the executive committee was instructed to take the recommendation in regard to the filing of the tank car tests, up with the Bureau of Explosives.)

SPECIFICATIONS FOR FREIGHT CAR TRUCK SIDES AND BOLSTERS.

In the committee's first report, presented at the 1912 convention, it proposed for truck sides and bolsters specifications concerning the manufacture, chemical properties, physical properties, and inspection of truck sides and bolsters. By subsequent action these specifications have been added to the recommended practice of the Association. In its first report the committee also proposed tentative specifications for tests of truck sides and bolsters. It recommended that if the committee were continued, funds be provided for making tests, in order to develop information

which could form the basis for final specifications for testing truck sides and bolsters. The executive committee of the Association has not found it feasible to provide funds for this work during the past year and the committee has, therefore, been unable to make progress along the lines originally laid down. In the expectation that during the coming year funds may be made available to carry on this work, we recommend that the committee be continued.

E. C. SCHMIDT.

Chairman, Committee on Specifications for Tests of Steel Truck Sides and Bolsters for Cars of 80,000, 100,000, 150,000 Pounds Capacity.

The report is signed by:—Edward C. Schmidt (Univ. of Ill.), chairman; J. S. Sheafe (Ill. Cent.), and C. D. Young (Penna.).

(The report was referred to the executive committee and the committee instructed to work jointly with the committee on freight car trucks.)

RETIREMENT OF 20- AND 25-TON CARS FROM INTERCHANGE SERVICE.

The question of the use of cars of 40,000 lbs. and 50,000 lbs. capacity in interchange is one that is being considered very seriously in different parts of the country, and it has been suggested that it be taken up and discussed at the convention. The suggestion is made that the subject be given a thorough airing at the convention, and if thought advisable, to take the matter up with a view to ascertaining whether it is practicable at this time to withdraw from interchange service all cars of 40,000 lbs. and 50,000 lbs capacity, and restrict their use to the owning line.

Signed—Jos. W. Taylor, Secretary.

President Fuller: This is a subject, gentlemen, that I believe warrants more than passing notice. We all know, especially in the mountain countries, that the light capacity cars are getting in our heavy tonnage trains ,and it is believed by a good many that a large number of these cars should be confined to their home lines, and not used for any interchange work. We will in the West notice particularly that a large number of cars loaded to the coast and which have to go over the mountains, by the Eastern roads, are very old, light-capacity cars and it is necessary for us to either transfer the load or take the chances of hauling these light cars. From the point of safety, if nothing else, as well as economy, we believe that every effort should be made to keep the light capacity cars, 40,000 and 50,000 lbs., at home where they belong.

F. W. Brazier, (N. Y. C. Lines): I believe we should set a date in the very near future that cars of 50,000 lbs. capacity and under will not be accepted in interchange. I realize in the past year there has been a great shortage of cars. However, the light capacity cars that are in service to-day are not strong enough to be handled in trains with heavy equipment. The draft attachments and construction of the cars are such that they are constantly being sent to the shops for repairs. I have recently received a letter from one of the large trunk lines calling attention to the number of foreign cars repaired and his records show that 50 per cent. of the total number of cars receiving repairs were foreign cars. I find on our own system that our percentage of foreign cars repaired runs very much higher than this, in fact, our percentage of foreign cars is about 60 per cent. Another important point is many railroads to-day are not making proper repairs to the equipment and are maintaining certain parts of cars that are expensive, if not obsolete they are repaired one day then go on the repair track again in a few days doing the same work over and over again. It is all very well to save a few dollars on the first cost, but is it a wise policy to build cars that will not stand two years service without being practically rebuilt and the money saved on the first cost is spent ten times over in maintaining them. I refer particularly to cars built of steel construction with the view of keeping the light weights down to the lowest possible point, the result is, there are in this country some steel cars and steel underframe cars that are really weaker than the old standard wooden cars.

I want to refer to matters that were brought up last year, that is the condition of box car doors on freight equipment and other parts of cars that are constantly needing repairs, and when they do receive repairs, the parts that fail are simply perpetuated, no aim taken to improve the defective parts, the results are they only make a short mileage before they go to the repair tracks for the same defects caused by not improving the parts that fail.

We had quite a number of accidents caused by light arch bars and arch bar bolts not properly fastened giving way, and it might interest this convention to know that during 30 days in the months of February and March on the Western District alone, we used a little over a ton of nuts a day and these were applied to trucks on loaded cars received in and around Buffalo to make them safe to run over our lines. It has been advocated and recommended for years that on all forms of trucks that depend on bolts to hold them together, that attention should and must be paid to keep the nuts in proper place. You are aware that this is an owner's defect. I firmly believe that all arch bar type of trucks should have proper nuts put on the bolts and a spring cotter or a spring key put into every bolt to keep the nut in place, and if the spring cotter is properly applied, there will be no danger then of the arch bars spreading.

I desire to emphasize again the importance when getting up designs of cars and trucks of paying more attention to the cost of maintenance and overcome the weak features in construction that are so apparent on railroad equipment throughout the country. The question again comes in of the first cost. Were cars designed with the thought of keeping them off the repair tracks instead of saving the first cost, when they are built, it would be money well invested. More care should be taken to watch the defects spoken of here in this paper and others too numerous to mention that would in the end save hundreds of thousands of dollars throughout the year in the cost and maintenance of freight equipment and help reduce periodical car shortage in that the cars will be carrying freight instead of awaiting and undergoing repairs.

I therefore make the following motion:

After January 1, 1915, cars of 50,000 capacity and under, will not be accepted in interchange unless such cars are equipped with steel underframe and all metal trucks.

C. F. Giles (L. & N.): We have 958 refrigerator cars, 40 ft. in length, 50,000 lb. capacity. These cars have metal-body bolsters and all metal trucks. They are comparatively new. They are used in the banana and fruit trade, and we feel there should be an exception made in connection with refrigerator cars in which fruit is handled.

J. J. Hennessey (C. M. & St. P.): It seems to me the way this question has been put before the convention, it is hardly the correct proposition, the question of barring cars on account of light capacity. I can show a great many figures on any class of cars you want to put up. It is not the capacity of the car which should count. There are any number of 60,000 lb. cars built, and in service, with the old wooden bolsters and the short draft timbers. Then you got away from the old wooden bolster, and put in the cast wheel bolster, but you did not increase the length of your draft timbers, you did not increase the number of your bolts. There are many of the 40,000 and 50,000 lb. capacity cars which have long draft riggings, continuous side sills, the side sills running the full length of the car. That car, in my opinion, is a better car in interchange than a car with a poor set of draft timbers. How many stock cars are there of 40,000 or 50,000 lb. capacity? How will you load them beyond the capacity while they are in the service they are fit for? I think, if we do anything at all, we had better confine ourselves to the draft timber construction, the character of the draft timber, and the draft springs. I do not think it would be wise for this association, and I do not think the association is in a position to say that we will not use a certain capacity car. Every road, under rule 2, has a right

to reject any car they do not consider safe to run over their lines, and I do not believe we can go any further, gentlemen.

D. R. MacBain (L. S. & M. S.): I want to endorse every word that Mr. Brazier has said. The idea of this movement is to bring the whole standard of equipment up after a certain time, so that it will be better than it is at the present time. There are a great many railroads in the country that are spending large amounts of money to bring their equipment up to a point where it will stand modern operation and modern handling in long trains, and hump yard service, but there are, on the other hand, a considerable number of roads which do not have the long trains and do not have the hump yard service, which are not doing this. Possibly, too, this small equipment in the hands of such railroads is suitable for the district in which they are operated, but when it comes to the matter of interchanging freight cars on railroads like the New York Central lines it becomes a serious proposition.

The New York Central lines never operate more than 50 per cent. of their own equipment on their own rails. The other 50 per cent., or a little less, is foreign equipment, hence the chances for failure due to light construction of draft gear, etc., is very great. A short time ago I obtained a report of all draft gear and draft bar failures that occurred from April 15 to June 1. Briefly stating the matter, by totals, there were 47.6 per cent., outside of the New York Central Line's cars, operated on the Lake Shore and Michigan Southern Railroad, and out of that 47.6 per cent. there were 73.8 per cent. of the drawbar failures which occurred on the foreign equipment. That is why, gentlemen, we are trying to bring about a better standard. Now in connection with this whole thing, I want to state that the New York Central Lines have adopted a policy in the maintenance and repairs of their cars which is designed to bring the equipment to the highest possible plane of efficiency, a standard which we believe will be suitable for all the conditions of modern service. I want to endorse strongly what Mr. Brazier said regardless of any arguments to the contrary.

F. F. Gaines (C. of Ga.): I not only want to endorse what Mr. Brazier and Mr. MacBain said, but I want to comment on what Mr. Hennessey said: Our experience is that the low capacity cars are not in line with the other cars, and we found it so much so that our operating department put an order into effect whereby if we get a car in interchange less than 60,000 lb. capacity, we consider it more economical to transfer the load rather than to handle the light capacity car.

R. E. Smith (A. C. L.): I inquire as a matter of information, whether this Association has the authority to pass the resolution which has been offered? It seems to me that the owners of railroad properties in this country ought to have the first say in this matter. It seems to me that this matter being, to a very considerable extent a transportation matter, that the movement for the retirement of low capacity cars ought to start from some other source than this Association.

As far as the line with which I am connected is concerned, we unfortunately have a number of low capacity cars, but they were designed and built for a class of commodity that cannot be loaded in high capacity cars, not even 60,000 lb. or even 50,000 lb. cars. I am speaking now of perishable fruit of which we handle a very large amount. In the case of these 40,000 lb. capacity cars, we are very materially improving their sub-structures and the draft arrangement, and we are bringing these 40,000 lb. capacity wooden cars up to the same degree of strength and improved design as we practically have in the case of our 60,000 lb wooden cars, which were built a few years ago. We have gone to the extent of putting in 6 in. centre sills and 1¼ in. branch bolts and improved the draft gear.

C. A. Schroyer (C. & N. W.): I question very seriously as to whether this association has the authority to say that on a certain day we will not accept certain cars of certain capacity in inter change. It might be well enough for us to recommend to our superior officers a rule of that kind, which they can adopt would be put in force on a certain day. The 40,000 and 50,000 lb. cars are going out of service very rapidly. There are no more of them being built, and those which are in operation today were built of such class of timber as cannot be produced today. Many of these cars are built with ten to twelve ft. draft timbers, the draft timber extending between the upper and lower plate of the body bolster, and as a draft apparatus aside from the element of the coiled springs now in there, there is no better apparatus which was ever put into a car. I would prefer that 12 ft. draft timber with the coiled springs than I would many of the [illegible] modern built steel cars, with coiled spring draft apparatus in them. We would have less trouble. We have about 10,000 cars of 50,000 lbs. capacity. You can put on just as poor side doors on a 100,000 capacity car as was ever put on a 40,000 lb. capacity car. The whole proposition applies more generally to the general upkeep of the car.

D. F Crawford (Penna.): I agree with both sides of the argument. For some time past I have been following up what we call "truck accidents." The conditions on the Pennsylvania Lines, West, are quite similar to those on the Lake Shore in that approximately 50 per cent. of our traffic is handled in foreign cars. Since 1904 I have had a monthly report of truck accidents. I regret to say that 80 per cent. of the truck accidents occur on foreign cars brought to our lines. I feel that this association is the proper association to bring this subject up, but not the proper association to decide it. I would move that a committee of this association obtain from each of the members the situation as to each of their cars, and ascertain if it will not be possible to make a recommendation to the American Railway Association which will permit, that for the benefit of the traffic conditions of the country, we may set aside the older cars which are giving every one of us trouble that are moving them.

I. S. Downing (L. S. & M. S.): I want to agree with Mr. Hennessey as to what he says about some of the heavier cars. I think that the 50,000 lb. capacity cars and under, are not being properly maintained and should be taken out of service. There are cars heavier than these, with short draft timbers, which are not as good as some of the lighter capacity cars, as far as draft timbers are concerned. I think we should legislate to take these short-draft timber cars out of service in the near future.

M. K. Barnum (Ill. Cent.): I second Mr. Crawford's motion. I do not think there is anyone in this room who will contend that the 40,000 lb. or 50,000 lb. capacity car is sufficiently profitable to maintain and operate, or that we are justified in keeping up these cars beyond their normal life, as many have been kept in service up to the present time. Some of these cars are 25 years old. They are going into the heavier modern trains with better equipment and jeopardizing the better equipment, and I venture to say that not a day passes that some one of these cars does not double up and damage many thousands of dollars worth of modern cars besides the track, lading and other railroad property.

The road with which I am connected has had a very serious time with this class of equipment. About 54 per cent. of the cars in service on the road have been foreign cars during the last six or eight months, and a very large percentage of bad order cars have been taken out of that number, even though we have given them preference in making repairs. In the case with Mr. Giles mentions, that of the refrigerator cars, of course the refrigerator cars would be excepted from any action taken. In my opinion, one of the principal causes of the increasing cost of freight car repairs is the larger and unwarranted amount of money spent in maintaining the old light capacity cars.

H. J. Small (So. Pac.): These small capacity cars are passed on out to the coast, and there is nothing to do with a great many of them but to dump them in the Pacific Ocean, and that is what we feel like doing with a large number of them. We have considered that the 40,000 lb. capacity car is obsolete. We have placed the value of a 40,000 lb. capacity car at $100. If it costs more than that to repair it, we break it up. We fixed up an arrangement among ourselves to keep the cars on our own rails, and I think we have succeeded to a very great extent. We ought to adopt the idea contained in this circular letter. We are great sufferers on account of this. These cars come out to us 3,000 miles over the mountain grades with Mallet locomotives hauling them and by the time they get to San Francisco or Los Angeles, it is a pretty difficult proposition to repair them so that they can go back east, which we are obligated to do, or to pay for the cars.

J. J Tatum (B. & O.): I believe our company would advocate the recommendation made by Mr. Brazier It has been said that it would not be within the power of this organization to legislate the 40,000 lb. and 50,000 lb. capacity cars out of the interchange of cars As I understand Mr. Brazier's recommendation, that is not its object He has suggested that the cars would be accepted if equipped with steel underframes and all metal trucks. If that is the case, I think the Association has just as much right to render such a decision in regard to applying steel underframes and legislating the use of wooden 40,000 lb an 50,000 lb. capacity cars out of interchange, as they have the right to say that they will not after a certain date, accept cars not equipped with the American Continuous draft gear.

C. A Schroyer: No one with any of these cars is advocat-

ing their rejection from interchange, and those opposing it are the only ones who own lots of these cars. It is not for you to stand in judgment on these cars, or on the roads that have them; or to ask why they cannot destroy them and get others. I hope the chief representatives of this association will canvass among their officers as to what their wishes are in regard to this matter; and when we come here next year, reinforced by their wishes, then we are in position to say that after a certain day we will not accept a certain car of that kind, but we cannot do it until we are so reinforced.

M. K. Barnum: The effect of this movement means to check the interchange of these cars, and consign them to the scrap heap unless you wish to continue them in service. But I do believe that the time has come when some more definite action toward retiring these light capacity cars should be taken. Therefore, I second Mr. Crawford's amendment to Mr. Brazier's motion.

R. L. Kleine: The reason the roads that handle the heavy equipment today do not have the 40,000 and 50,000 lb. capacity cars in service was that they were compelled to take them out of service, and are still doing it; and therefore it is an injustice to place on these roads in interchange, these 40,000 and 50,000 lb. capacity cars, which are liable to result in accidents. Furthermore, on the door question, the situation is so serious that irrespective of the interchange rules, it is almost necessary to put a prohibition on that account. We all have got to put our shoulder to the wheel and do something more to put the car door in safe condition for transportation.

Samuel Lynn, (P. & L. E.): Our road doesn't have 40,000 and 50,000 lb. capacity cars. We did have thousands of them, but we have got rid of them; and every car up to 60,000 lb. capacity, that requires $100 or $150 repairs, must be torn down. There is another thing in connection with delegating a car to the scrap pile—a number of industries are refusing to load 40,000 and 50,000 lb. capacity cars.

F. W. Brazier: Some of our roads are furnishing your roads with 100,000 lb. cars, and you send your 60,000 lb. ones to us. I touched on the condition of car doors and trucks and general repairs and many car men in here are glad that I said it, as they have managers and officers who will not give them the means or the facilities to repair the cars. And the sooner it goes up to the management, the better for us.

D. F. Crawford: My idea in making the motion was that we will be as far along with a good investigation of this subject as to put in our resolutions today, and that after January 1, 1915, something should happen. It would not benefit the immediate conditions more than to have a thorough knowledge of the condition when it is presented to the convention next year.

D. R. MacBain: The man with the modern equipment is getting 45 cents a day from the man maintaining the old little things; and it is not fair on the face of it, that the railroads who have spent the money should be penalized all the time. That is aside from any traffic or operating conditions.

(Mr. Crawford's motion was put and carried).

ABUSE OF THE REPAIR CARD.

The following is the discussion on this subject which was presented at the close of yesterday's session. (See *Railway Age Gazette* June 17, page 1416).

D. F. Crawford: Now, in the abuse of the repair card, it has been intimated that many of us are dishonest in making out bills. I wanted to see how dishonest we were. I therefore obtained for one year the number of car days the Pennsylvania Railroad pooled cars, all lines East and West of Pittsburg, were on foreign roads, and the number of days foreign cars were on our roads, and divided the car days into the amount of money we paid and received respectively. I found that for Pennsylvania cars on foreign roads, it was 5¾ cents a day; and in the case of foreign cars on the Pennsylvania roads, twelve cents a day. Gentlemen, I do not think we are dishonest.

My idea is that there undoubtedly have been improper bills for repairs, but in our worrying about the abuse of the repair card, I am afraid we are straining at a gnat and swallowing a camel. On one line, the General Superintendent of Motive Power, who kindly looked the information up for me, advised me that our cars on other lines cost us 2.6 cents a day, and other cars on our lines cast 15.8 cents a day. In other words, you can cut that bill in the middle and multiply the other by two and still have 50 per cent. discrepancy.

Now, if instead of spending so much time on the abuse of the repair card, and writing letters to each other and trying to find these minute amounts which are billed improperly, let us repair the cars. I took the annual report of the two roads in question for those figures, 2.6 and 15.8, and I found they cost the owner $58 per car per year; and I am advised that one-half the equipment is wooden underframe and one-half steel underframe; whereas the Pennsylvania Railroad is paying over $80 per year per car, with an equipment of nearly 40 per cent. of steel cars, and 40 per cent. of steel underframes, and less than 30 per cent. wooden cars.

Gentlemen, if we will repair our cars and keep them in service, we will not worry about the repair cards. As Mr. Brazier said: Start with a good car and keep the good car up. We are interested in 2,400,000 live cars, built to handle the traffic in this country. But I was interested yesterday in the amount of time we spent in discussing a few of those cars which died while away from home—in other words, the depreciation rate.

First I would say, build good cars; look at all the annual reports of all the railroads and compare the cost of all the railroads are spending to maintain their cars. It gives a very clear indication of what you are paying for. Our cars are on the lines of 20 roads, and the same twenty roads have cars on our line, and with the expectation of comparing cost of repairing cars, with the bills they make against us, as well as those that we make against them! and I think you will find a clear relation between the cost per mile in the annual report of each railroad against whom you make the bills.

R. E. Smith (A. C. L.): The debit balance against us for nine months of the present year was something like $235,000 on cars repaired. That is, bills we paid to foreign lines for repairs of cars exceeded the repairs, charges paid us by foreign lines for repairs of cars by $235,000. You will admit that was quite a serious situation, and when I was called upon to explain—and I could not explain it—and I cannot explain it today—but I made an honest effort to get some facts. I want to say that 50 per cent. of the cars that pass over our railroad for light, medium and heavier traffic, amount to 50 per cent. of all cars we repair, and I am not prepared to accept the insinuation Mr. Crawford made that we do not maintain our cars. That $58 may refer to the character of our equipment and the character of our service. I think it is a question that needs some light.

I found in my investigation, that our men were not thoroughly posted. I believe part of the explanation of the discrepancy is due to the fact that we have failed to put in all the bills we should have put in. But it does strike me as peculiar that we should be the only line that should make such replies. Many gentlemen said they were in the same fix—that the debit was against them. I am simply after light on this subject.

D. F. Crawford: The charge of dishonesty in the freight car repair bills was made in the convention of 1909; it was referred to by F. A. Delano in the report made to you yesterday. Mr. Smith's letter gave me an opportunity, and started me on an investigation which I wished to make. Mr. Smith's entire force is welcome on the entire Pennsylvania Line west of Pittsburgh, at any time.

Several gentlemen have stated that 50 per cent. of the cars repaired on their lines are foreign cars. I had a census taken and that showed that on our Southwestern System that a little more than 50 per cent. were foreign cars; but on our Northern System about 35 per cent., and on our Central System almost 50 per cent. On the Lake Shore, 50 per cent. were on foreign cars. Now, there are horse cars somewhere. So I took the figures of the Pennsylvania cars away, and all the roads of the Pennsylvania, and I was interested to find that we practically have Mr. Smith's figures, taking all of his cars away and all his cars home. Mr. Smith's figures, as I recollect, were 6 and 12 cents, but who got the 12 and who got the 6? My whole idea is to guard this situation, we must look for a larger thing than errors. I do not know but there are 10, 12 and 13 per cent., but I think they will not run much over 10.

I will take the cost line Mr. Smith referred to, and if we divide his by two and multiply ours by two, there would still be a discrepancy of 50 per cent. that would exist. You will find that by inspection of our accounts or methods. If anyone was in doubt as to car bills, we wish they would ascertain the car days at home and the car day abroad. The cost of cars per day, and then take it up with each other, as we all want to maintain the Mast Car Builder Rules of Interchange which have ben based on inherent honesty.

E. W. Pratt, (C. & N. W.): This method, it seems to me, is about as vague as to say how much coal. We try to to keep as many of our cars at home as we can, and as few on the road as possible; and we are repairing as few foreign cars as possible, compared with our own. We can see why your bill would be higher on the Pennsylvania Railroad and the B. & O., the Santa Fe or other high grade railroads. We

have divisions that have three or four times the draft values. Our percentage of doubt heading is almost nothing. When such cars as ours go over the Pennsylvania hills with heavy engines on them, why the defects of course develop.

F. F. Gaines: I found the situation was that a large number of our inspectors at interchange points were putting in as few interchange repair cards as possible, partly from weakness and partly from laziness. Although our bills against us are considerably greater than our bills against foreign roads, and we expect them to be, partly on account of the territory. Still we have made a decided increase by checking up our car inspectors and educating them; and at the same time laying down the law that we did not want anything that was not our own.

President Fuller: Did you notice any difference between "Since November 1st" and "Prior to November 1st"?

F. F. Gaines: Yes, sir, we did.

I. S. Downing (L. S. & M. S.): I want to raise a question in regard to different roads, in saying there is such a percentage of foreign cars as compared with their own cars. I think your own cars get much heavier repairs than the foreign cars. Taking them as a unit, your foreign cars go ahead.

CAPACITY MARKING OF FREIGHT CARS.

The committee sent out to the members a circular of inquiry to which 35 replies, representing 924 votes were received. A careful analysis of these replies is as follows:

Sixteen lines, representing 322 votes, reported owning or knowing of weak cars or cars that would prove structurally weak if loaded to full axle capacity. These cars are for the most part wooden cars in coal trade, which would not permit the maximum capacity stenciling. Fourteen lines, representing 349 votes, do not own or know of any cars that are structurally weak. Five roads did not vote directly on this question.

In answer to the question as to whether the railroad owns or operates any cars the body or trucks of which are strong enough under the present stenciled capacity, but which would not be strong enough under the proposed light-weight and maximum-weight stenciling, the majority of the roads voted in the affirmative. Out of the 924 votes, 662 report owning certain cars that are not strong enough and to which it would not be advisable to apply the maximum capacity plan of stenciling. While there does not seem to be any doubt, as a rule, regarding the structural strength of the modern car, and its ability to carry the increased load permitted by the maximum capacity plan of stenciling, 23 roads report certain types of structurally weak cars, such as flat, gondola, and wooden-underframe cars, which would develop higher stresses under the maximum loading than would be proper or permissible.

The third question was "Whether there can be any objection in applying the rule of light-weight and maximum-weight stenciling so far as it is applicable, consistent with strength of body or trucks which are not structurally weak, thereby restricting the stenciling of cars where the body or trucks may be structurally weak to the present light-weight nominal capacity.

Twenty-seven lines of the 35 who voted, or 75 per cent. of the total cars represented by the votes, are in favor of stenciling the maximum-weight capacity on cars whose strength will permit it. Two companies did not vote on this question, and the other 6 are opposed to it on the grounds of the confusion to shippers, etc. While the majority of the votes cast are in favor of limiting the proposed stenciling to cars that are strong enough, the question has naturally arisen as to what cars are strong enough, and how this strength should be calculated—that is, by the individual car owner or by a standard adopted by the association.

The fourth question was "Whether or not it would be more advisable to apply the rule of light-weight and maximum-weight stenciling to steel and steel underframe cars exclusively, and moreover to such cars of this class as have a factor of safety sufficient to carry the maximum load; also, in the opinion of the members, what the minimum factor of safety should be for maximum loading stenciling."

In line with the limited views expressed as to factors of safety, the committee felt that the light-weight and maximum-load stenciling should be confined to cars of steel or having steel-underframes that have a factor of safety of 3 or better in the body structure, when figured for the maximum load, and with respect to trucks under such cars, the rule should be applied to all trucks having arch bars of M. C. B. dimensions or better, and to all trucks having cast-steel side frames, and to the various forms of special trucks such as pedestal type trucks of the box and other varieties, where the strength of factor of safety is equal to or greater than the equivalent M. C. B. arch bar.

On new cars the committee feels that the rule should be applied in its entirety, owing to the fact that practically all new cars are steel or steel-underframe construction, and will in all probability be built to meet the proposed requirements of 24-in. minimum cross-sectional area of center sills recently proposed by the committee on car construction to take care of buffing shocks, which imposes a construction which we feel will result in a high factor of safety on underframes from a load standpoint. With relation to trucks under new cars, the rule should be applied only when such trucks meet M. C. B. requirements or better as to arch-bar construction, or have steel side frames, or have pedestal type trucks where the factor of safety is equal to or greater than the equivalent M. C. B. arch bar.

The committee endorse the recommendation of a member that the subject of stenciling the light-weight and maximum load be referred to the American Railway Association in order to ascertain whether there are operating or traffic conditions with which the proposed method of stenciling would interfere.

The report is signed by: C. E. Fuller, (U. P.), chairman; M. K. Barnum, A. W. Gibbs, (Penna.); F. H. Clark, (B. & O.), and D. R. MacBain, (L. S. & M. S.).

DISCUSSION.

D. R. MacBain (L. S. & M. S.): As a member of the Committee on the Marking of freight cars, we want to call attention to trouble in billing freight loaded in private line cars, due to the fact that the private line companies do not follow the M. C. B. practice of stenciling the right weight on the car. As a result, the loading in refrigerating cars is in a sense estimated and corrected by weighing the car after it is unloaded; but then the ice is included.

Another point is that these companies do not all follow the I. C. C. order to publish the necessary detailed data regarding their cars in the Railway Equipment Register, which publication has been designated for the purpose. The minimum car load rating is based on the inside length of cars, and without such data available in this publication, it is hard to properly bill out. Auditors want to know if the association can require all car owners to stencil light weight on cars and also recognize the order of the Commission in publishing data in the Register.

M. K. Barnum (Ill. Cent.): I move that this subject be referred to Special Letter Ballot to ascertain the views of all the members of the association, and then referred to the American Railway Association for their information and further instruction. (The motion was carried.

LETTERING CARS.

At the meeting of the executive committee in the office of the secretary, August 13 and 14, 1912, the present committee on lettering of cars was continued another year, and to this committee was referred a copy of the proceedings of the American Association of Railroad Superintendents' meeting, held September 9, 1910, in which the subject of car lettering was considered. Subsequent to this, correspondence was carried on between D. F. Crawford and J. A. Sommerville, then president of the American Association of Railroad Superintendents, at Kansas City, regarding the lettering of cars. This correspondence resulted in the appointment of Charles Burlingame, superintendent of the Wiggins Ferry Company, St Louis, Mo., to represent the members of the Association of Superintendents and meet the committee of this association and consider the matter further. After some subsequent correspondence between Mr. Crawford and Mr. Burlingame, a subcommittee was appointed to investigate the matter and to meet with the Superintendents' Association of St. Louis and ascertain just what further changes and additions were desired. Mr. Burlingame appointed M. Marca, general superintendent of the St. Louis, Troy & Eastern R. R., to represent the Superintendents' Association, while the following subcommittee was appointed to represent this association: W. L. Wilt, Penna. Lines, chairman; C. B. Young, C. B. & Q.; O. C. Cromwell, B. & O.; and Ray M. Brown, New York Central Lines.

The subcommittee met with the Superintendents' Association of St. Louis in February last, with the view of ascertaining what their wishes were, and found that all they request was that seperate letters be placed on each side of the car, near the door hasp for seal record purposes, so that such records could be taken by letters instead of using the words north and south or east and west with reference to sides of cars, as at present

They claimed that on account of cars going across the ferry at St. Louis and the switching in congested districts, they are turned on Y's destroying their seal records. This they feel is necessary on account of the large amount of pilfering going on in the St. Louis district. These letters were to be placed on the cars with respect to the A and B ends, using the letters R and L, or any other letters, to signify the side.

The subcommittee does not recommend the application of the additional lettering, but on account of the fact that this marking is entirely for the benefit of the operating department, it is suggested that a special letter ballot be taken to ascertain the views of all members of the association.

The report is signed by: D. F. Crawford, (Penna. Lines), chairman; F. H. Clark, (B. & O.); F. A. Torrey, (C. B. & Q.); and D. R. MacBain, (L. S. & M. S.).

DISCUSSION.

D. R. MacBain. I move the recommendation of the committee be acted upon, and that the question be submitted to letter ballot. (The motion was carried.)

D. F. Crawford, (Penna.): In connection with the report of the Committee on Standards, yesterday, the question of the Car Body Marking, there is this to be said: The standard of the Association requiring specified lettering, is as follows:

"That for other car body markings on sides and ends, such as capacity, couplers, brake-beams, class of car, date built, outside and inside dimensions and markings inside of car, two or three-inch letters and figures be used with the following exceptions," then he presents certain exceptions.

Now I would like to offer to the Association a recommendation that we be permitted to use on cars having steel outside frames, badge plates with smaller letters, in regard to figures relating to coupler, brake-beams, class of car, date built, outside and inside dimensions and markings inside of the car, with one in. letters; and it makes a much better appearing car than the standard requirement. And have it run over the vertical oblique outside structure. I would like to move that that subject be referred to the proper committee. (The motion was carried.)

RETIRING PRESIDENT'S BADGE PRESENTED TO PRESIDENT ALLEN.

The executive Committee of the Railway Supply Manufacturers' Association yesterday presented the retiring president's badge to Samuel G. Allen. The presentation remarks were made by E. H. Walker, who said:

"Mr Samuel G. Allen, you have been president of the Railway Supply Manufacturers' Association for the past year. This organization, composed as it is, of many men of many minds, of interest that at times clash, of corporations rich in established business and of those rich only in hope, of concerns with their thousands of men and of individuals for the first time submitting to a hoped for market a new device, requires for its chief executive a man skilled in diplomacy, full of tact, strong in emergency, unqualifiedly fair, calm in judgment, unswayed by clamor, with infinite patience and with that rare quality that inspires confidence in his leadership.

"These be strong specifications, but you have qualified in every essential, and the Association is to be especially congratulated that its affairs have had your able, earnest and effective guidance during this year.

"We have had many exhibitions in connection with these conventions, but for conception in design, completeness in detail and smoothness of operation this exhibition has eclipsed them all. It is written that by your works men shall know you. By your work, this year the members of this association know you better, and the better we know you, the greater is our admiration and the deeper is our regard for you.

"The payment for the faithful performance of public duty is the commendation of the public, and so this association, through its Executive Committee, with its grateful appreciation of your services, presents to you this past president's badge, that all men may know that you have been faithful to trust, efficient in office and that the highest honor at the disposal of this association has been conferred upon you."

THE "CRECO" BABY.

The magnitude of the exhibits that have appeared at Atlantic City for so many years have naturally developed interests peculiar to them. In connection with the erection of the booths and their care, many things have happened, and perhaps one of the most amusing is the story of the "Creco Baby."

In 1909, the first year the M. C. B. and M. M. conventions went to Atlantic City, Mr. Timothy Stanley Higgs, colored, was first employed by the Chicago Railway Equipment Company in the installation of its exhibit. Stanley was afterwards uniformed, and so was the first uniformed attendant in connection with the convention exhibits. "Stanley" has since become very well known, if not famous, and has always displayed a remarkable devotion to "Creco" interests. In fact, he is faithful to such an extent that care is really necessary to prevent his destroying competitors. Overhearing a discussion about advertising one day Stanley suggested that an excellent and novel way to advertise the "Creco" brake beam would be for one of the beams to be

The Creco Baby.

dropped overboard from the steel pier, and for him to dive after it. Stanley explaining that his talents as a swimmer were such that they should be used to this advantage. In 1909, the Chicago Railway Equipment Company had some special beams brass plated. These "gold" brake beams profoundly impressed Stanley, and he labored very ponderously over the problem of using them. One could hear his mental machinery creak and groan under the strain, and he finally evolved the idea of giving a so-called "Creco Cake Walk." He explained in detail how he would have four colored couples, the best dancers in Atlantic City, and that after going through the evolutions in the ball room, he, as a great climax to the cake walk, would suddenly clasp his hand to his brow, leave his lady and disappear. In a few moments he was to reappear, triumphantly carrying above his head one of the "gold" brake beams, after which the remaining cake walkers were to fall on their knees in worship of the same. This, Stanley suggested, would not only advertise the beam, but would be "suttinly powful fine and new."

In many ways Stanley has always proved that he thinks at all times very intensely and solemnly of "Creco" welfare, and when he recently named his first and only child "Creco

Leilia Higgs" he certainly manifested a beautiful loyalty, that has never been surpassed. We take pleasure in illustrating herewith a photograph of the "Creco Baby."

STEEL FRAME AUTOMOBILE CAR.

The Pennsylvania Railroad has recently adapted its new type of steel freight car frame to an automobile car and is now having several thousand built by the Pressed Steel Car Company. This car is shown in the illustration and has single sheathing, pressed steel underframe, body frame and roof, while the side and end doors are of steel plates. The center sills of pressed steel are of the fish-belly type, 20 in. deep at the center, and 11 in. deep at the bolsters and are reinforced at the bottom with a 4 in. x 4 in. x $\frac{9}{16}$ in. angle extending between the rear draft lugs and on the top with a 24 in. x $\frac{3}{8}$ in. cover plate running the full length of the car. The side sills are 6 in. channels extending between bolsters and 6 in. x 4 in. x $\frac{3}{8}$ in. angles from the bolsters to the end sills.

There are two crossbearers, each composed of four pressed steel diaphragms and one cast steel center sill brace securely riveted to the center and side sills and connected by top and bottom cover plates. In addition to the crossbearers there are six diaphragms on each side connecting the center and side sills of the door. Switchmen for local crews should be prohibited and six pressed steel braces between the center sills. The body bolster consists of two pressed steel "U" shaped members extending from the center sills to the side sills, with a cast steel combined center brace and rear draft lug between the center sills. The end sills are pressed steel, connected to the side sills by malleable iron push pocket castings and reinforced at the coupler opening with cast steel combined striking plates and front draft lugs. The corners of the car are further braced by pressed steel diagonal braces, extending from the body bolster and center sills to the side and end sills.

The side and end plates are composed of 6 in. x 4 in. x $\frac{3}{8}$ in. angles, the side and end posts and braces of pressed steel and the side door posts of bulb angles. The sides are tied together at the top by ten pressed steel carlines, to which the roof sheets are riveted. The roof sheets, in addition to being welded together, are reinforced at the splices by inside and outside butt strips.

These cars have one solid end, and one door end for use in the shipping of automobiles. The end doors are made of steel, are hinged to the corner posts and the opening extends from the floor to the roof. The side and end sheathing is $1\frac{1}{4}$ in. thick and is bolted to the posts and braces. The floor boards are $2\frac{3}{8}$ in. thick. The side doors are wide and are made of steel in two parts, one sliding towards each end of the car. The side steps, ladders, grab-irons, etc., are in accordance with the United States Safety Appliance standards.

The trucks are of the Pennsylvania Railroad standard arch bar type with $5\frac{1}{2}$ in. x 10 in. journals. The cars are of 100,000 lbs. capacity and have the following general dimensions:

Length inside	40 ft. 5 in.
Width inside	8 ft. 10 in.
Height inside	6 ft. 1 in.
Height at eaves	12 ft. 10 in.
Width at eaves	9 ft. 2 in.
Length overall	42 ft. 6 in.
Width overall (at door tracks)	9 ft. 11 in.
Height, rail to top of running board	13 ft. 4⅝ in.
Height, rail to top of brake mast	14 ft. 1⅝ in.
Height, rail to top of floor	3 ft. 7½ in.
Height of side door openings	8 ft. 5 in.
Width of side door openings	12 ft. 0 in.
Height of end door openings	9 ft. 0 in.
Width of end door openings	8 ft. 6 in.
Weight of car body	32,500 lbs.
Weight of trucks	16,600 lbs.
Total weight	49,100 lbs.

CIVIL SERVICE EXAMINATIONS FOR ENGINEERS FOR RAILWAY VALUATION.

Secretary McGinty, of the Interstate Commerce Commission, received yesterday circulars of the United States Civil Service Commission announcing open competitive examinations for a number of important positions for mechanical, civil and electrical engineers of railway experience for service with the Interstate Commerce Commission, mainly in connection with its work of making a physical valuation of the railways, from the register of eligibles, resulting from these examinations. Certification will be made to fill vacancies as they may occur in the several positions in the commission, under the act providing for the valuation of the property of common carriers, and vacancies as they may occur in other branches of the service in positions requiring similar qualifications, unless it is found to be in the interest of the service to fill any vacancy by reinstatement, transfer or promotion.

The positions for which the examinations are announced include senior mechanical engineer, mechanical engineer, senior inspector of car equipment, inspector of car equipment, senior inspector of motive power, inspector of motive power, senior structural engineer, structural engineer, senior civil engineer, civil engineer, senior electrical engineer, electrical engineer, senior railway signal engineer, railway signal engineer, senior architect and architect. For the senior positions applicants will not be required to appear at any place for examination, but will

Pennsylvania Class X-24 Steel Frame Automobile Car.

be rated upon the evidence adduced as to their general and technical education and training, and their practical experience and fitness.

As a result of the examination for senior mechanical engineer two grades of eligibles will be established, the salaries in the first grade ranging from $3,000 to $4,800 per annum, and in the second grade from $1,800 to $2,700, and expenses. It is desired to secure eligibles having a thorough technical training and several years' practical experience in connection with the design, construction, operation, and maintenance of railway machinery, motive power, and equipment, and having a thorough acquaintance with the methods of appraisal and cost-estimating of railway machinery and equipment.

Applicants for positions under grade 1 must show that they are graduates in mechanical engineering from a reputable technical school and that they have had at least five years' actual responsible practical experience in mechanical engineering work subsequent to graduation; or, if not graduates, that they have had not less than ten years' actual responsible practical experience in the above line of work. Applicants for grade 2 must have had three years' such experience subsequent to graduation; or, if not graduates, not less than eight years' such experience. For grade 1 applicants must be between 30 and 60 years of age and for grade 2 between 25 and 50.

For the position of mechanical engineer the salaries range from $1,080 to $1,500. Three years' practical experience in mechanical engineering will be required for admission to this examination. Graduation in mechanical engineering from a technical school of recognized standing will be accepted in lieu of two years of these three. Applicants must have reached their twenty-third year, but not their fortieth birthday, on the date of the examination.

For senior inspectors of car equipment the salaries range from $1,800 to $3,600. It is desired to secure eligibles having several years' practical experience in car construction or repair shops and in cost-estimating of car construction and repairs. Applicants must show that they have had at least five years' experience as master mechanic, master car builder, general car foreman, or in similar service, and that they have within two years next preceding the date of their application been in active service in such capacity.

For inspectors of car equipment the salaries range from $1,200 to $1,500. Three years' experience in the employ of a railway in the department of equipment or with a company manufacturing railway car equipment is required for admission to this examination. Graduation in mechanical engineering from a technical school of recognized standing will be accepted in lieu of two years of these three.

For senior inspector of motive power the salaries range from $1,800 to $3,600. It is desired to secure eligibles having several years' practical experience in locomotive construction and repair shops, in locomotive operation, and in cost estimating of locomotive construction and repairs. Applicants must show that they have had at least five years' experience as master mechanic, road foreman of engines, roundhouse foreman, locomotive shop foreman or engineman, and that they have, within two years next preceding the date of their application, been in active service in any such capacity or in the capacity of inspector of locomotive equipment under the government of the United States.

For inspector of motive power the salaries are from $1,200 to $1,500. Not less than three years' experience in the motive power department of a railroad or with locomotive works is required for admission to this examination. Graduation in mechanical engineering from a technical school of recognized standing will be accepted in lieu of two years of these three.

Appointments to the positions named will be principally for duty in the field, but some appointments will be made for duty in Washington.

Persons who desire to take the examinations should apply for Form 2039 to the United States Civil Service Commission, Washington, D. C., or to one of several other officers named in the circulars, before July 21.

Conventionalities.

You bet it was hot!

Those who were regretting last week that they did not bring their overcoats were regretting yesterday that they brought any coats at all.

The Enrollment Committee, headed by Chairman Yardley,

J. T. Carroll, Assistant General Superintendent Motive Power, B. & O., Little Miss Carroll and her aunt, Miss McGuinn.

certainly made a fine showing yesterday noon as it marched along the boardwalk in military formation.

If you didn't know that yesterday was Bunker Hill day, it was because Frank Barbey missed handing you a reminder in the form of a small American flag.

T. S. Lloyd, formerly superintendent of motive power of the Delaware, Lackawanna & Western, is reported to be making his

Left to Right: C. A. Brant, Mechanical Engineer, C. C. C. & St. L.; M. H. Haig, Mechanical Engineer, A. T. & S. F.; A. R Ayers, Mechanical Engineer, N. Y. C. Lines West.

home at Richmond, Va. He is not attending the conventions this year.

R. D. Smith, superintendent of motive power of the Boston & Albany, came on the pier early yesterday morning with a small

flag in his buttonhole and reminded us of the fact that Boston was having a holiday in celebrating "Bunker Hill" day.

William St. John, of the Safety Car Heating & Lighting Company, is following his old time custom of celebrating his birth at these conventions. He is just 73 years old today; but he looks not one day older than he did ten years ago.

For the third time in their short lives the four-year-old twins of A. E. Ostrander, of the American Car & Foundry Company, are attending the convention. Mr. Ostrander brought his family down Saturday and expects to remain in Atlantic City through the week.

H. Hammett and Bill Steel, the Short and the Long of the Convention.

Charles W. Waughop, for many years chief joint interchange inspector at St. Louis and East St. Louis, died within the past year and is missed from the conventions this year by his wide circle of friends. He had attended the M. C. B. conventions for 20 years or more.

W. L. Robinson, Superintendent of Fuel Consumption, Baltimore & Ohio

C. L. Kemmel, special inspector in the motive power department of the Baltimore & Ohio, spent a couple of days at the conventions last week. Among other things in which he has been specially interested during the year has been an extensive series of safety valve tests.

Wm. Elmer, superintendent of motor power of the Pennsylvania at Buffalo, who is attending the M. C. B. convention, was elected first vice-president of the Central Railway Club at its last annual meeting. H. C. Manchester of the Lackawanna is the second vice-president.

H. E. Blackburn, Apprentice Instructor, Erie Railroad, Dunmore, Pa.

W. M. O'Brien, master mechanic Kanawa & Michigan, is attending his first convention and has Mrs. O'Brien with him. He has been with the road he is representing for 27 years and received his promotion to his present position within the past year.

Left to right—J. E. Keegan, S. M. P., G. R. & I.; John Connolly, S. M. P., D. S. S. & A.

They are using power on his division which is handling upwards of 100 cars per train.

George T. Wilson, formerly purchasing agent of the Delaware, Lackawanna & Western, and who retired because of ill health, is now stopping at the Water Gap House, Water Gap, Pa. C. L. Bundy, general foreman of the car department of the Lackawanna at Kingsland, N. J., who is attending the conventions, saw him last Sunday and says he is in fine shape.

Warren J. Lynch, third vice-president of the American Steel Foundries, is another supply man at the convention

who was formerly in the railroad service, but his railway work has been in a different department from most of those who desert the transportation business for that of making and selling supplies. Most of his experience has been in the line of selling tickets and he was for several years passenger traffic manager of the New York Central Lines West.

E. C. Hall, general manager of the East Broad Top Railroad & Coal Company, was in Atlantic City on Sunday and looked over the exhibits on the pier with his master mechanic, J. F. Prendergast. The new narrow gage Mikados which were recently put in service are hauling 650 tons over a 2.6 per cent. grade and each one of them is replacing two of the older locomotives.

Samuel Lynn, master car builder of the Pittsburg & Lake Erie, stopped in at the editorial offices yesterday morning and threatened to bring suit against us for libel. In speaking in the *Daily* of June 17, of the number of steel cars which were given heavy repairs at McKee's Rocks, we said that they were being turned out at the rate of four per month. This should have been four per day.

C. H. Carman, who was recently promoted from the position of general foreman of the Missouri Pacific at Kansas City to general foreman in charge of the Sedalia, Mo.,

C. E. Chambers, Superintendent of Motive Power, C. of N. J. with F. D. Waller, Flower Resilient Packing Co., at his Right.

shops, is attending the conventions for the first time since 1907 and 1908 when he came as supervisor of air brakes of the C. & E. I. He went to the Missouri Pacific when the Kansas City shops were first opened.

H. Osborne, of the Canadian Pacific, came down to attend the M. C. B. convention. Within the past year he has been promoted to the position of assistant superintendent of motive power, Eastern Lines, and was succeeded as shop superintendent by G. I. Evans. Mr. Osborne still makes his headquarters at the Angus shops and finds it possible to get out into the shop more or less frequently, thus keeping in touch with the work which he has been interested in developing and extending for many years.

When M. J. McCarthy, superintendent of motive power of the Baltimore & Ohio Southwestern, left the Big Four, the employees presented him with a very fine automobile. Mr. McCarthy had to leave this with his family at Indianapolis while he was getting settled on the new job and when he finally moved the family to Cincinnati and had an opportunity to use the car he found that his 13-year-old son had become so proficient in driving it that he has not attempted to interfere and has not not yet learned to drive the car himself.

There was an enjoyable birthday party at the Traymore Saturday evening and although there were 40 candles burning on the cake, the "richin," A. R. Wilson, Detroit, declared to his friends present that the number of candles testified falsely the number of years he had lived. However, the evening was pleasantly passed by those present. Among his guests being Mr. and Mrs. P. P. Mirtz, Mr. and Mrs. W. D. Thompson, Mr. and Mrs. A. M. Rudel, Mr.

Left to right—J. Milliken, S. M. P., Philadelphia, Baltimore & Washington, and Alex. Kearney, Asst. S. M. P., Norfolk & Western.

and Mrs. Wing, D. Hawkesworth and Mr. and Mrs. Carter Blatchford.

George Gibbs, chief engineer of electric traction of the Long Island Railroad, is attending the conventions again, after having missed them last year. At the time of last year's conventions he was in Europe. Mr. Gibbs has seldom failed to be present at the meetings during the last quarter century. As is well known he was in charge of

Left to Right—J. F. De Voy, Assistant Superintendent of Motive Power, C. M. & St. P., and James E. Keegan, Superintendent of Motive Power, G. R. & I.

some of the most important work in connection with the construction of the Pennsylvania terminal in New York, and in recent years he has devoted most of his time to work more or less closely related to electrification being done by the Pennsylvania Railroad system.

MASTER CAR BUILDERS' REGISTRATION.

Alexander, J. R., General Road Foreman, Penna., Iroquois.
Beaghen, Thos., Master Car Builder, Union Tank Line, Shelburne.
Davis, M. J., Asst. Engr. M. P., Penna., Chalfonte.
Felton, Henry E., President, Union Tank Line, Shelburne.
Geisking, Charles, General Foreman, Penna., Seaside.
Gibbs, Geo., Chief Engineer, Penna. Tunnel & Terminal, Chelsea.

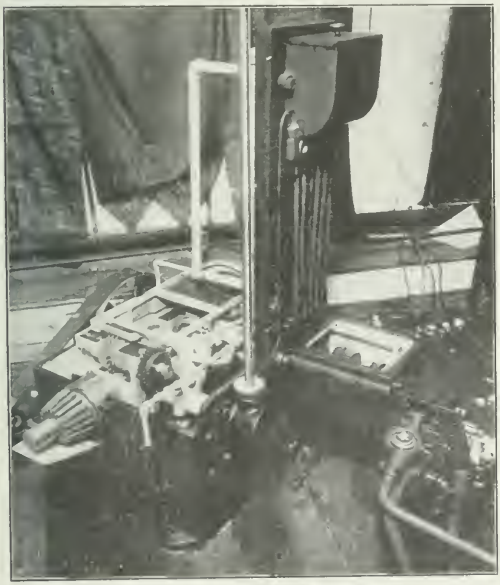
SPEED CHANGE MECHANISM OF BULLARD VERTICAL TURRET LATHE.

The maintenance of shop equipment has long been a serious item in railway, as well as in other shops, and while replacement and repair charges have been high and are constantly growing greater there is a side to the question which seldom receives consideration: that is the delay in work schedules and the increased cost of shifting the work from the machine which has fallen down under the stress of modern feeds and speeds.

An investigation of a series of breakdowns indicated that there were two principle causes for the delay and expense. The first in importance was the failure of gears, which indicated that the material was at fault. The second most frequent explanation of a tie-up was that sufficient oil had not been supplied to the bearings, either through the carelessness of the operator or because the oil-way had become clogged and oil could not reach the bearing.

After a long series of experiments the Bullard Machine



Lubrication of Speed Change Mechanism Used on Bullard Vertical Turret Lathe.

Tool Company adopted for its gearing material a crucible chrome nickle steel which, with proper heat treatment, shows a physical test of 270,000 lbs. tensile, 245,000 lbs. elastic limit, 11.5 per cent. elongation and 40 per cent. contraction together with an exceptional wearing surface of 70 scleroscope test. A sample of this material, bent double while cold, is exhibited at its space and shows absolutely no fracture or break or apparent strain in the outside surface of the bend.

As an illustration of the continuous flow system of lubrication adopted by it after the investigation referred to above it also has on exhibit a testing stand which shows the copious supply of oil which literally floods the bearing and gears in the vertical turret lathe.

From the return sump in the base of the machine the oil is pumped to the filtering and distributing reservoir and from there flows by gravity through the various leads to the bearings and gear boxes. Seven quarts of clean oil per minute is passed through the machine and as the volume is so great there can be no destruction by distillation, the bearings having no opportunity to become even warm under the heaviest service.

Some two hundred and fifty machines of this type are in operation throughout the country and in not a single case has there been any expense for maintenance of gears or bearings.

FASTNUT WASHERS AND AUTOMATIC WRENCHES.

One of the most popular exhibits this year is that of the Fastnut, Ltd., London, England, represented by Walter H. Cook. Mr. Cook came to the United States to obtain patents on his automatic wrenches and is taking advantage of the convention to demonstrate their utility. He is exhibiting a "Fastnut" washer, a "Fastfit" wrench and a "Fastnut" spanner.

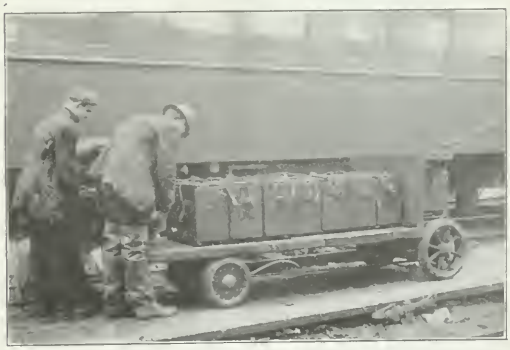
The "Fastnut" washer in use on over 40 foreign railroads will hold nuts under any vibration, the action being as follows: Drop the washer on the bolt in place of the ordinary washer and screw down the nut. The action of screwing down the nut flattens the teeth and automatically fixes the washer to the bolt, the springs engaging with the sides of the nut and holding it.

The "Fastfit" wrench is operated with a fixed and sliding jaw with teeth. The action of closing the sliding jaw fixes the wrench tight to the nut, allows it to hold automatically and ratchets on it. This wrench takes from 3/8 in. nut up to 7/8 in., automatically adjusting itself.

The "Fastnut" spanner is similar in appearance to the ordinary engineer's drop forge spanner, except that it has a movable head at each end. It is operated with a spring which is guaranteed to wear for two years. This spanner takes four different size nuts at each end.

ELECTRIC TRUCKS.

Self propelled trucks are proving most valuable in some cases, in railroad shops and passenger car yards, as well as in freight terminals and passenger stations. As is shown in the illustration, these trucks are capable of handling very heavy loads and are practically unlimited in their radius of action. They will transport heavy castings to various parts of a building or shop where crane service would not be possible, as well



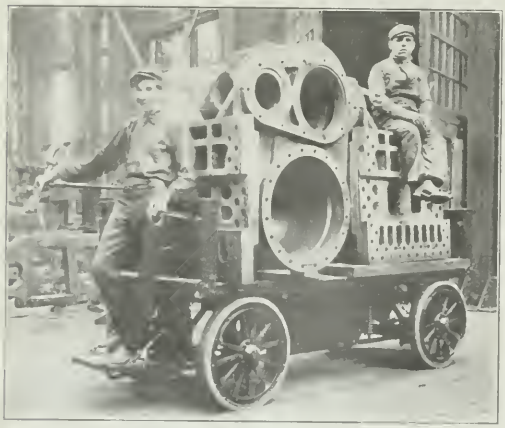
Electric Truck in a Passenger Car Yard.

as between different shops. In the latter case they have a decided advantage over industrial tracks in view of the fact that they can receive or deliver material at practically any desired point.

Trucks of this kind, as manufactured by the Elwell-Parker Electric Company, Cleveland, Ohio, are on exhibition. On several designs the steering apparatus is arranged to operate all four of the wheels, which permits the truck to turn very sharp corners and to work its way in between machines where a

hand operated truck could not be used. Several designs with very low bodies which permit the convenient manual loading of heavy material are shown, as well as those with an elevated platform, suitable for smaller parts or for use in connection with a crane for cylinders and similar large parts.

The source of power is a compact type of storage battery located in a convenient position where it will not interfere with the operation or loading of the truck and also where it can be easily removed if necessary. This drives a small series-wound water and dust proof motor which is geared to a countershaft. The countershaft in turn is geared through universal pinions to the driving wheels. Both of these sets of gearing are arranged to give a reduction in speed so that the motor will operate at an economical speed while driving the truck at a slow rate. The operator stands on a platform at the front of the vehicle and controls its direction by a horizontal steering lever and its speed by a controller lever on the opposite side. The controller allows three speeds forward or reverse and there is an automatic switch combined with both the controller and the operator's platform which will open the main switch and return the controller to the "off position" whenever the operator steps from the platform. At the same time, twin brakes enclosed in the countershaft column will automatically



Self Propelled Truck in a Railroad Shop.

stop the truck. These come in action whenever the operator's platform is allowed to lift by the operator stepping or being thrown from it.

These trucks of various designs have a weight from 1750 lbs. to 3150 lbs. depending on the size of the truck and the type of storage battery employed. They operate at a speed of from 5 miles to 6 miles per hour when loaded and from 7 miles to 8 miles per hour when empty. In most cases a capacity of 4,000 lbs. is provided.

PINTSCH GAS LIGHT WITH ELECTRIC IGNITION.

Occupants of sleeping car staterooms which are lighted by gas are apt to complain of the necessity of calling the porter to turn on and diminish the lights in the compartment and the objection has been cited against the use of gas lamps in staterooms. The electric light has overcome this objection, but on transcontinental trains, where a long stretch of open country presents adequate maintenance of equipment, electric light has disadvantages that may outweigh the advantage of convenience in lighting.

The Canadian Pacific has equipped several of its transcontinental trains with an improved type of Pintsch mantle lamp that gives the occupant of the stateroom full control of the lamps in the room without any necessity of calling the porter. In these lamps ignition is obtained by an electric spark, and a combination gas cock and electric switch is located in each stateroom so that to light the lamp it is only necessary to turn the handle of the switch. The lamps in the body of the car are also Pintsch mantle lamps, and are operated by an electric spark. The porter does not have to go through the car with a torch or taper and light each lamp individually, but lights all the lamps from a convenient'y located point by simply turning on the gas at

Canadian Pacific Sleeping Car Equipped with Pintsch Gas Light and Electrical Ignition.

the main cock and pushing the buttons, which are similar to those used on electric lamps. Electric berth lamps are employed in these sleeping cars and are operated from 1 k. w. Safety generator. This system has been developed by the Safety Car Heating & Lighting Company, New York.

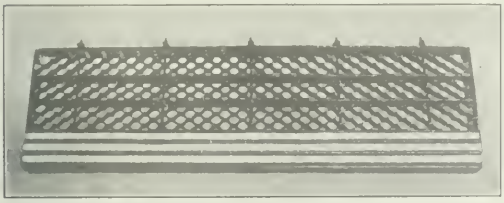
WATER COOLER FOR POSTAL CARS.

Among the fittings in the steel postal car which is being exhibited on Mississippi Avenue by the American Car & Foundry Company, is a galvanized iron water cooler having separate compartments for ice and water, and a drain for each compartment. The water compartment can be easily removed from the ice compartment by unscrewing the faucet and drain cock, and the ice compartment is provided with an overflow, having the opening located about one third of the way below the top, so that the water from the melting ice is retained to assist in cooling the drinking water. If it is desired to drain off the water from the melted ice, it can be accomplished by opening the valve in the bottom of the ice compartment. Both the inner and outer walls of the latter are thoroughly insulated with granulated cork.

This cooler is made in two sizes, one for full postal cars, having a capacity of 8.9 gal., and the other for compartment cars, having 4.45 gal. capacity. It is manufactured by the American Car & Foundry Company, New York and meets the requirements of the postoffice department.

SAFETY DEVICES.

A new non-slipping safety car step is being made by the American Mason Safety Tread Company, Boston, Mass., which embodies features of the Stanwood step and the Mason safety tread. The step hangers and toe guards are of pressed steel, while the tread proper is made up as shown in the illustration. The front portion consists of a 3 in. strip of Mason safety tread and the rear portion of ⅞ in. x 19 in. gage high carbon Stanwood crimp steel. This makes a stiff and rigid step, and while essentially a safety tread



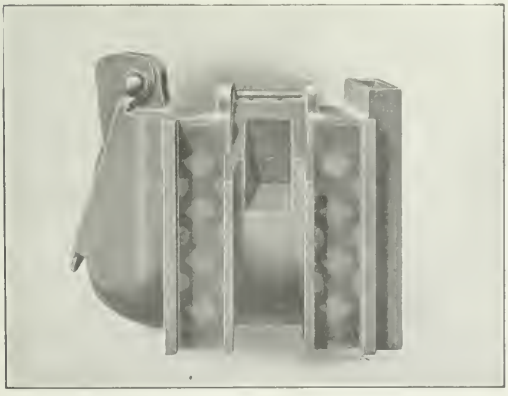
Combination Stanwood Step and Mason Safety Tread.

it also has the advantages of a foot scraper, thus keeping the dirt from being carried into the cars.

Another safety device made by this company is the Mason non-slipping safety ladder shoe. These shoes are applied to the bottom of the ladder rails, and the base, which comes in contact with the floor, consists of a carborundum surface of a hard, gritty nature. The method of attaching permits the base of the shoe to lie flat on the floor, no matter at what angle the ladder is placed. These shoes are furnished in either cast iron or aluminum.

PEDESTAL JOURNAL BOX WITH STEEL INSERTS.

After two years service, McCord & Company, Chicago, state that their pedestal type journal box fitted with continuous steel inserts in the pedestal wearing faces, has proved to have great durability and wear-resisting qualities. The steel



McCord Journal Box with Steel Inserts in the Pedestal Face.

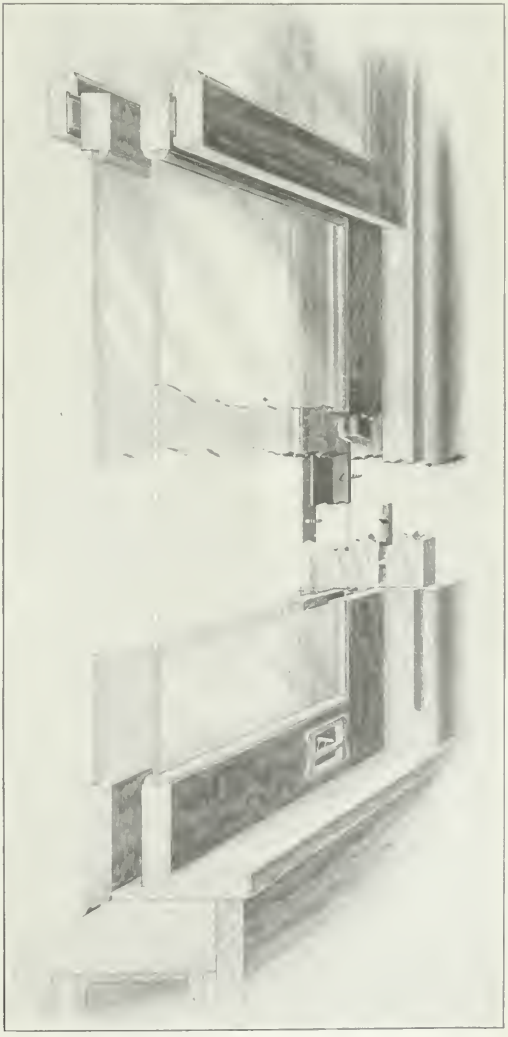
inserts are so constructed and set in place that it is claimed there is no danger of their becoming loose. This box also possesses the advantages of malleable iron over grey iron and insures an accurate fit in the pedestal. It is arranged for use with the McCord journal box lid if desired.

PRESSED STEEL FREIGHT CAR END.

The W. T. Van Dorn Company, Chicago, Ill., is exhibiting a two-piece pressed steel freight car end at the track exhibit. These new ends have the concentric corrugations similar to the single-end type except they are not made in the form of a circle. The two sheets are riveted together along the horizontal center line of the end of the car. Designs are also shown for corrugated end doors for automobile cars. Both designs have the strengthening features of the concentric corrugated sheets.

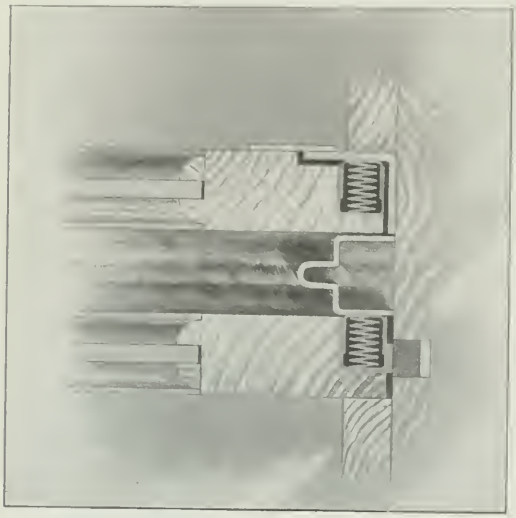
WEATHER-PROOF WINDOW.

During the past few years a great deal of attention has been given by various manufactures to the development of a weather- and dust-proof car window. The Acme Supply Company, Chicago, which has previously placed several designs of windows



Latest Design of Acme Weatherproof Window.

on the market, has just introduced a type in which the post battens of the window frame form a lip which extends into the rabbeted space in the sash stile. Facing springs are applied to the sash, forcing the window away from the lip, which draws the brass sash strips to a tight joint against the post battens. This joint is set away from the corner so that it is claimed the wind cannot force its way in, but the wind pressure assists the action



Facing Springs for Acme Weather-proof Window.

of the facing springs to tighten the joint between the sash strip and the batten lip. The top of the window is sealed by a plush strip and the bottom by a weather strip of double-lip rubber, held by a brass holder. This gives double weather-proofing at the bottom and also tends to stiffen the sash and prevent its bending in the center.

BOX CAR DOORS.

In the exhibit of the Camel Company of Chicago are several new designs of box car doors. One is for ordinary cars and has a hanger arranged for use with a combination Z-bar track at the top. As the rollers run between the two horizontal flanges there is no sticking of the door when being opened or closed and the track also provides a weather shed over the top of the door and the upper horizontal flange provides a weather shed over the hanger. This door is also equipped with interlocking weather and burglar-proof strips and has a deep flanged bottom Z-bar.

A door which gives a 10 ft. opening, intended for automobile cars is also on exhibition. This is double, one part being 4 ft. in width and the other 6 ft. The 4 foot door is equipped with a movable post which has an automatic locking arrangement at the top and is substantially fastened at the bottom when the door is in a closed position. This post wedges between the side plate of the car and the sill and gives the necessary support to the upper portion of the car.

Another door exhibited is designed for cars with a steel superstructure with wooden sheathing on the inside. In this case a T-iron door track is riveted to the Z-bar side plate on the car and double rollered hangers are arranged to operate on this track. The double rollers prevent the lifting of the door, making it easy of operation. The Z-bar at the top edge of the door works in conjunction with the T-iron track.

FLEXIBLE METALLIC HOSE.

Among the new exhibitors at this convention is the Goodyear Tire and Rubber Company, Akron, O., which has recently decided to manufacture all classes of mechanical rubber goods. One of the most interesting new features shown is a flexible metallic hose designed for air, pneumatic tool, steam, water, wash-out and all conditions where high service duty is required. The armoring consists of compound wires made of high carbon wire effectively galvanized, which completely protects the inner hose. The inner hose is made of high tensile strength and quality material adaptable for the particular service desired. The unique feature of this hose is its great flexibility. The question of expansion, contraction, elongation and twisting or writhing is thoroughly controlled. The armor is designed to withstand severe crushing strains and has been given the trade name of Kantkink.

STEAM HOSE COUPLER.

An improved form of hose coupler is being shown at the conventions by the Consolidated Car Heating Company, Albany, N. Y. The angle of the hose nipple is such as to prevent the hose from kinking, and at the same time the lines of the cams are so formed that when two couplers are connected, a perfect joint is secured without depending on the stiffness or kinking of the hose to hold the coupler heads in place. A guide is provided which acts as a hinge when coupling, and by its use the vertical travel is reduced to a minimum, thereby saving the kinking of the hose. The gasket and gasket holder are of a one-piece form, and are combined in such a manner as to give full protection to the gasket and at the same time to facilitate the changing of gaskets. The locking device of this coupler is automatic and is arranged to work whether the connecting coupler is of the same or a different form.

STERILIZING WATER COOLERS.

The United States Government now requires that the water coolers used in passenger cars be disinfected by sterilizing with steam every seven days. This requires, in yards where a large number of cars are handled, the laying of a great deal of pipe, with frequent branches leading out to hose connections through which the steam is conveyed to the coolers, the whole requiring a large expenditure. In order to provide a simple means for performing this work, the West Disinfecting Company, New York, has developed a portable steam generator, which can readily be moved from car to car by one man. It consists of a blow stove or burner using kerosene oil and mounted on a frame below a small boiler, which generates steam at from three to five pounds pressure per square inch. The steam is taken from the top of the boiler through a copper pipe, on the same principle as the dry pipe in a locomotive boiler, and is led directly through the flame of the burner in order to superheat it and provide against undue condensation; it then passes through a valve to a hose in the hands of the operator. A bracket and clamp are provided on the frame to hold the coolers and by using a longer hose the coolers which are only accessible through the car roof are easily reached.

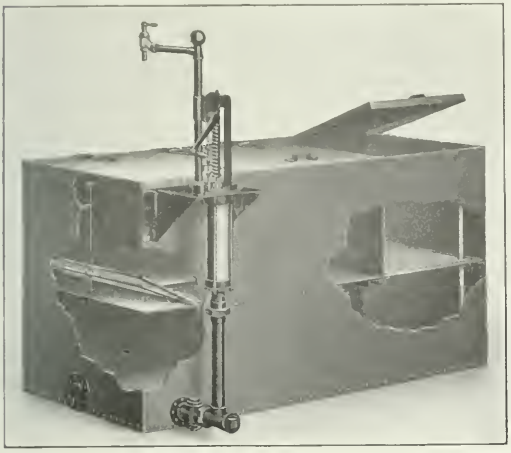
WASTE SOAKING TANKS.

Among the new appliances being exhibited by S. F. Bowser & Company, Fort Wayne, Ind., is a specially designed tank for soaking waste in oil without wasting any of the surplus oil. This tank is built of heavy galvanized steel and consists of three compartments, one for storing oil, one for soaking the dry waste and the third for storing the drained oil after the waste has been soaked.

Dry waste is put in the compartment designed for this purpose and is then covered with oil pumped from the storage compartment by a Bowser hand pump. When the waste

has soaked a sufficient length of time, a valve is opened and the extra oil is allowed to drain back into the third compartment. The oil has to pass through two screens, one of ¼ in. mesh and the other of ⅛ in. mesh. These prevent any lint, dirt, etc., being carried along with the oil. They can be readily removed for cleaning. The waste screening compartment has a special galvanized wire screen on the bottom so that any waste thrown in will quickly drain out; this is in case it is desired to use a little waste while the rest is soaking.

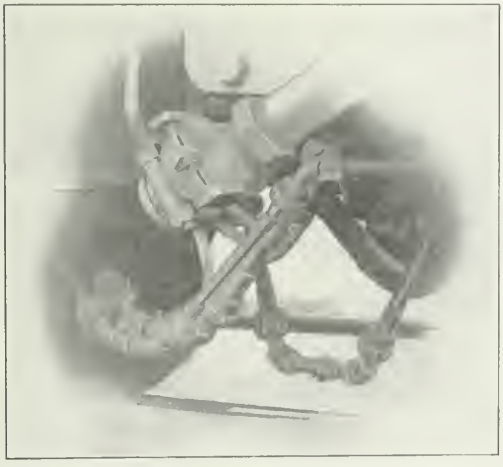
This tank has a 3½ in. clean out opening and the partition may be left out between the two upper compartments if desired and the whole upper compartment can be made oil tight. The storage compartment for oil will hold approximately 230 gal. and the dry waste compartment will hold 200 lbs. of waste. The oil soaked waste compartment will hold 100 lbs. of waste.



Waste Soaking Tank.

FLEXIBLE METALLIC CONNECTORS.

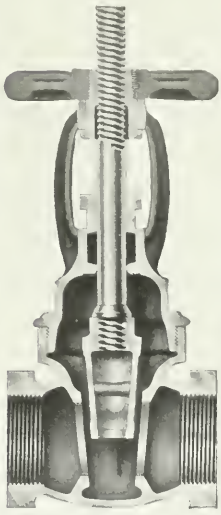
The flexible metallic connection which is shown in the illustration is intended for conveying steam, air, oil or water under any pressure common in railway practice, and is made by the Greenlaw Manufacturing Company, Boston, Mass. It is claimed for this connector that the only repairs necessary in normal use are the occasional renewal of the gasket, and as this does not contain rubber it is not affected by the action of heat or oil. The connectors are made in sizes ranging from ¾ in. upward and are used for pipe connections between locomotive and tender and between cars, and particularly in electric lighting systems where steam has to be supplied to the generating unit. Between the locomotive and tender a union is used, making it possible to disconnect the two joints without unnecessary delay when cutting off the tender. These connectors are also much used in engine houses for blowing off locomotives, etc., and for the heating of passenger cars in terminal yards.



Greenlaw Flexible Metallic Joint.

BRASS GATE VALVE.

Jenkins Brothers, New York, are exhibiting a brass gate valve which is similar to their inside screw type with the exception that a yoke and traveling spindle are substituted for the usual bonnet and inside screw; in many cases the outside screw type is more suitable than the inside. The threads on the spindle being exposed are easily lubricated, which increases their durability, particularly when the valve is used in dry or superheated steam. The traveling spindle, which raises or lowers through a stationary hand wheel as the valve is opened or closed, turns an indicator by means of which the position of the wedge or gate is readily ascertained. The valve has a solid double-faced metal wedge or gate, and the wedge is guided by ribs cast on the inside of the body which fit in corresponding channels in the wedge, thereby preventing the latter from dragging across the seat. There is a difference in thickness between the ribs on the two sides of the body, and as each channel in the wedge fits its corresponding rib it is impossible to reverse the wedge in the valve.



Brass Gate Valve.

UNIVERSAL WINDOW WEATHER STRIPPING.

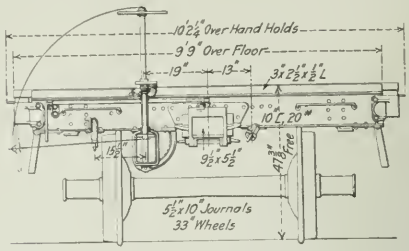
The McCord Manufacturing Company reports some very interesting service given by wooden sash, equipped with its universal weather stripping on steel cars. During the recent floods in Ohio several cars were in a railroad shop for revarnishing, and all windows except those equipped with these fixtures were removed. The cars stood under water for about five days, and were found with mud about 6 in. deep on the floor and 1½ in. deep on the window sills. As the locks had been removed from these window sash, they were blocked open for about 3 or 4 in. On entering the car after the flood had subsided it was found that the windows could be raised by one hand even though the wood work was considerably warped. This is explained by the comparatively large lateral play between the sash and the window post. That these windows were air and dirt proof was shown by an air test a short time before the flood. An air pressure of 90 lbs. was applied at the joints without affecting a lighted match on the inside of the window. The reason these sash were not removed

when the car was being varnished is because they are provided with a brass wearing strip, called a cinder deflector, which bears on the outside metal stop, and does not wear into the wooden sash.

FOUR-POINT BEARING FLAT CAR.

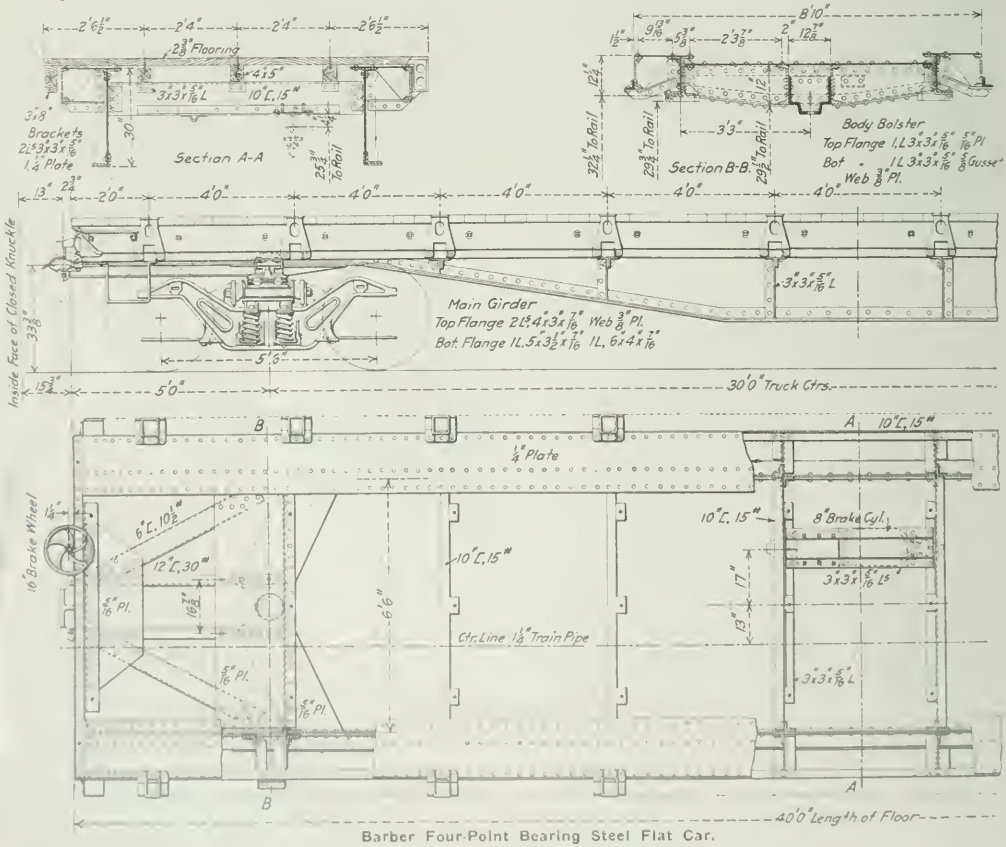
A new design of the Barber four point bearing flat car is being exhibited by the Standard Car Truck Company, Chicago, on the Philadelphia & Reading tracks near the pier. The car, as shown in the illustration, is especially designed for the Barber double action truck, and so that the load is delivered directly through the sills to the four bearings which are directly over the center line of the journals and half way between the journals of each truck. The radial travel is taken care of by special anti-friction devices, and the lateral motion is of the well known Barber type. There are two main drop girder sills which form a box section with the auxiliary side sill, all substantially connected with cross bearers. The end construction is a specially strong unit made up of end sill, body bolster, tie plates, braces and draft sills. The stake pockets are flush, being made of cast steel and secured to the main sills through the cover plate of the box section.

The truck side frames are of cast steel I beam drop girder type. The truck springs are arranged in pairs, each side supported on a seat cast solid with the truck frames. The truck bolsters are rolled I-beams with the web of the beam placed horizontal. The center pivot in place of center plate provides for and takes care of the switching shocks. It is, of course, understood that there is no vertical load on this center pivot. The roller caps are of malleable iron



End View of Barber Four-Point Bearing Steel Flat Car.

and are secured to the under side of the bolster. The radial roller seats are cast steel secured on upper side of the bolster. The radial roller cap is also of steel. The



Barber Four-Point Bearing Steel Flat Car.

three parts of the radial device are so arranged that they are interlocked into one member with freedom to move with the curving of the truck or car body.

The car on exhibition represents the latest design, and contains many improvements over that shown last year. It has been in service for about one year, and has carried a load of 165,000 lbs., although its rated capacity is 100,000 lbs. The car weighs 36,500 lbs.

ACME DIAPHRAGM ATTACHMENT.

Acme Diaphragm Attachment.

The Acme Supply Company, Chicago, is exhibiting its latest method of attaching the end diaphragm to a car. This attachment consists of three pieces of 1 in. x 5/8 in. x 1/8 in. rolled angles, two for the legs and one for the arch or top. The diaphragm is first riveted or stapled to the attachment, which in turn is fastened to the car with nine slotted lag screws provided with spring cotters such as is shown in the illustration. Two of these screws are located in each leg and five across the top. With the old method of attaching diaphragms to the car, it is impossible to release the diaphragm at the lower end of the legs without removing a large number of screws. Damage is done to the diaphragm in many instances when the men in the yards do not take the time to do this when repairing buffer springs; they sometimes put a jack screw back of the buffer plate and screw out so far that it tears the diaphragm and renders it useless. By removing four of the spring corners, in the new diaphragm, two in each leg, the diaphragm may be swung out to any required angle, the five screws in the top piece being sufficient to sustain the weight of the diaphragm.

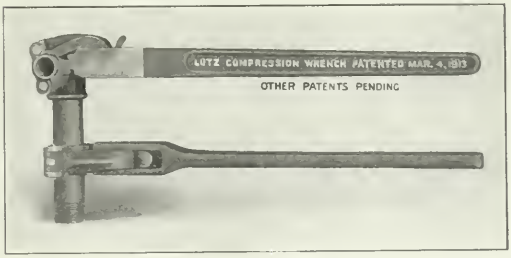
HIGH CAPACITY TRUCK.

A new type of heavy capacity truck, designed for 70-ton freight cars, is being exhibited by the Bettendorf Company, Bettendorf, Iowa. It has been so designed that the height of the center plate and side frames has not exceeded that of the truck of less capacity, although the strength of the structure has been increased throughout. The main feature of the truck lies in the manner of applying the load on the side frames which is at points near the journal boxes, rather than at the center of the side frame. This reduces the stresses in the frames and permits the introduction of larger ends on the bolster, and at the same time provides for the application of longer springs than could otherwise be employed.

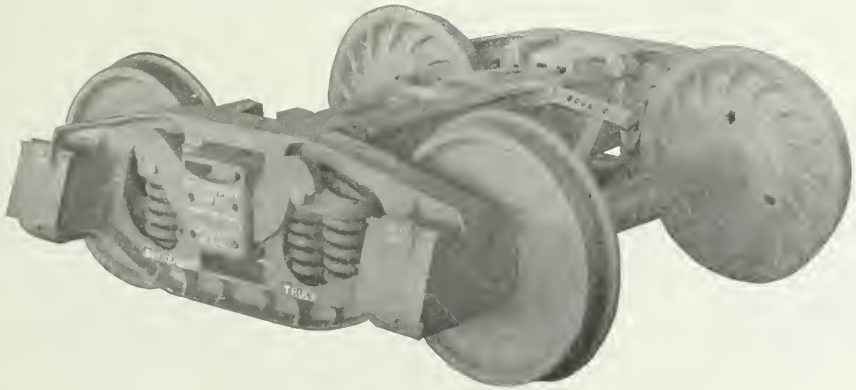
The manner of guiding the bolster is accomplished by providing slots in the ends of the bolster, both forward and behind the columns, through which the carrier bars pass and rest on the trunnions on the spring caps, thereby forming the support for the bolster and locking the side frames securely in position as well as dispensing with the ordinary spring plank. In designing this truck, care has been taken to produce one having the necessary flexibility, ease of dismantling for changing wheels, as well as having ample strength with a reduction in the number of parts. The truck illustrated has 6 in. x 11 in. journals; a 5 ft. 6 in. wheel base; a clearance of 5 5/8 in. above the rail; an over-all height of side frame of 30 3/4 in.; springs 11 in. high and a bolster 12 in. deep at the ends.

COMPRESSION WRENCH.

An interesting type of wrench is being shown by the Lutz-Webster Engineering Company, Incorporated, Philadelphia. This is intended for use on pipe, studs, bolts, etc., and it is claimed gives a positive hold that will not slip even on a polished rod. While the grip is sufficiently firm to prevent the wrench slipping, it is also claimed by the maker that the wrench will not injure the surface in any way, and that it can be used directly on the thread of a pipe or stud and on brass or nickel plated pipe without causing any injury. Its construction and method of operation are clearly shown in the photograph. This company also makes a friction ratchet which can be set up without the handle in position, thereby eliminating the overbalancing effect. It is possible to operate this ratchet with a movement at the handle of as little as 1/2 in. which will be recognized as an advantage when working in a limited space.



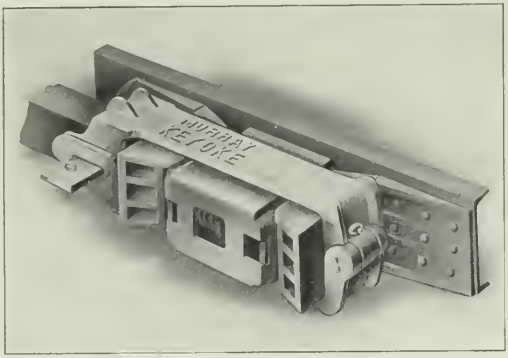
Lutz Compression Wrench.



Bettendorf Truck for 70-Ton Freight Cars.

KEYOKE DRAFT GEAR ATTACHMENT.

The Murray cast steel Keyoke, which is on exhibition in Booth 321, is, it is claimed, the only keyed draft gear attachment by which the pull is transmitted from the yoke direct to the coupler lugs instead of being taken on the key. This avoids elongation of the slots in the sills, yokes and couplers, and the wear on the keys. In addition to the yoke shown in the illustration, this company is also exhibiting a cast steel yoke which does not require a coupler key or rivets but locks below the coupler; this device incorporates the feature of taking the pull on the coupler lugs. The manufacturer states that in a recent test it was demonstrated that these yokes will stand a pull of 474,000 lbs. before breaking, and in an M. C. B. coupler jerk test seven couplers were destroyed before the yoke was fractured. This device is manufactured by the Keyoke Railway Equipment Company, Chicago, Ill.



Cast Steel Keyoke and Assembled Draft Gear.

EXTENSION CAR STEP.

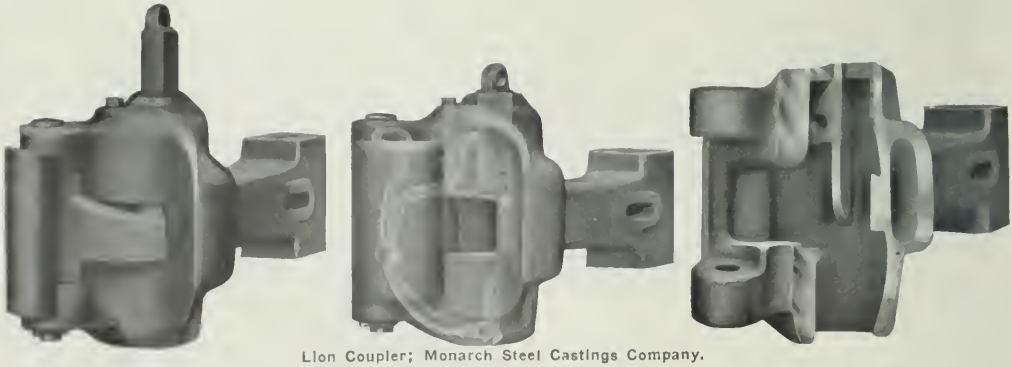
While there have been many attempts to design an extension car step which can be lowered and take the place of the usual stool, when passengers are alighting, and be raised up under the bottom permanent step while the train is in motion, the arrangement being exhibited by the Crofut Extension Car Step Company, Scranton, Pa., appears to answer the requirements without introducing the objections that have appeared in many of the earlier designs. It consists of a full width step carried by two heavy round bars which extend along the inside of the step timbers under the other steps, each having a sliding support in two brackets. Between the ends of each of these rods and the top bracket is a coiled spring around the rod which holds the step in the raised position. A connection at the center of the step to an arm on a cross shaft near the top forces it down when the lever at the side is drawn out. Notches in this lever hold the step down against the compression of the springs. Releasing the lever allows it to again assume the raised position. A connection is made to the trap door so that the step is automatically released when the trap is closed.

STREET LOCOMOTIVE STOKERS.

The reason of the general interest in mechanical stokers is easily understood when the illustrations in a pamphlet being distributed by the Locomotive Stoker Company, New York, are examined. These show seven different classes of locomotives that are now being successfully operated by Street Stokers, and an inspection of the list of dimensions given on the facing pages makes it clear that they are beyond the range for proper hand-firing. Three of them are of the Mallet type weighing from 540,000 lbs. to 405,000 lbs., and four are Mikados weighing from 330,000 lbs. to 273,500 lbs. The Street Stoker shown in operation on the pier includes a number of improvements over the design exhibited last year. These, however, are mostly of a minor nature and the principle of operation has not been changed in any way.

LION FREIGHT COUPLER.

To meet the exacting demands of modern freight service, the Monarch Steel Castings Company, Detroit, Mich., has placed on the market a new coupler known as the Lion. It is being shown in this company's exhibit, and a number of advantages are claimed for it. The construction is such that without additional parts the coupler may be operated either as a top or bottom lift, and all the working parts are protected by a housing on the bottom of the coupler head, which furnishes an additional wall connecting the face of the coupler to the shank. The strength of the shank is also increased by a rib located between the side walls and connecting the top and bottom walls, as well as extending into the head 1½ in. beyond the coupler horn. The lock is made in a solid piece, and has a bearing of 6 in. on both the knuckle tail and the wall on the guard arm side of the coupler. The knuckle opener, which is of the bell crank type, is designed to engage the knuckle as near as possible to its trunnion and thereby decrease the power necessary to start the knuckle open; the opener also follows the knuckle during the full opening. The lock-set is so designed that it is claimed the lock cannot be jarred off and allowed to drop. The construction of the coupler is clearly shown in the illustration.



Lion Coupler; Monarch Steel Castings Company.

Subscriptions, including 52 regular weekly issues and special daily editions published from time to time in New York, or in places other than New York, payable in advance and postage free:

United States and Mexico	$5.00
Canada	6.00
Foreign Countries (excepting daily editions)	8.00
Single Copies	15 cents each

Engineering and Maintenance of Way Edition and four Maintenance of Way Convention Daily issues, North America, $1.00; foreign, $2.00.

Entered at the Post Office at New York, N. Y., as mail matter of the second class.

WE GUARANTEE that of this issue more than 9,200 copies were printed; that of these more than 9,200 copies, 7,048 were mailed to regular paid subscribers, 200 were provided for counter and news companies' sales; and 1,700 were printed for distribution at Atlantic City and for use as sample copies.

THE arch bar truck for freight cars was for many years practically standard. Numerous designs intended to replace it were developed from time to time, but the arch bar type retained its position as a favorite, and has given excellent service under both freight cars and locomotive tenders. With the increase in the weight and capacity of freight cars, however, the problems of maintaining these trucks have increased enormously; not the least of these is the cracking of the arch bars, and the construction of this type of truck makes repairs in a case of this kind slow and expensive. Broken column bolts are another source of annoyance and expense, and the difficulty of keeping the various bolts supplied with nuts is well illustrated by the fact that recently on the western district of the New York Central a ton of nuts was used for this purpose in one day. In view of these conditions, and the proportion which car maintenance repair bills have assumed, the general adoption of a type of truck which will give better service under heavy equipment than the arch bar type would seem worthy of the most careful consideration. There are several satisfactory designs of the cast steel frame truck now in use, and it is probable that it is in this direction the railroads will have to turn to find relief.

THE convention started out yesterday morning with something that might be construed into a semblance of an indignation meeting. It was on the subject of damage inflicted on cars in their passage through car dumping machines. The matter has been one causing constant annoyance and trouble for a number of years, and representatives of the railroads have made suggestions before this for minimizing the damage. Cars have been strengthened along the upper edge so as to withstand the crimping effect of the clamps, and the method of blocking has been criticised and suggestions made for bettering it. In some cases agreements have been made that certain improvements in the machine should be made. It was agreed that the work should be done, but nothing was changed. It is a matter regarding which the roads on which the machines are located are especially interested, because the majority of cars handled are home cars; but every road in the country that has a car liable to go through the machine is interested. Evidently some of the car owners are getting to be very much in earnest, and as Mr. Crawford suggested, they want the weight of the influence of the association behind them in the form of a definite recommendation to enable them to bring an effective pressure on machine owners and builders to compel them to so adjust and build their machines that the injuries shall cease to be inflicted.

HAVE we taken "into consideration also the question of reducing the cost of maintenance and operation of equipment?" This question was asked by President Fuller in his address Monday morning. The capacity of cars has been increased so rapidly during recent years and the stress to which they have been subjected because of the use of more powerful locomotives and the more general introduction of hump yards has increased so much, that the designer in trying to keep up with the other demands has perhaps lost sight of the question of the cost of maintenance and operation; in many cases the management has cut out important features which have been recommended by the designers in order to save a few dollars on the first cost of the equipment. The result of this short-sighted policy is evident on many roads in the high cost of maintenance. As the claims for damaged freight have grown to excessive proportions and more attention has been given to the possibility of reducing maintenance costs it has become evident that it is often good policy to spend more money in building the cars right in the first place. Attention was greatly diverted to the desirability of doing this by the series of articles on "Defective Box Cars and Damaged Freight," which was published in the *Railway Age Gazette* during the early part of 1912. The committee report on Overhead Inspection of Box Cars at the 1912 convention also emphasized this, and the report of the same committee this year will undoubtedly direct still further attention to it. Meanwhile the car designers have been giving more attention to studying the performance of different designs in order to develop more practical construction and the railway managements have been disposed to pay more to get the right kind of cars, realizing that it is economy to do this because of the resulting better service, reduced maintenance costs and greater safety to the public and employees. This is real economy, if rightly done, but as suggested by President Fuller, the railways should be sure that such additional expenditures as are made will justify themselves fully.

THERE is a question in the minds of some of the members of the M. C. B. Association as to just what was intended by the action which was taken on the section of the report of the committee on Brake Shoe and Brake Equipment relating to a standard brake beam. Last year the committee recommended the adoption of a standard No. 2 brake beam, but this recommendation was rejected when it was referred to letter ballot. In bringing the matter before the convention this year the committee made a slight change in the No. 2 beam recommended last year, and referred it to the association with this suggestion: "The committee would also recommend the beam as shown on M. C. B. Association Sheet 17-B for consideration and trial by members of the association, with a view of adopting such a beam as recommended practice for No. 2 M. C. B. brake beam." Without doubt the committee's intention was not to submit the question to letter ballot, but rather to have the different members experiment with the beam with the idea of adopting it as standard practice at some future time. Mr. Kleine moves that the recommendation be submitted to letter ballot, but A. W. Gibbs directed attention to the fact that the brake head shown on sheet 17-B was covered by two patents which were held by one company. C. D.

Young therefore made an amendment to Mr. Kleine's motion to the effect that the patent situation be disposed of by the executive committee before the matter is referred to letter ballot. The motion thus amended was carried. As the matter now stands the question will, it would seem, be referred to letter ballot if the executive committee can adjust the patent situation, although, judging from the wording of the committee's report it was not its intention to have it take quite this course.

PRESIDENT Fuller's experience meeting was a happy thought to fill in a few minutes made available by the run ahead of schedule yesterday morning. To those who listened to the men who eased their minds, if not their consciences, it seemed as though such an experience meeting might well be made a permanent feature of the convention. It happened to come just after the report on car construction had been read and discussed, so it is but natural that the major portion of the comments were directed towards faulty cars, but if so much could be brought out in so short a time bearing on this one topic, there must be a tremendous reserve of material stored away that might well be brought to light. Doors and end construction were the principal points of attack, and the former may well be taken as an item of crucial anxiety. It is a matter common to hear expressions of anxiety at the possibility of danger to passing trains caused by loose doors, and as for end construction, we have been talking about it for decades and now it really seems that something will be done. And such talks as these cannot fail to stiffen the recommendations of committees and encourage the association to take a stronger and more definite stand than it has sometimes done in the past in regard to seemingly minor affairs.

THE discussion on the subject of car construction seemed strongly to indicate the necessity of a standing committee on that subject, and the motion of Mr. Crawford for the appointment of such a committee was enthusiastically carried. While the committee presented a very interesting and instructive report, there were many questions asked by the members that were not touched upon. With a standing committee these questions could be carefully studied and a report be made for the benefit of all the members of the association. A standing committee is especially apropos at this time since the American Railway Association is looking forward to, and asking the various railroads for, a standard box car. Again, the work of this committee would be of special value toward the developing of standard designs and the passing on of special designs which would eliminate many of the difficulties experienced in the interchange of cars. It would be the duty of the committee to prevent such 60,000 lb. capacity cars, as were mentioned in the discussion on the retirement of the 40,000 and 50,000 lbs. capacity cars, from being constructed and in general would be of vast importance not only to the mechanical department, but to the transportation department as well. With the adoption of the new and heavier couplers there must be some change in the end construction of cars. The various parts must be carefully designed to back up the work the coupler is supposed to do, and this standing committee is just the one to advise and recommend what should be done. With the backing of the association for stronger and more substantially designed cars the committee is in a position to do the railroads of this country a very valuable service. The committee, however, cannot be expected to do its work successfully without the assistance of all the members of the association, and if the way in which the report was discussed is any indication, this assistance will be forthcoming.

AIR BRAKE HOSE.

AN average life of ten months for air brake hose manufactured under the present M. C. B. specifications, as the investigation of the committee showed to be the condition now existing, is a conclusive argument in favor of a revision. The committee has evidently given the subject most careful study and submitted, at yesterday's session, a proposed specification which would seem to insure a materially better product. A good air brake hose is a matter of more importance than the cost of replacing it after a short life and the fact that the new hose will cost considerably more than at present should not enter into consideration. Train delays due to a leaking train pipe, the occasional wreck due to a bursted hose and the cost of frequently keeping two of the largest air pumps running at full speed all the time are worth avoiding even if the longer life of the hose itself does not offset the increased cost.

Permission to use a machine made tube is given in the new specifications, which will be submitted to letter ballot for adoption as a standard. As a matter of fact a large percentage of the present hose has a machine made tube, although the specification calls for three, hand made calenders. It is practically impossible for an inspector to determine the presence of the three calenders unless one is of a different color, as is required in the specifications of a few railroads. The objection to the machine made tube is not that it is machine made, but that; when made of poor material, it shows a serious porosity. The new specification attempts to insure a high quality of material by means of new tests and in that case it is felt that advantage should be taken of the lower cost of the machine made product.

A tensile strength requirement and a more rigid stretching test are the principle means offered for insuring a good quality of rubber. Experience covering several years will tell if they do it. At present they seem to be the most available means. At a later date there is a slight possibility that a chemical analysis will be perfected which can be used to make the quality more uniform and positive. The tensile test now proposed requires that with a speed of the machine of 20 in. a minute the inner tube must have a strength between 800 lb. and 1200 lb., per sq. in. after an elongation from 2 in. to 10 in. The cover material must have a strength between 700 lb. and 1100 lb. per sq. in. under the same conditions. The stretching test required at present is from 2 in. to 8 in., released, remarked, again stretched from 2 in. to 8 in. and held 10 minutes. A permanent set of ¼ in. is allowed after it has been released for 10 minutes. In the proposed specification, both stretches shall be from 2 in. to 10 in. and the set immediately after releasing the second time is not to exceed ½ in. and the set 10 minutes later is not to exceed ⅜ in.

Other new features of the proposed specifications are the introduction of a porosity test and the more severe hydrostatic and bursting tests. The new porosity test is made by putting the test hose under 140 lb. air pressure for 5 minutes and then splitting the cover with a knife and submerging the hose in water. Any escape of air of sufficient volume to indicate leakage through the inner tube will condemn the lot of 200. The new hydrostatic test is 200 lb. instead of 100 as at present and the bursting test has been increased from 400 lb. to 500 lb. both for 10 minutes.

More definite instructions are also given in connection with the quality of the wrapping and its application. The weight and width remain the same but the warp is required to have 25 threads, of a strength of 12 lb. each, to the inch and the filler 18 threads of 9 lb. strength. The edges are required to lap ½ in. No change is suggested in the friction test, but less than four ply hose will not be accepted.

In connection with the new hose specification, the committee made no sugestion about the proper way of mounting. This is fully as important as insuring a good hose and instructions are sadly needed by some railroads. Good hose spoiled before it is put in service is not as safe as poorer hose properly handled and applied.

MASTER CAR BUILDERS' ASSOCIATION PROCEEDINGS.

Closing Session—Unloading Machines, Air Hose, Revision of Specifications, Car Construction; Election of Officers.

President Fa[illegible] called the meeting to order at 9.30 A. M., June 18.

Secretary Taylor read a proposal to elect C. A. Seley, an associate member and under the rules of the association this will be over until the next meeting.

DAMAGE TO FREIGHT EQUIPMENT BY UNLOADING MACHINES.

The committee finds that considerable damage has been done not only by the Pennsylvania and Lake Shore & Michigan Southern, as reported last year by the Baltimore & Ohio, Wheeling & Lake Erie, Hocking Valley, Toledo & Ohio Central, and others.

There are two types of car dumpers in use; one in which the track or platen on which the car rests is moved transversely, bringing the side of the car against the side of the cradle, and referred to as the movable-platen type; the other is that in which the track is built solid with the cradle, and the cradle side is moved in against the car side by means of hydraulic cylinders, and is referred to as the solid-floor type.

MOVABLE-PLATEN TYPE.

The supporting track on the platen has its center coincident with that of the supply track leading to the machine, when cradle is at its bottom or normal position, as in Fig. 1, this being controlled by cams underneath the platen. When cradle is raised the cams become disengaged and chains which are attached to platen, and which pass through hollow clamps and extension clamps to counterweights, move the platen transversely, bringing car against side of cradle. As the cradle continues to rise the hook clamps, which move by their own weight in guides, bear on the top of car and hold car to platen by

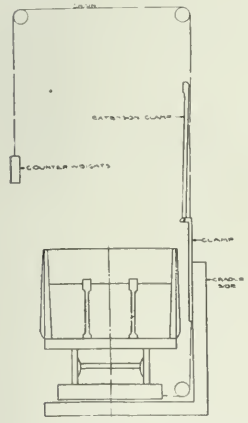

Fig. 1—Showing Car in Position Before Cradle is Raised.

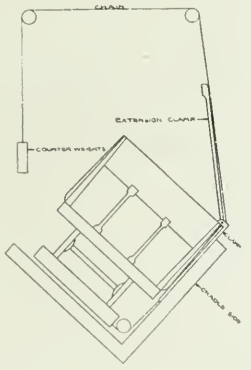

Fig. 2—Showing Position of Clamps as Cradle is Turned.

the combined weight of the clamps. When the cradle rotates to dump the car the extension clamps are brought over the top of car as shown in Fig. 2.

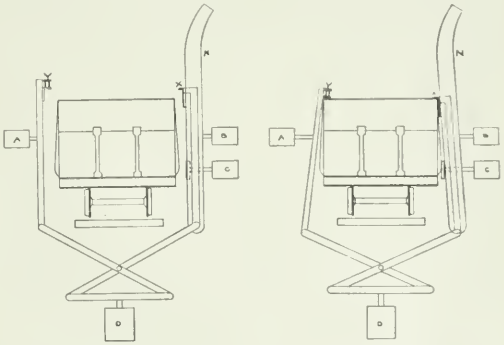
SOLID-FLOOR TYPE.

Diagrams of cradle and method of clamping car is shown in Figs. 3 and 4. It must be understood that the sequence of clamp operations can be varied, as the movement of hydraulic pistons is controlled by independent valves. When car is placed on supporting track the pistons *A*, *B*, *C* and *D* are all in release position. The cradle side is first moved in against top of car by piston *B*, bringing clamp *N* over car side and outside. Clamp *Y* is brought over car side by piston *A*. Both clamps are next brought down on top of car by piston *D*. Buffer is then brought out against car by piston *C*, thus making all clamps in operation, as in Fig. 4, and cradle is then rotated about center *N*.

With machines of movable-platen type the damage occurs when the cradle of the car dumper is rotated, due to their not having proper bearing against the side of the cradle, the side of car coming in contact with the clamp housings or side of cradle, and damaging or destroying the side ladders, handholds, roping staples or door-operating mechanism, and by the absence of extension clamps.

With machines of the solid-floor type the damage is done by hydraulic-operated clamps in the sides of the car and bending down the top of the car, and I beam of floor system outside of rail being too high and striking column bolts.

To prevent the damage to cars, the cradle on both types of



Figs. 3 and 4—Method of Clamping Car on Solid Floor Type.

dumpers should be faced with timber, preferably 10 inches thick, on specified areas and with openings between the timbers. The timbers are provided for the car to rest against when rolled on its side, and the openings are to permit of contents that have fallen into cradle being dumped on the next turn of the cradle. The blocking is so arranged as to protect the extending appliances by providing for them in areas not covered with blocking. On the machines of solid-floor type the method of moving cradle side will have to be changed so that the side pressure on car will not be greater than the combined weight of the heaviest car and its contents, and so that the vertical clamping will not exert a pressure on top of the car greater than that now used on the movable-platen type.

The principal features to be considered in providing the protection for both types of machines are, therefore:

First: Provide as much bearing as possible on the cradle side of the car and at the same time insure ample clearance for safety appliances and other attachments projecting beyond side stakes of the car.

Second: Allow for sufficient variation for spotting cars in the cradle, so that time will not be lost in placing the cars, with a resulting decrease in the capacity of the car dumper. The protection should be so placed that when a car is stopped anywhere within two feet the blocking will be ample to support the car on its side. A greater allowance than two feet is to be preferred when it can be provided without making a supporting area so small that the car will be damaged.

Third: Provide blocking so that the bearing face can be quickly renewed, so that it may be maintained in proper condition at all times by applying it when the machine is idle, to avoid the necessity of shutting down the dumper to apply the blocking.

Fourth: Provide a guide plate at the in-bound end of cradle for entering cars with spread sides.

Fifth: Machine to be provided with not less than four vertical clamps, and each of these to be equipped with an extension clamp.

Sixth: Grade of yard track leading into cradle to be of 100 ft. radius, to prevent damage to carry irons when cars are moved into machines coupled.

Seventh: Timber lining to be cut at an angle at lower ends to permit the contents spilled into the cradle to get out on the

next turn of the cradle. Features to be considered in addition to the above, but only on solid-floor type machines, are:

Eighth: No side pressure to be used which will force the car against the lining in the cradle with a pressure greater than the combined weight of the car and contents.

Ninth: Vertical clamps to be operated by gravity so that the pressure on top of the car will not exceed that now used in movable-platen type machines.

Tenth: Top of I beam in floor system and just outside rail to be made the same height as rail.

The committee finds that to provide a lining or blocking for gondola and hopper cars owned by all railroads, could only result in insufficient support for a great many cars. It is therefore necessary for each railroad to make a study of the cars handled by machines on its lines and apply blocking according to the foregoing principles, and the typical example shown in Fig. 3. The modifications for the solid-floor type alone, as given in the eighth, ninth and tenth items, will have to be provided for by the machine designers.

Fig. 5 is a typical blocking used by the Pennsylvania and Lake Shore & Michigan Southern on machines of the movable-platen type, and the committee calls attention to the additional clearance necessary in the Sandusky car dumper to prevent damage to the side wheel operated cars of the Norfolk & Western. If it were not necessary to provide this clearance in this particular machine, a greater bearing could be given cars by cutting the blocking along the line *F G H* instead of *C D E*, along *V K L* instead of *U I J*, and along *M N* instead of *O P*. Furthermore, the recessed portion below the line *Q R* is for existing vertical handholds, and the surface can be brought out full with the balance of the blocking down to the line *S T* after July 1, 1916, when vertical handholds are no longer permissible, for all horizontal handholds will then pass below the line *S T*. Fig. 6 shows manner of applying guide for entering car with bulged sides and method of securing blocking to cradle. In securing blocking the 6-in. timber next to the cradle side is secured by ¾-in. bolts passing through wrought washers, recessed into the timber and through the cradle side. The bearing face, 4 in. thick, is secured by ¾-in. bolts in the same manner through the permament timber. The same blocking should be applied to the solid-floor type machines after the designers have modified the cradle side and clamps as per the ninth and tenth items.

Attention is also called to the following, and the necessity of each railroad giving the proper consideration in connection with car dumpers operated by it and by plants along its line:

Composite drawings of all cars to be handled by machines should be prepared and drawings for the blocking furnished to the contractor when the machine is purchased, in order that he may provide the necessary blocking, means of securing it, and reinforcement back of the cradle to support the weight of the car when on its side. When designing new cars, some

There are other machines and appliances used in loading and unloading cars which require additional study. Regarding recommendations for a suitable wrench for opening hopper-bottom cars, and a uniform size of shafts under these cars, the committee finds that in order to fully cover this subject it is

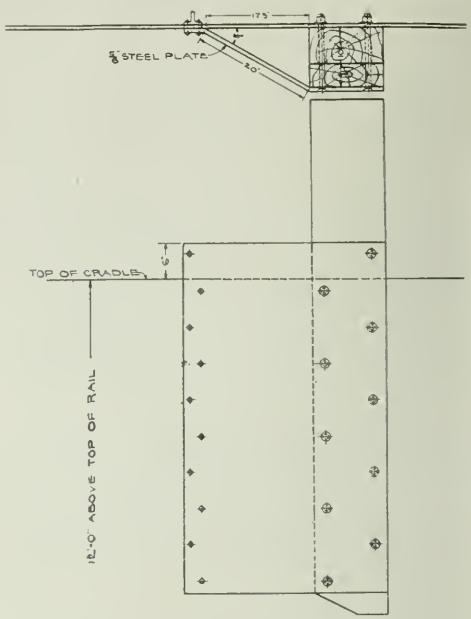


Fig. 6—Guide Plate for Cradle with Top of Cradle 12 ft. Above Top of Rail.

necessary to collect and consider all forms of operating mechanism for hopper-bottom cars, but it has not yet been able to get this information, and would therefore ask for further time.

The report is signed by:—P. F. Smith, Jr. (Penna. Lines)

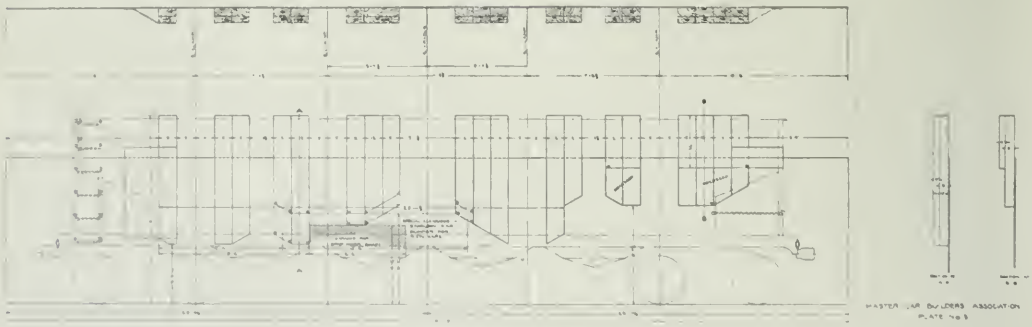

Fig. 5—Typical Blocking Used by Pennsylvania and Lake Shore on Machines of the Movable-Platin Type.

thought should be given to their use on car-dumping machines. The providing of protection in accordance with this report should be taken up with plants operating car dumpers along the line of railroad, as much damage is done at steel and other manufacturing plants. When applying this blocking to existing machines, the back of the cradle wall or side should be reinforced to prevent bulging and making the blocking useless. Extension clamps through which chains pass must be used at all times to prevent damage to the car sides by chains. Face plates must not be used on the face of timbers, as cars will slip on metal plated blocking.

This report has been made covering car-dumping machines

chairman; J. J. Tatum, (B. & O.); E. A. Westcott, (Erie), I. S. Downing, (L. S. & M. S.); J. J. Birch, (N. & W.), and C. S. Morse, (W. & L. E.).

Discussion.

D. F. Crawford (Penna. Lines). This subject is very important to several of the roads that handle coal and ore between Pittsburgh and the lakes. Recently an examination of some of the machines was made by some of our people, and we find that the blocking has not been put in in accordance with the recommendations of the committee, representing those roads which gave this subject particular atten-

tion before this committee was appointed. It is most important that this subject receive the attention of the roads on which these machines are located, and also that the roads jointly take the matter up with the various manufacturers who have machines of this kind. A large number of cars is being very seriously damaged. I have had some reports sent to me since I have been here, of a number of cars belonging to our lines, the Lake Shore and the B. & O., and the other lines that run into this territory. I think this committee should be continued to not only make definite recommendations on this machine, but others that can do damage to these cars. These machines will damage the best and latest cars we have. In one case a new car was put in and clamped, and the side was deflected two and one half inches. I have some photographs of the hopper cars of the Pennsylvania, the Lake Shore and the B. & O., and the sides are bulged; and undoubtedly it was due to the clamping of this machine. I hope the Committee will make definite recommendations, and have your people devise a machine that will stop injury to the latest and best cars we own.

J. J. Tatum (B. & O.): The committee was very much surprised to find the conditions existing on the various machines which they inspected. Cars were being unnecessarily damaged and it seems that it was due principally to lack of careful watching and considering what was necessary to be done to the machine to prevent damage. The clamping action of the machine is very considerable. There is one machine which has a hydraulic buffer on the side. That machine crushes in the sides of the car and causes them to be thrown out of alignment, and the result is that the girder effect, the principle on which the car is built up for strength, is rendered practically worthless. An I-beam put along the floor of the platform of the machine comes close to the side of the track. All of us have had column bolts sheared off and we found that when the car was approaching the machine, the grade was not properly adjusted and the result was that the column bolts were sheared off. The grade was not adjusted to suit the spacing in the couplings, and when the machine would approach the car, it would bind the knuckle and break the carrier iron. There are a number of items about the machines which must be given consideration by each railroad to prevent damage to the cars.

Samuel Lynn (P. & L. E.): I am a member of the local committee which proposed some of these machines on our line. One of the troubles we have had is the shearing off of the carrier iron. I think, though, that is a condition that we have corrected to a large extent with the mill people.

D. F. Crawford: Are these diagrams in shape to be submitted to the association for adoption as recommended practice, so that we can put the weight of the association behind our arguments with the various people who own these machines, both individuals and railroads?

J. J. Tatum.—The recommendation of the committee is in such shape, and it would be proper to make such a suggestion.

D. F. Crawford.—I move that the recommendations of this committee be properly prepared to be submitted to letter ballot as recommended practice of the association. Remember that the cars of every railroad company which go through the machine, suffer just the same.

The motion was carried.

AIR BRAKE HOSE SPECIFICATION.

One of the items discussed by the committee was that of labels for air hose. The inspection of any pile of scrap hose will indicate that the calendar, from which is supposed to be cut the date of application and removal of the hose, is seldom used. It is, therefore, evident that the ends for which this label was designed are not being lived up to, and that its usefulness is questionable. The addition of a second label, which is supposed to indicate to car inspectors, without the necessity for their going between cars, that such hose is M. C. B. standard, means considerable extra and unnecessary expense. In the opinion of the committee, both the present labels should be discontinued, and in place of them the following design is recommended:

This label should be applied around the hose within 6 inches of one end. In mounting the air hose, the coupling is applied to the end near which this label is located, so that the drawbar will not obscure it when an inspector is on the right forward or left back side of a car. As this label contains all necessary information, and as the life of a hose can be exactly known from the date of manufacture shown, it is recommended that this question receive the most careful consideration of each member voting.

Following is the specification which the committee feels will accomplish a large improvement of air-brake hose.

Proposed Revision of Specification for Air-brake and Signal Hose.

Adopted as Recommended Practice in 1901. Advanced to Standard in 1903. Revised 1905. In 1911, detail specifications of label were placed under the heading "Label for Air-brake Hose."

I. MANUFACTURE.

1. All air-brake hose shall be soft and pliable, and not less than four-ply. It shall be made of rubber and cotton fabric, each the best of its kind for the purpose. No rubber substitutes or short-fiber cotton to be used.

II. PHYSICAL PROPERTIES AND TESTS.

Hose will be subjected to the following tests:

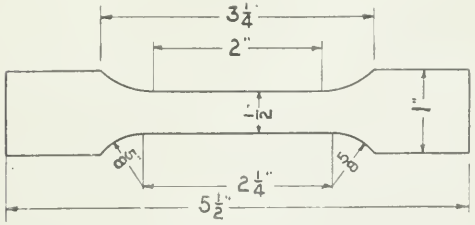
2. *Porosity Test.*—A hose will be selected at random and filled with air at 140 pounds pressure for five minutes. At the end of this time the rubber cover will be split with a knife and the hose submerged under water. This test is to determine the porosity of the inner tube. The escape of air must be distinct enough so that the porosity will not be confused with the escape of air which is confined within the structure of the hose. This test determines whether or not the lot of two hundred is accepted or rejected.

3. *Bursting Test.*—The hose selected for test will have a section 5 in. long cut from one end, and the remaining 17 in. will then be subjected to a hydraulic pressure of 200 lbs. per square inch, under which pressure it shall not expand more than ¾ in. in circumference nor develop any small leaks or defects. This section must then stand a hydraulic pressure of 500 lbs. per square inch for ten minutes without bursting.

4. *Friction Test.*—A section 1 inch long will be taken from the 5-in. section previously cut off and the quality determined by suspending a 20-pound weight to the separated end, the force being applied radially and the amount of unwinding shall not exceed 8 in. in ten minutes.

5. *Stretching Test.*—Another section 1 in. long will be cut from the remainder of the 5-in. piece, and the rubber tube or lining will be separated from the ply and cut at the lap. Marks 2 in. apart will be placed on the section, and then the section will be quickly stretched until the marks are 10 in. apart and immediately released. The section will then be re-marked as at first and stretched to 10 in. and will remain so stretched 10 minutes. It will then be completely released, and within thirty seconds of the time of releasing the distance between the marks last applied will be measured, and the initial set must not be more than ¼ in. At the end of ten minutes, distance between the marks will be again measured, and final set must be not more than ⅛ in. The small strips taken from the cover will be subjected to the same test.

6. *Tensile Strength.*—With a specially designed die of the following dimensions:



Tensile Specimen.

Test pieces will be cut from the tube and cover and pulled in a tensile machine with a test speed of 20 in. per minute. After an elongation of at least 10 in., the inner tube must have a tensile strength of between 800 and 1,200 lbs. per square inch, and the cover 700 to 1,100 lbs. per square inch.

7. *Sampling.*—For each lot of two hundred one extra hose shall be furnished free of cost.

8.

III. SIZE AND DIMENSIONS.

Length—	Air-brake Hose, Inches.	Air-Signal Hose, Inches.
Maximum	22½	22½
Minimum	22	22

III. SIZE AND DIMENSIONS—Continued.

	Air-brake Hose, Inches.	Air-Signal Hose, Inches.
Outside diameter—		
Maximum	2 1/16	1 7/8
Minimum	2	1 13/16
Inside diameter—		
Maximum	1 7/16	1 5/16
Minimum	1 3/8	1 1/4
Thickness of cap vulcanized on—		
Maximum	3/32	3/32
Minimum	3/32	3/32

9. Hose shall be smooth and regular in size throughout its entire length.

IV. WORKMANSHIP.

10. *Tube.*—The tube shall be made either by hand or machine. It shall be free from holes and imperfections, and in joining must be so firmly united to the cotton fabric that it can not be separated without breaking or splitting the tube. The tube shall be of such a composition and so cured as to successfully meet the requirements of the tests given in Section 6 and 7, the tubes to be not less than 8/32 in. thick at any point.

11. *Wrapping.*—The canvas or woven fabric used as a wrapping for the hose is to be made of long-fiber cotton, loosely woven, from 38 to 40 inches in width, and to weigh not less than 20 to 22 ounces per yard, respectively, this to be determined by the following number of threads to the inch:

Warp .....25 threads per inch.
Filler .....18 threads per inch.

Tensile strength of single threads:

Warp .....not under 12 pounds.
Filler .....not under 9 pounds.

The wrapping shall be frictioned on both sides, and shall have in addition a distinct coating or layer of gum between each ply of wrappings. The canvas wrapping shall be applied on the bias and edges lapped at least ½ in. Woven or braided covering should be loose in texture, so that the rubber on either side will be firmly united.

12. *Cover.*—The cover shall be of the same quality of gum as the tube and shall not be less than 1/16 in. thick.

V. MARKING.

13. *Serial Number.*—Each lot of two hundred or less must bear the manufacturer's serial number, commencing at "1" on the first of the year and continuing consecutively until the end of the year.

14. *Label.*—Each length of hose shall have vulcanized on it the label for air-brake hose of red or white rubber as shown under the specifications for "Label for Air-brake Hose."

VI. INSPECTION.

15. *Rejection.*—If the test hose fails to meet the required test, the lot from which it was taken may be rejected without further examination and returned to the manufacturer.

16. *Inspection.*—Inspection shall be made at destination. If the test hose is satisfactory, the entire lot will be examined and those complying with the specifications will be accepted.

17. *Freight Charges.*—Rejected material will be returned to the manufacturer, who shall pay freight charges both ways.

TABLE SHOWING DIFFERENCES BETWEEN PRESENT STANDARD AND PROPOSED SPECIFICATIONS.

	Present M. C. B.	Proposed.
1. Number of ply..	Not less than two nor more than four.	Not less than four.
2. Porosity test....	Not required.	See Paragraph 2.
3. Hydrostatic test..	100 pounds pressure, with not more than ¼ in. expansion of diameter.	200 pounds pressure with not more than increase of ¾ in. in circumference.
4. Bursting test.....	400 pounds pressure (water) for ten minutes without hursting.	500 pounds pressure (water) for ten minutes without bursting.
5 Friction test.....	20 pounds to unwind not more than 8 in. in ten minutes.	Same requirement.
6 Stretching test...	Tube and Cover 2 In. marks to stretch to 8 In., released, remarked and new 2 in. stretched to 8 in Held for ten minutes, released, and ten minutes afterward to have a permanent set of not over ¼ In. Strip not to break.	Same test, except that 2 in. marks must stretch to 10 In. Finally, initial set must be not over ¼ in. and the final set (after resting ten minutes) not over ¼ in.
7. Tensile strength..	No requirement	Speed of machine 20 In. per minute. After elongation of 2 In. to 12 in. the inner tube must have a tensile strength between 800 and 1,200 pounds per sq. in. and the cover between 700 and 1,100 pounds per sq. in.
8. Sizes:	Present M. C. B.	Proposed.
Length	21¾ to 22¼ in.	22 to 22½ in.
Outside diameter.	Not over 2⅛ in.	2 1/8 to 2⅛ in.
Inside diameter...	1⅜ in. to 1 7/8 in.	Same.
Thickness of cap.	Swelled ends, 1/8 to ⅛ in.	Same diam. throughout, 1-32 to 3-32 in.
9. Tube	Hand-made of three calendars of rubber, thickness 3/32 in. min.	Hand or machine-made. Same.
10. Wrapping	Loosely woven cotton, 38 in. wide, wt. 20 oz. per yd.; 40 in. wide, wt. 22 oz. per yd.	Same, also cotton to have specified number of threads to inch in warp and filler, and of a required tensile strength for each thread.
	No requirement as to sewing edges or to lap the same.	Edges of fabric to overlap ½ in.
11. Cover	Same quality as inner tube.	Same.
12. Inspection		Inspection to be made at destination.

The report is signed by:—M. K. Barnum, chairman; T. H. Goodnow (C. & N. W.); I. S. Downing (L. S. & M. S.); C. D. Young (P. R. R.); A. J. Cota (C. B. & Q.), and J. R. Onderdonk (B. & O.).

M. K. Barnum, in presenting the report, said: The committee has held a number of meetings and has invited the manufacturers to present their views, in the first place in writing, and later on in conference with the committee, and we have simply given you the net result of our work and have not encumbered our report with details which can be obtained from the secretary if anyone wishes them. The report should be divided into parts and acted upon under two heads, one covering the proposed new label and the other the specifications.

You will remember that the Train Brake and Signal Equipment committee had a report on the hose label, and the action on that report was deferred until the report of this committee. I would suggest that separate action be taken on the air hose label, and that afterwards the specifications be acted upon by the convention by themselves.

DISCUSSION.

M. K. Barnum (Ill. Cent.): We have here a sample piece of hose with the proposed new label, which might be passed around.

T. H. Goodnow (C. & N. W.): If the action of the association is favorable to the proposed label here, I would suggest that with the approval of the executive committee, the Secretary be instructed to send out at once a circular notifying the companies of this label, as this will not be distributed until the proceedings are, so that the purchasing departments will be advised, and can eliminate the present two labels.

Secretary Taylor: The result of the letter ballot will show whether it is adopted or not. Still, if it is desirable, I can send out a special letter on this subject.

F. F. Gaines, (C. of Ga.); I would like to know when this new badge will be adopted, and whether we will be penalized if it is not adopted on time.

M. K. Barnum: I do not recall just what action was taken on that, but the arbitration committee discussed it and intended to allow until October 1, 1915, before making the new badge a requirement for the hose, so that gives everybody a chance to use up the old hose.

C. A. Schroyer (C. & N. W.): I see a joker in this, and do not know whether it was intended so by the committee or not. You have not forgotten the troubles with the present label, and the thousands of hose thrown out for the slight variation. Now, there is a higher grade of rubber to be used in this hose, and if this label carries, which I hope it will, the question is whether we are to sit in this convention hall and vote whether all hose after a certain date without this label is not M. C. B. hose. It is not M. C. B. because it has not as high a stretching quality. There is a copyright in it. There is nothing to be said as to whether the manufacturer is to charge anything for that; but it was intimated to me that there would be an advance in the price of this hose as they had to use this copyright. I am heartily in favor of this new brand, but I hope we will not have to go through the same thing that we have had for the last few years with our present brand. This new brand will mean an advance of three or four cents.

M. K. Barnum.—If there is any joker in the report, the committee has not discovered it. As far as the use of the copyright of badge is concerned, it was to protect the association against unauthorized persons using it. There will be no charge for its use; the copyright will belong to the association.

C. A. Schroyer.—Will the manufacturer get the right to use it; how will he get it?

M. K. Barnum.—By the order which he receives for hose from people who have a right to use it.

C. A. Schroyer.—Will there be a penalty if the method of manufacture is not followed?

D. F. Crawford.—In view of the conversation which has taken place on this subject of the label, I would suggest that the secretary send out a special ballot covering this one item alone, and send it out as quickly as he can. The result is to be announced immediately after the thirty days' time in which to vote. If sent out next week, we would have this ballot from the association considerably in advance of the regular letter ballot which does not come until September or October.

C. A. Schroyer.—That refers to the label only?

D. F. Crawford.—Yes.

The motion was seconded and carried.

President Fuller: We will now take up the second part of the report.

F. F. Gaines: Inasmuch as the committee has asked to be continued for another year, and they are not ready at this time to fully outline the specifications, I move that they be continued and suggest that in the meantime as many as can shall buy hose under this proposed specification and try it out so that we may see what results we get as far as possible.

M. K. Barnum: It has been the idea of the committee that their specification as drawn up here should be ready for adoption in place of the 1905 specifications now in use. It is a generally accepted fact that the 1905 specifications are not giving a satisfactory hose. The committee found that the average life of the hose purchased under these specifications was about ten months, and would recommend that the new specifications be adopted in place of the 1905 specifications, or at least be presented to letter ballot for adoption in place of them.

F. F. Gaines: I would be very glad to withdraw my original motion on that explanation. However, it is a fact, as I understand from the committee, that they have further refinements on this specification in view, and I thought that we did not want a new specification this year and then perhaps another new one next year.

C. A. Schroyer: We are requiring a hose that is parallel on its inside diameter, and as the result, it is costing us six or seven cents a hose more than if it was made 1-¼ in. inside diameter, with expanding ends. There is no benefit obtained in any respect in the use of a hose that is made parallel. There is not a fraction of a cent increased cost in making it 1-¼ in. diameter with an expanded end, and I do not think there is any need for the members of this association to pay an increased price for this hose simply because it has an increased diameter over what is required.

M. K. Barnum.—We have assurances from the manufacturers that it will not increase the cost of the hose to have it straight, and there seems to be some advantage in having it straight in the mounting and service.

C. A. Schroyer.—The manufacturers tell me that it is not reasonable to expect that they will make a hose 3-16 in. larger than the hose made heretofore and, make it at the same price as the smaller hose. It takes that much more material to do the work, and it is the material and labor in making the hose that costs the money. If any of you can show me a reason why the larger hose should be furnished at the same price as the smaller one would be, unless it is a matter of saving in labor, which it is not, then I would be willing to take into consideration that claim of the manufacturers that no additional charge would be made; otherwise, I cannot see it.

J. R. Onderdonk (B. & O.): The present M. C. B. specifications for air brake hose call for the same diameter as the proposed specifications, so that I do not see that the 1-¼ in. has anything to do with this specification over the present standard. If we expand the 1¼ in. hose at the present time, this specification makes no increase in price.

C. D. Young (Penna. Lines): I believe that the present standard of the association is a straight hose. It was agreed in the committee that we should continue that as a standard. I think there is a difference in the fabrication of hose, whether made with expanded ends or not. In practice, when the former M. C. B. standard hose had the expanded end, it was the custom of some manufacturers to vulcanize the hose after the expansion and then to wrap it. In so doing, it was practically impossible to wrap the canvas smoothly over the two diameters, one diameter at the swelled end, and the normal diameter over the balance of the length of the hose. It was also found difficult to wrap one piece of cloth over the hose; the cloth puckers at the point where the diameter changes.

Examination of a large number of pieces of hose will develop the fact that we practically have no protection at the point of curvature between the two diameters, and from a construction and manufacturing standpoint there is quite a decided advantage in being able to wrap a straight tube rather than one of two diameters. I think the committee's recommendation to continue the present standard of straight hose is entirely satisfactory. I am quite sure, from what the manufacturers told us in confidence, that they feel the same way. If anybody is at this time buying the expanded end hose, they are buying hose which is not standard under the present M. C. B. practice, as I understand it.

In reply to Mr. Gaines, I would explain that the investigation which the committee is making is along the line of adding additional requirements to our specifications and practices, making some slight modifications in the requirements. We are also providing, in case the association wants it, lettered air brake hose. The tests are directed largely to accumulating data with a view of getting a life test on hose in order to determine how fast it deteriorates, and the rate of deterioration from the time it is new until it is worn out. These experiments are being carried on in the laboratories of several railroads which are represented on the committee, as well as on the cars. It will take some three or four years (if the hose lasts that long, as the manufacturers tell us it will) for us to get the results of the investigation, which is rather elaborate and will take a good deal of work. I think it would be a great mistake, if the Association desires better air brake hose, to postpone sending this specification to letter ballot.

D. F. Crawford: I move that the recommendations of the committee on specifications for Air Brake Hose be referred to letter ballot for adoption as the standard of this association, in place of the one they now have.

C. A. Schroyer: I would like to have the courtesy of the floor extended to any manufacturers of air-brake hose who may be here and who will kindly advise us what difference there may be in the cost of the larger hose and the hose with the expanded end. Let us have it direct from them.

President Fuller: The expanded end is not in the question.

M. K. Barnum: I would move, if there are representatives of the manufacturers of air-brake hose here, that the courtesy of the floor be extended to them to give such information and present such remarks as they desire. The motion was seconded and carried. No representative of the air-brake hose manufacturers responded.

Mr. Crawford's motion was then put to vote and carried.

President Fuller: The committee on Air Brake Hose Specifications have a supplemental report which they wish to present.

M. K. Barnum: This report covers the air-hose gaskets which we thought would be so closely allied to the hose that it would be well to cover that also; and as the suggested specifications are short, I will read them: "Dimensions of gaskets: The dimensions of the gaskets must agree with those adopted by the M. C. B. Convention of 1909, and all gaskets shipped must be uniform in size and section."

Material desired: Gaskets ordered under this specification should be made of such a compound that they will be tough, and yet have enough elasticity to conform to the requirements for strength and elongation. They should sustain an ultimate load of 100 lbs., and show an elongation of original internal diameter of 350 per cent. when tested as described below.

Testing: When the samples for test are received, they will be examined for size and workmanship. The gaskets will be tested in tension in a manner similar to that of the tensile test of a single link of a chain. The half-links used to pull on the gasket will each be provided with a 180-deg. fillet of the same diameter as the original inner diameter of the gasket—that is, the two semi-circular fillets of the pulling links will just fill the inside of the gasket.

Rejection Limits: If any of the sample gaskets representing a lot should fail under a load of less than 90 lbs., or if the elongation is less than 250 per cent., the entire lot represented by the sample will be rejected. If the tensile strength of any sample tested is more than 125 lbs., the lot will be rejected, unless the elongation obtained from such samples is more than 350 per cent. If the dimensions vary more than 1-64 in. in any way from those adopted as standards, the entire lot will be rejected."

I suggest that in taking action on the recommendations of the committee in this supplemental report, it be sent to letter ballot with the other, and voted on separately; that would be three items to be voted on by special letter ballot.

F. F. Gaines: I presume that in case a letter ballot is favorable, the gasket will be included with the other two items. You would not have a separate specification for the gasket?

Secretary Taylor: I understand Mr. Barnum's motion to be that the special letter ballot shall include specifications for the label and the gasket. There will be three separate questions on which to vote.

F. F. Gaines: But suppose the three are adopted by letter ballot, is the separate specification for hoist gaskets to be joined with the others?

M. K. Barnum: It will be a separate specification and can be used separately or with the other.

F. F. Gaines: I would like to suggest that the committee, before they finally determine whether it is to be submitted as a separate question for letter ballot vote, whether we can have it made so that you can use them separately, or must they be together?

Secretary Taylor: It will be separated in the Standards, Mr. Gaines.

The motion was seconded and carried.

REVISION OF FORM OF PRESENT SPECIFICATIONS.

The committee has reviewed the existing M. C. B. specifications with a view of harmonizing the form without any change in substance, and, in order to accomplish this, an outline of instructions was prepared to guide the committee in its work. The subject matter of the outline was largely obtained from the existing standard of the committee on style of the American Society for Testing Materials.

After rewording the specifications, they were submitted to the various chairmen interested in the subjects for approval, which was obtained. The committee therefore recommends the following:

That the instructions covering the form of specifications be adopted by the association for future committees in preparing specifications.

That the specifications for iron axles be discontinued from the standards of the association, as material of this kind is no longer purchased in any quantity.

It was found in rewording the specifications that there are certain items in the rejection limits which could, to advantage, be corrected, and the committee recommends that a committee be appointed to review these specifications in order to bring them up to present-day practice. This refers especially to specifications covering steel axles.

Specifications do not exist for the following classes of material which are largely used by the members of the association, and we would recommend that consideration be given to the drafting of specifications covering this material for the use of the members:

Structural steel for passenger and freight cars.
Steel plate for passenger and freight cars.
Carbon steel forgings for passenger and freight cars.
Alloy steel for passenger and freight cars.
Blooms and billets for forgings for passenger and freight cars.
Steel castings for passenger and freight cars.
Malleable castings for passenger and freight cars.
Machine steel bars for passenger and freight cars, for miscellaneous parts such as bolts, handholds, step treads, etc.
Refined merchant bar iron for passenger and freight cars.
Journal box brasses for passenger and freight cars.
Insulating properties of refrigerator cars.
Hard-drawn copper wire.
Medium hard-drawn copper wire.
Soft or annealed copper wire.
Pipe for freight equipment cars.
Pipe for passenger and freight cars.
Galvanized sheets for passenger and freight cars.
Chain for passenger and freight cars.
Spring steel for passenger and freight cars.
Journal box packing for passenger and freight cars.
Cast steel knuckle pivot pins.

The work of this committee convinces it that there is a large amount of work which can be done by such a committee as this in assisting various committees on material in formulating their specifications, and recommend that this committee be continued, either as a standing committee or a special committee, but, if it is made a standing committee would recommend that the secretary of the association be made the permanent chairman.

The report is signed by: C. D. Young (Penna.), chairman; J. W. Taylor (Secretary and J. S. Sheafe (Ill. Cent.).

[illegible] Crawford: My understanding is that the report does not change the substance, but the form only, and I therefore move that the report be received and approved, and that the secretary be instructed in printing our specifications, to embody the suggestions of this committee.

The motion was seconded.

C. H. Gibbs (C. & N. W.): It would be dangerous to eliminate the specifications for iron axles. We may not use many iron axles, but we are manufacturing them in an axle forge [illegible] to some extent, and if we eliminate these specifications we are likely to get into trouble by reason of some broken axle coming up in connection with a lawsuit. If we abandon the iron axle we will put competition into the hands of someone else. On the first page of this report it says: "But the specifications for iron axles be discontinued from the standards of the association, as material of [illegible] purchased in any quantity."

[illegible] Fuller: Mr. Crawford's motion was to confine the results of this report to changes in accordance with the provision of this report, and not to eliminate any standards.

D. F. Crawford: Yes, as I understand it, to eliminate a standard it would have to go to letter ballot.

Secretary Taylor: Yes.

D. F. Crawford: I would like to add to my motion that the other subject requiring such consideration be referred to the executive committee.

The motion was carried.

CAR CONSTRUCTION.

Minimum Center Sill Strength, to Resist End Strains, for Steel and Steel Underframe Cars.

Part of a letter from D. F. Crawford, general superintendent motive power, Pennsylvania Lines West, outlines the reasons for this investigation as follows:

"Prior to the 1911 M. C. B. code, all steel underframe and all steel cars were subjected to the same combinations and the same delivering lines' defects as wooden underframe, composite underframe and all wooden cars. The consequences were that, in interchange, defect cards were being requested for damage which in no event would be repaired. In order to correct this situation Rule 43 was introduced. The interpretation of this rule is, in effect, that a steel underframe car or an all-steel car will not be damaged in fair usage; consequently, the combinations should not apply, and the handling company was made responsible for all damage which necessitated repair, except such damage as might occur through corrosion and weakening of the parts.

"I have been advised that, in some of the new all-steel and steel underframe equipment constructed recently, the center sill section has been reduced to such an extent that the steel and steel underframe cars are no stronger, if as strong, as the wooden cars, and under Rule 43 the owner will receive the same protection as he would if the car had been of proper strength."

The subject has been divided in two parts:

(a) Center sills for existing cars.

(b) Center sills for new cars.

The only precedent we have is that of wooden cars. The experience with steel and steel underframe cars extends over a period of about fifteen years. This experience covers a large number of car types, showing great variations in end strain resisting qualities.

It was agreed that the relative values of steel and wood used in car construction for direct tension or compression should be based on the elastic limits of these materials, and that the committee use a ratio of four for the elastic limit of steel to that of oak or yellow pine.

Compared with a wooden car having two 4-in. by 8-in. center sills, an equivalent steel car must have an effective center sill area of not less than 16 square inches between the points where end strain takes effect. The strains in car underframes due to lading do not add greatly to the stresses from end shocks. As a rule, a loaded car is less liable to damage from end strains than an empty car, for which reason it will not be necessary to introduce load strains, but base the minimum area and end-resisting strength on end strains only.

Modern steel cars have the center line of draft at varying distances below (seldom above) the horizontal neutral axis of the center sills, and draft stops riveted to the center sills. The distance between the neutral axis of any member of the car and the center line of strain acts as a lever arm, through which bending effect is added to direct tension or compression. Strains which do not act in line with the neutral axis of car members will be designated "Eccentric Strains." The ratio of stress to strain is $\frac{I}{\Lambda} + \frac{X}{SM}$, in which

I represents the area, in square inches

X represents the lever arm, in inches.

SM represents section modulus of the section.

Center sills not properly tied together at rear draft stops, located at some distance from the bolster, are subject to eccentric strains, which have a tendency to deflect them outward or away from the center line of car between the draft stops and bolster.

Compression strains acting on the car through the draft gear, or car ends, as the case may be, create strut action in the members of the car framing. Long struts are liable to buckle under compression, for which reason it is customary to set limits for ratio of length to radius of gyration of struts, in order to restrict the excess stress caused by this buckling tendency. The members, or parts of members, of a car framing which require consideration are generally flanges of channels or I-beams, and plates. Their cross sections are rectangular, or sufficiently close

to rectangular to be so considered in order to avoid theoretical computations.

The committee recommends the adoption of a ratio of 70 for length to radius of gyration, which corresponds closely with a ratio of 20 for length to depth "d" of a rectangular section. This depth must be measured in the direction in which buckling may take place.

To fulfill the restrictions just given, the length of a member should not be greater than 20 d., or the member must be securely anchored at intervals not exceeding 20 d.

The anchorage of center sills may be accomplished in various ways, the more common methods being by means of cover plates, or diagonal braces. The value of such braces increases the value of the center sills. Cover plates add direct value, and diagonal braces add partial value, depending on their angularity. Braces at right angles to the center sills add no value to the center sill area, unless specifically designed as horizontal girders of sufficient strength to transfer all of the end strains from the draft to the side framing, in which case the side framing must perform the functions of center sills, and must be subject to the same rules. The value of braces at point of minimum strength may be added to the center sill area, taking effect in the horizontal plane in which such value lies.

RECOMMENDATIONS.

Existing Steel or Steel Underframe Cars, which have less strength than that specified below, should be classified with wooden cars, and subject to the same rules for combination defects:

Area of center sills not less than 16 square inches.

Ratio of stress to end strain not more than 0.09.

The length of center or draft sill members, or part of member between braces, to be not more than 20 d. where "d" is the depth of the member, measured in the direction in which buckling might take place.

For new cars to be built after 1913 a greater strength should be required. Transportation requirements have increased greatly in the past ten years. Heavy freight locomotives, including Mallet road engines, greater efforts to pass cars through yards quickly, and rougher handling of cars, have increased the strains to cars, due to end shock, at least 50 per cent. Manufacturers of couplers, draft gears, draft attachments, etc., are all busy increasing the strength of their specialties, and are generally aiming to obtain double the original strength.

For new cars the area of center sills should not be less than 24 square inches.

Ratio of stress to end strain, not more than 0.06.

The length of center or draft sill members, or part of member between braces, to be not more than 20 d. where "d" is the depth of the member, measured in the direction in which buckling might take place.

BOX CAR END DESIGN AND STRENGTH.

F. F. Gaines suggested to the M. C. B. Association that designs of end framing of box cars, to prevent damage to car by shifting load, be submitted.

An investigation of box car repairs leads to a realization of the ever-increasing damage to box car ends and consequent expense of repairs. Wooden ends without metal reinforcement no longer meet transportation requirements; therefore, metal ends and metal reinforcements have been applied, tested and found much superior to wooden ends. Metal ends can be used either with or without wood lining. When using metal ends without wood lining, the inside surface of the plate must have no projections, such as bolt or rivet heads. Colonel B. W. Dunn, under date of March 21, 1913, advised as follows: "Paragraph 1662 (f), I. C. C. Regulations, prescribes that in a freight car to carry dangerous explosives, special care must be taken 'to have no projecting nails or bolts or exposed pieces of metal which may work loose or produce holes in packages of explosives during transit.' It is hoped, therefore, that you will be able to arrange the design so that the rivet heads will not project. If there is to be no interior wooden lining, and projection of the rivets can not be avoided, it would seem that the federal regulations would require a special wooden lining to be placed in the end of a car of this kind at least as high as the lading

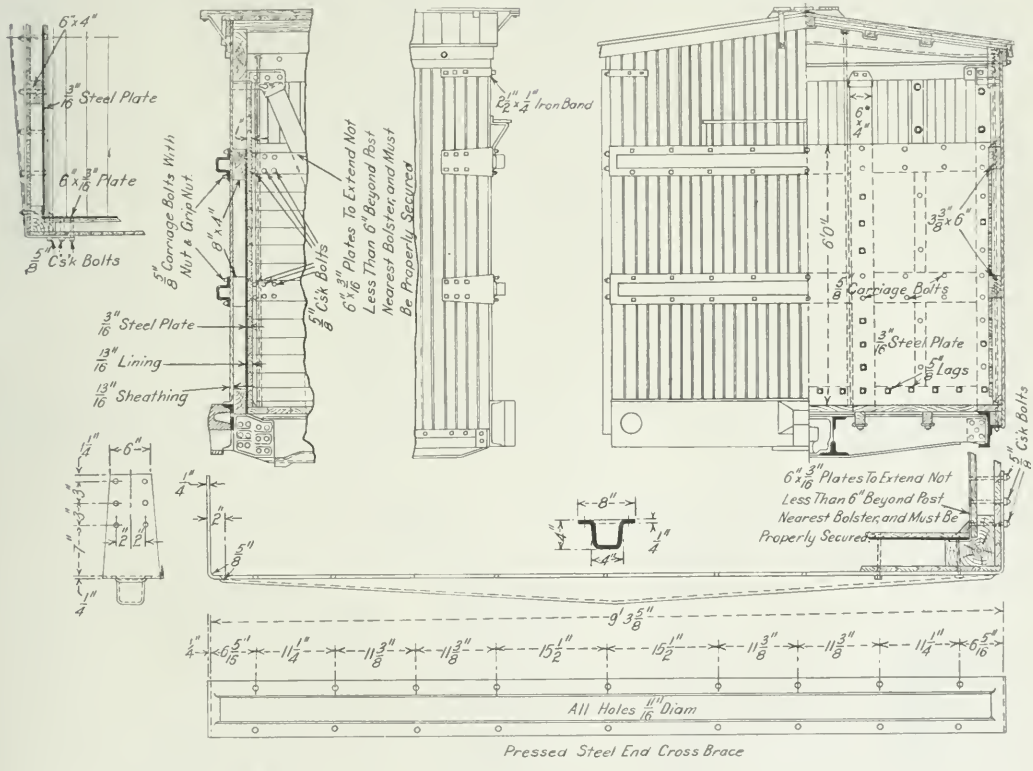


Diagram No. 1.

of explosive packages. I do not interpret the federal regulations to forbid the presence of flat metal surfaces, such as this reinforcing plate would be, if the rivet heads did not project."

RECOMMENDATIONS.

(a) Wooden cars with standard M. C. B. lining should have the ends reinforced with metal construction in accord with Diagram 1, or its equivalent.

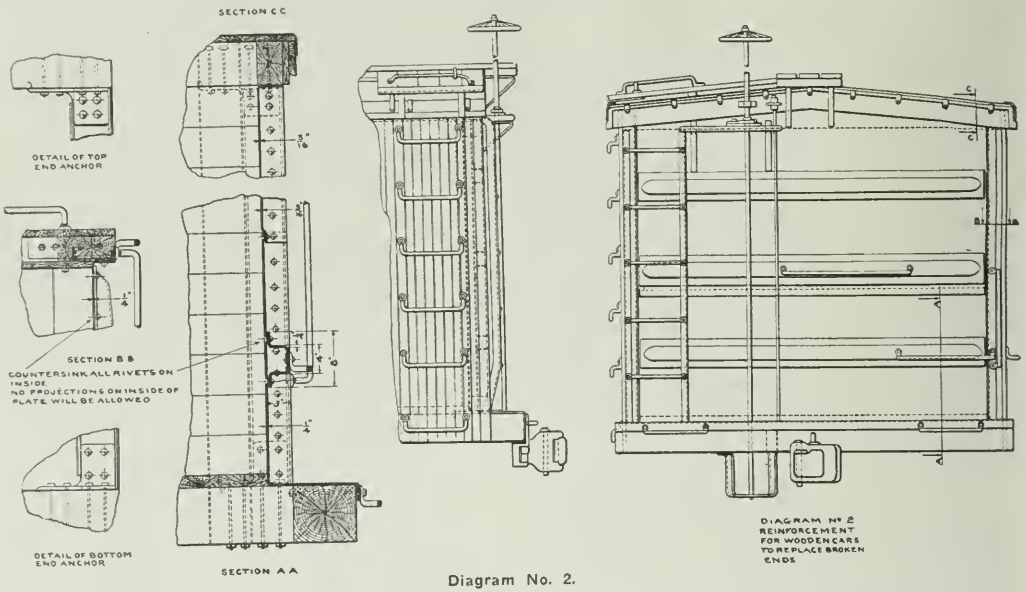

Diagram No. 2.

(b) Steel underframe cars with end lining 1½ in. thick and over should be equipped with outside braces, shown on Diagram 1, but the inside plate may be omitted.

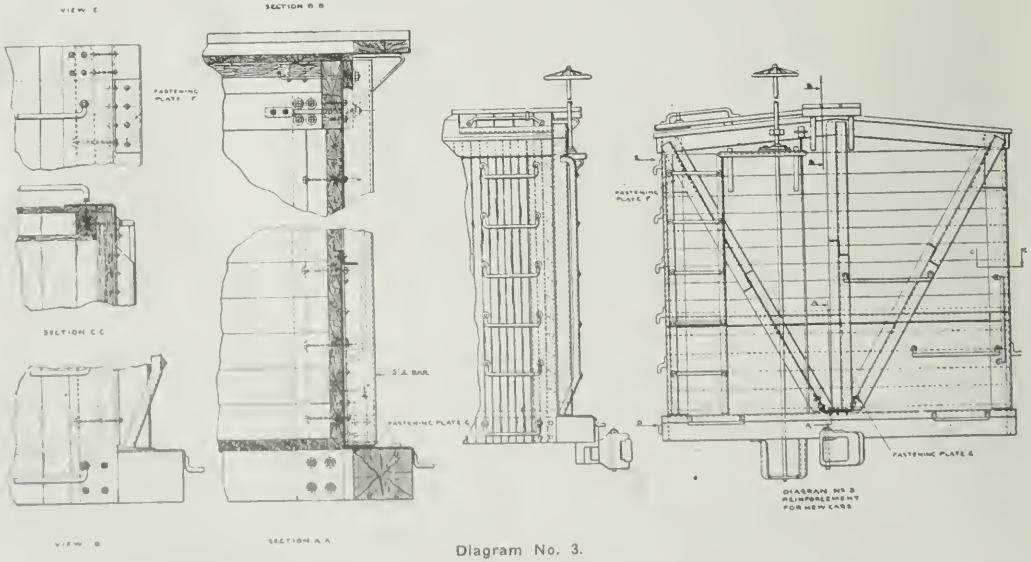

Diagram No. 3.

NOTE.—In applying outside braces, due regard must be given to compliance with United States Safety Appliance Rules for coupler and end ladder clearances.

(c) Cars with wood superstructure, requiring complete renewal of ends, should have steel ends applied, in accord with Diagram 2, or its equivalent.

(d) New cars should be equipped with ends of the type shown on Diagrams 3 and 4. The section modulus of the posts and braces, 2 feet above floor line, not including corner posts or flat end plate, should not be less than 15.

NOTE.—The Murphy or Van Dorn steel ends can be used instead of those shown on Diagrams 1, 2, 3 and 4.

(e) Each end must be attached to the longitudinal car members, either directly or through other members, by fastenings sufficient in strength to develop the full strength of the end.

(f) The construction shown in the diagrams are equally applicable to outside end sill cars as well as to inside end sill cars by modifying the attachment at bottom to suit the design of the end sill.

Seal Records of Box Car End Doors.

The following from Geo. A. Hancock, general superintendent motive power of the St. Louis & San Francisco originated this investigation:

"Much difficulty is experienced in having yard clerks obtain accurate seal records of end doors, on account of the inconvenient location and risk of personal injury. Claims are now being paid on account of no end door seal record, and cars are being pilfered by theft through the end doors, which can be entered with the least chance for detection. Is an end door in a standard box car essential? If so, could it not be placed near the side of car where seals could be read from the side ladder?

"It brought out the discussion that an end door is desirable for loading certain classes of lumber, and that in a shipment of lumber there sometimes are specially designed pieces that are too long to go into the side door, and that have to go in at the end door, so the agents have referred the matter to this office with request that we advise: (1) If it is essential to have end doors in box cars; (2) if end doors are necessary, if they can not be located where the seals can be read with less danger of personal injury than at present; (3) if some standard location can not be adopted so that all will be alike; (4) if the vertical height of the end door could not be made

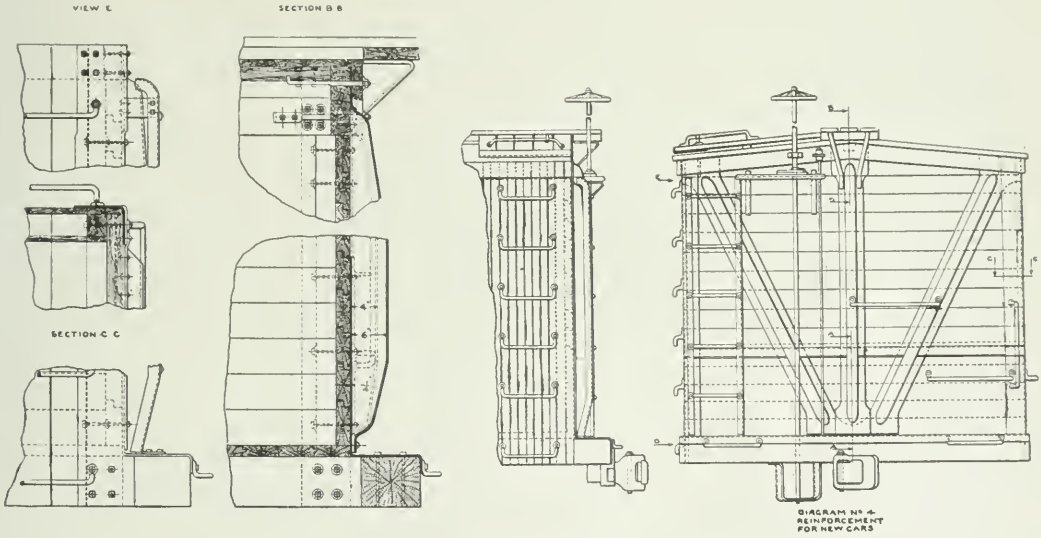

Diagram No. 4.

standard and door so designed that it could not be entered by a person intent on robbing the car, even though door was not sealed.

"As we are not putting end doors in our modern box cars, but as they are being placed in cars built by other companies, I believe that this is a matter that should be handled by the Committee on Standards and Recommended Practices, in connection with reports they made in 1912 on the height of seals on side doors."

Both kinds of cars, those with and those without end doors, used for the purpose of loading lumber, have been common in years past, but each year fewer new cars with end doors are built, because the end doors are valuable only on roads handling long lumber directly from the lumber regions as an important feature of traffic. Roads which formerly equipped all box cars with end doors have eliminated them from new cars, and are permanently fastening them in place on some of their old cars, leaving the end doors operative only on short box cars. This indicates that with the advent of the 40-foot box car the end doors will gradually become obsolete.

RECOMMENDATIONS.

(a) End doors used for loading lumber in box cars are essential only on roads having long lumber loading in box cars as an essential feature of traffic.

(b) End doors must be so constructed that when closed they lock automatically, by means of a lock accessible only from the inside of the car, thus avoiding the necessity of taking seal records.

(c) Seal appliances now in use, and not accessible from the ground or from end ladders, should be revised to be so accessible to promote the safety of employees.

The report is signed by:—W. F. Kiesel, Jr. (P. R. R.) chairman); C. A. Seley; A. R. Ayers (N. Y. C. Lines); S. G. Thomson (P. & R.), and C. E. Fuller (U. P.).

DISCUSSION.

R. E. Smith (Atlantic Coast Line): Has the committee in their recommendations overlooked a very common class of cars, used largely and primarily for perishable fruit and vegetables? These cars are necessarily equipped with end doors for ventilation of the lading, both top and bottom; they are provided with means for closing the solid door and also for applying seals when the end door is closed. It is important at one stage of the journey that the end door be opened to provide ventilation, and another stage, particularly in the case of citrus fruits moving from Florida to northern points, that the doors be closed and made as nearly frost-proof as possible with that class of car; from the standpoint of the southern lines I do not see how we could accept this recommendation. It would not be possible to so arrange the door that it could be locked automatically on the inside, for the reason I have stated, that the doors must be opened and closed en route according to the severity of the weather.

I ask if when the committee made this recommendation, they had in mind exactly what they say: "End doors used for loading lumber in box cars are essential only on roads having long lumber loaded in box cars as an essential feature of traffic," or whether they refer to all box cars with end doors.

W. F. Kiesel, Jr. (Penna.): The committee had in mind only the small doors used in the ends of cars in which lumber is loaded. It is the common practice, to put ventilators in the ends of cars in such a manner that no one can enter the car. There may be some old cars, with which we are not acquainted, in which the ventilators are of such construction that you can enter the car from the end door, but all of the recent cars built have the end doors put in solidly, so that they cannot be removed.

R. E. Smith: I will support what Mr. Kiesel has said in respect to modern cars. Certainly this end door construction in cars of modern type is of a very substantial nature, and the car cannot be entered or pilfered through means of the end door; and the older cars, of which we have still a considerable number, cannot normally be entered for the purposes of pilfering. But people who load these cars with long lumber have been ingenious enough to butt out the ventilating appliances

with their lumber and have failed to replace them. A thief who is properly equipped, can take out the end ventilators to get into the car, so that Mr. Kiesel is entirely right about that feature. The modern car cannot be entered for the purpose of pilfering. The pilfering of vegetable cars takes place principally from the side ventilator door and not the end ventilator door.

R. W. Burnett, (C. P.): The recommendations of this report are so far-reaching they should receive careful consideration. The company that I represent strongly objects to being forced to a standard which would mean a heavy increase in cost and weight, which experience has proved unnecessary. It is manifestly unnecessary to go back fifteen years, to make comparisons with wooden cars, considering that we have had 15 years' experience with steel cars. The comparison between steel and wooden cars is based upon the compressive strength of wood. The fact is that wooden sills fail from splitting or bending and from bending only when not properly supported, and practically never from compressive strength alone.

We have record of cars with 15 in. centre sills with an area of less than 20 in. being undamaged in accidents, while adjoining cars with centre sills of over 30 in. have collapsed at the bolster, due to the fact that the 15 in. sill was supported and the heavier sill was not supported.

There are many cars with 12 in. centre sills which have given excellent service for many years, from the fact that the sills have been supported. I think it is a mistake to use one formula for all class of cars. Within recent years we have had experience with steel superstructure cars which have shown the advantage of supporting the ends of the sills, and which has enabled us to use a much lighter centre sill, with practically no failure; where other cars with the heavier centre sills have failed, owing to the centre sills not being supported at the ends.

Experience with 20,000 cars with 15 in. centre sills, with a cross-sectional area of 19.8 in., has shown no failures except in demolishing wrecks. These cars at the end of five years are practically in the same condition as when built, while a wooden centre sill car rapidly deteriorates from the day it is put into use, due to the bolt holes wearing oblong, bolts bending, and the sills splitting. I mention the wooden centre sills again to show the necessity of comparing steel with steel, and not steel with wood.

Why not establish a minimum from facts obtained from experience with carefully designed cars where cars with 15 in. center sills have run in large numbers in the heaviest service all over the continent and in which carefully kept records for a long time show no failures of the centre sills.

With regard to recommendations (a) and (b), I feel that this association cannot give consideration to the contention that a car built last year be considered as a steel car, while a car which may be built next year of the same or superior construction would be classed as a wooden car. My understanding of this part of the committee's work is that it was to establish the difference between fair and unfair usage. If a minimum centre sill area is to be established, it should be based on the strength of the car, and not on the age. I would recommend as a substitute for recommendations (a) and (b), that in the future all cars constructed should have a minimum area of centre sills of 18 in. between bolsters and 20 in. between bolsters and end sills, when properly tied and supported, and a corresponding formula used when necessary to take care of eccentric loading; and after October 1, 1914, all cars with centre sills of less than these dimensions should be considered as wooden cars, regardless of when they were built.

F. F. Gaines: I cannot agree with Mr. Burnett in his remarks on the centre sill section. I have had some experience with cars with these light centre sills, and the experience has been especially disastrous. I do not think there is any question that in the building of steel cars in days gone by we have used too light material and that there was not sufficient strength in the car to take care of the buffing shocks. In my opinion, it is time that this association went on record as favoring good substantial car construction, and I would therefore move that recommendation (b), relative to new equipment, be submitted to letter ballot for adoption as recommended practice, and also that recommendations (a), (b), (c), (d), (e) and (f), under end construction, be separately submitted to letter ballot for adoption as recommended practice.

The end construction of box cars is something that has been neglected in the past to a very considerable extent, and I know from looking over our repair tracks that not only our own cars, but other cars which were built six, eight and ten years ago, are entirely inadequate to take care of the shifting loads. We are reinforcing our cars. I do think, therefore, that this association should put itself on record as favoring something more substantial than wooden construction in the ends of box cars.

L. C. Ord (C. P.): Mr. Gaines' remarks failed to take into consideration one point, which is not simply a question of the strength of the centre sills. If you take the old wooden flat car with wooden sills, and compare its strength with that of the box car, you know there is a very big difference as to the load which these sills will take. In other words, if you have a steel frame box car in which the strength of the car is in the superstructure as well as in the centre sills, why ignore the strength that is in the superstructure, which is preventing the end sill from dropping? Aside from any theoretical consideration of this subject, let us remember, after all is said, that the centre sills usually fail from the ends dropping. If your construction is such that the end sills will not go down, the area of 25 sq. in. that is called for is not necessary. It is manifestly unfair to make a specification which will call for a flat car, or a car with a steel underframe and light superstructure, requiring the same strength of centre sill as a steel superstructure house car in which the end sills are supported.

As to the service that they have given, prior to coming down here, we made a careful investigation and we have found that during the time our steel frame box cars have been in service, having carefully checked our records, we find that there is no case where we have been able to find a bill on owners' defects for the failure of these sills. They have been in service on practically every road on the continent, and therefore they get pretty well all the extremes of service.

We have had several wrecks, notably two in which some coal cars of our own construction, with 30 in. area sills, and almost double the depth of the oldest steel frame box cars, failed at the bolster due to the sills having gone down, whereas the box cars which were next to these coal cars came out of the wreck without the centre sills being damaged.

President Fuller in his opening address, spoke of the importance of not putting into the association records anything which would require additional or heavy expense, unless it was thoroughly warranted. The 25 in. sectional area for centre sills will be required under the form given. They put that limiting figure on cars without the supporting superstructure, and if you refer to the report of the committee it says:

"The side framing must perform the functions of centre sills, and must be subject to the same rules." Yet by establishing that minimum area of 24 in., it means the requirements must be in excess of that. The area of centre sills should be of sufficient strength, but not be required to take care of the eccentric loading; and they cannot do that without requiring as heavy an area as was required for the minimum; while the 24 in. is approximately as steady as for cars with supported ends.

F. F. Gaines: That is a supported car like a box car, and those cars have light channel centre sills and do not come up to the specifications mentioned here. We have any number of those cars coming in every week. They are simply what might be called yard damages, where the centre sills are buckled, or other slight damage, and we have to cut them loose and straighten them out. I am thoroughly in accord with the remarks that we are building centre sills too light. This is not making it obligatory, or standard, but simply favoring good car construction that will stay out on the road and not always be in the shop.

J. J. Tatum (B. & O.): President Fuller, in his address, brought economy forward very forcibly, and I believe it is the duty of this association to support his recommendation. Let us build a substantial car that will not find its way to the shop as frequently as the car of the past has done. We have had wood sill cars fail, and we have had steel sill cars fail because we have not constructed them substantially. The report made by the committee on Car Construction is an able one, worthy of adoption by this association and I hope the organization as a body will support the motion as made and the letter read by the President.

J. J. Hennessey (C. M. & St. P.): Does that wipe out the whole report, or can we refer back to the end of it? I think there are some vital points not discussed at all.

J. J. Hennessey (C. M. & St. P.): I would rather have the sill construction go. There is another class of cars not referred to at all—automobile cars. There are a great many cars where it would be impossible to seal the end doors. Some have double doors; when used as an automobile car they open out and an inside door which can convert the car into a grain car is closed. The recommendation on the end door is too broad and inconsistent, and could not be carried out in many lightly-built cars.

C. A. Schroyer (C. & N. W.): I am of the opinion that if this association does not appoint a special committee on Car Construction, to which committee railroads may refer their drawings of car construction, and from whom they could receive suggestions what to do relative to these matters, that it will not be many years before the U. S. Govern-

ment will do for us in the matter of car construction what he has done in the way of safety appliances. Trainmen without mechanical knowledge have told us what should be done in the matter of safety appliances and that is what will be done on car construction.

We have had a great deal of trouble with sills, light in weight, small in size, and of such shape that there was no lateral strength in them, and in the ordinary emergency application of brakes, they have collapsed on the road. That is not good construction, and insofar as the doors are concerned on the ends of cars, there can be no general rule laid down to meet the conditions. I think that with a standing committee we could reconcile many of the weaknesses that now exist in our construction.

W. F. Kiesel, Jr.: All the box car ends I am acquainted with have inside locks. Do you know of any other, Mr. Hennessey?

J. J. Hennessey: Yes.

W. F. Kiesel: There is no reason why inside locks could not be supplied. It is the best way to close the door and to keep it in shape; therefore it seems the same rule for small end cars could apply to large end ones for automobile cars.

J. J. Hennessey: Where would you seal so it could be read from the outside?

W. F. Kiesel: With the bar you could not open it from the outside; only from the inside.

D. F. Crawford: I would like to endorse all that has been said as a necessity for the railroads of this country producing good cars, and to make a motion that the report of the committee with their recommendations be referred to letter ballot as the recommended practice of this association.

The motion was seconded.

L. C. Ord: The association does not need to specify an area of centre sill as covered by this committee. The only thing is that in the one particular case of the car with the steel superstructure, some consideration should be made of that additional strength. The fact is that the formula which Mr. Kiesel has given is thoroughly satisfactory, if the exception of the sill area recommended is ignored and if the outside end eccentric loading is negligible. It seems to be the understanding of the committee on Car Construction, that not only may the area of centre sill braces be considered on the proper basis, but that where the end sill is of sufficient strength, the value of the support of the sides may be considered as supporting the centre sills and may properly be considered in establishing the minimum centre sill area required. Mr. Burnett's motion was that this should be considered. It does not matter in what form it is considered as long as the case is given sufficient consideration to be sure that it is right. I mean that the recommendation as to standard is not consistent throughout. The area is necessary under all conditions of the cars except where the end of the sill is supported.

W. F. Kiesel: The value of such braces increases the value of the centre sill; and that is supposed to be added as available for centre sill area. Then in the type of car you spoke of, if you have proper bracing between the sides and the centre sill, you are at liberty to add the minimum value of the braces to your centre sill area in considering the construction; but in a box car that is empty other questions arise. If the box car is loaded, you get a decided area, but in the empty car you have no better conditions than in the flat car.

The motion was carried.

The report of the committee on Correspondence and Resolutions was read in abstract by Secretary Taylor as follows:

"The committee on Correspondence and resolutions made its report expressing its appreciation and thanks to President Fuller for his address and for the splendid manner in which he had conducted the affairs of the association during the convention; and to the officers of the association generally for duties well done in handling the many details in connection with the convention; to the various committees that have considered and reported on the various subjects assigned to them; to the committee on arrangments for its effective services in making such complete plans for the meeting; to the railways for courtesies extended; to the hotel men of Atlantic City for their hospitality; to the Railway Supply Manufacturers' Association for their complete exhibition of railway appliances; to the technical press generally and to the *Railway Age Gazette* especially, for the daily report of the convention."

DISCUSSION (CONTINUED).

O. C. Cromwell (B. & O.): I think there are some other subjects which should be referred to the committee on Car Construction. In connection with the application of certain draft gears, where there is an insufficient distance from the bolster to the end of the car, there should be a minimum distance, because we find that certain draft gear works close into a bolster, and you cannot get good construction. That point should be given some consideration, and a minimum distance allowed or in other words, the bolster placed a certain distance from the end sill so as to give sufficient space in which to apply the gear, which requires the maximum distance of space.

Then there is another consideration: Going into a heavy coupler, we want to provide sufficient means of attachment without conveying the stresses to the underframes.

The end sills should be so arranged as to provide for the proper application of the angle cover. They are not in the same location on many cars, and that should be considered. In connection with the coupler proposition you must give attention to the support of the carrying-iron. There is a great deal of expense involved at the present time in renewing carrying irons, or equivalent support for the couplers. That matter should be assigned by the executive committee to some committee of the association. The difference in forms is resulting in the spreading of the end sills and the castings surrounding them.

D. F. Crawford: As perhaps many of you are aware, the American Railway Association has before it the consideration of the construction of a standard box car, and it has expressed in some circulars which it has sent to some railways, the hope that we may reach some day a standard box car. In view of that, and the discussion which has gone on before, I would like to move that the committee on Car Construction be transferred from a special committee to a standing committee.

The motion was carried.

O. C. Cromwell: Let us give careful consideration to the question of the strength of the end of open cars in connection with our consideration of the box car. We have all kinds of designs, and many of them are not very effective; that is a matter which should have some consideration.

F. F. Gaines: Mr. Brazier made a remark which was apropos regarding the subject of car doors. Regarding those photographs which were passed around, you fasten the hasp from the door with one bolt, and the first time the car gets a good thump it takes the whole door with it. There are ways to get around it, and we would like to hear more about this car door business.

D. R. MacBain (L. S. & M. S.): This meeting of this association is one of the best that has ever been held. We have gone on record as being in favor of better things. In going through all the big yards of the country, we see not only old cars, but new ones that are fitted with devices unsuited for present-day operation; and while I listened attentively and did not make any comment, I am fully in accord with the recommendations of the car committee, because it tends to better construction which is something that we need. I recently visited a big yard on the New York Central with Mr. Garstang and others, and we were impressed with the condition of the ends of cars—many cars had ends bulged out. We tried to see how many were of the old design and how many of the new design, and in the case of certain class of loading, the same results were had with the new cars as with the old. They were all wooden, indicating that wooden ends, such as we used in the past, are unfit unless you are satisfied to have your car come in for a new end every time it carries a certain kind of freight.

What is true of the end of the car is true of the other parts. The doors are ridiculous. We have made a strenuous effort to bring our door conditions up to a better plane in the last three years, and have succeeded to a very satisfactory degree.

C. A. Schroyer: We are largely a lumber road, and haul a great deal of dressed lumber; there is no commodity we handle that is more destructive on the ends of cars than is dressed lumber, and I note with a good deal of satisfaction the new improved ends for box cars that recently came on the market. I have considered the matter of strengthening car ends, and recently I find that we are depending entirly on the corner post which is improperly secured to the side of the car, as well as the two end posts, to resist the thrust and prevent the shifting of freight on the inside. In our later designs we strengthened the corner posts and secured them to the side of the car, and substituted 2¾ in. lumber to be used up to the height of 4 ft. We are doing that for the reason that we want the inside lining to assist in resisting the stress.

In some tests we made, we have found the timber used was not of sufficient strength. Then we used a thicker timber and under a load of 500 lbs. it showed a defection of 1¾ in. With the thicker stuff we gain that much in the strength of the end provided the end is secured properly to the side. We then put 2¾ in. plank under the testing machine, and we found that we could get about 1,200 lbs. with the same amount of deflection; and because of this increased strength, we are using the increased thickness of board to obtain increased strength in the ends of the cars. I regret we cannot get closer together on these matters, but the conditions

under which we operate have much to do with the designing of cars.

I regret as far as our association is concerned, that we do not have a larger representation on our road. We should have more general foremen and general inspectors here. They know more about the interchange of cars in one minute than we know in a month, and they would be good men to have here, insofar as our interchange work is concerned.

G. F. Giles: We all realize we have had a great deal of trouble with defective doors and door fastenings, and the ends of box cars, but those are not the sources of all our troubles. We have had more troubles and more wrecks caused by defective arch-bars than anything connected with our equipment, and it is very surprising to me to find that some of the best railroads in this country are still using arch-bar trucks in their new equipment.

One year ago we tried to inspect them by means of a hand-mirror so that the inside could be inspected as readily as the outside. We have found thousands of defective arch-bars. It has resulted in saving a great deal of expense and I am satisfied it prevented many accidents.

J. J. Tatum: It has been said that we expect a better convention next year. I see no reason why we should not have it. We have a committee now on car trucks, we have another committee on couplers, we have another on car construction; and it has been suggested that we take up other important matters. It has also been suggested that something be taken up as to improved ends of cars. That is being taken care of. Just recently in one of our yards, it developed that 65 per cent. of the cars unfit for grain, had wooden ends. Many of them had steel underframes, showing that the designer considered what was needed in the underframe; but failed to consider what was needed in the superstructure.

There is one subject which has not been brought out, which I think should be. A large number of cars are sent out over a line after being received in bad order due to heated journals. It not only represents the expense of replacing the sponging, but it requires renewal of axles due to cut journals. It delays freight traffic on the road and it delays passenger traffic.

The M. C. B. Rules require that the matter of tension of sponging should be given very careful attention—as good as they give their own lines—but it does not specify what the owner of the car should give us. Over 40 per cent. of the cars cut out on the B. & O. are cut out because of hot journals. Cars are delivered with such short time between the time of leaving and receiving, that there is not the necessary time left to withdraw the sponging from the boxes and renew it; therefore, the owning line must help, as well as the operating line.

F. W. Brazier (N. Y. C.): The Coupler committee in its report said that the thanks of the association are due to the manufacturers We feel that we should take some special action and extend a vote of thanks for their co-operation, and the work they have done in connection with the Coupler committee. I move a vote of thanks be tendered to manufacturers who have worked in connection with the Coupler committee, for the aid which they have given in bringing about the results so far as we have gone.

The motion was seconded and carried

F. W. Brazier: The New York Central has practically adopted the all-steel ends We have made some very severe tests with box cars loaded with wheels, and tried to destroy the cars and I am glad to say that with our standard wood end which costs us within $15 of the all-steel end, we practically destroyed the cars; while in the case of those equipped with the steel end, we simply had to take off a little section, and repair it and put it back on the track. We are lining these cars, as we believe it stops sweating in case of rain. We have about a thousand of these cars now running

D. F. Crawford: The statement just made by Mr. Tatum and the one made by Mr. Schroyer and the discussion yesterday seems to bring out that there is no such thing as a box car. We all have so many foreign cars on our lines that we must consider them as home cars, and we must all try to lubricate them and keep them in shape with running repairs, and keep up our own cars also, so that we can systematize the traffic of the country. There is a great shortage of steel cars, and the old local conditions that made us design particular cars like these, have disappeared or are disappearing. I see a great deal of hope from the committee on Car Construction taking up the problems raised in this discussion

A. Sternberg: This association should get up a standard door and fixtures for box cars. It would tend to stop the pilfering from cars

F. W. Brazier: The trouble is we do not follow our own standards. That is why we have the Federal Standards. We had a committee on doors. It would cost fifty cents a car more, however, to put on three hangers in place of two, as recommended by the association ,and so people didn't do it. I want to second the remarks of Mr. Schroyer to the effect that if we do not get busy, the government will get busy. They have been here at our meetings looking for practical man for certain positions. We must unite on some standard. If the railroads had been united in the matter of safety appliances, matters would not have been handled by the government as they were. You will remember that we were then 85 against 15 per cent. If the committee recommends, as I said, three hangers for a door, the superintendent of motive power or some one else connected with him says, put on two, and save fifty cents on each one. I say, get some standard and stick to it.

J. J. Hennessey: The most hopeful thing I heard expressed at this convention was expressed by Mr. Crawford when he stated that the American Railway Association was drifting toward a standard box car. If the American Association may adopt a standard box car, and the association lives up to those dimensions and recommendations, I think it could then build a car that all the railroads of the country could build and maintain at less cost than at the present time.

J. J. Tatum: I am very much interested in this heated journal proposition. I do not know whether or not the association has any standard method for treating for a sponge. That matter should be considered carefully, and a method might be proposed for use as a guide for the companies.

F. W. Brazier: We have with us J. W. Marden, who has been in the car department fifty years, has been retired and pensioned. He is a past president of this association. We will be glad to hear from him:

J. W. Marden: I feel quite complimented at the action which you have taken, and I wish to assure you of my appreciation. The only thing that I can say further is that quite a number of years ago I could do the talking and Mr. Brazier had to listen, but today and for a number of years past, Mr. Brazier has done all the talking and I have been listening. I thank you very much for the opportunity of speaking.

ELECTION OF OFFICERS.

The following officers were elected; President, M. K. Barnum; first vice-president, D. F. Crawford; second vice-president, D. R. MacBain; third vice-president, R. W. Burnet; treasurer, John S. Lentz; executive committee, C. E. Fuller, T. M. Ramsdell, G. F. Giles; committee on nominations, F. W. Brazier, F. H. Clark, A. W. Gibbs, C. E. Fuller and F. F. Gaines.

President Fuller: Before turning over the gavel to my worthy successor, I want to express my appreciation of the work of this convention. I have been coming to these conventions for a good many years, and as has been remarked frequently at this convention, they seem to be growing more and more in favor and more attention is being paid to their work.

We have a duty to perform, but I am sorry to say that I feel that we have not performed that duty to the full extent that we should have done. The managers of the railroads look to us to recommend what should be done in car construction. I am sure that a great many of us believe, and it was so stated on the floor here, indirectly, that the General Managers Association ought to be consulted. We do consult with the General Managers' Association, and our own managers, but it is our function to recommend and to try to bring about conditions that will meet with the requirements of the American railroads; and I feel that in place of being backward and hesitating to recommend standard parts of cars, or anything else that is to our mind for the good of the railroads and the good of the car departments, that we should boldly recommend them. We will make mistakes; if we did not make mistakes we would not do anything, but let us make some mistakes, if necessary, and make them with a view of advancing. The questions of car construction and specifications for car construction are before you. They are a part of your work, and I think this association should take the initiative and give the railroads the benefit of our experience

I thank you for your kindness and co-operation, and the assistance that I have received. I now have pleasure in turning the gavel over to my worthy successor, Mr. Barnum, and in doing so I want to add one thing, that I hope you will give him full support, and if you give him the same support you have given me, and give him ten per cent. or twenty per cent. more support, you will have next year the best convention you have ever had.

President-Elect Barnum: I believe it is generally conceded that the Master Car Builders' Association represents the largest

vested interests in the United States, and that means in the world; and it is also generally conceded that it is the most influential body in directing the principles which are of most importance to the railroads of this country.

With that preface, I will simply say that I appreciate fully the very great honor that has been conferred upon me in my election to the presidency of this association, and I assure you that I will give the duties of the office my very best efforts. I thank you.

Secretary Taylor: Mr. President, Mr. Scott H. Blewett told me this morning he would like to say a word to this convention. I would like to ask that the privileges of the floor be extended to Mr. Blewett, representing the Railway Supply Manufacturers' Association.

Scott H. Blewett: I trust that my being with you as frequently as I have been in the past few days does not make me a joke, because I assure you that I appreciate the courtesy that you have extended to the Railway Supply Manufacturers' Association, of which I am a member, and to myself personally, in asking me to be with you at other times and at this time.

Mr. Fuller, there have been but few, if any other occurrences in the history of the Master Car Builders' Association and Master Mechanics' Association, like the present, that one man has been honored by being the president of both associations; I think it has never before occurred. I may be mistaken. It is no small evidence of the rare esteem and confidence that the members of these associations have in you. This badge will remind you in the future of this esteem and of this confidence. There are things which words cannot tell. Man's love for man is spoken by deeds. It was man's love for man, and his tender sympathy for man, which indited the telegram last year that informed you of your election to the presidency of this association.

Ex-President Fuller: I regret that I cannot express in words my appreciation of the honor of having held the chair as president of this association, and of being the possessor of this badge. This association is one of the most important in the transportation world, and any man may esteem it an honor to be elected to fill the position of president.

D. F. Crawford: I promised your predecessor, Mr. President, I was not going to say any more. I ask the privilege of you to say a word more. I think this association should acknowledge by a suitable vote of thanks, the splendid service which Mr. Fuller has rendered as president. I have been with Mr. Fuller on the executive committee now for several years, and no one knows more fully than I do, how much he has had the interests of the association at heart. I therefore move that we extend to Mr. Fuller a rising vote of thanks for his highly esteemed services.

The motion was put to a vote and carried, and the meeting then adjourned.

TWO OLD FRIENDS.

Two of the convention visitors who are often seen together are E. B. Leigh, president of the Chicago Railway Equipment Company, and E. L. Adreon, president of the American Brake Shoe & Foundry Company. Messrs. Leigh and Adreon have been friends almost all their lives. They were boys together, both having grown up in St. Louis; and for years they were associated in business. In 1887 Mr. Adreon succeeded Mr. Leigh as president of the American Brake Company. At the same time Mr. Adreon became a director of the National Hollow Brake Beam Company, of which Mr. Leigh became president. This concern was the predecessor of the Chicago Railway Equipment Company. It will be seen that the business relations between the two have extended over a period of over a quarter of a century.

NEW HAVEN ELECTRIC SWITCHING SERVICE.

The New York, New Haven & Hartford now has a heavy freight and switching service operated by electric locomotives, in addition to the passenger service, and it is believed that this is the first instance where a large installation of electric locomotives has been made exclusively for switching service. There are sixteen 80-ton Baldwin-Westinghouse electric switching locomotives used at different points on the system and in the Oak Point and Westchester freight yards. The first electric switching locomotive of this installation displaced two steam switchers that were working on twelve-hour shifts, this being possible because the length of efficient service of electric switchers is not controlled by fire and boiler conditions. By September 1, it is expected that the electrification of the New Haven will be complete between New York City and New Haven.

RAILWAY SUPPLY MANUFACTURERS' COMMITTEE CHAIRMEN.

At a meeting of the executive committee of the Railway Supply Manufacturers' Association, held during the noon hour yesterday, J. D. Conway was re-elected secretary-treasurer.

The following committee chairmen were also elected to serve for the coming year: Finance committee, Geo. N. Riley; exhibit committee, O. F. Ostby; entertainment committee, J. F. Schurch; enrollment committee, Harold A. Brown; transportation committee, Geo. H. Porter; badge committee, C. B. Yardley, Jr.; hotel committee, Geo. L. Morton; by-laws committee, F. M. Nellis.

ATLANTIC CITY DAYS ARE O'ER.

Atlantic City days are o'er,
The time of all the year,
When we are gladdest to go home
Yet glad that we were here.

Not for a year will the M. M.'s,
Nor yet the M. C. B.'s,
Glide gently along in roller chairs,
Fanned by the ocean's breeze.

For one year more they'll stay at home,
Nor stick around at night;
Cafés, supplymen, on the left,
Wife, daughter, dance, on right.

For twelve months more they can't discuss—
Not for another year;
But next June sure will see them back
On the Boardwalk and the Pier.

DEATH OF F. O. KETCHAM.

F. O. Ketcham died of heart failure at 12.30 Wednesday morning after a few hours' illness. He had complained of indigestion for several days but thought it would pass away and gave it little attention. About 9 o'clock in the evening he was found unconscious on the walk near one of the hotels. He was taken to his room and became conscious again but sank rapidly to the end. Mr. Ketcham was 68 years of age, and this is the twenty-eighth consecutive meeting of these associations he had attended. He had been with the firm of E. L. Post & Company for many years. He began his business career in the oil trade, and was the associate of H. H. Rogers and others of that great group of men. His son arrived from Brooklyn, N. Y., early on Wednesday.

CAR DOOR STARTERS.—A new device in the form of a car door starter is being exhibited by the Camel Company, Chicago. It will prevent the use of crow bars or similar instruments for releasing a door from the closed position and operates without damage to either the door or the car.

CANTON-HANKOW RAILWAY, CHINA.—The Canton-Hankow Railway is opened to Lienkiangkou, a point seventy-five miles from Canton. At present owing to the lack of funds a fifteen-mile section between Lienkiangkou and Yingteh, the construction of which was started in May, last year, had been completed at the end of last month. This will be opened to traffic as soon as the iron bridge over the Wengyuanho river extending for the length of 750 ft. is completed.

NEW VICE-PRESIDENT OF THE M. C. B. ASSOCIATION.

At the election of officers of the M. C. B. Association yesterday two of the vice-presidents were advanced and R. W. Burnett, general master car builder of the Canadian Pacific, was chosen as the new vice-president. Mr. Burnett was born at Farmer City, Ill., in 1868 and in 1890 entered the service of the Union Pacific in the car department at Denver, Colo. In 1892 he was connected with the Pennsylvania Railroad at Chicago as a car inspector, and from August, 1892, to July, 1899, was with the Lake Shore & Michigan Southern at Chicago as a foreman and general foreman of the car department at Englewood. The early part of 1900 he spent as general foreman of the car department of the Long Island, going in the latter part of the year to the Central of New Jersey at Elizabethport, N. J., as general foreman of the car department. He remained with that road about five years, and in 1904 went with the Erie, and

R. W. BURNETT,
Newly-Elected Third Vice-President, M. C. B. Association.

was connected with it in the capacities of assistant master car builder and master car builder, with headquarters at Meadville, Pa., until January, 1907. He left the service of the Erie to go with the Canadian Pacific as assistant master car builder, and in 1909, when W. E. Fowler retired, was promoted to general master car builder of the Canadian Pacific.

The importance of his present position is evident when we consider that in addition to being in charge of the car repair and maintenance facilities of this large system, he has charge of the building of new equipment at the Angus shops. This amounted last year to about 300 passenger cars, a large number of which were sleepers, diners and first-class passenger cars, and over 4,000 freight cars. About 4,000 men are employed in the car shops at Angus.

Mellen Chamberlain Mason Hatch, Superintendent Fuel Service of the Lackawanna.

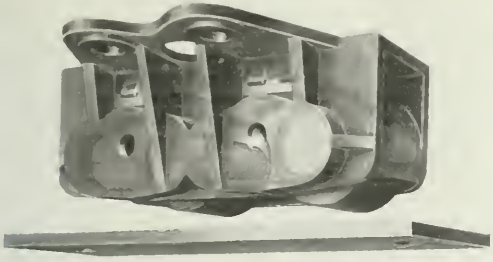
H. J. Small, General Supt. Motive Power, Southern Pacific.

A. M. Darlow, S. M. P., Buffalo & Susquehanna.

A Hankow Tramway.—The *Ta Han Pao* reports that a tramway car company has been organized at Hankow and that orders have already been sent to Shanghai for the purchase of material.

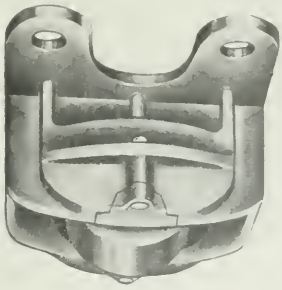
ROLLER SIDE BEARINGS.

The Joliet side bearing is so constructed that when a car is passing around an ordinary curve the rollers of the bearing run between high carbon steel plates, while on very sharp curves the rollers run free from the upper plate and



Joliet Double Roll Unlimited Travel Side Bearings.

the load is carried on large trunnions. These bearings are made in three different types to suit service requirements, and it is claimed that trouble from "slid flat" rollers and the pounding of side bearings is overcome by their use. The coned roller type are provided with a wear plate that



Joliet Single Roll Unlimited Travel Side Bearings.

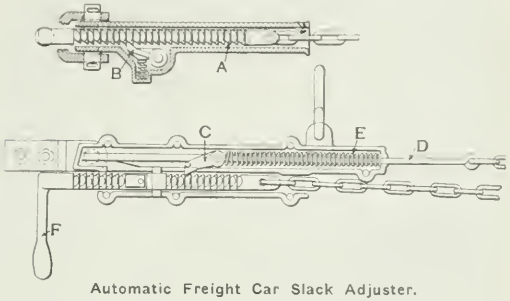
distributes the load equally to the roller at all times. They are manufactured by the Joliet Railway Supply Company, Chicago.

FREIGHT CAR SLACK ADJUSTER.

Among the slack adjusters that are exhibited on the Pier is an inexpensive design for use on freight cars. It is known as the dead lever adjuster. A chain fastens the upper end of the dead lever of the truck to a rack ratcher *A* that is held in place by the dog, *B*. The take-up is effected by means of the dog *C* that is carried on a rod that is attached to the live lever of the truck by means of a chain or rod.

The operation is as follows: When the brakes are applied a certain determined amount of motion of the rod *D* is provided for before the dog *C* drops into the teeth of the ratchet *A*. Then if the brake cylinder travel exceeds this amount the dog drags over the teeth until the end of the stroke. Meanwhile the dog *B* has held the ratchet in place and the stress of the upper end of the dead lever is carried on it. When the brakes are released the spring *E* pushes the rod *D* back into place and the dog *C* carries the ratchet *A* with it by the amount that it moved before engaging in the teeth. As the ratchet is carried back it moves over the dog *B* which finally engages it and holds it in its new and proper position. The arrangement is such that any excess of brake cylinder travel is taken up at the first application either by hand or air.

When it is desired to slacken the connections for the application of brake shoes or for any other purpose the ratchet is moved through a quarter turn by the handle *F*. This shows both dogs on to a smooth part of the ratchet bar, which is round, and it can be pushed ahead until everything is slack. Then, when the shoes are applied the handle drops back into



Automatic Freight Car Slack Adjuster.

place by gravity and the dogs are again in mesh. A pull on the rod readjusts the brakes and everything is ready for work. In case the repairman should fail to adjust the ratchet after applying the shoes the first application of the brakes does it and that one application is all that is lost.

SINGLE-PHASE MOTOR.

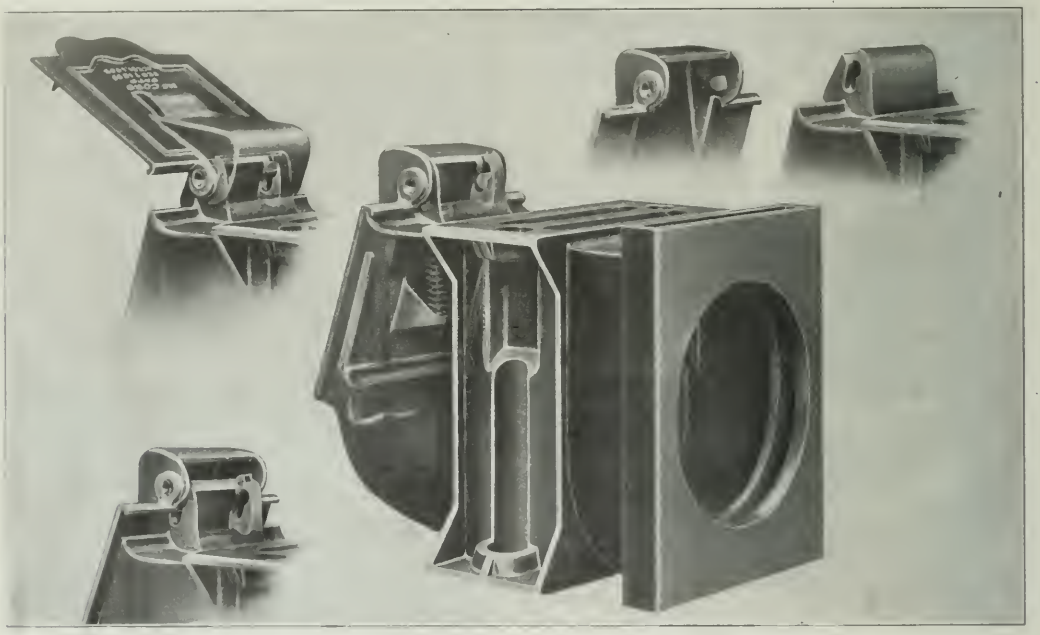
The Westinghouse Electric & Manufacturing Company, Pittsburgh, Pa., has placed on the market a new single-phase motor, made in capacities of from two to ten horsepower and suitable for constant speed application. This motor is of the repulsion-starting type and runs, when up to speed, as an induction motor. For most applications it can be connected directly to the line but where very low starting current is desired, a starting rheostat can be used. The frame combines strength and radiating capacity with minimum weight and over-all dimensions. The laminations are riveted together under pressure and pressed steel end plates are riveted to the unit thus formed; the foot, or base, is of pressed steel plate securely riveted to the end plates. The bearings are large and the rotor coils are form-wound and arranged to provide good ventilation. The commutator is of the radial type with undercut mica segments and the shaft can be pressed out of the rotor without disturbing the windings or the commutator. The motor will operate on either 110 or 220-volt circuits.

AIR AND ELECTRIC DRILLS.

The Independent Pneumatic Tool Company, Chicago, is showing several new tools at the convention this year, among which are the Thor roller bearing piston air drills. These are not only equipped with roller bearings on each end of the crank shaft, which reduces friction, but also have one-piece connecting rods, Corliss valves, telescopic screw feed and removable crank chamber plates. The sizes T and U Thor turbine air drills for telltale holes in stayholts and other light drilling, are also exhibited, as well as a two-piece long stroke riveting and a single valve chipping, calking and flue beading hammer. The Thor electric drills, which have recently been placed on the market, are also shown. These machines are equipped with roller bearings and a specially designed electric motor suitable for operating on alternating and direct current, or a universal motor for operating on either direct or alternating current.

PINLESS LID JOURNAL BOX.

A change has been made in the McCord pinless lid journal box, by cutting a slot in the top of the hinge lug, which is covered by the hood of the lid when closed. The trunnions are made with a flattened side and are cast integral with the lid on the inside of the hood; the slot in the hinge lug of the box is just wide enough to admit a trunnion with a flat side, in line with the side of the slot. The flat side of the trunnion is so located as to necessitate the sliding upward of the lid close to the face of the box and compressing the spring to within 1/16 in. of the solid position before the lid can be removed. This cannot be done by hand, but requires a special tool which insures against loss of lids. The lid is carried on the upper and lower lips of the box and the trunnions have no bearing on the hinge lug, but perform service only when the lid is being opened or is in an open position. These boxes have been in use for three years and are manufactured by McCord & Co., Chicago.



McCord Pinless Lid Journal Box Showing Method of Applying the Lid.

OIL BURNERS.

Trouble is often experienced with oil or kerosene burners used for heating damaged car parts because there is a cold area in the centre of the flame which requires the burner to be held so far away from the sheet or frame that much of the heating value is lost. A burner that is being shown in operation at the end of the pier by the Mahr Fuel Oil Burner Company, Minneapolis, Minn., is designed to overcome this fault. This burner has two chambers. The oil and air are ignited in the first chamber and the flame emerges through a choke to the second chamber. On passing through this it draws in free air through an auxiliary air intake, completing the combustion and giving a steady broad flame that will heat the whole area even when in very close contact with a plate.

SECURING SAFETY VALVES DURING TESTS.

The Coale Muffler & Safety Valve Company is exhibiting in the booth of the Nathan Manufacturing Company a device for securing safety valves when making hydrostatic boiler tests. This is in the form of a tool designed to be quickly applied or removed from the safety valve, thus avoiding the expense and delay occasioned by the removal of the safety valve and capping the opening; this and another common practice of screwing the spring bolt down are exceeding objectionable methods. This tool has been developed by H. C. McCarty and is made in a substantial form, with drop forged steel parts and a steel stem extending through the spring bolt and pressing on the lower spring button. It is threaded at its upper end, which makes it applicable to all sizes of valves. Steel jaws engage the spring bolt on the under side of the head, the jaws being held firmly in place by a lock washer.

THERMOSTATIC CAR HEATING CONTROL.

Relying on the judgment of a trainman, who is constantly in and out of a car, for the control of the heating system is often as unsatisfactory as to follow the ideas of individual passengers. The maintaining of a suitable temperature without variation is the ideal condition which is impossible with many of the present car heating applications. The Gold Car Heating and Lighting Company has recently perfected an automatic control which is operated by a thermostat. This is on exhibition together with a number of other recent improvements in car heating and ventilating equipment.

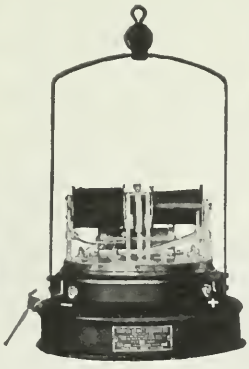
The thermostatic car temperature regulating system consists of a thermostatic temperature regulator, actuating, by hydraulic transmission a control valve placed between the inlet valve and the radiating pipes of the car. The regulator consists of a temperature-sensitive main diaphragm filled with a volatile liquid, with a positive action on a temperature difference of 5 per cent.

By means of a simple lever arrangement the movement of this diaphragm operates a subsidiary diaphragm (forming the transmitter of a hydraulic system) by exerting pressure on the liquid with which this diaphragm is filled, transmitting it through a pipe to a diaphragm in the control valve which is normally held open. The diaphragm of the control valve is adapted to receive the pulsations in hydraulic pressure coming from the thermostatic temperature regulator. An increase of pressure against the plate of the control valve tends to close the valve against the tension of the spring. Thus the rise of temperature of the air surrounding the regulator will operate to close the valve, and when this temperature falls the consequent lowering of the hydraulic pressure in the diaphragm of the control valve will allow this valve to open, thereby again admitting steam to the radiating pipes.

QUARTZ LAMP.

The Cooper Hewitt Electric Company, Hoboken, N. J., has placed on the market a quartz lamp which is based on the same principle as the Cooper Hewitt lamp. Both lamps use the vapor of mercury as the radiant or luminous body, but in the older type of lamp a long tube of lead glass is employed, while in the quartz lamp a short tube of pure fused quartz or silica is used. Like the Cooper Hewitt lamp, the quartz lamp produces a bluish-green light and is adapted for the illumination of machine shops, drafting rooms, rolling mills, etc., as well as for outdoor use. There is, however, a difference in the light produced in that the quartz lamp gives a larger proportion of yellow and some orange rays. The lamp consists of two elements, the quartz burner and the auxiliary. The burner consists of a quartz tube containing a small amount of mercury, and aluminum supports and a white enameled reflector. The auxiliary consists of a simple apparatus for automatically starting the mercury arc by tipping the burner and of the series inductance and resistance coils necessary for operating the lamp. The mechanism is enclosed in a ventilated canopy of sheet copper, which is readily removed, and the burner is suspended in the lower part of the auxiliary and enclosed in a glass globe. These lamps are made in two sizes, the 110-volt and the 220-volt and have a candlepower of 1000 to 2500.

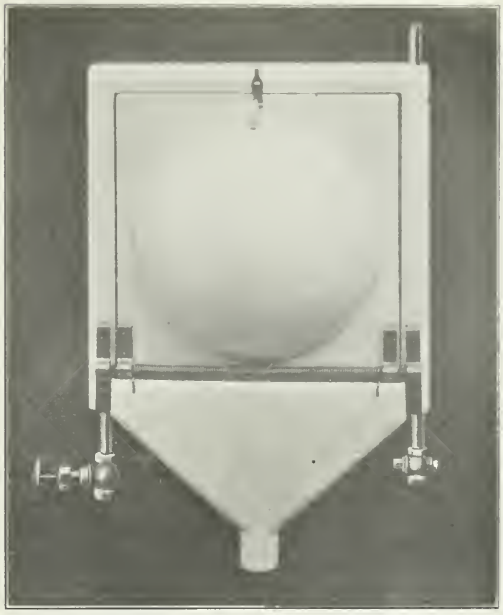
Cooper-Hewitt Quartz Lamp.



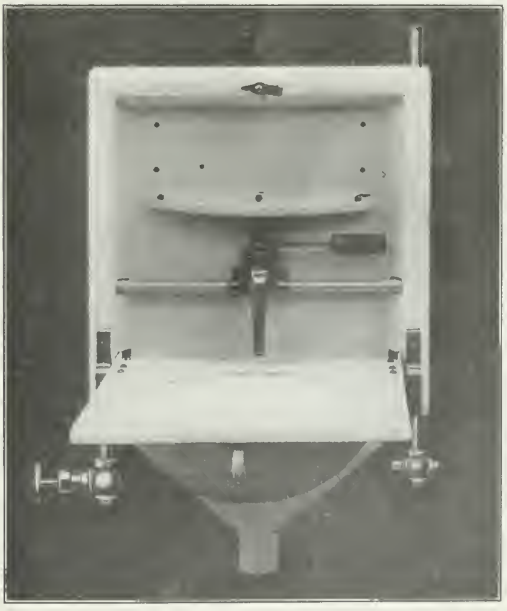
Auxiliary for Cooper-Hewitt Quartz Lamp.

FOLDING LAVATORY.

The steel postal car, which is in the track exhibit on Mississippi Avenue, has included in its fittings an all-steel folding lavatory, arranged for both hot and cold water. It meets all the requirements of the railway mail service standards.



Pressed Steel Folding Lavatory—Closed.

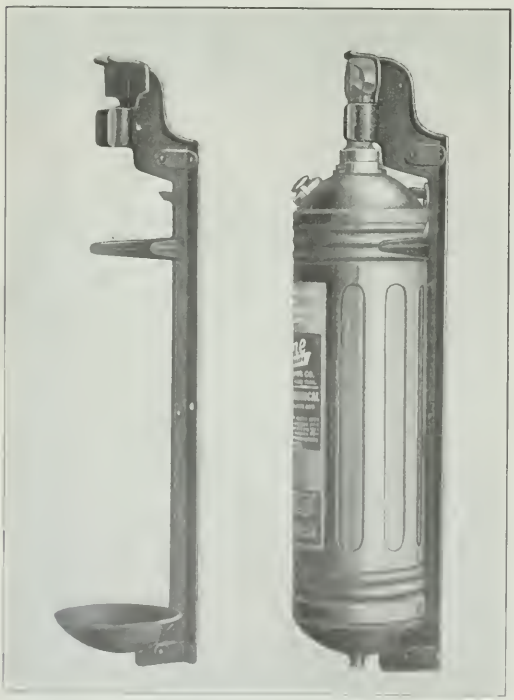


Pressed Steel Folding Lavatory—Open.

and projects only 6 in. from the back of the frame to the outside of the bowl when in the closed position. Being enameled throughout it is quite sanitary. A graduated valve, located in the center of the wash stand frame and connected for both steam and cold water, serves as a mixing chamber from which can be obtained either cold or warm water, the temperature being varied by means of this valve. The port or opening for the steam is small enough to make it impossible to allow enough steam to be mixed with the water to produce a heat that would be liable to scald the operator. The basin itself is provided with a drain at the back of the bowl, so located that when raised to the closed position the bowl automatically drains into the waste pipe connection at the base of the lavatory. The hinge rod is provided with a spring in order to cushion the bowl when swung down into the open position. A perforated soap dish is secured to the frame, and is so located that when the bowl is in the closed position it will, with all the other parts of the mechanism, be covered by the bowl itself. The lavatory is manufactured by the American Car Foundry Company, New York.

PYRENE FIRE EXTINGUISHER BRACKET.

It has been found that in a great many cases where employees use the Pyrene extinguisher, through carelessness the handle is left unlocked after use. The Pyrene Manufacturing Company, New York, in addition to the Pyrene extinguisher, has on exhibition a new type of bracket which

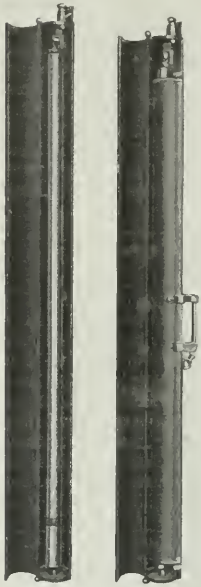


Pyrene Fire Extinguisher and Bracket.

will prevent this. It is so constructed that the extinguisher cannot be placed in it unless the handle is locked, thus preventing evaporation and leaking of the liquid. This bracket is specially designed to withstand the jarring of passenger cars.

VESTIBULE CURTAIN SHIELD.

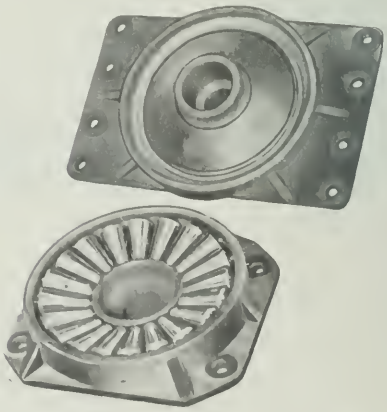
The illustrations show the new Rex vestibule curtain shield which is being exhibited by the Curtain Supply Company, Chicago. The shield is made of heavy gage material and only requires one latch at the top to hold it closed. Brass washers are placed between each hinge and a brass hinge pin is used to prevent rusting. Both curtain brackets are fastened to the casing, the upper bracket being adjustable and held in position by a thumb screw. This arrangement is considered a decided improvement over the old method of adjusting the length of the roller. The adjustable roller, however, can be used in this shield. The shield is so designed that, when opened, the curtain may easily be removed and both edges of the shield are rolled back so as to make a smooth surface for the curtain to pass over. This latter feature also provides an extra large opening for the curtain to pass through. Another improvement in the curtain is in the Rex automatic release handle. The latch has been redesigned to make a more neat arrangement and is simpler in its construction. It is arranged to trip with either a chain or tape, the curtain exhibited being provided with the tape. The device is strong, has but few parts and is adapted to either wood or steel cars.



Vestibule Curtain Shield.

TRUCK CENTERING CENTER PLATE.

The center plate shown in the illustration will, it is claimed, center a truck after rounding curves and assist in returning it to the proper position on the straight track. It is provided



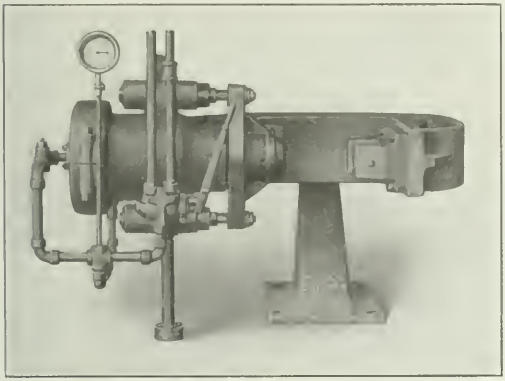
Improved Form of Hartman Center Plate.

with coned rollers which are pitched centrally and operate on an inclined race-way, and have trunnions to prevent their dropping out. The rollers are self-adjusting under load, and the pitching largely overcomes the outward thrust, while the larger ones, if any, work outwardly, and the smaller ones work

toward the center until each roller carries its share of the load. This center plate is an improved form of the Hartman center plate, and it is claimed gives three times the bearing surface of the latter. It is manufactured by the Joliet Railway Supply Company, Chicago.

COUPLER YOKE SHEAR AND RIVETER.

A new type of machine for shearing apart or riveting the yokes to the coupler shank is on exhibition at the booth of the Watson-Stillman Company, New York. Provision is made for having the ram work in either the horizontal plane, as shown



Coupler Yoke Shear and Riveter.

in the illustration, so that the parts are conveniently handled by a crane, or it can be swung to a vertical position if the coupler is to be handled by hand.

LOCKED LID JOURNAL BOX.

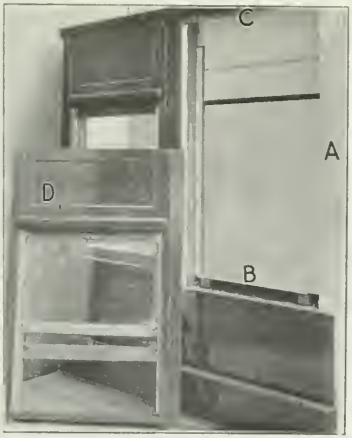
A type of journal box with a lid which locks in place when the box is closed, is included in the exhibit of McCord & Company, Chicago. It is shown in the illustration, and is so constructed that a lip on the lower edge of the lid engages with the box and in order to open the lid it is necessary to slide it up the face of the opening far enough to disengage this lip. The lid is made flush with the box all around so that it is impossible to obtain a purchase to slide the lid up with anything but a standard packing tool, which fits the slot formed by the two bosses below the mouth opening. This box is made for use with any McCord or M. C. B. lid.

Journal Box with Locked Lid.

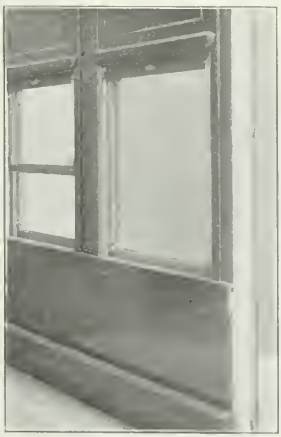
STEEL INTERIOR FINISH FOR PASSENGER EQUIPMENT.

When all-steel passenger cars began to come into extended use the problems of insulation, repairs and appearance were given serious consideration, but no scheme of construction was developed that satisfied all these three requirements. The result was that a good many roads hesitated about making the change from wood to steel in the interior finish although they built the framing and outside sheathing of steel.

The Hale & Kilburn Company, Philadelphia, Pa., has developed a system of interior finish, which is shown in the illustrations, for making the interiors of steel cars as comfortable and handsome as were those of the old wooden cars.



Integral Steel Finish and Car Interior Before its Application.



Interior of Car Fitted with Integral Steel Finish.

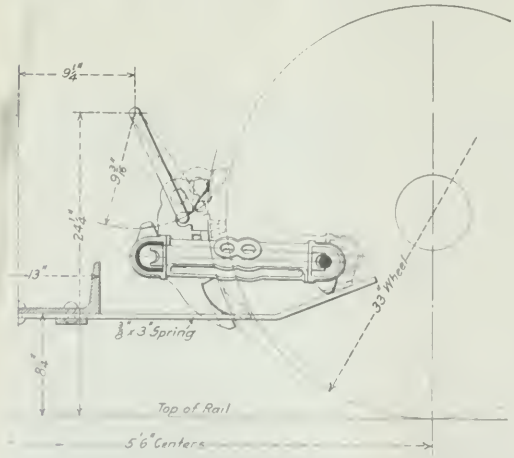
Exterior of Car Fitted with Integral Steel Finish.

and which can be so erected that it may be taken down for repairs without destroying the material, and applied again by the most ordinary labor and without any unusual shop equipment. One of the illustrations shows a partial interior view of a passenger car to which this integral finish is being applied. It will be noted that the side post *A* is surrounded by a channel of insulation so that the post itself is enclosed in a dead air space. The window frame, panel, curtain box, sash, hardware, etc., are all assembled in a unit as shown at *B*, and this unit slips between the posts *A*, the window sill *B* and the top member of the car framing *C*. It is then fastened in place by a row of bolts across the window sill and the bolts which also support the basket rack at the top of *D*, so that machine screws and rivets are entirely eliminated. In addition to the insulating effects of the dead air space and the insulation around the window frame and post, the latter also forms a pad between the interior finish and the car framing and the cheek plates of the window frames themselves are broken by insulated wedges where they overlap.

All of the members are so arranged that there is no metal connection between the outside and the inside of the car, and the frames being made in one piece and all from the same jig do not depend on the framing of the car to be kept square, which should be of material assistance in keeping the windows tight at all times regardless of the shifting of the car framing. The erection of the interior finish in new cars, as can be readily seen, is much simplified, it being possible to assemble each of the units at a convenient place in the shop entirely outside of the car, leaving nothing to be done later but the bolting in place. The bolts are so located that they are easily accessible for removal and any part of the finish can be taken down and erected again without damage, which should materially reduce the cost of repairs. A large number of cars are in service on various trunk lines equipped with this finish, which is part of the exhibit of the Hale & Kilburn Company at booths 408-410.

CRECO BRAKE BEAM.

The illustration shows the application of the new Duplex strut casting to the Creco brake beams as they have been installed on the Boston & Maine. The new strut is provided

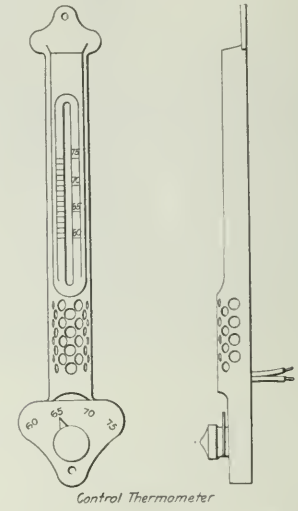


Creco Third Point Support Brake Beam with Duplex Strut Casting.

with two more bolt holes, to both of which may be used. This [illegible] the life of the strut casting, and thereby [illegible] for longer periods, but allows the beam to be used either right or left hand. The sliding third point support feature is the same as has been installed by the Chicago Railway Equipment Company, Chicago, in their recent Creco brake beam installations. This combination in addition to the operating and safety advantages given by the sliding third point support has a further advantage of remaining in active service for longer periods.

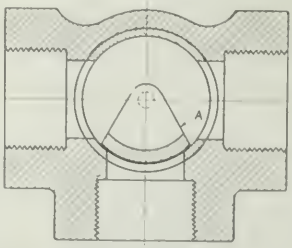
TEMPERATURE REGULATING DEVICES.

The Railway Utility Company, Chicago, is exhibiting this year an improved electric control valve and a by-pass valve for use in regulating the temperature of passenger cars. One of the illustrations shows the control thermometer and



Utility Thermometer and Electric Control Valve.

the application of the thermometer and the automatic electric control valve to the piping system. The valve is connected to the steam supply pipe of the heating system either



By-pass Valve for Use with Hot Water.

in place of or in series with the usual hand controlled valve. Two wires run from the magnetic coil in the upper part of the valve to a junction box containing a fuse box and from

this box two wires run direct to the electric lighting system of the car from which current is available at all times. Two other wires connected the control thermometer with the fuse box. The thermometer is constructed with four platinum wires fused into the glass, one at 60, one at 65, one at 70, and one at 75 degrees. These wires are connected to a switch on the thermometer and by turning the button of this switch to whatever temperature it is desired to maintain, the platinum wire fused in at that temperature will operate the electric control valve and shut off the steam supply when the car is at the temperature desired.

The by-pass valve shown in the other illustration is controlled by the thermometer in a similar manner and is arranged so that it by-passes the circulation of water from any particular state room in sleeping cars which are heated by hot water. In the illustration the valve A is in the position that it would occupy when the temperature of the air was below that for which the thermometer was set, and the hot water can enter the state room heating pipes.

HYDRAULIC SPEED GEAR.

Among the most interesting of the new devices that are being shown this year is a hydraulic speed gear exhibited by the Waterbury Tool Company, New Britain, Conn. While it has been in use in the United States navy and various foreign

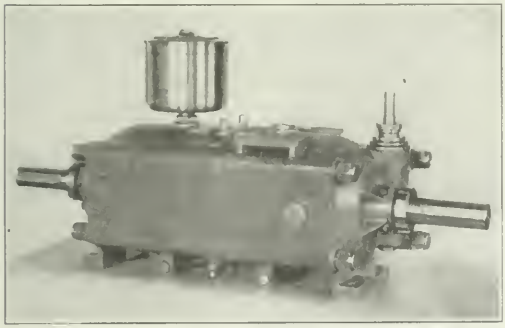


Fig. 1—Hydraulic Speed Gear Assembled.

countries for a number of years, it has only recently been introduced for commercial purposes. In its various sizes it is suitable for the transmission of power at variable speeds for any desired purpose. In the navy it is used for the operation of the turrets carrying the large 12-in. guns. On railroads, possibly its most valuable use will be in connection with direct connected motor cars where the gas engines can be driven at a constant speed and the speed of the car varied as desired. It is also suitable for use on cranes, hoists, machine tools, automobiles, etc.

Among the unique features are the fact that the driven shaft can be at any desired angle with the driving shaft without the loss of efficiency or convenience in the gear. The range of speed control is fully universal and depends on the angle of a plate on the interior of the mechanism.

The complete transmission device is made up essentially of two parts, an oil pump designated as the A-end and an oil engine designated as the B-end. The A-end may be driven by any source of power and is supposed to run at a constant speed in one direction. By the turning of a small control shaft connected with this end the stroke of the pump pistons is varied at will to deliver oil to the engine, or B-end, at the rate necessary to give the required speed and in the direction called for. The B-end is so constructed as to furnish a constant cylinder capacity for each rotation of the shaft. The speed of the B-shaft is therefore definitely determined by the rate at which oil is supplied to the B-end by the pump. No oil is by-passed without doing its share of work in the B-cylinders. The leakage averages about .13 of one per cent. of the oil used in doing the work. All of this takes place between the high and low pressure parts of the mechanism. There is practically no leakage from the gear as a whole. The speed ratios between the A- and B-shafts are, therefore, positive and are definitely determined by the angular position of the control shaft in either direction from its zero, or neutral, position.

Fig. 1 shows an external view of the gear in its most compact form. In this type the A- and B-ends are combined into one working unit; the power enters the unit by the A-shaft which rotates at a constant speed, and is taken out by the B-shaft, at the opposite end of the machine, which rotates at any required speed and in either direction. The small vertical shaft shown in the figure at the right end is the control shaft, and the direction of rotation of the B-shaft is determined by the direction the control shaft is rotated from its zero position and its speed by the angle through which the control shaft has been rotated.

On top of the B-end is an oil expansion box communicating with the oil in the machine. The whole enclosing shell of the gear is entirely filled with oil, although only a small portion of it is under pressure and active in transmitting power. The chief purpose of the expansion box is to provide for the difference of coefficient of expansion between the oil and the metal. The interior of the box is in communication with the

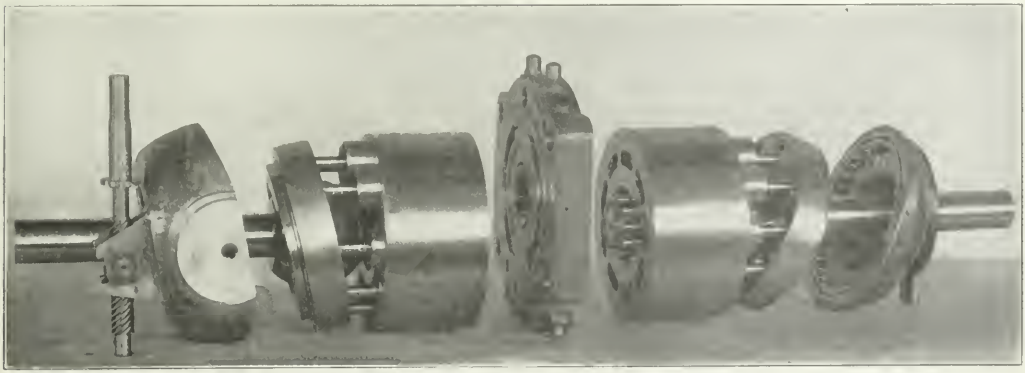

Fig. 2—Working Parts of the Hydraulic Speed Gear.

air through a small hole in its lid; the general oil supply is therefore under only atmospheric pressure.

In Fig. 1 the two ends are united by a common valve plate located across the middle of the machine and through which the oil is circulated between the two ends. This valve plate may be made in almost any shape, permitting the placing of the two ends at any angle or in any position with reference to each other. If desired each end may be provided with a separate valve plate and located in any desired position, the oil circulation being provided for by connecting pipes.

In Fig. 2 the outer cases are removed, leaving the internal parts, the two shaft groups being separated a little from the valve plate, and the angle and tilting boxes being pulled away from the socket rings.

The valve plate stands in the middle It is also shown alone in Fig. 3. Passing through the plate about half way between its center and periphery are two semi-annular passages. These are for the circulation of the oil between the A- and B-cylinders. When the gear is transmitting power one of these passages is under pressure while the other is in suction. These

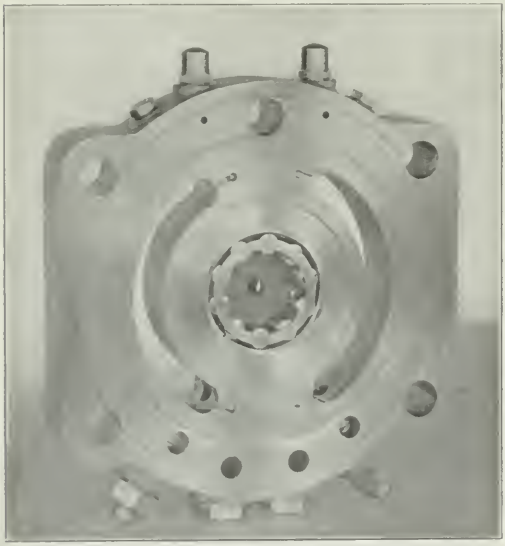

Fig. 3—Valve Plate of the Hydraulic Speed Gear.

two functions are changed according to the direction of rotation of the driven or B-shaft Connected with the passages are three pairs of valves, at the top are two small needle air valves used only for the escape of air from the passages and cylinders while being filled with oil At the bottom are two ball check valves used for replenishing any leakage that may take place from the high pressure oil to the low pressure. At the bottom near the replenishing valves are two safety valves to provide relief should the gear be overloaded There is also connected with each passage near the top a plugged hole for attaching gages in case it is desired to measure the oil pressure, or the load carried Near the top of the valve plate, and also in connection with all the valves, are holes passing through the plate giving free circulation of the oil between the two ends of the gear within the enclosing cases, or shells. There are also bolt holes for securing the cases In the center of the plate are roller bearings for the inner ends of the shafts.

The shaft groups of parts in the two ends are almost identical. A cylinder barrel is keyed slidably and rather freely to the inner end of each shaft Each barrel has nine cylinders parallel with the shafts and fitted with pistons provided with ball ended connecting rods. The faces of the barrels slide in their revolution against prepared faces on the valve plate, and the cylinder ports in the barrel faces register with the semi-annular passages except as they are passing over the separating "lands" at the top and bottom of the plate. The barrels are held lightly against the faces of the valve plate by spiral springs around the shafts, which are compressed between shoulders on the shaft and counterbored recesses in the barrels. These springs are only intended to hold the barrels in position under no load. When the gear is transmitting power the barrels automatically support themselves.

The piston connecting rods are formed with a ball on each end of each rod, one ball end being secured in a piston and the other in a socket in the socket ring. The socket rings are connected by special universal joints with the shafts, so that while they revolve with the shafts, their planes of revolution may be at any angles to the shafts provided by the setting of the roller bearings on which the socket rings revolve.

The socket ring bearings must carry a very heavy thrust load and at high speed. It is therefore important to use the best possible steel for the purpose. This is made to a special analysis by two companies, one in the United States and one in England.

In the B-end of the gear the socket ring runs in what is called an angle box, which is secured in the end of the case itself through which the shaft passes. It stands at a fixed angle of 20 degrees, giving a constant reciprocation to the B-pistons. In the A-end the box is hung on trunnions and may be adjusted to any desired angle while the gear is running by turning the threaded control shaft. As the load on the trunnions of the box is practically a balanced one, the turning of the control shaft is easy.

The A-shaft, which is connected with the source of power, is supposed to run at a constant speed and in one direction. If the tilting box stands in its vertical or neutral position at right angles to the shaft the pistons are carried around with the cylinder barrel but do not reciprocate. No oil is, therefore, taken from or delivered to the passages in the valve plate. If, however, the tilting box is inclined by turning the control shaft a little, the pistons reciprocate approximately to the extent of the sine of the angle of tilting multiplied by the diameter of the circle of centers of the sockets in the socket ring. Every cylinder during one half of the shaft rotation is in communication with one of the passages in the valve plate and is then receiving oil, which it carries across the "land" and delivers into the other passage during the other half of the shaft rotation. The amount of oil transferred from one passage across to the other passage depends entirely on the displacement of the pistons. But there can be no transfer unless there is a supply to draw from and a space to deliver it into. These are provided by the cylinders of the B-end. When oil is being forced into one of the passages (already full) the pistons in the cylinders of the B-barrel in communication with this passage make room for the oil by sliding back from the valve plate; but they cannot do this without forcing their respective sockets in the socket ring farther from the valve plate. This can only be done by turning the socket ring as a whole in its inclined plane in the angle box. It must be remembered that the B-socket ring, unlike the other, is always inclined in its angle box at an angle of 20 degrees, so that the B-pistons always reciprocate to their full extent at every rotation of the B-shaft. While the pistons facing the high pressure passage of the valve plate are receding to make room for the incoming oil and so imparting rotation to the B-shaft, the pistons facing the low pressure passage are moving towards the valve plate and delivering the oil from their cylinders through the low pressure passage into the suction cylinders of the A-barrel Since the receiving capacity of the B-cylinders is constant and the delivery capacity of the A-cylinders is varied at will by turning the control shaft, the speed of the B-shaft is corres-

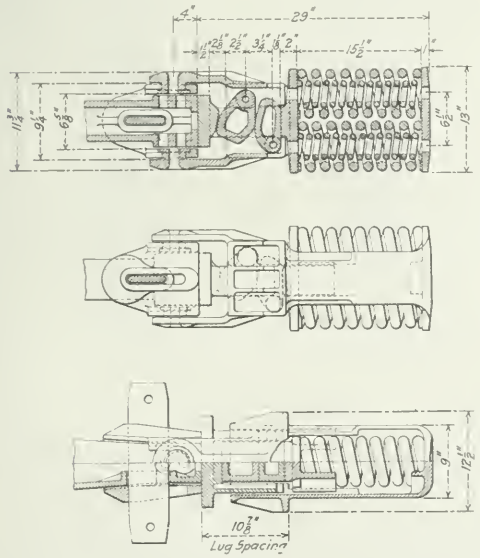
pondingly varied. It will be seen that the only oil actively employed in transmitting power is that in the oil passages of the valve plate and in the cylinders. The enclosing outside cases merely serve as a retaining reservoir and are not subject to any pressure.

The oil pressure in the cylinders and valve plate passages varies directly as the torque resistance which the B-shaft must overcome. The horse power transmitted varies directly as the product of the oil pressure and the speed of rotation of the B-shaft. The normal working oil pressure ranges usually between 300 and 500 lbs. but it may rise to 1000 or even 2000 lbs. to overcome an unusual resistance. In tests pressures as high as 4000 lbs. per square inch have been attained.

The chief advantage of this type of transmission is its great flexibility. The B-shaft may be started under a dead load of any magnitude within the strength limits of the machine, without any fear of overloading the motor or source of power; the speed may then be increased gradually and positively to its maximum without steps or abrupt gradations. Its remarkable flexibility must necessarily give wide differences of efficiency. Under the best conditions efficiencies ranging from 85 per cent. to 91 per cent. are common; under average working conditions the efficiencies vary between 80 per cent and 85 per cent.; under small loads and low speeds of the B-shaft the efficiencies range from 80 per cent. down to 50 per cent. or less. Of course at a zero speed the horse power efficiency must be zero per cent. while the torque efficiency remains at 95 per cent., and so the horse power efficiencies have a wide range from zero per cent. to 91 per cent., while the torque efficiencies throughout the whole range remain between 90 per cent. and 96 per cent.

IMPROVED LEVER DRAFT GEAR.

The lever type draft gear manufactured by McCord & Company, Chicago, has now been on the market for about seven years. The company is this year exhibiting an improvement of this type which retains the lever principle embodied in former designs, but is equipped with a cast steel sleeve and a key connection, together with integral cast steel yokes. This gear has, in addition, two sets of springs where the older type used but one [illegible] pulles its capacity



McCord Draft Gear With Adjustable Center Bearing Drawbar Attachment.

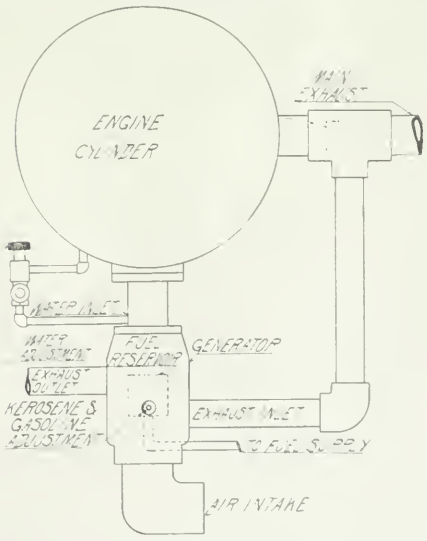
NICKELIZED CAR WHEELS.

A nickelized car wheel which was broken up after completing its full mileage in service is shown in the [illegible] to the Nickel-Chrome Chilled Car Wheel Company. The flange of this wheel shows very little wear and wheels of this type after making 80,500 miles in freight service on a mountainous road have withstood 175 blows in an M. C. B. drop test and 30 drop blows directly on the flange. There are now 3,000 of these wheels in use, some of them on the Pennsylvania having run for four years, and after making 90,000 miles are still in service. These wheels are in use under 50 ton capacity coal cars, refrigerator cars and in suburban electric service

KEROSENE GAS GENERATOR

The National Oil Gas Generator Company, Chicago, has recently placed on the market a kerosene gas generator that is applicable to any gasolene engine on the market, working equally well on a "hit and miss" engine as any other. By its use the fuel cost for operating such engines may be greatly reduced, as the cost of kerosene is much less than gasolene and it also has a greater heat value. The generator is very simple in its construction, and requires little care after once installed and adjusted, no carburetor being required.

The illustration shows in a general way how the generator



Application of Kerosene Gas Generator to Pump Feed Engine.

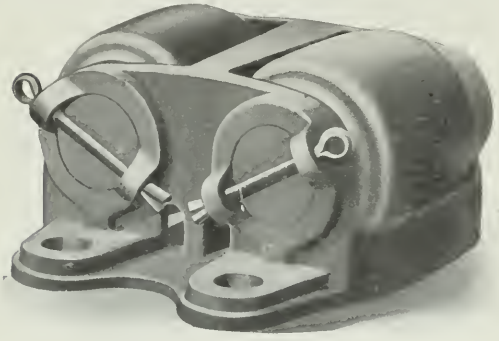
is connected to a pump feed engine. The gas generator contains a fuel reservoir from which the flow of kerosene is regulated through an adjustment valve to the vaporizing pipe, the air for the mixture being drawn up through the bottom of the generator, and a certain proportion of water admitted into the mixing chamber above the generator. Part of the exhaust is diverted to a chamber surrounding the generator, heating the oil to its boiling point so that it will vaporize more freely. This makes it necessary to heat the generator with a blow torch before starting, or to start the engine on

gasolene, shifting to kerosene after the generator has been sufficiently warmed up. When once adjusted, the generator is automatically regulated by the suction of the engine, working equally as well with no load as with full load.

With the correct mixture of kerosene gas, water and air, no carbonaceous or other fouling deposit will be formed in the cylinder. The use of kerosene reduces the loss due to vaporization, and is less affected by climate or altitude.

ROLLER SIDE BEARING.

The illustration shows the "Economy" roller side bearing that is being exhibited by the Chicago Railway Equipment Company, Chicago, for the first time. The bearing is self-lubricating and dust-proof. A large roller revolves on a good sized pin that is



Economy Roller Side Bearing.

held in place by a lug on one end and a split pin on the other. This gives a large bearing area and with this design an unlimited travel is obtained.

ROUMANIAN RAILWAYS JOURNAL BOX.

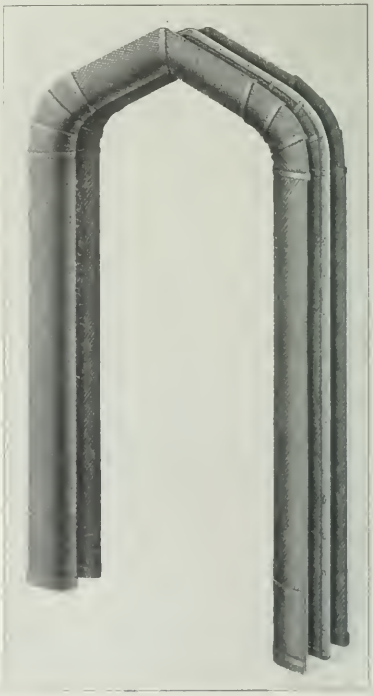
C. C. Orghidan and Dimitri Petrescu, government mechanical inspector and mechanical engineer respectively of the Roumanian state railways, are here and have an interesting model of a journal oil box that is in use on the Roumanian roads. It is on exhibition at the booth of the National Tube Company and was designed by M. G. C. Cosmovicy, engineer of material and traction of the Roumanian state railways. The object sought in the design was to provide a box that would be free from the troubles in the heating, to which the box formerly used was subject, by keeping the journal flooded with oil. It consists of a box cast in a single piece, and a rapid circulation of oil is maintained over the brass and journal. The front of the box is closed by an air tight cover and the circulation is maintained by a disc bolted to the face of the collar at the end of the axle.

The oil reservoir is located at the bottom of the box and is divided into four compartments. These compartments are not only in communication with each other but with a well at the outside of the box in which the disc mentioned turns. The connections between these compartments is such that all of the waste oil, as it flows down from the journal, must pass from the bottom of the second compartment to the third, from the top of which it flows to the fourth. This gives all sediment carried down from the journal ample opportunity to sink to the bottom of these compartments, while the clear oil passes through holes at the top of the third compartment into the fourth. Here it is caught by the revolving disc attached to the axle and carried to the top of the box where it is thrown off into a cavity whence it flows down to the top of the brass and upon the journal, and down into the compartments again, thus completing the cycle of a complete circulation.

The dust guard at the back consists of two parts, one of which is of wood and the other of a cupped leather ring. The wooden guard is in two pieces held together by a spring which holds them firmly against the axle. At the center of the guard is a groove mating with a similar circumferential one cut in the axle and communicating with a drip passage at the bottom leading down into an oil cellar. Any oil escaping through the leather packing is caught at this groove and prevented from flowing out at the back. The result is that no oil escapes at all. The statement is made that these boxes run on an oil consumption of 1 pint of oil per 100,000 miles.

ACME APEX DIAPHRAGM.

A new style of car diaphragm is being exhibited by the Acme Supply Company, Chicago. This diaphragm, as shown in the illustration, has a pitched roof which sheds water, dirt and cinders readily. It can be used with the old face plate by using a piece of ¼ in. iron sheet attached to the upper



Acme Apex Diaphragm.

part of the face plate and cut to conform to the shape of the diaphragm. It is so constructed that simple repairs may be easily made in the yards. It is self-cleaning, there being no sharp valleys to collect dirt, cinders or moisture, thereby prolonging the life of the diaphragm.

COMBINATION PIPE FITTINGS.—Special fittings made for air brake work which have a ground joint and have been tested to 250 lbs. air pressure while under water, are being exhibited by the Crane Company, Chicago. It is claimed that by the use of these fittings it is possible to save from 20 per cent. to 30 per cent. in the number of screwed joints in the air brake equipment of a locomotive alone.

Railway Age Gazette

PUBLISHED EVERY FRIDAY AND DAILY EIGHT TIMES IN JUNE, BY THE
SIMMONS-BOARDMAN PUBLISHING COMPANY,
WOOLWORTH BUILDING, NEW YORK.

CHICAGO: Transportation Bldg. CLEVELAND: Citizens' Bldg.
LONDON: Queen Anne's Chambers, Westminster.

E. A. SIMMONS, *President.*

Subscriptions, including 52 regular weekly issues and special daily editions published from time to time in New York, or in places other than New York, payable in advance and postage free:

United States and Mexico	$5.00
Canada	8.00
Foreign Countries (excepting daily editions)	8.00
Single Copies	15 cents each

Engineering and Maintenance of Way Edition and four Maintenance of Way Convention Daily issues, North America, $1.00; foreign, $2.00.

Entered at the Post Office at New York, N. Y., as mail matter of the second class.

WE GUARANTEE, that of this issue 10,200 copies were printed; that of those 10,200 copies, 8,708 were mailed to regular paid subscribers and 350 were provided for counter and news companies' sales; that the total copies printed this year to date were 216,759—an average of 8,670 copies a week.

VOLUME 54 JUNE 20, 1913. NUMBER 25.

CONTENTS

*Illustrated.

THE cause of the rear collision on the New York, New Haven & Hartford is discussed elsewhere in this issue. There is, however, a question raised by the discussion, especially in the more sensational daily papers, of one phase of this collision which is deserving of the most serious consideration by higher railroad officers. It is one of purely public relations of the railroads. The routine on the New Haven, and probably on a good many other roads, provides for the destruction of the debris of a wreck immediately after such debris has been cleared from the track. Many of the traveling public are probably not unfamiliar with the sight of smashed freight cars being burned near the site of a recent wreck, and, in itself, of course, the fact that the remains of the wooden parlor car Skylark were burned shortly after the debris had been removed from the New Haven tracks at Stamford is of no importance one way or the other. The short-sightedness of the management in permitting the ordinary routine to be carried out in this particular case seems almost inconceivable. Every responsible railroad officer might be absolutely satisfied in his own mind that the wooden Skylark was no different in construction, design, capability of resisting shock, etc., from any other wooden parlor car built about the same time, but every intelligent, responsible railroad officer ought by this time to have learned that he cannot manage his own business in his own way regardless of the effect it may have on an easily aroused public sentiment. A man must be lacking indeed in yellow news sense who could not see the possibilities of red headlines, 2½ in. high, proclaiming "Mellen Orders the Wooden Skylark Burned." What if the New Haven management is lending every facility to the various and numerous investigations that have been begun to inquire into every detail of the fatal New Haven collision? The officers of the road are no doubt correct in declaring that the preservation of the debris of the Skylark would not have helped the scientific investigation of the circumstances surrounding the collision in the very slightest degree, but this can no more serve as an adequate excuse for what must appear as an utter blunder than would any other academic argument which omitted to take into consideration human nature.

THE letter printed elsewhere states in a quite clear manner one very common misconception as to the possibility of the government regulation of the issue of railroad securities. It is a misconception, however, which is not confined to our correspondent, but has been made manifest in various state laws and has even appeared in the writings of students of the railroad question whose views carry a good deal of weight. Our correspondent suggests that a law be passed prohibiting railways from issuing bonds except to the extent of 90 per cent. of their stock. By this he can only mean one thing, that railroads shall be prohibited from issuing bonds except to the extent of 90 per cent. of the *par value* of their stock. The Chicago, Milwaukee & Puget Sound was organized in a state which permitted the sale of bonds only to the extent of 50 per cent. of the issue of stock. When the Puget Sound, therefore, desired to issue $100,000,000 of bonds, it was compelled to first authorize and issue $200,000,000 of stock. The issue of this stock did not add one cent of equity behind the bonds, nor could any law be passed which would compel investors to buy this $200,000,000 of stock. The only possible way in which the bondholders' equity in a railroad property can be strengthened is from the voluntary purchase by investors of stock, and the only way that railroad stock can be sold is through making an attractive enough offer to investors to induce them to buy stock. The only reason why an investor should make a purchase of railroad stock is with the hope of making a profit on his investment. If we increase the profit we increase the attractiveness of stock as compared with bonds. In a way, our correspondent's letter is an unconscious appeal for higher railroad rates in so far as it is a recognition of the need of a greater margin of safety.

THE exchange of about $38,000,000 Southern Pacific stock for the stock of the Baltimore & Ohio held by the Pennsylvania Railroad represents probably not so much the hope that either the Union Pacific or the Pennsylvania Railroad will benefit materially from any change that might be brought about in traffic conditions, as it does one of the desperate efforts which the Union Pacific directors are being forced into by the attitude of the Attorney General in regard to carrying out the orders of the Supreme Court. There never has been, in the literal sense of the word, a transcontinental railroad system in the United States. Before Mr. Harriman's death, he was a director in the Baltimore & Ohio, and unquestionably a very influential member of the board. He was also director in the New York Central, and would, presumably, if he had lived, become an influential member of that board. The transfer of a considerable block of Baltimore & Ohio stock from the Pennsylvania Railroad to the Union Pacific will not probably in practice greatly change the present traffic relations either of the Baltimore & Ohio or of the Union Pacific. From an entirely theoretical point of view, it would be hard to conceive of any move which would more thoroughly carry out the intent of the Sherman law as it was interpreted by the former administration at Washington when it brought the Harriman Lines' dissolution suit than this exchange of Southern Pacific for Baltimore & Ohio. If it were true that any considerable portion of the freight traffic originating at the eastern seaboard for movement over the Baltimore & Ohio and Pennsylvania Railroad was destined for the Pacific coast, and could be given at the will of the originating railroad to either the Union Pacific or Southern Pacific, or that any considerable traffic originating in California could in the same way be delivered to either the Pennsylvania or the Baltimore & Ohio for carriage to the Atlantic coast states, the alliance between the Pennsylvania and the Southern Pacific on one hand and the Baltimore & Ohio and the Union Pacific on the other hand would open a way for the keenest sort of competition. As a matter of fact, however, the proportion of traffic coming under this category is so inconsiderable, the free choice of routing off its own lines by the originating carrier so slight, and the give-and-take relations between eastern trunk lines and so-called transcontinentals so complicated and delicate that such potential competition is hardly likely to ever become an important factor either in the rate situation or in the routing of traffic.

ONE of the most arbitrary of all the arbitrary things done by the Post Office department during the past dozen years, in its efforts to reduce the compensation paid to the railroads, when Congress has refused to authorize reductions, was the issuance of the orders of March 2 and June 7, 1907, to include Sundays in the days counted to ascertain the average daily weight of mails carried. Those orders have now been declared by the Court of Claims unlawful, in a decision which is reported in another column and which, it is estimated, will take $20,000,000 out of the government treasury. The decision will be found interesting reading. Congress had not merely neglected to act in the matter; it had considered the question of changing the divisor from 6 to 7, and had definitely rejected the proposition. Moreover, the use of the higher divisor puts a premium on inefficiency, as it tends to induce the railroad to carry no mails on Sunday. The court says "The injustice of using 35 as a divisor for the seven-day roads is easily illustrated. Suppose there are two lines or roads the same length and carrying the same amount of mail (say 30 tons a month) One carries these mails six days a week, excluding Sundays, and the other within the full seven days. The Post Office department weighs these mails for a period embracing 30 successive working days for both these lines, which must necessarily be for five weeks, or 35 days, if it weighs the Sunday mails, in order to cover 30 successive working days for the six day road, and thus would obtain an aggregate of 30 tons for each road. It divides this aggregate sum by 30 for the six day road, as that was the number of successive working days the mails were weighed for that road, and obtains the correct average of 1 ton per day for that road; it divides the same aggregate by 35 for the seven-day road, as that was the number of days the mails were weighed for that road, and gets a daily average only of six-sevenths of a ton, which allows the latter road no pay whatever for carrying the Sunday mails." And for a road carrying no mails on Sunday the injustice of the seven-day division, directed by the order of June 7, 1907, is too bald to need to be stated. The Chicago & Alton, in the letter which it sent to Washington before taking its claim to court, protested also against fines for late trains, against furnishing rent free in stations, the performance of messenger service and other well known unreasonable requirements now in force; but these points are not dealt with in the decision, and on the Alton, as on the other roads, remain to be fought out in the future. The messenger service alone constitutes one glaring absurdity. A certain small road has a mail route of 10 miles, terminating at one end about 1 mile short of the post office, and, under the law and the regulations, must carry the mails that mile; and it collects pay for 11 miles. But the wages of the messenger for this eleventh mile amount to nearly double the sum that the road receives for the 11 miles!

THE STAMFORD COLLISION.

THE salient feature of the wreck which occurred at Stamford, Conn., last week is that, as regards cause, it comes within the same class as those at Bridgeport, in 1911, and at Westport, in 1912. In all three the trouble centered in the cab of the locomotive—failure to control speed. In each of the three cases there were two men in the cab, all of the six long familiar with locomotives, and thoroughly acquainted with the road. That three such notable disasters, happening within a space of 20 miles, should arouse the public, is not surprising, even if the Massachusetts and Rhode Island critics of Mr. Mellen were to be left out of the account. For the newspapers to call for drastic remedies and the theorists to demand the general adoption of automatic train stops is but natural; though it is gratifying to see that the press is somewhat more rational in its criticisms than on former occasions. Since the widespread discussions of the past year, the fact that many of the problems met by the railway manager in his quest for safety are intricate and difficult seems to be better appreciated.

As the evidence, at this writing, is not all in, a conclusion as to the responsibility for the collision would be out of place; but the main facts may be traced with little chance of error. Doherty had been a "qualified" locomotive runner for over a year, but he had actually had charge of an engine, outside of yards, only a small part of this time, and had run passenger trains less than ten days altogether. He had run a 125-ton engine only three days. He had had ten years' experience as fireman, with a good record, but whether during this time he had been well taught by his engineman, and whether he had learned all about the responsibility felt by the runner of a fast train when he is behind time and dreads to meet the criticisms of the trainmaster, are questions on which no light has been thrown, except the brief statement of the road foreman. (A young runner, on his first passenger runs, usually experiences these anxieties even if he is not behind time.) A natural conclusion would be that, being young and inexperienced, Doherty did not realize the importance of insisting, at all hazards, on prompt and adequate attention to his complaint that the air brakes were not in satisfactory condition, and of running his train with extreme caution until his brakes were made satisfactory. As we have said, this is a natural conclusion. The alternative conclusion is that he was not lacking in caution, on this particular run, but that the air brake apparatus failed in some unaccountable way after he had passed the last block station (where he slackened speed and, so far as appears, found no special trouble with the brakes). The absence of any de-

tailed criticism of the brake apparatus, the testimony of the road foreman as to the cause of the failure to stop at Bridgeport on Tuesday, and the testimony of other runners that the brake apparatus of this engine had behaved all right, discredit this conclusion. It remains to be seen whether it will receive support from evidence yet to be brought out.

Whether the brake apparatus was or was not any less efficient at Stamford than it had been on the two days preceding, two or three lessons are already quite plain. For one, the rule that an engineman with a year's experience as spare runner, possibly all on freight trains, shall be deemed fit to run a fast passenger train, with an engine much more powerful than those to which he is accustomed, is, obviously, inadequate. It assumes that the year's experience will have been varied and will have educated the runner. In this case it was not varied. Real, not constructive, experience is the only kind that will surely fit a man for fast trains. Apparently, Doherty ought to have had the road foreman or some other competent guide with him on the big engine many more trips than he did. It is evident also that the efforts of the officers of the road to train the engineman since last year's disaster, though vigorous, were not sufficiently vigorous. Mr. Woodward said that the epidemic of carelessness (or ignorance) was as surprising to the officers of the road as to the coroner. But, surely, after six months, the division officers must have some inkling of the reasons. It may seem harsh to demand further effort from officers who say that the State and Federal commissions are taking up all their time; but, surely, in the matter of safeguarding fast trains it may well be questioned whether duties connected with close supervision of enginemen ought not to take precedence over a summons to a protracted government hearing, where lawyers ask a thousand useless questions—even at the risk of being in contempt of court!

The mind of the runner of a fast train has constantly to act in opposite directions under high pressure; on the one hand he must keep within the bounds of safety and on the other he must make time. If the power of his engine is ample and he has no trouble with fire or water, the second horn of this dilemma may be easy; but uncertainties are usually not far distant and, as we see in this case, a powerful engine is not a sure protection against anxiety. It may be that Doherty, like Wisker, the New York Central engineman whose tragic failure in New York City in 1902 made such a profound impression, is a man who can make a good record in an examination and in the work of a fireman, but who lacks the right temperament to be an express engineer. The peculiar demands to be cautious, and to be bold, alternating every few minutes, or oftener, call for a mental poise or self control that, except in rare cases, can be acquired only by experience. Except as the road foreman can testify from personal knowledge that young runners have had that experience, the superintendent's confidence must depend on a bunch of uncertain factors. Judging by the small number of road foremen on many roads, the New Haven is not the only company which has accepted constructive or presumptive experience as satisfactory.

What have the Interstate Commission's or the Connecticut Commission's investigations done for the public? As we have said, the main problem is the same now that it was in 1911; how to get the most competent and reliable enginemen. The successive accidents have been studied, and various things have been officially proposed as remedies; but on this most vital point nothing has been done. Everybody wants to know what kind of men the New Haven road employs as engine runners, and how they are disciplined. People asked the same questions two years ago, and also on the occasion of the subsequent accidents, but our costly governmental machinery has given them no answer. When an officer of the road says that there has been a lot of bad luck, an explanation is needed; for safety in travel is too important an issue to be trusted to "luck," so long as there is any possibility of finding a better course.

BULLETINS COMMENDING EMPLOYEES.

WHAT is the value of a "roll of honor" for railroad employees who do specially meritorious acts? Without attempting to answer this question with definiteness it may be said that such a list of names is prized in proportion to the rarity of the cases in which men are held to be entitled to a place in it. If the aim of the officer in charge is to record acts of "conspicuous" bravery or devotion (to use the words of some of the general managers' announcements) he must, to fully carry out the idea, be careful not to include commonplace acts. The "safety-first" movement has made rolls of honor so numerous that there is a considerable variety of treatment of the subject; and it would be a good thing if there could be a standard to which all railroad managers could conform. Occasions for acts of special bravery, as that term is usually understood, are rare; but "devotion" and "loyalty" include every-day matters concerning which it is doubtful whether they should be made the subject of special public commendation; the occasions would be too numerous. A line must be drawn somewhere; and if it must be an arbitrary line there ought to be some little discussion of the subject, so that whatever is settled on shall meet the views of the majority. That specific commendation of subordinates by a superior is a good thing, on general principles, is too obvious to need argument; the only serious questions concerning public commendations are When? To whom? What for? It would be profitable, no doubt, for nearly everybody who supervises the work of others to consider whether he ought not habitually to be more prompt, frank and generous in expressing commendation by a personal word or by a brief and informal note; but that is beyond our present purpose; the subject in hand is "rolls of honor"—commendatory notices made known all over the road.

George R. Brown, superintendent of the Fall Brook Coal Company's Railroad and the originator of "Brown's discipline" (about 1886) was a pioneer in the systematic use of commendatory written notices and letters in the railroad service, and perhaps *the* pioneer; though there were superintendents who took a "human interest" in their subordinates long before his time, and they did not always stifle their natural inclination to praise good work. With the advent of "safety first," which has stimulated men of all classes to try to correct things that are wrong, public commendation has become the fashion on roads which do not employ Brown's methods in other respects.

Brown dealt more particularly with cases where a man had manifested good judgment in an undertaking of some magnitude, and where the appropriate thing to do was to write a letter; such as the case of a conductor who did well in clearing a wreck, or one who skilfully managed a lot of trains in a difficult emergency. With the introduction of Brown's discipline on large roads his discriminating, personal management of this matter was to a large extent superseded by practices suggestive of machine methods; and such commendations as have been made public, while still rational and usually justified, seem not to have received the careful attention of officers which their importance demanded.

One possible rule, quite simple, would be to use different terms in commending a man for going beyond his duty to avert damage or disaster from what would be used for the same act in the line of duty. A station agent, sitting in his office, and averting a derailment by reporting a fallen brake beam in a passing train is to be commended; and so is a brakeman on the train who makes a similar discovery. The brakeman, however, is only doing his duty. But he is to be commended for that. There is no use in decrying the practice of praising the simple performance of duty. There will always be a few warm-hearted souls who will follow that practice, and others may as well fall in line. The only care required is to see that good judgment is exercised. It is well not to "slop over." The same man who is praised today may have to be reprimanded within a short time. But the station agent, in our supposed case, is

on a footing different from that of the brakeman. Not the slightest fault is to be imputed to the agent if he does not watch every truck of a passing 80-car freight train. And yet it is his duty to promote safety in every reasonable way. In his office, when not engrossed in work, he may be talking to a passenger, or may be engaged in unprofitable conversation; he may be half asleep or may be gazing out of the window with an empty mind. Commendation for noticing a defective car, therefore, cannot be said to suggest to the agent the definite idea of a specific duty; but probably it will be useful as a stimulus to habitual thoughtfulness concerning the safety of trains. This, however, is well worth while, is it not?

The coldest theory is that men *must* be reprimanded for falling below par; and that, logically, commendation is appropriate only when their conduct goes above par. With a record just reaching par, nothing special is called for. In that case the pay roll provides for the only and the sufficient recompense. But, surely, this theory cannot be said to embody the highest standard. It has been followed widely, and through a long period of years; and as we are still far from perfect, no very specific fault can be found with managers or superintendents who try a policy less austere; at least not until unfavorable results are manifest because of the change.

Superintendents, trainmasters and others who have to decide on the awards to a considerable number of employees in matters like those here mentioned would do well to tell of their experiences; to report their successes and their difficulties, for the benefit of others who have to deal with the same problems. To aid in the carrying out of this suggestion we append a few notes on the honor rolls of a half dozen prominent roads. The items in these records, of which we notice only a small fraction of those for a single month, range all the way from heroism down to everyday duty; bravery, quick wit, the ordinary wit of an alert mind, unusual promptness in doing a duty, and simple faithfulness. How many classes should our roll of honor contain?

One of the things sure to be noticed, apparently, is the discovery of a fire and preventing it from doing damage. On the Illinois Central a brakeman, for this, had "favorable entry" made on his record. The *Illinois Central Magazine*, however, uses this phrase for everything, and "meritorious service" is the heading, not "roll of honor." How favorable was the mention, is not stated. On some roads a definite number of marks is announced. Whether this fire was in the brakeman's own train is not stated. On the Rock Island a brakeman was credited five marks for firing an engine when the fireman was taken sick. Another one, a few weeks later, received the five merits and also a letter of commendation. This one prevented an embarrassing delay to a red ball train.

Firemen also get credit when they fire for a sick man. One on the Illinois Central, called in an emergency of that kind, and being sent over another road to the point where the train was in distress, was stranded, by his train being indefinitely delayed; and he got off and walked, ten miles, through a snowstorm, to the point where he was needed

On the Rock Island a passenger engineman received a letter of commendation for responding, when off duty, to a call to run a switching engine. Some *conductors* of passenger trains might be embarrassed by a call to thus go back to early days; they would feel that their technique was too rusty!

On the Missouri, Kansas & Texas a conductor, presumably freight, was given 20 days' credit for "noticing something wrong" under his train. He found a spring plank dragging. This item in the record serves as a reminder that credit may be due even if no definite defect be discovered—and even if there be doubt whether anything at all is actually dangerous. When "something wrong" is discovered about a moving train, a conductor or trainman must immediately think of Rules 105 and 106—take no risks

On the Buffalo Rochester & Pittsburgh a conductor was commended for acting promptly on his discovery of marks on the ties after a train had passed. The despatcher was enabled to stop the train and have a fallen brakebeam attended to.

On the same road a conductor was commended for discovering a bent axle on a foreign freight car—perhaps because bent axles are not easy to discover. On the Rock Island a conductor received a "letter of appreciation" based on good work done in connection with repairing an engine. On another road a conductor and his whole crew received "favorable mention" for picking up a lot of scrap brass and rubber.

Other kinds of specially commendable service are: a switchtender assisting a brakeman, in the yard, who was in danger of losing control of his cars; an agent noticing an open door in a passing freight train, in freezing weather, and sending a message which saved the fruit in the car; an operator discovering a sliding wheel, and a bridge watchman stopping a train which had a brakebeam dragging. A car inspector reported a broken rail. On the Illinois Central a number of conductors got favorable entries by detecting improper or fraudulent use of passes; a part of their duty, but a part often shirked. A freight checker on the B. R. & P. found that a car had been robbed, followed two suspicious looking men and, having got a police officer, had them arrested; and they were tried and convicted.

As a final suggestion toward answering the questions that have been outlined we will cite the last issue of *Safety*, a "Periodical of Progress and Protection," which is issued by the New York Central Lines. It is Volume 1, Number 2, and is edited by Marcus A. Dow, secretary, New York City. Of the twenty pages of this pamphlet two are occupied by the "roll of honor." One of the two is filled with the notes on five cases (and the portrait of an operator who stopped a train in which was a broken wheel); and on the other page is a list of 24 other cases, each item giving name, occupation, town and date, and filling only one line. This condensation is to be commended. No one would wish to detract in the least from the credit due any employee, but news published 500 miles from the place where it happened inevitably suffers by the mere fact of distance. If detailed notices are the more desirable then it is a question whether they would not better be confined, in their circulation, to a single division of the road, or some small territory where they would be most appreciated. Editor Dow apparently picked out, for his first page, the five most notable cases, from the whole 29 before him; but often it would be difficult, probably, to make a fair selection. A record of exceptional things must be somewhat one-sided, because circumstances for which the individual person deserves no credit usually figure as one of the main elements in the case. A hero often has to credit his heroism partly to "luck." The propriety of publishing portraits is questionable. We do not presume to criticise definitely in the present case, for the whole matter is still in the experimental stage; but where can one draw the line in the matter of portraits?

Private, personal commendation is a practice which every superior, even the superior of a very few employees, will find profitable. Even if he make mistakes, he will soon discover how to avoid mistakes in the future; and the correcting process will be good exercise. (The word "private" as here used is not necessarily synonymous with "secret.") But as to printed notices, to be published throughout a railroad system of 5,000 to 10,000 miles, there is room for discussion.

The *Baltimore & Ohio Employees' Magazine* for May contains an extreme instance of the difficulty of doing the satisfactory thing. In the Ohio floods of last March that company lost $3,000,000 worth of property and, in addition, suffered a shrinkage of $2,000,000 in freight and passenger receipts. Vice President A. W. Thompson, commending the devotion to duty of thousands of employees, says that "it is difficult to find suitable words of comment." The best that he could do was to direct that credit be entered on the record of every employee who assisted in restoring the road to normal condition, and that "the record be made in red ink."

DEPRECIATION IN RAILWAY VALUATION.

C. F. LOWETH, chief engineer of the Chicago, Milwaukee & St. Paul, discusses in a letter published elsewhere the editorial in our issue of May 30 on "Some Disputed Points in Railway Valuation: Depreciation." It will help to an understanding to state that the editorial Mr. Loweth refers to was not meant to deal with valuation for the purpose of purchase, but solely with valuation for rate-making. Furthermore, it was meant to be rather a statement of opposing views and practice than a discussion of the correct way to deal with depreciation in making a valuation for rate-making.

Whether one will believe that a deduction for depreciation should be made in valuation for rate-making will depend largely on his theory as to the way railway rates and profits should be regulated. The theory now most generally accepted is that ordinarily a railway company is entitled only to a fair return on the fair value of its property, and that the main factor in fair value is the cost of reproduction of the physical property. Assuming that that principle is correct, the question to be considered here is, what deduction, if any, should be made from the cost of reproduction new because of depreciation.

Mr. Loweth apparently takes the position that, in valuation for rate-making, no such deduction should be made. Let us test this by some hypothetical cases. When the construction of a railway has just been finished, doubtless its actual cost should be accepted as its cost of reproduction new. Depreciation of its ties, rails and so on immediately sets in, and will not for some years be offset by renewals, simply because there is no sense in renewing things the depreciation of which has been so slight as not measurably to affect their serviceability. *Other things being equal,* the fact that the necessary expenditures for maintenance during the first few years are relatively small will nominally keep down operating expenses and increase net earnings. In consequence, the nominal net earnings during this period may be more than a fair return. The management may pay out the net earnings nominally in excess of a fair return in dividends. As time goes on, however, the amount of renewals that have to be made annually increases until finally a point is reached when year by year depreciation is just offset by expenditures for maintenance. Meantime, *other things being equal,* the increasing cost of maintenance has increased operating expenses and reduced net earnings, so that there are now no surplus earnings over a fair return, and only a fair return can be paid. At about this time a commission comes along to make a valuation for rate-making. The original cost of the road was $50,000 a mile. The commission ascertains that this would be its present cost of reproduction new, but holds that a deduction of $2,500 a mile should be made for depreciation because the depreciation of the ties, rails and so on since they were put in service has actually decreased the value of these parts of the road that much. The railroad protests against this deduction because if its valuation is made only $47,250 a mile, and its rates are adjusted accordingly, it will be unable to earn a fair return on the original investment of $50,000 a mile. The commission, in reply, points out that the earnings in excess of a fair return which have been paid out in dividends amount to $2,500 a mile, which just equals the amount of the depreciation; takes the position that, in effect, the stockholders have received back this much of their principal; and therefore holds that they have no right to complain if it is not included in the valuation on which they are in future to be allowed a return. Is the commission right?

Perhaps the question will be made easier to answer by changing the illustration. Suppose that during the first few years of the road's history, when the necessary renewals were small, the nominal operating expenses relatively small and the nominal net earnings in excess of a fair return, the management had recognized the fact that depreciation really was going on, even if it was not necessary yet to take it up in the maintenance expenditures, and had paid the stockholders only a fair return, investing the nominal surplus net earnings in additional ballast, the filling in of wooden trestles, and other improvements costing, all told, $2,500 a mile. When the valuation was made the management naturally would contend that these expenditures from earnings should be included in the value of property investment. Would it be right?

Railway officers will have no difficulty in answering this question in the affirmative. But if appreciation due to expenditures from earnings for some parts of the property should be considered in a valuation, why should not depreciation of some other parts of it be considered? It is a poor rule that will not work both ways. Of course, every one knows that actually a new road ordinarily falls far short of earning a "fair return."

Mr. Loweth says that "if the valuation of the property is for rate-making purposes, then no account of the depreciated condition of the property need be taken, as the owner will be obliged to continue to maintain it, and must necessarily be allowed a sufficient return over and above the interest on the investment and the cost of operating the property, to take care of all appreciation."

If the owner has been allowed to earn enough for all these purposes, and has used the earnings for them, then there is no depreciation to be allowed for in a valuation, simply because there is no depreciation in fact. If he has not earned enough for all these purposes, and his property has been managed with reasonable prudence, he is clearly entitled to be reimbursed with earnings more than sufficient for all these purposes in future. And if he has earned enough for all these purposes, but has failed to use in the maintenance of the property the funds that were needed to prevent depreciation, why, on the same principle, should not an allowance for depreciation be made in the valuation of his property?

Innumerable editorial discussions of valuation have been published in these columns during the last five or six years. In view of them it is doubtless needless to say that the *Railway Age Gazette* firmly believes there are many things that should be considered in railway valuation besides the original cost and the depreciation and maintenance of the various elements of the property. What has been said in the foregoing has been intended only to bring out clearly our reasons for thinking that depreciation of certain elements of the property is a factor to be considered. Consideration of it is made no less necessary because it may be many times more than offset by appreciation due to adaptation and solidification of road bed, to increased value of real estate, to permanent improvements made from earnings, and to the going value inherent in an old and established concern. These elements and many others ought to be considered; and there can be no doubt that if a fair valuation is made these things will be found in the cases of a great majority of roads to weigh many times heavier than any allowance that can properly be made for depreciation.

Furthermore, it is far from our intention to convey the impression that we believe the interest and dividends, or the net earnings, of individual railways should be limited to any arbitrary percentage on their valuations, even though such percentage be given the specious name of a "fair return." In the first place, it would be physically impossible to make different roads operating in the same territory, but having widely different densities of traffic and operating expenses, earn the same percentages of return on their valuations, no matter how rates were adjusted. In the second place, to restrict all to the same return would be unjust and inexpedient even if it were possible, because what would be a "fair return" for a railway that is incapably and expensively managed would be a wholly unfair return for one that is ably and economically managed. The conditions to be dealt with in regulating railway rates, securities and profits are so exceedingly complex that the difficulty of making a valuation that will give due weight to all the factors that should be considered will be very great. The difficulty of making any practical use of the valuation after it is finished will be yet greater.

Letters to the Editor.

MR. LOWETH ON DEPRECIATION IN VALUATION.

Chicago, June 3, 1913.

To the Editor of the Railway Age Gazette:

The editorial in your issue of May 30 entitled, "Some Disputed Points in Railway Valuation: Depreciation," seems to me to come quite wide of hitting the mark.

Whether depreciation should be considered or not, depends entirely upon the purpose for which the valuation is made. If the property is to change ownership from a ready seller to a willing buyer, the valuation should take full account of depreciation. If the owner, in the case of a railroad, has for several years renewed less than the due proportion of rails and ties, or otherwise has let the property run down, he has profited to that extent, and has thereby placed a greater burden of future maintenance on the property, which the prospective purchaser should take into account. Of course, property is sometimes sold when for certain reasons either one or both of the parties to the transaction are willing to overlook depreciation.

If, however, the valuation of the property is for rate-making purposes, then no account of the depreciated condition of the property need be taken, as the owner will be obliged to continue to maintain it, and must necessarily be allowed a sufficient return over and above the interest on the investment, and the cost of operating the property, to take care of all depreciation.

It is presumed that the kind of valuation referred to in your editorial is that made by the various states, and now proposed to be made by the Federal authorities, of the railroads of the United States; and unless it is a question of the purchase of these properties, it is difficult to see what would be gained by taking into account depreciation or "condition per cent.," as it is sometimes termed, except, possibly, for the purpose of determining the fair average rate of depreciation to be allowed to the owners of the properties, in addition to the costs of operation, interest and profit.

C. F. Loweth,
Chief Engineer, Chicago, Milwaukee & St. Paul.

THE DANGER OF HIGH FIXED CHARGES.

Washington, D. C., June 14, 1913.

To the Editor of the Railway Age Gazette:

The history of railway financing, culminating in the St. Louis & San Francisco misfortune, raises doubt as to the propriety of the government allowing public carriers to increase their indebtedness ad libitum. In 1900 the amount of railway funded debt outstanding, based on official sources, bore a proportion to railway capital stock of 96.56 per cent., in 1905 110.62 per cent., and in 1910 126.98 per cent. The inquisitive observer wonders whether he will live long enough to see the outcome. Obviously there may be two kinds of restriction on the ever increasing tendency to expand funded debt: (1) the natural or economic, and (2) the artificial or governmental. The first is to be most dreaded because it comes with unexpected force and is curative only; the second is to be most desired, because it establishes in advance a rule of action and is preventive rather than curative.

Doubtless the railways are in the hands of their friends, the investors, who in the main appear to prefer bond investments, hence the floating of new bond issues goes on unchecked. But bankruptcy brings railway manager, stockholder, and bondholder alike into predicament; the manager loses control, the stockholder steps down and out, and the bondholder is forced against his will to become a stockholder. Nor is the conversion of bondholdings into stockholdings a painless and inexpensive metamorphosis. Many a stockholder today was formerly a bondholder and now faces another set of bondholders. Perhaps the shipper and the employee should be allowed to get in a word edgewise as to their opinion in the matter.

The fear that lies behind a debt cannot be minimized by calling it "funded" debt or "bonded" debt; the day of maturity arrives strictly on time. A reasonable amount of borrowed capital may be used with profit and advantage to all parties, but there must be a safety valve somewhere. The schoolboy asks, "Why have stockholders at all?" "If the railways can borrow in amount beyond 100 per cent. of their capital stock, why not borrow the entire necessary capital and let the bondholders operate the road?" While the question is illogical, it suggests a serious proposition, which is that every road should be prohibited by law from borrowing capital in excess of its capital stock, and also should not be granted permission by the regulating commission to issue bonds in excess of, say, 90 per cent. of its capital stock unless extraordinary necessity can be shown.

E. S. Hobbs.

PROPOSED NATIONAL VALUATION CONVENTION.

Chicago, April 17, 1913.

To the Editor of the Railway Age Gazette:

Referring to your issue of April 11, 1913, page 836, on "National Valuation Convention Urged," I beg to comment as follows:

In my opinion, a convention such as that proposed would be so large and unwieldy that no results could be accomplished. If one valuation engineer from each railroad system was included this item alone would mean 1,306 men. The American Railway Association, the American Railway Engineering Association and the Interstate Commerce Commission have thus far appointed no valuation commissions, therefore could not be represented. A large number of consulting engineers are, or have been engaged more or less upon valuation of public utilities. These latter would not be especially equipped to handle railway valuations.

If the convention were represented by members as proposed there would be upwards of 2,000 in such a conference, a multitude among which no decision upon a single point could be made unanimous.

It is a mistaken idea that railways are not equipped to properly make valuations of their properties. Among the western roads, especially in states where valuations have already been made to state commissions, this work is already well in hand and with little effort can be systematized and made uniform. The forms, methods, unit prices, depreciation, engineering interest, appreciation, adaptation, solidification and seasoning and the many other items entering into a valuation are already well established, and while it is true differences exist among the various valuations already prepared, the difference is in degree only and the principles are well established.

Any well organized engineering department of our railways is already equipped, or can be so equipped on short notice to perfect an organization to value its property.

When the Interstate Commerce Commission promulgated the classification of operating and construction expenses on railroads, Prof. Henry C. Adams, statistician of the commission, was aided in the work by a "Committee of Twenty-five," who were representatives from the accounting departments of representative railways, and this committee succeeded in establishing a classification, which has as important a bearing on the interests of the railroads as the valuation of its properties is likely ever to have, and if such an important work can be accomplished by such means, it would be more practicable if the Interstate Commerce Commission would invite the railroads to appoint as representatives at a conference about twenty-five men, composed of railroad engineers and accountants who would meet with the Interstate Commerce Commission officers and promulgate rules and establish principles covering every item entering into a railroad valuation. Real constructive work and definite results would be more readily and satisfactorily accomplished by such a body than a mass meeting of 2,000 persons, each having divergent views.

L. C. Fritch.
Chief Engineer, Chicago Great Western.

THE SUPREME COURT'S COMMENTS ON VALUATION

In the Minnesota Rate Case the Supreme Court in the Opinion by Justice Hughes Discusses Railroad Valuation.

The following is an abstract [omissions consist principally of citations and are indicated thus * * *] of that part of the Minnesota Rate Case decision dealing with valuation:

The rate-making power is a legislative power and necessarily implies a range of legislative discretion. We do not sit as a board of revision to substitute our judgment for that of the legislature, or of the commission lawfully constituted by it, as to matters within the province of either. *San Diego Land & Town Co.* v. *Jasper*, 189 U. S. 439, 446. The case falls within a well defined category. Here we have a general schedule of rates, involving the profitableness of the intrastate operations of the carrier taken as a whole, and the inquiry is whether the state has overstepped the constitutional limit by making the rates so unreasonably low that the carriers are deprived of their property without due process of law and denied the equal protection of the laws.

The property of the railroad corporation has been devoted to a public use. There is always the obligation springing from the nature of the business in which it is engaged—which private exigency may not be permitted to ignore—that there shall not be an exorbitant charge for the service rendered. But the state has not seen fit to undertake the service itself; and the private property embarked in it is not placed at the mercy of legislative caprice. It rests secure under the constitutional protection which extends not merely to the title but to the right to receive just compensation for the service given to the public.* * *

In determining whether that right has been denied, each case must rest upon its special facts. But the general principles which are applicable in a case of this character have been set forth in the decisions.

(1). The basis of calculation is the "fair value of the property" used for the convenience of the public. * * *

(2). The ascertainment of that value is not controlled by artificial rules. It is not a matter of formulas, but there must be a reasonable judgment having its basis in a proper consideration of all relevant facts. The scope of the inquiry was thus broadly described in *Smyth* v. *Ames*. * * *

(3). Where the business of the carrier is both interstate and intrastate, the question whether a scheme of maximum rates fixed by the state for intrastate transportation affords a fair return, must be determined by considering separately the value of the property employed in the intrastate business and the compensation allowed in that business under the rates prescribed. This was also ruled in the *Smyth* case (*id.* p. 541). The reason, as there stated, is that the state cannot justify unreasonably low rates for domestic transportation, considered alone, upon the ground that the carrier is earning large profits on its interstate business, and, on the other hand, the carrier cannot justify unreasonably high rates on domestic business because only in that way is it able to meet losses on its interstate business.

In the present cases, the necessity of this segregation of the domestic business in determining values and results of operation, was recognized by both parties. Voluminous testimony was taken before the Master, and numerous exhibits containing data and calculations were submitted for the purpose of showing their respective estimates of the value of the entire property of the carriers in Minnesota, the amount of income and expense in that state, their theories of apportionment between the interstate and intrastate business, and their contentions as to the net return for intrastate transportation under the state rates. The multitude of facts which are involved makes it impossible here to present a comprehensive review, even in a summary way. We must be content with a statement of the salient points and deal only with those matters which, after a careful consideration of the entire record, we regard as controlling our decision.

In each of the three cases (save in certain particulars, which we need not now mention, with respect to that of the Minneapolis & St. Louis) the method adopted by the Master was as follows:

The period taken for the purpose of testing the sufficiency of the rates was the fiscal year ending June 30, 1908. During this period, all the rates in question, freight and passenger, were actually in force, with the exception of the commodity rates prescribed by the act of April 18, 1907, which had been enjoined. The amount of the reduction in the intrastate revenue which would have been caused by the application of the commodity rates is shown.

The Master found the present value of the entire property of the carrier, used in the public service in the state of Minnesota. This valuation was as of June 30, 1908, and was made on the basis of the cost of reproduction new. The Master also made findings as to the original cost of construction, and as to the present value on the basis of cost of reproduction new, of the entire system of the carrier. The estimated value of the railroad property within the state was divided between the freight and passenger business upon the relation of the gross revenue derived from each. The part of the total value which was thus assigned to the freight business within the state was then divided between the interstate and intrastate freight business on the basis of gross revenue; and a similar division was made between the interstate and intrastate business of the property value assigned to the passenger department. In this way the Master found the value of the property used in intrastate transportation, freight and passenger, upon which he computed the net return received by the carrier.

There was no substantial dispute as to the amount of the entire revenue assignable to the state or as to its division between interstate and intrastate business, as an examination of the transactions in which the revenue was obtained permitted the making of the requisite apportionments with reasonable certainty.

The Master also ascertained the total expense incurred by the carrier within the state. This expense was first divided between freight and passenger business. Those items of cost which were directly incurred in each sort of business, and not common to both, were directly assigned; and such items were found to cover about 60 per cent. of all expenses. The remaining items, those of common expense, were divided between the freight and passenger business upon the relation, as to most of them, of revenue train-miles, and others, of revenue engine-miles.

Having thus ascertained the share of the expense within the state of the freight and passenger departments respectively, it remained to divide that share, in each case, between the interstate and intrastate business. This apportionment was made, in the case of freight expense, upon what was termed an "equated ton-mile basis"; and in the case of passenger expense upon an "equated passenger-mile basis." That is to say, the Master concluded that the cost per ton-mile of doing the intrastate freight business was at least two and one-half times the cost per ton-mile of the interstate freight business, and hence he divided the total freight expense according to the relation of the interstate and intrastate ton-miles after the latter had been increased two and one-half times. In the case of the passenger expense, he concluded that the cost per passenger-mile in the intrastate business was at least 15 per cent. greater than that in the interstate business, and the total passenger expense was divided upon the relation of passenger-miles after increasing the intrastate passenger-miles 15 per cent. By the use of equalizing factors, the same result was obtained upon what was called an "equated revenue basis."

The net profits of the interstate and intrastate businesses, respectively, passenger and freight, were then found by deducting the apportioned share of expense from the apportioned share

of revenue, and the rate per cent. of the net profit upon the property value assigned to each sort of business was computed. The Master concluded that the returns from intrastate transportation were unreasonably low and hence that the rates in question were confiscatory.

The validity of the result depends upon the estimates of the value of the property within the state and the apportionments both of value and of expense between the interstate and intrastate operations.

It will be convenient to take up the three cases separately:

Northern Pacific Railway Company.

The par value, April 30, 1908, of the stock of this company was found to be $215,539,634.99, and of the bonds $190,256,577.66; total, $405,796,392.65. (Included in this statement of capital stock is the sum of $60,539,634.99 received to April 30, 1908, upon subscriptions to new capital stock ($95,000,000) authorized by stockholders' resolution January 7, 1907.)

These securities and their value in the market rest upon the entire property of the company. They include assets of considerable value (for example, the stock of the Northwestern Improvement Company owning extensive coal lands) which, however, do not form part of what may be called the operating property of the company or that devoted to the public service, upon which the fair return is to be calculated (15 I. C. C. 376, 397, 407). Referring to the market value of the securities, the Master said: "Assets and property not devoted to public service have not been valued, and as they are a large element in stock valuation it follows that value of bonds and stocks is wholly unreliable and cannot be used in these cases as an element in determining the value of operating property or as a basis for rate-making." In this view the Master was undoubtedly right.

Much evidence was produced before the Master for the purpose of showing the actual cost of construction and equipment of the entire railroad system from the beginning down to April 30, 1908. This, the Master states, could be shown only by the corporate books and records; and in the early history of the original company these are somewhat obscure and uncertain and, by reason of lapse of time, could not be verified by other proof. The total investment cost of the railroad system of the Northern Pacific thus shown, was $369,252,755. This included certain items which the Master held not to be properly allowable as a part of the cost, and after their deduction the cost was found to be $312,243,555. Of this investment cost, it appears from the evidence submitted by the company's controller that the sum of $128,184,985.82 was expended for construction and equipment, and for improvements and betterments, during the period from September 1, 1896, to April 30, 1908. The Master found that the Minnesota track mileage is substantially 21 per cent. of the track mileage of the whole system and that if the cost were apportioned accordingly, the amount assignable to the state of the entire cost of construction and equipment, as stated, would be $65,571,462.

The Master, however, and the court below in confirming his findings, held that rates were not to be predicated upon the original investment.

Taking, as the basis, the cost of reproduction new, the Master found that the value of the entire railroad system or operating property of this company to be $452,666,489. The value of that portion of the system which was in the state of Minnesota was separately found, on the same basis, to be $90,204,545. It was upon this estimate of the value of the property in the State, as apportioned between the interstate and intrastate business, that the Master computed the rate of return.

The total net profits of the company for the fiscal year ending June 30, 1908, from its Minnesota business (interstate and intrastate) was found to be $5,431,514.56. This was equal to 6.021 per cent. on the entire estimated value of the property. This showing of the results of the entire business at once directs attention to the importance of the methods adopted in making apportionments, but before considering these, the question is presented as to the soundness of the underlying estimate of value. May it be accepted as a basis for a finding that the rates are confiscatory?

Values. The items entering into the valuation are 40 in number.

The first item is:

"Lands for right-of-way, yards and terminals—$21,024,562."

This is for the bare land, without structures or improvements of any sort, as the entire cost of reproduction in building the road and erecting all the existing structures is covered in other items. The Master states that the amount thus allowed for land is made up as follows:

Terminal properties, St. Paul appraisement of Read, Watson & Taylor, as modified by railroad company	$7,645,100.24
Add 5 per cent. for the cost of acquisition and consequential damages	382,255.01
Property acquired after appraisement	328,725.69
Minneapolis appraisement of Elwood, Barney and Ridgeway, as modified by railway company	4,027,616.17
Add 5 per cent. for acquisition and consequential damages	201,380.80
Property acquired after appraisement	227,737.26
Duluth, appraisement of Stryker, Mendenhall and Little	3,602,443.43
Add 25 per cent. for railway value, cost of acquisition and consequential damages	900,610.85
Total value of terminals	$17,315,869.45
Lands outside of terminals	3,708,693.45
Grand total	$21,024,562.90

The appellants insist that no more than $9,498,099.27 should have been allowed.

It is contended that the valuation was made upon a wrong theory; that it is a speculative estimate of "cost of reproduction"; that it is largely in excess of the market value of adjacent or similarly situated property; that it does not represent the present value, in any true sense, but constitutes a conjecture as to the amount which the railway company would have to pay to acquire its right-of-way, yards and terminals, on an assumption, itself inadmissible, that, while the railroad did not exist, all other conditions, with respect to the agricultural and industrial development of the State, and the location, population and activities of towns, villages and cities, were as they now are.

We may first consider the basis for the finding with respect to the "lands outside terminals," that is, the right-of-way and station grounds, etc., outside the three cities.

(a) *Lands outside terminals.* The complainants' witness was Mr. Cooper, the land commissioner of the company, who has charge of the land grants for its entire system, of its right-of-way and land purchases, and has had a wide experience in connection with land values along the lines of the railway. In the latter part of 1906, the state notified the company to report the value of its properties, requiring a statement in one column of the "market value" and in another column, of the "value for railway purposes." Mr. Cooper was instructed to prepare the valuation for this report. From the information he received in special inquiries, and his own knowledge, and following what he understood to be the instructions from the state, he set down under the heading of "market value," not the market value in the proper sense of that term, but what in his judgment it would cost the railroad company to acquire the land. This included an excess which he estimated the company would have to pay over the market value of contiguous and similar property if it were called upon to undertake such a reproduction of its right-of-way. It did not, however, embrace an allowance for payments which might have to be made for improvements that possibly might be found upon the property in such case, or for the consequential or severance damages which might possibly have to be met, or for the expense of acquisition. These supposed additional outlays he undertook to estimate. For this purpose he increased the "market value" as stated (in the case of agricultural lands generally multiplying it by three) and thus reached the amount set down as the "value for railway purposes." * * *

The "market value" of the lands (outside of the three cities), thus fixed and reported to the state was $2,008,491.50, and the increased amount estimated, in the manner stated, which was reported as the "value for railway purposes" was $4,944,924.60

The latter amount was submitted by the complainants in this case as the value of the lands. The Master thought that the complainants' witness used too large a multipher and allowed 75 per cent. of the amount thus claimed, or $3,708,693.45, stating that this was determined upon as the "fair reproduction value of the property." This allowance, it will be observed, was about $1,700,000 in excess of Mr. Cooper's estimate of "market value" as that term was used in making the report.

(b) *Terminal properties.* This term is used to designate the lands for the right-of-way, yards and terminals in St. Paul, Minneapolis and Duluth. The total original cost of these lands to the company (according to its statement based on the best information obtainable) including purchases to April 30, 1908, was $4,527,228.76. The Master allowed as their value, apart from the improvements made by the company which, as we have said, were embraced in the other items of reproduction cost, the sum of $17,315,869.45.

In preparing the valuation for the report to the state, Mr. Cooper employed real estate men in each of the cities to make an appraisement. He instructed them, as he testifies, "to make a conservative report of the cost of reproducing the properties owned by the company in each of their respective cities." They divided the property into districts and reported their estimate of units of value, as, for example, by the square foot. Mr. Cooper took these reports, discussed their valuations with the appraisers and aided by his own knowledge, formed an independent judgment, in no case increasing and in some instances (with respect to certain St. Paul and Minneapolis property) reducing the appraisers' values. He then set forth under the heading "market value" in the report to the state, as described in the testimony we have quoted, his estimate of what it would cost the company to purchase these lands, exclusive of improvements that might be upon them, severance and consequential damages and expenses incident to acquisition. The amounts he thus fixed were as follows: For the property in St. Paul, $7,645,100.24; in Minneapolis, $4,027,616.17; in Duluth, $3,555,593.93. In the case of the St. Paul and Minneapolis properties the amounts are precisely those adopted by the Master in his findings and to this he adds 5 per cent. to cover cost of acquisition and consequential damages. The Master was of the opinion that the appraisers of these properties were "fully impressed with their value for railroad purposes" and that their appraisement as verified by them before him and modified by the railway company "is a generous valuation and should be accepted as full railroad value of the terminal properties," and it was so accepted with the addition above stated. With respect to the Duluth property, where the appraisement appears to have rested upon the ordinary values of real estate, the Master sets forth as the appraised value, $3,602,443.43, to which he adds 25 per cent. or $900,610.85 "for railway value, cost of acquisition and consequential damages."

In reviewing the findings, the court below reached the conclusion that "the Master in effect found that the cost of reproduction and the present value of the lands for the terminals in the three great cities, including therein all cost of acquisition, consequential damages, and value for railroad use which he allowed, was only about 30 per cent. more than the normal value of the lands in sales between private parties. He found the value of the lands outside the terminals to be only twice their normal value."

From our examination of the evidence we are unable to conclude that the excess stated may be thus limited. What is termed the normal value does not satisfactorily appear. It further will be observed that the amount thus allowed in Item 1 for lands, yards and terminals, both in and out of the three cities ($21,024,562), was included in the total on which 4½ per cent. was allowed in Item 30 for "Engineering, superintendence, legal expenses," and again was included in the total on which 5 per cent. was allowed in Item 37 for "Contingencies," and, in addition, was included in the total on which 10 per cent. was allowed in Item 39 for "Interest during construction."

These are the results of the endeavor to apply the cost-of-reproduction method in determining the value of the right-of-way. It is at once apparent that, so far as the estimate rests upon a supposed compulsory feature of the acquisition, it cannot be sustained. It is said that the company would be compelled to pay more than what is the normal market value of property in transactions between private parties; that it would lack the freedom they enjoy, and, in view of its needs, it would have to give a higher price. It is also said that this price would be in excess of the present market value of contiguous or similarly situated property. It might well be asked, who shall describe the conditions that would exist, or the exigencies of the hypothetical owners of the property, on the assumption that the railroad were removed? But, aside from this, it is impossible to assume, in making a judicial finding of what it would cost to acquire the property, that the company would be compelled to pay more than its fair market value. It is equipped with the governmental power of eminent domain. In view of its public purpose, it has been granted this privilege in order to prevent advantage being taken of its necessities. It would be free to stand upon its legal rights and it cannot be supposed that they would be disregarded.

It is urged that, in this view, the company would be bound to pay the "railway value" of the property. But, supposing the railroad to be obliterated and the lands to be held by others, the owner of each parcel would be entitled to receive on its condemnation, its *fair market value* for all its available uses and purposes. * * * There is no evidence before us from which the amount which would properly be allowable in such condemnation proceedings can be ascertained.

Moreover, it is manifest that an attempt to estimate what would be the actual cost of acquiring the right-of-way, if the railroad were not there, is to indulge in mere speculation. The railroad has long been established; to it have been linked the activities of agriculture, industry and trade. Communities have long been dependent upon its service, and their growth and development have been conditioned upon the facilities it has provided. The uses of property in the communities which it serves are to a large degree determined by it. The values of property along its line largely depend upon its existence. It is an integral part of the communal life. The assumption of its non-existence, and at the same time that the values that rest upon it remain unchanged, is impossible and cannot be entertained. The conditions of ownership of the property and the amounts which would have to be paid in acquiring the right-of-way, supposing the railroad to be removed, are wholly beyond reach of any process of rational determination. The cost-of-reproduction method is of service in ascertaining the present value of the plant, when it is reasonably applied and when the cost of reproducing the property may be ascertained with a proper degree of certainty. But it does not justify the acceptance of results which depend upon mere conjecture. It is fundamental that the judicial power to declare legislative action invalid upon constitutional grounds is to be exercised only in clear cases. The constitutional invalidity must be manifest, and if it rests upon disputed questions of fact, the invalidating facts must be proved. And this is true of asserted value as of other facts.

The evidence in these cases demonstrates that the appraisements of the St. Paul and Minneapolis properties which were accepted by the Master were in substance appraisals of what was considered to be the peculiar value of the railroad right-of-way. Efforts to express the results in the terms of a theory of cost of reproduction fail, as naturally they must, to alter or obscure the essential character of the work undertaken and performed. Presented with an impossible hypothesis, and endeavoring to conform to it, the appraisers—men of ability and experience—were manifestly seeking to give their best judgment as to what the railroad right-of-way was worth. And doubtless it was believed that it might cost even more to acquire the property, if one attempted to buy into the cities as they now exist and all the difficulties that might be imagined as incident

to such a "reproduction" were considered. The railroad right-of-way was conceived to be a property *sui generis,* "a large body of land in a continuous ownership," representing one of the "highest uses" of property and possessing an exceptional value. The estimates before us, as approved by the Master, with his increase of 25 per cent. in the case of the Duluth property, must be taken to be estimates of the "railway value" of the land; and whether or not this is conceived of as paid to other owners upon a hypothetical reacquisition of the property is not controlling when we come to the substantial question to be decided.

That question is whether, in determining the fair present value of the property of the railroad company as a basis of its charges to the public, it is entitled to a valuation of its right-of-way not only in excess of the amount invested in it, but also in excess of the market value of contiguous and similarly situated property. For the purpose of making rates, is its land devoted to the public use to be treated (irrespective of improvements) not only as increasing in value by reason of the activities and general prosperity of the community, but as constantly outstripping in this increase, all neighboring lands of like character, devoted to other uses? If rates laid by competent authority, state or national, are otherwise just and reasonable, are they to be held to be unconstitutional and void because they do not permit a return upon an increment so calculated?

It is clear that in ascertaining the present value we are not limited to the consideration of the amount of the actual investment. If that has been reckless or improvident, losses may be sustained which the community does not underwrite. As the company may not be protected in its actual investment, if the value of its property be plainly less, so the making of a just return for the use of the property involves the recognition of its fair value if it be more than its cost. The property is held in private ownership and it is that property, and not the original cost of it, of which the owner may not be deprived without due process of law. But still it is property employed in a public calling, subject to governmental regulation and while under the guise of such regulation it may not be confiscated, it is equally true that there is attached to its use the condition that charges to the public shall not be unreasonable. And where the inquiry is as to the fair value of the property, in order to determine the reasonableness of the return allowed by the rate-making power, it is not admissible to attribute to the property owned by the carriers a speculative increment of value, over the amount invested in it and beyond the value of similar property owned by others, solely by reason of the fact that it is used in the public service. That would be to disregard the essential conditions of the public use, and to make the public use destructive of the public right.

The increase sought for "railway value" in these cases is an increment over all outlays of the carrier and over the values of similar land in the vicinity. It is an increment which cannot be referred to any known criterion, but must rest on a mere expression of judgment which finds no proper test or standard in the transactions of the business world. It is an increment which in the last analysis must rest on an estimate of the value of the railroad use as compared with other business uses; it involves an appreciation of the returns from rates (when rates themselves are in dispute) and a sweeping generalization embracing substantially all the activities of the community. For an allowance of this character there is no warrant.

Assuming that the company is entitled to a reasonable share in the general prosperity of the communities which it serves, and thus to attribute to its property an increase in value, still the increase so allowed, apart from any improvements it may make, cannot properly extend beyond the fair average of the normal market value of land in the vicinity having a similar character. Otherwise we enter the realm of mere conjecture. We therefore hold that it was error to base the estimates of value of the right of way, yards and terminals upon the so-called "railway value" of the property. The company would certainly have no ground of complaint if it were allowed a value for these lands equal to the fair average market value of similar land in the vicinity, without additions by the use of multipliers, or otherwise, to cover hypothetical outlays. The allowances made below for a conjectural cost of acquisition and consequential damages must be disapproved; and, in this view, we also think it was error to add to the amount taken as the present value of the lands the further sums, calculated on that value, which were embraced in the items of "engineering, superintendence, legal expenses," "contingencies" and "interest during construction."

By reason of the nature of the estimates, and the points to which the testimony was addressed, the amount of the fair value of the company's land cannot be satisfactorily determined from the evidence, but it sufficiently appears for the reasons we have stated that the amounts found were largely excessive.

Finding this defect in the proof, it is not necessary to consider the objections which relate to the sources from which the property was derived or its mode of acquisition, or those which are urged to the inclusion of certain lands which it is said were not actually used as a part of the plant; and we express no opinion upon the merits of these contentions.

The property other than land, as the detailed statement shows, embraced all items of construction, including road-bed, bridges, tunnels, etc., structures of every sort, and all appliances and equipment. The cost of reproduction new was ascertained by reference to the prices for such work and property. In view of the range of the questions we have been called upon to consider, we shall not extend this opinion for the purpose of reviewing this estimate, or of passing upon exceptions to various items in it, as their disposition would not affect the result.

The Master allowed the cost of reproduction new without deduction for depreciation. It was not denied that there was depreciation in fact. As the Master said, "everything on and above the road-bed depreciates from wear and weather stress. The life of a tie is from eight to ten years only. Structures become antiquated, inadequate and more or less dilapidated. Ballast requires renewal, tools and machinery wear out, cars, locomotives and equipment, as time goes on, are worn out or discarded for newer types." But it was found that this depreciation was more than offset by appreciation; that "the road-bed was constantly increasing in value"; that it "becomes solidified, embankments and slopes or excavations become settled and stable and so the better resist the effects of rains and frost"; that it "becomes adjusted to surface drainage, and the adjustment is made permanent by concrete structures and rip-rap"; and that in other ways, a road-bed long in use "is far more valuable than one newly constructed." It was said that "a large part of the depreciation is taken care of by constant repairs, renewals, additions and replacements, a sufficient sum being annually set aside and devoted to this purpose, so that this, with the application of road-bed and adaptation to the needs of the country and of the public served, together with working capital . . . fully offsets all depreciation and renders the physical properties of the road not less valuable than their cost of reproduction new." And in a further statement upon the point, the "knowledge derived from experience" and "readiness to serve" were mentioned as additional offsets.

We cannot approve this disposition of the matter of depreciation. It appears that the Master allowed, in the cost of reproduction, the sum of $1,013,612 for adaptation and solidification of road-bed, this being included in the item of grading and being the estimate of the engineer of the state commission of the proper amount to be allowed. It is also to be noted that the depreciation in question is not that which has been overcome by repairs and replacements, but is the actual existing depreciation in the plant as compared with the new one. It would seem to be inevitable that in many parts of the plant there should be such depreciation, as for example in old structures and equipment remaining on hand. And when an estimate of value is made on the basis of reproduction new, the extent of

existing depreciation should be shown and deducted. This apparently was done in the statement submitted by this company to the Interstate Commerce Commission in the Spokane Rate case in connection with an estimate of the cost of reproduction of the entire system as of March, 1907. (See 15 I. C. C. 395, 396.) In the present case, it appears that the engineer of the state commission estimated the depreciation in the property at between eight and nine million dollars. If there are items entering into the estimate of cost which should be credited with appreciation, this also should appear, so that instead of a broad comparison there should be specific findings showing the items which enter into the account of physical valuation on both sides.

It must be remembered that we are concerned with a charge of confiscation of property by the denial of a fair return for its use; and to determine the truth of the charge there is sought to be ascertained the present value of the property. The realization of the benefits of property must always depend in large degree on the ability and sagacity of those who employ it, but the appraisement is of an instrument of public service, as property, not of the skill of the users. And when particular physical items are estimated as worth so much new, if in fact they be depreciated, this amount should be found and allowed for. If this is not done, the physical valuation is manifestly incomplete. And it must be regarded as incomplete in this case.

Apportionment of Values. As the rate of net return from the entire Minnesota business (interstate and intrastate) during the test year was 6.021 per cent. on a valuation of $90,204,545, and would be greater if computed upon a less value, we are brought to the question whether the methods of apportionment adopted are so clearly appropriate and accurate as to require a finding of confiscation of property used in the intrastate business.

The apportionment of the value of the property, as found, between the interstate and intrastate business was made upon the basis of the gross revenue derived from each. This is a simple method, easily applied, and for that reason has been repeatedly used. It has not, however, been approved by this court and its correctness is now challenged. Doubtless, there may be cases where the facts would show confiscation so convincingly in any event, after full allowance for possible errors in computation, as to make negligible questions arising from the use of particular methods. But this case is not of that character.

In support of this method, it is said that a division of the value of the property according to gross earnings is a division according to the "value of the use," and therefore proper. But it would seem to be clear that the value of the use is not shown by *gross* earnings. The gross earnings may be consumed by expenses, leaving little or no profit. If, for example, the intrastate rates were so far reduced as to leave no net profits, and the only profitable business was the interstate business, it certainly could not be said that the value of the use was measured by the gross revenue.

It is not asserted that the relation of expense to revenue is the same in both businesses; on the contrary, it is insisted that it is widely different. The Master found that the revenue per ton-mile in the intrastate business, as compared with the revenue per ton-mile in the interstate business, was as 1.4387 to 1.0000. And, on his assumption as to the extra cost of doing the intrastate business, he reached the conclusion that the cost per ton-mile in proportion to the revenue per ton-mile in the intrastate business, as compared with the interstate business, was as 1.7377 to 1.0000. It is contended, according to the computations, that only a little over 10 per cent. of the entire net revenue of the test year ($5,431,514.66) was made in the intrastate business, and that 90 per cent. thereof was made in the interstate business; but approximately 21 per cent. of the total value of the property was assigned to the intrastate business.

If the property is to be divided according to the value of the use, it is plain that the gross-earnings method is not an accurate measure of that value. . . .

The value of the use, as measured by return, cannot be made the criterion when the return itself is in question. If the return, as formerly allowed, be taken as the basis, then the validity of the state's reduction would have to be tested by the very rates which the state denounced as exorbitant. And, if the return as permitted under the new rates be taken, then the state's action itself reduces the amount of value upon which the fairness of the return is to be computed.

When rates are in controversy, it would seem to be necessary to find a basis for a division of the total value of the property independently of revenue, and this must be found in the use that is made of the property. That is, there should be assigned to each business that proportion of the total value of the property which will correspond to the extent of its employment in that business. It is said that this is extremely difficult; in particular, because of the necessity for making a division between the passenger and freight business and the obvious lack of correspondence between ton-miles and passenger-miles. It does not appear, however, that these are the only units available for such a division; and it would seem that, after assigning to the passenger and freight departments respectively, the property exclusively used in each, comparable use-units might be found which would afford the basis for a reasonable division with respect to property used in common. It is suggested that other methods of calculation would be equally unfavorable to the state rates, but this we cannot assume.

It is sufficient to say that the method here adopted is not of a character to justify the court in basing upon it a finding that the rates are confiscatory.

RAILWAY SIGNAL ASSOCIATION.

The June meeting of this association was held in New York City beginning June 11 and 12, with President B. H. Mann in the chair. Mr. Mann mentioned the work being carried on in connection with committees of other associations and heartily recommended the joint committee work. Mr. Anthony spoke of the work being done in connection with the superintendents of telegraph regarding the joint use of pole lines. Mention was also made of the necessity of making early hotel reservations for the annual convention at Nashville. Mr. Rosenberg will issue a circular in regard to this matter.

In the entertainment which was furnished by the Signal Appliance Association Wednesday afternoon—a boat trip around the city, landing at Coney Island for dinner—moving pictures were taken as the members and guests boarded the steamer.

The first business was the report of Committee No. 2, submitted by C. J. Kelloway, chairman. A long discussion followed on R. S. A. drawing No. 1260, mechanical single switch layout with one facing point lock and one detector bar. W. H. Elliot suggested that the plans be discussed as information but not as standards, stating that there was an unnecessary duplication of parts. Mr. Rudd suggested that a note be added stating that certain parts shown have not yet been standardized. Mr. Mock suggested that the committee observe page 212 of the *Journal* of the Association for June, as a guide in showing dimensions. A disagreement arose concerning the duties of Committees 2 and 6, and it was suggested that the committee submit new plans at the Nashville Convention, accepting the suggestions offered. This was put to vote and carried. The other drawings submitted by this committee were then discussed, suggestions being made for guidance of the committee.

The report of Committee No. 3 was submitted by R. C. Johnson. The specifications for the installation of a vitrified clay conduit system were read and slight changes made in the wording. C. E. Denney moved that the specifications for construction be compiled separately from those for material. This motion was carried. It was then voted that the specifications as corrected be accepted for presentation at the annual convention. The recommendation shown on page 138 will be presented to the annual convention as printed.

The report of Committee No. 4 was presented by A. R. Fugina

in the absence of Messrs. Adams and Phinney. In Section 5 of the specifications for relays the word "water" was substituted for "moisture." The suggestion was made that the specifications for lifting armature, neutral type D. C. interlocking relays be corrected to conform to the present methods of manufacture and that representatives of the supply houses be consulted in preparing these specifications for the annual convention. This suggestion was accepted by the committee. The report of Sub-committee No. 12, of Committee No. 4, was presented by Mr. Fugina. T. S. Stevens said that paragraph b, of part 2, of the specifications for vibrating crossing alarms, was unnecessary; but after it was shown that four roads needed this clause the paragraph was accepted as a part of the specifications. Mr. McCready, of the Union Switch & Signal Company, suggested that the committee look into the working resistance of crossing bells. This was put in the form of a motion and carried. Mr. McCready moved that, "Normal Working Voltage" be inserted under part 16, and this was carried. Mr. Elliot moved that the word "Alarm" be stricken from the title. This motion was carried. Mr. Stevens moved that paragraphs b and c of part 2 be reconsidered, on account of the practices of the various roads. This motion was carried and the committee was then excused.

The report of Committee No. 5 was presented by T. S. Stevens. C. C. Anthony suggested that where the word "operator" appears the word "signalman" be substituted. Mr. Rudd suggested that part 2-b of the paragraph on Controlled Manual Block be reconsidered and be changed so as to provide for a broken train. These suggestions were accepted by the committee. Mr. Stevens then explained that the drawings shown were so arranged that the cost of any combination might be easily estimated. Mr. Denney suggested that a note to that effect be added to parts m. b. 1 and m. b. 2. Mr. Elliot suggested showing a bill of material and Mr. Morrison recommended the insertion of a note stating that R. S. A. Standards be used where possible. In part m. b. 1, paragraph d, and m. b. 2, paragraph c, the word "Arranged" was substituted for "Complete." The word "Written" was removed from paragraphs d and f of part m. b. 1, and paragraph c of m. b. 2.

The report of Committee No. 6 was presented by J. C. Mock. Drawings 1008, 1009, 1085, 1099 and 1063, were accepted. In drawing 1084 the dimension of $\frac{1}{8}$ in. was inserted to show the thickness of web, in accordance with a suggestion by Mr. McCready. Drawing 1095 was accepted with the proviso that the committee arrange for a removable cap. Mr. Stevens moved that a multiple unit bolt lock be designed, and Mr. Anthony moved that an adjustable unit bolt lock be designed. These motions were carried and the committee instructed to so proceed. The color of blades was discussed and the committee instructed to send circular letters to get information as to whether a combination of red and white or yellow and black is preferred. The committee reported that designs for lamp brackets and for bridges are being considered.

The report of Committee No. 8 was presented by H. S. Balliet. Regarding paragraph 602 on page 161 the committee accepted a suggestion that the part referring to contracts read "front and back contacts shall carry four amperes and break 10 amperes." In paragraph 545 the words "Core type" were taken out. The specifications for A. C. and D. C. Core Type Impedance Bonds were accepted. The other specifications presented by this committee were read and accepted, Mr. Balliet recommending that they be carefully studied before the annual convention.

The report of Committee No. 9 was presented by Mr. Elliott as information. He stated that about one-half of the users of the R. S. A. formula for insulation found it satisfactory. There was a short discussion by Messrs. Rudd, Stevens, Wilson and Martin, and the committee was excused.

The report of Committee No. 10 was presented by R. B. Elsworth. The report of the committee was accepted after a long discussion on paragraphs a and c of part 5. It was finally carried that the word "Pure" be inserted before "Lead" in the title.

J. E. Saunders was highly complimented on the presentation of his papers, and particularly by Messrs. Morrison, Waldron, Stevens and McCready. Mr. Leisenring suggested the addition of a note stating that the papers applied chiefly to steam roads practice. This suggestion was accepted. The discussion and a notice of the papers will appear in the *Journal* of the Association for September.

HEATING SMALL STATIONS.

By D. E. Lamon.*

After carrying coal and keeping fires going in a set of three stoves in my station for ten years I have come to the conclusion that from about every possible point of view, the use of stoves for heating the ordinary station of two waiting rooms and an office is a failure.

If a small basement were made under the building just large enough for a furnace, a coal bin, and an ash heap, with a coal chute from the platform and a window in the rear for getting the ashes out, the plan would prove decidedly better. If a furnace, made upon the plan of the present stove, solid and substantial but cheap, were to be installed, the first cost would not be a great deal more than the cost of the three stoves with their pipes and chimneys, and this difference would be quickly made up in the fuel saved.

Not so much coal would be burned; not so much time required to keep the fire going; less fire risk from one chimney than from two; no ashes on the floor, and less smoke and soot on the walls. The rooms would have a more up to date appearance, space in the office and waiting rooms would be saved, and the comfort of passengers and efficiency of the service would be increased.

Three separate fires for the three rooms are too many. They burn too much coal, and in many cases employees will not keep them up properly. If the fire in the office is going all right and they are comfortable, they do not worry about the waiting rooms. I have noticed this at many offices, more especially at night when the agent is not on duty to see how things are attended to. Many times, too, during the daytime, when the agent or man on duty is very busy he unintentionally overlooks the fact that the fire in the waiting room is getting low until it is out; and usually about that time someone leaves the outside door open and the room becomes cold in a very short time, giving just cause for complaint. If the fire that kept the office warm also warmed the waiting rooms he would not forget it.

The station stove is an old offender in the way of throwing out dirt. It is almost impossible to avoid having more or less ashes and coal dust on the floors. It is also out of the question to keep stoves properly blacked, as the polish will burn off in two or three days; and at their best they are not an ornament. The introduction of the furnace would do away with all of this dirt, and would give passengers the impression that the road was trying to keep up to date.

This plan could not be used at a station situated on ground so low that the basement would be flooded during rainy weather but I believe that the majority of stations are built at places where flooding could be avoided.

Sunday Trains in Scotland.—An influential deputation of Scottish religious bodies waited upon the Caledonian Railway board of directors to press home the public outcry against the Sunday railway service which is to be inaugurated immediately. Sir Charles Renshaw, refusing the prayer of the petition, said the Scottish railways had not by any means moved rapidly in the direction of developing Sunday traveling. The public demanded it, and, as Glasgow cars had long since given these facilities and citizens had not objected, there was no reason why railways should not share in the traffic.

SUPERHEATING AND FEED WATER HEATING.*

Theoretical Discussion of These Features in Various Combinations Checked by Results on Egyptian State Railways.

By F. H. Trevithick and P. J. Cowan.

The tendency in recent years to increase trainloads and average speeds has, in the main, resulted in larger locomotives. By putting proportionately more weight into the boiler, the evaporative capacity has been increased, and, since boiler capacity limits the tractive effort at anything above low speeds, this has been quite a logical development. The same provision, at equal loads, results in increased economy, since the rate

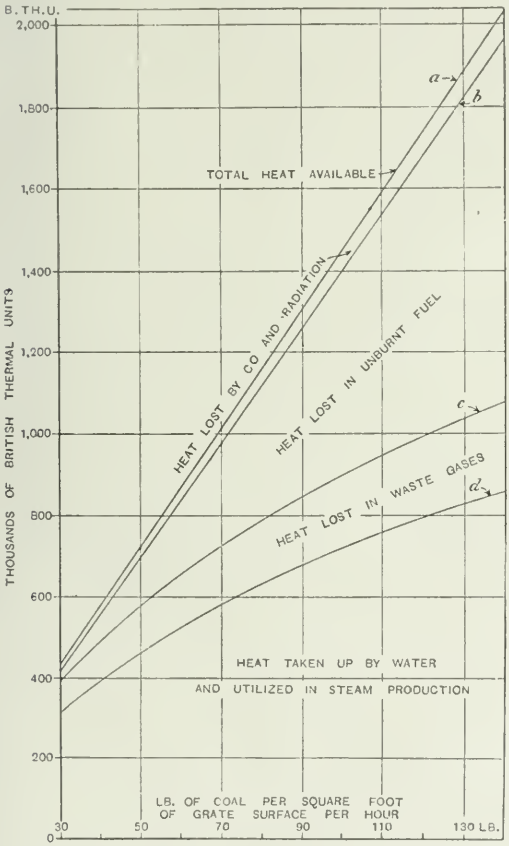

Fig. 1—Heat Utilized and Lost at Different Rates of Firing, Based on the St. Louis Tests (Series 200).

of firing is brought down to a point where the boiler efficiency is greater.

Fig. 1 shows the nature of the losses of heat in steam production in the form of a diagram of heat available, taking 14,500 B. t. u. as a typical calorific value for the coal. The line *a* represents the total heat available in the fuel at any rate of firing per square foot of grate area per hour. This diagram is merely typical. A comparison of numerous published results shows that it may fairly be taken to be so.

*Abstract of a paper presented before the Institution of Mechanical Engineers (London), March 14, 1913.

In locomotive operation, engine output, steam output, rate of firing, draft, smokebox temperature and other factors are interdependent. Engine output for a large part of the range of working is limited by boiler output, which is dependent upon the rate of firing. This, in its turn, depends on draft,

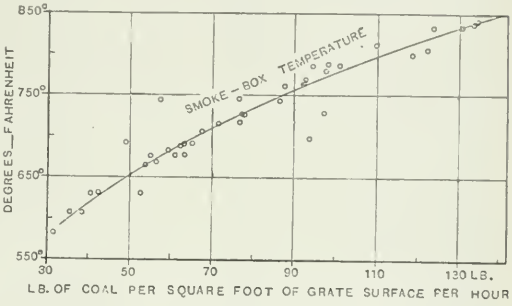

Fig. 2—Relation of Smokebox Temperature to Rate of Firing.†

which, other conditions being unaltered, is a function of the steam exhausted. The vacuum in front of the diaphragm in American engines is often twice as intense as that behind it.

The net loss of heat in the waste gases is dependent upon their quantity and specific heat and the smokebox temperature. In quantity the waste gases increase with the rate of firing, though the amount of gas per pound of fuel burned tends to diminish. The manner in which smokebox temperatures increase with the rate of firing is shown in Fig. 2. The St. Louis tests on modern large boilered engines show lower temperatures than the Purdue tests represented in Fig. 2. The specific

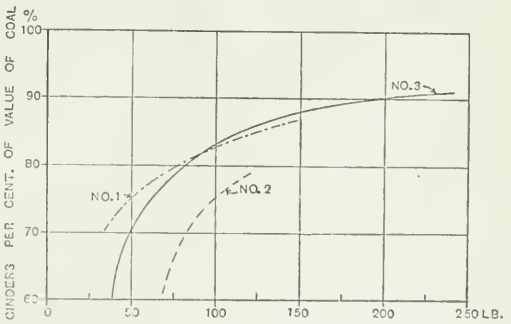

Fig. 3—Relation of Calorific Value of Cinders Passing Through the Boiler Tubes to Rate of Firing.‡

heat of the waste gases increases with smokebox temperatures. As a net result of the combination of these three factors, the proportion of the loss in the waste gases to the heat available in the coal gradually falls, but in amount increases with the rate of firing.

†Values are from Goss' "High Steam Pressures in Locomotive Service" (Youghiogheny coal).

‡Values for No. 1 are taken from Goss' "Superheated Steam in Locomotive Service" (Pocahontas coal); No. 2, for Youghiogheny coal; No. 3, from "Locomotive Sparks" (Brazil black coal).

Of the loss by unburnt fuel, part, occurring at the grate, is not usually preventable, except such as arises from inexpert firing. The larger portion of this loss is involved with rate of firing has on the relative amounts of the smokebox cinders, and those passing out of the stack, but it appears probable that so long as the smokebox capacity is not taxed,

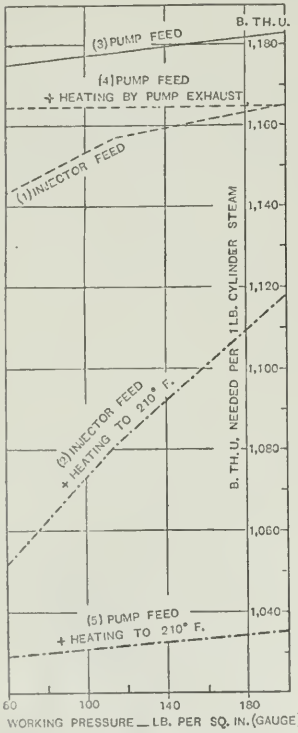

Fig. 4—Saturated Steam Boiler Output in B.t.u. Necessary with Various Conditions of Feed for Each Pound of Steam Used in the Cylinders.

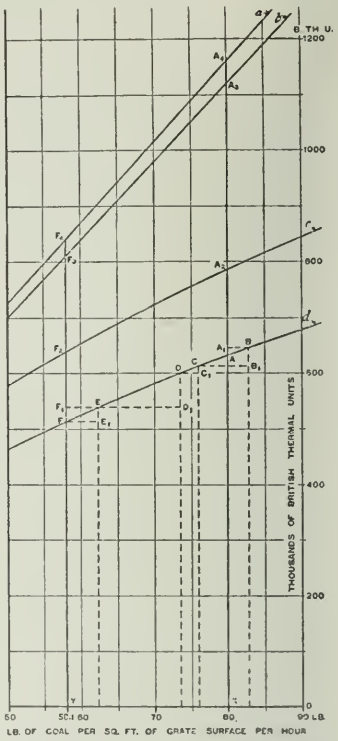

Fig. 7—Diagram Showing the Economy of Feed Heating to 210 Deg. Fahr., Combined with Superheating by Waste Gases to 85 Deg. Fahr.

engine output and draft. The greatest loss is traceable to the quality and quantity of the smokebox cinders, and of those passing out of the chimney. Both these increase with the rate of firing. It is not possible to state definitely what effect the

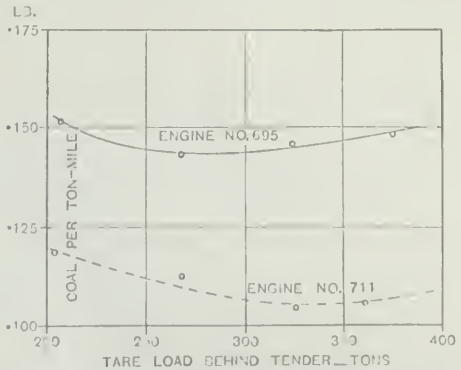

Fig. 6—Coal Consumption per Ton-Mile for Engine 711 (Feed Heating to 270 Deg. Fahr.) and Engine 695 (Non-Heater).

the smokebox cinders are greater in amount than those passing out of the chimney when the work is light, and that when the engine is forced, those emitted from the chimney exceed those retained in the smokebox.

An idea of the way in which the calorific value of these cinders increases with rate of firing is given by Fig. 3. The curves are for three different kinds of coal. Their value is thus high, being shown to be about 90 per cent. of the original value of the coal at the highest rates of working. In the St. Louis tests the highest calorific value found for smokebox cinders was 65 per cent. of the value of the original coal, and for the cinders ejected 87.6 per cent. of the coal value. The average for all tests was for smokebox cinders 80.7 per cent., and for cinders ejected through the chimney 72.5 per cent. of the original value of the coal.

The facts which show so rapid an increase in the boiler losses at the higher rates of firing emphasize the statement already made that improvement will be realized if the necessary output can by some means be secured at a reduced rate of firing. Two processes which meet this requirement are feed-water heating and steam superheating.

FEED WATER HEATING.

For feed-heating agents, providing a direct saving of otherwise waste heat, there are available the exhaust steam and the

waste gases passing out of the chimney. If these agents are used in series, heating by the waste gases must be accomplished last. As the process may be arranged to result in temperatures being reached at which even the so-called hot water injectors will not work, its successful adoption involves a reconsideration of the feeding system generally.

The ordinary injector will not pick up water above about 120 deg. to 125 deg. F., and the feed water cannot, therefore, be effectively heated before it reaches the injector, while the admixture in that apparatus of live steam with the feed, so raises the temperature of the latter that full advantage cannot be taken of subsequent heating by either of the agents available. An injector may feed into a boiler at 180 lbs. about 11.2 lbs. of water for every pound of steam used. If the supply be at 65 deg. F. the delivery will be about 160.5 deg. F. This increase is not an economic gain. Delivery falls off as the boiler pressure rises, and the temperature of delivery is higher at the higher pressures. Subsequent feed heating is of less advantage now than it would have been when pressures were lower.

For each pound of steam used in the cylinders (1 + a fraction) must be produced in the boiler, from the temperature of the injector discharge, in order to supply both the engine and injector. The B. t. u. thus to be produced are given for various pressures in Fig. 4, by curve 1, which is based on data published by S. L. Kneass.* If, subsequent to delivery from the injector, the feed be heated by the cylinder exhaust to 210 deg. F., the boiler work is reduced, as denoted by curve 2. The work needed increases with the boiler pressure. Heat can further be transmitted from the waste gases, and an average feed temperature of 280 deg. to 290 deg. F. obtained, but compensation can in no way be secured for heating during part of the process with live steam.

At modern pressures the ordinary exhaust injector shows a thermal saving over the live steam injector of some 9 per cent. The supplementary portion of the exhaust injector is handicapped by the water fed to it being already at a high temperature (about 180 deg. F.). Its steam consumption is thus high, and the final temperature of discharge is about 280 deg. F. Additional feed heating is thus impracticable, even by the waste gases. The only gain procurable with this injector is that due to the use of part of the exhaust steam; this, however, may exceed the thermal gain of 9 per cent. or so. In a more recent form of exhaust steam injector the efficiency of the exhaust steam jet has been improved, and much less supplementary live steam is needed. Though the thermal position is the same with both types, the discharge temperature is thus lower with the later pattern. The final temperature with the later type is 195 deg. F. compared with 280 deg. F. with the earlier, and further feed heating is practicable.

The pump offers advantages over the injector in connection with feed heating, since, with it, the feed temperature is not increased in the process of raising the pressure, and the temperature head is sufficient for the effective transfer of heat to the pump delivery, successively from the exhaust steam and the waste gases. On account of the sudden demands which a locomotive feed pump is called upon to meet, such an appliance should be arranged to work with water at moderately low temperatures, and the greater part of the feed heating process should be carried out between the pump and the boiler check valve.

Independent steam pumps suitable for locomotive work will deliver 100 lbs. of water for about 1.5 lbs. of steam, working at and against 180 lbs. pressure. Curve 3, Fig. 4, shows the B. t. u. to be provided by the boiler for each 1 lb. of steam delivered to the cylinders, using pump supply and feed at 65 deg. F. Curve 4 shows the work required if the pump exhaust be utilized for feed heating, about the same amount being required at all pressures. The pump and injector are then on an equal footing at modern pressures. Heating, further, by the main cylinder exhaust to 210 deg. F., reduces the boiler work to the amounts shown by curve 5. This system has a considerable advantage over the injector feed combined with heating to 210 deg. F. (see curve 2), and this is maintained if the feed heating be carried still further.

*"Practice and Theory of the Injector." (Wiley.)

SUPERHEATING.

In superheating, a final benefit may be due to different causes according to the system. In one system the heat in the waste gases discharged from the boiler is utilized to raise the temperature of the steam. In another a directly fired superheater is employed, commonly incorporated for convenience in the boiler, in order that one grate may serve both.

Contrary to general experience in other branches of steam engineering, and also in conflict with testimony from many railways, it has been maintained that waste-gas superheating effects little or no benefit in locomotive work. This system combines improvements in two directions, namely, in the efficiency of steam generation and in the engine's consumption. The gain in generation has been commonly ignored or actually denied so far as locomotive work is concerned, while the engine gain has been fairly generally admitted. A true waste-gas superheater forms an adjunct to the ordinary boiler. Its installation should not disturb the heating capacity of the boiler, nor altar its efficiency. The over-all efficiency of the generator is improved, the proportion of heat available in the coal, put to use, being increased.

Directly fired superheater locomotives, using superheat from 100 deg. F. upwards, which can lay claim to no improvement in the efficiency of steam generation, but rather suffer in an adverse sense, admittedly prove satisfactory in service. There appears, therefore, to be no valid reason why the waste-gas heating system, with which superheat of about 90 deg. F. can be obtained, should not likewise give good results. The difference between the temperatures just cited is more than made up by the higher over-all efficiency of the combined waste-gas heater and boiler.

It is difficult to determine the economical position of the directly fired superheater installations of the moderate degree or high degree types, as applied in locomotive service. For the generator efficiency to be undiminished, no more heat must be lost from a superheater boiler than in the ordinary boiler. In some installations the average amount of heat absorbed through the smoke-tube superheater surface may about equal, as far as can be gathered, the average amount transmitted through the water-heating tube-surface. This may be so in the double-loop high-degree type in which high steam velocities are used, and the ends of the loops are brought fairly near the firebox. Locally, transmission is then very great and the average is high. With the single-loop types giving moderate degrees of superheat, the elements are often short and the speeds low. The transmission, at the best, is then comparatively low, and, on the average, lower than that of the water-heating tube surface. As regards efficiency of steam generation, therefore, the combination of the waste-gas superheater and boiler ranks first. Probably the ordinary boiler ranks second and the high degree smoke-tube superheater boiler third, but this does not appear yet to have been definitely determined; it is possible their relative positions are not the same at all powers. Last of all stands the moderate degree smoke-tube superheater boiler.

Though the above aspect of superheating is often treated with indifference, it is generally conceded that there is more or less saving in steam at all degrees of superheat. Even with no superheat the use of a heater may reduce the feed necessary, if the steam normally sent over is wet. Part of the economy shown on road tests undoubtedly arises from this. With any temperature above that corresponding to dry steam, there is an improvement in the engine. This has been determined in road tests, and also on testing plants. Dr. Goss and others responsible for the work at Purdue University have concluded that steam consumption falls with increasing superheat. This determination is naturally only approximate. The data issued from Purdue con-

stitute the only records yet published, showing the effect of progressive superheat on steam consumption in locomotive service. As regards coal consumption, however, they do not fairly indicate the possibilities of moderate superheating (though it is sometimes held they do), since they do not embrace investigations with the more efficient installations of that class.

COAL CONSUMPTION.

Feed-water heating and superheating may be employed in various arrangements or combinations. For moderate feed-heating, the pump exhaust and part of the main cylinder exhaust are used. The former raises the feed temperature by 25 deg. to 30 deg. F., the latter to about 210 deg. F., or slightly more. High degrees may be attained by continuing the process with a smoke-box heater in series. Temperatures of 280 deg. to 290 deg. F. may thus be reached, with even 360 deg. F. for short supplies feeding to a boiler working at a pressure of 180 lb. The smoke-box heater may be used alternatively for moderate superheating, when a superheat of about 90 deg. F. may be secured. Thus feed-heating to 210 deg. F. and moderate waste-gas superheating may be combined. Finally, with the smoke-tube type of superheater, moderate and high degree feed-water heating may also be adopted.

High Degree Feed-Water Heating.—Unless conditions are unfavorable, feed-heating is purely a gain to the boiler. If an engine be overrated, hot feed may be accompanied by the production of somewhat drier steam. The effect of feed-heating may be studied by the aid of Fig. 5, which is part of Fig. 1 to an enlarged scale.

Taking, as typical, a rate of firing of 80 lbs. per square foot of grate area per hour, by the scale, AX, the amount of heat utilized in steam production is 632,000 B. t. u. This is equivalent to the evaporation of 591 lbs. of water from and at 160.5 deg. F., the temperature of discharge of the injector with supply at 65 deg. F. and boiler pressure at 180 lbs. Dividing this in the proportion of 11.2 to 1, gives 542.57 lbs. as the steam taken by the engine, and 48.44 lbs. as that used in working the injector. For a pump-fed engine (with supply at 65 deg. F.) to develop the same power, the same number of pounds of steam must be furnished to the cylinders. This requires 542.57 (1197.7 — 33.07) = 631,890 B. t. u., 1197.7 representing the total heat in steam at 180 lbs. pressure, and 33.07 that in the water at 65 deg. F., both above 32 deg. F. The pump consumption will be taken as 2.2 lbs. of steam per 100 lbs. of water delivered, and therefore (542.57 × .022) lbs. = 11.94 lbs. of steam are needed for the pump, equivalent to a demand on the boiler of 13,910 B. t. u. The total number of thermal units to be generated is thus (631,890 + 13,910) = 645,800 B. t. u. This is supplied in stages, namely, by the pump exhaust heating by 25 deg. F., or to 90 deg. F.; by the main cylinder exhaust to 210 deg. F., by the waste-gas heater to, say, 270 deg. F. (a temperature easily reached); and finally by the boiler. The total heat supplied per 1 lb. of steam is (1197.7 — 33.07) = 1164.63 B. t. u. Of this, therefore, the pump exhaust furnishes (58.0 — 33.07) = 24.93 B. t. u.; the main exhaust (177.99 — 58.0) = 119.99 B. t. u.; the waste gases supply (238.8 — 177.99) = 60.81 B. t. u.; and the boiler furnishes (1197.7 — 238.8) = 958.9 B. t. u. The total heat is supplied to the engine and pump as follows.

TABLE I.—HEAT SUPPLIED WHEN FEED HEATING TO 270 DEG. F.

Source of Heat	Proportion of total supplied	B. t. u. supplied To Engine	To Pump.	To Engine and Pump.
Pump exhaust heater	24.93 / 1164.63	13,530	300	13,830
Main cylinder exhaust-heaters	119.99 / 1164.63	65,100	1,430	66,530
Waste gas heater	60.81 / 1164.63	32,990	730	33,720
Boiler	958.9 / 1164.63	520,270	11,450	531,720
Totals		631,890	13,190	645,800

Instead of 632,000 B. t. u. to be supplied by the boiler in the injector-fed engine, coal has now only to be burnt to furnish the reduced supply of 531,720 B. t. u. Following this out in Fig. 5, the requirements have first to be increased from A to A_1 (= 645,800 B. t. u.), on account of the substitution of the pump for the injector. This corresponds to a point B on the curve ***d***. The use of the pump-exhaust reduces the demand by 13,830 B. t. u., namely to B_1 and C_1 or slightly below the original point for the injector-fed engine. The main exhaust furnishes a further 66,530 B. t. u., and the demand is brought down to C_1 and D_1 and again of this 33,720 B. t. u. (DD_1) is derived from the waste gases, leaving EY (= 531,720 B. t. u.) to be provided by the boiler itself. The rate of firing which will produce this is 60.8 lbs. per square foot of grate area per hour, compared with the original 80; a saving of 24 per cent. is thus indicated for the system.

The diagram shows how this comes about, supposing smoke-box conditions to remain normal. The heat represented by DD_1 is drawn from the waste gases. This length may, therefore, be set up over E at EE_1. Then E_1E_2 represents the final loss in the waste gases compared with the original AA_1, that is, 96,000 B. t. u. instead of 156,000, or a reduction of 38.5 per cent. in this loss. The loss by unburnt fuel has been reduced from A_1A_2 (332,000 B. t. u.) to E_2E_3 (193,000 B. t. u.), a reduction of more than 41.5 per cent. The proportion of the heat utilized, to the total available, has been greatly increased. The savings by feed-heating are, in locomotive work, on a rather higher scale than in other branches of steam engineering.

Trials of this system were made on the Egyptian State Railways. Engine 711, with heaters, ran against a sister engine, 695, without heaters, on expresses between Cairo and Alexandria (130 miles), the fastest timing being 3 hours with two intermediate stops. The ton-miles accomplished were 1,939,847 by engine 711 and 1,926,054 by engine 695. The average coal per ton-mile worked out at 0.1116 lb. for 711, and 0.1450 lb. for 695—a saving of 23 per cent. for the heater engine. The results of the trials are shown in Fig. 6. The consumption of the non-heater engine increased much more rapidly with the loading than did that of the heater engine. The economy shown by the latter improves at the heavier loads.

The service data for engines in regular service confirm all trials made with this system. Table II gives such records for engines 711 and 677 and non-heater engines.

The large difference between 711 and sister non-heater engines is probably in part due to 711 being constantly used for investigation work, and being kept in first-class order. Coal was also most likely booked to it more carefully than it would otherwise have been. The figures for 711 with and without heaters are fairly comparable. Engine 677 is of another class. An all-round improvement in this case of 18 per cent. is shown for the heaters, but if the comparison be confined to periods of like climatic conditions (an important point when work in a country such as

TABLE II.—SERVICE WORKING OF FEED-HEATER AND NON-HEATER ENGINES.

	Engine 711 without heaters.	Engine 711 with heaters.	29 Sister Engines without heaters.	Engine 677 with heaters.	Engine 677 without heaters.

Difference in favor of heaters on coal per ton-mile		0.367 lb.	0.0473 lb.		0.031 lb.
Ditto Per cent.		22	27		18

Egypt is being considered) this engine, fitted with heaters, showed an improvement of 20.5 per cent. over working without them.

Considering the modified smokebox arrangement, the result shown for the trials of 711 (an economy of 23 per cent.) is in remarkably good agreement with the saving indicated by the method of Fig. 5. If part of the exhaust steam be efficiently employed in raising the feed to temperatures approaching the maximum, its utilization in this manner is productive of more economical working than its use in the blast would be, in maintaining a higher smokebox vacuum.

Moderate Degree Feed-Heating and Moderate Superheating by Waste Gases.—With supply at 65 deg. F. the pump-exhaust warms the feed to 90 deg. F., and part of the main cylinder exhaust subsequently carries it to about 210 deg. F. The waste-gas heater gives superheat of about 90 deg. F. on a boiler pressure of 180 lbs per square inch. For the sake of moderation 85 deg. F. will be taken.

This degree of superheat reduces the steam consumption by about 9 per cent. Instead of the 542.57 lbs. necessary in the previous case, only 493.74 lbs., therefore, need to be supplied to this engine for the same work. Each pound contains, however, 1215.33 B. t. u. above 65 deg. F., and the total heat to be supplied for engine purposes is now $(493.74 \times 1215.33) = 600{,}060$ B. t. u. The pump requires $(493.74 \times 0.022) = 10.86$ lbs. of steam, which, taken from the dome, is saturated. This represents $(10.86 \times 1164.63) = 12{,}650$ B. t. u., and the total engine and pump requirements amount to 612,710 B. t. u., supplied as in Table III.

In this case coal has only to be burnt to supply the 514,560 B. t. u. demanded of the boiler (see Fig. 7). As before, the demand is first increased from A to A_1 by the adoption of the pump. From the corresponding point B on the curve *d*, superheating reduces the total demand to B_1 and C (612,170 B. t. u.). Thence to C_1 and D (600,130 B. t. u.) the demand is lowered by the use of the pump-exhaust, and to D_1 and E (539,590 B. t. u.) by the main exhaust heaters. The superheater completes the process by relieving the boiler of duty equal to 25,030 B. t. u., and the demand is brought down in this way to E_1 and F (514,560 B. t. u.), corresponding to a coal rate of 58.1 lbs. per square foot of grate per hour, compared with the original 80 lbs., or a saving of nearly 27.4 per cent.

TABLE III.—HEAT SUPPLIED WHEN USING MODERATE FEED-HEATING AND MODERATE SUPERHEATING.

Source of Heat.	Proportion of Total.	B. t. u. supplied—To Engine.	To Pump.	To Engine and Pump.
Pump exhaust-heater	24.93 / 1215.33	12,310		12,580
	24.93 / 1164.63		270	
Main exhaust-heaters	119.99 / 1215.33	59,240		60,540
	119.99 / 1164.63		1,300	
Boiler	1019.71 / 1215.33	503,480		514,560
	1019.71 / 1164.63		11,080	
Superheater	50.7 / 1215.33	25,030		25,030
Totals		600,060	12,650	612,710

EE_1 and FF_1 represent heat taken from the waste gases in superheating, and the loss in these gases is reduced from AA_3 (156,000 B. t. u.) to F_1F_2 (102,500 B. t. u.)—a saving of 34.3 per cent. The loss by unburnt fuel is restricted to F_2F_3 (173,000 B. t. u.) in lieu of A_2A_3 (332,000 B. t. u.)—a fall of 48 per cent.

Among others, two long series of trials of this class of installation have been conducted on the Egyptian state railways. The heaviest scheduled trains between Cairo and Alexandria, having average speeds, deducting for stops, of between 42.4 and 43.3 miles per hour, with loads usually above 330 and frequently over 400 tons tare behind the tender, were worked. The heater engine 706, five sister engines without heaters, and one engine of the same class (712, as then fitted) with a high degree superheater and piston valves, were all run in one link working with three De Glehn compounds. Coal was dealt with as before described, but the records were kept for over-all service working, and not as in the trials there alluded to, for running time only. The figures in Table IV, therefore, include lighting up, and some unavoidable light mileage, the latter, however, being negligible. In all these trials the checking of the coal was officially carried out by the stores department and by representatives of the general manager. The provision of the coal in sealed sacks effectually prevented the favoring of any engine with selected coal. On these railways the stores department is always responsible for the coal until it is actually on the tenders.

Engine 700 proved the most economical of the whole link, and showed 30.8 per cent. economy over the non-heater engines, and handled throughout the heaviest trains. It showed an economy of 20 per cent. on the De Glehn compounds. The difference between the 30 per cent. economy shown in these trials and the 27.4 per cent. deduced by means of Fig. 7 may be due to several causes. The average superheat may be nearer 90 deg. F. than the 85 deg. F. taken above, or the saving indicated by the Purdue tests may not quite coincide with the actual saving, or again the difference may be due to excessive moisture in the steam produced in the ordinary engine.

Another test is interesting, though made with a lighter class of engine, fitted with a type of installation since greatly improved upon. On light trains, with three stops only, the non-heater engines took 36.7 lbs. of coal per mile and the heater engines took 28.4 lbs. For similar trains, with thirteen stops and seven slacks, the consumptions were 42.9 lbs. and 33.5 lbs. respectively, the heater engine taking 5.1 lbs. extra per mile, but the non-heater 6.2 lbs. extra. For the heavy trains the difference is increased. For trains of 337 tons tare behind the tender, the non-heater engines took 38.4 lbs.; as against 47.1 lbs., a difference of 8.7 lbs., while the heater engines took 30.6 as against only 34.4, a difference of 3.8 lbs.

Economy in favor of Engine No. 706		30.8%	20.25%

High Degree Feed Heating and High Degree Superheating.—Owing to the lack of sufficient data it is not proposed to go at length into calculations regarding this combination. It is not known how far the curve *d*, Fig. 1, agrees with the performance of a combined high-degree superheater and boiler. Further, when high-degree feed heating is combined with superheating, the superheater is reduced, but to what extent is yet uncertain. Also, superheater engines are commonly fitted with piston valves, to which part of their performance should rightly be credited, instead of the improvement being wholly imputed to the superheating system.

If, however, superheating to 200 deg. F. with feed heating to 290 deg. F. be considered, using the curve *d*, Fig. 1, as the basis, the following results are shown: For this superheat 21.15 per cent. steam economy will be obtained. The original 542.57 lbs. of engine steam would therefore be reduced to 427.82 lbs. and the heat needed would be $427.82 \ (1{,}307\text{-}33.07) = 545{,}010$ B. t. u. The pump takes saturated steam representing $(427.82 \times 0.022 \times 1{,}164.63) = 10{,}960$ B. t. u., the total being 555,970. Subdividing this among the pump heater, the main exhaust heaters, the smokebox heater, and the superheater and boiler, it is found that 457,050 B. t. u. have to be provided by the superheater and boiler. The point on the curve *d* corresponding with this represents a rate of firing of 49.1 lbs. per square foot, as against 80, or a saving of 38.64 per cent. The loss in the waste gases has been reduced 57 per cent., and that by unburnt coal 75 per cent. These large savings seem to be substantiated in practice.

A smoke tube superheater, giving 200 deg. F. superheat, may not be considered to be representative of usual practice, but the figure is chosen because of the unavoidable fall of superheat already referred to. With the lessened boiler duty the intensity of draft is reduced, and as, for a wide range, superheat varies approximately as the draft, a drop on conversion is natural.

On the Egyptian state railways an engine, 712, giving about 200-220 deg. F. superheat before conversion, gave after the addition of the feed water heaters superheat of about 150 deg. F. Nevertheless the results proved very satisfactory.

Engine 712 was run against the heater engines 706 and 714, and, compared with them, with average tare loads behind the tender of 346.8 tons, showed a consumption of only 27.7 lbs. per mile or 0.0798 lb. per ton mile; this is an economy of 20.0 per cent. over the heater engines 706 and 714. In the 1911 trials engine 706 worked at exactly the same consumption as during this latter period, and the consumption of engine 712, fitted with the high degree feed and high superheat combination, may, in default of more direct means, be compared with that which the non-heater engines then showed. If running at an economical load, engine 712 would thus show an economy of 45 per cent. over sister non-heater engines.

Direct comparison being impossible on the heavy workings, engine 712 was transferred, for a short time, to a link of lighter trains handled by the non-heater engines. On these trains, however, engine 712 was underrated and was not working at its best. It averaged, for trains of 262 tons tare behind tender, 0.0952 lb. per ton mile, against the average for several non-heater engines of 0.1528 lb. on trains of 256.5 tons load, or an economy of 37.7 per cent.

ECONOMICAL FEATURES OF THE SYSTEMS.

The use, in all the heater systems here dealt with, of part of the cylinder exhaust for feed heating, is equivalent to an enlargement of the exhaust tip. The volume of steam driven through the orifice is diminished by over 12 per cent. Again, enclosing the blast in a comparatively small chamber, as in the later Egyptian state railways systems, increases the inducing action and results in comparatively high vacua with a larger nozzle than is used in the standard engine. In the latter a tip of 4½ in. is used above the netting, and produces in front of the tube space a vacuum of about 6 in. in normal working. With the high degree superheat system alone, as fitted to engine 712, it was necessary to reduce the tip from 4½ to 4⅜ in. to obtain a proper vacuum with the reduced quantity of steam then used. Since fitting the feed-heaters to this engine the blast pipe has been again enlarged to 4½ in., and as part of the exhaust is used for feed heating, it is now virtually one 4¾ in. in diameter for about 15 per cent. less steam than passes through the standard tip of the ordinary engine. The size to which this 4½ in. tip actually corresponds is thus about 5 in. in diameter. With these exhaust tips a vacuum of from 6 in. to 8 in. is obtained in the small blast chamber. This is reduced by the resistance offered by the heater tubes, and there is a vacuum in the smokebox proper of from 2 in. to 3 in. compared with 6 in. or more in the ordinary engine.

The lighter draft just considered results in less loss in unburnt fuel. The Egyptian state railways' engines show, progressively, less accumulation of cinders in the smokebox with increased economy. The reason why the heater engines show greater economy over the ordinary engines when on stopping trains than when on fast non-stop expresses, is connected with the blast and heater. The smokebox heater offers some resistance to the flow of the gases, and has the effect of damping the heavy pulsations of the blast when the engine is working at or near full gear. The fire is not lifted in the same way; the loss of coal is thus reduced.

RAILWAY ACCIDENT IN MACEDONIA.—On May 23 a collision occurred at a junction of the railway between Poroi and Andjista as the result of which two engines were completely ruined. The accident is said to have been due to an error either of the Bulgarian military station master at Poroi or the station master at Andjista, and it is reported that the one who was held to be responsible has been shot by order of Colonel Ivanoff, the inspector of Bulgarian Railways. Discipline in Macedonian railway service is rather abrupt.

SIX PASSENGERS KILLED AT STAMFORD.

In a rear collision of passenger trains on the New York, New Haven & Hartford at Stamford, Conn., at 5 p. m. on Thursday, June 12, six passengers were killed and eighteen injured; and the criticisms of the management of the road which filled the newspapers last October on the occasion of derailments at Westport and other places have been renewed with increased vigor.

The trains in collision were the first and second sections of westbound express No. 53. The first section had stopped to change engines, and while standing was run into by the second section at about 20 miles an hour or faster; and the rear car of the first section, a Pullman parlor car, well filled, was ripped open for more than half its length. All of the killed were in this car. The other cars of the train were not seriously damaged. The parlor car was of wood, and criticisms of the company for not introducing steel cars more rapidly were heard on every hand.

The collision was due to failure of the engineman of the second section, Charles J. Doherty, to control the speed of the train. He and his fireman were unhurt and testified before the coroner at Stamford on the 13th. Doherty said that the air brakes, when applied, failed to reduce the speed. The train consisted of a new Pacific type locomotive, No. 1338, and 8 cars. The engine weighs about 126 tons. Doherty was a spare runner and had run this train only 3 days; and until June 10 had run passenger trains altogether only about 4 days since he was promoted, which was in March, 1912. He is 33 years old, of good character, and an abstainer from liquor; has a perfect record as fireman 10 years, and spare runner about 1½ years, all on the New Haven road.

From the testimony of Doherty before the coroner and from statements of officers of the road to the newspapers we gather the following summary:

Doherty had found on a former trip (Tuesday) that the brake apparatus on the engine apparently was not in proper condition, "the brakes did not hold"; he had entered the fact on the proper book, but nobody had taken any action about it. He had mentioned this difficulty to other runners and got the reply that all of the new engines of that type had been subject to the same complaint. The road foreman had warned him that with the new engines, on account of their weight, it was necessary to apply brakes earlier than with the smaller engines. Doherty had overrun the platform at Bridgeport on Tuesday, and later on the same day, at South Norwalk, because of danger of running over a child, he had strained his back in reversing the engine, so that on Wednesday he worked only a half day. He came on duty Thursday with plasters on his back because of the strain. The fact that he had been off, sick, for half a day was not noticed by any superior or inspector. In the Stamford emergency, after it was plain that the brakes would not stop the train soon enough, he tried to reverse, but found his strength insufficient. Some difficulty with the reversing gear appears to have existed from the time the engine was put in service.

The distant signal at Stamford is about 2,100 ft. back of the home (the home was close to the standing train) and was properly observed. At this point in the hearing Doherty's testimony is not clear; the most that can be made out is that the line of the road is straight and the grade slightly descending; that he shut off steam before reaching the distant signal and that on finding the home signal against him he could not make the brakes hold; in short that the speed was not reduced soon enough. When within a few hundred feet of the standing train Doherty sanded the rails, and motioned frantically to a couple of trainmen standing on the ground near the rear car of the train ahead, to move that train forward. Doherty's train broke apart, behind the third car, a few hundred feet before striking the standing train, and the rear portion stopped 200 ft. or 300 ft. back of the leading portion.

Doherty said that another engineman, John Harmon, running the same train, had been suspended three days before for running past a stop signal at South Norwalk.

Doherty was held by the coroner on a charge of manslaughter in $5,000 bail on Friday, bail being furnished by his wife's brother, J. H. Dillon, of New Haven.

C. N. Woodward, general superintendent of the road, testifying before the coroner on Saturday, said that within the last six months 30 enginemen had been discharged for running past signals; this notwithstanding that there had been a campaign of education, in which the majority of enginemen took a lively interest, and in which the officers of the road had spent a great deal of time in talking with and educating the men. He could not explain the hard luck that apparently had visited the road.

C. F. Carroll, road foreman of engines, told the coroner that he had known Doherty for seven years; that he was a first-class engineer and a fine young man. Carroll himself instructed Doherty in running No. 1338. "I told him not to let her get away from him, as she was a new engine and pulled strong. He told me of being two minutes late one run, and I told him not to mind that, but to consider safety first of all. He also told me of his running by the signal at Bridgeport last Tuesday, and I told him why he did it."

"You mean he told you why, don't you?" the coroner asked.

"No, I told him why," replied Carroll. "I told him the reason was he came into the station like the devil and let her get away from him."

"Didn't he tell you the reason was that the air brakes weren't working right?" the coroner said. Carroll replied that Doherty did not say anything to him about the air.

Three enginemen who had had experience with No. 1338, including Harmon, who had been suspended on Monday, testified before the coroner. Harmon said that while he found the levers and especially the reverse lever hard to work, as might be expected, he did not attribute his running past the signal to that fact. He claimed that his air was all right, and that the trouble was that the distant signal was clear while the home was against him. All three of these enginemen testified that they had found no fault with the air.

On Saturday the New Haven road invited a number of men from other roads to come to New Haven to inspect the air brake equipment on engine 1338 and the cars of its train. These men are: P. J. Langan, chief air brake inspector of the Delaware, Lackawanna & Western; C. W. Martin, of the Pennsylvania Railroad; T. L. Burton, of the Westinghouse Company, and Charles E. Joy, chief inspector of the New Haven.

Mr. Dillon, Doherty's brother-in-law, who was the close companion of the engineer at the coroner's hearing said:

"Doherty came to me as soon as he could after the wreck. He was at my home when it was said he had disappeared. He wanted my advice. I took him in charge and shall remain in charge of him.

"I think that an engineer's story, free from the heart, has been told today for the first time. There was no advice that he misremember things or forget things. There was no previous rehearsing of his story. I saw that he came in contact with nobody until he faced the coroner, and that all suggestions that he 'come to the office,' of which five or more were made, were turned down."

The wrecked Pullman car, being worthless, was destroyed by fire at 11 p. m. on the 12th. The coroner complained of this and the officers of the road replied that there was nothing about the car which would be of any value as evidence concerning the cause of the deaths of passengers.

General Manager Bardo said that prior to March 1 last spare enginemen had been assigned to all trains, except limited trains, without special reference to their experience; but that since that date there is a rule that those men who have had less than one year's experience as runner shall not be assigned to through passenger trains.

On the 16th the coroner took testimony concerning the condition of the engine on the day when Doherty reported that the air brakes were not in good condition. It appears that the page in the book on which entries are made contains a printed list of questions relating to different parts of the engine. Doherty made notes against piston rods, water glass, and some other things, but against air brakes there was no entry; and the statement that the brakes were "no good" was made at the bottom of the page, under the head of "other work needed." Main reservoir pressure was given as 150, and the train line pressure as 110.

Doherty gives a somewhat different version of the conversation between himself and the road foreman which was referred to by the foreman at a previous hearing. According to Doherty the foreman recognized that the brakes on the new engines did not diminish speed satisfactorily.

Joseph J. Gash, the roundhouse man who attended to Doherty's report of engine 1338 on Tuesday, told the coroner that he had looked the brakes over and that they appeared to be all right; and he took no further action. He found that the piston and the air pump were all right and concluded that Doherty must have been mistaken in his statement that the brakes did not work satisfactorily.

The counsel for the road presented transcripts of a number of roundhouse records made at Springfield and New Haven which showed trips where engine 1338 had come in from passenger train runs and no complaint was made concerning the air brakes or other parts of the engine.

Engine No. 1338 weighs 251,500 lbs.; weight on drivers, 154,000 lbs.; weight of engine and tender, 384,100 lbs. The cylinders are 24 in. x 28 in.; diameter of driving wheels, 73 in.; boiler pressure, 200 lbs.; tractive effort, 37,558 lbs. The engine was built by the American Locomotive Company.

On Tuesday, June 17, eight experimental runs were made between Noroton and Stamford with the same train that caused the wreck—8 cars, 1 baggage car, a mail car, three day cars and three parlor cars, and the locomotive, the locomotive having been sufficiently repaired to be run. The air brake apparatus had not been injured and had not been changed since the day of the collision.

The grade of the road is slightly descending.

In the first trial the train was stopped from a speed of 64.5 miles an hour in 2,077 ft. In the second trial a reduction of 30 lbs. was made at once and the train was stopped from a speed of 55 miles an hour, in 1,994 ft. From a speed of 57.5 miles an hour with the emergency application of the brakes the train was stopped in 1,617 ft. The next run was made at 59.5 miles an hour, with a reduction of 15 lbs., followed by another of 15 lbs. The stop was made in 2,586 ft. In the next run the engineman, by order of the manager of the tests, attempted to duplicate the operations made by Doherty on the day of the collision, as narrated by him before the coroner. The speed at the time of the application of the brakes was 57 miles per hour. A 10 lb. reduction was made, then a 5 lb. reduction, and then full emergency application. The distance run was 2,567 ft., time 49.6 seconds, and the train ran about 350 ft. beyond the point where the collision occurred. We give these reports for what they are worth, but their value is questionable because of indefiniteness as to the exact location of the point where the brakes were applied, and also as to where they should be applied; that is to say, the accuracy of Doherty's narrative in that portion in which he tells where he applied the brake. Other tests are in progress as we go to press.

FLOOD DAMAGE IN NATAL.—It is estimated that the total cost of repairing the damage done to the railways in the province of Natal by the recent floods, and of effecting certain improvements with a view to reducing the possibility of similar damage occurring in future, would be $276,250, all of which will probably be charged to capital account.

THE ELECTRIFICATION OF TRUNK LINE RAILROADS.

An Estimate of the Cost, of the Saving in Operating Expenses and in Upkeep That Would Show a Profit of 6.8 Per Cent.

By Charles P. Kahler,

Electrical Engineer, Oregon Short Line.

The great objection to operating many of the large steam railroads by electric power is the extremely heavy investment necessary for the electric apparatus and equipment. The ability of the steam locomotive to handle railroad traffic in a very reliable and expeditious manner is very well known.

Very little of the past work of steam railroad electrification was done on account of the financial return expected on the money so expended. The smoke trouble with steam locomotives has been one of the most important reasons for the past progress in heavy electric railroad work. Irrespective of what caused the past heavy electric railroad work, the actual operation of large electric locomotives showed that they could in some ways handle railroad traffic more advantageously than steam locomotives. The published records of the steam and electric locomotives of the New York Central, the New York, New Haven & Hartford, and the Pennsylvania, indicate that electric locomotives are probably even more reliable in operation than steam locomotives. The published records of these roads also indicate that the quantity of fuel required to generate power in a steam-electric plant for railroad operation is much less than the fuel required by steam locomotives in the same service, and the locomotive repair expense was found to be much less on electric than on steam locomotives.

Further, as the electric locomotives do not have to take fuel and water, nor have a boiler or firebox to be cleaned out, they are nearly always ready for service, and take less time to handle trains than steam locomotives, especially on long runs. The perfection of the multiple unit control has made the number of driving units which can be controlled by one man practically unlimited, and, consequently, it is possible to make the size of electric locomotives much greater than steam locomotives with the boiler limitations.

Another important point in connection with electric operation has been brought out by the great success of the interurban electric railways. The gasolene motor car and the gas-electric motor car would probably not have been developed were it not for the trolley lines taking local passenger business away from the steam railroads.

If roads were electrically operated, the weight of the freight trains could in most cases be made much heavier than possible by steam operation, on account of the characteristic of the electric locomotive to operate overload without dangerous overheating, long enough to get over the short heavy grade sections, and on this account the ruling grade of an electrically operated railroad will seldom be as great as the ruling grade of a steam operated railroad.

Only one engine crew would be required on helper districts where more than one electric helper locomotive is used, as two or more electric locomotives can be coupled together and operated as a single unit by one man, while with steam locomotives as many engine crews will be needed as there are steam locomotives used.

The locomotive is directly responsible for from 30 to 40 per cent of the operating expenses of a steam railroad. At a speed of 16.5 miles per hour, which is only a little greater than the usual average speed of freight trains, the tractive power of a consolidated steam freight locomotive and an electric locomotive for freight service is the same. Above this speed the steam locomotive can exert a higher tractive effort than the electric locomotive, while below this speed the electric locomotive has the higher tractive effort.

The steam locomotive can exert the tractive effort of 15,000 lbs. at the higher speeds only for short intervals, on account of the inability of the boiler to continuously supply the necessary steam. On the other hand, the electric locomotive cannot continuously exert the high tractive effort at low speeds without overheating. The maximum tractive effort which can be continuously exerted by the electric locomotive with safety is 34,600 lbs. at a speed of 16 miles per hour. Below this speed the high tractive efforts can only be secured for certain periods of time. Thus, for one hour, 45,000 lbs. tractive effort can be exerted without overheating the motors, with the speed at about 14 miles per hour.

At starting, as much as 55,000 lbs. can be exerted by the electric locomotive, while the steam locomotive can, under favorable conditions, only exert a tractive effort of about 43,000 lbs. at starting. One of the causes of the higher power of the electric freight locomotive at starting is that all its weight, 220,000 lbs., is on the drive wheels, while although the steam locomotive with loaded tender weighs 185 tons, it has only 187,000 lbs. on the drive wheels. Also the coefficient of adhesion is greater for an electric locomotive than for a steam locomotive.

DESCRIPTION OF RAILROAD CONSIDERED.

Let us consider a single-track railroad constructed through a semi-arid region, similar to many parts of the West, which contains numerous irrigated and dry farm districts. The length will be taken as 467 miles, divided into three engine districts, respectively 167, 160 and 140 miles long, from the west towards the east, and will be referred to as engine district No. 1, No. 2 and No. 3, in the order named. The curvature averages about 12 deg. of central angle per mile and the ascents and descents of grade average 18 ft. per mile. The engine terminals will be referred to as No. 1, No. 2, No. 3 and No. 4, from west to east. It will be assumed that there is a helper district 9 miles in length for westbound trains on engine district No. 1 and also one of the same length on engine district No. 2 for eastbound trains, the foot of these helper grades to be located 11 miles west of and 7 miles east of terminal No. 2, and the helper locomotives of both districts to be hostled and taken care of at terminal No. 2. The limiting grades of the three engine districts are shown in Table II.

Table 1.

	Engine districts.			
	No. 1.	No. 2.	No. 3.	Total.
Miles of main track	167.5	160	140.5	468
Miles of side track	54.5	51	50.5	156
Total main and side track	222	211	191	624
Miles curved track	35	33	32	100
Degrees of central angle per mile	12	12	12	12
Maximum curvature, deg.	6	4	4	6
Ascents and descents of grade per mile, ft.	14	22	18	18
Average grade, per cent	0.14	0.21	0.17	0.17
Weight of rail per yard, lbs.	90	90	90	90

For steam equipment the through passenger trains are to be handled by Pacific type locomotives of 192 tons weight with loaded tender to handle from 5 to 14 coaches per train. The local passenger trains consist of a 110-ton locomotive with loaded tender baggage car, smoking car and day coach, all cars being of 45 tons weight. The freight trains are to be handled by consolidated locomotives of total weight with coal and water of 185 tons, and with 187,000 lbs. on the drive wheels. The local freight trains are to be handled by 130-ton locomotives.

For comparison of steam and electric operation, the above line will be considered as equipped with an 11,000-volt, single-phase, 15-cycle trolley, with 110,000-volt, 15-cycle high-tension

*Abstract of a paper presented before the American Institute of Electrical Engineers, New York, on May 20, 1913.

line to supply power to 14 substations, the power to be received into the high tension system at terminal No. 3. The local passenger trains are to consist of two electric motor cars and one trailer, the through passenger trains to be hauled by 100-ton electric locomotives. The local freight trains are to be hauled by 85-ton locomotives, which class of locomotives will also be used in switching service. The through freight trains, both expedite and drag, are to be hauled by 110-ton locomotives.

The passenger traffic consists of six through trains per day, three each way over the entire road. On engine district No. 1 there will be four local passenger trains per day, two each way, while on engine districts Nos. 2 and 3 there will only be two local passenger trains per day.

The annual freight traffic over each engine district will be assumed as follows:

Engine districts.	Tonnage of cars and contents. No. 1.	No. 2.	No. 3.
Westbound:			
Expedite freight	800,000	700,000	800,000
Drag freight	1,700,000	1,700,000	1,600,000
Local freight	200,000	.....	160,000
Eastbound:			
Expedite freight	600,000	600,000	600,000
Drag freight	1,300,000	1,300,000	1,200,000
Local freight	100,000	.....	100,000

To determine the number of freight trains necessary to handle the above traffic, the maximum tonnage which the locomotives can haul over each engine district will have to be determined. For steam operation, this can be closely computed if the ruling and starting grades are known. Also a close approximation of the maximum tonnage by electric operation can be made if the average grades and their length are known, together with the maximum grades at starting.

However, the most accurate way of determining the maximum tonnage which can be hauled by a locomotive is to draw the velocity diagram for the limiting grade sections of the engine districts. This will also give an idea of the variety of conditions for which a locomotive of a trunk line railroad is used.

The limiting points are determined by the starting grades, the helper grades and the ruling grades. In computing the hauling capacity for steam locomotives, it is usual to make 10 miles per hour the minimum speed in order to allow for weather conditions, the personal equation of the engineer, and other variable conditions. Westbound steam freight trains of 2,040 tons get down to 10 miles per hour at about mile post 152, on the helper section, and hence the helper section limits the weights of steam freight trains. The starting capacity of the steam locomotive is also nearly reached with the same tonnage. For westbound electric trains, the starting grades limit the weight to 3,350 tons. The weight of eastbound steam freight trains is limited to 2,240 tons by the ruling grade, 0.55 per cent. The starting grades also will not permit a heavier steam train. The weight of the eastbound electric freight trains (2,470 tons) is limited by the long 21-mile grade from mile post 82 to mile post 111, which averages 0.45 per cent., the maximum grade in this distance being 0.6 per cent. It is on these long grades, where the electric locomotive operates on its continuous rating, that the steam locomotive compares most favorably with the electric locomotive. But even here the steam locomotive's hauling capacity is determined by the ruling grade, 0.55 per cent., which is very short, while the hauling capacity of the electric locomotive is determined by the average grade, 0.45 per cent.

The electric locomotive can haul from 50 per cent. to 60 per cent. greater tonnage than the steam locomotive over these engine districts.

Table 3 shows the number of freight trains per year necessary to handle the freight traffic given above.

TABLE 3—NUMBER OF FREIGHT TRAINS PER YEAR.

	Steam locomotive. West.	East.	*Total.	Electric locomotive. West.	East.	*Total.
Engine Dist. No. 1:						
Expedite trains	656	442	1,312	309	318	636
Drag trains	1,149	793	2,298	656	688	1,376
Local trains	400	400	800	400	400	800
Totals	.....	.....	4,410	.....	.....	2,812
Engine Dist. No. 2:						
Expedite trains	809	741	1,618	404	335	808
Drag trains	1,417	1,300	2,834	859	727	1,718
Totals	.....	.....	4,452	.....	.....	2,526
Engine Dist. No. 3:						
Expedite trains	428	741	1,482	225	372	744
Drag trains	711	1,200	2,400	450	747	1,494
Local trains	320	320	640	320	320	640
Totals	.....	.....	4,522	.....	.....	2,878

*As it is necessary to operate the same number of trains in both directions on account of train crews and equipment, the totals, of course, are twice the greatest number of trains required in one direction.

*Without weight of helper locomotives.

On all railroads the traffic at some seasons of the year is greater than at others. However, it is seldom that the passenger and freight busy seasons happen at the same time. The writer has been often surprised at how uniform the train mileage and ton mileage per mile of line is during the year. For the railroad considered, the maximum and average number of trains per day is taken as follows:

Table 4—Number of Trains per Day—(Both Ways).

	Eng. dist. No. 1.		Eng. dist. No. 2.		Eng. dist. No. 3.	
	Average day.	Maximum day.	Average day.	Maximum day.	Average day.	Maximum day.
Steam trains:						
Passenger	10.0	10.0	8.0	8.0	8.0	8.0
Freight	12.1	16.0	12.2	17.0	12.4	18.0
Total	22.1	26.0	20.2	25.0	20.4	26.0
Electric trains:						
Passenger	10.0	10.0	8.0	8.0	8.0	8.0
Freight	7.7	11.0	6.9	10.0	7.9	12.0
Total	17.7	21.0	14.9	18.0	15.9	20.0

Table 5 shows the train mileage, ton mileage, and locomotive mileage necessary to handle the assumed traffic over the railroad considered. The locomotive mileage includes the mileage to and from trains and the switching locomotive mileage.

Table 5.

	Steam operation.	Electric operation.
Train miles:		
Local passenger trains	462,820	000
Local motor trains	000	462,820
Through passenger trains	1,022,730	1,022,730
Total passenger	1,485,550	1,485,550
Local freight trains	233,200	233,200
Through trains	1,858,670	953,344
Work trains	81,120	81,120

Passenger locomotives	1,559,828	1,073,867
Local freight locomotives	240,196	240,196
Through locomotives	1,914,430	981,944
Work train	107,624	107,624
Helper locomotives	225,474	102,111
Switching	397,000*	*397,000
Total freight, work, helper and switch	2,884,724	1,828,875
Total locomotive mileage	4,444,552	2,902,742
Locomotive ton mileage:		
Motor cars	000	83,307,600
Passenger locomotives	259,638,174	107,386,700
Freight locomotives	385,395,130	129,631,480
Work train locomotives	15,067,360	9,686,160
Helper locomotives	41,712,690	8,386,510
Switching locomotives	55,880,000	35,730,000
Total freight, work, helper and switch	498,055,180	183,434,150
Total all locomotives and motor cars	757,693,354	374,128,450
Ton mileage—cars and contents		
Passenger trains	744,424,800	675,001,800
Freight trains	2,113,300,000	1,940,045,780
Work trains	40,560,000	40,560,000
Switching	158,800,000	158,800,000
Total cars and contents	3,057,084,800	2,814,407,580
Grand total ton miles	3,814,778,154	3,188,536,030

*Six miles allowed for each hour a switch engine [illegible] over.

Number of Locomotives Required

An examination of the records of numerous steam railroads will disclose the fact that a steam locomotive spends a good portion of its time in the shops undergoing heavy repairs, also that a larger part of its time is spent in or near the engine houses where the boiler washing is done, the fire boxes and flues cleaned, and the light running repairs are made, etc. The records of two western steam roads show that their passenger locomotives spent respectively 21 per cent. and 17 per cent of their time in the shops, and that the freight locomotives of the same roads were in the shop 30 per cent. and 24 per cent of their time.

The most complete record of the actual distribution of engine service I have seen is given in Table 6, which is for a section of [illegible] between 500 and 600 miles in length.

Table 6.

	Passenger locomotives.		Freight locomotives.	
	Per cent. of total time.	Days per year.	Per cent. of total time.	Days per year.
Time in shops	22.4	82	28.2	103
Time spare	1.4	5	2.7	10
Time in enginehouse (having running repairs done, boilers washed, fire boxes cleaned)	53.2	194	35.9	131
Time running to and from trains	1.6	6	1.1	4
Time in helper service	1.1	4	4.3	16
Time on road	20.3	74	....	....
Actually running	....	..	17.1	62
Standing on sidings, taking water, etc.	....	..	10.7	39
Totals	100	365	100	365

It will be noted that each passenger locomotive was actually on the road, running or standing on sidings, only 74 days of the year, while each freight locomotive, exclusive of those used for helper service, was actually running only 62 days of the year and standing on sidings, etc., 39 days, not considering the helper locomotives.

The number of locomotives required to handle the traffic of any railroad depends of course upon the quantity of traffic, number of trains, the arrangement of the train schedule, ratio of maximum and average traffic, etc. An estimate of the number of steam locomotives required to handle the trains over the road can be made from the train sheets, and to this number will have to be added an allowance to cover time in engine house, shops, etc., as shown above in Table 6. However, the total number of steam locomotives shown in Tables 7, 8, 9 and 10, as required for operating the railroad discussed in this paper, is the same as that actually used on a western railroad where the quantity of traffic and other conditions are similar. The number of electric locomotives given was estimated from the steam figures.

Table 7—Passenger Service.

	Steam locomotives.			Electric locomotives.		
	Per cent. of time.	Days of year.	No. of locomotives.	Per cent. of time.	Days of year.	No. of locomotives.
In shops	22.1	81	6.2	19.2	70	2.5

	Per cent. of time.	Days of year.	No. of locomotives.	Per cent. of time.	Days of year.	No. of locomotives.
In shops	37.5	137	6	27.3	99	3
In service	62.5	228	10	72.7	266	8
Totals	100.0	365	16	100.0	365	11

Table 10—Summary.

	Steam equipment.	Electric equipment.
Passenger service:		
Motor cars	0	14
Passenger locomotives	28	10
Freight locomotives	96	43
Switching locomotives	16	11
Total motor cars	0	14
Total locomotives	140	64

The time in the engine house where the inspection, cleaning and light repair work is done, will manifestly be much less with electric than with steam locomotives. A steam locomotive receives a thorough inspection after each run, whereas the practice with electric locomotives is to inspect them after they have made a certain mileage, which varies from 1,200 to 2,500 miles, the

former figure being the New York Central standard, while the latter is the practice of the Pennsylvania at New York.

The boiler washing, firebox cleaning and other things required on a steam locomotive, and which consume a large part of the time in the engine house, would not be necessary with electric locomotives and, consequently, the time spent by electric locomotives in or near the engine house would be much less than with steam locomotives. Likewise, electric locomotives would spend less time in the shops than steam locomotives, as there would be no boiler, firebox smoke stack or tender to repair.

As a check on the above figures for number of locomotives required some data will now be given of electrified steam lines in operation. Table 11 below was computed and condensed from data given in a paper by W. J. Wilgus, concerning the electric operation of the N. Y. C. & H. R., and which shows the distribution of steam and electric locomotive time out of the shop.

TABLE 11.

	Hours.		Per cent.	
	Steam locomotives.	Electric locomotives.	Steam locomotives.	Electric locomotives.
Busy	138.00	203.92	20.7	30.3
Waiting	174.10	229.19	26.2	34.2
Total	312.10	433.11	46.9	64.5
Dead	354.90	238.89	53.1	35.5
Grand total	667.00	672.00	100.0	100.0

This data, which is for all classes of locomotives, would indicate that for conditions on the New York Central the steam locomotives were having fireboxes cleaned, boilers washed, light repairs made, and other things which are done in the engine house, a little over half the time out of the shops, while the time spent by the electric locomotives in the engine house being inspected, having light repairs made, etc., was only about one-third of the time out of the shops.

ESTIMATED COST OF ELECTRIFICATION.

The following is an estimate of the money needed to electrify the 467 miles of steam railroad considered:

High tension lines (steel tower), 450 miles		$2,250,000
Trolley and feeder wire:		
3/0 grooved copper trolley, 468 mi. at $650	$304,200	
Steel trolley wire, 156 mi. at $320	49,920	
2/0 feeder wire, 468 mi. at $500	234,000	
		588,120
Overhead construction:		
Bracket arm construction, 420 mi. at $1,650	$693,000	
Span construction, 92 mi. at $2,600	239,200	
Steel bridges, 4 mi.	36,000	
Section breaks	6,600	
Additional for curved track, 100 mi. at $300	30,000	
		1,004,800
Track bonding:		
624 mi. at $450		280,800
Substations:		
14 substations, 56,000 kv-a	$616,000	
3 portable stations, 6,000 kv-a. (complete)	96,000	
		712,000
Rolling stock:		
14 motor cars, $18,000	$252,000	
10 passenger locomotives, $45,000	450,000	
43 freight locomotives, $50,000	2,150,000	
11 switching locomotives, $35,000	385,000	
		3,237,000
Changing block signals and telegraph (468 mi.)		561,600
Engineering and supervision, 5 per cent.		431,716
Contingencies, etc., 10 per cent		905,964
Total		$9,972,000
Credit for steam equipment:		
140 locomotives	$2,520,000	
241 coal cars	241,000	
14 passenger cars	112,000	
Give credit for, say, about 70 per cent. of new value.	$2,873,000	2,012,000
Net estimate		$7,960,000

The figures given apply to the intermountain regions of the West. As the actual construction cost was available of a high tension steel tower line parallel to a railroad, the material being distributed by work trains of the railroad, the estimate for this item given should be very close. The trolley line and substation estimates were based upon interurban construction cost of two lines in the west, a liberal allowance being made for the heavier work needed for trunk lines. No item is shown for electric shop machinery as credit for steam locomotive shop machinery will offset this expense.

COMPARATIVE COST OF MAINTENANCE AND OPERATION BY STEAM AND ELECTRIC POWER.

Having determined the amount of traffic of the railroad, and the number of trains necessary to handle the same by steam and electric locomotives, the comparative cost of operation by steam and electric power will now be given.

TABLE 12—MAINTENANCE OF WAY AND STRUCTURES.

	Steam. Per et.	Electric. Per et.	Steam.	Electric.
1. Ties	100	92.5	$163,800	$151,515

	Steam operation.	Electric operation.
A. Maintenance of way and structures	$671,540	$572,096
B. Maintenance of overhead structures and substations	000	95,710
C. Depreciation of overhead structures and substations	000	144,084
D. Maintenance of equipment	1,025,879	619,041
E. Depreciation of equipment	86,190	64,740
F. Transportation expense	2,064,800	1,381,187
G. Taxes		31,551
Totals	$3,848,409	$2,908,409

Steam operation expenses	$3,848,409
Electric operation expenses	2,908,409
Annual saving effected by substitution of electric power	$940,000

The published figures of the N. Y. C. & H. R. show that the steam locomotives cost $1,842 for repair during 335 days, while the electric locomotives cost $704 during 350 days, for the same service. The electric locomotive repair cost on the N. Y. C. & H. R. is thus only 36.5 per cent. of the steam locomotive repair costs.

The figures published by Mr. Gibbs of the Pennsylvania give the electric locomotive repair cost as 5.91 cents per locomotive mile, the New Jersey division steam locomotive repair cost as 8.83 cents per locomotive mile, and the average of steam locomotives for all divisions of the Pennsylvania as 11.9 cents per locomotive mile. The electric locomotive repair expense is thus only 67 per cent. of the steam expense on the New Jersey division and only 50 per cent. of the steam repair expense on all divisions. The annual mileage of the electric locomotives was 26,000, 28 per cent. of which was switching. The heavy grades on the electrified section of the Pennsylvania of course make the repair cost of electric locomotives considerably higher than if they were operated over a section with the grades as low as the average of the whole road, and consequently the relative cost of steam and electric locomotive repairs will be even less than shown. The electric locomotives of the P. R. R. are also much more powerful than the steam locomotives.

All things considered, it is probable that the electric locomotive repair cost will be even lower than 45 per cent. of the steam locomotive repair cost, which was estimated above for the road considered and used in making the comparative estimate of steam and electric operating expenses. For the road considered, the repair expense for steam passenger locomotives was taken at 10 cents per locomotive mile, and steam freight, helper and switching locomotives 14 cents per locomotive mile, which figures were based on the present locomotive repair costs on a western railroad where similar conditions exist. The electric locomotive repair expense will thus be 4.5 cents per locomotive mile for passenger locomotives and 6 cents per locomotive mile for freight service.

An electric locomotive will have a longer life than a steam locomotive, and thus the rate of depreciation will be less. The statement below shows the depreciation percentages used in the above tables. The steam locomotive figures were obtained from the auditing department of a western line. The electric figures were estimated, and although the modern electric locomotive has been in use only half the time allowed below for its life, I think past experience justifies the expectation of life allowed.

	Steam locomotive. Per cent.	Electric locomotive. Per cent.
First cost of locomotive	100	100
Salvage value when worn out	20	30
Total cost	80	70
Estimated life	26⅔ yr.	35 yr.
Annual depreciation	3%	2%

The wages of the motormen on the electric locomotives were assumed to be the same as those of the enginemen on the steam locomotive, but the motormen on the electric motor cars were taken as equal to about what would be paid for trolley car service. Although no fireman is needed on electric locomotives, two men were assumed necessary for all electric road and helper locomotives; but on switching locomotives, which have a conductor, and sometimes two or three switchmen, only a motorman was allowed. When two electric locomotives are used on a helper district to assist the road locomotive, only one crew was allowed, as the electric helper locomotives, being equipped with multiple-unit control, can be operated by one crew.

All coal used on a steam locomotive is not utilized in hauling trains, but a good deal is wasted by radiation while the locomotive is standing on sidings, imperfect combustion in the firebox, starting fire, etc., and the loss of energy is very much greater than would be the case in a steam electric plant generating power for electric operation of a railroad. The figures published by W. S. Murray in the March, 1908, Proceedings of the American Institute of Electrical Engineers, indicate that it requires about double the coal for operation of the steam locomotives of the N. Y. N. H. & H. that it does to generate power in a steam electric power plant for operation of its electric locomotives in the same service.

The quantity of electric power needed was computed from the grades, train weights, speed and other necessary data, the average power for a train of two motor cars and trailer, making stops every six or eight miles, being taken at 40 watt hours per ton mile, the passenger locomotive trains being allowed 31 watt hours per ton mile. The freight trains were allowed 25 watt hours per ton mile and the switching locomotives 45 watt hours per ton mile. As stated above, the power is to be purchased and delivered into the railroad's high tension transmission line at terminal No. 3. The rate to be paid for electric power in any locality depends upon the local conditions, the load factor, etc.

In many sections of the West, the development of numerous extremely low construction cost hydroelectric plants has made it possible to obtain power to some points at considerably lower cost than 0.75 cents per kw-hr., which was used in the above estimate. For instance, the Great Falls Power Company has made a rate of 0.536 cents per kw-hr. to the Chicago, Milwaukee & Puget Sound, and agrees to construct some of the high tension lines.

It is estimated that it only costs one-third as much to handle an electric locomotive through the engine house as it takes to handle a steam locomotive. At $2.50 per locomotive for steam operation would mean about 80 cents per locomotive for electric operation. The New York Central figures published by Mr. Willgus gives $3.37 per day for steam locomotives and 55 cents for electric locomotives, or the electric cost of engine house expenses only 16.3 per cent. of the steam.

Return on Investment.

The estimated cost of the electrification of the 467-mile railroad considered above was $7,960,000. The return on this investment on account of the saving in operating expense was estimated at about $940,000 per year. The interest earned on the money used for the electrification of this road would thus be 11.8 per cent. If it is necessary to borrow the money for this purpose, and if it can be obtained at 5 per cent. interest, there would remain a profit to the railroad of 6.8 per cent. of the net cost of electrification.

Maintenance of Way Section.

THE statistics of the Interstate Commerce Commission for the year ending June 30, 1912, show that 565 track and bridge men were killed and 645 injured by being struck by trains, in addition to 95 who were killed and 1,115 who were injured in other accidents. The number of track and bridge men employed for one killed was 579, and for one injured, 21.7. This record is emphasized by an accident on one of the eastern roads recently, where in a gang of foreigners recently arrived, ten were killed and a number injured by being run down by a passenger train, while running away from a blast and dodging another train. These figures show the necessity for placing special emphasis on the instruction of foremen regarding their responsibility in protecting their men from accidents. By far the larger proportion of accidents is avoidable if proper care be exercised. And the need for this care has risen greatly within the past few years owing to the largely increased number of foreigners employed in this department. The matter referred to is one that cannot be left solely to the foremen, but should be constantly brought to their attention by the higher officers.

THE extent to which the application of heavier rail and more ballast will actually reduce the cost of maintenance of branch lines with only a moderate traffic is often overestimated. The results secured are quite different from those on main lines carrying a heavy traffic, where heavy construction is essential, if maintenance charges are to be kept from becoming excessive. Very frequently in requesting an appropriation for the improvement of a branch line the local officers will make the statement that the cost of maintenance will be materially reduced. An actual comparison of the expenditures before and after improvement of the track will generally fail to show any marked reduction. Undoubtedly, less work is required to maintain a branch line track with 85 lb. rail and good ballast, than, for instance, one with 65 lb. rail with little or no ballast, but the difference usually is not sufficient to justify taking a man off a section. Rather, the result is that a better track is maintained for the same expenditure, and the track forces are given opportunity to keep up fences, buildings and other work which may have been neglected previously. Another important result not always considered is in the increased facility with which the trains are enabled to get over the road or in the increased tonnage which they are enabled to haul in the same time. While individually slight, many irregularities in line and service, as well as in greater elasticity and increased wave motion with light track construction, are cumulative in effect. Thus, rather than a decreased cost of maintenance, the result usually secured is a better track for the same money, and a better train movement or loading.

THE defects in the railway scale and weighing conditions have been brought out prominently in the recent hearing before the Interstate Commerce Commission, and a number of conditions not entirely creditable to the railways have been exposed. As a result, this subject has been given more attention by the railways themselves than ever before, and a large number of new scales has been installed, while many others will be in the near future. For this reason the action of the American Railway Association in adopting the specifications published in another column as good scale practice is timely and valuable. Up to this time there has been almost no authentic information available regarding the design of scales, and the railway official studying the question has been severely handicapped. Scales have been generally purchased upon the ratings and designs of the manufacturers, and there has been no opportunity to compare one design with another on any equitable basis, or to ascertain if any individual design met the actual service requirements. This situation has resulted from conditions for which the railways and manufacturers are jointly responsible. Because of the inability to intelligently compare different designs of scales they have been purchased very largely upon the basis of first cost. As a result, in an effort to reduce the cost of manufacture the weight of the various parts has been reduced to a minimum and the scale rating has come to mean very little. This cheapening of the design by some manufacturers has forced others to do likewise if they were to secure any business. With a general specification which the railways can use when installing new scales, and in accordance with which all the manufacturers can design on an equal basis, the present situation should be materially improved.

THE layout of a ballast pit or quarry has an important influence on its economic operation; and it is usually difficult to correct errors in the original plans after the pit has once been operated. As the cost of the ballast on board cars forms a large part of its total cost in track, the effect of this cost on maintenance expenditures is substantial. For these reasons the description of the El Paso & South Western quarry at Tecolote, N. Mex., and the figures of the cost of operation, published in this issue, are valuable. Very often ballast is purchased from outside parties on the assumption that the road cannot prepare it as cheaply as it can buy it. This may be true when washed gravel is used, and when the profits are largely secured from the by-products of sand and roofing gravel. It may also be true when, under favorable local conditions, stone is used. There are, however, many places where a road can afford to build its own quarry to good advantage. It is interesting to note that following a visit to this Tecolote quarry by representatives of another western road, the latter has authorized the installation of a crushing plant of its own and, incidentally, has brought down the contract price of its crushed stone several cents at other points. In view of the large quantities of ballast of various kinds required on the average large system a comprehensive study of the best materials to use on various lines should prove advantageous. This study should include the demands of the traffic, standards of maintenance, the kinds of material available, the sources of supply, etc. One road is now seriously considering the assignment of one man to devote his entire time to studies of this nature and to supervise the preparing and distribution of ballast at the various pits and quarries on the system.

IN common with other branches of railway service, maintenance work very generally suffers from a lack of sufficient supervision. This results largely from two causes. In the first place, the average supervisor is given charge of more forces than he can intelligently handle. Again, many men place too much dependence on correspondence and inspections made from the rear end of trains accompanied by the promiscuous use of "butterflies," and spend too little time with the various gangs on the work. While the first condition is beyond the control of the supervisor, he is responsible for the latter condition which is largely one of method. At this season of the year when repair work of all kinds is at its height, it is important that he spend as much time as possible with his gangs. As the money is actually being spent in the field it is more important that the supervisor be on the ground directing its economical expenditure than in the office explaining how it is being spent. Probably the most promising field of study for him is that of devising means of eliminating lost time. The amount of time actually wasted by the average gang is a surprisingly large percentage of the total. Although this has come to be commonly regarded as a necessary evil, it can in many cases be remedied

to a large degree. By studying the proper distribution of men in each gang, the proper size of gangs, the ability of the different foremen to direct men, and more particularly, by training the foremen themselves to study and correct these leaks, surprising results can be gained. Without such encouragement by his superior officers the average foreman will pay little attention to this matter. Again, by maintaining thorough familiarity with conditions, a supervisor can keep his foremen keyed up where they will make their best efforts. When they learn that he can detect at once when they have made a creditable showing or have failed to do so, they are more likely to do their best. Likewise, with such supervision, inefficient or incorrect methods can be detected and corrected so that they will be avoided in the future. In these ways the efficiency of the forces can be increased and the foremen themselves strengthened. These advantages are not fancied, but are being realized by numerous men today. One officer in charge of a portion of a main trunk line recently made a study of his expenditures for the past year as compared with five years ago, and found that although the amount of work actually done has steadily increased, he has made a saving of over $100,000 yearly in actual expenditures. He attributed this to the fact that he has aimed to spend nearly all his time with the foremen in the field assisting them to close leaks here and there. Similar results are possible on many other lines where the officer, perhaps unconsciously, has allowed himself to be tied down too closely to his desk to the detriment of the work on the line.

BOARDING CAMPS AND THE LABOR SHORTAGE.

NOT many years ago any railway man who ventured to suggest that common laborers employed on construction and maintenance work be provided with anything beyond the actual necessities, exposed himself to ridicule. This condition has changed. Many contractors have been quick to see the direct advantages of providing good quarters for their men and taking an interest in their welfare, even to the extent of providing recreation after working hours; and some railways are following their lead. The old idea still prevalent on many roads that any car not fit for anything else can be used for a bunk car, and that the boarding privilege should be let to the contractor making the company the largest percentage, is fast losing ground. Changing public sentiment, combined with the distinct labor shortage of the past few years, is prompting the giving of greater attention to these details.

The problem of sanitation is a serious one about any camp, for if it is unhealthy, the efficiency of the men will be affected. The average railway laborers' bunk car has been conspicuous for years for its lack of attention. Greater care exercised in the fitting up of these cars and in their maintenance and fumigation will eliminate much of the present complaint. Better cars are now being used on many roads, the wooden bunks are being replaced with metal and help is employed by the camp to keep the cars in proper condition.

In adopting precautionary measures against disease, contractors have again led the railways. Many contractors have had doctors, at least in their larger camps, for years, who supervise the condition of the men and camps and give aid to the sick and injured. While the average railway camp would undoubtedly not justify such an expenditure, it should be possible for one doctor to supervise a number of camps located on the same or adjoining divisions. Such precautions are especially advisable in handling contagious diseases. The prompt discovery and isolation of any laborer so afflicted will, in most cases, prevent the disease from spreading through the entire camp and eventually shutting down work entirely.

Public opinion is strongly against allowing camps where large numbers of men are herded together in unsanitary quarters to be maintained in the vicinity of towns or cities, and complaints frequently arise from this source. A number of investigations and reports on this subject have been made, particularly in eastern states, and the fact that the subject is still a live one is shown by a recent report of the Bureau of Industries and Immigration of the State of New York, in which it is stated that there are at present 2,000 unsanitary camps in that state housing 50,000 employees. If publicity continues to be given to such reports some states will soon give their boards of health authority to control conditions in construction camps. The best way the roads can control the imposition of stringent requirements by such boards is for the roads voluntarily to remedy the conditions.

Appearing even more radical than the precautions taken to safeguard health in the camps are the measures provided in some cases for recreation for the men outside of working hours. This class of welfare work has been done in other industries for several years, evidently with good results. Contractors engaged in railway and other heavy construction in remote parts of the country have also found that Y. M. C. A. branches or recreation rooms have been a valuable means of holding labor. As an instance one large contractor employing large numbers of negroes early this spring provided an electric piano and a dance floor in his camp. Upon discontinuing this a few weeks ago he noticed at once such an increased difficulty in securing labor that he has put the piano and dance floor in service again. The installation of shower baths in the recently constructed timber treating plants has proved a valuable adjunct in holding labor at these places, and at least one railroad is now considering the installation of shower baths in a construction camp. This same road is also planning to put up a recreation building at this camp where the men can read or talk outside of the cars in which they sleep, believing that the small amount of money spent for improving the condition of their living quarters and providing amusement for them while not at work will be money well spent.

While these measures undoubtedly appear unwarranted to the average men familiar with conditions of a decade or more ago, they are nevertheless attracting the serious consideration of those railway men who are beginning to feel a greater responsibility for the welfare of their laborers and who also feel that as a business proposition, money spent in providing more attractive quarters will repay a good interest on the investment as a means for holding laborers.

NEW BOOKS.

Proceedings of the Ninth Annual Meeting of the American Wood Preservers' Association. Published by the association. F. J. Angier, secretary and treasurer, Baltimore, Md. Size 6 in. x 9 in., 481 pages. Price, cloth, $3.50; paper, $2.50.

The standing which the American Wood Preservers' Association has attained by the earnest work of its officers and members in the past few years is reflected by the character of the annual proceedings which have just been issued. This book is the largest ever published by the association and in many respects is the most valuable.

It contains a full report of the convention held in Chicago, January 21-23, 1913, at which more papers were presented than at any preceding meeting and the discussions were fully up to the standard set in recent years. In addition to the report of the meeting, the list of members and the constitution and by-laws of the association, the book contains considerable statistical information of interest to railway men in general. A number of maps and tables presented show the production of lumber in the United States, the number of crossties and poles purchased, the location of treating plants in reference to the timber bearing regions and a complete list of timber treating plants in the United States, Canada and Mexico. There is also a brief resume of Forest Service investigations including brief abstracts of the most important bulletins that have been published from time to time.

TUNNEL LINING ON THE VIRGINIAN RAILWAY.

Details of the Methods Used in Placing Concrete Linings in Eighteen Main-Line Tunnels without Interruption to Traffic.

The Virginian Railway let a contract about two years ago for the lining of 18 tunnels on the upper portion of the road. Three are now completed, work is under way on two more and the others will be undertaken at a rate which it is expected will finish this contract in about three years more. Most of these tunnels were timber lined when they were built, but some, which are located in hard material, were left unlined. A rather serious cave-in of one of these tunnels showed that the unlined ones are not as safe as could be desired, and it was therefore decided to undertake the lining of all tunnels about the safety of which there was any question. The concrete linings which are being placed are built to four standard plans, for large and small sections, and with and without reinforcement, as shown in the accompanying cross sections. Work is being done without interruption to traffic, and on account of the size of the contract the contractor and the company's engineers have together developed a system for handling the work which is proving very efficient.

The details of the work at the tunnel about two miles east of Princeton, W. Va., will serve to illustrate the methods used on all of these jobs. This tunnel is 1,700 ft. long, the material being comparatively soft stone, which is loose in many places and is rather wet. On account of the character of the material the reinforced concrete lining is being used, and on account of the size of the bore the large section is required. This section is 23 ft. 6 in. high from sub-grade to invert and 18 ft. 4 in. wide, the walls being vertical from the springing line down to a line 5 ft. 7 in. above sub-grade. From that line down they are battered to give a footing 3 ft. 6 in. wide for the support of the wall. The minimum thickness of the lining inside the old timber rings is 15 in., the walls being 2 ft. 3 in. thick from the face of the old lagging. An 18 in. gutter is provided inside the footing. The reinforcement in the footing consists of three ¾-in. rods laid longitudinally, which are used only in yielding material. The reinforcement in the side wall consists of vertical ¾-in. rods spaced from 2 to 3 ft. apart, as required by the character of the material. These rods are long enough to extend about 4 ft. above the springing line and are bent to form a bond with rods in the arch ring. The ring reinforcement also consists of ¾-in. rods placed in three pieces; the lower pieces coming down to the springing line overlapping the wall rods by 4 ft. and the middle rods, or key reinforcement, overlapping the upper ends of the other rods 3 ft. In addition to this reinforcement there are 19 ¾-in. rods placed horizontally, as shown in the accompanying cross section.

The concrete mixture is 1:3:6. The section used in this tunnel required 5 cu. yds. of concrete and 100 lbs. of reinforcing rods per lineal foot of tunnel. The small section unreinforced requires 4.7 cu. yds. of concrete per lineal foot, the small section reinforced, 4.4 cu. yds of concrete and 100 lbs. of steel, and the large section without reinforcement, 6.4 cu. yds. of concrete. Refuge niches 3 ft. wide are provided at intervals of 200 ft. on each side, staggered. Weep holes in the side walls just above the gutters are spaced a maximum of 50 ft. center to center, 3 in. galvanized iron pipe being used for this purpose. In particularly wet places, holes were bored through the old lagging and 4 in. drain tiles were placed over these holes to carry the water to the weep holes. Where necessary, these drains are provided at intervals as close as 10 ft. In some cases wooden boxes were substituted for the drain tiles, these boxes being 3 in. square inside and framed of 1 in. material, unfinished. The back of the portal is sloped to drain all surface water to a concrete basin built into the back of the portal wall at one extreme end, from which the water is carried through a hole in the parapet wall and down a concrete drain to the roadway ditch. The construction of this drain is clearly shown in one of the accompanying photographs.

The concrete plant for handling this work is located at the

Concrete Car with Two High Levels for Shoveling into Upper Portion of Forms.

Placing Concrete in Parapet Wall at Portal by Shoveling Twice.

end of the cast approach cut, about 300 yds. from the portal. The sand and stone for concrete are brought in in coal cars, the stone being secured from the Sinking Creek quarry about 35 miles away, and the sand from Norfolk, Va. This material is unloaded by a 65 ft. derrick and one yard clam-shell bucket into storage piles having a capacity of 250 yds. of sand and 350 yds. of stone. The cement house holds 2,000 bbls. A water tank with a capacity of 3,000 gal. supplies water by gravity to the mixer and the dinky engine which operates the concrete car in the tunnel. In order to carry on the work in cold weather, a small vertical boiler near the mixer is used to heat the mixing water and steam pipes are laid in the sand and stone storage piles to heat these materials. The water is heated whenever the temperature falls as low as 32 deg. and the sand and stone when the temperature reaches 28.

The unloading derrick which takes the material from cars is

Concrete Drain for Carrying Water from Back of Parapet Wall Down to Roadway Ditch.

used to place the sand and stone from the storage piles into hoppers over the mixture plant. These hoppers have a capacity of 25 yds. of stone and 20 yds. of sand. From these bins the material is dropped into a steel proportioning hopper directly over the mixer. Two men are stationed on the platform above the mixer to proportion the materials, being guided by lines ruled on the inside of the steel hopper so placed as to give the exact quantities of the aggregate needed to secure a 1:3:6 mixture. Each mix is proportioned on the basis of two sacks of cement. The cement is trucked out from the storage house and loaded on a steel skip which is set up on the platform in front of the mixing hopper by a second derrick which is used to handle the concrete buckets. From this skip the men in charge of the proportioning of the material take their bags of cement. The half yard Smith mixer dumps into 1 yd. buckets, two batches being dumped into each bucket and two buckets being filled during the interval that is required for the train to run into the tunnel and place the concrete. When the train returns to the mixing plant the derrick swings these two buckets of concrete that have been loaded over the cars and they are dumped on the shoveling platforms.

To provide electric power for lights in the tunnel and in the

Concrete Mixing Plant, Material Hoppers at Top, Proportioning Platform Below, Mixer at Bottom.

camp, a generating plant is installed which has a 14 k. w. generator furnishing 112 volt d. c. current. The generator is driven by a 20 h. p. engine, belt connected, which receives steam from the 40 h. p. boiler that serves both the light plant and the pumping plant.

The forms are built of long leaf pine dressed on all four sides. By careful handling this form lumber is used four or five times. All forms are framed in place, the posts being set up and lined after which the lagging is put in as required. The waling strips at the top of the battered section of the side wall and the wall

Portal of the Tunnel Near Princeton, W. Va.

plates at the springing line are bolted back to the old timber lining, the waling strip at the top of the footing being wired. The concrete is placed in sections 48 ft. long. The footings are first laid, then the side walls are put in up to the springing line in a single operation. During the placing of these side walls the vertical reinforcing rods are held in place by nailing 2 in. by 4

in. scantlings longitudinally along the old timber rings a little above the springing line to which the tops of the rods can be wired. The longitudinal rods in the side wall are placed as the concrete is carried up. With the exception of the key, the arch ring is also placed in sections 48 ft. long by placing three or four boards and filling over these and then placing more until the entire ring is turned with the exception of the 3 ft. key section at the top. This key section is placed in 4 ft. lengths by

Building the Portal.

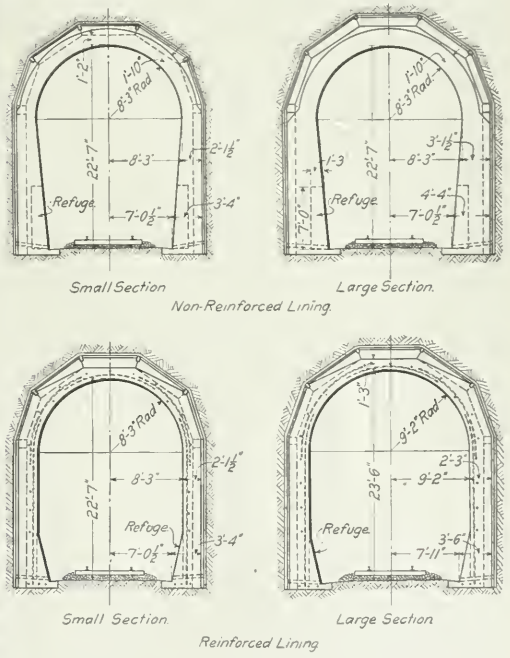
shoveling back after the closing forms have been placed. About 2 in. of mortar is placed over the forms in the key section before the concrete is put in order to insure a neat cement finish. Expansion joints are provided at the end of each 48 ft. section and adjacent sections are firmly keyed together. Forms are never removed within 72 hours after placing the concrete. The use of corrugated tin for protecting the concrete from moisture is being tried in this tunnel. This tin is placed in sheets behind the side walls and above the arch ring before any concrete is placed and before the forms are completed. The sheets are bent around the old timber posts and arch rings so as to fit the old

Train Used for Carrying Concrete from Mixing Plant to Tunnel.

timber lining closely and allow the concrete to fill the entire space. Where necessary, holes are cut through the old timber lining in order to allow the water collecting above to flow down behind these tin sheets to reach the weep holes at the bottom of the wall.

The concrete is brought into the tunnel in 2 yd. batches on a train consisting of a dinky locomotive and two cars. One of these cars is an ordinary flat car from which the concrete in the footings and lower section can be placed, and the other is a flat car on which staging has been built to provide two higher floor levels from which the concrete can be shoveled into the upper portion of the side walls and the arch ring. The shoveling platforms are covered with sheet iron. Eight laborers are used on this car to shovel concrete into the forms and four men are kept in the tunnel to spade back the concrete from the face of the forms. The sequence of operations has been very carefully worked out so that no time is lost in the operation of this train. When the lower portion of the side wall is being placed it is possible to handle 125 yds. of concrete in a ten hour shift, although the delay occasioned by the difficulty in placing the upper portions of the arch ring, and particularly the key section, cut down the general average to 50 or 60 yds. per shift. In order to eliminate delay caused by the building of forms, concreting is carried on at two points in the tunnel alternately.

As it is necessary to operate the concrete train over the main line, it is necessary to protect regular train movements very



Cross Section of Completed Tunnel Linings.

carefully. A man is placed at each end of the tunnel with telephone equipment connected to the despatching circuit, who warns the dinky of an approaching train and who gives clearance cards to all main line trains. No train is allowed to enter the tunnel without first stopping for this clearance. There are two regular passenger train movements a day, and from 5 to 12 freights. On account of the length of these freights and the slow speed at which they move and the occasional delay due to breakdowns in the tunnel, the total amount of delay from trains is a very considerable item.

This work is being handled under the supervision of H. Fernstrom, chief engineer, B. T. Elmore being division engineer in direct charge of the work in the field. The contract is being executed by W. W. Boxley & Co., Roanoke, Va.

RUSSIA'S PURCHASE OF RAILWAYS.—The Budget Committee of the Duma has agreed to the early purchase of the Moscow-Kasan Railway, and has expressed a wish that a bill for the purchase of the Lodz-Raisan-Ural Railway be drafted.

BRIDGE MAINTENANCE.*

By Engineer.

Bridge work is a perpetual and continuous job like track and all other classes of railroad work, but the kind and amount of the different varieties of the work changes with the seasons. In the winter surveys should be completed and plans made for future work, and maintenance should be kept up at the least possible expense. Light construction work should be dropped while heavy construction work on abutments, piers, and mass concrete can be pushed to advantage, especially in localities where the ice is strong enough to be of assistance in handling the work, and also where low water is necessary.

In the spring all bridges should be closely inspected and the necessary repairs ordered. Various methods for making inspections are in vogue. The general inspection may be annual or semi-annual, and be added to by periodical local inspections. When semi-annual, the fall inspection is made with a view of seeing that everything is in shape for the winter and to decide on the construction or heavy maintenance work to be considered and investigated for the next season's operations, while the spring inspection is for the purpose of planning and starting the work to be done in the immediate future.

On many roads the bridge engineer makes the general inspection of the large bridges and permanent work, while the inspection of the smaller temporary or wooden structures is left to the local officers. On at least one of the large western roads this process is reversed and the bridge engineer inspects the temporary structures yearly, leaving the permanent structures for the local officers. Possibly it would be well for bridge engineers to combine the two methods and inspect all bridges.

The maintenance and construction forces should be built up and work started as early in the spring as possible so that the beginning of summer will see the work well under way. All pile drivers, machinery and tools should be overhauled and repaired; material ordered, delivered and unloaded, and complete preparations made so that once work is started it can be pushed ahead without delay. A definite program in the delivery of material to each bridge or each job of work should be outlined and insisted on so that there need be no delays waiting for material, and it should be so arranged that gangs can fully complete each job and then go to the next job without any delay.

The summer is the season for doing the systematic work of repairing, renewing, filling or replacing with permanent structures every bridge on the line as it may need. The work is done by gangs of various sizes which may be either permanent or extra gangs as the work may demand. The pile driver is generally handled by a regular gang, although the method of having each bridge gang educated so that it can also handle the pile driver is sometimes advocated. However, as each road tries to get along with a minimum number of pile drivers so that it is desirable to keep them working at their maximum efficiency at all times, this latter method is of doubtful economy.

On account of the scarcity of foremen and of labor and the advantage of getting work done immediately with as little traveling as possible the combining of the bridge work with section work signal work and other maintenance work is beginning to be advocated. There are many strong arguments in favor of this and should it be found successful it is likely to re-organize our entire maintenance system and methods. The past 15 years have witnessed very radical changes in the construction of permanent waterway openings due to the use of concrete and steel and the future will be likely to add to these and thereby also change our methods of maintenance.

As temporary bridge structures are replaced by steel and concrete the amount of maintenance work is very materially decreased. Bridge gangs are replaced with carpenter gangs, paint ers' gangs, plumbing gangs, etc., as development of the country necessitates. The building up of towns and cities makes it necessary to do much more work around the station grounds than formerly, and the quality and kind of work varies with the nature of the public improvements. Sewers, pavements, permanent platforms, water supplies, plumbing, electric lighting, electric power and other features of latter day progress make it necessary for the railroads to employ specialists who can best handle the necessary work.

Small jobs of construction work and indeed all construction work that it is possible for them to handle should be done by the regular maintenance organization, but large construction jobs require a separate organization which should be flexible as to size and which can be moved from place to place as exigency requires.

Permanent structures in the past have been largely put in by contractors, mainly for the reason that the railroads have not had the necessary equipment for handling the work. However as they have become larger and permanent work has become more general, it is now becoming customary for the railroads to do their own masonry and steel erection work. Whether they save money in all cases by doing this is questionable, when the cost of the equipment with interest and depreciation is taken into consideration. Undoubtedly where construction work is continued from year to year requiring permanent forces, outfits and machinery, they save the contractor's profit, but in many cases the amount of work and the inexperience of the men makes the cost more to the railroad company, although this fact may not be evident on the surface of their accounts.

During the summer months all the bridge work should be pushed to completion as rapidly as possible, so that in the fall all that remains to do will be to get every bridge and opening in shape for the winter. This not only means that its strength and condition should be cared for, but that the waterways themselves, including the channels and ditches, should be clean and free from obstructions, so that there will be a free flow of water to and from the openings, that the openings may fulfill the purpose for which they were constructed.

As most of the railroads in this country were constructed in a time when timber was cheap, many pile and trestle bridges and timber culverts were built which are being replaced more or less rapidly with permanent structures. This has been accelerated of late years by the use of concrete and the consequent cheapening of the permanent openings. The life of the timber bridges has also been lengthened in many cases by the use of creosoted timber. This material is especially applicable in cases where the bridge decks have to be replaced oftener than the piles, and many years are often added to the life of the bridge by the use of a creosoted deck which may be filled in and ballasted.

When the original timber bridges were built, but little attention was paid to the size of opening required to properly carry the water, so long as it was large enough.

With permanent structures this is not a sufficient rule on account of the greater cost, and the size of openings should be proportioned to the use required of them. This makes necessary complete surveys and investigations of the bridge, its drainage area and outlet. These surveys should be made or started as early in the fall as possible, so that time may be had for considering each bridge and designing the necessary structure, culvert or pipe for the opening in order that the material may be ordered and delivered in time for the next summer's building.

In considering the amount which can profitably be spent for replacing temporary with permanent structures, the first cost of the temporary bridge should be taken together with such an amount as will, when put at interest at current rates, provide for it maintenance and periodical replacement at such times as it may wear out. A common wooden pile bridge can be replaced by a permanent reinforced concrete pile bridge on a ratio at present day prices of about 3 to 1, while there are many cases of bridges or trestles which can be replaced by reinforced concrete culverts, boxes or pipes for even less than the cost of a

*The first of a series of articles on timely maintenance topics. The first appeared on page 351 of the issue of February 11, the second on page 4[illegible] of the issue of March 11, the third on page 505 of the issue of April 1[illegible] and the fourth on page 1091 of the issue of May 16.

wooden structure. The use of reinforced concrete for many railroad structures is growing rapidly and merits the full investigation of every railroad engineer. Pipes, culverts, boxes, highway bridges, subways and over-crossings, arches, trestles, bridges and retaining walls are now being permanently and cheaply constructed of this material, to say nothing of buildings, tanks, coal chutes and other uses for which it is being rapidly adopted.

THEW STEAM SHOVEL USED AS A PILE DRIVER.

A No. 0 Thew steam shovel was recently used in a novel manner in constructing the foundation for a passenger subway for the New York Central station at Utica, N. Y. The shovel was originally used to make an excavation about 165 ft. long, 40 ft. wide and 10 ft. deep, with three bays on each side each about 20 ft. square. After the excavation was completed it was necessary to drive piles under the sidewalks, center piers and stair piers in these bays. In all about 250 spruce piles 13 to 16 ft. long were used.

Owing to the limited working space and the difficulty of moving an ordinary pile driver into these bays it was decided to convert this small steam shovel into a pile driver, to obtain the advantage of its self propulsion and the full circle swing of the boom. The bucket was removed from the shovel and a pair of 26 ft. leads were attached by means of 3-in. x 10-in. plank bolted to the boom as shown in the accompanying photograph. The thrusting arm was bolted to the leads so that when it was fully extended they were in a vertical position. A No. 3 McCoy "Monarch" steam hammer weighing 2,800 lbs. was mounted in the leads.

Thew Steam Shovel Used as a Pile Driver.

When moving this driver the hammer was staged just above the foot of the leads. When over the location of a pile the hammer was lowered to the ground, permitting the leads to rise slightly as the load was removed. The foot of the leads was then supported roughly on blocking, a rope was passed through the bale of the hammer and it was hoisted, carrying the pile with it, as there was no way to attach a separate pile fall. After driving a pile the foot of the leads was pulled in toward the shovel by the thrusting arm until it cleared the pile, permitting the shovel to move or revolve in the usual manner.

Although considerable trouble was experienced with soft bottom, requiring the shovel to be carried on plank throughout the work, an average of 19 to 20 piles were driven in a ten-hour day, the smallest number being 15 and the highest 27. The actual time of driving averaged from 10 to 14 min. While a heavy hammer would have been desirable for faster driving, it could not have been placed on this shovel. As it was, it was necessary to weigh down the back of the shovel by suspending about 400 lbs. of iron from the I beams beneath the boiler. When the driving was completed the leads were removed and the bucket replaced in less than three hours.

The performance of so small a steam hammer on piles of 11 and 12 in. butts is interesting. The piles were driven until a penetration of about one-half in. was secured under 40 blows. A drop hammer weighing 1,800 lbs. was used on an adjoining contract which touched the subway at one point. Hardwood piles of the same size were used here and were driven to a penetration of one-half in. under a 30 ft. fall. As the steam hammer had driven its piles from three to four ft. lower than the drop hammer it was thought desirable to try it on the piles which the drop hammer had been unable to put down deep enough. The steam hammer was therefore substituted for the drop hammer and although the piles had been driven several days before the small steam hammer was not only able to start them but secured a penetration of three ft. additional.

The alteration of this Thew shovel was devised by A. A. Parker, of Waterford, N. Y., associated with H. R. Beebe, Utica, N. Y., the contractor on the subway.

ABSTRACT OF ENGINEERING ARTICLES SINCE MAY 16, 1913.

The following articles of special interest to engineers and maintenance of way men and to which readers of this section may wish to refer, have appeared in the regular weekly issues of the *Railway Age Gazette* since May 16, 1913:

Some Disputed Points in Railway Valuation.—A series of editorials discussing variations in the methods adopted in the different valuations made up to this time, including investment from earnings, depreciation and intangible values, appeared in the issues of May 23, page 1018; May 30, page 1164, and June 6, page 1208, respectively.

New Kansas City, Mo., Passenger Terminal.—The next to the largest terminal development now under way in this country is that at Kansas City, Mo., where a new $5,000,000 station, a belt line around the city and freight yards are now being built, requiring a total expenditure of $40,000,000. This project was described in detail and illustrated in the issue of May 23, page 1121.

The Problem of Railway Valuation.—The change in the public's attitude toward the railways and the problems connected with the making of a fair valuation were discussed by Logan G. McPherson, director of the Bureau of Railway Economics, in the issue of May 23, page 1131.

Plans for New Union Station at Chicago.—The plans for the proposed new passenger terminal for the Pennsylvania, Burlington, St. Paul and Alton at Chicago, as presented by the railways, were described in the issue of May 23, page 1147.

Canadian Pacific Coal Unloading Dock.—A new dock for the unloading of coal from lake boats onto storage piles or cars, similar in design to the more recent ore unloading plants, has recently been completed at Fort William, Ont. This dock was described May 30, page 1173.

Relocating the Chicago Railway Terminals.—The Chicago Plan Commission, appointed by the mayor to study the terminal situation, has prepared a plan providing for the location of passenger and freight terminals along Twelfth street. This plan was described and illustrated in the issue of May 30, page 1184.

Grand Trunk Grade Separation in Toronto.—The Grand Trunk is now engaged in the work of separating its grades in Toronto, Ont. This project will also involve the construction of a new union station and is divided into three sections, the first of which is now practically completed. This work was described and illustrated in the issue of June 6, page 1213.

New Extension of the Norfolk Southern.—The consolidation of a number of lines to form the Norfolk Southern has been further augmented by the extension to Charlotte, N. C., giving it a direct through line from Charlotte to Norfolk. A number of interesting construction problems were presented in this work and were described and illustrated in the issue of June 13, page 1315.

Thirty Mile Electrification on Norfolk & Western.—The Norfolk & Western has recently authorized the electrification of a 30 mile section of its main line between Bluefield, W. Va., and Vivian, to handle a very heavy coal traffic over the mountains. The general details of this work were given in the issue of June 13, page 1319.

Doubling the Load Capacity of an Old Iron Railroad Viaduct.—An interesting method of strengthening an old iron viaduct on the Pere Marquette by the addition of reinforcing trusses and center posts, was described in a paper by W. T. Curtis, presented before the Western Society of Engineers and abstracted in the issue of June 13, page 1323.

New Yards of the Chicago & Alton near Chicago.—The Chicago & Alton is now engaged in the construction of a new yard and engine facilities at Glenn, Ill., about 10 miles southwest of Chicago. A number of interesting features in the design of this yard and buildings were described and illustrated in the issue of June 13, page 1327.

TRACK SCALE SPECIFICATIONS AND RULES.

Recommendations Adopted by the American Railway Association Provide a Standard to Which Railroads Can Work.

The following recommendations were adopted by the American Railway Association at its session in New York on May 21, with the view of setting an ultimate standard towards which railroads generally may work, but are not intended to condemn scales, methods of installation or reinstallation, etc., now in service, which come within the sensibility and tolerance prescribed in section 4 and respond to the tests as prescribed in section 12 below. These specifications and rules are also not intended to cover installations for special weighing such as twin loads, etc.

SELECTION, INSTALLATION AND LOCATION OF NEW SCALES.

1. When selecting track scales, the following should be considered:

(a) Maximum loads to be moved over scale for weighing or otherwise, considering the spacing of and the concentration of weight on axles.

(b) Length of wheel base of cars or other equipment to be weighed.

(c) Whether cars are to be weighed, spotted or in motion.

2. When track scales are to be installed, consideration should be given to:

(a) Location with respect to yard work and grade.

(b) Character of foundations.

(c) Method of installation.

(d) Drainage, lighting, heating, ventilation.

3. Having the above information, the three essentials of a track scale are:

Design, capacity and length.

4. SCALE DESIGN.

(a) Scales should be so designed that the load is suspended from (and not superimposed on) the main supporting levers, unless intermediate means are provided between the bridge supports and the bearings to absorb the oscillations and prevent the displacement of the bearings at points of contact on the knife-edges.

(b) They should be constructed in four sections with vital parts as accessible for cleaning and inspection as practicable.

(c) Practical means of adjustment should be provided to secure uniform distribution of load on the scale at points of support.

(d) Parts of the same type of scale should be of uniform dimensions and interchangeable as far as practicable. The position of each nose iron should be clearly indicated by a well-defined mark, showing its position when the lever is sealed.

(e) Scale design which contemplates the use of check rods should be checked longitudinally and transversely, preferably at the point of least resistance

(f) Beams should be so designed as to weigh all loads on main and fractional bars without use of hanger weights. The main bar of the beam should have not more than six notches to the inch, assuming each notch to represent 1,000 pounds. Fractional bar should be graduated to 50 lb. subdivisions, with not more than four subdivisions to the inch, which would correspond to 200 lbs per inch. A shoulder stop must be provided on all beams to prevent the poise traveling back of the zero graduation. Where the scale is not equipped with a full capacity beam, the maximum capacity must be clearly and permanently placed on the scale where it can be easily seen.

(g) Multiplication at butt of beam should not exceed 800 to 1 High multiplication in levers is undesirable.

(h) Type registering beams should be used where spot weighing is performed.

(i) The sensibility reciprocal is the weight required to move the beam a definite amount from pointer or other indicating device of a scale. In scales provided with a beam and trig loop the sensibility reciprocal is the added weight required to be placed upon the platform to break and turn the beam from a horizontal position in the middle of the loop to a position of equilibrium at the top of the loop. This may be determined by subtracting the weight instead of adding it, or by using the sliding poise on the beam, if this is done without jarring the beam.

For railroad track scales the angular movement or play should be 2 per cent. and the sensibility should correspond to 1 per cent. angular movement of the beam.

The sensibility reciprocal of a track scale should never be greater than 100 lbs., and when the scale is new should be not greater than 50 lbs., that is, a load of 50 lbs., when applied to the scale platform, should cause the beam to move from a position in the middle of the trig loop to the top of the loop. For verification purposes when new, a scale should be capable of adjustment to within 1/2000 (one-half pound to the thousand pounds) of the capacity, and should be considered inaccurate after it cannot be maintained in adjustment to within four pounds to the thousand pounds, in excess or recess. Track scales should be kept in the closest possible adjustment.

(j) Bearings, wherever practicable, should be compensating to insure full length contact of pivots with bearings.

(k) Friction in all parts of the suspension should be reduced to a minimum by providing hardened steel contacts, and the design of scales should contemplate this important factor.

5. CAPACITY.

In determining the sustaining capacity of the scale, there is still a diversity of opinion among the best scale engineers as to the better method of procedure, and it is true that in figuring the scale levers the prime factor is to figure for deflection, which may necessitate deviating from standard engineering practices somewhat. It matters not if we assume a very small fiber stress neglecting the impact or assume a higher fibre stress and add a percentage for impact.

As a basis of calculation from an analytical point of view it seems quite natural to first assume the capacity of the scale and then proportion the amount beyond that which will apparently eliminate deflections, and we here approach what may be determined an undeveloped state in the higher art of scale building at this time.

One of the most logical ways of arriving at a conclusion would be to take the maximum weight on a pair of wheels (whether they be cars or locomotives), which at present is about 65,000 lbs., located on a transverse center line of main levers, plus the dead load divided by the number of supporting knife-edges. The above may be expressed in the shape of a formula, as follows:

w = Dead load.

a = Maximum weight on a pair of wheels.

n = Number of supporting knife-edges.

$$\text{or maximum load} = q = \frac{w}{n} + a.$$

The load "q," which is applied to both main levers of each section at the points of load support, is distributed as follows:

1. Main Levers. Maximum load "q" at point of load application.

2. End Extension Levers. A percentage of "q" based on the multiplication of the main lever.

3 Middle Extension Levers. A percentage of "q" based on the multiplication of the main lever and the reaction of the end extension lever.

4. Fifth Lever. The combined reaction from the two middle extension levers.

By taking these loads at their respective points of application,

the moments can be determined and the size of cross-section computed according to the stresses recommended.

Levers. The design of levers, and the classes under which they appear should be governed by the use of such sections, that under the load or weight determined from the capacity, the deflections and stresses are within the limits specified.

Stress—

Cast iron, tension	2,500 lbs. per sq. in.
Cast iron, compression	5,000 lbs. per sq. in.
Cast steel, tension	8,000 lbs. per sq. in.
Cast steel, compression	8,000 lbs. per sq. in.

Maximum deflection—

Cast iron	0.040 in.
Cast steel	0.080 in.

Loops. All loops should be so designed that the respective strengths are equal to those of the pivots, the latter being the basis for calculation. The combined stress in tension due to flexure plus direct tension should not exceed 8,000 lbs. per sq. in.

Pivots. All knife-edges, pivots, and bearing surfaces for same should be made from a steel which possesses such properties as will insure a maximum toughness combined with the necessary degree of hardness to insure minimum wear under maximum loads. The following physical properties, based on steel with the internal strains relieved by drawing after hardening, should be as follows:

Ultimate tensile strength	200,000 lbs. per sq. in.
Elastic limit	165,000 lbs. per sq. in.
Elongation in 2 in	5 per cent.
Reduction in area	25 per cent.
Maximum working stress	20,000 lbs. per sq. in.

Application of load and method to be followed in determining the cross-section, based on the stress specified:

In determining the bending moment, the lever-arm "L" should be defined as half the length of the bearing surface in the loop or connection, plus ¼ in., plus the difference between the dimensions of the friction faces in the loop and the friction faces on the lever, as expressed in the following formula:

Let L = Lever arm required.

I = Bearing surface in loop.

T = Distance between friction faces of loop.

W = Width of boss or sustaining member enveloping pivot.

Then:

$L = \frac{1}{2} I + (T - W) + \frac{1}{4}$ in.

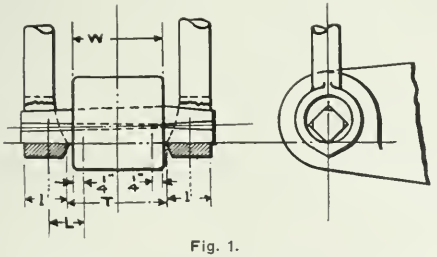


Fig. 1.

(i) The bearing per lineal inch of knife-edge should not exceed 7,000 lbs. when the hereinbefore mentioned loading is considered.

Structural steel used in connection with the installation of scales shall be properly braced, including diagonal stays, if necessary, and should conform to steel structures furnished by the American Railway Engineering Association.

6. LENGTH.

(a) The length of scales should be considered as the distance between ends of scale rail.

(b) The ends of scale rails should not project beyond the knife-edges of the end main levers.

(c) When cars are to be weighed spotted, the scale should be of sufficient length to place the entire car on the scale and preferably longer to facilitate spotting.

(d) When the cars are to be weighed in motion, cut at both ends at a speed not to exceed four miles per hour, the scale should be approximately 1/3 longer than the wheel-base of the longest cars ordinarily weighed. Humps for gravity weighing should be so constructed that cars with wheel-bases longer in comparison to scales should pass over scales at a slower rate of speed or be spotted if necessary.

7. LOCATION.

The proper location of scale depends principally on the following conditions:

(a) The volume of traffic to be weighed in comparison with that switched over the scales and not to be weighed.

(b) Whether scale is to be equipped with dead rail or relieving gear.

(c) Whether run-around track will be installed for switching with a separate track for weighing.

(d) Whether cars are to be weighed spotted or in motion.

(e) The cost of extra switching, when the scales are not located on a lead to classification track.

(f) Cost of maintenance when scale is located on lead to classification track and only a small proportion of cars are to be weighed.

(g) The necessity for quick despatch of cars that are weighed.

So much depends on local conditions affecting the different carriers that it would be difficult to give exact rules in connection with the above suggestions. It is recommended, however, that there be not less than 50 ft. of tangent track at both ends of scale rail. When only a small proportion of the cars handled are to be weighed the rails leaving the scale in the direction of weighing may be curved and the dead rail straight, or the curvature may be equalized between them.

8. GRADE.

(a) When the scales are located on a lead to classification tracks in hump yards they shall be at a sufficient elevation that cars will run by gravity as far as desired into the classification yard, considering a maximum speed of four miles per hour over the scales.

(b) When scales are not located on the hump, they should be at a sufficient elevation to provide the necessary grade on the track leaving the scale in the direction of weighing that the usual cut of cars to be weighed will run away from the scale by gravity in order to prevent impacts on the scale.

(c) The length of the hump and the grade thereon should be such that free running cars as above will pass over the scales at a speed not to exceed four miles per hour without brake application.

(d) Where it is the practice for one car rider to take several cars together into the classification track, the same grade as on the scale should be maintained for at least 100 and preferably 200 ft. beyond the scale in the direction of weighing so that cars may be stopped easily by the car rider and so that succeeding cars will not cause excessive impact when striking the car ahead which should occur not less than one car length from the scale.

9. FOUNDATIONS.

(a) Scale foundations should be constructed of concrete or cut stone. When the latter material is used it should be laid in cement mortar.

(b) Foundations should be constructed in accordance with the best engineering practice.

(c) Piers or parts of foundations supporting scale stands or the rail system should be of sufficient area that the pressure per square inch in accordance with the best engineering practice will not be exceeded and must be constructed as nearly as possible to exact elevations. Grouting is undesirable. The tops of piers or supporting walls should be finished with a layer of cement mortar in the proportion of one to one to the depth of approximately 1½ in. and after setting dressed to exact elevations.

(e) Where necessary to prevent seepage of water through foundations into the scale pit, they should be water-proofed and drained into a water-proofed cistern located outside of the scale

pit, and equipped with either hand pump, air siphon, or steam siphon.

(f) Drainage should be provided in all cases where there is a possibility of water getting into the pit and where excessive seepage is not present and there is sufficient fall, pipe drainage should be used.

(g) The minimum period of ten days should elapse between the placing of the last concrete and the putting of the scale in service to permit proper setting of the concrete. The proper setting will be influenced by the prevailing temperature and weather conditions during that period, and this should be given due consideration.

10. INSTALLATION.

(a) Scales should be installed with dead rail or relieving apparatus.

(b) The deck or platform should be of the rigid type, so that the balance of the beam is not affected by weather conditions, etc. It should be made as nearly dirt and water proof as possible.

(c) Scales to be used for spot weighing should be constructed with scale rails level and approach rails level with scale rails for a distance of 50 ft.

(d) Scales to be used for motion weighing should be constructed with scale rails at not greater than one per cent. grade.

(e) Wedge or other means of adjustment used between bridge and scale supports to secure uniform distribution of loading should be set as low as possible when scales are installed, as future lining usually requires raising the bridge rather than lowering it. The end of the check rod on scale should be ¼ in. higher than at point of anchorage.

(f) Material such as wooden ties, placed between the bridge and scale rail, will absorb the shock and protect the vitals in case of derailment. This should not be framed until the bridge is installed in order to secure proper elevation of the scale rails and should be fastened securely to the bridge to prevent shifting.

(g) Scale should be set directly on foundations or on metal bed plates resting on foundations.

(h) Scale parts, where necessary, should be securely anchored to foundations, and it is desirable that means of slight adjustment longitudinally and transversely be provided for properly setting scale, interchanging scales in the same pit, etc., in order to secure perfect freedom of action for all parts in suspension.

(i) Scale beam supports should rest directly on scale foundation.

(j) The use of extension levers between the fifth lever and scale beam is undesirable.

(k) Scales and structural steel should be cleaned and painted with one coat of red lead paint before being installed, one coat after installation and at such other times as may be necessary.

(l) Minimum clearance for the working of scale parts through or about parts of installation not connected with scales, should not be less than ¾ in., except that when scale end approach rails are securely anchored a clearance of not less than ½ in. will be permitted.

(m) Open hearth scale rails of full length and sufficient capacity for supporting the load are desirable.

(an) An efficient transfer rail, or other connection, may be used to prevent impact of cars moving over joint between approach and scale rails, such contrivance to be so designed as not to interfere with the action of scale.

(o) Approach and scale rails should be anchored to prevent creeping and should be maintained in proper line and surface.

(p) Scale pits should be heated wherever practicable and necessary to prevent freezing and rust.

(q) Effective means should be provided for ventilating the scale pit where practicable. Openings in side walls are desirable. Means should be provided for closing such opening when there is possibility of wind pressure affecting the scale when weighing.

(r) Scale pits should be properly lighted for purposes of cleaning, inspection and testing.

(s) Scale houses should be constructed at track scales for proper housing and protection of scale beam and protection of weighmaster.

(t) The interior and exterior of scale houses should be amply and properly lighted to afford proper facilities for weighing and the prevention of mistakes in reading scale beam, car numbers and stenciled light weights. This applies more especially where cars are weighed at night.

11. MAINTENANCE AND OPERATION.

(a) All track scales should be numbered and referred to by number and location.

(b) Extensive repairs to scales, such as renewal of or sharpening of pivots, should be made in properly appointed shop.

(c) When scales are in service regularly, scale parts, substructure and foundations should be cleaned at least twice a month, and, when exposed to the elements, or otherwise located so that they are liable to become clogged with ice or dirt, should be cleaned as frequently as necessary.

(d) The application of rust preventives to bearings is desirable, but they should be so applied as not to interfere with the proper working of the scale.

(e) If ice obstructs the levers, salt should not be used to melt it; artificial heat should be used wherever practicable.

(f) Equipment should not be allowed to stand on the scales except when being weighed.

(g) Engines or other equipment not to be weighed should be passed over the dead rail, except on authority of the weighing department.

(h) Cars should not be bumped off scales by an engine or another car on the dead rail, nor be pulled across the scale coupled to another car moving over the dead rail.

(i) Enginemen should not apply sand to scale or dead rail, nor should the injector on the engine be applied when the engine is standing on or passing over the scale.

(j) The weighing beam should be balanced before the scale is used and when not in use should be locked with the beam catch.

(k) Cars should not be violently stopped on the scale by impact, by the sudden application of brakes or by throwing obstructions under the wheels. When pushing off scale cars which have been stopped for weighing or otherwise, impact must not occur at a speed greater than two miles per hour. When necessary for any reason to run cars over the scale rails, the speed must not exceed four miles per hour.

(l) The weighmaster should familiarize himself with the construction of the scale and make such inspections at such intervals as are necessary to determine if the scale is in proper working condition.

(m) Parties appointed to inspect and clean scales should be properly instructed, and it is desirable that they be present with the scale inspector when scales are tested.

12. TESTING.

(a) The standards of mass for testing scales should be derived from primary weights, verified by the National Bureau of Standards, Washington, D. C., to within what is known as their "Class B Tolerance." Such weights can be obtained either direct or through scale manufacturers. The 50 lb. secondary or working cast iron weights, which are transported from place to place and used directly in testing scales, should be rectangular, and of such design as to facilitate stacking; they should be free from pockets, blow holes, etc., which are liable to catch and hold foreign matter. No adjusting cavity or cavities in the bottom of the weights should be permitted.

These weights should be tested and adjusted in comparison with the master-weight, which has been verified to within "Class C Tolerance." The working weights shall be adjusted to within 25 gr., and maintained to within 100 gr. of their true values.*

(b) Scales in regular service shall be tested at least every three months with a test car or test weights up to at least ten per cent. of their rated capacity.

(c) Scales should be given a graduated test up to their work-

ing capacity when installed and periodically thereafter. The necessity for the frequency of such a test depends on the design, capacity and method of installation of the scale used, the wear of scale pivots, and the amount of weighing performed.

(d) A test shall be made each week by weighing a heavily loaded freight car with as short a wheel base as is obtainable, on each end and the center of scales. When a scale is equipped with an automatic weighing attachment, the car should, in addition to the above, be weighed spotted on the trip end of the scale and in motion with the automatic attachment connected. A report of these tests should be sent to officer in charge of scales and weighing.

(e) In addition to the above a daily test should also be made on each scale equipped with an automatic attachment, by weighing a car spotted on the trip end of the scale with beam, also in motion with the automatic attachment connected. A book record of this and other tests is to be kept by weighmaster.

13. EQUIPMENT FOR TESTING.

It is desirable for verifying or sealing test weights and test cars to have, in addition to standards of mass prescribed above:

(a) An accurate even arm balance of 100 lbs. capacity in each pan, sensitive when loaded to two grains.

(b) A master scale of sufficient length and capacity for sealing test cars, sensitive to within 5 lbs. in 50,000, should be installed under cover and properly maintained and tested to insure accuracy.

(c) For the proper design of scale test cars consideration should be given to the following:

(d) All metal construction.

(e) Length of wheel base.

(f) Uniform distribution of load on axles.

(g) The elimination as far as practicable of ledges or projections likely to catch and hold dirt.

(h) The elimination of all unnecessary parts.

(i) Strength and durability so that frequent repairs will not be necessary.

(j) Surface area to be reduced as much as possible to limit wind pressure.

(k) The accessibility of all parts for inspection.

(l) The ease with which it may be barred or moved by scale inspector.

(m) Weight of car and weight of super-cargo if used.

NOTE.—There is a wide variation of practice in regard to the design of scale test cars. It is thought, however, that the majority of cars weigh from 30,000 to 60,000 lbs., and have a wheel base of from 6 ft. to 8 ft. Some have a body made up of solid castings with space provided for a small super-cargo; others have a body of plate steel with space for super-cargo or test weights, weighing about as much as the car. Local requirements principally determine the type of construction to be followed. It is not thought, however, desirable to have test car weigh less than 30,000 lbs., nor greater than 60,000 lbs., for general testing. Heavier cars on two axles up to 80,000 lbs., are desirable for use in making graduated tests up to the capacity of the scales or the capacity of loads to be weighed.

NOTE.—The standards for testing scales in the Rupublic of Mexico must be in accordance with the metric system standards and will be verified by a federal scale inspector in accordance with the federal laws.

14. AUTOMATIC WEIGHING AND RECORDING DEVICES.

Efficient automatic weighing and recording devices may be used where desired. There has been, in the past, however, and may be at present, an impression, by some, that the automatic weigher and recorder will overcome all outside influence and give correct results regardless of scale and track conditions and the speed at which the cars are handled over the scale. This is an erroneous impression as it is absolutely necessary that the scale and the automatic device as well be in first class condition with properly maintained approach tracks and cars must be run at a slow rate of speed with particular attention to steadiness of motion if best results are to be obtained.

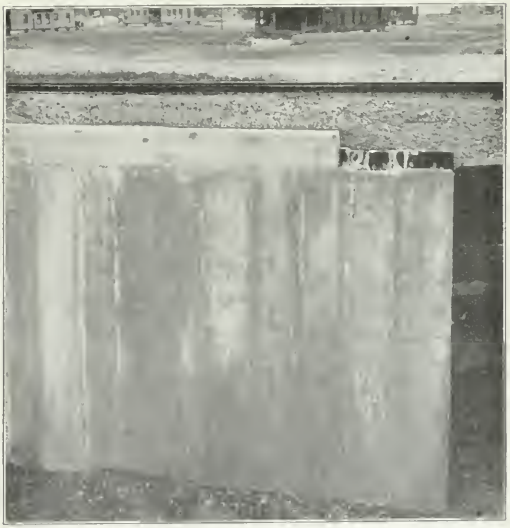
NEW BRANCH LINE FOR INDIA.—A branch line, 8.58 miles long of the 3 ft. 3 in. gage has been sanctioned from Nidamangalam, on the South Indian Railway, to Mannargudi; to be constructed on behalf of the District Board of Tanjore.

NEW FORMS OF STEEL SHEET PILING.

The use of steel sheet piling for cofferdam work has become quite general in recent years, and a number of forms of such piling have been placed on the market. The Lackawanna Steel Company, Buffalo, N. Y., manufactures sheet piling in a number of different designs for various purposes and has recently added to these designs two new ones: the arched web piling and the concrete protective piling.

The arched web design differs from the straight web type in the fact that the web is curved or arched so that the entire web lies to one side of the neutral axis. The outer side of this arch is flattened to lie in the same vertical plane as the extreme edge of the interlock, this flat face furnishing a large bearing area for waling strips used for internal bracing. This type of piling is recommended where transverse or beam strength is required and for such location the section is very effective as it has a decidedly higher section modulus for a given weight of section than the straight web piling.

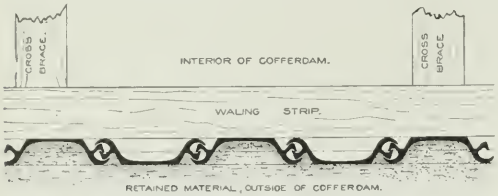
The protected steel piling consists of any of the standard sections coated with concrete which is mechanically bonded to the



Lackawanna Protected Steel Sheet Piling.

steel piling. These combination piles are designed for use in permanent structures in which the use of exposed steel would be objectionable on account of the rapid corrosion that would take place due to the intermittent wetting of the steel surface or from the chemical action of acids contained in the materials in contact with the piling. The piles are encased in concrete before driving; the facing being so mechanically and adhesively bonded to the pile as to permit its driving with the concrete facing attached. The lower ends of the piles for a length of 6 in. are left exposed to serve as a cutting edge and the lower end of the concrete facing is tapered to facilitate driving. The tops of the piles for a length of 6 in. are also left exposed to receive the blows of the driver. The portion of the piles below the ground surface need not be protected if they are coated with a good preservative. If it is desired, the piles thus protected can be completely driven and the upper portion can then be encased in concrete by the use of removable forms, the same bonded wires being used as in cases where they are encased before driving. A great number of combinations of steel sections can be secured in these protective pilings, and if desired, two or more piles may be encased together to form solid slabs

which may be driven as a single unit. When the piles are encased before driving the section is so designed that the interlocking portion of the steel bonding can act in the same manner as in the uncoated piles; the pockets in the interlock and between the faces of the concrete coating being filled with grout after the wall is driven. The mechanical bond is secured in the case of center flange piles by inserting reinforcing rods through holes drilled in these center flanges. In the straight web and arch web sections, rectangular bars are placed through rectangular holes in the web, the bars having holes near their ends for the insertion of the bonding bars. The entire thickness of the coated piles is either 9 in. or 12 in., as desired. These piles can also be made for any desired angle or bend, and can



Arched Web Steel Sheet Piling.

be driven to form circular structures without any radical change in the design.

The principal use for such protected piling is for sea walls or retaining walls built on soft material which would otherwise call for submarine foundations of timber or stone. For walls where it is necessary that adjacent structures be protected from disturbance which would be involved in the building of large foundations and where quick action is required in the construction or repair of permanent foundations requiring strong and impervious walls. An installation of these protective piles requires no sub-foundation, no sub-aqueous foundation nor rip rap along the outer face to protect against the action of waves or tides. A number of suggested designs for shore revetments, dikes, bulkheads, levees, docks, sea walls and piers have been worked out by the Lackawanna Steel Company, as well as the complete details for the forms used in encasing the steel piles.

THE PRESERVATIVE TREATMENT OF RED-OAK AND HARD-MAPLE CROSSTIES.

Much has been published upon the durability of railway ties treated by various preservative processes, but there is little available information concerning ties treated by different processes and laid in one track, where the treatments can be compared. In order to gather data for such a comparison the Forest Service of the Department of Agriculture, through its Forest Products Laboratory, in co-operation with the University of Wisconsin and the Chicago, Milwaukee & St. Paul, has completed the first stage of an extensive experiment, the purpose and scope of which are given in Bulletin 126 of the Forest Service, recently issued. The ties used in the experiment were ordinary stock of the co-operating railroad, and 100 of each of the two species, red-oak and hard-maple, were treated by each of six processes, selected so as to include at least one from each general type of pressure processes in common use. Thus, there were treated for the experiment 600 red-oak and 600 hard-maple ties, and 100 untreated ties of each species were laid. The history of each tie up to the time of laying is recorded, the preservative processes described, the methods of handling and laying given in detail, and everything needful for comparison of results of future inspection carefully worked out.

In selecting a location for the test track the effort was to secure normal conditions of site and traffic. The location is on a single track road which carries a fairly heavy traffic in both directions. The track at the point where the ties are laid is gravel ballasted, well drained, straight and practically level. Nearly all the treated ties are placed on a fill, but a few included in the test were laid in a cut.

Screw spikes with flat tie-plates were used on 50 per cent. of the ties and the remaining 50 per cent., unprotected by tie-plates, were fastened by ordinary cut spikes. An extension to the original experiment included red-oak and chestnut ties treated by a commercial plant, and a few spruce ties contributed by another firm were used. In order to avoid disturbing the track in the future, new rails were laid at the time the ties were placed, and new fastenings were used throughout.

It is thought that a series of observations and inspections covering several years will yield valuable information relative to the preservation of timber and its behavior in actual use. The bulletin is illustrated with reproductions of drawings and photographs of apparatus and material, and all details as to ties are given in tabular form.

THE FOREMAN PROBLEM—HOW TO PROVIDE A SUPPLY FOR THE FUTURE.*

By L. W. Strayer,
M. of W. Department, B. & O., Pittsburgh, Pa.

The criterion of a good roadmaster is his ability to build an organization of foremen about him, to efficiently and economically conduct the maintenance on his territory. Track foremen are made and not born. They should have at least an ordinary common school education, be skilled in track work, have foresight and be capable of meeting all emergencies that arise. In order to develop foremen, we must begin with the track laborer and familiarize him with the work and standard practices of maintenance. Generally the plan of increasing wages to attract a more intelligent class of men and educating those who show a disposition for advancement, will produce results. In the rural districts, mountain divisions, on branch lines of our railways and on some trunk lines that traverse the middle western agricultural belt, there are American trackmen who can be worked into foremen. If we could develop all this talent and use it wherever we need new foremen, our problem would be much easier. Some of these men, however, are averse to handling foreign labor, others shun promotion for lack of initiative, still others have family connections or perhaps some property that holds them to a certain place and they will work at lower wages rather than be transferred to a strange community.

There should be a leading laborer or assistant foreman to each section at an increased rate of 15 or 20 cents a day, this man to act as foreman in the absence of the regular one. The most promising of these assistants can be used as assistant foremen on extra gangs during the summer months. In this way one can develop men and at the same time stimulate a rivalry for the promotions as they are bound to come. This method should be supplemented by keeping not less than four men and a foreman to each section regularly, these men to be paid an increase over the ordinary extra gang and temporary section men. Such places would be permanent ones and at a premium. The efficiency of such a class of skilled trackmen would easily cover the increased rate of pay, attract a better grade of men and eventually produce better foremen. This scheme is being successfully carried on locally in several instances.

Another phase of the problem is to educate the best of the foreign element, in and near the industrial centers, for scarcely any men of American birth can be found doing track work in a vicinity where other employment can be had. By a little timely observation and instruction, the best laborers can be picked out and made leading laborers, then assistant foremen of extra gangs for a season or two, during which time they should be encouraged to attend night schools, or instruction should be furnished by the railway company in order to teach them to read

*Received in the contest on The Section Foreman Problem, which closed March 25, 1912.

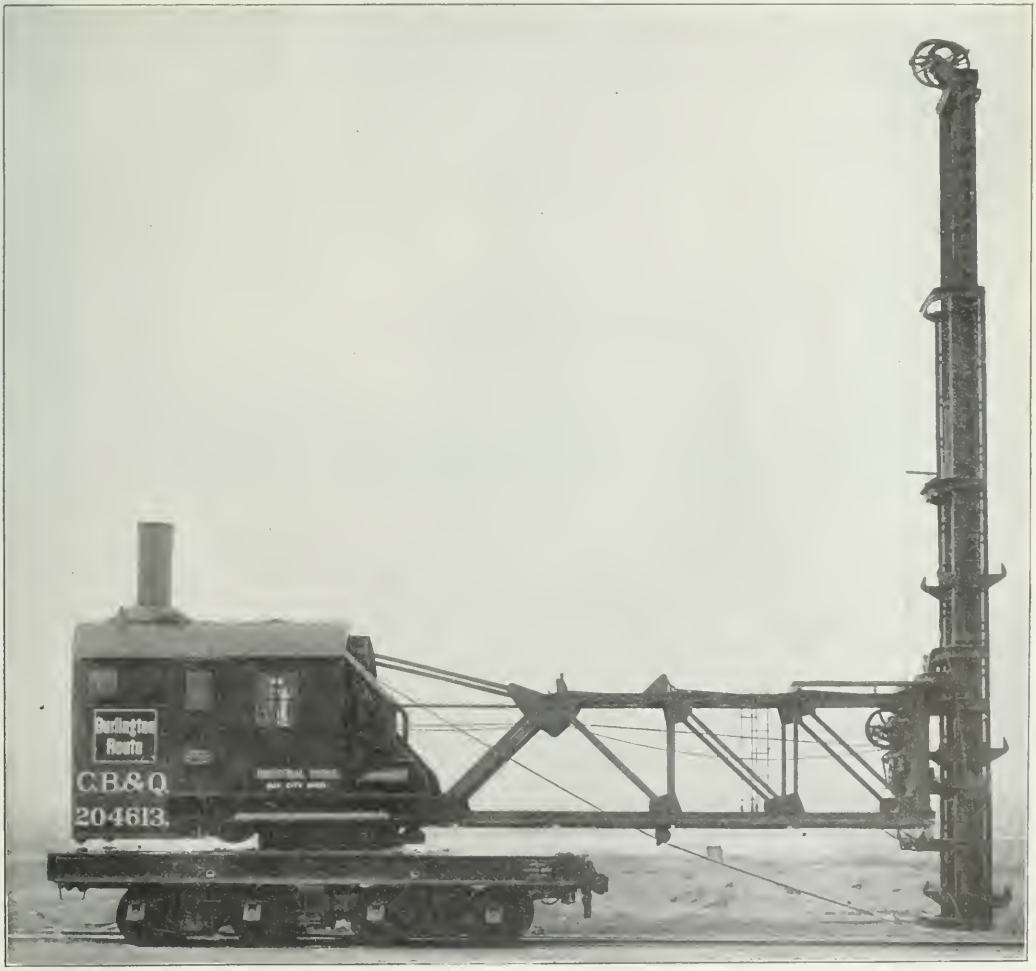
and write the English language and the rudiments of bookkeeping, so they can handle the reports required of them as section foremen. Anyone in close touch with foreigners realizes that they are quick to learn. I have found them eager to advance themselves if some one will take the time to direct and encourage their efforts. Once they become foremen, they are likely to settle down and their efforts are an asset to their employers.

In the South, where negro labor is used largely, there is practically no opportunity to recruit foremen from trackmen. The railways in the Southwest have been having success with Mexicans and some Indians during the past years, especially so as sectionmen, but for the most part they are not aggressive enough to promise much as future foremen. Japanese and some Chinese on the Pacific coast do not offer much in any grade above that of laboring men. On most all the roads foremen are of American birth, with some Italians. It is necessary therefore to develop foremen in the favorable localities and transfer them at an increase of salary sufficient to meet the conditions.

It is possible since the introduction of automatic track circuit signals, interlocking plants and other signal devices that the maintenance forces can be combined under one foreman's supervision. This is practical on territory subjected to heavy traffic, where several departments patrol the same sections to inspect and make minor repairs. In such a combination we could draw on any of the various departments for a foreman and get a broader man, at the same time eliminating the friction between departments. Such an organization has been successfully tried out locally, in a small way, so that several trunk lines are contemplating such a move where traffic is heavy. It seems very reasonable to predict that such a maintenance organization will work out and in the end be a decided improvement over the present system. If such can be made a universal success, we have our foremen problem solved.

A CONVERTIBLE LOCOMOTIVE CRANE PILE DRIVER.

A combination locomotive crane and pile driver has recently been developed by the Industrial Works, Bay City, Mich., for the use of railroads and contractors requiring a pile driver only a portion of the time. As shown in the photograph, this is not a crane with leaders suspended from the boom, but is a com-



New Convertible Locomotive Crane Pile Driver.

plete pile driver with a built-up leader truss, a battering attachment and regular leaders. Ordinary locomotive cranes are frequently equipped with steam hammers, either with or without leaders, and good results are obtained where the service is not too severe or where it is not necessary to drive the piles on a batter. However, such a combination is not sufficiently rigid to be able to force into position and hold upright while driving, a pile that is not inclined to drive straight. It is to overcome these objections that this new driver has been designed.

The construction of this machine does not differ in any important detail from that of a regular 30-ton crane. The 24-ft. car is built entirely of steel and is equipped with standard draft rigging, complete air brake equipment and telescopic outriggers. A boiler of large steam capacity is provided to meet the demands of varying conditions of service. All of the important castings are of steel and all of the gears are either of cast steel or bronze. The operations and functions are the usual ones of a locomotive crane, making it available for use with a hook, lifting magnet, grab bucket, etc.

As a pile driver, the distinctive feature is the leader truss, which is easily substituted in the place of the regular crane boom. This truss is constructed of structural shapes and is fastened to the crane by a steel pin and tension rods. At the outer end is provided the support for the leaders and the battering attachment. The leaders are self supporting and are of all steel construction similar to those on ordinary pile drivers but correspondingly lighter. All of the operating movements are power driven, it being possible to raise or lower the leaders in a few seconds. The adjustment for battering is made by hand by means of a crank and gearing.

This machine will drive piles 29 ft. either side of the center of the track or 21 ft. ahead of the wheel base without the use of outriggers or blocking, and because of the full circle swing it will work equally well at either end of the car. The machine shown is a 30-ton crane built for the Chicago, Burlington & Quincy. Similar arrangements can also be provided on the larger size cranes, thus making them available for a greater variety of service.

DETAILED SUPERVISION ESSENTIAL TO SAFETY OF MEN.*

By G. R. Talcott,

Assistant Division Engineer, Baltimore & Ohio, Baltimore, Md.

Although it is not generally considered that the risk of personal injury is great in maintenance of way work, a large number of accidents occur which are primarily due to carelessness or ignorance, and are, therefore, preventable. General instructions covering the conduct of employees do not accomplish the desired result unless the men themselves, and especially the foremen, are impressed with the importance of protecting their men and themselves from personal injury. Instructions requiring foremen to blow a shrill whistle to notify the men of the approach of trains, and requiring the men to stand clear of all running tracks while trains are passing, have brought good results. When working around yards and terminals, constant vigilance on the part of the foreman is necessary and in addition to giving a warning signal, he should each time designate the place the men are to stand in the clear, and the men should thoroughly understand that this will be done. A foreman's qualifications in this respect should be one of the important considerations governing his selection for yard and terminal work.

The use of worn out or broken tools causes accidents which are entirely preventable. The use of such tools is not desirable from any point of view, and the men should be encouraged to report such defects to the foreman as soon as discovered. The elimination of dangerous physical conditions along the road is an important part of a general safety movement, and increases the safety of maintenance of way employees as well as of other employees and the public. While the introduction of special devices and appliances will promote safety in specific cases, the greatest good is to be accomplished by education, which can best be attained by periodical meetings of the division engineer or roadmaster, as the case may be, with the supervisors, followed by meetings of the supervisors with the foremen. These meetings need not be safety meetings primarily, but for the discussion of all matters pertaining to the work with safety as a subject to be reported on. When once an interest is aroused, numbers of small risks taken by the men will become apparent which would otherwise escape notice until an accident resulted.

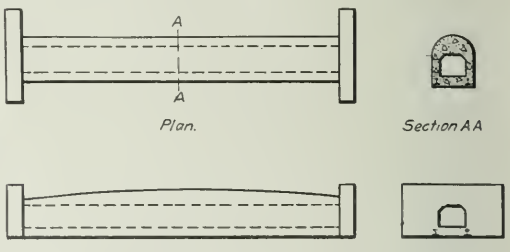
*Received in the Safety contest which closed October 25, 1912.

A SMALL MONOLITHIC CULVERT.

By C. T. Musgrave,

General Foreman, Bridges and Buildings, Oregon Short Line, Idaho Falls, Idaho.

The accompanying plan shows a type of culvert which has been built in several instances on the Montana division of the Oregon Short Line. This culvert is built monolithic, with two scrap rails in the lower corners for reinforcement. Where the inside width does not exceed 20 in. a culvert of this kind can be put in without stopping traffic, as it is not necessary to take out more than one tie, and the excavating can be done, the concrete poured and covered over, and the tie replaced in a few hours. A wooden form was used for these culverts, in which the bracing could be knocked out with a long pole, allowing the sides to collapse. The estimated cost for such a culvert 22 ft. long with end walls was $100.



Small Monolithic Concrete Box on Oregon Short Line.

Three of these culverts have now been in service over two years and are still in perfect condition. One of them was built in a swamp with the top within 2 ft. of the rail at a point where it has been difficult to maintain any kind of pipe under the pounding of trains which drove it down in the center while the frost raised the ends. This culvert replaced a timber box, the middle of which has been driven down more than a foot below the ends.

TEN STATES PRODUCE BULK OF PORTLAND CEMENT.

The production of Portland cement in 1912 in the United States was 82,438,096 barrels. This production was reported from twenty-four states, the first ten states, namely, Pennsylvania, Indiana, California, New York, Missouri, Illinois, New Jersey, Michigan, Iowa and Kansas given in the order of their importance reported 69,682,321 barrels, or about 85 per cent. of the total. These states ranged in production from 26,441,338 barrels in Pennsylvania, or over 32 per cent., to 3,225,040 barrels in Kansas, or about 4 per cent. of the total. Indiana, the second largest producing state, reported 9,924,124 barrels, or 12 per cent., and California, the third state, reported 5,974,299 barrels or over 7 per cent. of the total. These first three states reported over one-half of the total production.

NEW TIMBER TREATING PLANT OF THE B. & O.

A Modern Installation Recently Placed in Service at Green Spring, W. Va. A Number of Original Features Introduced.

By F. J. Angier,

Superintendent of Timber Preservation, Baltimore & Ohio System, Baltimore, Md.

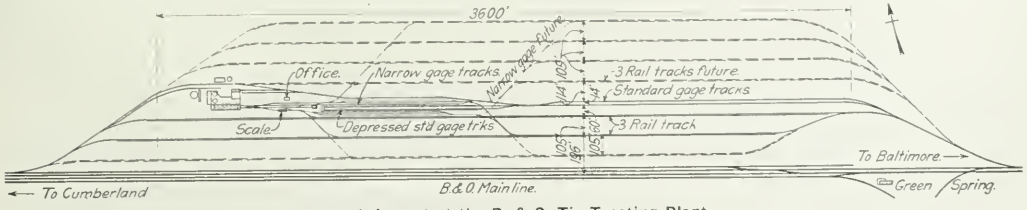
The Baltimore & Ohio has put into operation a new timber treating plant which has just been completed at Green Spring, W. Va., and which is one of the most complete and modern timber treating plants in America. It covers 60 acres and is situated close to large areas of timberland along the South Branch valley of the Potomac river. The requirements of the Baltimore & Ohio system approximate 2,500,000 ties annually for renewals, and with the new plant in operation a large proportion of these ties will be treated by the company. Other timber for railroad use will also be treated here.

The plant is equipped with two cylinders 7 ft. in diameter and 132 ft. long, made of ¾ in. steel and built for a working pressure of 175 lbs. per sq. in. Each of the retorts rests on nine concrete piers and is securely anchored to a center pier with six 1¼ in. bolts. On the remaining eight piers the retort rests on cast steel saddles, and between the saddles and an iron plate imbedded in the concrete are nests of steel rollers, each nest being made of three rollers 2 in. in diameter and 10 in. long.

The retort doors swing on steel rollers and can be opened and closed easily by one man, notwithstanding their weight of 6,400 lbs. each. The doors are steel frames with flanged steel dished heads 1 in. thick. The retorts are equipped with heating coils and also with perforated pipes. The pipes are inserted to obtain a more perfect distribution of steam when green timber is being artificially seasoned as well as for the circulating device used in the Card process.

Track Layout and Tie Yard at New B. & O. Treating Plant.

The main building of the plant is of steel frame construction with corrugatd iron sides and concrete roof. The floors are of concrete and a concrete basement is provided so that should any of the preservative be spilled it can be recovered. In the basement is a concrete sump equipped with an electric device which indicates to the engineer in charge when the sump is filled. The sump is emptied by means of an ejector, the liquid passing into a settling tank about 50 ft. from the building. The settling tank is also of concrete, 20 ft. wide, 50 ft. long and approximately 10 ft. deep. The tank has four compartments, the drain-



Track Layout at the B. & O. Tie Treating Plant.

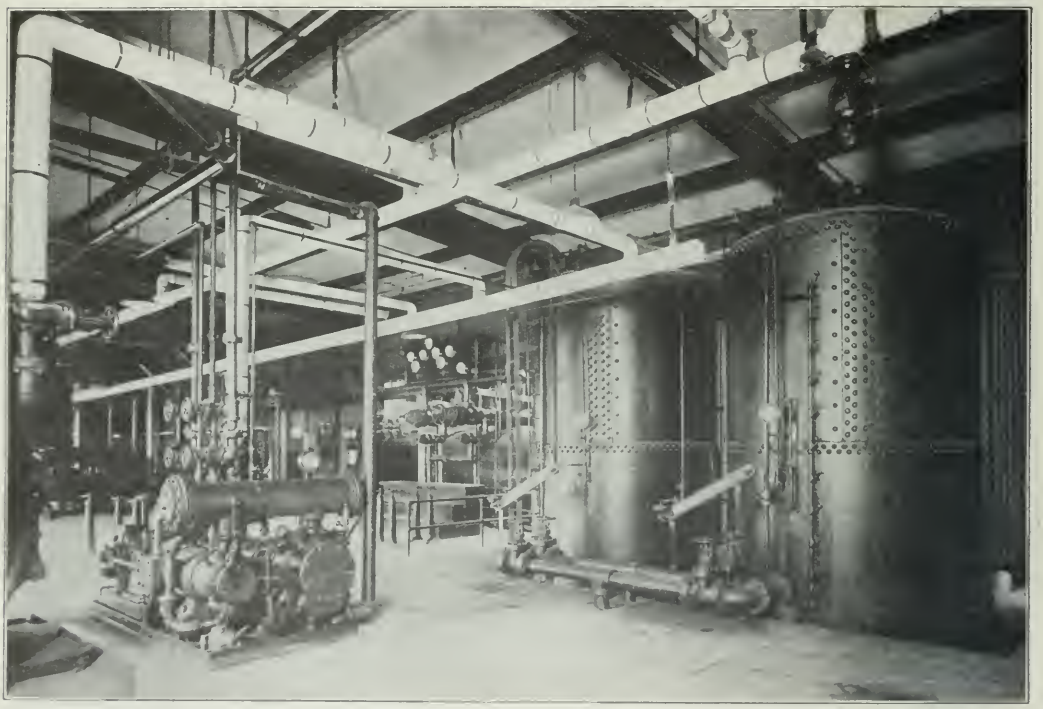
ings from the plant entering one compartment and passing through each of the others in a circuitous path to the last compartment. By this time any creosote carried from the plant falls to the bottom, because of its greater specific gravity, and enters a well in the bottom of the last compartment. Here a bilge pump, operated by electricity, picks it up and carries it to an underground tank from which it is carried into the working tanks by compressed air.

The boiler room is adjacent to the main building, being 30 ft. wide and 40 ft. long. It contains two horizontal return tubular boilers of 150 h. p. each, built for 125 lbs. per sq. in. working pressure, and space is provided for a third boiler to be installed when required. A boiler feed heater, injector and feed water pump complete the equipment in the boiler room.

The oil storage tank is 40 ft. in diameter by 30 ft. high, having a total capacity of 280,000 gal. There is also a storage tank for a concentrated solution of zinc-chloride, which is 15 ft. in diameter by 20 ft. high, with a capacity of 25,000 gal. The oil storage tank is equipped with a system of heating coils made in four sections, the combined heating surface of which is 500 sq. ft. An angle stem thermometer is placed in the side of this tank to enable the oil to be kept at a constant temperature of about 120 deg. F.

Near the storage tank is an underground unloading tank, 6 ft. in diameter by 60 ft. long, enclosed in a concrete pit, to prevent waste of the creosote if leakage occurs. The tank will withstand an air pressure of 50 lbs. per sq. in., and creosote is forced from this tank into the storage or working tanks by air also. The working tanks and pressure tanks are all located inside the building, so that they can be kept warm and the temperature of the working solution retained at 190 deg. The working tanks are each 24 ft. in diameter and 20 ft. high, with a capacity of 68,000 gal. Each tank is equipped with mercury gages, syphon regulators and dial thermometers. The location of these tanks inside the building also effects a further economy in the consumption of fuel, particularly in cold weather.

The working tanks are 24 ft. in diameter by 20 ft. high, each having a capacity of about 68,000 gal. They rest on concrete foundations 6 ft. above the floor line, being equipped with cast iron radiators for heating the solution. Each tank has three sets of radiators working independently. The combined heating surface of the radiators is 441 sq. ft. Each tank is also equipped with air coils for agitating a mixed solution of creosote and zinc chloride. Air is admitted at 100 lbs. pressure and distributed in such manner as to completely mix the solution in from two to five minutes. The tanks have mercury gages which show the true reading in tub feet and gallons, regardless of the temperature. This avoids the necessity of making correction for temperature readings. Besides the mercury gages each tank has a syphon regulator which regulates the steam supply to the radiators and automatically opens and closes the steam supply valve in maintaining the required temperature.



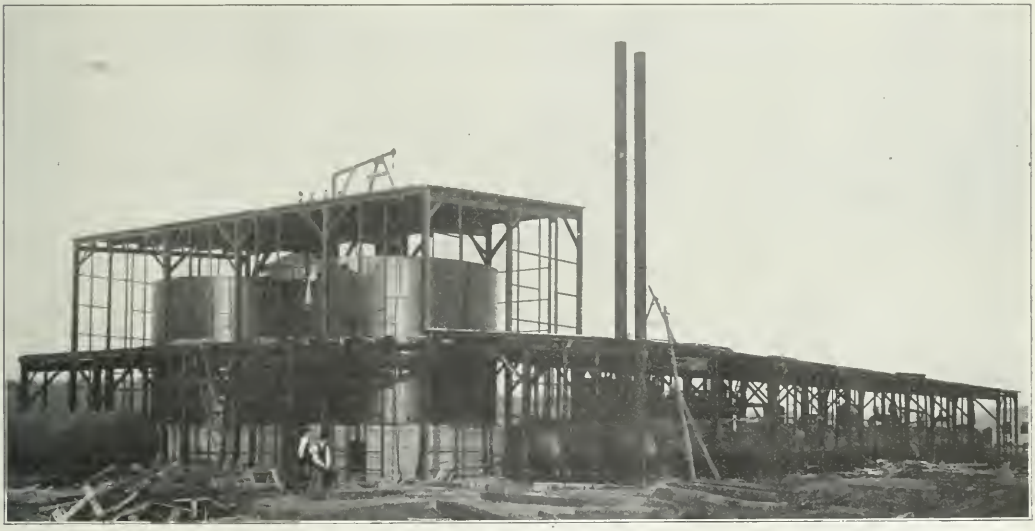
Interior of Treating Plant Showing Combination Measuring Tanks on the Right and Retort in the Background.

The pressure tanks are 8 ft. in diameter and 14 ft. high, made of 7/8 in. steel for a working pressure of 175 lbs. They are in reality a combination of pressure, measuring and drain tanks, and are located in such a way that they are readily filled while the treating cylinders are being filled preparatory to treating a charge of timber. Compressed air is then applied through the top of these pressure tanks and the preservative is forced through a pipe in the bottom connected with the cylinders. Pressure is maintained until the required absorption is obtained in the timber, after which the valve is closed and any preservative remaining in the tank can be returned to the working tank by means of the compressed air already in the pressure tank.

There is also a sufficient amount of compressed air in this tank to force all of the solution in the treating cylinder back to the working tank. The tanks are also used for measuring purposes, being equipped with mercury indicators which show the amount of solution, and thus inform the engineer as to the amount of solution going into the timber he is treating. They are also used as drain tanks to catch and measure the solution taken from the timber during the vacuum and draining process. The bottoms of the pressure tanks are only slightly lower than the treating cylinders, and though all of the drainings from the charge would not flow into the pressure tank by gravity, this is easily and quickly accomplished by admitting atmospheric pressure to the treating cylinder, while the pressure tank still contains a vacuum. This combination of pressure-measuring-drain tank is unique with the plant at Green Spring. It was worked out by the writer, assisted by Messrs. Card and McArdle, who were the draftsmen in getting out the pipe plans. This plant has now been in operation about two months, and these tanks have worked very successfully. It has been found that large

ratory. The experimental cylinder is 30 in. in diameter and 9½ ft. long, or large enough to hold three or four ties. There are two working or pressure tanks, underground drain tank, pressure pumps and electric centrifugal pump. The tanks are equipped with the latest gages and thermometers, and the entire plant is so designed that any process can be used and pressure can be supplied as high as 300 lbs. The chemical laboratory adjoins the physical laboratory, and creosote distillations, zinc-chloride analyses, etc., will be made.

The office building is of concrete, and is fireproof in its entire construction, as are all the other buildings in the plant. The hose and engine houses are of wood, but these are small and located some distance from the other buildings. A fire system has been installed, and a fire department will be organized among the employees, which will be similar to that at large terminals, shops and other centers on the Baltimore & Ohio. A 6-in. water main has been laid the entire length of the tie yard and there is a hydrant every 300 ft. The hose house is near the office and is equipped with a reel of 300 ft. of hose. Water pressure for fire



Main Building During Construction, Showing Cylinders and Inside Oil Tanks.

oak ties can be treated to absolute penetration by the Card process in six hours, with an injection of from 14 to 16 lbs. of solution per cu. ft. It eliminates entirely the dirty and expensive pressure pumps commonly in use in timber treating plants.

Recording gages and recording thermometers are connected to the treating cylinders. This places the superintendent in complete touch with the treatment in all of its details, the charts indicating the temperature, pressure and vacuum recorded for every moment the plant is in operation.

The plant is heated throughout by steam, the vacuum system being used, all condensation being returned to the boiler feed heater and thence to the boilers. A 50 k. w. generator furnishes the light for the plant and the yard, there being three arc lamps and about 50 incandescent lamps in the system. The electric plant also furnishes current to operate two 10 h. p. centrifugal pumps and a one h. p. bilge pump. Eight inch centrifugal pumps are used to circulate the mixture of creosote and zinc-chloride in the retorts while using the Card process. The latter is placed in the settling tank and is used to pump creosote into the underground unloading tank.

An experimental plant is situated adjacent to the main building. This plant consists of a complete physical and chemical labo-

emergency is maintained by a high 50,000-gal. water tank kept filled at all times.

At the present time the water used in the timber treating plant is being pumped from the Potomac river, but this arrangement is but temporary until a permanent joint system can be built for the timber treating plant and for supplying water to locomotives in train service. The permanent water plant calls for two pumps located at the plant in a concrete well about 100 ft. below the surface of the ground. The depression was deemed necessary on account of the lift from the river. Water will be pumped into the high storage tanks and fed by gravity throughout the plant and yard.

Practically all of the ties treated at the plant to date have been oak, the number being approximately 200,000. The standard tie in use on the Baltimore & Ohio is 7 in. x 8 in., and 8½ ft. long, containing 3⅓ cu. ft. These ties are unloaded and cribbed in piles of seven and one, and are handled by piecework. It is the intention to air-season all ties. However, if they are not received in quantities sufficient to properly air-season, the plant is designed to give a preliminary steaming and vacuum before the injection of preservatives.

All storage yard tracks have three rails, the outside pair being

of standard gage and the inside rail fixing a 30 in. gage for the tram cars. In loading for treatment the ties are classified as hard and soft woods, and as No. 1 and No. 2. For this work the men are paid at a rate per tram instead of per tie, as in the case of unloading and cribbing for seasoning. Thus it makes no difference whether there are 30 or 40 ties on a tram, the cubical contents are practically the same and the amount paid is the same. One hundred and thirty tie cars are used to deliver the ties to and from the treating cylinders.

The cars are moved with a narrow gage locomotive, to which is

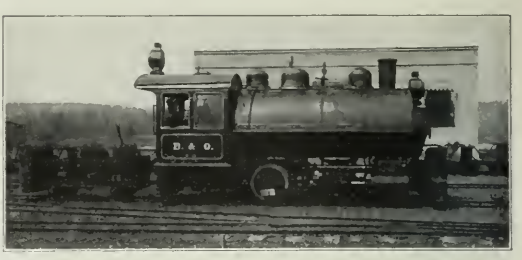
Concrete Settling Tank for Collection of Creosote.

attached a bumper car as shown in the accompanying photograph. This car is also thought to be original with this plant. It carries two drums, each carrying 150 ft. of 5/8 in. wire cable. The cable from one drum passes underneath the engine out through the front bumper, and the other passes back through the back bumper. The engineer sitting in the cab can tighten the cable at any point along its length by means of cam and lever, and the switchman can pull out 10 ft., 50 ft. or 150 ft., as required. The cable is hooked to the links provided in the little tram cars, one

Power House, Sump, Retort Building and Storage Tanks.

of which can be seen in the little car just at one side and in front of the locomotive. An entire charge can be switched to any point in the yard by means of this arrangement

The location of the timber treating plant is believed to be admirably suited for all purposes, being in near proximity to large timber areas. Green Spring is at the junction of the main line of the Baltimore & Ohio system, with the Romney branch, which extends 16 miles to Romney, W. Va., and the Hampshire Southern Railroad, extending 38 miles farther to Petersburg, tapping a timber tract of several thousand acres, much of it being virgin timber. The outlet for all timber adjacent to the lines men-

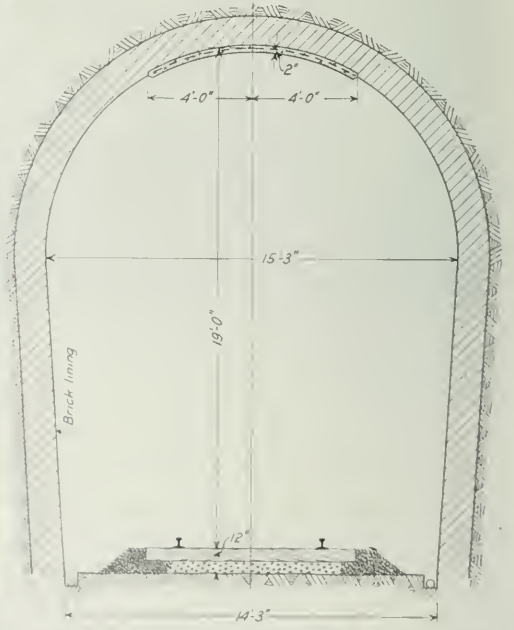


Narrow Gage Locomotive and Bumper Car.

tioned is by way of Green Spring, so it is merely a question of stopping the timber at the plant to have it seasoned and treated.

REPAIRING A TUNNEL LINING WITH A CEMENT GUN.

The brick lining in the single-track tunnel on the Chicago, Milwaukee & St. Paul, near Tunnel City, Wis., was repaired in an unusual manner last summer. This tunnel is located on the La Crosse division, on the double-track main line between Chicago and St. Paul. This line handles a very heavy traffic, there



Cross-Section of Chicago, Milwaukee & St. Paul Tunnel Showing Concrete Protection.

being an average of 32 train movements per day at this point during the period that the work was under way. The tunnel is located on the ruling grade and all tonnage freights are operated with pushers. The fact that both engines are worked to capacity has caused unusual wear of the lining by the locomotive blasts, and the doubling back of the pusher locomotives greatly

increases the number of movements. The old tunnel, which is 1,330 ft. long, was built in 1872, and was lined with brick, the arch having four rings. The mortar filling in the roof of the tunnel had been so damaged and the lower course of bricks so worn away as to make necessary some repair to the strip over the center line of the track to prevent the possibility of bricks falling out. The method adopted was to place a cement coat over a strip 8 ft. wide by the use of the cement gun, and the results secured have been very satisfactory.

It was the intention to place a coat of concrete which would extend 2 in. below the old face of the lining, making the total thickness from 4 to 6 in. in some places where the wear of the bricks had been most severe. The concrete never extended into the old lining for a distance greater than the thickness of one brick. Before placing the concrete, the surface was cleaned with a sand blast which was also handled by the cement gun, the water and cement, of course, being omitted for this process. The sand used both for cleaning and for the cement was the same as that used for ordinary concrete in that locality. It was dried and screened to remove pebbles and to prevent the clogging of the gun nozzle the water was also put through a wire gauze screen before going into the supply barrel. It was planned to use a ¼ in. square mesh wire reinforcement for the concrete coating, and some of this material was used at the beginning of the work. It was found, however, that this mesh was too small for the best results, and No. 4 American Steel & Wire triangular mesh reinforcement was substituted. This was cut to 8 ft. lengths and placed at right angles to the tunnel axis. From two to five coats of cement were required, depending on the thickness necessary.

In planning for this work it was thought that some form of shield would be necessary to protect the newly placed cement from locomotive blasts until it had thoroughly set. A movable shield to be supported from the roof was accordingly built and was used at the beginning of the work. It was soon found, however, that the cement placed by the gun was so hard immediately after placing that the locomotive blast had no effect upon it and the use of the shield was accordingly discontinued. Weep holes were drilled through the old brick lining near the edge of the concrete coating to allow water above the arch ring to escape and prevent its freezing there.

The air compressor plant was located at the east portal, a 2 in. air pipe being carried through the tunnel with connections at frequent intervals, to which rubber hose for operating the gun could be attached. The air was dried at the condensing plant to eliminate condensation in the pipe line. A water line was also carried through the tunnel to supply water at the gun nozzle. The plant at the portal also included a generator used for lighting the tunnel. Lighting wires were carried through the tunnel which could be tapped wherever necessary to provide illumination at the point where work was being carried on. Both the compressor and the generator were driven by gasolene engines.

The cement gun and the mixing board were carried on staging supported by two standard gage cars coupled together. A Fairbanks-Morse gasolene locomotive operating on a 2 ft. gage track having one rail in common with the main track was used to push this staging in and out of the tunnel. It was necessary to remove the entire outfit to a siding near the east portal for every train movement. For the protection of trains and also to enable the work of placing the cement to be carried on as long as possible between train movements, an operator was stationed at the east end of the tunnel and a flagman at the west end, both of whom were provided with telephones cut in on the despatcher's line. The despatcher notified the operator whenever a train entered an adjacent block and such train was held in that block until the track in the tunnel had been cleared.

The work was carried on for about two months, the progress being about 210 ft. a week. Two 10-hour shifts were used for six days in the week. The total cost, including labor and material, installation of the plant and preliminary cleaning was 23 cents per sq. ft. of protection placed.

This work was carried out under the general supervision of C. F. Loweth, chief engineer, Chicago, Milwaukee & St. Paul. L. D. Hadwen, engineer of masonry construction, was in charge of the plans for and execution of the work, and F. E. King, assistant engineer, directed the work at the tunnel.

A LOCAL SAFETY COMMITTEE.*

By F. Dohr,

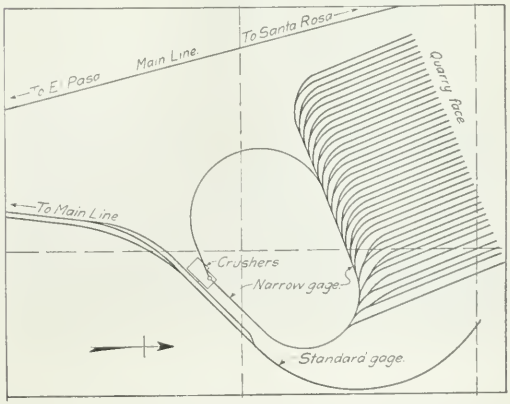
Section Foreman, Chicago & North Western, Chicago.

About two years ago the roadmaster of the Chicago & North Western Chicago terminals appointed four of his section foremen as a safety committee in the terminal, arranging it so that none of the foremen went over his own section. The first time that these men went out on an inspection trip over the sections they were surprised at what they saw. They found safety blocking out of guard rails, switches and frogs, and found old rails, ties, draw bars, side doors and all kinds of old scrap lying around the tracks. There was also considerable old material piled so near the track that no one could walk alongside of the cars. This committee made a report to the roadmaster, who in turn reported to the central safety committee, sending a copy of his report to all his section foremen. At first some of the foremen did not like this, but the reports were continued each month and soon some sections were reported without criticism since when all the men have come into line and when the committee now goes over the territory a great improvement is noted and the yard looks 100 per cent. better than when the committee started its work.

*Received in the Safety contest which closed October 25, 1912.

BALLAST CRUSHING PLANT OF THE EL PASO & SOUTHWESTERN.

The El Paso & Southwestern operates a stone quarry for the preparation of ballast at Tecolote, N. M., on the Eastern division, 177 miles east of El Paso, which is of interest to railway men because of its arrangement and also for the highly creditable results secured. The crushing equipment consists of one No. 8, one No. 7½ and one No. 5 gyratory crushers. Stone is delivered to the crushers from the quarry by the system of



Track Layout at E. P. & S. W. Tecoloto Quarry.

tracks indicated on the accompanying plan. The primary quarry track is oval in shape, the front side of the oval passing over the top of the No. 8 and the No. 7½ crushers. The rear side of the oval lies parallel to the quarry face. This track begins to drop from the crushers on a 2½ per cent. grade which diminishes to a 1 per cent. grade on the rear side of the oval, this grade continu-

ing around to a point on the front side of the oval adjacent to the No. 8 crusher, at which point the track rises on an incline of 1 in 3, the difference in elevation from the bottom to the top of the incline being 20 ft. On the rear side of the oval, spur tracks lead off approximately at right angles to the face of the quarry, these tracks being on a level grade and extended as the quarry face recedes. The gauge of the tracks is 3 ft.

The quarry cars are all steel cars of 3 cu. yds. capacity, dumping from both sides directly into the hopper of the crusher. They

View Looking Towards Quarry Face.

run by gravity from the crusher, around the oval to the foot of the incline. On the rear side of the oval they are intercepted by the men loading the rock and switched out to the quarry face. After being loaded they are pushed back to the oval track and resume their gravity run to the foot of the incline, where they drop into a pocket, are automatically picked up by the chain hoist of the incline and also automatically released at the top.

The rock is loaded into the cars at the quarry face by contract at 25 cents per car, from 15 to 20 cu. yds. of ballast being loaded per nine hours per man actually engaged in loading. The quarry

Crushing Plant with Cars Ascending to Crusher.

face is about 20 ft high. Drilling is done with air, the holes being sunk to the floor of the quarry in one drilling. The rock is a very hard limestone, broken to ballast of a maximum size of 2 in. It is elevated from the crushers to bins and loaded by gravity from the latter into Rogers ballast cars, which are spotted on the track above the ballast bins and are dropped by gravity to and away from the bins as required, one switching per day only being required for this service.

During the working seasons of 1910, 1911 and 1912, comprising 365 days actual working time, 254,272 cu. yds. of ballast were produced, averaging 700 cu. yds. per day. During the first 105 working days in 1910, the average daily output was 900 cu. yds., during which time the average cost of ballast on board the cars at the crusher was $0.30314, the maximum for one month being $0.34612 and the minimum $0.24363 per cu. yd. During this time the total cost of finished ballast in the track was $0.56522, the maximum for one month being $0.61072 and the minimum $0.48214. This was with a short haul of 40.3 miles and the common labor at $1.25 per day. During the seasons of 1911 and 1912, common labor advanced to $1.50 per day and the average total haul for all time to 94.3 miles. The average cost per cu. yd. of ballast on board the cars at the crusher for the entire work was $0.40541, and the average total cost of completed ballast in the track was $0.74352. All figures herein include total cost of maintenance and operation in producing ballast and finishing it in the track, but they do not include cost of inserting new ties and gaging track. The detailed cost data for finishing the entire 254,272 cu. yds. of ballast in the track, averaging 2,500 cu. yds. per mile of single track, are as follows:

	Total cost.	Cost per cu. yd.
Superintendence	$4,441.20	$0.01747
Drilling and blasting	5,934.68	0.02334
Powder	18,143.10	0.07135
Loading in quarry	34,308.12	0.13492
Haul to crusher	10,587.66	0.04164
Crushing	18,190.55	0.07154
Tools and supplies	11,490.57	0.04515
Opening track	11,244.24	0.04422
Haul to track	34,846.45	0.13704
Unloading	1,542.48	0.00606
Raising track	16,964.05	0.06672
Lining, surfacing and dressing	21,365.10	0.08402
Total cost	$189,058.20	
Cost per cu. yd.	$0.74352	
Cubic yards	254,272.00	
Average haul in miles	94.30	

A NEW SPIKE PULLER.

The spike puller illustrated in the accompanying cuts has been invented by J. E. Jones, Carneyville, Wyo., and is being used on one of the western divisions of the Chicago, Burlington & Quincy. The principal advantage of this puller over a claw bar is that it will pull a spike straight up, eliminating the friction caused by the bending of the spike and leaving the old

Spike Puller for Track Spikes.

spikes in condition to be redriven. A straight pull also causes less damage to the tie than is the case when the spike is pulled to one side, greatly enlarging the old hole. The device is easily attached to the spike and has a very short lever arm from the support on the head of the rail to the grip on the tie, allowing the spike to be pulled without exerting an excessive effort at the end of the bar. The length of the bar is about 30 in. The device complete weighs about 10¼ lb. On account of the fact that leverage is secured on the head of the rail, this device can be used to pull spikes between main rails and guard rails at frogs or crossings as easily as in other locations.

RENEWING TWO SWING SPANS UNDER TRAFFIC.

Use of Open Timber Caissons in Building Concrete Piers for Grand Trunk Bridges at Lacolle, Que., and Portland, Me.

During the year 1912 the Grand Trunk renewed two single track swing bridges, one at Lacolle, Que., over the Richelieu river which is the northern outlet of Lake Champlain and the other at Portland, Me., over Back Cove bay, both renewals being undertaken in order to strengthen the bridges to accommodate the heavier motive power now in use. Coopers E 50 loading was used in the design.

RICHELIEU RIVER BRIDGE.

The Richelieu river bridge originally consisted of a swing span 180 ft. long, with two clear channels of 73 ft. each, with a pile

Fig. 1—Motor Boat Towing a Barge of Rock for Riprap.

trestle approach 500 ft. long on the west end and one 350 ft. long on the east end. The center and rest piers under the swing span consisted of timber cribs filled with rubble stone surrounding the supporting piles which were capped with timber grillages on which were carried concrete tops. The center pier was 26 ft. square and 33 ft. high. In renewing this pier a double wall caisson 38 ft. square over all, built up of 10 in. by 10 in. horizontal wall timbers and 12 in. by 12 in. vertical timbers, was sunk around the old pier, leaving a space between it and the old crib of 3 ft. 2 in. This caisson rested on a heavy shoe, the outside edge of which was vertical and the inside beveled at an angle of 45 deg. The shoe was made up of a longitudinal 10 in. by 14 in. oak timber beveled to form a cutting edge, and upon it two transverse sections of 12 in. by 12 in. timbers also beveled and all drift bolted together.

The caisson of the center pier and all the double wall caissons, were sunk by filling the 12 in. space between the walls with concrete. If one or more points reached a firm bearing with the caisson level before other points touched the bottom, an even bearing was secured by filling in bags of concrete placed by a diver. After the bottoms were sealed with this concrete, loose concrete was placed between the caisson and the old crib by means of a bottom dump bucket.

When the 3 ft. 2 in. wall of the center pier was filled up to approximately 3 ft. below low water level, reinforced concrete walls were carried up on this wall to the top of the old pier to support the 11 by 26 in. 166 lb. special I beams on which the swing span was carried during the completion of the pier. The reinforcement consisted of ¾ in. and 1 in. twisted rods placed as shown in the accompanying cut.

It was originally intended to complete the center pier by cleaning out all the rubble stone filling in the old crib one pocket at a time, but this was found to be impracticable owing to the slaty character of the rock foundation which made unwatering almost impossible. Instead of unwatering the pier, water was pumped into it creating a head of about 3 ft., which was utilized in forcing a 1:2 mortar through the voids in the rubble stone. This process was continued until all the voids were filled when the regular concrete was used. The mortar was deposited on the rubble by tremie. This method gave excellent results, as the concrete with the rubble stone as an aggregate resulted in a 1:3:5 proportion. The old concrete pier top was allowed to remain with the exception of the upper 18 in., which was broken up by blasting. The 108 cedar piles which supported the old pier top were also left in place, thus adding somewhat to the supporting power. The completed pier contained 1,620 yds. of concrete.

The new swing span is 250 ft. long providing two clear channels of 97 ft. each. It was erected on falsework driven under the old span. Construction work started January 1, 1912, and the new swing, the two rest piers and the outside portion of the center pier were completed March 20, 1912, in time for the opening of navigation. This work was handled during a very severe winter, some of the concrete being placed at temperatures as low as 20 deg. below zero. The center pier was protected during construction by steam pipes connected with a 30 h. p. boiler located on the old protection work. This boiler also supplied steam for the pumps.

All the protection piles and cribs of the old bridge had to be replaced, the new work consisting of six cribs built of 10 in. by 10 in. timbers loaded with rubble stone. These cribs are joined to each other and to the rest piers by floating booms. The booms consist of 12 in. by 12 in. timbers spaced 1½ in. apart by blocks, and bolted with 1⅛ in. bolts at intervals of 3 ft. These booms average 30 ft. long and are held in position by two 12 in. by 12 in. vertical timbers bolted to the cribs and rest piers.

The old center protection work below low water was allowed

Fig. 2—Framing Timber Caissons for Richelieu River Bridge.

to remain and after strengthening it by the addition of five new cribs, a continuous new top with a double row of walings was built. The center pier and protection work was built in 30 ft. of water.

The approaches to the new swing span consist of seven spans of 60 ft. each on the west and five spans of 60 ft. each on the east end. Deck plate girders resting on concrete piers have been used for these approaches. The three shore piers on the west end and the two shore piers on the east end were built with single wall caissons, the other seven piers being built with

double wall caissons similar to that used for the center pier. These double wall open caissons rest on a heavy shoe as described above. The 10 in. by 10 in. wall timbers were well caulked and pumping was started generally after about two-thirds of the concrete required below the elevation of low water was placed. The intermediate piers are practically 50 ft. long and 16 ft. wide. Both the upstream and downstream ends are pointed, the angles being 45 deg. and 30 deg. respectively.

The pier noses are protected by one-half in. plates. All the piers rest on the natural bottom of hard pan and slate rock, except two piers and one abutment, on the east end, where it was found necessary to drive piling. The foundations on natural bottom were well cleaned of the loose top material by a diver.

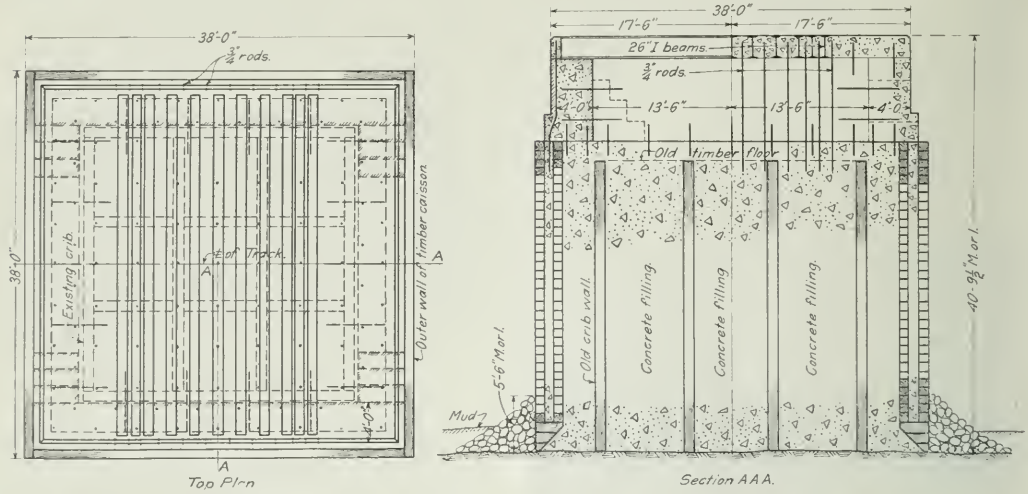


Fig. 3—Plan and Section of Caisson for Center Pier of Richelieu River Bridge.

Fig. 4—New Span in Place on Completed Rest Piers, Showing Construction of Center Pier and Protection Work.

Blasting was resorted to very frequently in removing large boulders that were in the path of the cutting edges of the caissons. All the old protection work, rest piers, and piles of the old trestle approaches were removed by blasting and generally the dynamite was placed by the diver. Rip-rapping was done quite extensively and as much as 5 ft. of rubble stone was placed around the lower edge of the caissons.

The concrete plant was located on the west bank between the main line and a standard gage material siding. All sand and stone was unloaded directly from this siding at a convenient distance from the mixer, the storage piles being covered. A one-half yd. cube mixer with side loader was used, steam being furnished by a 45 h.p. horizontal boiler. Exhaust steam from this plant was turned directly through the sand and stone and served to keep these materials sufficiently warm during the severe winter. A hoist alongside the mixer handled the buckets into which the concrete was dumped, placing them on narrow gage cars which were operated on a track from the mixer out across a temporary trestle alongside the bridge for its full length. While the river was open a 30 ft. motor boat with an 18 h.p. engine capable of making 15 miles per hour was used to very good advantage in towing barges and handling material to and from the bridge site.

Fig. 5—New Swing Span and Approaches at Lacolle, Que.

The twelve deck plate girders weighing 28 tons each were erected in 5½ days. The old pile bents were cut off below low steel, and the old bridge floor removed by a derrick. As the grade line was raised 3½ ft., temporary timber approaches were used at both ends.

BACK COVE BAY BRIDGE AT PORTLAND.

The work at Portland consisted of renewing a single track

bridge 225 ft. long, replacing the two rest piers and retopping the center pier. The grade line was raised 3 ft. at this bridge, requiring a new top on the old masonry center pier which proved to be in very good condition after 20 years of service. The same design of open caisson was used as that described above for the Richelieu river bridge. In this case the caissons were sunk through blue clay. One was driven to rock 42 ft. below high tide and the other to the same elevation being supported on piles driven inside the caisson as the rock at this point was 75 ft. below the old base of rail or 67 ft. below high tide. The concrete was deposited by bottom dump buckets under water and by tremie, special cars being taken to secure the best quality of work in order to withstand the action of sea water.

The piers were of concrete faced with granite masonry, thus insuring permanent results, as investigations showed that concrete suffered from frost owing to the variations in tide level. The difference between average low tide and average high tide at this point is 10 ft.

The J. S. Metcalf Co. Ltd., were the contractors for both bridges. The Dominion Steel Co. fabricated and erected the Richelieu river bridge and the Pennsylvania Steel Co. had the contract for the Back Cove bridge. The work was handled under the supervision of H. R. Safford, chief engineer, and R. Armour, masonry engineer, Albert Larsen being the resident engineer in direct charge of the work.

EFFICIENCY IN BRIDGE WORK.

By L. C. Lawton,

Division Engineer, Atchison, Topeka & Santa Fe, Newton, Kan.

It is not a paradox that some of our most successful superintendents or general foremen of bridges are making their individual gangs all-round workmen and specialists too. It is necessary that every regular bridge gang should be able to man a pile-driver, crib a bridge or build any kind of false work. One gang may do all the difficult driving, but if the gangs are assigned to certain districts, each one should be able to, and should have the opportunity to drive the bridges or false work on that division. It frequently happens that the best gang is caught away from the pile-driver during a washout and that is no time to break in a green gang and foreman, nor even for an experienced foreman to take men who are not trained. No doubt this has been impressed on many officials in the flood districts recently, especially where their permanent work has called for little use of a pile driver. In such cases the pile driver drill should be a part of their work, as the fire drill is of most shopmen.

Not only should each man be taught his place on the driver, but should be able to make a driver in short order from a hoisting engine and with swinging, or in a pinch, with no leads at all. In this way an old drop hammer would be all the extra equipment needed to carry on this work. We had an experience of this kind during the last year, when an old drop hammer was swung from the boom of a derrick car, and swinging leads made in a few hours, enabling us to drive false work for a steel bridge on a distant branch line when the regular driver was in the shop for repairs and no other could be secured. By so doing, we avoided tying up a very expensive steel gang.

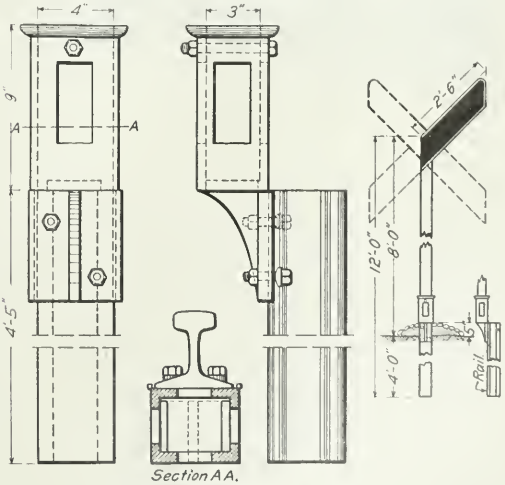
A part, at least, of each gang should also be familiar with cribbing. Every engineer knows how exasperating it is to get a gang of inexperienced men in water 4 to 6 ft. deep and with more or less current and start a crib. The chances are that they will build up without a foundation, or if one is started properly it will wash out or topple over when half completed. Few old time bridge men are left, and those of the present day are often only second rate carpenters and helpers, as the better men can get higher wages and an easier life in other work.

With reference to creating an efficient organization, I would not advocate an apprenticeship, but would suggest that all gangs have some drill in caring for bridges or track in case of flood, fire or other disaster. On the other hand each extra gang, and there should be several, should be specialists in their line. One or more, if needed, should do the building, and in this can be placed the best house carpenters that can be picked up. This will make a gang entirely unlike any other on the road and should be so. Another will be the concrete gang and, in a large part, composed of concrete laborers. Added to this will be one or more form carpenters, although it is often an advantage to use these men on light repair work in buildings when form building is not under way. After a little training, this gang can be used on rough false work at but little over the average wage for concrete work. This has been found much cheaper than contracting this class of work, as in any case, the company is responsible for the false work and usually keeps a bridge gang either on the work, or accessible to it. The concrete is often placed by our men in the time that was lost by the old method and the contract price saved. During the last few years much of the cut masonry placed when our road was built has shown signs of decay and is being replaced by monolithic concrete. The cost of false work varies in each job, but cost of labor in removing the old masonry runs from $1.50 to $2 per yd. on forms fifty to sixty cents, and of placing concrete $1.75 to $2 per cu. yd. The cost of embankment or foundation excavation varies greatly, running from $0.40 to $1.25 per yd.

Light repair work on both bridges and buildings is carried on by a small floating gang, either made up on a large district, by two or three men detached from the regular gang, or by a few men who accompany the bridge inspector and who go over the entire division in a month or six weeks. By having these light jobs, which need immediate attention, taken care of, the gang foreman can so plan his work as to move from one station to the next, or at least in the same direction all the time and avoid the expensive moving back and forth.

A REMOVABLE FLANGER SIGN.

The standard flanger sign of the New York Central & Hudson River is made in two pieces, the base being set in the ground permanently, and the upper, or sign, portion being removed during the summer when there is no occasion for its use along the track. The lower portion or base extends about 4 ft. below the ground, with a socket 9 in. long extending above

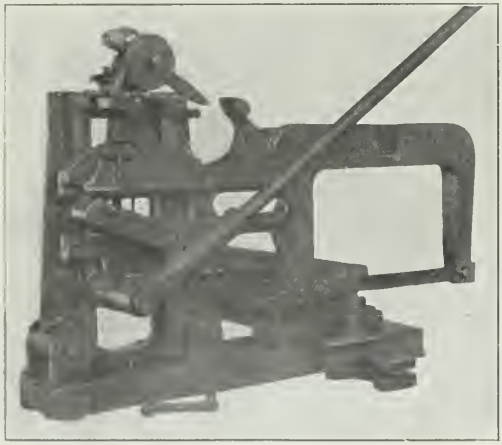


A Removable Flanger Sign.

ground into which the post of the sign is inserted, the latter being held in place by one bolt. When serving solely as a flanger sign, only one wing is put on, as shown solid on the drawing. Where the sign serves also as a snow plow wing sign, the upper arm on the left is added as shown in heavy dotted lines. At points where the flanger has to be raised and the wings of the snow plow closed in at the same time, a cross is used as indicated in light dotted lines. We are indebted to C. E. Lindsay, division engineer, for this information.

THE FLESTER RAIL SAW.

With the rapidly increasing use of open hearth rails the difficulty in cutting rails quickly and accurately has been greatly increased. To meet the demand for a saw to perform this work the Flester rail saw has been devised, an important feature of which is its positive automatic feed. This automatic feed is secured by means of a ratchet, the cam of which is moved at each stroke of the handle. The rate of speed is adjustable by a slide arrangement on the cam so that it can be changed as desired. In actual performance the lowest feed is used in cutting through the top of the rail, a much higher feed through the web, and a medium feed through the base. The saw is rigidly built so that



The Flester Rail Saw.

it does not vibrate in service and cuts clean. By removing a pin the saw can be adjusted to cut at any angle. By removing one bolt it can be tipped back to clear trains without disturbing the adjustment and when thrown back in position it will strike the same cut without breaking the teeth of the blade. A ring is inserted in the top of the saw over the center of gravity through which a handle can be placed enabling two men to carry it. The machine weighs 120 lbs. A test on the New York Central showed that the machine would cut through their standard high carbon rail in 125 min. while girder rails on the Interborough Rapid Transit Lines in New York have been cut in 145 min. This saw is sold by Flynt & Chester, 237 Lafayette street, New York City.

THE RINK HINGED RAIL STOP.

The accompanying photographs show a hinged rail stop which is designed especially for use on car floats, docks and terminal tracks and on tracks leading to car floats and transfer tables. The device is not intended to stop cars running at high speeds, but rather to prevent cars from starting because of impact shocks or wind. When in use, it is thrown up on the rail as shown, and if a through track is desired, the stop is easily thrown on its side.

The stop consists of three parts, a lower casting or bracket which is secured to the web of the rail by four bolts, the top casting which normally rests upon the head of the rail when in service, and a coil spring. The top casting is provided with a wedge protection and the face of the stop toward the wheel is also curved upward to offer resistance to a wheel climbing up on the stop. This casting is also provided with flanges projecting over both sides of the head of the rail to hold it in position. The coil spring opposes the longitudinal movement of the top

Rink Hinged Rail Stop in Service and Out of Service.

casting along the rail and serves to absorb the momentum and shock imparted to the device by a moving wheel. The friction between the stop and the rail is greatly increased by the weight of the wheel on the stop, and also materially assists in retarding the movement. One of these devices is placed on each rail when in use. This stop has been in service in tracks leading to the transfer table in shop yards of the Central R. R. of New Jersey at Elizabethport, N. J., for some time, and is also in use on tracks of the Lake Shore & Michigan Southern at Collinwood, Ohio. It was devised and patented by Geo. W. Rink, mechanical engineer, Central Railroad of New Jersey, Jersey City, N. J.

A PENNSYLVANIA WORK CAR.

By C. H. Thomas.

The accompanying photograph shows an old style passenger coach which the Pennsylvania has remodeled and is now using in the maintenance of way department. This car is fitted up at

A Pennsylvania Work Car.

the rear end with an office for the work train conductor. Back of this there are two rooms with seats on either side for the use of track hands and other laborers. A commissary is also located in this car.

General News.

The anti-noise campaign in Chicago is receiving the co-operation of the railways, several of which have promised their assistance by eliminating some of the whistling of locomotives and ringing of bells which the city council committee deems unnecessary.

The twenty-first annual meeting of the Society for the Promotion of Engineering Education will be held at Minneapolis June 24, 25 and 26. Among the papers to be presented will be one on the "Revision and Standardization of English Technical Terms."

An elevated railroad is being built in California at the Oakland terminal of the Southern Pacific—the only elevated railroad west of Chicago. The elevated line will be a double track structure with ballasted floor, 12 blocks (3,844 ft.) long, and will accommodate the suburban electric passenger trains.

The "Diamond Special" Express of the Illinois Central, northbound, was stopped by robbers about 13 miles south of Springfield, Ill., on the night of June 17, and the engineman was compelled to pull the express car some distance away from the passenger cars where a stop was made and the express messenger was overpowered and the safe blown open.

Special despatches from Washington say that the bill, or one of the bills, for the construction by the government of a railroad in Alaska, is to be urged for early passage in Congress, and that President Wilson has in a general way approved the project. The bill in its present shape will put the control of this enterprise in the hands of the president, the committee having cut out the provision for a special commission. The amount of bonds authorized to be issued, as now stated in the bill, is $40,000,000.

The bill to amend the Erdman Act, providing for conciliation and arbitration in controversies between interstate railroads and their employees, which was reported in the *Railway Age Gazette* last week, page 1328, is understood to have the approval of all important interests, the railroads, the officers of the railroad brotherhoods and the National Civic Federation; and a committee representing these different interests expects to have conferences with congressional committees at Washington this week, looking to early action.

"How to Repair and Maintain the Roads" is the title of a bulletin which has been issued by the Office of Public Roads of the Department of Agriculture. It does not treat the subject of road building, but takes up the repair and care of roads after they are built. All classes of roads, from the natural earth road to the macadam roads with bituminous surfacing, have received attention. The action of automobiles on road surfaces is explained. The systems of road management in Massachusetts, New York, England and France are given, with tables of costs.

The Public Service Commission of New York, for the First District, has written a letter to Governor Sulzer asking him to urge upon the special session of the Legislature, convened this week, to make an appropriation of $1,278,025 as the State's one-quarter of the estimated cost of eliminating grade crossings on the Atlantic Avenue Division of the Long Island Railroad, between the end of the present elevated structure and the westerly end of the Jamaica improvement. The commission sets forth the number of accidents which have occurred since the commission was organized, July 1, 1907. These include 15 fatalities and a large number of serious injuries. The conditions at the most dangerous of the crossings are set forth in detail.

Railway Terminal Discussion in Chicago.

New plans for the solution of the terminal problem in Chicago continue to be presented to the committee on terminals of the city council. The latest is that of William Drummond of the architectural firm of Guenzel & Drummond, who suggests a main trunk line at Englewood to be used by all through traffic entering from the south, and a three-sided loop with connections to handle the traffic from the west and north.

Following the Pennsylvania's ultimatum last week, to the effect that unless the road's plan for a west-side terminal is approved the present inadequate facilities will be continued indefinitely, the council committee has held several meetings at which the various plans were discussed by interested parties. Architect A. J. Graham presented arguments for the Pennsylvania plan, and F. O. Butler of the J. W. Butler Paper Company—whose opinion is probably representative of that of the business men in localities embraced in the various plans—supported Mr Graham's contentions.

On Saturday of last week Jarvis Hunt, sponsor of one of the plans, gave the committee of councilmen a long address, the burden of which is well expressed by the word "ouch." He accused Joseph Wood, one of the vice-presidents of the Pennsylvania, of saying that "he didn't give a cuss about Chicago," and later of reiterating his statement to the effect that he "cared nothing about Chicago." Mr. Hunt also accused Darius Miller, president of the Burlington, of changing front on the subject without sufficient reason. He referred to a book written by President Rea of the Pennsylvania, called "The Railways Terminating in London," in which he said the segregation of traffic was urged; disclaimed all but altruistic motives in spending his own time and money in the preparation of his terminal plan; and expressed himself otherwise in a manner which tended to show that he was considerably aggrieved because the railroads involved have not seen fit to discard the results of seven years of planning on their part and accept his proposition.

The Chicago Association of Commerce, on June 11, addressed an open letter to the mayor, the city council and the citizens of Chicago urging delay in passing the proposed smoke abatement and electrification ordinance which would demand electrification of all railroad terminals by June, 1915, and which has received the recommendation of the council committee on terminals. The association denies vigorously the accusation that it has attempted to thwart electrification or smoke abatement in the city, and says that its report, which has been in course of preparation for three years, will be ready in 1914, and will come nearer the desired solution of the problem than any haphazard action which may be taken by the council without a comprehensive investigation.

At one of last week's meetings of the Council Committee, Robert C. Sattley, valuation engineer for the Rock Island Lines, presented a scheme for a union station to include all the railways entering the city, even the Illinois Central, and to be located west of the river at a distance from the loop district not much greater than the new North Western terminal. Mr. Sattley's plan is the one that was originally presented in 1901 before the Western Society of Engineers and published in proceedings of that organization, but with revisions to bring it up to date.

Engineers Wanted for Valuation Work.

The United States Civil Service Commission, Washington, has issued its announcements of examinations to be held for filling positions in the Interstate Commerce Commission under the act providing for the valuation of the property of railroads. The examinations will be held July 23, at the usual places in different parts of the country, and the places to be filled are as follows:

Senior structural draftsman	Salary $1,800 to $4,000
Senior mechanical engineer	1,800 to 4,800
Senior railway signal engineer	1,800 to 4,800
Senior electrical engineer	1,800 to 4,800
Senior inspector of car equipment	1,800 to 3,600
Senior civil engineer	1,800 to 4,800
Senior inspector of motive power	1,800 to 3,600
Senior architect	1,800 to 4,800
Architect	1,080 to 1,500
Inspector of motive power	1,200 to 1,500
Civil engineer	720 to 1,500
Inspector of car equipment	1,200 to 1,500
Electrical engineer	1,080 to 1,500
Railway signal engineer	1,080 to 1,500
Mechanical engineer	1,080 to 1,500
Structural engineer	1,080 to 1,500

In the case of positions for which the salaries are $1,800 or more the applicants are not required to assemble at any place for examination, but are rated according to the documentary evidence presented.

Persons desiring to enter an examination should at once apply for blank form 2039 to the United States Civil Service Commission at Washington, D. C.; or to the secretary of the Board of Examiners, at Boston, Philadelphia, Atlanta, Cincinnati, Chicago, St. Paul, Seattle, San Francisco, New York, New Orleans, Honolulu, St. Louis, or to the chairman of the Porto Rican Civil Service Commission, San Juan.

Disastrous Fire at Oak Island, N. J.

In the burning of a trestle bridge of the Lehigh Valley across Newark Bay between Waverly and Greenville, N. J., on Sunday morning last, about 3,000 ft. of the bridge, together with the same length of the bridge of the Pennsylvania Railroad adjacent, were destroyed above the waterline, and the lines of both these roads to their freight termini at Communipaw and Greenville were put out of business for perhaps two weeks. The loss, including cars, is estimated variously at from $500,000 to $1,000,000. The fire is said to have started from sparks thrown by a locomotive, without a train, running at high speed. The floor of the trestle was of new creosoted ties and burned rapidly; and it is said that drippings of oil had made the floors of both bridges highly combustible. Both of these bridges are double track. Thirty cars of freight were either burned or fell into the bay, a freight train having been held on the trestle because of a blockade on the track ahead of it. Firemen from the nearby cities were obliged to pump water more than a mile to reach the fire, and fireboats in the channel were kept a long distance from the fire because of the low tide.

New Railroad Law in Massachusetts.

The legislature of Massachusetts has passed a law empowering the New York, New Haven & Hartford to own, operate and extend electric railways in the western part of the state—the law covering, it is said, all of the city and interurban lines west of Worcester. This law was adopted on June 12 by very large majorities in both houses after it had been vetoed by the governor. On June 12 also the governor vetoed the bill to enlarge the number of men in the Railroad Commission, to change the title of the commission, and to give it many new powers; and this law also was soon adopted over the governor's veto.

Under the new law, which is called the Washburn law, the railroad commission becomes the Public Service Commission and will have five members instead of three. It gives extensive power of regulation of railways, similar to those of the public service law of New York, and the board will have the same authority to enforce its orders reducing rates, etc. There is the usual elaborate prohibition of free passes and free service. The commission is specifically authorized to order changes in the number of men in train crews. Two sections concerning which there was much controversy and the terms of which were given by the governor as the chief reasons for his veto, sections 15 and 16, authorize railways to incur indebtedness equal to twice the amount of their capital stock, but every act of a corporation in financial matters is under the close supervision of the commission.

The Wicked Express Companies.

We are constantly hearing complaints about the high cost of living. The pessimist, who is always with us, cries out that we are taxed from the cradle to the grave; but the worst, it seems, is yet to come. The Pennsylvania State Anatomical Board, which has charge of the pleasant task of the distribution of the bodies of the unclaimed dead to medical schools, has complained to the Railroad Commission that the express companies are about to double the rates for carrying this class of freight. The only explanation of it is that the express companies, being no longer able to practice extortion on the living, propose to take it out on the dead.—*Philadelphia Inquirer*

Tool Foremen's Convention.

The American Railway Tool Foremen's Association will hold its fourth annual convention at the Sherman Hotel, Chicago, July 22, 23 and 24. All foremen in charge of the tool department of steam and electric railway shops are eligible to membership, and all railway foremen are invited to the convention whether members or not. There will be elaborate exhibits of tools and machinery in the exhibition hall adjoining the convention room, in charge of A. H. Ackerman.

It is expected that there will be a number of higher railway officers present as speakers, and the program is as follows: 1. Reclaiming of Scrap Tool Steel; J. J. Sheehan, chairman. 2. Making of Thread Cutting Dies; A. W. Meltz, chairman. 3. Making of Forging Machine Dies; B. Hendrickson, chairman. 4. The Electric Furnace for Tempering Tool Steel; Method of Operation, Cost of Maintenance, and Results Obtained; C. A. Schaffer, chairman. 5. Superheated Tools and Their Care; H. Otto, chairman. 6. The Form of Thread and Degree of Taper for Boiler Studs and Boiler Plugs; A. M. Roberts, chairman.

American Society for Testing Materials.

This association, affiliated with the International Association for Testing Materials, will hold its sixteenth annual meeting at Atlantic City, N. J., next week, Tuesday, Wednesday, Thursday, Friday and Saturday, at the Hotel Traymore. There will be business meetings morning and afternoon, and on Tuesday and Wednesday evenings. Following are the principal subjects on which reports and papers will be presented: Standard Specifications for Coal; Standard Specifications for Rubber Products; Preservative Coatings for Structural Materials; Standard Tests for Lubricants; Tests on the Rate of Corrosion of Metals; On Heat Treatment of Iron and Steel; Heat Treatment of Hypo-Eutectoid Carbon-Steel Castings; Tests Made on Rail-Steel Concrete Reinforcement Bars; Standard Specifications for Steel; Rail Failures and Their Causes; Resistance of Steels to Wear in Relation to Their Hardness and Tensile Properties; Effect of Small Percentages of Vanadium on the Physical Properties of Steels; Standard Specifications for Wrought Iron; Standard Specifications for Cold-Drawn Steel; Tests of Welded Boiler Tubes; Mechanical Tests of Heat-Treated Spring Steel; Oxygen in Iron and Steel; Value of Ledebur Method in its Determination; Standard Specifications for Cement; Reinforced Concrete; Method and Apparatus for Determining Consistency of Concretes; Autoclave Tests for Cement; Waterproofing Materials; Tests of Reinforced Concrete Slabs Under Concentrated Loading; Test Data on an Experimental Concrete Bridge; Ceramics and Road Materials (seven reports); Standard Specifications for Copper Wire; Metallographic Study of Lead-Tin-Antimony Alloys; A Study of Bearing Metals and Methods of Testing; Conservation and Shipping Containers; Efficiency and Safety in Explosives Used in Blasting; Large Capacity Testing Machines in this Country and Europe.

MEETINGS AND CONVENTIONS.

The following list gives names of secretaries, dates of next or regular meetings, and places of meeting.

Air Brake Association.—F. M. Nellis, 53 State St., Boston, Mass.

American Association of Demurrage Officers.—A. G. Thomason, Boston, Mass. Convention, May 19, 1914, St. Louis.

American Association of General Passenger and Ticket Agents.—W. C. Hope, New York. Annual meeting, October 14-15, Philadelphia, Pa.

American Association of Freight Agents.—R. O. Wells, East St. Louis, Ill. Annual meeting, June 17-20, Buffalo, N. Y.

American Association of Railroad Superintendents.—E. H. Harman, St. Louis, Mo.; 3d Friday of March and September.

American Electric Railway Association.—H. C. Donecker, 29 W. 39th St., New York.

American Electric Railway Manufacturers' Assoc.—H. G. McConnaughy, 165 Broadway, New York. Meetings with Am. Elec. Ry. Assoc.

American Railway Association.—W. F. Allen, 75 Church St., New York. Next meeting, November 19, 1913, Chicago.

American Railway Bridge and Building Association.—C. A. Lichty, C. & N. W., Chicago. Convention, October 21-24, 1913, Montreal.

American Railway Engineering Association.—E. H. Fritch, 900 S. Michigan Ave., Chicago.

American Railway Master Mechanics' Association.—J. W. Taylor, Old Colony building, Chicago.

American Railway Tool Foremen's Association.—A. R. Davis, Central of Georgia, Macon, Ga.

American Society for Testing Materials.—Prof. E. Marburg, University of Pennsylvania, Philadelphia, Pa.; annual, June, 1913.

American Society of Civil Engineers.—C. W. Hunt, 220 W. 57th St., New York, 1st and 3d Wed., except June and August, New York.

American Society of Engineering Contractors.—J. R. Wenlinger, 11 Broadway, New York; 2d Tuesday of each month, New York.

American Society of Mechanical Engineers.—Calvin W. Rice, 29 W. 39th St., New York.

American Wood Preservers' Association.—F. J. Angier, B. & O., Baltimore, Md. Next convention, January 20-22, 1914, New Orleans, La.

Association of American Railway Accounting Officers.—C. G. Phillips, 143 Dearborn St., Chicago. Annual meeting, May 28, Atlantic City, N. J.

Association of Railway Claim Agents.—J. R. McSherry, C. & E. I., Chicago.

Association of Railway Electrical Engineers.—Jos. A. Andreucetti, C. & N. W. Ry., Chicago. Annual convention, October 18-24, Chicago.

Association of Railway Telegraph Superintendents.—P. W. Drew, 112 West Adams St., Chicago.

Association of Transportation and Car Accounting Officers.—G. P. Conard, 75 Church St., New York. Summer meeting, June 25-26, Charlevoix, Mich.

ASSOCIATION OF WATER LINE ACCOUNTING OFFICERS.—W. R. Evans, Chamber of Commerce, Buffalo, N. Y. Annual meeting, October 8, Philadelphia, Pa.

BRIDGE AND BUILDING SUPPLY MEN'S ASSOCIATION.—H. A. Neally, Joseph Dixon Crucible Co., Jersey City, N. J. Meeting with American Railway Bridge and Building Association.

CANADIAN RAILWAY CLUB.—James Powell, Grand Trunk Ry., Montreal, Que.; 2d Tuesday in month, except June, July and Aug., Montreal.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—Clement H. McLeod, 413 Dorchester St., Montreal, Que.; Thursday, Montreal.

CAR FOREMEN'S ASSOCIATION OF CHICAGO.—Aaron Kline, 841 North 50th Court, Chicago, 2d Monday in month, Chicago.

CENTRAL RAILWAY CLUB.—H. D. Vought, 95 Liberty St., New York; 2d Thurs. in Jan. and 2d Fri. in March, May, Sept., Nov., Buffalo, N. Y.

CIVIL ENGINEERS' SOCIETY OF ST. PAUL.—L. S. Pomeroy, Old State Capitol building, St. Paul, Minn.; 2d Monday, except June, July, August and September, St. Paul.

ENGINEERS' SOCIETY OF PENNSYLVANIA.—E. R. Dasher, Box 704, Harrisburg, Pa., 1st Monday after 2d Saturday, Harrisburg, Pa.

ENGINEERS' SOCIETY OF WESTERN PENNSYLVANIA.—E. K. Hiles, Oliver building, Pittsburgh; 1st and 3d Tuesday, Pittsburgh, Pa.

FREIGHT CLAIM ASSOCIATION.—Warren P. Taylor, Richmond, Va.

GENERAL SUPERINTENDENTS' ASSOCIATION OF CHICAGO.—E. S. Koller, 226 W. Adams St., Chicago; Wed. preceding 3d Thurs., Chicago.

INTERNATIONAL RAILWAY CONGRESS.—Executive Committee, 11, rue de Louvain, Brussels, Belgium. Convention, 1915, Berlin.

INTERNATIONAL RAILWAY FUEL ASSOCIATION.—C. G. Hall, 922 McCormick building, Chicago.

INTERNATIONAL RAILWAY GENERAL FOREMEN'S ASSOCIATION.—Wm. Hall, 829 West Broadway, Winona, Minn. Next convention, July 15-18, Chicago.

INTERNATIONAL RAILROAD MASTER BLACKSMITHS' ASSOCIATION.—A. L. Woodworth, Lima, Ohio. Annual meeting, August 18, Richmond, Va.

MAINTENANCE OF WAY & MASTER PAINTERS' ASSOCIATION OF THE UNITED STATES AND CANADA.—W. G. Wilson, Lehigh Valley, Easton, Pa.

MASTER BOILER MAKERS' ASSOCIATION.—Harry D. Vought, 95 Liberty St., New York.

MASTER CAR BUILDERS' ASSOCIATION.—J. W. Taylor, Old Colony building, Chicago.

MASTER CAR AND LOCOMOTIVE PAINTERS' ASSOC. OF U. S. AND CANADA.—A. P. Dane, B. & M., Reading, Mass. Annual meeting, September 9-12, Ottawa, Can.

NATIONAL RAILWAY APPLIANCE ASSOC.—Bruce V. Crandall, 537 So. Dearborn St., Chicago. Meetings with Am. Ry. Eng. Assoc.

NEW ENGLAND RAILROAD CLUB.—W. E. Cade, Jr., 683 Atlantic Ave., Boston, Mass.; 2d Tuesday in month, except June, July, Aug. and Sept., Boston.

NEW YORK RAILROAD CLUB.—H. D. Vought, 95 Liberty St., New York; 3d Friday in month, except June, July and August, New York.

NORTHERN RAILROAD CLUB.—C. L. Kennedy, C., M. & St. P., Duluth, Minn.; 4th Saturday, Duluth.

PEORIA ASSOCIATION OF RAILROAD OFFICERS.—M. W. Rotchford, Union Station, Peoria; 2d Thursday.

RAILROAD CLUB OF KANSAS CITY.—C. Manlove, 1008 Walnut St., Kansas City, Mo.; 3d Friday in month, Kansas City.

RAILWAY BUSINESS ASSOCIATION.—Frank W. Noxon, 2 Rector St., New York. Annual dinner, second week in December, 1913, New York.

RAILWAY CLUB OF PITTSBURGH.—J. B. Anderson, Penna. R. R., Pittsburgh, Pa.; 4th Friday in month, except June, July and August, Pittsburgh.

RAILWAY ELECTRICAL SUPPLY MANUFACTURERS' ASSOC.—J. Scribner, 1021 Monadnock Block, Chicago. Meetings with Assoc. Ry. Elec. Engrs.

RAILWAY GARDENING ASSOCIATION.—J. S. Butterfield, Lee's Summit, Mo. Next meeting, August 12-15, Nashville, Tenn.

RAILWAY DEVELOPMENT ASSOCIATION.—W. Nicholson, Kansas City Southern, Kansas City, Mo.

RAILWAY SIGNAL ASSOCIATION.—C. C. Rosenberg, Bethlehem, Pa. Convention, October 14, Nashville, Tenn.

RAILWAY STOREKEEPERS' ASSOCIATION.—J. P. Murphy, Box C, Collinwood, Ohio.

RAILWAY SUPPLY MANUFACTURERS' ASSOC.—J. D. Conway, 2135 Oliver bldg., Pittsburgh, Pa. Meetings with M. M. and M. C. B. Assocs.

RAILWAY TEL. AND TEL. APPLIANCE ASSOC.—W. E. Harkness, 284 Pearl St., New York. Meetings with Assoc. of Ry. Teleg. Sups.

RICHMOND RAILROAD CLUB.—F. O. Robinson, Richmond, Va.; 2d Monday except June, July and August.

ROADMASTERS' AND MAINTENANCE OF WAY ASSOCIATION.—L. C. Ryan, C. & N. W., Sterling, Ill. Convention, September 8-12, 1913, Chicago.

ST. LOUIS RAILWAY CLUB.—B. W. Frauenthal, Union Station, St. Louis, Mo.; 2d Friday in month, except June, July and Aug., St. Louis.

SIGNAL APPLIANCE ASSOCIATION.—F. W. Edmonds, 3860 Park Ave., New York. Meetings with annual convention Railway Signal Association.

SOCIETY OF RAILWAY FINANCIAL OFFICERS.—C. Nyquist, La Salle St. Station, Chicago.

SOUTHERN ASSOCIATION OF CAR SERVICE OFFICERS.—E. W. Sandwich, A. & W. P. Ry., Montgomery, Ala.

SOUTHERN & SOUTHWESTERN RAILWAY CLUB.—A. J. Merrill, Grant bldg., Atlanta, Ga.; 3d Thurs., Jan., March, May, July, Sept., Nov., Atlanta.

TOLEDO TRANSPORTATION CLUB.—J. G. Macomber, Woolson Spice Co., Toledo, Ohio; 1st Saturday, Toledo.

TRACK SUPPLY ASSOCIATION.—W. C. Kidd, Ramapo Iron Works, Hillsburn, N. Y. Meeting with Roadmasters' and Maintenance of Way Association.

TRAFFIC CLUB OF CHICAGO.—W. H. Wharton, La Salle Hotel, Chicago.

TRAFFIC CLUB OF NEW YORK.—C. A. Swope, 290 Broadway, New York; last Tuesday in month, except June, July and August, New York.

TRAFFIC CLUB OF PITTSBURGH.—D. L. Wells, Erie, Pittsburgh, Pa.; meetings monthly, Pittsburgh.

TRAFFIC CLUB OF ST. LOUIS.—A. F. Versen, Mercantile Library building, St. Louis, Mo. Annual meeting in November. Noonday meetings October to May.

TRAIN DESPATCHERS' ASSOCIATION OF AMERICA.—J. F. Mackie, 7042 Stewart Ave., Chicago. Annual meeting, June 17, Los Angeles, Cal.

TRANSPORTATION CLUB OF BUFFALO.—J. M. Sells, Buffalo; first Saturday after first Wednesday.

TRANSPORTATION CLUB OF DETROIT.—W. R. Hurley, L. S. & M. S., Detroit, Mich.; meetings monthly.

TRAVELING ENGINEERS' ASSOCIATION.—W. O. Thompson, N. Y. C. & H. R., East Buffalo, N. Y. Annual meeting, August, 1913, Chicago.

UTAH SOCIETY OF ENGINEERS.—R. B. Ketchum, University of Utah, Salt Lake City, Utah; 3d Friday of each month, except July and August.

WESTERN CANADA RAILWAY CLUB.—W. H. Rosevear, P. O. Box 1707, Winnipeg, Man.; 2d Monday, except June, July and August, Winnipeg.

WESTERN RAILWAY CLUB.—J. W. Taylor, Old Colony building, Chicago; 3d Tuesday of each month, except June, July and August.

WESTERN SOCIETY OF ENGINEERS.—J. H. Warder, 1735 Monadnock Block, Chicago; 1st Monday in month, except July and August, Chicago.

Traffic News.

The new schedule for the new extra-fare Overland Limited of the Chicago & Northwestern and Union Pacific which went into effect, Sunday, June 8, decreases the time between Chicago and San Francisco another hour. The running time is now 63 hours and 30 minutes.

The New York State Public Service Commission, Second district, which has authority over telephone rates throughout the state, including New York City, last week issued an order reducing toll rates for long distances in New York City from 10 cents to 5 cents, to such an extent, it is said, that the reduction in the receipts of the company will amount to $750,000 a year. The telephone company had already signified its acquiescence in this order.

The Empire Express Company, a new independent organization in Texas, is the defendant in a case recently filed in the Federal District Court at Dallas, to test the legality of an exclusive contract with a railroad. The proceedings are in the nature of an application for injunction by the Missouri, Kansas & Texas against itself to restrain it from receiving express packages from the Empire Express Company and also restraining the express company from offering such packages for transportation. The defendant claims that the exclusive contract with another express company, upon which the railroad bases its application, is in violation of the laws and constitution of the state of Texas.

INTERSTATE COMMERCE COMMISSION.

The commission has suspended from June 20 until December 20, certain advances in rates for the transportation of potatoes from points in Oklahoma to points in Colorado.

The commission has suspended from June 23 until December 23, certain advances in rates on lumber from points in Texas, Louisiana and Arkansas to destinations in Oklahoma and Missouri.

The Commerce Commission has suspended from June 18 until September 12 the operation of an item in Supplement No. 1 to Hocking Valley tariff No. 1534, containing a proposed increase in the charge for the privilege of fabrication in transit at Toledo of structural iron and steel.

Cotton Seed Rates.

Refuge Cotton Oil Company et al v. St. Louis, Iron Mountain & Southern et al. Opinion by Commissioner Meyer:

The complainant contends that the rates on cotton seed from points on the St. Louis, Iron Mountain & Southern in Arkansas and Louisiana to Vicksburg, Miss., are unreasonable as compared with rates on the same commodity to St. Louis, Mo.; Memphis, Tenn.; and Natchez, Miss., and asks that just and reasonable rates be established. The commission decided that the rates in question were unreasonable and that the remedy which the complainant seeks could be found only in the establishment of joint through rates. As the complainant did not request the establishment of such rates, no orders could be issued, but the commission recommended that certain joint through rates be established. (27 I. C. C., 117.)

Coal Rates Not Increased.

Shoal Creek Coal Company v. Toledo, St. Louis & Western et al. Opinion by the commission:

The complainant contends that the rates on bituminous coal from Panama, Ill., to points on the west bank of the Mississippi river, are unreasonable. On December 1, 1910, these rates were increased and the complaint is directed against these advances. The commission decided that the advances had not been justified and ordered that in future the same rates should be charged as those in effect prior to December 1, 1910. (27 I. C. C., 107.)

Lumber Rates from Southern Mills Sustained.

Suspension Docket No. 145. Opinion by Commissioner McChord:

Proposed increased rates on lumber in carloads from certain

groups in southeastern territory (Florida, Georgia and Alabama) to Washington, Baltimore, and points related thereto, and to certain points in New Jersey, not found to be unreasonable or unjustly discriminatory. Order of suspension vacated. As to certain rates the protests (filed last August) were withdrawn, and the principal contention remaining was as to the reasonableness of the increased rates to Washington, Baltimore and intermediate stations. The increases were from 1 to 4 cents per 100 lbs.

The proposed tariffs, generally, establish the same rates to Washington, Baltimore, and all intermediate stations on the Baltimore & Ohio. At the present time the rates to Washington proper are higher than to stations on the line of the Baltimore & Ohio Railroad immediately beyond Washington as far as Hyattsville and Alexandria Junction, Md.; the rates to Washington are the same as to stations on the Baltimore & Ohio between Alexandria Junction and Relay; and these Washington rates are higher than the rates to stations Relay to Baltimore, inclusive. At the present time, and for some years past, the rates to stations on the Philadelphia, Baltimore & Washington between Washington and Baltimore are and have been the same as the proposed rates. From some of the points of origin here in issue and from a large part of the southern territory, the Seaboard Air Line has had in effect since September 10, 1910, rates to Baltimore & Ohio stations east of Washington, including Alexandria Junction and Hyattsville, the same as the rates here suspended.

The grounds upon which the carriers seek to show that these proposed increased rates are just and reasonable are that they were published to establish rates in line with the normal basis between the points named, the same as the rates now in force via the Seaboard Air Line and the same as now apply to stations between Washington and Baltimore on the line of the Philadelphia, Baltimore & Washington; to eliminate certain violations of the fourth section of the act at destination points: and to correct clerical errors in the present tariffs. As a part of their defense the respondents show the revenues per ton per mile the proposed rates would yield, and compare these ton-mile earnings with those now received under the rates from the same general territory of origin to central freight association territory.

The protestants claim that the maintenance of the present rates to Washington and Baltimore for a long period has resulted in an adjustment of commercial conditions that should not be disturbed, and that the rates to Baltimore may well be less than to Washington in view of its location and the possibility of water competition. To this the respondents reply that the present rates to Baltimore were erroneously constructed in the first instance by using, on traffic moving through Richmond, the divisions applicable to Norfolk; that the divisions on lumber up to Norfolk accruing out of all rates to eastern points have never properly been applicable to Baltimore; and that while Baltimore is a great port it has never been called a water-competitive point, because that term in this territory is restricted to points on or served in connection with the New York, Philadelphia & Norfolk

The unweighted average distance from 17 of the more important points of origin served by the Southern Railway to Washington is 792 and to Baltimore 832 miles. The average revenue per ton per mile on this traffic from these points, if the proposed rates be permitted, will be 6.58 mills to Washington and 5.63 mills to Baltimore. Comparing these distances and revenues with those from the same points of origin to Springfield, Ohio, the respondents show that the average short-line distance is 691 miles and the average revenue per ton per mile on the rates now in force 7.64 mills. For the Central of Georgia it was shown that from 13 representative points in the various groups served by it the average short line distance to Baltimore is 887 miles and to Washington 847 miles. The proposed rates would yield an average ton mile revenue of 5.55 mills to Baltimore and 5.75 mills to Washington. These distances and revenues are compared with the short-line distances to Dayton and Columbus, Ohio, and to Indianapolis and Logansport, Ind., from the same 13 points. The average distance from these points of origin to these four points of destination is 794 miles, and the average revenue per ton per mile 6.57 mills. For the Atlantic Coast Line it was shown that from 12 representative points of origin served by it to Baltimore the average distance is 849 miles and the average ton mile revenue 5.77 mills. Apparently to Washington the average distance is 809 miles, and the average revenue under the proposed rates would be 6.05 mills.

No part of the advances here involved will accrue to the lines north of Richmond and Potomac Yards. The southern roads, on whose lines the traffic originates, proposed the rates here considered and will receive whatever additional revenue may be produced. Respondents have sustained the burden of proof, and a careful investigation of the record failing to show unreasonableness or unjust discrimination in the proposed rates it follows that the order of suspension should be vacated. (27 I. C. C., 189.)

Coke Rates Reduced.

Coke Producers' Association of the Connellsville Region v. Baltimore & Ohio et al. Opinion by Chairman Clark:

Rates on coke in carloads from the Connellsville producing region of Pennsylvania to various destinations are attacked as unreasonable *per se*, unjustly discriminatory, and unduly preferential. The commission holds:

1. That the rates to Youngstown, Canton, Cleveland and Toledo, Ohio; North Cornwall, Robesonia, Reading and Philadelphia, Pa.; Baltimore, Md.; and Newark, N. J., are unreasonable *per se*.

2. That the present relationship of rates as between the Connellsville district and the Fairmont district in West Virginia is not unduly discriminatory against Connellsville or unduly preferential to Fairmont and must be maintained.

3. That participation by defendants in through rates from West Virginia and Tennessee fields, which yield lower earnings per ton-mile than their rates from the Connellsville field, is, under the conditions of competition between carriers which defendants cannot control, neither unduly discriminatory nor unduly preferential.

In its conclusion the commission says:

"In this and in other cases herein referred to, the rates upon a vast tonnage are involved. We feel impelled to give most careful consideration to the effect which changes will have upon the carriers' revenue. Under the circumstances we would not feel warranted in requiring the serious reductions that have been sought unless it were necessary in order to remove unjust discrimination or to correct manifest unreasonableness. There is nothing here to indicate that the volume of traffic will be augmented by drastic reductions in these rates or change in the relationship as between Connellsville and Fairmont. Other carriers have heretofore maintained, to markets that could thus be reached from other districts, rates approximately equal to those from Connellsville, and there is no reason to assume that they will surrender that traffic and allow the industries served by them to die rather than to meet reduced rates from Connellsville. Manifestly, the loss of revenue which would result from drastic reductions in the rates upon the tonnage involved in these cases cannot be compensated for by increases in rates upon other traffic.

The commission orders that the defendants (16 roads) desist, on or before August 1, 1913, and for a period of two years thereafter from charging their present rates for the transportation of coke in carloads from the Connellsville region to the various destinations in Ohio, Pennsylvania, Maryland and New Jersey named below, and that they establish, on or before August 1, 1913, the following rates (in dollars per net ton): Youngstown, Ohio, $1.20; Canton, Ohio, $1.40; Cleveland, Ohio, $1.60; North Cornwall, Pa., Baltimore, Md., and Robesonia, Pa., $1.80; Reading, Pa., and Toledo, Ohio, $1.85; Philadelphia, Pa., $2.05; and Newark, N. J., $2.30. It is further ordered that they apply to the transportation of coke in carloads from the Fairmont district of West Virginia to the said destinations the same relation of rates that at present exists, which relation is found to be reasonable. (27 I. C. C., 125.)

Youngstown Sheet & Tube Company et al. v. Pittsburgh & Lake Erie. Opinion by Chairman Clark:

Complaint attacks the rate on coke from Connellsville to points in the Mahoning Valley of Ohio and the Shenango Valley of Pennsylvania as unreasonable *per se*. Reparation is sought. It is held that following the decision in the case above reported (27 I. C. C., 125) the rate of $1.35 per net ton from Connellsville district to points in the Mahoning Valley of Ohio is unreasonable to the extent that it exceeds $1.20. Transportation to points in the Shenango Valley is not within the commission's jurisdiction. In the case above noted a general readjustment of rates on coke is prescribed, and under such new adjustment reparation will not be awarded. (27 I. C. C., 165.)

Coke Rates Sustained.

Tidewater Steel Co. et al. v. New York Central & Hudson River et al. Opinion by Commissioner Meyer:

The present rates for transportation of coke from the Connellsville fields in Pennsylvania to Buffalo, N. Y. not found unreasonable; complaint dismissed. (27 I. C. C., 168.)

Wisconsin Steel Company v. Pittsburgh & Lake Erie, et al; same v. Pennsylvania Railroad et al; Inland Steel Company v. Pittsburgh & Lake Erie et al. Opinion by Chairman Clark.

After maintaining for a substantial period rates on coke from the Connellsville producing region in Pennsylvania to Chicago of $2.35 per ton when for furnace use, and $2.65 per ton when for foundry use, defendants, in conformity with ruling of the commission, abandoned the maintenance of rates dependent upon the use to which the commodity was put, and established a rate of $2.50 per ton from Connellsville to Chicago. Complaints attack the rate of $2.50 per ton as unreasonable, and pray for reparation; it is held that the rate of $2.50 per ton is not unreasonable *per se*, and the complaints are dismissed. (27 I. C. C., 151.)

Iron Ore Rates Found Unreasonable.

Pittsburgh Steel Co. v. Lake Shore & Michigan Southern et al. Opinion by Commissioner Meyer:

After careful deliberation upon all the elements in this case, together with a consideration of the relation of this case to all the other cases in the group of which it is one, and which together affect the vital part of the total traffic of all these carriers, it is held, that the rate on iron ore from Lake Erie ports to the Pittsburgh district should not be higher than to the Wheeling district, and an order is issued requiring the rates to be readjusted by August 15. (27 I. C. C., 173.)

Rates on Glass to High Point Found Too High.

Standard Mirror Company et al. v. Pennsylvania Railroad et al. Same vs Lake Shore & Michigan Southern et al., and Snow Lumber Company et al. v. Pennsylvania Railroad et al. Opinion by Commissioner Meyer:

Present rates on window glass, rolled glass and plate glass from Pittsburgh, Pa., to High Point, N. C., found unreasonable to the extent that they exceed 40 cents per 100 lbs. on window glass and rolled glass, and 53 cents on plate glass. Present rate on plate glass from Toledo, Ohio, to High Point, N. C., found unreasonable to the extent that it exceeds 64½ cents per 100 lbs. The former differential from Reynoldsville, Pa., on window and rolled glass of 1 cent over Pittsburgh should be maintained. Upon receipt of proper statements prepared by complainants and verified by defendants, the commission will issue orders of reparation. It is expected that the carriers will correct their tariffs by July 15; if they do not an order will be issued. (27 I. C. C., 200.)

Complaint Dismissed.

Merchants Freight Bureau of Little Rock, Ark., v. Waterloo, Cedar Falls & Northern et al. Opinion by the commission:

The complainant contends that the rates on canned goods in carloads from points in Iowa to Little Rock and Pine Bluff, Ark., are unreasonable. These rates were increased in May, June and July, 1912, the advances ranging from 5 to 7 cents per 100 lbs. The commission decided that the advances in the rates in question had been justified. (27 I. C. C., 111.)

STATE COMMISSIONS.

The Railroad Commission of Louisiana has ordered the Yazoo & Mississippi Valley to enlarge and improve its pagoda at Gurley. Pagoda, we infer, means flag station.

The Louisiana Railroad Commission will hold a hearing on June 24, at which the matter of whether or not the commission shall issue a compulsory order to install block signals will be considered. The commission hopes to issue at that time a final order.

Chairman O. F. Berry, of the Illinois Railroad & Warehouse Commission, has been investigating for several weeks the conditions with reference to the demand for and the supply of grain cars throughout the state and, as a result he says that Illinois roads are not equal to the demands made upon them for cars of this kind.

The Montana Railroad Commission has filed a protest with the Interstate Commerce Commission against an increase in passenger rates from points in Montana to points in Wisconsin, Illinois and other eastern states, which amounts to about $2 over present rates, and was to have gone into effect July 1. An investigation of the reasonableness of the proposed increase is asked.

The Railway Commission of Canada has called upon the railway companies to show cause why the commission should not issue an order requiring all roads within three years to install interlocking signals at grade crossings of one railway with another, and also at all crossings of electric roads. The commission "is impressed with the large number of accidents occurring at grade crossings of one road with another."

The Kansas Public Utilities Commission on June 9 denied the application of the railroads of Kansas to increase the minimum carload weights on grain, grain products, salt, cement, and a number of other commodities, holding that if the application were allowed the increase would work a hardship on the small dealer, because the present minimum of these commodities is the maximum amount that the small dealer can buy.

The Public Service Commission of Missouri on June 13 made public its report on a butting collision between passenger trains at Brant Sidings, Mo., on the Missouri Pacific, May 27, in which four persons were killed. The cause was negligence of a train despatcher in giving conflicting orders and the failure of a block signal operator in block working. The commission recommends that employees be instructed every six months in the operation of the manual block system.

The railroad commissioners of Massachusetts reporting on a collision which occurred on the New York, New Haven & Hartford, near Braintree, Mass., April 28—a butting collision between a local passenger train and a work train in a fog—orders the road forthwith to install block signals on the West Quincy branch, 5½ miles long, the style and location of signals to be subject to approval of the commission. The cause of the collision was failure of an engineman to look at a train register and failure of conductor and engineman to identify a passenger train. They saw train No. 5011 and assumed that it was 5037.

The Kansas Public Utilities Commission finds four causes for the annual car shortage. These are: (1) Failure of the carriers to add to their equipment proportionately with the increase of freight tonnage; (2) and to secure maximum use of the cars which they have; (3) the practice of consignees in using cars for storage purposes; and (4) the practice of farmers in selling their grain from the machine. "After reading practically everything that has been said," says the commission, "we are unable to discover a single suggestion that points to a remedy. The railroads can lessen the trouble by increasing the number of cars and improving the efficiency of their management; the millers and elevator men by being more expeditious in loading and unloading, and the grain grower by delaying the shipment of his grain."

C. M. Larson, assistant chief engineer of the Wisconsin State Board of Assessment and of the Railroad Commission of Wisconsin, has been appointed chief engineer, with headquarters at Madison, Wis., succeeding Professor W. D. Pence. Mr. Larson was born in 1874 in Wisconsin. He was graduated from the University of Washington in 1899, and from the University of Wisconsin in 1905. He became connected with the Wisconsin State Board of Assessment in 1903 as assistant inspector on steam railroad valuation and special investigations of land values. During 1905-06 he was in Mexico on railroad construction work for a year. He then returned to the Wisconsin State Board of Assessment, and the railroad commission. He was appointed real estate engineer of the Chicago & Alton; Toledo, St. Louis & Western; Minneapolis & St. Louis and the Iowa Central in 1909, remaining with those roads until 1911, when he returned to the Wisconsin State Board of Assessment.

Car Balance and Performance.

Arthur Hale, chairman of the committee on relations between railroads of the American Railway Association, in presenting statistical bulletin No. 146, covering car balances and performances for February, 1913, says:

The miles per car per day, for February were 24.7, compared with 24.3 for January. This figure for February, 1912, was 22.9.

Ton miles per car per day, for February were 395, compared with 392 in January. This is an increase of 6.76 per cent. over the figure for February, 1912, which was 370.

The proportion of home cars on line increased one point over January, 1913, which was 51 per cent. This figure for February, 1912, was 54 per cent.

The per cent. of loaded mileage for February was 70.1 per cent., compared with 68.5 per cent. in January, 1913. This figure for February, 1912, was 71.9 per cent.

The average earnings per car per day for all cars on line were $2.54. This is an increase of 3.67 per cent. over the figure for January, 1913. This figure for February, 1912, was $2.49.

The table gives car balance and performance in the month covered by the report, and the diagrams show car surpluses, car shortages, car earnings and car mileage and different car performance figures monthly from July, 1907.

In bulletin No. 144, covering car balances and performances for January, 1913, Mr. Hale commented on the first diagram as follows:

Attention is called to the diagram which shows graphically the relation between car surplus and shortage with car balance, the cars away from home and the general performance of cars.

It will be noted that when there is a large car surplus the percentage of home cars on line is large, as the surplus drops this percentage decreases, that is, cars begin to go away from

*Denotes deficiency.

home. After the surplus has reached a minimum and has begun to increase, the cars start home again.

If there were an equal interchange of cars, the car balance would, of course, remain constant, but with our present unequal interchange the originating roads do not receive an equivalent in cars as their own cars begin to leave home, and therefore when the surplus has dropped the car balance rises. The balance against the originating roads reaches a maximum before the minimum percentage of home cars on line is reached. Apparently the originating roads are enabled to hold on to foreign cars more effectually when surpluses are at a minimum.

The shortages, of course, become marked only after the surpluses are well reduced, so that the shortage line has points of resemblance with the car balance.

The succession seems to be: First, a reduction in the surplus; second, the cars leave home; third, the car balance is seriously affected; fourth, a car shortage develops; fifth, the car balance improves; sixth, the cars begin to go home again; seventh, the shortage diminishes; eighth, a surplus comes again. The other two lines showing miles per car per day and the percentage of loaded mileage follow very closely the lines of car shortage, that is, when cars are most needed, they are moved fastest and loaded oftenest, and this happens in the periods when a maximum number of them are away from home.

Certain seasonal conditions are manifest. There is always a shortage in October and November. Even in 1908 there was a little one. There is generally a shortage in March. In 1911-12 it was bigger than the October shortage. And these are the months of good mileage and heavy loaded mileage, and the times when cars are away from home. There are also general tendencies noted between 1907 and 1913. Cars leave home more year by year, the car balance tends to increase, the percentage of loaded mileage increases and so do the miles per day.

This looks like greater efficiency.

COURT NEWS.

Court of Claims Reverses Postmaster General's Weighing Orders of 1907.

In an opinion handed down June 2, the Court of Claims, at Washington, decides in favor of the Chicago & Alton in its suit to recover additional compensation for the carrying of the mails from July 1, 1907, to April 30, 1911, the suit being based on the charge that from the date first named the weighing of the mails had not been carried out in accordance with the law; and the amount of reparation awarded is $82,605. The government has appealed from this decision to the Supreme Court. If the decision is sustained other roads will also recover and it has been estimated that the aggregate amount of reparation, for the four years during which the compensation of the railways has been calculated on the wrong basis, will amount to $20,000,000.

The annual compensation made to railways for carrying the United States mails is based on the average weight per day and the number of miles carried; and prior to the issuance of the orders in question the average was ascertained by weighing the mails during periods of 105 days every four years. The weight having been thus ascertained the total was divided, not by 105 but by 90, Sundays being excluded. For a single week the weight could be ascertained for 7 days and the total divided by 6. The second and final order which was issued by Postmaster General Von Meyer was No. 412, dated June 7, 1907, and was to the effect that the whole number of days included in the weighing period should be used as a divisor for obtaining the average weight per day; in other words, by a stroke of the pen, the postmaster general reduced the pay of the railways about 8 per cent.

In its discussion of the case the Court of Claims goes back to the year 1867. The earlier practice of dividing by 6 rather than 7 is sustained by the court mainly on the ground that the practice had been of long standing, was fully known to Congress, as shown by debates on appropriation bills, and was more reasonable than the 7-day arrangement.

The postoffice department first weighed the mails systematically in 1867. The weighing period was five weeks and the aggregate was divided by 30. This was the practice until July 1, 1873. In that year the law was amended and the statute required the weighing of the mails for at least 30 successive working days, and at least every 4 years. Prior to 1876 the weighing was done

by the railroads, but after that by the postoffice employees. Sunday mail trains were not numerous in 1873; but the practice of weighing for 7 days and dividing by 6 was continued for more than 30 years, until the issue of the special order referred to in 1907. In 1881 and 1884 the postmaster general, in reporting to Congress, explained the workings of the law, and a bill was introduced in the house cutting out the word "working" from "working days," but no action was taken on the bill. The postmaster general issued an order to divide by 7 instead of 6, away back in 1884, but the attorney general advised that the old practice was correct and this order was never put into effect. But another attorney general, 20 years later, said that the old plan was based on "an impossible construction of the law" of 1873. In 1885 the postmaster general again, complying with a resolution of the Senate, sent to Congress a detailed history of the railway mail service, calling attention to this detail. The appropriation act of 1905 again used the term "successive *working* days," and thereafter, in compliance with the law, the postmaster general had the mails weighed 105 days, once in 4 years, and used as the divisor 90. In the appropriation bill of 1907 it was proposed in the house to again direct the use of the larger divisor, but, after a good deal of discussion, the bill was passed without this provision. Then the postmaster general issued the order making the change.

The decision, by Justice Barney, says that the word "working" was doubtless used to designate particular days; if Congress had not intended to exclude Sundays why did it use that word? To weigh the mail for 35 days, including Sundays, and then divide by 35 would be unjust to roads which ran no mail trains on Sunday. If the mails had not been weighed on Sundays injustice would have been done to the roads carrying mails on that day.

A fair examination of the law of 1873, taking into consideration all of the circumstances then existing, shows that it was designed to provide payment upon the basis of the average weight of mails carried on six days, leaving to the postmaster general the problem of doing justice to those roads which carried mails on Sundays. He did this in the way before described. Even if some other reasonable basis could be calculated, the court thinks that the long continued construction given to the law, in the administration of the postoffice department, was equivalent to writing this method into the law. And, Congress having continued to make appropriations with full knowledge of the situation, it is to be assumed that Congress approved of the course taken by the postoffice department. The decision then goes on to cite many authorities to the effect that where a statute is ambiguous the uniform practice of the department in carrying out the law must be accorded much weight by the courts.

Prior to 1907 the laws had specified a *maximum* rate for the transportation of the mails and the postmaster general had some discretion; and he had always paid the full maximum; but in that year the law was made absolute; the pay on such and such routes "shall be," etc. Congress having thus made an absolute rate, and the order of June 7 having been found contrary to law, and therefore no regulation at all, the court sustains the Chicago & Alton claim

State Rate Laws Sustained.

The Supreme Court of the United States this week rendered decisions in the remaining 22 cases, known as the Missouri rate cases. These opinions, handed down by Associate Justice Hughes were comparatively brief, following the principles laid down in the Minnesota decision reported last week.

The state laws of Missouri, Oregon, Arkansas and West Virginia were upheld. In the case of three roads in Missouri, where the state rates manifestly would result in confiscation, those rates were declared confiscatory but with permission to take future action as in the case of the Minneapolis & St. Louis.

The legislation dealt with in these decisions included the two-cent passenger laws in Missouri, Arkansas and West Virginia, maximum freight rate laws in Missouri and Arkansas and freight rates out of Portland in the Oregon cases. The only exception to the sweeping approval of state statutes was in the case of several weaker roads in Missouri. The West Virginia case was originally brought by the Chesapeake & Ohio to restrain the enforcement of the 2 cent fare law of that state passed in 1907.

The Oregon cases were brought to restrain the enforcement of an order of the State Railroad Commission made April 22, 1908, prescribing freight rates, and another similar order, made September 21, 1910. The question of confiscation did not arise in these cases. The Arkansas decision sustains the act of 1907 fixing passenger fares at 2 cents a mile, and orders of the railroad commission, made in June, 1908, prescribing maximum rates for both freight and passengers.

Justice Hughes in announcing the decisions referred back to the Minnesota cases wherever the point was raised that the state laws interfered with interstate commerce.

"We need not review the arguments addressed to conditions of transportation in Missouri and the relation of intrastate to interstate rates," he said, "for while the case has its special facts by reason of location of the state and the use of the Mississippi and Missouri rivers as basing points the controlling question is not to be distinguished from that which was decided in the Minnesota rate cases."

The Oregon and West Virginia cases were decided in favor of the states in a few words, the only point raised by the railroads being that the laws interfered with interstate commerce. Justice Hughes went fully into the claims in the Missouri and Arkansas cases.

As a result of the court's action in the Missouri cases the state-prescribed rates will go into effect on the Chicago, Burlington & Quincy, the Atchison, Topeka & Santa Fe, the Kansas City Southern, the Missouri, Kansas & Texas, the Chicago, Rock Island & Pacific, the St. Louis & San Francisco, the St. Louis Southwestern, the Missouri Pacific, the St. Louis, Iron Mountain & Southern, the Wabash, the Chicago, Milwaukee & St. Paul and the Chicago & Alton. For the present the rates will not become operative on the St. Louis & Hannibal, the Kansas City, Clinton & Springfield, the Chicago Great Western, the Quincy, Omaha & Kansas City, and the St. Joseph & Grand Island.

The court refused to accept the valuation placed on railroads in Missouri by the state's assessing board as a basis for fixing "the fair value" for rate making. Justice Hughes took the case of the Burlington and showed that by applying the assessment value (multiplied three times as was done by the federal court in Missouri) to the whole system, a result would be obtained $115,000,000 in excess of the capitalization of the system. Besides, he said, there was nothing to show upon what the assessors fixed their valuation, nor was it demonstrated that the assessors avoided the mistakes criticised in the Minnesota rate decision.

"Manifestly, a finding of confiscation would not be based on such a valuation, in the absence of clear and convincing proof that the values actually existed and that the different items of property were estimated by correct methods and in accordance with proper criteria of value. . . . The proof was lacking. In the case of the other roads, although the special considerations applying to the Burlington property may not be applicable, still we are left in uncertainty as to the correctness of specific valuations which have been made." Apportionment of property values between interstate and intrastate passenger and freight traffic according to gross revenue was disapproved "for reasons stated in the Minnesota rate cases."

Justice Hughes said that the plan adopted by the lower court of applying the revenue basis in apportioning expenses was open to the same objection as in the Minnesota cases. However, as to the St. Louis & Hannibal and the Kansas City, Clinton & Springfield, he said, the experts of both the state and the railroads united in declaring that no basis could be found upon which the proposed rates would yield an adequate return. As to the Chicago Great Western, he said, errors of valuation and apportionment were not sufficient to warrant a reversal of the finding of the lower court that the rates were confiscatory. The rates as to the Quincy, Omaha & Kansas City and the St. Joseph & Grand Island were annulled because of a stipulation between the state and the railroads that the finding as to the Chicago Great Western should control them.

The Kentucky case was not decided. It involves an attack upon state rates from river points to inland distillery cities and involves in addition an attack on the constitutionality of the law enabling the state railroad commission to fix reasonable rates on intrastate commerce. The court adjourned until next October without announcing a decision in the intermountain rate cases.

Railway Officers.

Operating Officers.

C. W. McCoppin has been appointed general manager of the Riviera Beach & Western, with headquarters at Riviera, Texas.

W. F. Sheridan has been appointed assistant superintendent of transportation of the Louisville & Nashville, with office at Louisville, Ky.

J. R. Jones has been appointed trainmaster of the International & Great Northern at San Antonio, Tex., succeeding J. L. Otis, assigned to other duties.

H. H. Smith, heretofore chief clerk to general manager of the Canadian Northern, Quebec, has been appointed car service agent of the same company, with office at Montreal.

J. J. Rhoads, hitherto division engineer of the middle division of the Pennsylvania, has been appointed superintendent of the central division of the Philadelphia, Baltimore & Washington, with office at Media, Pa.

George R. Sinnickson, hitherto division engineer of the West Jersey & Schuylkill and the Pennsylvania at Camden, N. J., has been appointed superintendent of the Schuylkill division of the Pennsylvania, with office at Reading, Pa.

N. W. Smith, heretofore division superintendent of the Philadelphia, Baltimore & Washington at Media, Pa., has been appointed superintendent of the middle division of the Pennsylvania, with office at Altoona, Pa., succeeding C. A. Preston.

James Fitzsimons, heretofore general eastern freight agent of the Delaware & Hudson, at Albany, has been appointed general manager of the Quebec, Montreal & Southern, with office at Montreal, Que. The Q. M. & S. is a subsidiary of the D. & H.

L. E. Abbott has been appointed safety commissioner of the Oregon Short Line, with headquarters at Salt Lake City, Utah. He will be in general charge, under immediate direction of the Central Safety Committee, of all matters pertaining to the "Safety First" movement of that road.

W. R. Scott, general manager of the Southern Pacific, announces that Paul Shoup will assume charge of the operation of the Oakland, Alameda and Berkeley suburban lines. The ferry boats and piers will be operated by the Western division, as at present. Effective June 8.

Joseph James Rhoads, whose appointment to the position of superintendent of the Central division of the Philadelphia, Baltimore & Washington, is noted above, has been in the service of the Pennsylvania Railroad and its controlled lines since March 1, 1899, when he entered the engineering department as rodman. He was born at Bellefonte, Pa., August 23, 1868, and was educated at Swarthmore College, whence he was graduated in the class of 1888 in the engineering department. His first railway service was on the Pittsburgh, Monongahela and Philadelphia divisions of the Pennsylvania. In June, 1892, he entered the office of the engineer of maintenance of way, at Altoona; January 15, 1893, he was appointed assistant supervisor on the Amboy division, at Jamesburg, N. J.; was transferred to the Maryland division of the P. B. & W. as assistant supervisor, at Washington, D. C., December 1, 1897; and 16 months later went back to New Jersey as supervisor on the Amboy division, at

J. J. Rhoads.

Jamesburg. He was appointed supervisor on the New York division, at Tacony, Pa., March 1, 1901; assistant engineer of the Williamsport division, at Williamsport, July 1, 1905; division engineer of the Philadelphia Terminal division, West Philadelphia, April 1, 1907, and division engineer of the Middle division, at Altoona, January 15, 1910. This position he held up to the present month.

C. H. Marshall, formerly division superintendent of the Chicago, Milwaukee & St. Paul, at Missoula, Mont., and more recently superintendent of construction of the Chicago & Council Bluffs division, with headquarters at Marion, Iowa, has been appointed division superintendent, with headquarters at Perry, Iowa.

J. B. Carothers, who has been appointed assistant to the general superintendent of the Baltimore & Ohio Southwestern and the Cincinnati, Hamilton & Dayton, with office at Cincinnati Ohio, was born on February 26, 1863, at Cutler, Washington county, Ind. He was educated at a normal university and began railway work in 1888, as a rodman in a surveying party. From 1889 to 1891, he was with the Seattle, Lake Shore & Eastern, and its successor, the Northern Pacific, as transitman, and was then for four years out of railway service. In June, 1895, he was appointed assistant engineer on the Baltimore & Ohio Southwestern at Cincinnati; a year later he was made division engineer on the Springfield division, at Flora, Ill., where he remained until April, 1902 except for a year, when he was out of service on leave of absence. He was later division engineer on the Ohio division, and also on the Indiana division. In February, 1904, he was made superintendent of the Ohio division at Chillicothe, Ohio, and in November of the following year, became superintendent of the Illinois division, with office at Washington, Ind. In April, 1910, he was appointed chief engineer of maintenance of way at Cincinnati, Ohio, and was then consecutively superintendent of the Philadelphia division of the Baltimore & Ohio at Philadelphia, Pa., and engaged in a special engineering capacity on the staff of the chief engineer.

J. B. Carothers.

George P. Johnson, for the past year receiver of the Detroit, Toledo & Ironton, has been appointed general manager of the Chesapeake & Ohio, with office at Richmond, Va., the appointment to take effect July 1. This office has been vacant since about one year ago when E. W. Grice, general manager, was appointed to the position of assistant to the vice-president in charge of operation. Mr. Johnson is 39 years old and is the son of President L. E. Johnson, of the Norfolk & Western. He was born at Aurora, Ill., where his father was an officer of the Burlington road. He began his railroad service on the Burlington as a clerk, January 1, 1890. He held this position only a few months, however, and then started to make himself an all around railroad man by working as brakeman, freight conductor, yard master, station master and in other positions, on the Burlington, the Great Northern and the Lake Shore & Michigan Southern, until July 1, 1898, when he was appointed general yardmaster of the Norfolk & Western, at Kenova, W. Va. A year later he was promoted to the position of trainmaster at Lynchburg, and in October, 1902, he was made superintendent of the Shenandoah division, at Roanoke. In 1904 he was sent to the Scioto division, and on July 1, 1907, was appointed general superintendent of the Western general division, with office at Bluefield, W. Va. In May of last year he resigned this position to take the management of the Detroit, Toledo & Ironton, as above noted.

Cecil Anthony Preston, whose appointment as valuation engineer of the Pennsylvania Railroad is noted above, has been superintendent of the Middle division of that road for the past ten years. He was born in Philadelphia and was graduated from the Polytechnic College of Philadelphia in 1872, as civil engineer. He at once entered actively into railroad construction work, but he did not enter the service of the Pennsylvania until 1879. In 1878 he was associated with the Collins Expedition in the construction of the Madeira & Mamore, in Brazil, where he served as engineer. His first service for the Pennsylvania was in connection with surveys for new lines. On March 1, 1880, he was appointed assistant supervisor of the Baltimore section of the Northern Central; but after a few months he resigned and went to Mexico, where he was engaged as principal assistant engineer of the Mexican National Construction Company. He returned to the United States in 1882 and again entered the service of the Pennsylvania (Northern Central), being appointed assistant supervisor at York, Pa. He was promoted to different positions (in 1882, 1890 and 1893) until, in July, 1900, he was made superintendent of the Elmira and Canandaigua divisions of the Northern Central, with office at Elmira, N. Y. Two years later he went to Williamsport as superintendent of the Eastern and Susquehanna divisions, and in the next year, 1903, was appointed superintendent of the Middle division of the Pennsylvania at Altoona, as above noted, the duties of which position he has now been relieved from.

C. A. Preston.

Traffic Officers.

R. O. Von Steuben has been appointed commercial agent of the New York Central, and all of its controlled lines, at Newark, N. J.

W. E. Taylor has been appointed commercial agent of the Chicago, Rock Island & Pacific, at Lincoln, Neb.; in place of E. O. Miller, deceased.

C. S. Blackman has been appointed general agent of the Missouri Pacific and St. Louis, Iron Mountain & Southern, at Hot Springs, Ark.

John J. Coyle, heretofore general southern agent of the Delaware & Hudson, at Philadelphia, has been appointed general eastern freight agent of the same company, at Albany, succeeding James Fitzsimons, promoted.

W. M. Hughes has been appointed traveling passenger agent of the Chicago, Burlington & Quincy, with headquarters at St. Paul, Minn., to succeed W. H. Snyder, who has been appointed city passenger agent at St. Paul.

A. M. Reinhardt has been appointed assistant general freight agent of the Atchison, Topeka & Santa Fe Coast Lines, with headquarters at Los Angeles, Cal. F. A. Bell has been appointed general agent at San Francisco, Cal.

J. M. Ball, division freight agent of the International & Great Northern at San Antonio, Tex., has been appointed cotton agent. He is succeeded as division freight agent by J. W. King, heretofore traveling freight agent for the St. Louis, Iron Mountain & Southern.

H. M. Mayo, assistant to the president of the Sunset-Central Lines of the Southern Pacific, has been appointed manager of the industrial, immigration and advertising bureau, with headquarters at Houston, Tex. This is a new department to be established by the Sunset Central Lines of Texas and Louisiana on July 1.

George T. Bell, whose appointment as traffic manager of the Grand Trunk Pacific has been announced in these columns, was born at Montreal, September 7, 1861. He entered the railway service at the age of 17 as a clerk in the car mileage office of the Great Western Railway of Canada, now part of the Grand Trunk. He was soon transferred to the passenger department, and held various positions in that department until April, 1892, when he was appointed assistant general passenger agent of the Grand Trunk. Four years later he was made assistant general passenger and ticket agent, and in 1899 was promoted to a higher position at Chicago. In May, 1900, he was made general passenger and ticket agent, with headquarters at Montreal, which position he held until May 1, 1909, being also during the latter part of this time general passenger agent of the Grand Trunk Pacific; and for the last two years he has been assistant passenger traffic manager.

George T. Bell.

Engineering and Rolling Stock Officers.

Thomas B. Kennedy has been appointed engineer of the Cumberland Valley in place of George C. Koons, resigned, to go to the Pennsylvania.

The headquarters of B. B. Shaw, assistant engineer of the Chicago, Rock Island & Pacific, have been moved from El Reno to McAlester, Okla.

George C. Koons, hitherto engineer of the Cumberland Valley, has been appointed assistant engineer of maintenance of way of the Pennsylvania, in charge of bridges and structures, with office at Philadelphia.

C. A. Preston has been appointed valuation engineer of the Pennsylvania Railroad. Mr. Preston hitherto has been superintendent of the middle division at Altoona, in which position he is succeeded by M. W. Smith.

C. I. Leiper, hitherto division engineer of the New York division of the Pennsylvania Railroad, has been appointed principal assistant engineer of the Philadelphia, Baltimore & Washington, with office at Wilmington, Del.

F. S. Schorndorfer, general foreman of shops of the Cincinnati, Hamilton & Dayton, at Ivorydale, Ohio, has been appointed general foreman of shops of the Baltimore & Ohio Southwestern, at Chillicothe, Ohio, in place of J. G. Hyson, resigned.

Joseph T. Richards, chief engineer of maintenance of way of the Pennsylvania Railroad, Philadelphia, has been appointed consulting engineer of maintenance of way. L. R. Zollinger, engineer of maintenance of way, retains his present title.

A. B. Clark, hitherto assistant engineer of the Philadelphia, Baltimore & Washington, at Wilmington, Del., has been appointed assistant engineer of maintenance of way of the Pennsylvania, in charge of roadway and track, with office at Philadelphia.

I. D. Salome has been appointed terminal engineer, at the Grand Central Terminal, New York City (N. Y. C. & H. R. R.), in place of W. L. Morse, who has gone to Florida, as noted below. Mr. Salome has served in the engineering department at the Grand Central for several years past.

M. K. Barnum, heretofore general superintendent of motive power of the Illinois Central, has been appointed general mechanical inspector of the Baltimore & Ohio, the appointment to take effect July 1. A portrait of Mr. Barnum, with a sketch of his life, appeared in this paper May 23.

President Geo. W. Stevens, of the Chesapeake & Ohio, announces the appointment of a valuation committee, to devote its entire time to valuation work, the members of which are F. I. Cabell, chief engineer, chairman; J. P. Nelson, real estate; E. M. Thomas, accountant. These men are relieved of all duties in connection with their own departments. W. F. Steffens, assistant chief engineer, will perform the duties of chief engineer.

W. L. Morse, heretofore an engineer on the Grand Central Terminal improvement, New York City, has been appointed chief engineer of the Jacksonville Terminal Company, Jacksonville, Fla. Mr. Morse was graduated from Boston University in 1895 and began railroad work in 1896 in the surveying corps of the New York, New Haven & Hartford. He has been with the New York Central at Grand Central Terminal, New York City, since 1902, having been appointed resident engineer in 1906.

The Pennsylvania announces six appointments in the engineering department as follows: H. H. Russell, heretofore engineer of the Allegheny division, has been appointed engineer of the Middle division, with office at Altoona, Pa.; the appointment to take effect June 16. D. T. Easby, heretofore supervisor on the Middle division, has been appointed division engineer of the Allegheny division, with office at Oil City, Pa. F. W. Smith, Jr., heretofore engineer of the Conemaugh division, has been appointed engineer of the New York division, with office at Jersey City, N. J. C. E. Zortman, heretofore supervisor on the Pittsburgh division, has been appointed engineer of the Conemaugh division, with office at Pittsburgh, Pa. C. E. Brinser, heretofore on the New York, Philadelphia & Norfolk, has been made division engineer of the West Jersey & Sea Shore, at Camden, N. J. T. J. Skillman, heretofore on the Pennsylvania road at New York City, has been appointed division engineer of the New York, Philadelphia & Norfolk, with office at Cape Charles, Va.

Julius E. Willoughby, whose appointment as assistant chief engineer of the Atlantic Coast Line has been announced in these columns, was born at Arkadelphia, Ala., October 12, 1871, and was educated at the University of Alabama, from which institution he was graduated in 1892 as Bachelor of Civil Engineering. He had done some work on railway surveys when in college, and his first regular service was with the Louisville & Nashville, where he was engaged on surveys and new construction from 1892 to 1900. In April, 1900, he was appointed assistant chief engineer of construction of new lines, and the following year was made engineer of construction of the Alabama & Florida, a subsidiary of the L. & N. He was engaged in other similar positions until 1905, when he was appointed engineer of construction, which position he held until March, 1912. During this time he was chief engineer on a number of subsidiary lines. In 1912 he was chief engineer of the Caribbean Construction Company and of the National Railroad Company of Haiti, which position he held until the present month. He is a member of the American Society of Civil Engineers and of the American Railway Engineering Association.

OBITUARY.

John Heimrich, president of the Great Southern, died at his home in Portland, Ore., on June 11, aged 67 years.

William K. McAllister, general agent of the Southern Pacific at Denver, Colo., died in that city on June 12, aged 63 years. Mr. McAllister had been connected with the Southern Pacific since 1893, and was made general agent in March, 1895.

George Oudtshoorn Railway, South Africa.—The very important George-Oudtshoorn line has now been linked up at Doorn river. The line was commenced in 1908, and it is estimated that the cost will be something like $1,850,000. It will probably be open for traffic this month. After leaving George, the line winds in and out of the gorges of the Outeniqua range, passing through seven tunnels and climbing 1,600 ft. It then descends 1,300 ft. before reaching Oudtshoorn. From the tourist point of view, climbing along a precipitous mountain side and presenting a magnificent panorama of mountain, sea and plain, the line bids fair to be one of the show lines of a system that includes many stretches of very wonderful scenery.

Equipment and Supplies.

LOCOMOTIVE BUILDING.

THE GRAND TRUNK has ordered 25 locomotives from the Baldwin Locomotive Works.

THE SIOUX CITY TERMINAL RAILWAY has ordered from the American Locomotive Company 1 six-wheel switching locomotive weighing 117,000 lbs. The cylinders are 19 x 24, and the driving wheels 50 in

CAR BUILDING.

THE INTERCOLONIAL has ordered 500 steel underframe box cars from the Nova Scotia Car Works.

IRON AND STEEL.

GENERAL CONDITIONS IN STEEL.—New business is coming in at the rate of about 60 per cent. of shipments. Consumers are not making any objection to receiving deliveries, and manufacturers are more aggressive in their bidding for new business. The tariff situation still is used by consumers as an argument for waiting to place orders, and German steel conditions, which are demoralized, possibly have a bearing on the steel market in this country.

SIGNALING.

The Central of New Jersey has ordered from the Union Switch & Signal Company automatic block signals for its line between Red Bank, N. J., and Lakehurst, N. J., 28 miles of single track.

The seven mile line of the Butte, Anaconda & Pacific at the Anaconda Mines, Montana, recently electrified, is to be equipped with alternating current automatic block signals, the contract having been given to the Union Switch & Signal Company. The propulsion current is 2400 volts d. c. The track circuit has double rail return, and alternating current is used for everything including switch indicators and track circuits. Current will be distributed at 2080 volts, single phase, 60 cycles. The signals are semaphores, one arm, style B, moving in the upper left hand quadrant, similar to those which have been put up by the Union Company on the lines of the Illinois Traction Company.

The Canadian Pacific is to install five interlocking plants in Western Canada as follows, the contracts having been given to the Union Switch & Signal Company, Swissvale, Pa. Calgary, tower No. 1, mechanical interlocking with a 48 lever machine. At tower No. 2, Calgary, a 60 lever machine. At Whittier Junction on the Manitoba division electric interlocking, type F, 28 working levers in a 41-lever frame. The signals will be style T-2 top post. This interlocking will control the draw bridge over the Red river. At North Transcona at the crossing of the Canadian Northern a 64-lever mechanical interlocking, Saxby & Farmer machine. At Transcona a 36-lever mechanical interlocking, with electric distant signals, style T-2. The Canadian Pacific has also contracted with the Union Company for the installation of automatic block signals on the seven miles of double track east and west of Calgary. These signals will be style T-2, three-position. There will be eighteen switch indicators.

OPENING OF THE LOTSCHBERG RAILWAY, SWITZERLAND.—The new Bernese Alps Railway, Berne-Lötschberg-Simplon, will be opened this month to traffic. This event will denote the deviation of a large proportion of Swiss railway traffic into new channels and the opening of a new important approach to Italy. The completion of this railway crowns the railway policy which has been followed by the canton of Berne during the last 50 years. It realizes the idea of a passage through or over the Bernese Alps which has been attempted again and again since the Middle Ages, and so solves an ancient traffic problem. Berne, besides taking a leading part in the construction of the new railway, has lately steadily worked for a consolidation of the several subsidized Berne railways.

Supply Trade News.

William C. Jones, Ltd., Boston, Mass., with head office in Manchester, England, have completed a new patented demonstration plant at Boston, Mass., for the manufacture of wiping waste in rope form, known as Boa waste. It is understood that the company has put up this plant for demonstration purposes only and does not intend to itself go into the manufacture of wiping waste in this country.

TRADE PUBLICATIONS.

STEAM COUPLERS.—The Gold Car Heating & Lighting Company, New York, has just issued an illustrated description of the Gold wedge lock steam coupler, together with a comparative diagram showing the action of the Gold steam couplers oscillating gasket and the non-oscillating soft gasket.

THE DENVER & RIO GRANDE.—The passenger department has just issued several little booklets of interest to tourists—one containing a list of hotels and ranch boarding houses, giving also specific information regarding rates, post office address, distance from railroad station, etc., and another devoted to Yellowstone Park.

A COMBINATION STEEL TIE AND TIE BAR.—A pamphlet has been published by J. F. Donahoo, Birmingham, Ala., describing the International Safety Railway Tie, which consists of a steel casing carrying two wooden blocks upon which the rail rests. The rail is held in position by special steel tie bars and bolts through the tie, eliminating the use of spikes.

COPPER RIVER & NORTHWESTERN.—This company has just issued a rather attractive little leaflet describing some of the Alaska country traversed by the Copper river route, which runs from Cordova to Kennecott, 196 miles. With this leaflet is being distributed a folder of the Alaska Steamship Company, giving information as to steamship routes to Alaska and along the coast.

COMPARATIVE STATISTICS.—Thompson, Towle & Company, New York, have prepared and are distributing to their customers a table showing "Essential Statistics on Important Railroads," covering results of operation for the year ended June 30, 1912. The table shows capitalization, dividend rate, fixed charges, net earnings, etc., and certain per mile of road figures, with the dividend record for six years, and high and low stock quotations for six years for about 55 roads.

RAILWAY DIFFICULTIES IN ARGENTINA.—Notwithstanding the remarkable progress which is manifested year by year by the great majority of Argentine railways, some of the troubles from which they have suffered, almost from the beginning of their successful career, have still to be faced. Among these difficulties may be included the native jealousy which exists in regard to foreign enterprises and which it would appear is most difficult to overcome. This jealousy manifests itsself in particular in the relations existing between the companies and the municipalities; so acute is this at times that several important improvements had to be abandoned, and as a consequence the public suffers and the companies sustain financial losses. A case in point is the dispute which of late has raged between the Central Argentine Railway and the Cordoba municipality. It had been the wish of the company to erect a handsome station in the city of Cordoba. From the commencement, however, the company has met with scant consideration from the municipality; on the contrary, a spirit of opposition has been displayed even in regard to the most simple matters. At length the patience of the company has been exhausted and the board of directors in London, acting upon information sent to them from Cordoba, have telegraphed instructions to their local representatives in Cordoba, to suspend all work upon the new station building, to sell the materials already received and to dismiss all the workmen employed. The directors' action was precipitated by the persistent and unreasoning difficulties placed in the way of progress by the municipality, especially in regard to the matter of approaches to the new station building. While the interests of the company are bound to suffer by this drastic decision, those of the traveling public will be more seriously affected still.

Railway Construction.

Columbia & Nehalem.—An officer writes that work is now going on, principally by the company's own forces, on this line which is being built from Ross Landing, south 30 miles. Contracts for part of this work would be let to outside contractors, if favorable bids could be obtained, the officer says. For the first 15 miles the work is quite heavy, and for the balance comparatively light. There will be one 225 ft. Howe truss bridge and one 1,300 ft. tunnel. A. S. Kerry, 716 Spaulding avenue, Portland, Ore., president, and G. A. Kyle, Portland, Ore., chief engineer.

Hiawassee Valley Railway.—An officer writes that contracts will be let for grading, etc., on this road about July 15. The road is projecting from Andrews, N. C., on the Southern Railway via Marble, Peach Tree and Hayesville to Hiawassee. The work will not be difficult and the standard adopted has been a 2 per cent. grade and 10 deg. curves. J. Q. Barker, president, and W. C. Sanderlin, chief engineer, Andrews, North Carolina.

Huntsville, Moberly & Randolph Springs.—An officer writes that the Jennings Construction Company, of Joplin, Mo., has been given the contract for grading this electric road from Randolph Springs to Moberly, Mo., and that Edward Freed, of Moberly, Mo., has been given the contract for the concrete work.

Kansas City, Kaw Valley & Western.—An officer writes that contracts will be let for grading about July 1 for this road which is projecting from Kansas City via Muncie, Kan., Edwardsville, Bonners Springs, Lanape, Loring and Linwood to Lawrence. About three miles of track have been laid. The work is fairly easy except on one three-mile section. One and one-half per cent. grades and 70 deg. curves have been adopted as standard. There will be a steel bridge about 1,000 ft. long across the Kaw River. J. D. Waters, president, and O. W. Williamson, chief engineer, Bonners Springs, Kansas.

Salt Lake & Utah.—An officer writes that this road is being built in two sections, the first running from Salt Lake City, Utah, via Taylorsville, West Jordan, Riverton, Lehi, American Fork and Pleasant Grove to Provo, Utah, about 24 miles. The second section is projected from Provo via Spanish Fork and Springville to Payson, Utah, between 18 and 20 miles. Contracts are now being let for the grading from Provo to a point between Lehi and West Jordan. Two miles of track has been laid in Salt Lake City, and about two miles each in Provo and American Fork. This work has been done by the Inter-Urban Construction Company, which has been incorporated to build and equip the roads. Contracts for steel construction will be let in the near future. The road is to be operated by electricity as an interurban passenger and freight road. It is expected that freight will consist largely of farm products and supplies for farmers. The orders for rolling stock have already been largely placed. W. C. Orem, Newhouse building, Salt Lake City, Utah, is president, director and general manager; Jas. G. Berryhill, Des Moines, Iowa, is vice-president and a director.

Temple, Northwestern & Gulf.—An officer writes that 3.3 miles of track have been laid and the company expects to immediately build a line from Temple northwest to Gatesville and Dublin, Tex., 100 miles. The company's own construction company is the general contractor. The work to be done in the near future consists of track laying, and in about 90 days two steel bridges of about 150 ft. each are to be begun. There is one rock cut to be excavated about a mile and a half long, and from 3 to 7 ft. deep. J. F. Sadler, president, Houston, Tex.; W. F. Dozier chief engineer, Temple, Tex.; W. A. McGregor, vice president and general manager, Temple, Tex.

RAILWAY STRUCTURES.

Pawnee Springs.—See Kansas, Kaw Valley & Western under construction.

Temple, Tex.—Gulf, Colorado & Santa Fe. This company asked for bids on June 9 on a $25,000 six-stall engine house.

Topeka, Kan.—The Atchison, Topeka & Santa Fe has begun work on an addition to the shops to cost about $20,000.

Railway Financial News

Baltimore & Ohio.—The $20,000,000 1-year 5 per cent. secured notes, which were bought from the railroad company by Kuhn, Loeb & Company, and Speyer & Company, both of New York, are being offered to the public at 99¼. The notes are dated July 1, 1913, and are secured by the deposit of $29,000,000 Baltimore & Ohio Chicago Terminal first mortgage 4 per cent. bonds, due April 1, 1960.

John F. Stevens, at the request of President Williard, has made an inspection of the Baltimore & Ohio. In commenting on this inspection, he said in part: "The road's gross earnings this year will be about $100,000,000. I haven't a doubt that in ten years it will be earning fully $150,000,000. The only difficulty will be to furnish facilities and to avoid congestion. That is a matter of raising the capital, and I hold that the Baltimore & Ohio will be able to find the money, if any railroad will. Baltimore & Ohio flood damage, with the exception of bridges, has been substantially made good. Baltimore & Ohio construction work is a good deal like that of the continental European roads, done to last for all time."

Chicago & Western Indiana.—W. J. Jackson, president of the Chicago & Eastern Illinois, has been elected a director of the Chicago & Western Indiana, succeeding B. L. Winchell, resigned.

Kansas City, Mexico & Orient.—Application for a final decree to permit a foreclosure sale has been made to Judge Pollack in the United States District Court by the United States & Mexican Trust Company. The new company has been in process of organization for several weeks.

Missouri, Kansas & Texas.—Frank Trumbull, chairman of the board, after an inspection trip, said in part: "This company will earn between 2½ and 3 per cent. on its common stock for the year ending June 30. The road was never in better physical condition. In the southwest, through Kansas, Oklahoma and Texas, the crop prospects are excellent, and bankers through the territory told me that they looked for a big business in the fall. One of the most encouraging features of my trip was the evidence of a more friendly spirit toward railroads in the west and southwest."

Pennsylvania Railroad.—See editorial comments in regard to the exchange of Baltimore & Ohio stock for Southern Pacific stock.

Pittsburgh, Youngstown & Ashtabula.—The Public Service Commission of Ohio has authorized the company to issue $640,000 series A first general mortgage, 4 per cent. bonds of 1908-1948 at not less than par, the money to be used to reimburse the Pennsylvania Company for advances for additions and betterments amounting to $640,296.

San Pedro, Los Angeles & Salt Lake.—This company has recently applied to the Railroad Commission of California for authority to issue $1,119,000 of bonds, the proceeds to be expended for new equipment, extensions and improvements.

San Pedro, Los Angeles & Salt Lake.—The company has asked permission of the California Railroad Commission to issue $1,119,000 bonds, to pay for new equipment and for the carrying out of certain betterment work, including grade reduction and construction of branch lines.

Southern Pacific.—This company has authorized an issue of $30,000,000 1-year 5 per cent. notes, of which $20,000 are to be underwritten by the syndicate headed by Kuhn, Loeb & Company, New York, who expect to offer them to the public at 99. The notes will be dated June 16, 1913, and are to be secured by the deposit of $17,500,000 Northwestern Pacific first and refunding mortgage 4½ per cent bonds, due 1957; $17,500,000 Pacific Electric Railway refunding mortgage series A, 5 per cent. bonds, due 1961, and $4,000,000 Galveston, Harrisburg & San Antonio, Galveston-Victoria division, first mortgage 6 per cent. bonds, due 1940.

Union Pacific.—See editorial comments in regard to the exchange of Southern Pacific stock for Baltimore & Ohio stock.

Subscriptions, including 52 regular weekly issues and special daily editions published from time to time in New York, or in places other than New York, payable in advance and postage free:

United States and Mexico	$5.00
Canada	6.00
Foreign Countries (excepting daily editions)	8.00
Single Copies	15 cents each

Engineering and Maintenance of Way Edition and four Maintenance of Way Convention Daily issues, North America, $1.00; foreign, $2.00.

Entered at the Post Office at New York, N. Y., as mail matter of the second class.

WE GUARANTEE, that of this issue 8,150 copies were printed; that of these 8,160 copies, 6,696 were mailed to regular paid subscribers and 345 were provided for counter and news companies' sales; that the total copies printed this year to date were 224,909—an average of 8,650 copies a week.

VOLUME 54. JUNE 27, 1913. NUMBER 26.

CONTENTS

*Illustrated.

THE State Railroad Commissioners of Massachusetts have investigated a collision which occurred between slowly moving passenger trains, injuring ten persons at a junction on the Boston & Maine at South Lawrence, June 3, and they report that the use of ball signals was largely instrumental in causing the collision; and they have issued an order requiring all such signals to be replaced by July 1, 1914, throughout the state of Massachusetts, by more dependable signals; that is to say, adequate interlocking. To many an old New Englander this will seem like desecration. Not that New England is the only old fashioned part of the world—ball signals and other archaic contraptions may be found not so very far from Philadelphia and Chicago, Kansas City and St. Paul—but the serene contentment based on the virtues of a couple of bushel baskets painted red and hung aloft has become ingrained in the eastern Yankee's character, like his pride in the Boston Public Library. Moreover, the ball signal deserves honor for its past. It is not very effective in fog, and nobody claims that its raised position and its lowered position are interlocked against each other; but think of the useful function it performed when it supplemented the former practices at grade crossings. Those practices were exactly like what we see on city street railways today (where the speed is only four miles an hour). In those old days Americans, in their conceit and ignorance, looked upon John Saxby (if they had ever heard of him) as a doctrinaire, and his interlocking machine as not worthy of the attention of practical railroad men. However, the world does move; and now, after Mr. Saxby is dead, though his departure was delayed till he was past 90, the Massachusetts Commissioners recognize his worth by ordering the adoption of his ideas

THE Missouri, Kansas & Texas has been trying a new experiment this last year in the way of industrial development of its territory. A comprehensive description of the work that has been done by railroad industrial departments would fill a fairly large volume. Most of this work has been along the lines of educating farmers and manufacturers as to the benefits to be derived from certain natural advantages reached by the particular railroad employing the industrial department. Of course, railroads having land grants found the most obvious and direct advantage from attempting to induce immigration on to their lands. In their efforts to accomplish this praiseworthy object they have established demonstration farms, have run demonstration trains, have given demonstration lectures and have conducted a general campaign of education. The Long Island's success in the establishment of demonstration farms which produced rich yields of truck produce on land which had previously been considered nearly worthless, was a notable and well known example of the material advantages which a railroad company could gain from such work, even when it had no land to sell. The Missouri, Kansas & Texas' experiment is not a demonstration or a campaign of education as to what *can* be done, but simply an opportunity which has been given to farmers along its lines to make an experiment for themselves at the expense of the railroad company. Fertilizer, so extensively used in the southeast for cotton growing, is comparatively little used in Texas. Texas black lands will raise a heavy crop of cotton without the use of fertilizer; but even on these black lands it is an established fact that the use of fertilizer will increase the yield of cotton or of other crops out of all proportion to the cost of its purchase and application. The Missouri, Kansas & Texas industrial department made an offer to a certain number of farmers in each community along its line to furnish free enough fertilizer to make a thoroughly practical try-out of its use. It will be a year or two until definite figures can be given for the results of this experiment; but in the meantime it is worth while calling attention to this departure, because it conforms to principles which are well recognized in modern educational methods. There is no argument so convincing as that furnished by a man's own experience, and it almost seems surprising that this experiment has not been tried before. To guard against the unintelligent use of the fertilizer the railroad company has selected with some care the farmers to whom it has made the offer, and the industrial department is keeping a close watch on the results that are being obtained. The cost of publicity, if we may call it so, is much less than would be that of the purchase and installation of experimental farms. Two farmers supplied with fertilizer in a community will draw the attention of the great mapority of that community even more surely than would the establishment of an experimental farm. While the results that these men may get will not be quite as striking, probably, as would be the results on a farm under the management of experts, these results will have a home application far stronger than would the results obtained by experts. The local interest that has been aroused already is quite intense, and it will now remain to be seen whether this interest will result in the purchase by the farmers of fertilizer at their own expense next year.

TO MAKE COMPETENT ENGINEMEN.

THE inquiries into the Stamford collision by the coroner, the Interstate Commerce Commission, the Connecticut Commissioners and the officers of the road, have been continued on four days during the past week. Not many additional facts have been brought out. Just what were Engineman Doherty's errors or omissions cannot be told with certainty; but all the evidence goes to confirm the opinion, expressed last week, that he simply waited too long before applying the brakes. The theory that he had made repeated applications unnecessarily, thus reducing the pressure in the main reservoir, has no support, and the theory that the brakes did actually go on effectively, when applied, is sustained by the testimony of the conductor of the train, who was thrown to the floor of the car by the sudden checking of the speed, and by the fact that the train broke in two. The conductor picked himself up as quickly as he could, and immediately thereafter the crash occurred. The brakes had acted satisfactorily at Noroton and at Bridgeport and also at another point where the engineman was alarmed by a man walking on the track, heedless of the train.

But the lesson to be learned does not depend on the facts of this particular case. It is admitted on all hands that Doherty had not had sufficient training in the management of fast and heavy passenger trains. Whatever may have been the drawbacks at Stamford he, by his own testimony, had had such clear warning of the possibility of inefficient action of the brakes that Mr. Bardo's conclusion, that no competent man in his right mind would have approached the distant signal at such high speed, seems to be the only conclusion possible. The road foreman had told Doherty that on [all] the new engines, as a class, the operation of the brakes was unsatisfactory. Doherty himself, on at least one occasion, had been unable to make a satisfactory stop, and Harmon had had that trouble three days before. No competent engineman reporting to the roundhouse man that an engine's brakes were "no good" would resume operation of the same engine on a fast train without knowing by personal trial whether the faults had been corrected. One is almost, if not quite, forced to the conclusion that Doherty, being a few minutes late, was so anxious to reach Stamford on time that he delayed the application of the brakes longer than his own judgment would have dictated.

The only remedy for such a condition is training. "Experience" is the word usually used, but the thing really meant is such a quality and quantity of experience as shall have taught the engineman how to guard against all possible pitfalls. Mr. Bardo, in speaking before the commissioners, said that safe service demanded that the men be made to understand that they are responsible to the public. This is an excellent idea; but no railroad manager can depend on it for practical results. His own reputation is bound up with that of his enginemen as a body and he must have something more tangible than such an undefined sentiment. To be loyal to the public involves not alone moral integrity but also intelligent knowledge of one's duties; and that is as definite as the study of the multiplication table. The public cannot go to a hundred enginemen and demand loyalty; the public does not know precisely what loyalty means. To the engineman it may mean that he must confess to inadequate knowledge of some detail of the brake apparatus or of its manipulation. To be wholly loyal to the passenger he may some day have to stay at home and skip a trip, and lose $5 or $10, because he is worried about a sick wife or a troublesome debt, and cannot keep his mind on his work. To make perfect enginemen under the restrictions suggested here, calls for a course of education; and the superintendent is the only man who can effectively administer it. Even if the enginemen of a division generally are disposed to educate themselves, what assurance can there be that 100 per cent. of them will do the thing and do it successfully? Mr. Bardo said that 90 to 95 per cent. of the New Haven men were all right. That means, simply, that the other 5 or 10 per cent constitute the problem. And the only way to reach the 10 is to examine these and also the other 90.

In short, the responsibility of running a fast train is so great that the only satisfactory standard of training is the highest possible standard. An inquiry into Doherty's qualifications would have to be very comprehensive, for his fault may be hard to define. So far as knowledge of air-brake operation is concerned, he ought to make a good showing, for his experience had been on freight trains, which usually are much more difficult to manage than are 8-car passenger trains. Mr. Bardo told the commission that he would proceed to revise the rule which was the subject of discussion. But if 90 per cent. of his men are satisfactory, perhaps the need is not for a revised rule but for more attention to the details of the enforcement of the rule. Surely, some men will learn in one-third the time necessary to educate others; why hold the bright ones back? The essential thing is a certain amount of education, not a certain number of months or miles which may be assumed to afford opportunity for education. There should, indeed, be a minimum number of months' service in each kind of work and each kind always in the proper order. On most roads the order is—1, firing on switcher or easy freight; 2, firing on freight (general); 3, firing on easy passenger; 4, firing on fast passenger; 5, running switcher; 6, running freight; 7, running fast freight; 8, running easy passenger; 9, fast passenger; but the main thing is that a competent man—the road foreman—shall be able to testify to the superintendent that each runner has demonstrated his ability. On a road where, as was the case formerly on the New Haven, there are not enough freight trains to serve as schools for passenger runners, the task of education is more complicated and more costly; but the course to be pursued is plain, nevertheless.

If the course here indicated seems too rigid and costly for every-day practice the reply is that rules are necessarily rigid; and that in matters where rigidity is in any respect intolerable, the rule should be suspended, but that the suspension should be attended to personally by a competent officer, in every instance. The best lesson in railroad discipline that has appeared for many a day is that published by the New York State Public Service Commission in its report on the Corning collision (*Railway Age Gazette*, January 17 and 31, 1913). In that report emphasis is laid on the necessity that the manager shall see that roundhouse foremen and trainmasters—the men who supervise train running—are individuals of strong character and that they shall be made to feel secure in their places. Here we see one of the main elements in the training of runners. It is to be added that these division officers should be paid well. What officer is more important, from the standpoint of safety? Some of these officers draw less pay than some of the enginemen whom they rule over. It may be added, also, that there should be enough of them. Many road foremen supervise the work of 100 runners, and often of more than that. It is difficult to see how one foreman can look after 100, or even 50, unless his territory is compact and he knows the runners pretty thoroughly *and favorably*, from long acquaintance.

We are not laying down an impossible standard, based only on academic considerations. If firemen have to be promoted rapidly the superintendent cannot always get his knowledge of the ability of young runners from the road foreman. Old runners must temporarily perform this function of the foreman. But these must be runners really qualified to instruct young enginemen and to clearly state the situation to the superintendent. A routine requirement, treating all the old runners as competent in this matter, is pretty sure to fall short of the needs of the situation. One of the four critics who were invited to New Haven from other roads said at one of the hearings that he would have kept Doherty on freight trains two years longer. That, however, does not meet the situation; the question is, What specific knowledge did Doherty lack, and what things must be done to supply the lack? This work might take one year and it might take three. Very much depends on what the

young runner learned while he was firing. Some learn much, others far less. No number of years could be considered a satisfactory training for a fireman who had to gather his knowledge from an unfriendly runner; and the unfriendliness which is known to exist between the enginemen's and firemen's brotherhoods is said to show its effects in the everyday life of the men in many cabs.

There is room for an extensive enlargement of the road foreman's work. Not only should there be an ample number of men; they should have the aid and co-operation of the enginemen in more thoroughly instructing firemen. The process of educating men to be runners begins, of course, while they are still firing. Why should not substantial premiums be paid to the enginemen who should best fit their firemen to be runners? If there is anything of the nature of unfriendliness in the cab, it is an indication of an intolerable situation, demanding to be cured.

Mr. Bardo quite directly charged the brotherhoods with weakening discipline. We shall not dispute a word that he said. There are all too many instances of such results on many roads. But it is pertinent to say that he did not show any connection whatever between this wrong influence and the particular failure now under discussion. Those newspapers which recognize the bad influence of the labor unions are quick to take up the matter of the abrogation of the two-year rule, and to argue from it. But it must be noted that two years, or four, might not have cured Doherty's deficiencies; and that two months, possibly two weeks, of instruction, rightly used, in all probability would either have made Doherty competent to handle the big new engine, or else would have demonstrated his lack of the qualities necessary for that position.

THE SIGNIFICANCE OF THE STATE RATE CASE DECISIONS.

THE meaning of the part of the Supreme Court's opinion in the state rate cases dealing with state interference with interstate commerce is clear enough. It is, in effect, that Congress has discretionary power to pass any legislation it may deem necessary to stop and prevent state regulation that directly or indirectly burdens or interferes with interstate commerce, but that Congress has not exercised its full authority, and until it does so the states may practically fix rates as they see fit as long as they do not make them confiscatory. This squarely "puts up" to Congress the entire question of regulation of rates. State legislatures and commissions repeatedly have so adjusted rates as to interfere with interstate rates and to promote local at the expense of national interests. The Interstate Commerce Commission and the Commerce Court, in their opinions in the Shreveport case, have described and discussed the heretofore successful effort of the Texas Railroad Commission to compel the railways to discriminate unfairly in favor of shippers in Texas as against shippers in Louisiana who were competitors against them for business in Northeast Texas.

Such state regulation has not been confined to Texas. For years the regulating authorities of certain states have sought to so adjust intrastate rates as to give the producers and jobbers of those states a practical monopoly of their markets. It is the plain duty of Congress, in the interest of the national welfare, to give the Interstate Commerce Commission power to so control state regulation as to prevent national interests from being subordinated to local interests. Likewise there is much state regulation of operation, such as full crew laws, that burdens interstate commerce without conferring the slightest benefit on the public. Whatever action may be necessary to relieve commerce of these burdens, Congress ought to take it.

While the meaning of the part of the opinion relating to state interference with interstate commerce is clear enough, the significance of the portion relating to valuation will be found, on a careful reading of the whole, to be far from certain. The court evidently accepts the view that valuation should be based on the present value of the property. It also evidently accepts the view that the main factor in present value is the cost of reproduction. But it does not make clear its idea as to how the present cost of reproduction is to be ascertained. The railways contended that it would cost them more to acquire their land for railway purposes than its value for other purposes, and that on the reproduction theory, land should be appraised at what it would cost them to acquire it. On this phase of the matter the court says:

> It is said that the company would be compelled to pay more than what is the normal market value of property in transactions between private parties; that it would lack the freedom they enjoy, and in view of its needs it would have to give a higher price. It is also said that this price would be in excess of the present market value of contiguous or similarly situated property. . . . It is impossible to assume in making a judicial finding of what it would cost to acquire the property that the company would be compelled to pay more than its fair market value. It is equipped with the governmental power of eminent domain. In view of its public purpose it has been granted this privilege in order to prevent advantage being taken of its necessities. It would be free to stand upon its legal rights and it cannot be supposed that they would be disregarded.

In other words, the court flatly refuses to see that railways, even when they take land under the power of eminent domain, do have to pay more than other persons, and says that their valuations must be made upon the theory that they do not have to pay more. It takes the theory and lets the true facts go. The Supreme Court must know, regardless of its dialectics, that in cases arising under the law of eminent domain juries habitually hold railways up. In the case of a new railway which has had to pay perhaps $200 an acre to acquire land that is worth only $100, the rigorous application of the principle laid down would mean the confiscation of $100 of its investment in every acre of its land.

The court also shows in another respect a singular aptitude for disregarding patent facts. In all the state rate cases decided last week and the week before it apparently holds that if a certain schedule of rates is confiscatory as to one of two competing railways and not confiscatory as to another, the railway as to which they are not confiscatory must accept them. It gives the weak railway Hobson's choice saying, in effect: "You may take either confiscatory or non-confiscatory rates. But in any event your competitor must make rates which as to you are confiscatory, and if you are not bankrupted by making the confiscatory rates you will be bankrupted by losing business because you do not meet them." The principle laid down is a principle of confiscation by indirection as distinguished from a principle of confiscation by direction. The conclusion of the Supreme Court is in substance, that a given schedule of rates may be unreasonable as to one road, and reasonable as to another operating in the same territory and handling the same kind of traffic. Only the judicial mind can tell how a given schedule of rates may at the same moment be both reasonable and unreasonable. This is law because the Supreme Court says so. But it is neither economics nor business. When Lord Eldon said that the law was common sense he did not foresee the decision in the Minnesota rate case.

The court is destructive, but justifiably so, in its criticism of the way in which some of the valuations made by the railways themselves and introduced in testimony in these state rate cases were made. Some of these valuations were hardly scientific guesses. It was on equally solid ground in criticising the use of gross earnings as a basis for dividing the value of railway property between state and interstate business. As it clearly pointed out, to use gross earnings as the basis of division is to reason in a circle. There will, however, be great difficulty in working up the data regarding "use units" and the cost of the various kinds of service which the decision will make it necessary for the railways to introduce in testimony in future cases involving the question of confiscation.

The more one studies the opinions in these state rate cases the stronger will his impression grow that the future of the

railways of the United States is in the hands of the public and the regulating commissions, and not of the courts. The Supreme Court seems to make plain that it will not set aside government made rates on any railway—at least those made by the authority of the national government—unless they are proved by each railway to be confiscatory as to it. Now, rates may be such that at least the more prosperous railways in each territory cannot prove they are confiscatory as to them, and yet such as to so reduce the net earnings of the railways as a whole as to gravely interfere with the adequate development of transportation facilities. As a matter of law, the question may be whether the rates are confiscatory. As a matter of public policy, the question always is, not whether they are confiscatory, but whether they are such as to promote the development of railway facilities and thereby further the public welfare. The courts, in determining whether rates are confiscatory, merely fix the minimum below which they may not be reduced. Congress and the Interstate Commerce Commission have a legislative discretion which they may so exercise as to permit the railways to earn whatever return public expediency demands that they shall be allowed to earn. The maximum which railways should be allowed is an economic question, a question of public policy, and it is to be hoped that it will be dealt with as such.

EQUIPMENT NOTES AND A BAD BOND MARKET.

NOW is a time when new issues of railroad long-term bonds are particularly difficult to float. Since this unfavorable bond market coincides with a heavy demand for improved railroad facilities, particularly equipment, and with prospects of further heavy demands for equipment, due to large crops, the comparative advantages of an issue of notes, secured by collateral or general credit, and of the issue of equipment trust certificates is a question that has faced a good many railroad officers. Recently there has been issued $19,700,000 Pennsylvania general freight equipment trust 4½ per cent. certificates, $4,410,000 5 per cent. equipment gold notes of the Chicago, Rock Island & Pacific, $5,000,000 Southern Pacific equipment trust 4½ per cent. certificates, and $1,900,000 Missouri, Kansas & Texas equipment trust 5 per cent. notes, and it was announced not long ago that the Boston & Maine had sold $7,500,000 equipment trust 4½ per cent. notes, which announcement superseded a previous announcement of the issue of 20-year debenture notes. On the other hand, the companies making up the New York Central system have outstanding more than $100,000,000 one-year notes.

The bankers for the Pennsylvania offered that company's equipment trust certificates at prices to yield 5 per cent. The Southern Pacific 4½'s were offered at 98; the Missouri, Kansas & Texas 5 per cent. equipment notes on a basis to yield 5⅛ per cent., and the Chicago, Rock Island & Pacific on a basis to yield about 5½ per cent. The New York Central's various issues of notes were offered at slightly varying prices, yielding in the neighborhood of 5⅛ to 5½ per cent. The New York Central itself issued earlier in the year $12,540,000 4½ per cent. equipment trust certificates on a basis to yield 4.65 per cent.

It would seem that equipment trust certificates command a somewhat higher price from investors than would notes of the same company, secured by an issue of general bonds. Certainly they command a better price than would notes secured simply by the general credit of a railway company. In the past it has been customary to require the payment of at least 10 per cent. of the cost of equipment on which equipment trust certificates are issued to be paid by the railroad company in cash. Sometimes this has been as high as 15 per cent., and in the case of the Missouri, Kansas & Texas equipment trust notes, 20 per cent. was paid by the railroad company in cash. Thus from the investors viewpoint, not only has he when buying equipment trust notes security directly on tangible property, but he is also assured of a substantial equity directly back of his investment. Furthermore, equipment is in the nature of a salable asset. Even if in the reorganization of a bankrupt property the receivers should decide to permit a default on equipment trust certificates and to let the security for these certificates be sold, a bidder other than the reorganization committee representing this railroad might possibly be obtained for the equipment. As a matter of fact, in the only instance that we know of where equipment trust notes were allowed to go to default by the receivers, these notes were guaranteed by the company which sold the equipment, and the equipment itself was taken back by the builders and resold without, so far as is known, loss to the holders of the certificates.

Receiverships, however, have never come at the beginning of a period of great car surplus when the roads going into bankruptcy also had a surplus of equipment. Whether a receiver might not feel justified in defaulting on an equipment issue under such circumstances is a question. If the condition of car surplus was country wide and severe, second-hand equipment would not probably be a salable asset. Under conditions such as these it is quite conceivable that holders of car trust certificates of a bankrupt road might suffer at least temporary loss in interest; but even then their position would probably be better than holders of unsecured notes or junior securities of the second or third class. There is a certain simplicity in the security of an equipment trust issue which is entirely lacking in the position of junior securities, even when secured by a mortgage on specific property. These are all points which the market price of equipment trust certificates reflects.

The chief advantage from the railroad company's point of view for the issue of equipment trust certificates is in the comparatively high market price for which they can be sold. There are, however, certain rather obvious disadvantages to a railroad company in burdening itself with equipment trust issues. The general use of equipment trust or car trust certificates is comparatively recent. Certain companies, however, have issued equipment trust certificates for a number of years. In 1874 the Pennsylvania had one thousand leased coal cars presumably represented by some sort of equipment trust or car trust certificates. At the end of 1912 the Pennsylvania had issued a total of 105,300,000 equipment trust certificates, the greater part of which, of course, have been retired at various times. Since the indenture securing equipment trust certificates usually provides for the retirement of a certain proportion of these certificates semi-annually or annually, the railroad company has to be continually providing cash to meet these maturing instalments of principal, and this to a road which cannot afford to carry a very large amount of cash on hand, is in itself a source of continual care. It may be under certain circumstances, an actual menace. It is not generally possible to renew equipment trust certificates. The road with a sound credit can always renew short term notes if it is willing to pay a high enough price for its money, but an issue of short term notes, part of the proceeds of which were to be used to provide funds for the retirement of equipment trust certificates, would not presumably be looked on with favor by bankers or investors.

The Interstate Commerce Commission's rules for accounting, provide for a charge to be made each month to expenses for depreciation of equipment. If a railroad company is forced to make a charge for depreciation of equipment and at the same time to provide funds out of current earnings to pay the principal of equipment certificates falling due periodically, it is in a position of both setting up a charge for depreciation and providing a sinking fund to take care of depreciation. Since, however, the charge to operating expenses is a bookkeeping charge only, it would seem that a railroad company might so adjust its equipment certificate maturities as to make the amounts in a given half year about equal the charges for depreciation. By doing this the company would overcome one of the objections to the Interstate Commerce Commission system of charging for depreciation, namely, that this charge is a matter of bookkeeping only, and at the same time avoid the duplication involved in setting up a sinking fund and a depreciation charge for the same property.

ILLINOIS CENTRAL MECHANICAL TERMINAL.

Construction of an Important Division Terminal at Centralia, Ill., Which Was Carefully Designed and Well Equipped.

The Illinois Central has recently installed at Centralia, Ill., a mechanical terminal for the handling of cars and locomotives that is one of the most complete and up-to-date terminals in this country. Centralia is one of the most important freight terminals on the Illinois Central system, being located on the main line from Chicago to New Orleans north of the junctions where the traffic from the Y. & M. V., the Birmingham line, the Kentucky division, and the southern Illinois coal fields joins that of the main line from New Orleans and just south of Branch Junction, where the northbound traffic separates that for Chicago and the east going up the main line and that for central Illinois, Iowa, Omaha and the west, going over the Springfield and Wisconsin divisions. This makes Centralia the logical point for a very complete classification of freight, so that a large part of the traffic can move to northern and western points in full train lots, thus relieving congestion and reducing switching in the yards north of Centralia, and making possible somewhat quicker delivery to northern and western points. To handle this classification, the company completed and put in operation last summer, a 3,000 car yard with a hump for northbound business, provision being made in the design for an ultimate capacity of 9,000 cars. The design and construction of this yard were described in the *Railway Age Gazette* of August 9, 1912. The new mechanical terminal cares for the engines of the St. Louis, Springfield and Illinois divisions, which terminate there, and includes complete facilities for making both heavy and light repairs to these locomotives, and also for repairing any bad order cars received at this point.

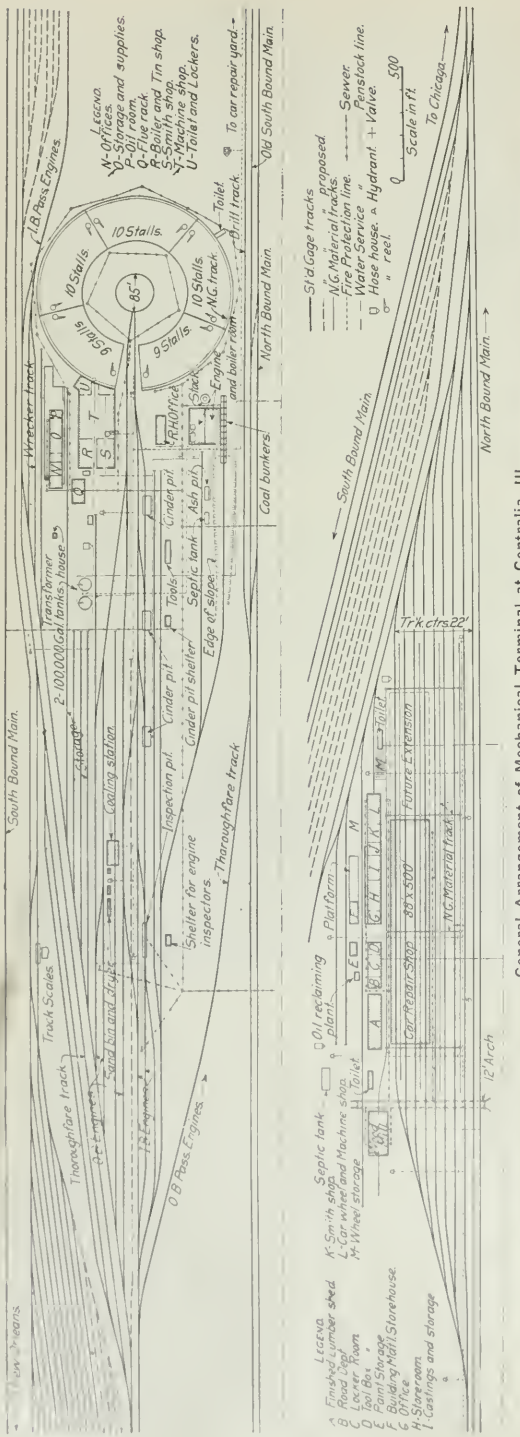
General View of Locomotive Group.

YARDS.

On account of the topography of the ground available for use, it was necessary to make the locomotive and car departments practically independent of each other, except for the common use of water, air, heat and electricity. The car group is located about 2,000 ft. north of the north end of the locomotive group. The arrangement of yards and buildings is shown in the accompanying illustrations. The engine house has a single opening, to the south, enabling all freight engines to enter and leave the house without reverse movements, but requiring passenger engines leaving or taking trains at the Centralia station, which is north of the yard, to run about 2,500 ft. south of the roundhouse and reverse. Passenger locomotives inbound to the house, leave the main track north of the extreme limits of the yard, taking an engine lead alongside the double track lead to the southbound tail switching yard. Passing just west of the roundhouse this track connects with the main ladder of the engine yard, at the south end of which connection is made with the inbound tracks to the house. Southbound freight engines pull their trains into the southbound switching yard, run through to the south end of this yard and return on the thoroughfare track which connects directly with the inbound engine tracks to the roundhouse. Northbound freight engines leaving their trains in the northbound receiving yard at the extreme south end of the terminal, use this same thoroughfare track to reach the house. There are two inbound engine tracks, one running straight into the house without passing over either the inspection pits or the cinder pits. The other crosses the inspection pit and the three cinder pits, with crossovers just beyond each cinder pit to enable an engine on the rear pit to run around an engine still standing on one of the pits ahead. Crossovers are also provided to reach the coaling station if it is desired to coal an engine before taking it into the house. Inbound engines may water at a penstock just back of the inspection pit.

Outbound engines from the house can use one of three tracks, two of which pass the coaling station. A penstock located just outside of the roundhouse, and another just beyond the coaling station, allowed outbound engines to take water conveniently. Freight engines take the southbound thoroughfare track directly from the outbound engine tracks to reach either the northbound or southbound departure yards. Passenger engines run down one of the outbound tracks to the main ladder, down this ladder to the thoroughfare tracks, take a crossover to the northbound thoroughfare tracks, reverse and take that track over to the old southbound main, which they use as a northbound thoroughfare track, to the north end of the yard.

In addition to the running tracks, the engine yard includes a wrecker track close to the roundhouse, an oil car track along-



General Arrangement of Mechanical Terminal at Centralia, Ill.

side the storehouse, a material track on the other side of the storehouse, three stub end switch tracks for coal and material, a coal track under the coaling station, a crane track and cinder track alongside the cinder pits, a cinder track to the boiler cinder pit, and a coal track to the power house bunkers. The car repair yard consists of eight tracks with a capacity of about 250 cars, exclusive of the tracks serving the lumber sheds and storerooms in connection with the car group. There is a separate lead

Interior of Erecting Shop.

track to this yard from the south alongside the engine thoroughfare track.

ENGINE HOUSE.

The buildings of the locomotive department are arranged in a compact group and are uniform in general design. They are built of brick on concrete footings with composite roofing, laid on concrete slabs in the case of the machine shop and power

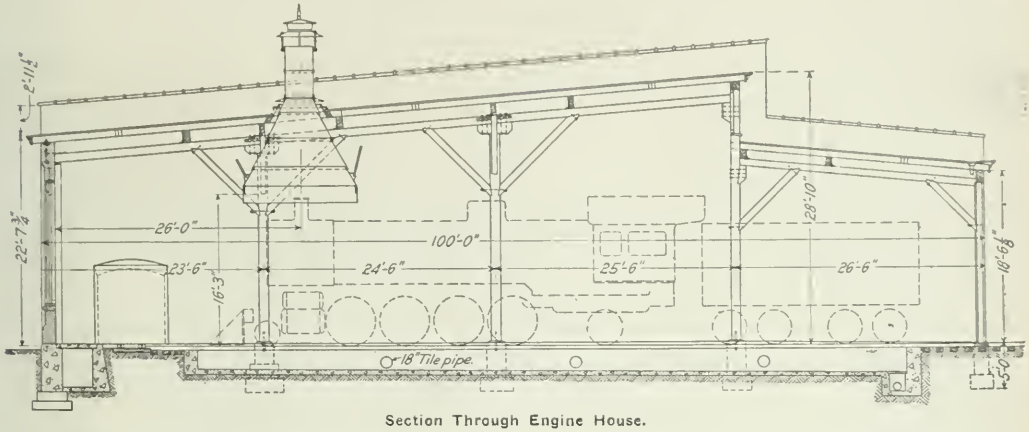
Interior of Engine House.

house, and on timber roofs for the roundhouse and storehouse; the office building roof being of slate.

The engine house has 48 stalls in a 50 stall circle, of which 39 stalls are used for housing engines. Since practically 100 engines are handled in and out of Centralia in 24 hours, this house provides one stall for 2½ engines per 24 hours. The house is 100 ft. deep from outside of back wall to inner posts, the

width of stalls center to center of posts being 14 ft. The circle is divided into five sections by four brick fire walls, three containing 10 stalls each and two containing nine each. One of the nine stall sections is designed for an erecting shop. Kinnear fireproof doors are used for all openings in the fire walls.

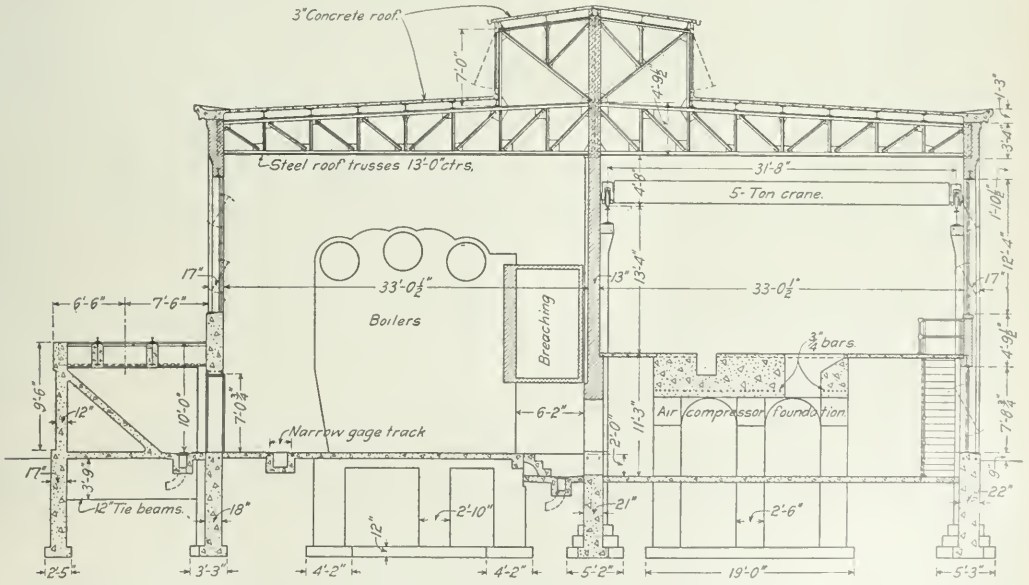
The continuous foundation under the outside wall and the sash. The smoke jacks are Dickinson 30 in. cast iron. The roof is five ply tarred felt and pitch with composition surface. The floor of the house between pits is of vitrified paving brick, laid on rolled sand with cement grout filling. A continuous 24 in. gage material track is laid just inside the outer wall of the house with connections to the erecting shop and machine shop.



Section Through Engine House.

pedestals under the interior columns are of concrete, designed for a bearing pressure on the soil of 3,000 lbs. per sq. ft. The outer wall is designed to confine the damage from a runaway locomotive to a single panel. This is accomplished by the use of 15 in., 42 lb. I-beams spanning between pilasters at the tops of the

The concrete walls of the engine pits are carried down 4 ft. below top of rail, each wall being 2 ft. 4 in. wide with a 7 in. slab connecting the two to form the bottom of the pit. This slab has a slope of 6 in. in the 75 ft. length of the pit and is crowned 1 in. along the longitudinal center line for drainage.



Section Through Power House.

windows, which carry the wall above that level. The windows and the portion of the wall between the pilasters may be torn out without injuring the support of the roof or the adjacent panels. Fenestra steel sash are used for the windows in all of the buildings, with the Peerless tension operating device for movable

The 85 lb. rails used on the pits rest directly on the concrete, being secured by rail clips through which are passed ¾ in. bolts set in the concrete. The 3 in. x 3 in. x ¼ in. angles protecting the inner corner of the concrete and the 6 in. x 12 in. and 6 in x 10 in. creosoted timbers which are placed outside of each rail

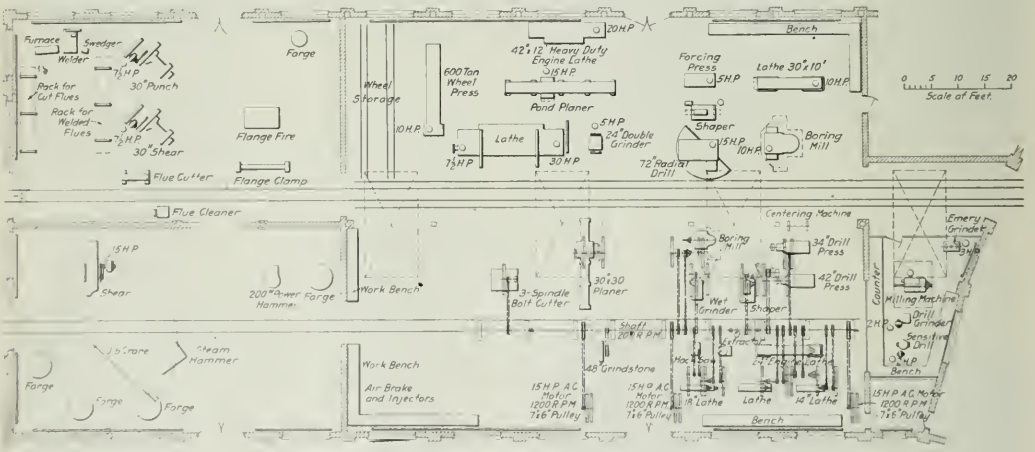
to protect the surface of the concrete, are also held in place by ¾ in. bolts set in the concrete. The water accumulating in the pits is drained to a concrete duct one foot square, laid around the inner circle of the house which collects all drainage into five manholes spaced at equal intervals about the circle from which an outlet to the sewer system is obtained.

The engine house, as well as all the other buildings in the locomotive department, is heated by exhaust steam from the power house. This steam is distributed through a pipe laid in a concrete duct about 3 ft. square just inside the foundation for the outer wall. A branch of this pipe at each pit leads to the pit radiators and other branches are carried up to the wall radiators which are supported on the pilasters between windows. Cast iron was used in preference to the ordinary iron or steel coils, as the latter are so susceptible to corrosion from gases and water. Each pit has 432 sq. ft. of radiation, and the total for the house, including wall radiation, is 26,000 sq. ft. The house is lighted by tungsten lamps, three of 250 c. p. each, being provided between engine pits with a switch and cutout box for each stall. Four Westinghouse receptacles for extension cord plugs are also provided for each pit, and a three phase, 440 volt power circuit along the wall of the outer circle allows the use of portable electrical tools, such as lathes, boring bars and flue cutters.

that of the roundhouse. Latticed steel columns support steel roof trusses on which is laid a timber roof of the same type as that used on the roundhouse. The steel construction in the erecting shop is necessary to support the cranes and is feasible, since no live engines are kept in this shop, the gases from which would corrode the steel. No smoke jacks are necessary in this section of the house, and the height of the roof is increased to allow room for the operation of the cranes and to provide additional light and ventilation. The ventilation is ample to remove any gases that may accumulate while getting locomotives in and out of the shop.

MACHINE, BOILER AND SMITH SHOPS.

The machine, boiler and smith shops are contained in a building 80 ft. x 160 ft., which closely adjoins the erecting shop, the triangular space between the square end of the machine shop and the curved outer wall of the erecting shop being enclosed to form part of the former. The shop is a steel frame building, latticed channel columns being set in the brick walls flush with the inner surface of the wall, and another row of columns being located on the center line of the building. The wall columns and the brick walls between them are carried on a continuous concrete foundation, and the center row of columns is carried



Arrangement of Tools in the Machine, Smith and Boiler Shops.

An overhead washout line and a compressed air line are carried on the roof bracing with connections at each stall.

The turntable is 85 ft. in diameter and built to the company's standard design. It is equipped with a Nichols electric tractor, designed to turn the table through one revolution in one minute. The standard pit of this road is now being provided with inspection pockets alongside the pit to allow a man to oil and inspect the tractor thoroughly and easily

The erecting shop is located in the nine-stall section of the roundhouse west of the entrance. It is designed for handling the heavy repairs to locomotives at this plant, the light running repairs being made in the roundhouse proper. Seven of the tracks are provided with driving wheel drop pits equipped with two 30 ton Watson Stillman hydro-pneumatic jacks. The other two tracks have truck drop pits which are equipped with a 15-ton jack of the same type. A 7½ ton Whiting crane having a span of 52 ft. serves this shop, being of the special compensated gearing type for operating on circular runways. Standard and narrow gage connections between the erecting shop and machine shop are provided to allow engine parts handled either by the crane or the crane to be moved easily into the machine shop, where work is to be done upon them.

The roof construction in the erecting shop is different from that of the roundhouse. Latticed steel columns support steel roof trusses on which is laid a timber roof of the same type as that used on the roundhouse. The steel construction in the erecting shop is necessary to support the cranes and is feasible, since no live engines are kept in this shop, the gases from which would corrode the steel. No smoke jacks are necessary in this section of the house, and the height of the roof is increased to allow room for the operation of the cranes and to provide additional light and ventilation. The ventilation is ample to remove any gases that may accumulate while getting locomotives in and out of the shop.

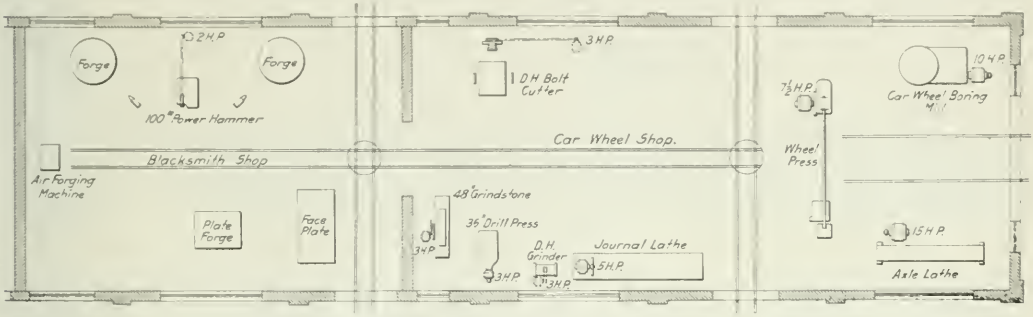
on concrete pedestals spread to a bearing 5 ft. 6 in. square. The columns are 21 ft. 10¾ in. high, with connecting struts at the top which reduce their unsupported length to 15 ft. 8¾ in. A 5-ton crane which serves the machine shop is supported by brackets on the steel columns 13 ft. 10¼ in. above the floor. These brackets carry 15 in. 42 lb. I-beams on which are laid the 60 lb. rails for the crane runway. The columns support steel roof trusses designed for a span of 40 ft., having a depth of 4 ft. at the wall and 6 ft. 2 in. at the center line of the building. These trusses are built up of angles with the exception of the lower chord of the trusses on one side of the building, which support a line of shafting. These chords have channel sections to facilitate the hanging of this shafting. On the roof trusses are laid 8 in. 18 lb. I-beam purlins 5 ft. center to center, spanning the 16 ft. between trusses and supporting the 3 in. concrete roof slab. This roof slab is reinforced with American Steel & Wire No. 4 triangular mesh reinforcement, and is covered with four ply tarred felt and pitch with a composite surface. Skylights and 36 in. ventilators are provided over the center of the building. Two lines of narrow gage and one of standard gage track serve these shops. The floor is of concrete 5 in. thick, with a granitoid finish. The machine shop proper is divided into two 40 ft. bays, all the tools in one bay being motor driven, and those in the

other being belt driven. The tool equipment is very complete, many new machines being installed besides those used in the old shops. The motor driven tools are operated on a three phase, 60 cycle, 440 volt a. c. circuit.

THE POWER HOUSE.

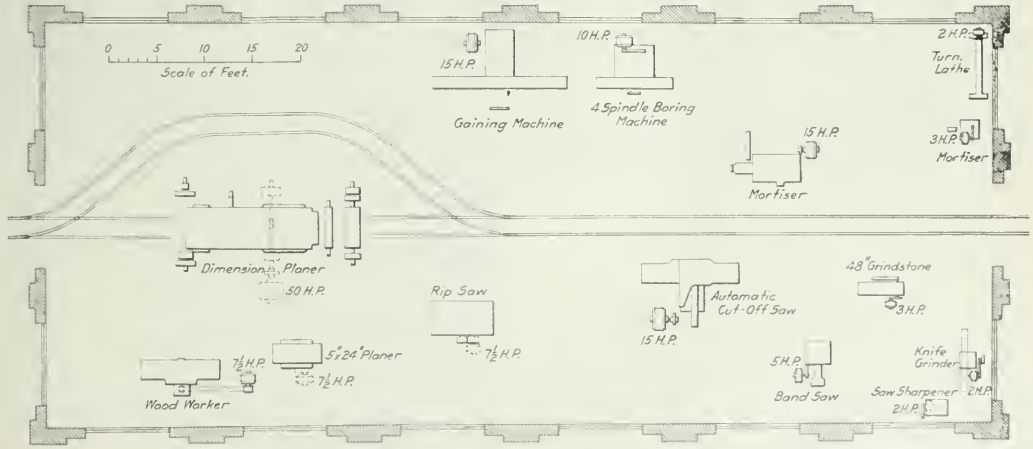
The power house is one of the most important buildings in the locomotive group. On account of the arrangement of the terminal it is necessary to drive all the machinery either directly or indirectly by electricity, and since there was not adequate central station service it was decided to install an up-to-date electric plant. The building is 60 ft. x 80 ft., divided longitudinally in the middle by a 13 in. brick wall into an engine room and boiler room. A heavy concrete foundation is required under the boilers and under the machinery in the engine room. The roof trusses and monitor framing are of steel carried directly on the brick walls. A 5-ton Whiting hand operated crane in the engine room is carried on 9 in. brick pilasters with stone caps which support longitudinal I-beam girders for the runways. The roof slabs are the same as in the machine shop. The floors are of concrete with granitoid finish.

The equipment consists of four 250 h. p. Stirling water tube hand fired boilers operating at 150 lbs., a 2,000 h. p. Cochrane horizontal feed water heater, two 250 k. v. a., 3 phase, 60 cycle, 400 volt General Electric, non-condensing, turbo-generators, two 1,000 cu. ft. air compressors, besides other auxiliary power equipment. An automatic oil storage and filtering system handles all the oil used by the turbines, air compressors and pumps. Space has been reserved in the engine room for the installation of a locomotive boiler washing and refilling system. The electric power is distributed to the other buildings by cables carried on steel transmission towers with concrete pedestals. The pipe lines from the power house to the roundhouse are carried in a 5 ft. x 6 ft. concrete tunnel, and the hot water pipes for heating the car department buildings are carried in a concrete conduit having special provision for expansion, which was an important consideration in the adoption of hot water in preference to steam for heating the buildings of the northern group. The pipes, which are about 2,500 ft. long, are carried on expansion rollers to allow free movement due to expansion and contraction, and two loops are provided in the line to take up this movement.



Arrangement of Equipment in the Car Department Wheel and Smith Shops.

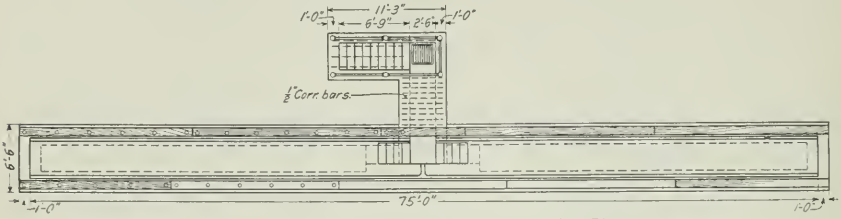
The coal bunker alongside the boiler room is of reinforced concrete of a special design, having a capacity of 400 tons. The outer wall of the bunker is 1 ft. 3 in. thick, reduced in the panels to 12 in. The inner wall is formed by the wall of the power-house. Concrete beams 12 in. thick and 3 ft. 9 in. deep on 13 ft. centers support the 6 in. floor slab of the bunker, and 6 in. vertical walls over these beams support a similar slab which is sloped up from the floor level at the inner wall on a slope of about 1 to 1 serving to hopper the bunker. The track over the bunker is carried by 24 in. 80-lb. I-beams under each rail, which are connected to the web of similar I-beams set transversely on the concrete walls at intervals of 13 ft. These beams are covered with concrete for protection. The base of rail is 10 ft. above



Layout of Machine Tools in the Wood Mill.

the floor of the boiler room and the extreme width of the bunker is 12 ft. 8 in. There are six 7 ft. doors in the wall between the bunker and the boiler room, allowing the coal to fall through on the boiler room floor. These doors have cast iron jambs and lintels. A drain pit is provided at the lowest point of the bunker to lead to the sewer any water which may collect.

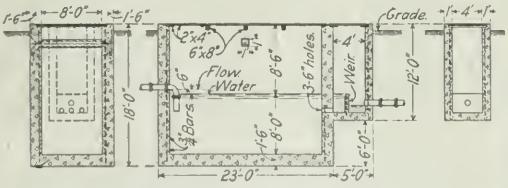
The chimney for the power house is of concrete, the shaft being 204 ft. high, and the footings carried down 5 ft. and spread to 28 ft. square. The outside of the shaft is tapered, the diameter at the bottom being 14 ft., and at the top 8 ft. 6 in. The concrete shall has a thickness of 15 in. at the bottom and 6 in. at the top, being reinforced with vertical bars. A lining of fire blocks is carried up 70 ft. from the top of the footing, this lining having a uniform inner diameter of 8 ft. The inside diameter above this lining is 7 ft. 6 in. The lining is 4½ in. thick, and is entirely separate from the concrete shell, leaving an air space between the two which is 16½ in. wide at the bottom. The smoke opening into the chimney is 4 ft. 6 in. x 12 ft. 3 in., the fire block lining being carried through this opening to connect with the flue lining. The chimney is designed to allow for a boiler overload of 50 per cent., and provides for the burning of low grade coal.



Detail of Inspection Pit.

STORE HOUSE AND OFFICE BUILDING.

The store house is 30 ft. wide and 170 ft. long. The south end, which is devoted to offices, is two stories high. The store keeper and master mechanic have offices on the first floor, and the second floor is taken up with a record room, rest room for engineers and firemen, and an apprentice classroom. The store house proper is one story high, with an oil room at the north end, separated from the rest of the building by a brick fire wall.



Details of Septic Tank for Sewage Disposal.

The oil room is provided with the Bowser system of distribution, power pumps being provided for handling fuel, car and kerosene oils from the storage tanks in the basement to faucets for filling barrels on the platform. Hand pumps of the self-measuring type are also provided for all kinds of oil held in storage. Some long distance rotary pumps are located in the erecting shop about 800 ft. from the oil room and have given satisfactory service.

The concrete platform 45 ft. wide across the north end of the building with extensions along both sides, is built at car floor level to allow material to be unloaded directly. The building is of brick construction with the same type of roof as that used on the roundhouse. The store house and oil room are to have a concrete floor which will be placed as soon as the danger of settlement in the fill is passed.

The roundhouse office is a single story brick building 20 ft. x 65 ft., with a slate roof. In addition to the office of the roundhouse foreman it contains shower baths, toilet rooms and locker rooms for the enginemen. Special care has been taken in the design of this terminal to provide for the comfort of the men off duty. Many of them have runs which allow them only a few hours at Centralia, and such men are enabled to take a shower bath and change clothes in the roundhouse office building, and then spend their spare time in the rest room in the store house building, where comfortable chairs, games and reading matter are provided for them. The comfort of the shop men is also well looked after, a large toilet and locker room being provided between the machine shop and the erecting shop, and special toilet rooms being included in each of the principal buildings.

CINDER, INSPECTION, COAL AND WATER FACILITIES.

The three cinder pits and the inspection pit are of concrete construction. The cinder pits are not unusual in design, the surface of the concrete being reinforced with old rails in the usual manner to prevent damage by the clam shell which is used in removing the cinders. The inspection pit is unique in having an underpass which allows the inspector to get under the locomotive without the danger and inconvenience incident to crawling under in the usual manner. It is the intention to develop the use of this pit as much as possible, and to handle as many of the minor repairs as can conveniently be done at this

Typical Engine Pit.

place instead of in the roundhouse. The pit is 75 ft. long, 4 ft. wide and 3 ft. 6 in. deep below the top of rail. It is formed by two concrete walls 1 ft. 3 in. thick supporting 8 in. x 10 in. timbers to which the rails are spiked. The footing connecting these two walls is carried down 8 ft. below the top of rail with a slab 1 ft. 6 in. thick at the bottom of the walls, and another 6 in. thick forming the bottom of the pit. The entrance for the inspector is opposite the center of the pit and 9 ft. 9 in. from the center line of track. A flight of 10 concrete steps leads down to a cross passage 6 ft. 6 in. below the top of rail, which is covered by a 4 in. reinforced concrete slab. After passing under the near rail in this passageway, the inspector goes up a flight of five steps toward either end to reach the pit level. All drainage from the pit and the entrance is led to a sump at the bottom of the entrance stairway from which an 8 in. drain leads to the sewer. The details of this design are shown in one of the accompanying drawings. The pit required 99.5 cu. yds. of concrete.

A number of small frame shelter buildings are provided for the men stationed in the yard, such as the inspector and the cinder pit men. No old box car bodies which are so frequently used as shelters in such yards will be allowed.

The coaling station was built by the T. W. Snow Construction Company. It is of timber construction with a storage capacity of 600 tons of coal and 20 tons of dry sand. The elevating machinery is of the double bucket, or semi-balanced skip hoist type, and is able to handle 75 tons of coal per hour. The track over the depressed hopper has a 0.5 per cent. grade rising from the hopper so that a switch engine can set in a string of loads on this track beyond the station to be dropped down by gravity one at a time and unloaded. The empties are allowed to accumulate on the other side of the station until an engine is available to remove them. A sand drying stove is provided in the building which shelters the motor equipment adjacent to the coaling station. The dry sand is elevated to the storage pocket by compressed air.

The supply of engine water is secured from two 100,000 gal. tanks, four Poague type penstocks being provided in the yard. These penstocks are set in concrete frost proof pits. The tanks are of select long leaf cypress, creosoted, the hoops being of wrought iron. Each tank support is carried on five piles.

CAR DEPARTMENT BUILDINGS.

The buildings in the car department consist of a covered shed over four repair tracks in which repairs can be made in weather which would prevent men working without shelter, and the service buildings arranged alongside the repair yard to facilitate the handling of material. The car repair shed is 500 ft. long x 88 ft. wide, and is of timber construction throughout. Three lines of posts support wooden roof trusses, the lower chords of which are 22 ft. above the top of rail. The ends of the shed are covered with siding down to the bottom of these trusses, and the sides are enclosed for 7 ft. below that line, a large portion of this space being occupied by windows, however. Skylights are provided in the roof in every other bay alternating on opposite sides. The posts are set on concrete pedestals 2 ft. square. The posts in the middle row are 8 in. x 10 in., and those in the outer rows 8 in. x 8 in. The roof trusses are framed of four 2 in. x 8 in. timbers in the lower, and four 2 in. x 10 in. timbers in the upper chord, with 2 in. x 8 in. timbers double latticed. These trusses have a roof pitch of 5/8 in. per ft. They are spaced 16 ft. center to center and support 2 in. x 8 in. purlins on 16 in. centers, which carry the roof boards covered with the composition roofing. The four standard gage tracks provide a capacity of about 50 cars, and the yard outside of the shed will accommodate about 200 cars more. The narrow gage material tracks in the shed and the yard make it possible to carry material on roller bearing cars to within 25 ft. of any desired point.

The service buildings are of brick, with the exception of the finished lumber shed, which is of timber construction. The wood mill has steel roof trusses supporting a 3 in. concrete slab of the same design as that used in the machine shop and power house. The other brick buildings have composition roofs laid on timber.

Open Car Repair Shed Before the Yard Was Surfaced.

An innovation in railroad shop practice is the use of hot water for heating all buildings of the car department. Heat for the system is obtained from a heater located in the engine room of the power house which utilizes exhaust steam for heating the water. Circulation of the water is effected through two 5 in. pipe lines. From the power house to the various buildings of the car department the two 5 in. circulating lines of the system are contained in a concrete conduit described above. The radiation in all of the buildings is of the cast iron wall type, and from observations taken during the past winter the hot water system has proved to be a decided success, satisfactory temperatures being maintained in the various buildings, even during extremely low temperatures outside.

The maximum distance through which the hot water is transmitted in one direction in the heating system is 2,035 ft., the extreme building being the toilet located north of the service building in the car repair yards. The obtaining of satisfactory heat

in buildings located over 2,000 ft. from the source of heat supply is practically impossible with the use of low pressure steam under ground conditions prevailing at Centralia, and the results obtained have fully justified the judgment of the engineers in departing from the usual practice of either using high pressure steam or providing a separate boiler plant conveniently located to furnish the required amount of steam. The heating plant was installed by the Kehm Brothers Company, Chicago.

WATER SERVICE FACILITIES.

The water service facilities of the terminal include three separate systems, the fire protection line, the penstock supply, and the service line which supplies water for drinking, flushing sanitary sewers, flushing cinder pits, boiler water supply, etc. All hydrants are plainly marked to eliminate confusion and errors due to using the wrong one. The water is secured from the city mains at 40 lbs. pressure. Since the water at times is unfit for drinking purposes, an alum filter and purifier is installed in the roundhouse from which the treated water is piped to drinking fountains at various points about the plant.

The elevation of the tanks gives a pressure of about 20 lbs. on the fire line, which carries 125 lbs. pressure, however, when the centrifugal fire pump is in operation. This pump has a capacity of 1,500 gals. per minute. The fire line runs from the tanks to the fire pump in the power house and, leaving this pump, divides, one branch going north to the car group and the other

Service Buildings Adjoining the Car Repair Shop.

subdividing to reach the buildings of the locomotive group. The line to the roundhouse is connected to the overhead washout line along which are located 10 swing wall hose reels, each with 100 ft. of 2½ in. hose. A similar hose reel is provided in the machine shop. An automatic sprinkling system is installed in the coaling station and there are four hydrants protecting the buildings of the south group, the one back of the roundhouse being enclosed in a hose house which is provided with 200 ft. of hose. The line to the northern group of buildings serves eight hydrants located at convenient points for the protection of the buildings and cars in the repair yard. The fire line from tanks to the pump is of 12 in. pipe, the main line to the northern group is 8 in., and most of the branches are 6 in., with a few short ones 4 in. The penstock line divides at the tank, one branch going north to the penstock at the roundhouse, the other going south to the three penstocks in the yard. These lines are all of 12 in. pipe. The service line has numerous branches reaching the machine shop, power house and cinder pits in the locomotive group and a locker room and toilet in the northern group. The three water systems required 7,000 ft. of 8 in., and 9,000 ft. of 6 in. wood stave pipe, and 3,400 ft. of 4 in., 2,730 ft. of 6 in., 3,865 ft. of 8 in. and 2,000 ft. of 12 in. cast iron pipe.

Separate storm and sanitary sewer systems were installed. All down spouts on buildings empty into 6 in. pipes leading to the storm water sewers, which also receive the drainage from the turntable pit, coal bunker, penstock pits, inspection pit, etc. Vitrified pipe to 8 in., 10 in., 12 in., 15 in., and 18 in. sizes is used for these sewer lines. The outlet for the storm water sewers of the southern group is a 60 in. pipe laid under the yard and for the northern group a standard 12 ft. arch. The sanitary sewers lead to septic tanks, as the terminal is surrounded by a farming district making necessary some treatment of the sewage before discharging it into drainage ditches. Two tanks are provided which are practically identical, being designed to retain the sewage for 24 hours. The one serving the southern group of buildings is a concrete pit 23 ft. x 11 ft. in plan and 18 ft. deep with the top of the concrete 1 ft. above grade. The walls are 1 ft. 6 in. thick, reinforced with ¾ in. rods set vertically and horizontally. The tank is covered with a wooden frame on which 2 in. x 4 in. timbers are nailed with narrow openings between in order to allow circulation of air over the contents of the tank. The sanitary sewer empties into this tank 8 ft. 6 in. above the bottom, the discharge pipe being turned down inside the tank to keep its open end below the level of the contents of the tank. This level is fixed by the outlet at the opposite end of the tank at an elevation 8 ft. above the bottom. The outflow is through three 6 in. holes in the concrete wall which connect with a second tank 5 ft. x 6 ft. in plan and 12 ft. deep with 1 ft. walls, attached to the large tank, having its top at the same elevation. The outlet from the large tank is just above the bottom of the small one and near the water level in the big tank. A weir is provided in the small tank over which the discharge flows to reach the outlet pipe.

The construction of the buildings in the mechanical terminal was carried on in connection with the construction of the yard. Work on the buildings was begun during July, 1912. The filling was handled with a standard gage steam shovel outfit. When the fill at a building was over 8 ft. deep, as in the case of the wood working shop, the concrete foundation was put in up to the floor level, the fill made around this foundation and the walls of the building placed afterward. The piers for the car repair shed and the lumber shed were also built before the fill was placed. In this case the fill was carried as close as possible to a row of piers, the construction track thrown over the piers and the process of filling continued. The car repair yard was put into operation December 10, 1912, and the locomotive facilities January 10, 1913.

The construction of both the yard and the mechanical terminal was carried out under the direction of A. S. Baldwin, chief engineer, and D. J. Brumley, formerly engineer of construction. The design of the mechanical terminal was under the direction of F. L. Thompson, formerly engineer of bridges; J. A. Taggart, architect, supervising the design of the buildings. The late M. H. Dance, division engineer of construction, was in charge of the field work. The mechanical details were handled by Willard Doud, formerly shop engineer, under the supervision of M. K. Barnum, formerly general superintendent motive power. T. S. Leake & Co., Chicago, were the general contractors for all masonry and building work, except the coal chute.

Shortening the Route Between Paris and Nice.—A scheme is afoot for shortening the present route between Paris and Nice. Some years ago the Paris Chamber of Commerce of the Maritime Alps passed a resolution in favor of constructing a new direct railway, but this recommendation was pigeonholed until recently. A congress was recently held at Nice, and an official commission has also been formed to investigate the proposal. The Nice congress had a number of schemes before it, each of which forms part of the main project. The first step advocated is the buying up of the Southern Railway, which it is proposed to hand over to the Paris, Lyons & Mediterranean. Then it is proposed to build several cut-off lines, specially built for fast running, and finally the construction of a new railway line from Draguignan to Castellane has been suggested. If these schemes are carried out, the present roundabout journey via Marseilles will become a thing of the past.

TRAIN ACCIDENTS IN MAY.[1]

Following is a list of the most notable train accidents that occurred on railways of the United States in the month of May, 1913:

Collisions.

Date.	Road.	Place.	Kind of Accident.	Kind of Train.	Kil'd.	Inj'd.
1.	C. C. C. & St. L....	Middletown.	bc.	P. & F.	0	22
12.	Mobile & O.....	Vick.	bc.	P. & F.	0	4
13.	Chi. R. I. & P.....	Seneca.	rc.	F. & F.	2	2
19.	Int. & G. Nor	Kouns.	bc.	P. & F.	1	27
23.	C. C. C. & St. L....	Belle Center.	bc.	P. & P.	0	9
26.	Baltimore & Ohio....	Parkersburg.	xc.	P. & F.	1	3
26.	Pitts. S. & N	Camp Burke.	bc.	F. & F.	1	1
27.	Missouri Pacific.....	Brant.	bc.	P. & P.	4	40
27.	Pennsylvania	Niles.	bc.	P. & F.	2	2
30.	Southern	Sheffield, Ala.	bc.	P. & P.	0	36

Derailments.

Date.	Road.	Place.	Cause of Derailm't.	Kind of Train.	Kil'd.	Inj'd.
1.	Chi. R. I. & P.....	Colby, Kan.	washout.	F.	2	0
9.	Baltimore & Ohio....	Triadelphia.	.....	F.	2	1
†13.	Northern Pacific	Lake View.	unx.	P.	4	8
14.	Seaboard Air Line...	Rice.	exc. speed	F.	3	0
18.	Erie	Preble, Ind.	exc. speed	P.	2	2
21.	Mobile & Ohio.....	Holman.	sand.	P.	1	2

The trains in collision near Middletown, Ohio, on the 1st, were southbound passenger No. 25 and northbound freight No. 82, first section. Both engines were wrecked and several cars in both trains badly damaged. Sixteen passengers,, four employees and two postal clerks, were injured. The cause of the collision was improper block working.

The trains in collision at Vick, Ala., on the 12th were southbound passerger No. 103 and northbound freight No. 178. Both engines were wrecked and four trainmen were slightly injured. The men in charge of the freight forgot about the passenger train.

The trains in collision at Seneca, Ill., on the 13th were eastbound freights, the leading train being at rest. Two passengers in the caboose of the standing train were killed and two others injured. The collision was due to disregard of automatic block signals, the second train having passed a distant and a home, both set against it.

The trains in collision near Kouns, Tex., on the 19th were southbound passenger No. 7 and a northbound freight The fireman of the freight was killed and 8 trainmen and 19 passengers were injured. Both trains were running at good speed and the engines were badly wrecked. The front end of the baggage car of the passenger train was demolished and three cars of cattle in the freight train were crushed. The passenger train had passed Kouns in disregard of an order requiring it to wait there for the freight.

The trains in collision near Belle Center, Ohio, on the night of the 23rd were southbound passenger No. 43 and northbound passenger No. 126. Five passengers and four employees were slightly injured. The collision is attributed to the failure of the headlight of the engine of No. 43. This train had right over No. 126 and later was given a meet order with No. 126 at Yelverton, a non-telegraph station. Under the orders No. 126 should have taken the siding. No. 43 arrived at the meeting point half a minute ahead of No. 126 and held the main track. The headlight being out, the engineman on No. 126, seeing no headlight, thought that No. 43 had arrived at the meeting point first and had taken the siding and covered the headlight in order to avoid delay.

The trains in collision at Parkersburg, W. Va., on the 26th were an engine drawing one sleeping car, and a freight train moving slowly. Two passengers and the conductor and the engineman of the freight were injured, the engineman fatally. There was a dense fog at the time.

The collision at Camp Burke, N. Y., on the 26th was between a northbound work train and an extra freight train, southbound. The engineman of work train was killed and its conductor slightly injured. Both engines and three freight cars were badly damaged. The cause of the collision was failure of the operator at Angelica to deliver an order to the work train.

The trains in collision near Brant, Mo., on the 27th were westbound passenger No. 11 and eastbound passenger No. 12. Both enginemen and two other trainmen were killed and 40 passengers were injured. The cause of the collision was the issuance of conflicting meeting orders by the despatcher, and a false clear manual block signal. Both men experienced.

The trains in collision on the Pennsylvania Lines near Niles, Ohio, on the night of the 27th of May were westbound passenger No. 215 and an eastbound freight. The engineman of the passenger and the fireman of the freight were killed and two other trainmen were injured.

The trains in collision at Sheffield, Ala., on the 30th were passenger No. 106 of the Northern Alabama and passenger No. 35, second section, of the Southern Railway. The N. A. engine was wrecked and 33 persons injured; few seriously. The collision was due to the neglect of the men in charge of Second 35, who overlooked the schedule of No. 106, which was superior.

The train derailed near Colby, Kan., on the 1st was a work-train consisting of an engine, caboose and platform car, the latter being ahead of the engine. The cause was the undermining of the roadbed because of an unusual flow of water following a cloudburst. The roadmaster, riding on the engine, was killed, and the fireman was fatally injured.

The train derailed at Triadelphia, W. Va., on the 9th was a southbound through freight, and ten cars fell down a bank. Two trespassers riding on the train were killed and a brakeman was injured. A part of the wreck fell on the track of the West Virginia Traction Company's street railroad.

The train derailed on the Northern Pacific, near Lake View, Wash., on the 13th, was a southbound passerger of the Oregon-Washington R. & N. Company. Three passengers and one brakeman were killed and 8 passengers were injured. The derailment occurred at a point where track repairs were in progress.

The train derailed at Rice Station, Ga., on the night of the 14th consisted only of a locomotive, running backward. It was running at high speed around a curve. The only explanation of the cause is that probably speed was excessive. Of the 3 men on the train, the engineman and the flagman were killed and the fireman was fatally injured. A tramp walking along the track saw the wreck and ran to the aid of the injured men; and he was severely scalded on the arms and hands in his efforts to rescue them. A passerger train following the engine was stopped by a farmer who had heard the sound of the wreck.

The train derailed at Preble, Ind., on the 18th, was eastbound passenger No. 8. The train was running at high speed and was not properly slackened on entering a detour track. The engineman and fireman were killed and two passengers were injured.

The train derailed near Holman, Ala., on the night of the 21st was southbound passenger No. 105, and the engine and baggage car were overturned. The fireman was killed and the engineman and one passenger were injured. The cause of the derailment was sand on the track which had been washed down from the bank by a heavy rain.

[1]Abbreviations and marks used in Accident List:
rc, Rear collision——bc, Butting collision——xc, Other collisions——t Broken——d, Defective——unf, Unforeseen obstruction——unx, Unexplained——derail, Open derailing switch——ms, Misplaced switch——acc. obst., Accidental obstruction——malice, Malicious obstruction of track, etc——boiler, Explosion of locomotive on road——fire, Cars burned while running——P. or Pass., Passenger train——F. or Ft., Freight train (including empty engines, work trains, etc.)——Asterisk, Wreck wholly or partly destroyed by fire——Dagger, One or more passengers killed.

HSIN-NING RAILWAY, CHINA.—The construction of a section for nearly 25 miles between Niuwan opposite Kungi and Kongmoon via Hsinhui on the Hsin-Ning Railway was started in October, 1909, and was opened to traffic in October, 1911. A distance of 3 miles from Kongmoon to Peichiehkow will be ready for traffic soon. Tracks are already laid from Kungi up to Toushan, but from Toushan to Sanchiahai the work is not completed.

NARROW GAGE EQUIPMENT FOR THE EAST BROAD TOP.

The East Broad Top Railroad & Coal Company, which operates about 50 miles of 3 ft. gage track in the mountains of Pennsylvania, has recently added to its rolling stock a mikado locomotive and a number of steel hopper cars, the latter, it is believed, being the only all-steel narrow gage hopper cars in use in the United States.

The locomotive was built by the Baldwin Locomotive Works, Philadelphia, and was designed to meet the following conditions: Curves, 17 deg. on main line, 23 deg. on Ys; grades, 2½ per cent.; rails, 60 lbs. per yard; tunnel clearances, height 13 ft., width, 8 ft. 8 in.; weight on driving wheels, not to exceed 124,000 lbs.; total weight of locomotive, not to exceed 150,000 lbs. It is similar to a lighter locomotive of the same type, constructed for this company in 1911. The increase in tractive effort and total weight is in each case about 25 per cent., while on a heating surface basis the new locomotive shows an increase of 32 per cent. over the design of 1911. With a boiler providing 283 sq. ft. of heating surface per cubic foot of cylinder volume, and a ratio of adhesion of 4.43, the new locomotive is similar in its proportions to many of the most successful standard gage locomotives having the same wheel arrangement and using saturated steam. The tractive effort exerted is 27,700 lbs.

The boiler is of the straight top type and designed for a working pressure of 200 lbs., but the safety valves are set at 180 lbs. in service.

The steam distribution is controlled by balanced slide valves, which are set with a lead of ¼ in. and are driven by a straight line arrangement of Walschaert valve gear. The structural parts supporting the gear are arranged to serve also as frame braces. The trailing truck is of the Rushton radial type, with outside journals.

The tender has capacity for 4,000 gal. of water and 7 tons of coal. The frame is composed of 8 in. channels, and the trucks are of the arch-bar type. All truck wheels under the locomotive and tender are steel tired. Air sanders, automatic couplers and Westinghouse schedule 6 ET combined automatic and straight air brakes are used, with two 9½ in. compressors.

Narrow Gage Mikado Locomotive for the East Broad Top Railroad & Coal Company.

The following are the principal dimensions and data:

General Data.

Gage	3 ft. 0 in.
Fuel	Soft coal
Weight on drivers	122,700 lbs.
Weight on front truck	9,000 lbs.
Weight on back truck	15,450 lbs.
Weight, total engine	147,150 lbs.
Weight, total engine and tender	230,000 lbs.
Wheel base, driving	13 ft. 0 in.
Wheel base, rigid	13 ft. 0 in.
Wheel base, total engine	27 ft. 5 in.
Wheel base, total engine and tender	53 ft. 0 in.

Boiler.

Type	Straight
Working pressure	180 lbs.
Diameter	62 in.
Thickness of sheet	13/16 in.

Narrow Gage All-Steel Hopper Car of 60,000 lbs. Capacity.

Staying	Radial
Firebox, length and width	96 in. x 54 in.
Firebox, depth, front	56½ in.
Firebox, depth, back	53¾ in.
Firebox, thickness of sheets, sides	5/16 in.
Firebox, thickness of sheets, back	5/16 in.
Firebox, thickness of sheets, crown	⅜ in.
Firebox, thickness of sheets, tube	½ in.
Tubes, number and diameter	230 2 in.
Tubes, length	17 ft. 6 in.
Heating surface, firebox	131 sq. ft.
Heating surface, tubes	2,097 sq. ft.
Heating surface, total	2,228 sq. ft.
Grate area	36 sq. ft.

Cylinders.

Kind	Simple
Diameter and stroke	19 in. x 24 in.

Wheels.

Driving, diameter	48 in.
Driving journals	8½ in. x 8 in.

Tender.

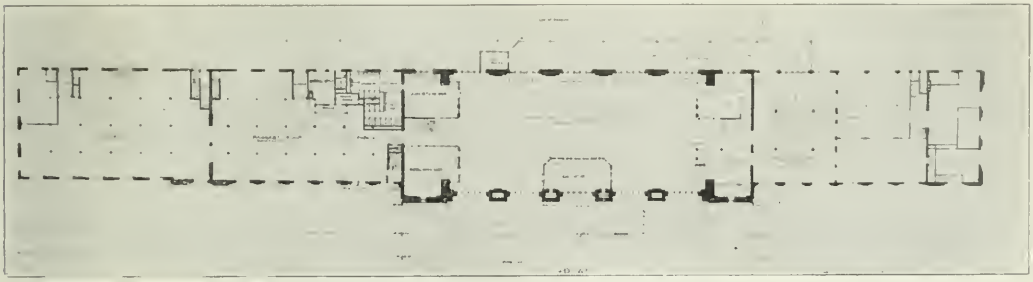
Wheels, number	8
Wheels, diameter	26 in.
Journals	4¼ in. x 8 in.
Water capacity	4,000 gals.
Coal capacity	7 tons

The hopper cars, which were built by the Pressed Steel Car Company, Pittsburgh, Pa., are of 60,000 lbs. capacity and weigh about 20,700 lbs. each, the body weighing 12,000 lbs., and the trucks 8,700 lbs. The body bolsters are built integral with the underframe and each bolster consists of one ¼ in. open hearth steel web plate with a malleable iron center brace, and is reinforced at the top with a flange and the floor of the car and at the bottom with a 12 in. x ⅜ in. plate and 3 in. x 3 in. x 5/16 in. rolled angles. There is one cross bearer located at the center of the car and composed of angles and 3/16 in. plates. The car is equipped with four doors, operated by the Lind door gear. The end sheets are ¼ in. thick, and are reinforced at the top and bottom with a flange; the floor and side sheets are 3/16 in. thick. The two center sills are made of 10 in., 20 lb. channels and extend between the bolsters, being tied together and reinforced at the top with a 15½ in. x ¼ in. plate. The draft sills are also 10 in., 20 lb. channels extending from the end of the car to about 2 ft. back of the bolster. The end sills are 6 in., 8 lb. channels, and the sub-end sills are of ¼ in. pressed steel, reinforced at the top and bottom with flanges; the side sills are 6 in., 8 lb. channels extending from the bolsters to the end sills. The general dimensions of the car are as follows:

Length inside	25 ft. 7 in.
Width inside	7 ft. 6 in.
Width over side stakes	8 ft. ⅜ in.
Length over striking plates	27 ft. 4¾ in.
Height from rail to center of coupler	2 ft. 2 in.
Distance center to center of trucks	18 ft. 4 in.
Height from rail to top of body	8 ft. 6 in.
Height from rail to top of brake mast	8 ft. 11½ in.

NEW SOUTHERN PACIFIC PASSENGER STATION AT LOS ANGELES.

Plans are now being completed for a new passenger station for the Southern Pacific, to be built at Fifth street and Central avenue, Los Angeles. This station and yard are designed to furnish facilities ample for a city of 1,500,000 inhabitants. As shown in the drawings, the classic style of architecture has been adopted. The station building proper and the approaches will cover an area 110 ft. x 600 ft., while the depot and yards will cover 15 acres. The station will be a through station with 14 tracks, each designed to hold 15 passenger cars and 2 engines.



Floor Plan of Proposed New Los Angeles Passenger Station.

Access to the trains will be gained by means of a subway running under the main passenger tracks and connected with each platform by an incline on an easy grade. This subway opens into a public exit concourse 50 ft. x 70 ft. in area. Adjacent to this will be the main concourse and waiting room, 80 ft. x 210 ft. in size, reached by four main entrances. Mezzanine floors provided with lounging chairs, writing tables and current magazines will be located at either end of the main concourse. Other facilities, including information bureau, baggage and check rooms, news stands, etc., will be provided. One important feature will be a dining room, kitchen and lunch counter, to which a space of 70 ft. x 80 ft. will be devoted.

A marquis 220 ft. long and about 30 ft. wide will be located in front of the building for taxicab and automobile passengers. The building will be wainscoted throughout with mosaic marble floors. An indirect lighting system will be installed. The upper floors in the north and south wings, comprising upwards of 25,000 sq. ft., will be occupied by division offices.

Front Elevation of Proposed New Southern Pacific Passenger Station at Los Angeles.

THE STAMFORD COLLISION.

The continued hearings have brought out little of value to add to our report of the Stamford collision printed last week. The air brake inspectors from other roads invited to Connecticut by the New Haven road gave testimony as to the condition of brake apparatus, but for evidence throwing real light on the question whether the collision was in any degree due to faults of the brake it will be necessary to await the full stenographic report. Evidence as to the extent of Doherty's experience as a runner is conflicting, as are his own statements as to where he applied brakes.

General Manager Bardo's statement, abstracted below, was in part denied by F. S. Evans, representative of the enginemen's committee. He said that his committee did not protest against the two-year rule but against the manner in which it was promulgated. He declared that the enginemen of the road were well qualified, all having fired on passenger trains for from two to six years. He said that the men involved in the accidents at Bridgeport and Westport were not inexperienced. Mr. Evans denied that the brotherhood had forced the adoption of any rule detrimental to safe operation.

STATEMENT BY GENERAL MANAGER BARDO.

Speaking at the hearing held by the Interstate Commerce Commission, C. L. Bardo, general manager of the road, explained the existing agreements between the engineers and the company. When Mr. Bardo came to the road on February 15, of this year, he found an agreement in force, made in 1910, which provided that—

> Spare engineers shall be run first in and out so far as it is possible with the requirements of the service and, when engineers are assigned to temporary vacancies, they shall remain on same provided they are competent, until the regular engineer returns. They shall receive rates of the regular engineers while on the road.

This rule had been in effect ten years or more. For many years the New Haven road had fewer men in freight service than passenger, so that the rule was necessarily different from that on most roads. Until recently firemen were promoted quite slowly and were probably better qualified than are the men who have been promoted during the past four years. On December 11, 1912, an order from the general manager directed a modification of the rule, to the effect that spare engineers who had less than two years, experience, or two years' rating as engineers, would not be allowed to run through passenger trains, and that engineers with less than one year's service would not be allowed to run local passenger trains. The enginemen protested against this rule and the protest was one of the first subjects for discussion when Mr. Bardo took charge of the road. He could not find that there had been a single case of accident or other trouble under the old rule of 1910; no case where a young engineer had been the cause of trouble. To this extent the protest of the enginemen against a change was well founded.

Mr Bardo held long discussions with the general committee of engineers, the chairman of which is a salaried officer He was dealing, he said, not with the Brotherhood of Locomotive Engineers, but with the road's employees. He held that the old rule ought to be modified and the men went back to discuss it with their constituents. After a month or so another conference was held and the committee submitted a rule to the effect that "no engineer who has less than one year's roster rating as an engineer shall be allowed to run through passenger trains." Though not entirely satisfied, Mr Bardo accepted this, because of the uncertain situation at that time. "The forces were in many respects disorganized. The train service was bad and things generally were out of gear." He and the vice-president had long discussions with the men at a number of division terminals. In every discussion the men were told that the question of safe operation was more important than anything else. As late as June 1 he had had a long conference with the division superintendents and on the following day discussed a half day with the engineers' committee in an effort to find, if possible, "what had crept into our engineers." Until within eighteen months the New Haven road has compared favorably with other roads. He believes that 90 per cent., probably 95 per cent., of the men in train and engine service are as good as there will be found on any road. "We had a right to expect that Doherty was a competent man. In all general matters he was. But I am satisfied now that his judgment was unjustifiably bad, and I cannot conceive how an engineer in charge of a train, following, as he did, the first section, and practically on the time of that train, could approach a place where he knew that he was to stop, where he knew that the other train must be ahead of him, would float down in there, and wait until he got within 300 ft. of the distant signal, before he took the necessary steps to stop. I cannot conceive of any man in his right mind doing a thing of that kind. . . . The brotherhoods have not intended to enforce rules which necessarily tend to break down the safety of the service, but they have been edging in, inch by inch. They have been encouraged by the milk and water investigations.

"The general manager of a railroad should have power to say what is right and wrong, and he should have the power to enforce what he says. He cannot have the power if the organization is going to point the pistol at him every time that he attempts to do something which he knows, from his own best judgment, is the right thing to do.

"It is time that the public should understand that this question of railroad safety is one in which they are vitally interested. There is a certain percentage of men in every organization who are going to take advantage of everything they can hear of. . . . You cannot expect, if you are going to criticize a railroad as this railroad has been criticized, but what that criticism is going to reach into the ranks. It is going to result in disloyalty and insubordination.

"When a man sees that the man he is working for is being criticized, he has got an axe to grind, and necessarily he is on the other side of the fence right away. . . . You cannot expect if your division superintendents have not got the power to inflict and enforce discipline and to make it stick that they are going to be able to enforce anything else."

As to whether he was being coerced when the committee refused to accept the two-year rule, Mr. Bardo said: "I would not say that I was being coerced, but under other circumstances I would have insisted upon an enforcement of that which I believe to be right. I was exceedingly anxious to avoid doing anything which might be misconstrued, on the part of the men, as an attempt to take away from them anything which they heretofore had had. I did not want to disturb their peace of mind. I wanted them to get back on their engines and begin to railroad, and to stop worrying about something that was not going to hurt anybody."

Railway Extension in Western Australia.—One of the most important features of the policy of the enterprising government of Western Australia is that of railway extension, by which the new settlers and producers are enabled to get their goods on the markets of the world. At the present time this policy is being pursued. There are now authorized and under construction in Western Australia nine new railways, totaling in length 631 miles. This is in addition to the Trans-Continental Railway, 1,030 miles in length, which the federal government is building to connect the famous mining center of Kalgoorlie with Port Augusta in South Australia, and thereby linking Perth, the chief center of Western Australia, with all the capitals of the eastern states. One of the lines under construction by the state government, that from Wickepin to Merridin, is a part of the new state railway which is to connect with the Transcontinental Railway at Kalgoorlie. Another important line is that from Wengan Hills to Mullewa, which traverses 83 miles of country, much of it admirably suited for wheat growing, it connects the Murchison Railway with the Eastern Goldfields Railway. The other lines under construction are being taken into new agricultural districts with the object of promoting settlement and development.

AMERICAN SOCIETY FOR TESTING MATERIALS.

The American Society for Testing Materials held its sixteenth annual meeting at Atlantic City this week, commencing on Tuesday, the twenty-fourth. At the first session the subject of preservative coatings for structural material was under discussion, and in the report by the committee a very prominent place was given to the annual inspections of the paints that are being tested on the Havre de Grace bridge and the panels at Atlantic City. The report in regard to the former is very elaborate, but inasmuch as the paints are referred to by number only, and there is no key appended to indicate what these numbers mean, it is worthless as a matter of reference and information.

The fourth annual inspection of the panels at Atlantic City is given in great detail both for the inspections of 1912 and 1913. From this it appears that American vermilion (chrome scarlet) is in an almost perfect condition. In fact four out of five of the inspectors so marked it, and the fifth marked it as 9, 10 being the perfect mark. This cut the average down to 9.8. The next highest average is zinc and lead chromate at 8.3; then comes zinc chromate at 8.0, followed by zinc and barium chromate and magnetic black oxide, both of which are at 7.8. Red lead and natural graphite are about the same, being 6.3 and 6.2 respectively, while artificial graphite drops down to 2.6.

The only discussion was brought out by the suggestion to the committee that it publish a key to the paints in the test on the Havre de Grace bridge, so that the data would be available to the members. It was explained that this would be impossible because the paints used were being tested in confidence and that they were known only by chemical composition. To which it was pertinently asked, what was the use of tests if no one was to know what they meant?

A report was made on the corrosion of metals in connection with a series of tests that have been conducted on plates exposed to the gases of the Weehawken tunnel, where the fumes from locomotives are very dense. The report gave, in considerable detail, the rate of corrosion of the different plates on the basis of a calculated rate over the whole of the exposed surface. The report was severely criticized on the basis that it was misleading to assume that the loss of metal was an indication of the value of a metal as a resistant to corrosion. For example, attention was called to the fact that if the corrosion extended uniformly over a plate the destructiveness would be much less than it would be if it occurred as pitting, even though the loss of metal might be greater. It is segregated corrosion that is most to be dreaded. Then it is quite important that the surface condition of the plates be considered in estimating the rate of corrosion. If the plates are exposed as they come from the mill with the scale on, it is evident that the results obtained will be dependent on the character of the scale with which each is covered. Again, to expose unprotected plates to the gases from locomotives is not to follow practice in any particular. No one does such a thing in actual work. Plates of iron or steel are always protected by some coating that is to protect them from rust. But if it is desired to obtain data as to the rust resisting qualities of metals they should always be freed from mill scale, as it will promote rust and it will be found that corrosion is always more rapid, so long as there is any scale on the metal, than it is afterwards.

M. McNaughton, of the Dixon Crucible Company, presented a paper on an "Outline of a Test for Indicating the Relative Priming and Top Coat Values of Different Paints."

The generally accepted conclusion, reached as a result of the experience of the past few years, is that the best protection against the corrosion of iron and steel is not to be secured by the use of any one kind of paint, but by the use of different kinds of paint in combinations. Certain paints are excellent as primers, while others give the best service when used as top coatings. The importance of a simple form to determine the value of paints in these particulars seems evident. Three years ago the writer started a test with this idea in view.

Briefly the scheme is as follows. The upper half of a steel plate (10 in. x 16 in. is a good size) is painted with one of the two paints being tested, while the lower half is painted with the other. When dry, the left half of the plate is painted with the first paint, and the right half with the second paint. This is the simplest form of the test, and gives four combinations of coats. The plate may be divided into thirds and three paints tested, giving nine combinations of two coats each.

It is quite evident that tests made on one plate are much more easily compared than when made on separate plates, with the added advantage of there being no uncertainty as to the character of the metal itself. The discussion drifted away from the text of the paper and centered about the value of red lead of 98 per cent. purity, as compared with one of 85 per cent. and 15 per cent. litharge, with the general opinion that the addition of litharge increases the protective qualities of the coating.

NEW RAILROAD LAW IN MASSACHUSETTS.

The law increasing the powers of the Massachusetts State Board of Railroad Commissioners was noticed in the *Railway Age Gazette* last week, page 1580. The full text of the law, which consists of thirty sections, shows that it includes in the term "common carrier" all railroads, street railways (which are called railways), electric railroads, steamships, express service, car service, telephone lines and telegraph lines. The commission—now to be called the Public Service Commission—has general supervision and regulation of and jurisdiction and control over all these facilities. The law takes effect July 1, and the governor is to appoint two additional members, so as to make a board of commissioners of five. The commissioners choose their own chairman. The salary of the chairman is $8,500, and of the other members $8,000 each. Not more than three commissioners shall be appointed from the same political party. The powers of the State Highway Commission, so far as they relate to telegraph and telephone lines, are transferred to the new commission.

No contested matter upon which a public hearing is required shall be heard or decided by less than three members of the new commission. The commission may appoint a counsel and may employ all necessary engineers, accountants, etc. It may inquire into rates, practices, etc.; may be represented at public hearings before any legislative committee or public board, of any state, with respect to proposed legislation in Massachusetts, and may confer with or appear before boards of other states having power over common carriers. It may provide for an annual audit of all accounts of common carriers, whenever found desirable. It may prescribe a system of accounts and shall make these conform as nearly as may be to the forms of the Interstate Commerce Commission. The commission may determine the fair value of property, for any purpose, and may make a revaluation when deemed necessary.

Sections 15 and 16 regulate the issuance of stocks and bonds, under the supervision of the commission. Authority must be secured from the commission for all issues which run over twelve months. The decision of the commission as to the amount of stock necessary for any given purpose must be based on the price at which such stock is to be issued. Under the old law bonds could be issued only to an amount equal to the par value of stock. The present law permits bonds to the amount of twice the par value of stock. Penalties are provided against directors, treasurers, etc., who vote for any illegal issue.

Section 17 requires all charges for service to be just and reasonable. Charges now lawfully in effect shall be deemed prima facie lawful until the commission otherwise orders; but this provision shall not give to such rates any greater weight,

as evidence of the reasonableness of other rates, than they would otherwise have.

Section 18 prohibits free transportation, with the usual exceptions, among the excepted classes being officers or employees of the legislature.

Section 19. Common carriers may make commodity rates and other special rates. Rates now in force by virtue of existing contracts, are not to be deemed discriminatory unless the commission so determines, but the commission shall not be prevented from taking action because of a contract now in force. Common carriers may issue mileage, school and other special tickets, unless the commission shall forbid. All season tickets, before issuance, shall be subject to the approval of the commission as to form and conditions.

Section 20 has provisions for publication of tariffs, etc., similar to the provisions of the Interstate Commerce Law. Section 21 allows the commission to suspend for six months any proposed increase in rates. In case of suspension, the burden of proof, to show that an increase is necessary, rests on the carrier. In case of a proposed decrease in a rate the commission may fix a minimum rate, if the one proposed is held to be insufficient to yield reasonable compensation.

Section 22. Whenever the commission, after hearing, finds that rates are unjust or are insufficient to yield reasonable compensation, it shall determine and prescribe reasonable rates. The commission may suspend the long and short haul provision of the law.

Section 23 gives powers in regard to practices, equipment, service, etc., similar to those relating to rates. The commission may, after hearing, require any standard gage railroad to be equipped for electric power, but shall consider the relative importance and necessity of the proposed changes, and other changes which may be needed; all in regard to the financial ability of the carrier and its duties to the public.

Section 24 gives power to regulate the number of men in the crew of a train.

Section 25 authorizes the establishment of through routes and through rates. The commission may grant locations for connecting tracks. Each road shall have full authority over trains on its own tracks. The commission may order connecting tracks laid to private side tracks if the probable amount of business is deemed sufficient.

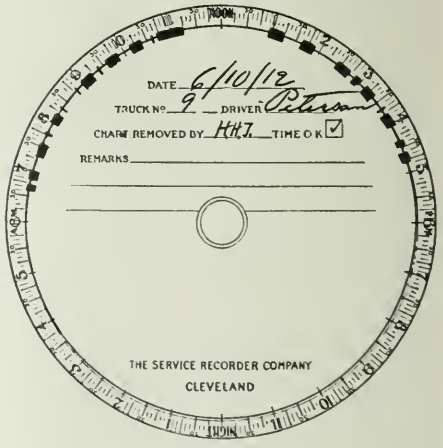
The Supreme Judicial Court has jurisdiction in equity to review, annul, modify or amend the orders of the commission, to the extent only of the unlawfulness of such orders. This court shall have jurisdiction to enforce all valid orders of the commission and all provisions of the Act.

THE SERVICE RECORDER.

The "service recorder" is a time-piece which carries on its face a paper dial for making a continuous record, like a pencil mark, throughout a period of 24 hours, and connected with which is a large pendulum that swings only when the clock is disturbed. The device is used on moving vehicles, such as automobiles or locomotives, for making a record, independent of the person in charge of the car or engine, of the time that it has been in motion, in other words, the time that the engine has been at work. When the engine is absolutely still a continuous thin line is recorded, but when it is in motion the pencil moves transversely, as related to the thin line, and the difference between time in motion and time at rest is thus clearly indicated to the inspector. Automobile trucks used largely on city streets for carrying merchandise, and switching locomotives used in extensive industrial plants, as well as in railroad yards, have been equipped with large numbers of these recorders, and the users express marked satisfaction with the results. A truck driver or a switching foreman who wastes time while out of sight of headquarters finds, next morning, when the clerk at headquarters takes out the day's record sheet and puts in a new blank for the succeeding day, that the amount of time that has been lost is revealed.

The recorder is contained in a cylindrical iron box about 8 in. in diameter, which can be fastened to the front wall of the locomotive cab, or to any vertical surface of the vehicle which is transverse to the road over which it travels. There is no connection from the clockwork to the running gear or to anything outside the case. When locked up, every part of the apparatus is concealed. Closing the door (the clock being wound up) starts the record, and at the same time makes a small cut in the edge of the record paper. Opening the door cuts the paper again, thus making a record of the times of opening and closing, which cannot be tampered with.

A record sheet is about 6 in. in diameter. A sample record, reduced somewhat less than one-half in diameter, is reproduced in the accompanying engraving. This record was made on a factory truck, and the periods that the vehicle was in motion are indicated by the heavy black spots. The longest one is that from 10:40 a. m. to 11:15 a. m. Work was begun at 6:35 a. m., and terminated at 4:47 p. m. The longest time not in motion was from 11:15 to 12:58. The thin line, showing that



A Sample Record.

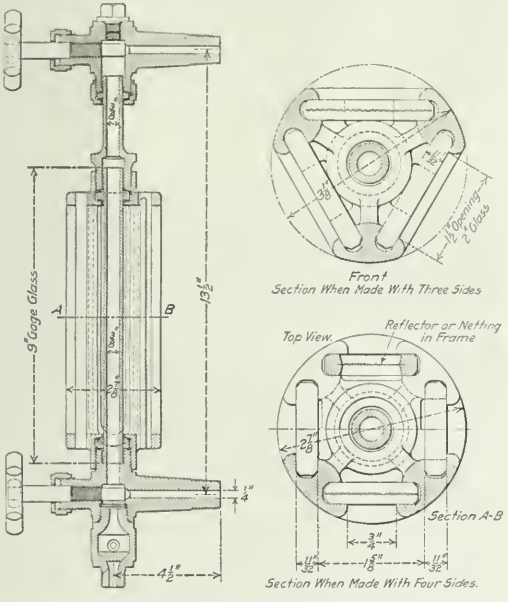
the truck was at rest, extends completely around the circle, except for the black sections, but is not distinctly shown in the engraving. If the driver had taken the truck out for a joy ride at midnight black marks at the bottom of the circle would have revealed the fact.

The makers of the service recorder give the following names of owners of locomotives who use it: American Car & Foundry Company; American Steel Foundries; Ann Arbor Railroad; Arizona & New Mexico Railway; Baltimore & Ohio; Buffalo Creek; Chicago, Burlington & Quincy; Chicago Great Western; Chicago Junction; Chicago & North Western; Chicago Short Line; Chicago & Western Indiana; Colorado & Southern; Columbia & Puget Sound; Delray Connecting; Duluth, Missabe & Northern Grand Rapids & Indiana; Great Northern; Ivorydale & Millcreek Valley; Kentucky & Indiana Terminal; Lake Shore & Michigan Southern; Lake Superior & Ishpeming; Lake Superior Terminal & Transfer; Manufacturers' Railway (St. Louis); Michigan Central; Newburgh & South Shore; New York Central & Hudson River; Pacific Portland Cement Company; Pennsylvania Railroad; Philadelphia, Baltimore & Washington. Many of these roads have given second orders for the service recorder.

The factory of the Service Recorder Company is at Cleveland, Ohio, and it has offices in Boston, New York, Philadelphia and Chicago.

DELCO SAFETY WATER GLASS SHIELD.

The Interstate Commerce Commission requires very close attention to be given to the protection of water glass gages in order to prevent injury to the occupants of locomotive cabs in case of the bursting of the gage glass. The Delco safety water gage shield, which is shown in the illustration, was devised to prevent the flying of broken glass and also the scalding of the hands of persons engaged in turning off the gage cocks after a water glass bursts. It consists of a one-piece body fitted with glands to receive the regular tubular glass, and with slots for the heavy glass protecting plates. The glass shield is omitted at the rear and a perforated plate or netting is inserted in its place to permit of the escape of the water and steam when a gage glass bursts; this prevents the steam and water from blowing down and scalding the hands of any one engaged in turning off the gage cocks. The shield is made in a standard length which permits the use of tubular glasses with fused ends, thus overcoming breakages due to rough edges which frequently start progressive fractures. The one-piece construction



Delco Safety Water Glass Shield.

also permits the water glass to be perfectly alined and overcomes the difficulty of the glass breaking due to a twisting action on account of one of the fittings being out of line. Tubular extensions are provided so that the shield may be assembled complete before application to the boiler, and may be applied between boiler fittings placed any distance apart. As the water glass is contained in the shield itself, it is impossible for any one in renewing a glass to forget the application of the shield.

A straight passage is provided entirely through the water glass and boiler fittings so that a wire may be passed through to clean out obstructions, as is required by law.

The Delco shield is the invention of H. C. Manchester, superintendent of motive power and equipment, Delaware, Lackawanna & Western, and over 750 of them are in use on that road. It is manufactured by the American Safety Lamp & Mine Supply Company, Scranton, Pa.

IMPROVED FLEXIBLE STEEL AIR BRAKE HOSE.

In addition to the troubles with the standard air brake hose, due to bursting, blowing off of fittings, chafing, etc., difficulty is encountered on some roads by uncoupling or pulling off of the fittings on the long passenger equipment when taking short crossovers. Armored hose, when applied to this equipment, did not uncouple, which increased the already high strain on the hose beyond the strength of the armor clamp on the nipple end, and this was remedied by eliminating the sharp corner at the base of the finger which extends forward to engage with the fittings. The design of clamp shown in the illustration was adopted after subjecting two lengths of hose, fitted with several types of clamps, to a reciprocating motion, approximating the hardest conditions to which it could be subjected in service. The hose, when extended the maximum distance, was on the point of uncoupling, and if the gaskets were not changed very frequently it was impossible to keep them connected. The new clamp withstood 51,960 alternations as compared with 1,400 with the old type. The old style failed in a manner exactly similar to those in service, while the new type corrected this trouble. The test of the new design showed that although the strain developed was so great that one of the fingers of the clamp slightly cracked, where it bends down to engage with the collar on the nipple, yet, even if this condition occurred in service, no danger would result as the other clamp, being intact, would prevent the danger of failure due to blowing out of fittings.

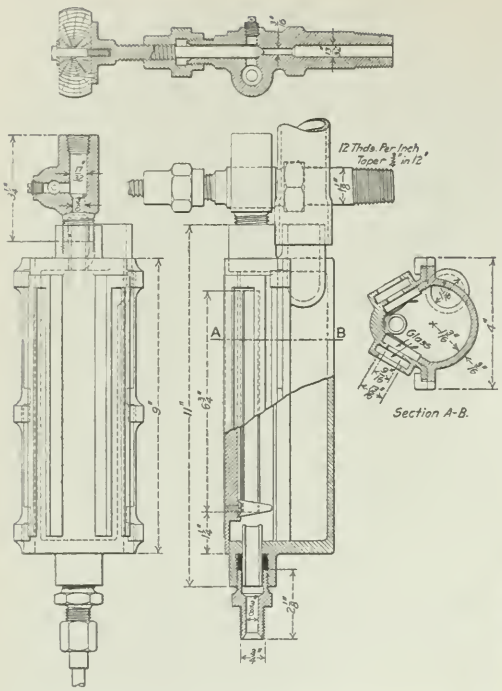
The armored air brake hose is intended not only to overcome chafing and kinking, but also to eliminate the source of other air brake hose troubles. The stretching test in the M. C. B. specifications explains this very thoroughly, as the quality of the

Armored Air Brake Hose with Improved Clamp.

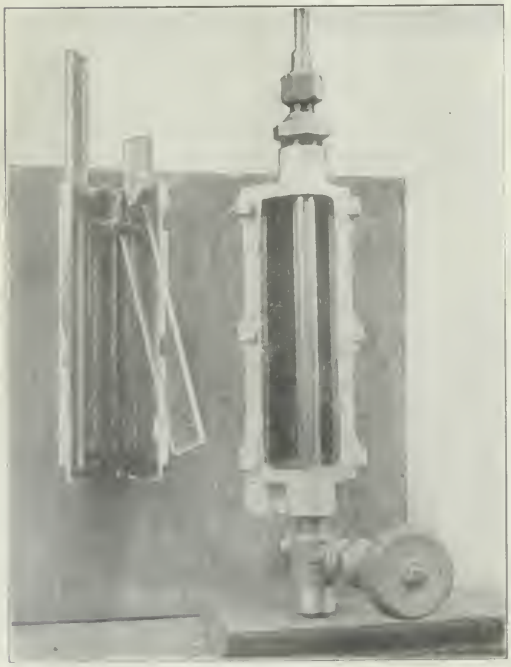
rubber is governed by its ability to resist deterioration when under strain. The armor offers very high resistance to internal pressures, thereby relieving the duck or canvas of the hose; consequently it is claimed there is no deterioration of the rubber due to stretching. Further, porosity enters into the question, as the tendency of internal pressure is not to develop defects, as in the case of unarmored hose, but to compress the wall of the rubber hose against the armor with exactly the opposite effect. Chafing of the inner tube by the nipple is also greatly reduced, and recent improvements in the flexibility of the armor showed, in the tests referred to, that there was no evidence of trouble from that source. This hose is manufactured by the Sprague Electric Works, 527 West Thirty-fourth street, New York.

BABCOCK SAFETY WATER GAGE.

In the designing of safety water gages it is most important that the passage provided for the escape of the steam and water after a water glass bursts be amply large, as otherwise pressure will accumulate and cause the breakage of the protective glass in the shield, and the steam will pass directly into the cab. In the gage which has been adopted as standard on the Pittsburgh & Lake Erie a pipe, shown in the illustrations, has been provided to carry off the broken glass, as well as the steam and water during the interval while the gage cocks are being closed. This safety gage is provided with two sets of heavy glass plates, an outer and an inner, the latter being held in place by steel springs.



Babcock Safety Water Gage.



Babcock Safety Water Gage with Glass Removed.

The purpose of the inner plate is to absorb the shock of the explosion and in case the inner plates should break there is still left the outer set to prevent the escape of the steam and broken glass into the cab. These protecting plates are set at such an angle that both the engineman and the fireman can get a plain view of the inner tubular glass. It is further claimed that the breakage of the inner plates is very unlikely, owing to their location permitting only a glancing blow from particles of broken glass.

This safety gage is the invention of F. H. Babcock, assistant boiler shop foreman, Pittsburgh & Lake Erie, McKees Rocks, Pa., and is manufactured by the American Car & Ship Hardware Manufacturing Company, New Castle, Pa.

ARMORED SQUIRT HOSE.

In our issue of May 2, 1913, page 976, attention was directed to the fact that the report of the chief inspector of locomotive boilers for the year ending June 30, 1912, showed that 243 accidents, or more than 28 per cent. of the total number, were due to defective squirt hose and connections. That the seriousness of this has not been more fully recognized before this is doubtless because none of these accidents prove fatal, and usually the men recover within a very short time. They are caused by the bursting of the hose or by the hose being forced off its connection, thus allowing the steaming hot water to scald the firemen, and in some instances the enginemen as well. In many cases a cheap grade of garden hose is used, which soon fails under the

Armored Squirt Hose.

severe service to which it is subjected and in other cases the hose is very insecurely fastened to its connection.

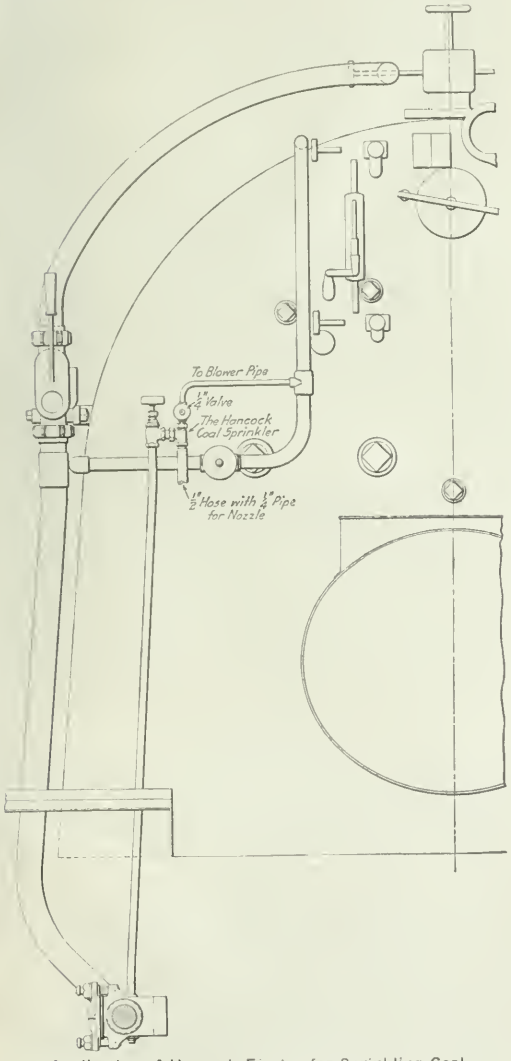
Various schemes are being devised to overcome this defect. These include the attempt to use cold water from the tender tank, or to use an ejector. Another means is to use a stronger hose, which is proof against bursting, and with fastenings such that it cannot be forced from its connection to the boiler. The Woven Steel Hose & Rubber Company of Trenton, N. J., has for a number of years been manufacturing a flexible armored hose. It was first adapted for use as a squirt hose about three years ago, and is reported to have given good results and to have an exceptionally long life. Five thousand locomotives are said to be equipped with it, on such roads as the Pennsylvania, Baltimore & Ohio, New York, New Haven & Hartford and the Boston & Maine.

The hose is made with a steam tube instead of a water tube,

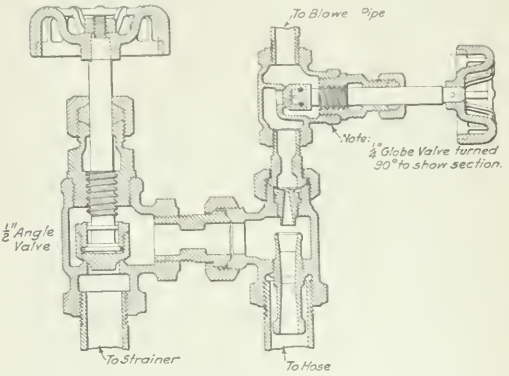
and will therefore last much longer under the action of the hot water. It is covered with a strong flexible covering of steel, protecting it against exterior wear and the chafing caused by the constant vibration of the locomotive. Special fastenings, which are clearly shown in the illustration, have been devised to prevent it from blowing off the nipple. Obviously the first cost will be much higher than for that of the ordinary type, but it is said to last so much longer that its cost per unit of time is considerably less.

EJECTOR FOR COAL SPRINKLING.

It is the general custom in wetting down the coal on locomotives to take the water supply from the delivery pipe of one of the injectors through a squirt hose and the necessary connections. The water in the injector delivery pipe is at a temperature and pressure sufficiently high to cause serious accidents in cases where the hose bursts. The device shown in the two illustrations, for the sprinkling of locomotive coal, is entirely independent of the injector, taking its steam supply from a pipe branching off from the blower pipe. The principle is the same as that of a lifting injector; steam is admitted through a ¼ in. globe valve and raises the water through the suction pipe which is connected to the main delivery pipe from the tender. A ½ in. valve is placed in this suction pipe to prevent waste of water in case the apparatus is located below the highest water level in the tender, and also to prevent air being drawn into the suction of the injector should there be an obstruction in the suction hose. The quantity of steam used is very small, and although there is an ample supply of water under sufficient pressure to sprinkle the coal, the temperature is so low that no serious accident can occur and there is an absence of the steam which is very commonly seen in the cab of a locomotive when the squirt hose is being used.



Application of Hancock Ejector for Sprinkling Coal.



Section Through Ejector for Coal Sprinkling.

This device was developed and is being manufactured by the Hancock Inspirator Company, Boston, Mass., and is being applied to 150 Baltimore & Ohio locomotives.

Australian Railway Construction Plans.—A commission will be appointed to advise the government on railway matters affecting the Northern Territory in Victoria, particularly as regards the adequacy of the present line, the necessity for further developmental work, and also the prospect of linking up the territory railways with the system of the other states. The committee will consult and ascertain precisely the railway construction program to be carried out in Queensland, Western Australia and South Australia, all of which states adjoin the Northern Territory. The final recommendations will include a large amount of construction work and will necessitate the expenditure of large sums of money.

Transportation in Madras.—It is suggested that the needs of better transportation facilities in the Madras presidency might be met, in the absence of railway extensions, by putting industrial motors on the roads. A Madras correspondent of an Indian contemporary remarks that the leap from railways to motor traffic is easy and that the increased utilization of road traction would be justifiable, if only from the point of view of not putting all your traffic eggs in one basket. The demand for more ample traveling and freight car facilities forms one of the principal themes at the meetings of the District Boards. It is constantly coming under the consideration of trades people and of their Chambers of Commerce. The need is universal and insistent.

General News.

Representative Willis of Ohio has introduced in Congress a bill to give the Interstate Commerce Commission certain authority over intrastate railroad rates.

Representative Levy of New York has introduced in Congress a bill to allow competing railroads to make traffic contracts, subject to the supervision of the Interstate Commerce Commission.

Maurice Prevost, a French aviator, on June 19, flew 217 miles at the rate of 117 miles an hour. This was a straightaway flight. The previous record made by Prevost was made on a circular course.

Officers of the conductors' and the brakemen's brotherhoods have distributed blank ballots for the proposed vote in regard to authorizing the officers to declare a strike if they deem such action necessary.

The United States Civil Service Commission announces examinations July 28 for candidates for the position of examiner of accounts, under the Interstate Commerce Commission; salary from $1,860 to $3,000.

The Missouri, Kansas & Texas has established a refrigeration department, in charge of G. D. Shafer, under the supervision of the superintendent of transportation, to encourage the use of refrigerator cars for fruit and vegetable shipments.

William H. Schroeder, engineman of Delaware, Lackawanna & Western train No. 11, and responsible for the collision at Corning, N. Y., July 4, 1912, was last week tried on a charge of manslaughter and was acquitted. The jury deliberated on the case two hours and 38 minutes. The trial lasted nine days.

Mr. Stevens of Minnesota has introduced in Congress a bill to amend the 28-hour law, relative to feeding and watering animals in transit, so as to exempt switching railroads over which live stock is carried for a distance of less than ten miles. The bill was referred to the House committee on interstate and foreign commerce.

The shops of the Denver & Rio Grande at Salt Lake City were mostly destroyed by fire on the night of June 18; estimated loss $200,000. The paint shop, blacksmith shop, planing mill, engine room and wheel shop were destroyed, together with 25 freight cars, 6 passenger cars and 3 cabooses. Officers of the road announce that the shops will be replaced by much larger ones, but the exact location has not yet been announced.

A. W. Smallen, chairman of the general safety committee of the Chicago, Milwaukee & St. Paul, has addressed a petition to the municipal court judges of Chicago, asking them to impose penalties on all trespassers brought before the courts. With the petition was a statement showing the number of persons killed while trespassing on railway tracks during the past 20 years, and a comparison of the number of trespassers killed and injured, and passengers and employees killed and injured during the year 1912.

The Illinois legislature, in its closing session, last week, passed a bill providing for a state public utilities commission with broad powers. It is being strongly opposed by the city of Chicago and by civic organizations because it does not provide "home rule" for Chicago, and the governor is being urged to veto it. He has agreed to give a hearing to the opponents of the bill. The legislature adjourned without passing the anti-pass law, and without taking action on a large number of railway bills, including the full crew bill and an electric headlight bill.

The Monthly Bulletin of the traffic department of the Chicago & North Western has recently begun a series of articles on station efficiency, in which questions pertaining to details of station organization and system will be discussed for the purpose of giving encouragement to agents by pointing out the importance of their work, and of assisting them by describing methods of obtaining better results. The first article is preliminary and calls attention to the need of system to prevent lost motion and to obtain better results with less work.

The new double-track railway and highway bridge to be built across the Mississippi river at Memphis by the Chicago, Rock Island & Pacific, Missouri Pacific, and St. Louis Southwestern, is to be called the "J. T. Harahan Bridge," in honor of the late president of the Illinois Central, who was killed in a collision at Kinmundy, Ill., in January, 1912, while on his way to Memphis on work in connection with the bridge. Mr. Harahan at that time was president of the Arkansas & Memphis Railway Bridge & Terminal Company, the corporation organized to build the bridge.

A petition for a receiver for the Southern New England Railroad has been filed in the Supreme Court of Massachusetts on behalf of John Marsch, one of the contractors for the proposed line between Providence and Palmer. The ground for the petition was the alleged neglect of the company to pay a claim of Marsch. Marsch says that he has already been paid about $500,000; that he is entitled to $1,510,000 damages for the breaking of the contract and that the officers of the defendant company and the Grand Trunk have admitted that he is entitled to receive $240,000.

Chapter 462 of the Laws of New York, passed this year, makes 10 hours' labor within 12 consecutive hours a legal day's labor in the operation of railroads and street railroads, except where the mileage system of [paying men engaged in] running trains is in operation. This law applies to all roads 30 miles long or longer. It forbids the employment of trainmen for more than 16 consecutive hours; and whenever a man has been on duty for 16 hours he must have at least 10 consecutive hours off duty. Among the exceptions allowed are cases where a man is delayed by "unexpected delays of connecting trains."

The bill, prepared by the committee of the Civic Federation, to amend the Erdman law relative to arbitration and conciliation, was introduced in Congress last week, and on Monday of this week was favorably reported by Senator Newlands, chairman of the Interstate Commerce Committee of the Senate. At a hearing before the Senate committee the bill was opposed by the Secretary of Labor, who argued that no amendment to the Erdman law was needed except to provide for a larger number of arbitrators. The bill has the effect of repealing that clause of the present law which designates the former Commissioner of Labor, now a subordinate in the Department of Labor, as mediator.

The Chicago city council committee on railway terminals, at a meeting on June 23, decided by a vote of 9 to 4 against the idea of a central union passenger station for all roads entering the city, which has been proposed in some of the plans submitted to the committee. No action was taken on the ordinances asked by the roads now entering the Union station in connection with their plans for a station between Jackson and Adams streets, but a conference was held in Mayor Harrison's office between the mayor, members of the terminal committee, the city subway commission, Vice-Presidents Wood and Turner of the Pennsylvania lines, President Miller, of the Chicago, Burlington & Quincy, and President Earling, of the Chicago, Milwaukee & St. Paul. The City Club has presented a resolution to the committee asking that it engage experts and engineers to make a complete investigation of the subject of the location of railway terminals before taking any action on the union station ordinances.

A Correction.

In the article on Mechanical Stokers from Operating Standpoint in the issue of June 13, 1913, the mileage on the Chesapeake & Ohio between Hinton and Clifton Forge should have been 80 instead of 180; and the 6,000 ton rating given between Handley and Hinton should have been 3,750, the former applying between Handley and Russell.

Another View of the Case.

We hate to look at it that way, but since Professor Taft took to bobbing in and out of New Haven so frequently the railroad has been all out of order. But this does not in the least exonerate the passengers. Reckless to the point of criminality, they have neglected the most elementary precautions. Perfect jumping daredevils, those passengers! Watch them! See them rush to that ominous little grated window and buy tickets of an inmate whose record they never stop to pry into! See them fling themselves aboard their trains without counting the wheels or so much as investigating the engine, whereas we have beheld

engines brazenly inscribed "1812," "1776," and even "1620"! And just consider their indifference to the engineer! Do they ask his age, and if his mother knows he is an engineer? Do they rub his back? Not they! Why, sakes alive, you might think they were off for a trip in a mere aeroplane!—*New York Tribune.*

Railway Boom in China.

A great wave of enthusiasm for the construction of new railway lines has of late been spreading through the provinces of China. The issue alone affords significant evidence of the awakening of the people to the need of new lines of communication. There is in all quarters a spirit of inquiry abroad. This is in marked contrast with the attitude of opposition adopted on all sides but a year ago to projects having for their object the opening of the country by railways. The revolution would seem to have wrought the change. It may or it may not have done so. What is certain, though, is that the prime mover of the agitation which led to the revolution has done more than any other person in the country to dispel the popular prejudices which militated against progress in railway development. Dr. Sun Yat-sen, by his campaign in the various sections of the country which he has visited, has opened the eyes of the people to the fact that in easy communication is the secret of strength and independence.

Safety of Passengers on the Pennsylvania.

One road—the Pennsylvania—has the courage to publish its passenger-accident record without waiting until it can show non-fatal statistics for a whole year. In 1912, 27 passengers were killed; but 85 per cent. of them were due to other than train accidents; falling off trains, walking in front of trains at stations, and getting on and off moving trains. A total of 837,121 trains were run for an aggregate distance of 40,000,000 miles, carrying all told 100,000,000 people, and two trains suffered wrecks causing loss of life. Of the passengers injured in 1912, 321 were hurt getting on and off trains. Two hundred and fifty-five persons classed as "passengers" were hurt in falling while on railroad property other than trains. In five years the number of passengers carried was nearly five hundred millions, and sixteen of them lost their lives in accidents to trains, nine having been killed in one accident. In five years, only five trains out of over 4,000,000 operated suffered wrecks which caused the death of any of the passengers carried on them. The figures are:

Year.	Passengers carried.	Train accidents in which passengers were killed.	Passengers killed in train accidents.
1908.....	88,328,604	0	0
1909.....	92,391,356	1	1
1910.....	100,844,477	0	0
1911.....	97,978,839	2	11
1912.....	101,755,061	2	4
	481,298,337	5	16

The company's statement says: "The management regards every accident of any kind as one too many. The number of accidents must be cut down. To that end efforts are being directed more definitely and systematically than ever before."

A Bold Statistician.

It is estimated by a Chicago alderman, Mr. Long, that smoke costs the city $18,461,106 annually, and this does not include cigarettes and other forms of the tobacco evil. The railroads are responsible for $7,938,276 of it, and factories for a great part of the rest. The average loss to each family is put at $15.48, which is greater than the annual personal property tax. To do about $21,000 damage a day the 1636 locomotives burn 5,601 tons of coal, which makes the damage from burning a ton of coal come to $3.75 or the value of the coal itself. Alderman Long is a bold statistician, but his figures suggest that it might be cheaper to push the freight trains by hand, provided the workers were not allowed to smoke short black pipes.—*Springfield Republican.*

137,804,768 Eggs B. O. at N. Y.; Not O. R.

This is the record for the year 1909, according to a pamphlet issued by the Bureau of Chemistry, Department of Agriculture. In an effort to reduce the enormous breakage of eggs in transit —to prevent the accidental scramble that means such a large loss to producers and consumers—the department is conducting extensive experiments to determine the safest manner of packing. The waste noted, over 11½ million dozen, is 9 per cent. of a total consumption in 1909 of 127,689,000 dozen eggs. In other words, this percentage of all eggs received in New York were cracked, and of these a large number were unfit for food use. The egg supply of large cities, and particularly New York, has to come from a long distance. The Middle Atlantic States in 1909 sold only about 110,000,000 dozen eggs, or not enough to supply New York alone, if every egg had been sent to that city. For the eastern coast cities, the distant corn districts are practically the sole source of supply, because the little gray hen does not have to scratch so hard for a living there as she does where grain is scarce. The Bureau of Chemistry regards the investigation of the methods of preventing egg breakage as particularly important because the many millions of dozens of eggs now broken in shipment naturally tend to keep the price of this valuable food higher than if there were no breakage, or if the breakage were materially reduced. The bureau, through the Food Research Laboratory, is now engaged in shipping eggs handled in different ways on long journeys to different points in the United States, and is carefully noting their condition on receipt at their destination. The situation is growing acute, for the railroads are claiming that their damage losses are such as to make the carrying of eggs unprofitable. Shippers and consignees have large sums of money tied up in claims and litigation with the roads.

New York Law of Signalmen's Work Days.

The new law of the state of New York requiring railroads to grant two days of 24 hours each off in every calendar month for rest, with regular compensation, applies to signalmen, tower men and gatemen; and to telegraph operators and telephone operators receiving or sending train orders. The same law says that train despatchers and train order operators must not work more than eight hours in a day of 24 hours; but extraordinary emergencies caused by accident, fire, flood, or danger to life or property may be treated as exceptions. For each hour worked beyond eight hours, in emergencies, employees must be paid at the rate of at least one-eighth their daily compensation. The provision for two days off in each month does not apply to operators working less than eight hours a day. Violation of the law is subject to a penalty of $100 and the fine, when collected, is to be paid one-half to the informer and the balance to the Free School Fund of the State. The law does not apply to any part of a railroad where the number of regular passenger trains each day, daily, is not more than eight, though if there are usually 20 freight trains each way daily, the law applies, even with less than eight passenger trains.

Rest Days in New York.

Chapter 740 of the Laws of New York for the present year establishes the rule of one day of rest in seven for the employees of all factories and mercantile establishments. Every such employee must have at least twenty-four consecutive hours of rest in every seven consecutive days; but there are exceptions in regard to bakeries, and persons caring for live animals are also excepted, as are superintendents, foremen and men who maintain fires or make necessary repairs to boilers or machinery. The proprietor of a shop must post in a conspicuous place the names of men who are required or allowed to work on Sunday, with the rest-day of such employee designated. The State Industrial Board, when necessary to preserve property, life or health, may make temporary exceptions to the law. This law goes into effect October 1 next.

Good Use of Nicotine.

The Long Island Railroad has had a strenuous fight against caterpillars or web-worms, millions of which have been infesting its tracks for some weeks, and reports a final victory; but what has become of the unfortunate farmers Mr. Peters does not tell us.

Early in June "tent caterpillars," as they are called, were reported "traveling westward a foot deep." President Peters instructed the road's agricultural department to go over the Montauk division and endeavor to exterminate the worms, which were causing many delays to trains. At one place for a mile and a quarter, the track, running through thickly wooded hills, was

covered with a sticky mass of caterpillars that had been crushed by trains. The first thing done was to destroy the worms already on the rails. This was accomplished by means of hand spray pumps containing "sulfocide" and a concentrated solution of nicotine, applied by men traveling slowly along the track on a hand-car. The army of caterpillars on the rails and ties was exterminated by these chemical solutions and the mass of crushed and cooked insects was softened so that the slippery coating that had caused so many delays to trains could be removed with a hoe.

To check further inroads on the right-of-way, from other armies of caterpillars leaving woods which they had defoliated completely, a stream of heavy crude oil was poured along the outer edge of the ties, and later ditches were dug on both sides of the track and filled with oil, to prevent the caterpillars from reaching the rails.

A Distant Hope.

William B. Wilson, Secretary of Labor, in an address at the annual memorial service of the railroad brotherhoods in Philadelphia, last Sunday, said that he hoped for a universal eight-hour law for railroad men and a system whereby trainmen may spend their off time at their homes.

"There is no economic reason why a railroad labor schedule should call for sixteen hours as the maximum of a day's labor, and the time will come when the day will be shortened. Such a change is essential in order that accidents may be prevented. I don't expect this in the near future, but I say it will come. I also hope to see the time when railroad men, instead of spending every other night or so away from home, will be enabled to spend all their off hours at home with their families."

President Rea on the Situation.

I can take no gloomy view of this great country and its possibilities, notwithstanding the present unfavorable outlook. I have unbounded confidence in the business men of this country that nothing approaching confiscation or unfair dealing to lower the standards of service will ultimately be permitted, provided the railroads themselves will put their cases in the hands of the business public and clearly emphasize their needs; it is for that purpose that we are in conference with you.

So far as the Pennsylvania Railroad itself is concerned, and stripping it of all obligations connected with the lines in its system which act as feeders, it perhaps cannot be said that at present it absolutely needs an increase in transportation rates for the ordinary maintenance of its property, the payment of its present fixed charges on the outstanding capital, or to maintain the present rate of dividend

This is the result of the conservative management I have already alluded to, which has conserved its capital account and applied all above a fair dividend to the betterment of the property; but the company itself cannot ignore the other companies in its system upon which it relies to be fed with traffic, and upon their investment and its own, as above stated, it received the low return of 4.83 per cent. in 1912.

One railroad, as you know, cannot be favored in this wise and the others excluded. If the position of the Pennsylvania system, as above stated, leaves it in need of the moderate advance in freight rates now requested, it is clear that such an advance is urgently needed on sound business reasons, by all other railroad companies, not to pay for inefficient management or undue capitalization of the past, but after exercising the best ability and foresight that can be obtained in the administration of the property, the railroads are not receiving just compensation under present rates.

Unless this reasonable treatment is accorded to the railroad companies and a fair return can be earned upon the money invested in railroad facilities, the railroads will come to a standstill because capital cannot be exacted from the public unless it is suitably rewarded. Therefore, is it not time for business men of your experience to take a hand and see that only fair-minded and impartial men are sent to legislatures and regulative bodies who will co-operate with these governmental agencies of transportation for that is what they have become in fact, although privately owned to the end that continued good service and facilities may be assured, necessary improvements made, protection secured for the capital already invested, and the new capital raised on a basis that shall yield a fair return to the owners of the properties?

And, furthermore, can you not also do something to guard against the unwise acts of organized labor when directed to securing what might be termed coercive and class legislation as illustrated in the extra crew laws? Railroads, like other corporations, are now generally prohibited from contributing to political parties, and rightfully, but without apologizing for what existed in the past, I do believe that such contributions were made oftener for the purpose of preventing unjust legislation than to influence legislation favorable to the railroad companies.

What, however, is the difference in morals between railroads currying favor with political parties through contributions to the party purse, and so-called labor committees sitting in almost every capital and in many cases, as we are informed, promising votes in return for such unnecessary legislation as the extra crew laws? I say there is no difference, and such action should also be prohibited, and you business men can do much in this direction, if you believe the railroad position just and will make your power effective.

Such action will also be in the most enlightened interest of the employees, and encourage those who intrust their capital to us. We must all work and advance together on a mutually fair basis if we desire our country to progress.—*From an address before the Shippers of Boston, June 12, 1913.*

Meeting of Valuation Engineers.

The Valuation Board of the Interstate Commerce Commission held its first meeting at Washington, June 30, and conferred with a number of railroad officers. The object of the conference was to consider arrangements for co-operation between the commission and the carriers in the preparation of maps, profiles and other necessary data. T. W. Hulme, general secretary of the railroads' valuation committee, headed the railroad delegation, which consisted of fourteen engineers and five attorneys.

O. P. Gothlin, of Ohio, president of the National Association of Railway Commissioners, has appointed a committee, with representation from several different states, to consider the matter of valuations and to keep in touch with the Federal Board at Washington; and one of this committee, W. H. Stutsman, of North Dakota, was present at the Washington conference. The chairman of the committee is Commissioner Martin, of Kansas. The committee will hold a meeting in Chicago on Saturday of this week.

In connection with this movement a number of the western state commissions have submitted their views to President Wilson and to Congress, demanding that "the people" shall be represented by special counsel and by experts in the valuation of physical properties.

The New Haven's Accident Record.

The New York, New Haven & Hartford, because of what it characterizes as the many erroneous statements and false reports placed before the public in the Brandeis campaign, which has been almost continuous now for six years, and which finds its opportunity in accidents as well as labor and political agitation, has issued an abstract of its record of passenger train accidents for ten years from June 30, 1903, to June 15, 1913. In that time the company ran 5,078,750 trains a distance aggregating 158,531,541 miles, and in these trains carried 755,678,338 passengers paying fare. In these ten years there were 6 accidents to trains in which persons traveling on them were killed, and the number of passengers killed was 29.

In six of these ten years not a single passenger was killed in a train accident. To correct the many erroneous statements that have appeared in print, the figures by years are here given:

Years.	Passengers carried.	Train accidents in which passengers were killed.	Passengers killed in train accidents.
1903 (last six months)	34,090,448	0	0
1904	63,234,687	0	0
1905	66,507,138	0	0
1906	73,531,069	0	0
1907	75,453,778	0	0
1908	74,382,023	1	1
1909	79,849,297	0	0
1910	83,860,031	0	0
1911	83,768,348	2	12
1912	85,350,409	2	10
1913 (to June 15)	36,661,110	1	6
Total	755,678,338	6	29

The statement continues: "In the five accidents preceding 1913 no coroner's verdict or investigation by state or national authorities found any defect in the construction of roadbed, the condition of motive power, or equipment, or in condition or operation of signals. It is because of this record for safety and because of the superior roadbed and equipment that the public is shocked over every accident, of any character, from any cause, that takes place on this road."

Work for the Accountants.

The decision of the Supreme Court in the Arkansas rate cases was not issued in complete form until June 24; and it then appeared that, in accordance with the Court's mandate, the adjudication of the cases will call for the presentation by the carriers of actual book accounts of receipts and expenditures in intrastate business. Nothing less will be accepted as a basis for annulling state rates as confiscatory.

Justice Hughes briefly announced the decision of the court that the freight and two-cent passenger rates in that state were not confiscatory on the court's last decision day, June 16, and has been engaged in writing the opinion in the cases since that day.

He pointed out in the opinion that the railroads in attacking the rates failed to sustain their case, because of too general methods employed in separating the intrastate operations from the interstate. And the value of the railroad property was improperly divided between intrastate and interstate business on a gross revenue basis. He also criticized the lower court's conclusion that intrastate freight traffic cost 210 per cent. more on the Iron Mountain road and 250 per cent. more on the St. Louis Southwestern than interstate traffic, and the intrastate passenger service on the Iron Mountain cost 10 per cent. more than the interstate.

Railroad Police.

The seventeenth annual convention of the International Association of Railway Special Agents and Police was held at Salt Lake City, Utah, June 18 and 19. The president of the association for the ensuing year is J. W. Connelly, Washington, D. C. The meeting next year will be held at Norfolk, Va. The secretary of this association is W. C. Pannell, Baltimore, Md.

MEETINGS AND CONVENTIONS.

The following list gives names of secretaries, dates of next or regular meetings, and places of meeting.

AIR BRAKE ASSOCIATION.—F. M. Nellis, 53 State St., Boston, Mass.

AMERICAN ASSOCIATION OF DEMURRAGE OFFICERS.—A. G. Thomason, Boston, Mass. Convention, May 19, 1914, St. Louis.

AMERICAN ASSOCIATION OF GENERAL PASSENGER AND TICKET AGENTS.—W. C. Hope, New York. Annual meeting, October 14-15, Philadelphia, Pa.

AMERICAN ASSOCIATION OF FREIGHT AGENTS.—R. O. Wells, East St. Louis, Ill.

AMERICAN ASSOCIATION OF RAILROAD SUPERINTENDENTS.—E. H. Harman, St. Louis, Mo.; 3d Friday of March and September.

AMERICAN ELECTRIC RAILWAY ASSOCIATION.—H. C. Donecker, 29 W. 39th St., New York.

AMERICAN ELECTRIC RAILWAY MANUFACTURERS' ASSOC.—H. G. McConnaughy, 165 Broadway, New York. Meetings with Am. Elec. Ry. Assoc.

AMERICAN RAILWAY ASSOCIATION.—W. F. Allen, 75 Church St., New York. Next meeting, November 19, 1913, Chicago.

AMERICAN RAILWAY BRIDGE AND BUILDING ASSOCIATION.—C. A. Liehty, C. & N. W., Chicago. Convention, October 21-24, 1913, Montreal.

AMERICAN RAILWAY ENGINEERING ASSOCIATION.—E. H. Fritch, 900 S. Michigan Ave., Chicago.

AMERICAN RAILWAY MASTER MECHANICS' ASSOCIATION.—J. W. Taylor, Old Colony building, Chicago.

AMERICAN RAILWAY TOOL FOREMEN'S ASSOCIATION.—A. R. Davis, Central of Georgia, Macon, Ga. Next convention, July 22-24, Chicago.

AMERICAN SOCIETY FOR TESTING MATERIALS.—Prof. E. Marburg, University of Pennsylvania, Philadelphia, Pa.

AMERICAN SOCIETY OF CIVIL ENGINEERS.—C. W. Hunt, 220 W. 57th St., New York; 1st and 3d Wed., except June and August, New York.

AMERICAN SOCIETY OF ENGINEERING CONTRACTORS.—J. R. Wenlinger, 11 Broadway, New York; 2d Tuesday of each month, New York.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS.—Calvin W. Rice, 29 W. 39th St., New York.

AMERICAN WOOD PRESERVERS' ASSOCIATION.—F. J. Angier, B. & O., Baltimore, Md. Next convention, January 20-22, 1914, New Orleans, La.

ASSOCIATION OF AMERICAN RAILWAY ACCOUNTING OFFICERS.—C. G. Phillips, 143 Dearborn St., Chicago. Annual meeting, May 28, Atlantic City, N. J.

ASSOCIATION OF RAILWAY CLAIM AGENTS.—J. R. McSherry, C. & E. I., Chicago.

ASSOCIATION OF RAILWAY ELECTRICAL ENGINEERS.—Jos. A. Andreucetti, C. & N. W. Ry., Chicago. Annual convention, October 18-24, Chicago.

ASSOCIATION OF RAILWAY TELEGRAPH SUPERINTENDENTS.—P. W. Drew, 112 West Adams St., Chicago.

ASSOCIATION OF TRANSPORTATION AND CAR ACCOUNTING OFFICERS.—G. P. Conard, 75 Church St., New York.

ASSOCIATION OF WATER LINE ACCOUNTING OFFICERS.—W. R. Evans, Chamber of Commerce, Buffalo, N. Y. Annual meeting, October 8, Philadelphia, Pa.

BRIDGE AND BUILDING SUPPLY MEN'S ASSOCIATION.—H. A. Neally, Joseph Dixon Crucible Co., Jersey City, N. J. Meeting with American Railway Bridge and Building Association.

CANADIAN RAILWAY CLUB.—James Powell, Grand Trunk Ry., Montreal, Que., 2d Tuesday in month, except June, July and Aug., Montreal.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—Clement H. McLeod, 413 Dorchester St., Montreal, Que. Thursday, Montreal.

CAR FOREMEN'S ASSOCIATION OF CHICAGO.—Aaron Kline, 841 North 50th Court, Chicago; 2d Monday in month, Chicago.

CENTRAL RAILWAY CLUB.—H. D. Vought, 95 Liberty St., New York; 2d Thurs. in Jan. and 2d Fri. in March, May, Sept., Nov., Buffalo, N. Y.

CIVIL ENGINEERS' SOCIETY OF ST. PAUL.—L. S. Pomeroy, Old State Capitol building, St. Paul, Minn.; 2d Monday, except June, July, August and September, St. Paul.

ENGINEERS' SOCIETY OF PENNSYLVANIA.—E. R. Dasher, Box 704, Harrisburg, Pa.; 1st Monday after 2d Saturday, Harrisburg, Pa.

ENGINEERS' SOCIETY OF WESTERN PENNSYLVANIA.—E. K. Hiles, Oliver building, Pittsburgh; 1st and 3d Tuesday, Pittsburgh, Pa.

FREIGHT CLAIM ASSOCIATION.—Warren P. Taylor, Richmond, Va.

GENERAL SUPERINTENDENTS' ASSOCIATION OF CHICAGO.—E. S. Koller, 226 W. Adams St., Chicago; Wed. preceding 3d Thurs., Chicago.

INTERNATIONAL RAILWAY CONGRESS.—Executive Committee, 11, rue de Louvain, Brussels, Belgium. Convention, 1915, Berlin.

INTERNATIONAL RAILWAY FUEL ASSOCIATION.—C. G. Hall, 922 McCormick building, Chicago.

INTERNATIONAL RAILWAY GENERAL FOREMEN'S ASSOCIATION.—Wm. Hall, 829 West Broadway, Winona, Minn. Next convention, July 15-18, Chicago.

INTERNATIONAL RAILROAD MASTER BLACKSMITHS' ASSOCIATION.—A. L. Woodworth, Lima, Ohio. Annual meeting, August 18, Richmond, Va.

MAINTENANCE OF WAY & MASTER PAINTERS' ASSOCIATION OF THE UNITED STATES AND CANADA.—W. G. Wilson, Lehigh Valley, Easton, Pa.

MASTER BOILER MAKERS' ASSOCIATION.—Harry D. Vought, 95 Liberty St., New York.

MASTER CAR BUILDERS' ASSOCIATION.—J. W. Taylor, Old Colony building, Chicago.

MASTER CAR AND LOCOMOTIVE PAINTERS' ASSOC. OF U. S. AND CANADA.—A. P. Dane, B. & M., Reading, Mass. Annual meeting, September 9-12, Ottawa, Can.

NATIONAL RAILWAY APPLIANCE ASSOC.—Bruce V. Crandall, 537 So. Dearborn St., Chicago. Meetings with Am. Ry. Eng. Assoc.

NEW ENGLAND RAILROAD CLUB.—W. E. Cade, Jr., 683 Atlantic Ave., Boston, Mass.; 2d Tuesday in month, except June, July, Aug. and Sept., Boston.

NEW YORK RAILROAD CLUB.—H. D. Vought, 95 Liberty St., New York; 3d Friday in month, except June, July and August, New York.

NORTHERN RAILROAD CLUB.—C. L. Kennedy, C., M. & St. P., Duluth, Minn.; 4th Saturday, Duluth.

PEORIA ASSOCIATION OF RAILROAD OFFICERS.—M. W. Rotehford, Union Station, Peoria; 2d Thursday.

RAILROAD CLUB OF KANSAS CITY.—C. Manlove, 1008 Walnut St., Kansas City, Mo.; 3d Friday in month, Kansas City.

RAILWAY BUSINESS ASSOCIATION.—Frank W. Noxon, 2 Rector St., New York. Annual dinner, second week in December, 1913, New York.

RAILWAY CLUB OF PITTSBURGH.—J. B. Anderson, Penna R. R., Pittsburgh, Pa.; 4th Friday in month, except June, July and August, Pittsburgh.

RAILWAY ELECTRICAL SUPPLY MANUFACTURERS' ASSOC.—J. Scribner, 1021 Monadnock Block, Chicago. Meetings with Assoc. Ry. Elec. Engrs.

RAILWAY GARDENING ASSOCIATION.—J. S. Butterfield, Lee's Summit, Mo. Next meeting, August 12-15, Nashville, Tenn.

RAILWAY DEVELOPMENT ASSOCIATION.—W. Nicholson, Kansas City Southern, Kansas City, Mo.

RAILWAY SIGNAL ASSOCIATION.—C. C. Rosenberg, Bethlehem, Pa. Convention, October 14, Nashville, Tenn.

RAILWAY STOREKEEPERS' ASSOCIATION.—J. P. Murphy, Box C, Collinwood, Ohio.

RAILWAY SUPPLY MANUFACTURERS' ASSOC.—J. D. Conway, 2135 Oliver bldg., Pittsburgh, Pa. Meetings with M. M. and M. C. B. Assocs.

RAILWAY TEL. AND TEL. APPLIANCE ASSOC.—W. E. Harkness, 284 Pearl St., New York. Meetings with Assoc. of Ry. Teleg. Sups.

RICHMOND RAILROAD CLUB.—F. O. Robinson, Richmond, Va.; 2d Monday except June, July and August.

ROADMASTERS' AND MAINTENANCE OF WAY ASSOCIATION.—L. C. Ryan, C. & N. W., Sterling, Ill. Convention, September 8-12, 1913, Chicago.

ST. LOUIS RAILWAY CLUB.—B. W. Frauenthal, Union Station, St. Louis, Mo.; 2d Friday in month, except June, July and Aug., St. Louis.

SIGNAL APPLIANCE ASSOCIATION.—F. W. Edmonds, 3868 Park Ave., New York. Meetings with annual convention Railway Signal Association.

SOCIETY OF RAILWAY FINANCIAL OFFICERS.—C. Nyquist, La Salle St. Station, Chicago.

SOUTHERN ASSOCIATION OF CAR SERVICE OFFICERS.—E. W. Sandwich, A. & W. P. Ry., Montgomery, Ala.

SOUTHERN & SOUTHWESTERN RAILWAY CLUB.—A. J. Merrill, Grant bldg., Atlanta, Ga.; 3d Thurs., Jan., March, May, July, Sept., Nov., Atlanta.

TOLEDO TRANSPORTATION CLUB.—J. G. Macomber, Woolson Spice Co., Toledo, Ohio; 1st Saturday, Toledo.

TRACK SUPPLY ASSOCIATION.—W. C. Kidd, Ramapo Iron Works, Hillsburn, N. Y. Meeting with Roadmasters' and Maintenance of Way Association.

TRAFFIC CLUB OF CHICAGO.—W. H. Wharton, La Salle Hotel, Chicago.

TRAFFIC CLUB OF NEW YORK.—C. A. Swope, 290 Broadway, New York; last Tuesday in month, except June, July and August, New York.

TRAFFIC CLUB OF PITTSBURGH.—D. L. Wells, Erie, Pittsburgh, Pa.; meetings monthly, Pittsburgh.

TRAFFIC CLUB OF ST. LOUIS.—A. F. Versen, Mercantile Library building, St. Louis, Mo. Annual meeting in November. Noonday meetings October to May.

TRAIN DESPATCHERS' ASSOCIATION OF AMERICA.—J. F. Mackie, 7042 Stewart Ave., Chicago.

TRANSPORTATION CLUB OF BUFFALO.—J. M. Sells, Buffalo; first Saturday after first Wednesday.

TRANSPORTATION CLUB OF DETROIT.—W. R. Hurley, L. S. & M. S., Detroit, Mich.; meetings monthly.

TRAVELLING ENGINEERS' ASSOCIATION.—W. O. Thompson, N. Y. C. & H. R. R., East Buffalo, N. Y. Annual meeting, August, 1913, Chicago.

UTAH SOCIETY OF ENGINEERS.—R. B. Ketchum, University of Utah, Salt Lake City, Utah; 3d Friday of each month, except July and August.

WESTERN CANADA RAILWAY CLUB.—W. H. Rosevear, P. O. Box 1767, Winnipeg, Man.; 2d Monday, except June, July and August, Winnipeg.

WESTERN RAILWAY CLUB.—J. W. Taylor, Old Colony building, Chicago; 3d Tuesday of each month, except June, July and August.

WESTERN SOCIETY OF ENGINEERS.—J. H. Warder, 1735 Monadnock Block, Chicago; 1st Monday in month, except July and August, Chicago.

Traffic News.

The federal grand jury at Detroit has returned five indictments against the Michigan Central, charging failure to observe its published tariffs regarding the assessment of demurrage charges at Detroit. Three of the indictments refer to demurrage accrued against the American Car & Foundry Company, and two to demurrage accrued against the National Fireproofing Company.

The Chamber of Commerce of Indianapolis, which was recently asked by a committee representing the eastern roads to approve their plan for a 5 per cent. advance in freight rates, has passed resolutions declining to approve the advance until the question has been determined by the Interstate Commerce Commission. As to intrastate rates the Chamber of Commerce declares that it will strenuously oppose any advance.

The New England Lines Industrial Bureau conducts a hundred-acre farm in Maine and this year is raising potatoes, sugar beets, grain and garden truck. This farm does not take in a whole county, as would seem to be indicated by some of the newspaper items which have been published concerning it, but it is an extensive experiment, nevertheless. The managers hope to show that potatoes can be grown as successfully in Washington County as in Aroostook County.

The Central of Georgia is the latest newcomer in the ranks of the railroads which publish a periodical for the benefit of ticket agents, conductors, baggage men, etc. "The Right Way" is the title of this paper, and Vol. 1, No. 3, is dated June, 1913. It is a small four-page sheet and is issued by the Passenger Traffic Department, Savannah. "Safety First" appears also to be a prominent feature of the publication, and an article by D. C. Boy, assistant chief of the Educational Bureau, contains exhortations to the employees in this line. The illustrations in this issue are one of a new station which has been opened at Barnesville, and one of Commodore W. H. Fisher, of the company's Ocean Steamship Line, who has retired after 41 years' continuous service.

The Lehigh Valley has remodeled one of its large dining cars, 77 ft. 8 in. long, to serve as a traveling exhibition and meeting hall to promote the road's industrial opportunities and its agricultural territory. This car will be put to much more diverse uses than the ordinary agricultural demonstration car. At times it will be divided into a kitchen, dining room and bedroom, and used to teach and illustrate domestic science. Experts from the New York State College of Agriculture at Ithaca have volunteered to carry on this work of teaching food values, proper methods of cooking and sanitary care of the home. At other times the car will be provided with literature, maps, models, photographs, drawings, blueprints, stereopticons, and moving pictures of factory sites and local industries along the line.

Reductions in Passenger and Freight Rates.

The railroads affected by the recent decision of the Supreme Court of the United States in the Minnesota cases, are quite generally announcing changes to be made in tariffs in compliance with the decision. The Chesapeake & Ohio will reduce passenger fares in West Virginia to 2 cents a mile, July 1. There are outstanding thousands of coupons which have been issued with tickets in West Virginia since the beginning of the lawsuits, entitling passengers to a refund of the difference between what they have paid and what is now declared to be the legal rate.

The railroads in Missouri affected by the decision announce that they will put the new rates in force "at the earliest practicable date." Attorneys representing thirteen roads concerned have notified J. M. Atkinson, chairman of the Missouri Public Service Commission, of their desire to meet the commission as soon as possible to formulate a method of putting the rates in operation and fixing the date when they shall be effective. Though the Supreme Court upheld the two-cent passenger rate, the matter of equitable adjustment of rates, the attorneys say, lies with the State Public Service Commission. It is expected that the new rates, both passenger and freight, will go into effect by July 1.

Seven roads operating in Minnesota have announced that they will take action under the terms of the recent decision of the court in the Minnesota cases, and that probably the new rates will be placed in effect by July 10. Refunds of overcharges will be made in all cases where proper proofs of such overcharges are produced.

At Red Wing, Minn., indictments have this week been returned by the county grand jury charging violation of the two-cent passenger rate law against the Chicago Great Western, the Chicago & North Western and the Chicago, Milwaukee & St. Paul. The indictments are the result of action taken by Judge Albert Johnson of the County Court nearly a month ago. At that time the United States Supreme Court had not rendered its decision in the Minnesota cases, and it was generally supposed that all state and county officers were restrained from acting in the matter; but Judge Johnson charged the grand jury that it should indict the railroads which have violated the two-cent law in the state. The jury failed to return any indictments; the judge was indignant and instead of discharging the jury at that time, said he would call the members together later. This week he repeated his demand that they indict the railroads, and the present action of the jury follows his charge.

Car Location.

The accompanying table, which is taken from bulletin No. 7 of the American Railway Association, gives a summary of freight car location by groups on May 31, 1913.

Car Location on May 31, 1913.

*Denotes deficiency.

Car Surpluses and Shortages.

Arthur Hale, chairman of the committee on relations between railroads of the American Railway Association, in presenting statistical bulletin No. 145-A, giving a summary of car surpluses and shortages by groups from March 13, 1912, to June 14, 1913, says: The total surplus on June 14, 1913, was 71,126 cars; on May 31, 1913, 60,281 cars; and on June 20, 1912, 73,464 cars. Compared with the preceding period; there is an increase in the total surplus of 10,835 cars, of which 9,331 is in box, 100 flat, 1,907 in miscellaneous, and a decrease of 503 in coal car surplus. The increase in box car surplus is in groups 2 (New York, New Jersey, Delaware, Maryland and eastern Pennsylvania), 3 (Ohio, Indiana, Michigan and western Pennsylvania), 5 (Kentucky, Tennessee, Mississippi, Alabama, Georgia and Florida), 6 (Iowa, Illinois, Wisconsin and Minnesota), 7 (Montana, Wyoming, Nebraska and the Dakotas), 8 (Kansas, Colorado, Oklahoma, Missouri and Arkansas), 10 (Washington, Oregon, Idaho, California, Nevada and Arizona), and 11 (Canadian lines). The increase in flat car surplus is in groups 4 (the Virginias and Carolinas, 8 (as above), 9 (Texas, Louisiana and New Mexico), and 10 (as above). The increase in miscellaneous car surplus is in groups 3, 5, 7, 8, 10 and 11 (as above). The decrease in coal car surplus is in groups 2, 4, 6, 7, 8 and 9 (as above).

The total shortage on June 14, 1913, was 7,199 cars; on May 31, 1913, 9,383 cars; and June 20, 1912, 5,746 cars. Compared with the preceding period; there is a decrease in the total shortage of 2,184 cars, of which 958 is in box, 23 in flat, 1,076 in coal and 127 in miscellaneous cars. The decrease in box car shortage is in groups 3, 5, 6, 7 and 10 (as above). The decrease in flat car shortage is in all groups except 1 (New England lines), 3 and 11 (as above). The decrease in coal car shortage is in groups 1, 2, 4, 10 and 11 (as above). The decrease in miscellaneous car shortage is in groups 3, 8, 10 and 11 (as above).

Compared with the same date of 1912; there is a decrease in the total surplus of 2,338 cars, of which 51 is in flat, 8,221 in coal, 640 in miscellaneous, and an increase of 6,574 in box car surplus. There is an increase in the total shortage of 1,453 cars, of which 36 is in box, 78 in flat, 1,583 in coal, and an increase of 244 in miscellaneous car shortage.

The accompanying table gives car surplus and shortage figures by groups for the last period covered in the report and a diagram shows total bi-weekly surpluses and shortages from 1907 to 1913.

CAR SURPLUSES AND SHORTAGES.

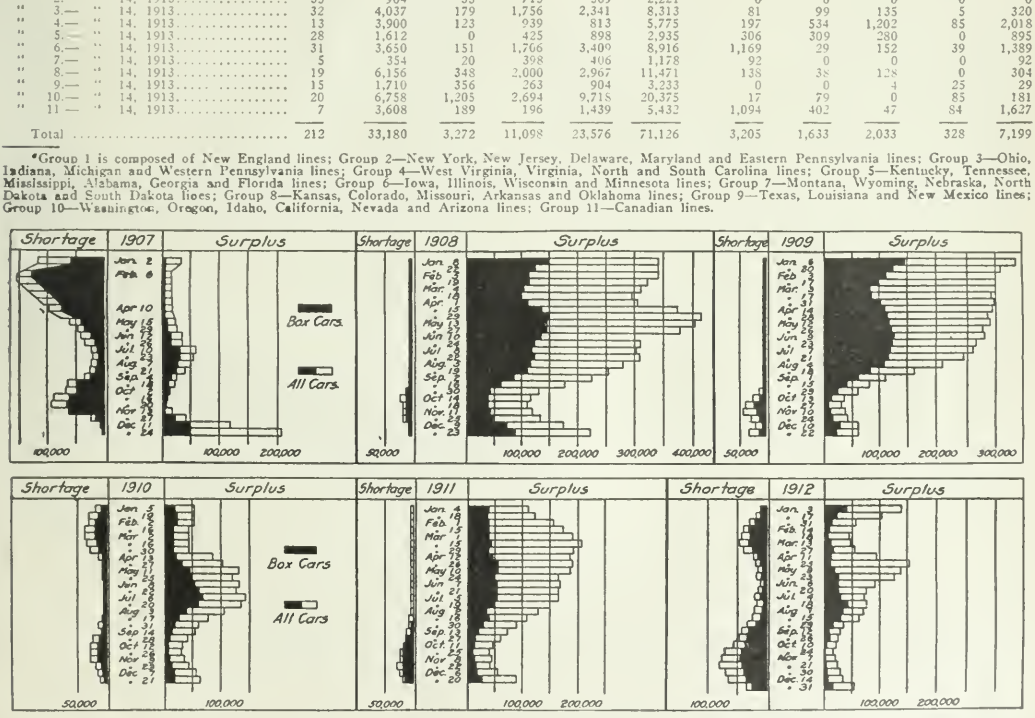
*Group 1 is composed of New England lines; Group 2—New York, New Jersey, Delaware, Maryland and Eastern Pennsylvania lines; Group 3—Ohio, Indiana, Michigan and Western Pennsylvania lines; Group 4—West Virginia, Virginia, North and South Carolina lines; Group 5—Kentucky, Tennessee, Mississippi, Alabama, Georgia and Florida lines; Group 6—Iowa, Illinois, Wisconsin and Minnesota lines; Group 7—Montana, Wyoming, Nebraska, North Dakota and South Dakota lines; Group 8—Kansas, Colorado, Missouri, Arkansas and Oklahoma lines; Group 9—Texas, Louisiana and New Mexico lines; Group 10—Washington, Oregon, Idaho, California, Nevada and Arizona lines; Group 11—Canadian lines.



Car Surpluses and Shortages, 1907 to 1913.

Summary of Revenues and Expenses of Steam Roads in April.

The Bureau of Railway Economics' summary of revenues and expenses and comments thereon for April, 1913, are as follows: The railways whose returns are included in bulletin

No. 49 operate 222,156 miles of line, or about 90 per cent. of the steam railway mileage in the United States. Total operating revenues for the month of April, 1913, amounted to $237,362,424. Compared with April, 1912, the total operating revenues show an increase of $22,893,968. These total operating revenues per mile of line averaged $1,068 in April, 1913, and $974 in April, 1912, an increase of $95, or 9.7 per cent. Freight revenue per mile increased 12.4 per cent., and passenger revenue per mile 2.5 per cent.

Operating expenses amounted to $179,024,990. This was $21,059,895 more than for April, 1912. These operating expenses per mile of line averaged $806 in April, 1913, and $717 in April, 1912, an increase of $89 per mile, or 12.3 per cent.

Net operating revenue amounted to $58,337,434. This was $1,834,073 more than for April, 1912. Net operating revenue per mile of line averaged $263 in April, 1913, and $257 in April, 1912, an increase of $6 per mile, or 2.4 per cent.

Taxes for the month of April amounted to $10,482,492, or $47 per mile, an increase of 7.9 per cent. over April, 1912.

Operating income averaged $214 per mile of line, and in April, 1912, $212, thus increasing $2, or 0.9 per cent. Operating income for each mile of line for each day in April averaged $7.13, and for April, 1912, $7.07.

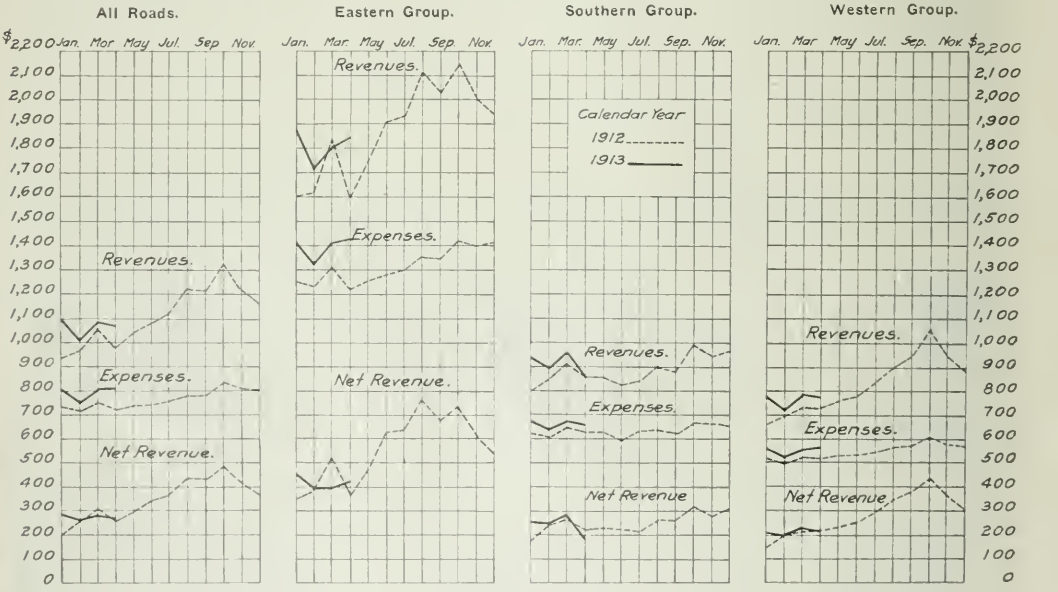
The operating ratio for April was 75.4 per cent., which is comparable with 73.9 per cent. in March, 1913, and 73.6 per cent. in April, 1912.

The railways of the eastern district show an increase in total operating revenues per mile of line as compared with April, 1912, of 16.5 per cent., the railways of the southern district show an increase of less than one tenth of 1 per cent., while the railways of the western district show an increase of 7.0 per cent. Operating expenses per mile increased 17.0 per cent on the eastern railways, 4.9 per cent on the southern railways, and 10.7 per cent on the western railways. For the eastern railways net operating revenue per mile increased 15.0 per cent., for the southern railways it decreased 13.5 per cent., and for the western railways it decreased 1.9 per cent. The increase in taxes per mile was 10.3 per cent in the eastern district, 6.7 per cent in the southern district, and 6.2 per cent in the western district. Operating income per mile increased 14.6 per cent in the East, decreased 16.5 per cent. in the South, and decreased 3.2 per cent. in the West.

Comparison of the returns for the ten months of the fiscal year 1913, with those of the corresponding months of the previous fiscal year reveals an increase in total operating revenues per mile of 9.5 per cent., an increase in operating expenses per mile of 9.3 per cent., and an increase in net operating revenue per mile of 9.9 per cent. This net operating revenue per mile of the eastern railways increased 7.1 per cent. as compared with the corresponding period of the previous year, that of the southern railways increased 4.1 per cent., and that of the western railways increased 14.8 per cent.

When the returns for the four months of the calendar year 1913 are compared with those of the corresponding months of 1912, they show an increase in total operating revenues per mile of 8.7 per cent., an increase in operating expenses per mile of 9.2 per cent., and an increase in net operating revenue per mile of 7.0 per cent. This net operating revenue per mile increased 2.6 per cent. in the eastern district as compared with the corresponding period of the previous year, increased 8.9 per cent. in the southern district, and increased 11.0 per cent. in the western district.

The diagram shows the variations in operating revenues, operating expenses, and net operating revenue per mile for the separate months of the calendar year 1912 and of the calendar year 1913 to date. The following table shows the per cent. of operating revenues consumed by each class of expenses:



Monthly Revenues and Expenses Per Mile of Line in 1912 and 1913.

PER CENT. OF TOTAL OPERATING EXPENSES.

	April,		Fiscal year ended June 30,		Calendar year ended December 31,	
	1913.	1912.	1912.	1911.	1912.	1911.
Maintenance of way and structures	15.5	13.5	12.7	12.9	12.8	12.7
Maintenance of equipment	17.8	16.8	15.8	15.5	16.0	15.7
Traffic expenses	2.1	2.3	2.2	2.2	2.0	2.1
Transportation expenses	37.4	38.3	35.9	35.5	35.5	35.4
General expenses	2.6	2.7	2.5	2.5	2.4	2.5
Total operating expenses	75.4	73.6	69.1	68.6	68.7	68.4

Important Change in Traffic Sources.

The steady development in recent years of the country between St. Louis and eastern Texas is demonstrated by a table issued by the St. Louis Southwestern, showing the decline in carload lots of farm products shipped to St. Louis from Texas.

The high-water mark for strawberries was in 1907, when 126 cars were shipped. The following year the number dropped to 80, in 1909 to 39, and to two in 1911.

This year's mark is 39. Cabbages have dropped from 39 cars in 1908 and 1909 to two cars this year. The largest drop is in potatoes, of which 853 cars were shipped in 1908, against 28 this year. A total of 411 cars has been shipped so far in 1913, and only 239 in 1912, against 1,883 in 1908.—*St. Louis Republic.*

A Shipper's Views as to Why Freight Rates Should Be Higher.

The following paragraphs are from an address by George W. Simmons, vice-president, Simmons Hardware Company, St. Louis, Mo., before the Traffic Club of Philadelphia on March 17 last, repeated before the Transportation Club of Indianapolis, April 10:

Ever since early in 1908, our firm and its officers have been advocating publicly that the railroads should be allowed to increase their rates. While the Simmons Hardware Company pays in freight charges to the railroads probably as much as any firm in the country, and from the nature of our business we could not add to our selling prices any increase in transportation charges, we still earnestly advocate an increase in freight rates, feeling absolutely confident that in the immense volume of business which would immediately result through the wonderful prosperity of the country caused by increased railroad development, we will reap our share of the harvest far and away in excess of the amount of increased expenses for freight. When we started talking this way five years ago, few shippers agreed with us and even many railroad men thought we were playing to the grandstand, or in some way bidding for railroad favor. Today, however, practically every one who studies this subject agrees with us and thousands of shippers in various states who vigorously opposed such an idea five years ago, are now convinced of the logic of it. That is but one of the many evidences of the change in public sentiment on this subject. The public is beginning to realize that in the event of calamity and disaster, such as occurred from the storms in this section a couple of weeks ago, the dollars and cents loss to the railroads from unexpected causes beyond their control is, in many cases, more than they might pay out in dividends to their stockholders in an entire year, and in others sufficient to change an entire year's profits into loss.

There is no longer any general desire to persecute the railroads, but simply the feeling that the rights of the public must be conserved. On the other hand, the impression is growing throughout the country that the railroads have gotten the sharp end of the stick in a good many ways of late—in labor disputes about wages and in the advance in the cost of everything they buy. Sooner or later this feeling will spread so that the members of the Interstate Commerce Commission will recognize the wisdom and common sense of such public opinion, and be influenced by it. The members of that commission are reasonable, honorable, sincere men of great ability. I believe that they will soon realize that the time has come to modify their policy towards the railroads, so that they may expand and grow upon conservative lines.

In considering the railroad problem, if we lay aside all technical arguments and look at it only from the basis of common fairness, and after all no transaction can be permanently successful unless it is based on fairness to all parties concerned, we find that the railroads' expenditures have increased in every way, most of them beyond the power or control of the railway management, partly from public demand and partly by legislation; therefore, common fairness would permit them to advance their selling prices to offset at least a part of this advance in cost, but the fact remains that railroad rates in this country have been constantly decreasing and are less today than they were thirty years ago.

INTERSTATE COMMERCE COMMISSION.

The commission has suspended from June 30 until September 29, certain schedules in the tariff of the Hocking Valley, which would advance rates on brick, c. l., from certain Ohio points to Huntington, W. Va.

The commission has further suspended from July 1 until January 1, the operation of the items in a supplement to Agent W. H. Hosmer's tariff which would advance rates on brick from Chanute and other points in Kansas to points in Iowa and Illinois.

The commission has suspended from July 1 until January 1, the supplement to Agent W. H. Hosmer's tariff which would advance rates on hay, in carloads, from St. Paul and Minneapolis, Minn., and points taking same rates to Ohio river crossings.

The commission has denied the petition of the eastern roads for the reopening of Case No. 3400—the application filed in 1910 for leave to increase freight rates—but has intimated that an original investigation of the whole rate question, to be made on the commission's own motion will soon be ordered.

The commission has suspended from June 20 until October 18, certain schedules in Agent R. H. Countiss' tariff, which by the elimination of routing from points in the state of Washington on the Bellingham & Northern via Sumas, Wash., the Canadian Pacific, North Portal, N. D., and the Minneapolis, St. Paul & Sault Ste. Marie, sought to increase rates applicable to the transportation of lumber and articles taking same rates to points in North Dakota and other states. The present rate applicable to shipments of cottonwood, fir, hemlock, larch and spruce lumber, in carloads, from Columbia, Wash., for example, to points in North Dakota on the line of the Minneapolis, St. Paul & Sault Ste. Marie is 40 cents per 100 lbs.; the proposed rate is 43 cents per 100 lbs. Rates to other destinations are affected in like manner.

Rates on Glazed Paper Reduced.

Eggerss-O'Flyng Company v. Chicago Great Western, et al. Opinion by the commission:

The commission decided that first-class rating on glazed or surface-coated paper in less than carloads from Chicago and Mississippi river crossings to Omaha, Neb., was unreasonable, and prescribed third-class rating for the future. In official and southern classifications this commodity in less than carloads is rated third class. (27 I. C. C., 280.)

Rates on Fertilizer Reduced.

Virginia-Carolina Chemical Company v. Atlantic Coast Line. Opinion by the commission:

The commission decided that the advanced rates for the transportation of fertilizer in carloads from Wadesboro, N. C., to various local stations in South Carolina were unreasonable and ordered the defendants to restore the rates in effect prior to February 26, 1912. (27 I. C. C., 234.)

Complaint Dismissed.

Clinton Manufacturers' & Shippers' Association v. Chicago & Alton et al. Opinion by Commissioner Harlan:

The commission decided that the rates on sugar and molasses from certain producing points in Louisiana to Clinton, Iowa, were not unjustly discriminatory as compared with the lower rates on such products from the same points of origin to Chicago. (27 I. C. C., 230.)

Dixie Cotton Oil Company v. St. Louis, Iron Mountain & Southern et al. Opinion by the commission:

A charge by defendants of $3 per car for switching service performed by the St. Louis Southwestern in transporting cars between its junction with the St. Louis, Iron Mountain & Southern's track and complainant's plant in Argenta, Ark., was not found to be unduly discriminatory. (27 I. C. C., 295.)

Rates on Bags, Bagging, etc., Reduced.

Corporation Commission of Oklahoma v. Arkansas, Oklahoma & Western et al. Opinion by Commissioner McChord:

The commission decided that the rates on bags, bagging, cotton-bale ties, and tie buckles from Galveston, Tex., to Oklahoma destinations were unreasonable and discriminatory, and prescribed reasonable rates for the future on a mileage basis. (27 I. C. C., 210.)

Rates on Barrels Reduced.

Alexandria Barrel Company v. Chicago, Rock Island & Pacific et al. Opinion by the commission:

The rate of 39 cents per 100 lbs., with a minimum weight of 20,000 lbs. for the transportation of tight barrels from Alexandria, La., to Houston, Tex., group points and Texas common

point territory was found to be unreasonable to the extent that it exceeds 25 cents to Houston group points and 39 cents to Texas common point territory, with a minimum weight in each instance of 12,000 lbs., subject to rule 6-B of Western classification. Reparation was awarded. (27 I. C. C., 196.)

Import Rates from Boston and New York.

Chamber of Commerce of the State of New York et al. v. New York Central & Hudson River et al. Opinion by Chairman Clark:

The original and supplemental reports in this case are at 24 I. C. C., 55 and 674, mentioned in the *Railway Age Gazette* of October 11, 1912, page 704, and November 1, 1912, page 855, respectively. After exhaustive consideration of all the matters presented on the rehearing the commission decided that the conclusions announced in the original and supplemental reports are correct. (27 I. C. C., 238.)

Import Rates.

The original and supplemental reports in this proceeding are at 24 I. C. C., 78 and 678, mentioned in the *Railway Age Gazette* of November 1, 1912, page 856. Prior decision herein adhered to upon the findings in *Chamber of Commerce case,* 27 I. C. C., 237, which is mentioned above. (27 I. C. C., 245.)

Export Rates on Flaxseed Products.

In re investigation and suspension of advances in rates by carriers for the transportation of linseed oil cake, linseed oil meal, and flaxseed screenings in carloads from Minneapolis and St. Paul, Minn., to Galveston, Tex., and other gulf ports. Opinion by Commissioner Meyer:

Certain respondents, by cancellation of the export rate of 16½ cents per 100 lbs. on flaxseed products from Minneapolis and St. Paul to Galveston and other gulf ports, attempted to withdraw from participation in this traffic. The commission decided that 16½ cents is an unreasonably low rate, but ordered the respondents to keep the route open at a rate not to exceed 22½ cents per 100 lbs. (27 I. C. C., 246.)

Macon, Ga., Discriminated Against.

Freight Bureau of Chamber of Commerce of Macon, Ga., v. Cincinnati, New Orleans & Texas Pacific et al. Opinion by Commissioner Meyer:

In this case the complainant alleges that in the transportation of leather in various forms from Cincinnati, Ohio, and various other points to Macon, Ga., Macon is discriminated against by the maintenance of differentials over Atlanta, Ga., of 27 cents per 100 lbs. in less than carloads and 13 cents in carloads. The commission decided that the present rates in effect to Macon are discriminatory and ordered that for the future rates be established based upon a differential of 3 cents over Atlanta on is rated when no commodity rates are in effect. (27 I. C. C., less-than-carload shipments and 2 cents on carload shipments, which are the differentials above Atlanta on second class in less than carloads and fourth class in carloads under which leather 263.)

Shipment Misrouted.

Lathrop Lumber Company v. Alabama Great Southern et al Opinion by the commission:

A carload of lumber was forwarded by the initial carrier from Fleming, Ala., to Huntsville, Ala., via an interstate route over which the rate was higher than via an intrastate route. The commission decided that the shipment was misrouted, and that complainant is entitled to reparation on basis of rate via the intrastate route. (27 I. C. C., 250.)

Chicago-Duluth Grain Rates.

In re investigation and suspension of the Chicago-Duluth Grain Rates. Opinion by Chairman Clark.

The suspended tariffs were filed pursuant to the findings in *Superior Commercial Club of Superior, Wis., v. G. N. Ry. Co.,* 24 I. C. C., 96, mentioned in the *Railway Age Gazette* of June 28, 1912, page 1622, and supplemental reports in same case, 25 I. C. C., 342, mentioned in the *Railway Age Gazette* of January 3, 1913, page 33. The commission decided that the previous findings should be adhered to and the order of suspension was vacated. The new adjustment will result in direct rates to Milwaukee for reconsignment to the East one cent per 100 lbs. higher than upon shipments moving through Minneapolis. (27 I. C. C., 216.)

Containers and Classification Rules.

Sea Gull Specialty Company. v. Baltimore Steam Packet Company et al. Opinion by Commissioner Meyer:

The complainant attacks the charge of 20 per cent. above third-class rates on shipments of baking powder in a fiber board container which the defendants allege does not comply with the provisions of classification rules. Refund is asked of charges in excess of third class and the amendment of rules so as to include complainant's container without penalty. The commission found that rule 4 (c) of southern classification No. 38 did not authorize the assessment of a 20 per cent. penalty in this particular instance.

The requirement in rule 9 (a) of southern classification No. 39 that metal bands should encircle the ends of Sea Gull boxes is unjust, unreasonable, and discriminatory. Complainant's box should be accepted without penalty.

"It is not just or fair to the shipping public to promulgate as a basis for determining rates a classification the terms of which are indefinite or impracticable of application, either in whole or in part."—*Pacific Coast Biscuit Co. v. S. P. & S. Ry. Co.,* 20 I. C. C., 546.

The duty should be placed upon carriers' agents to notify shippers whenever their containers do not comply with specifications laid down in classification rules. This responsibility should rest upon the initial carrier. Reparation was awarded. (27 I. C. C., 267.)

Milling-in-Transit Privileges at Decatur, Ill.

William H. Suffern Grain Company v. Illinois Central et al. Opinion by Commissioner McChord:

The commission decided that the refusal of the defendants to grant an elevation allowance on grain at Decatur, Ill., while such allowance is made at Cairo, Ill., was not unjustly discriminatory.

Decatur now has transit privilege under which it reaches a large portion of Mississippi valley territory at rates not higher than the combination on Cairo. Defendants proposed to extend this privilege via Illinois Central and connections to all points in Mississippi valley and the Southeast, and to accord to Decatur whatever Cairo has in respect of transit on through rates to Louisiana. When this is done, the complaint will be dismissed. (27 I. C. C., 192.)

Proportional Rates on Grain Products to Texas.

In re investigation and suspension of advances in rates by carriers for the transportation of grain products from southern Illinois points to points in Texas. Opinion by Commissioner Meyer:

The respondents attempted to cancel the proportional rates on grain and grain products from certain interior milling points in southern Illinois via St. Louis, Kansas City and other river crossings to various groups in Texas. The commission decided that the carriers should free these Illinois millers of the threatened disadvantage and remove the inconsistencies prevailing in the flat rates. Such relief may be by way of a milling-in-transit privilege specifically described in the tariffs at a charge not to exceed one-half cent per 100 lbs., or otherwise, as the carriers may elect. (27 I. C. C., 282.)

Boat Lines and Connecting Railways.

Truckers Transfer Company v. Charleston & Western Carolina. Opinion by Commissioner Meyer:

The complainant, a boat line, seeks the establishment of through routes and joint rates from certain river landings near Port Royal, S. C., and asks that it be made a connecting carrier upon the same basis as its competitor, the Beaufort Transportation Company. The commission held that as interstate commerce was not subject to state law, it would not fall within the prohibition of a charter granted by a state legislature. Incorporation is not a condition precedent to the right to be a common carrier, so far as interstate transportation is concerned.

The question of establishing joint rates or declining to do so rests in the discretion of the commission.

When boat lines have met all reasonable requirements of connecting railways with respect to security for freight charges, adequacy of service, efficiency of management, and any other guaranty which may justly and lawfully be required, they should be permitted to establish through routes and publish joint rates with their connecting railways.

The record does not show that complainant is capable financially and physically of assuming the obligations which through routes and joint rates would impose upon it. The complaint was dismissed. (27 I. C. C., 275.)

Pig Iron Rates Not Increased.

In re investigation and suspension of advances in rates by carriers for the transportation of pig iron in carloads from Buena Vista, Va., and other points to Philadelphia, Pa., and other destinations. Opinion by Commissioner McChord:

The commission decided that the proposed advances in the rates on pig iron, ranging from 10 cents to 45 cents per ton from producing points in Virginia to points in Pennsylvania and New Jersey were not shown to be reasonable and ordered the suspended tariffs withdrawn. (27 I. C. C., 343.)

Wharfage Practices Discriminatory.

In re discriminations in the use of wharfage facilities at Pensacola, Fla. Opinion by Commissioner Marble:

The Louisville & Nashville has wharfage facilities, including docks and spur tracks at Pensacola, Fla., which it claims are private facilities. Complaints were made against certain practices of the railroad in the administration of these facilities. The railroad admits that it affords ship-side delivery at these wharves on domestic traffic to or from non-competitive points, as well as on export and import traffic, while refusing such delivery in the case of shipments to or from points which are reached by it or its connections. It admits that it has refused to deliver shipments at the warehouse of a certain steamship company, while making delivery on these so-called private facilities to other consignees. It admits also that when it has application for more berth room than it can provide, it gives a preference in berthing to vessels consigned to the Gulf Transit Company, which is owned by it. In support of its contention that the wharf facilities are private, the railroad refers to the decision of the Supreme Court, *L. & N. R. R. Co. v. West Coast Naval Stores Co.*, 198 *U. S.* 483. That case was decided in 1905, and the commission found that since then the interstate commerce act had been amended so as to bring docks within its jurisdiction. The commission decided that the practice of refusing to deliver at ship side to vessels other than those belonging to or consigned to the Gulf Transit Company, or to receive at ship side from such vessels, property transported, or to be transported in commerce, subject to the act to regulate commerce, while delivering like property at ship side to, and receiving like property at ship side from vessels consigned to or belonging to the Gulf Transit Company, is unreasonable and unduly discriminatory. The refusal of the railroad to make deliveries of carload freight transported, or to be transported in commerce, subject to the act to regulate commerce, consigned to or in care of the Pensacola, St. Andrews & Gulf Steamship Company, at the Jefferson street wharf, while affording such delivery to Avery & Company, or any other person or corporation, is unreasonable and unjustly discriminatory. The practice of the railroad of discriminating in favor of the Gulf Transit Company in the berthing of vessels, is also unreasonable and discriminatory. An order was entered, forbidding the continuation of these practices. (27 I. C. C., 252.)

STATE COMMISSIONS.

The Public Service Commission of Massachusetts, provided for by the new law, which is noticed on another page of this paper, consists of the five persons named below, the governor having appointed the two new members on June 25: Frederick J. McLeod, of Cambridge, five years; George W. Anderson, of Boston, four years; George P. Lawrence, of North Adams, three years; Clinton White, of Melrose, two years; George W. Bishop, of Newton, one year. McLeod, White and Bishop are the members of the railroad commission, which goes out of existence after a life of 44 years.

COURT NEWS.

The Supreme Court of Illinois has handed down a decision holding that the extension of the charter of a railroad corporation does not require the corporation to again pay the original incorporation fee.

A decision of the Court of Claims declaring illegal certain collections made by the government from the Chicago & Alton for transportation of mails—illegal because of a wrong method of ascertaining average daily weight—is reported in another column of this issue.

The Court of Errors and Appeals on June 18 sustained the order of the Public Utility Commissioners requiring the railroads terminating in Jersey City, Hoboken and Camden to establish commutation fares, and not require passengers to buy tickets to New York or Philadelphia.

The decision of the Supreme Court of the United States in the Minnesota rate cases was reported last week, page 1318. An abstract of that part of the decision dealing with the question of valuation of railway properties for purposes of rate making is given in another column of this issue.

Judge Remster, of the Indiana Circuit Court, has rendered a decision which overrules demurrers of the Lake Erie & Western and the Cincinnati, Hamilton & Dayton, and holds that the Indiana law requiring the installation of automatic block signals is valid. The law as first passed was declared unconstitutional by the Supreme Court, because of uncertainty in its terms, and the railways contended that the same objection applied to recent amendments.

The Public Service Commission of Ohio has won its suit in the Supreme Court of that state, to compel compliance by the Baltimore & Ohio, with an order of the commission, requiring the company to load milk into the cars at all stations where agents are maintained. In this decision the Supreme Court sustains the action of the lower courts in refusing to enjoin the enforcement of the commission's order to abolish the rule which compels shippers to load the milk themselves.

The Supreme Court of the United States on Monday of this week, in the suit of the Missouri Pacific against Tucker, involving rates for the transportation of oil, decided in favor of the railroad, holding that damages awarded by the lower court were excessive. The law of Kansas fixing a minimum rate for the transportation of oil is declared unconstitutional because of the severe penalties provided for violation of the law. The railroad would have been unable to test its validity.

Adams Express Subject to I. C. Law.

The United States Supreme Court, in an opinion by Justice Holmes, deciding a case against the Adams Express Company, in Ohio, holds that the company was rightfully indicted for a violation of the interstate commerce law, requiring exact compliance with the tariff for the transportation of parcels. The decision reverses that of the District Court, which allowed the indictment to be quashed on the ground that the company is not a corporation, but is only a joint stock association. It has been notorious for many years, says the court, that some of the great express companies are organized as joint stock associations [and they have evaded certain responsibilities because of this fact] but, says Justice Holmes, the amendment of the interstate commerce law, in 1910, putting express carriers under the regulations of the law, could hardly have had any other purpose than to bring these joint stock associations under the act. Moreover, the Adams Express Company, in filing tariffs as required by the law, seems to have accepted the plain, ordinary meaning of the statute. If the statute imposes on express carriers the duty of filing tariffs, it is reasonable to suppose that the same law intended to impose upon them the penalty prescribed where the law is not obeyed. In the interstate commerce law, originally, there was doubt, in connection with the wording of Section 10, whether corporations were indictable or not, but this defect was corrected by the law of 1903. The interstate commerce law is constitutional as regards corporations, and no reason is suggested why Congress has not equal power over partnerships, including power to charge the partnership assets with a liability; and to personify the company, so far as to collect a tax, by proceeding against it by the company name. Under the laws of New York

a judgment against a joint stock company binds only the joint property. These express companies have had a semi-corporate standing in the popular mind, and the action of Congress was natural and to be expected.

Interstate Commerce Law Not Applicable to Street Railroads.

The decision of the Supreme Court of the United States holding that the street railroad of the Omaha & Council Bluffs Company between the two cities named, is not subject to the interstate commerce law, was reported in the *Railway Age Gazette* of June 13, pages 1304 and 1336. The full text of the opinion, which is by Justice Lamar, shows that the decision was based on the conclusion that the interstate commerce law, as passed by Congress in 1887, did not apply to street railroads. Congress did not intend that the word "railroad" should include such lines. Senator Cullom, in the debate on the passage of the interstate commerce law, said expressly that it did not apply to street railways in cities. This fact was brought up in the lower court, but the Supreme Court, agreeing with the Commerce Court, decides that the meaning of the statute cannot be determined from statements used in debates. It must be interpreted by its own terms. On this basis the conclusion is that Congress did not mean to apply the term "railroad" to street railroads. In 1887 the word "railroad" had no fixed, accurate meaning. The appellants cited decisions from twelve states holding that in a statute the word does not mean street railroads, but the other side cited decisions to the contrary from an equal number of states. There is a similar disagreement in the federal courts. The Commerce Court and the Circuit Court took opposite views, and the members of the Interstate Commerce Commission were divided on the subject.

But while the authorities differ on many points, they all agree that the meaning of the word is to be determined by the construction of the statute as a whole. The street railways crossing a state line are, indeed, engaged in interstate commerce, but not the commerce which Congress had in mind when legislating in 1887. Street railways carry passengers from street to street, and from ward to ward, from city to suburbs, etc.; but the Act refers to railroads which are required to post schedules and tariffs, not at street corners, but in "every station," etc. The law requires railroads to make joint rates and provide facilities for interchange of traffic. Every provision of the statute is applicable to railroads, but only a few to street railroads. The evils which the law was intended to cure did not exist on street railroads.

The rise of interurban railroads since 1887 is considered, but the road in question cannot be treated as an interurban. Its line is on private property to some extent, but to how great an extent does not appear.

In amending the interstate commerce law in June, 1910, Congress took notice of street railroads by providing that the commission should not establish any through route between street electric passenger railways, not carrying freight, and railroads of a different character. But this provision was inserted out of abundant caution. This law was passed after the order made by the commission in the Council Bluffs case; it cannot be given a retrospective operation. There is nothing to show that Congress expected to ratify the action of the commission, and it cannot be assumed that the amendment was intended to confer a jurisdiction which had not been originally granted.

The decision reverses the Commerce Court and makes the decree of the Circuit judges permanent.

Decision in the International Coal Mining Suit.

The Supreme Court of the United States, in the case of the Pennsylvania Railroad, plaintiff in error, against the International Coal Mining Company, held that the coal mining company, claiming damages because secret rebates were given to another company, must prove that it suffered some loss or injury. The court below had sustained a verdict of $12,013 against the road, but the Supreme Court has ordered a new trial. The decision is by Justice Lamar.

The International Company shipped large quantities of coal over the Pennsylvania during the seven years ending April 1, 1901. In 1904 it sued for $37,268, the difference between what it had paid and what it would have paid if it had got the same rebates as rival shippers. Prior to 1899, the International Company itself had received rebates and made a claim because it did not receive so large sums as did the rivals, but these claims were thrown out of court at an early stage of the proceedings. After 1899 the International paid tariff rates, while other companies received rebates of 5, 10, 15, 25 and 35 cents a ton, the differences being caused by the different rates in force at previous dates, the rebates being in the nature of adjustments to meet the conditions of long-time contracts. The road, on April 1, 1899, increased tariff rates and discontinued the payment of rebates, except that thereafter the varying rebates above noted were made to save shippers against loss on their contracts. The road claimed that, as these adjustments were in the nature of rate-making, and the rightfulness of the freight bills would be a question for the commission instead of the courts; but the court said that as the whole of the doings of the company in this matter were illegal, the jurisdiction of the court could not be defeated; the statute required the road to abide absolutely by its tariff.

The suit was brought under that section of the law which makes a carrier liable to any person injured; but the coal company did not allege specific damage or injury. A year before the passage of the Interstate Commerce Law a bill was passed, in the Senate, making carriers liable to shippers who had been discriminated against, and stipulating that the amount of the liability should be measured by the difference between the high rate charged and the lowest rate charged to others, but this provision did not get into the law, as it was finally passed.

The court finds very few decisions or authorities which treat of the elements and the measure of damages in cases of this kind, and therefore goes into a long discussion to determine the question on general principles. A number of illustrations are set forth by the court, for example:

If plaintiff and one of the favored companies had both shipped coal to the same market on the same day, the rebate on contract coal may have given an advantage which may have prevented the plaintiff from selling, may have directly caused it expense, or may have diminished or totally destroyed its profits. The plaintiff, under the present statute in any such case being then entitled to recover the full damages sustained;—

But the plaintiff may have sold at the usual profit all or a part of its 40,000 tons at the regular market price, the purchaser, on his own account, paying freight to the point of delivery. In that event not the shipper but the purchaser, who paid the freight, would have been the person injured, if any damage resulted from giving rebates. To say that seller and buyer, shipper and consignee, could both recover would mean that damages had been awarded to two where only one had suffered;—

Or, to take another example—a favored dealer may have shipped 10,000 tons of coal to the open New York market, receiving thereon a rebate of 35 cents a ton, or $3,500. The plaintiff at the same time may have shipped 20,000 tons and sold the same at the regular market price. Under the rule contended for it would then be entitled to 35 cents a ton on 20,000 tons, or $7,000 as damages. Such a verdict, instead of compensating it for losses sustained, would have given to the plaintiff a profit on the carrier's crime in paying a rebate of $3,500 and would have made it an advantage to it instead of an injury for the carrier to violate the law.

It is suggested that the plaintiff should only recover a rebate on 10,000 tons, or on the same weight upon which the carrier had allowed a drawback to the competitor. But, while less drastic, this is still an arbitrary measure and ignores the fact that the same anomalous result would follow if there had been, say, ten dealers, each shipping 10,000 tons on the same day. For each of the ten would have been as much entitled as plaintiff to recover $3,500 on their several shipments of 10,000 tons, and the ten verdicts would aggregate $35,000, because of the payment of $3,500 to the favored shipper.

It was further claimed that an injured shipper could recover if rebates had been habitually given, so as to establish a practice of discrimination. But, says the court, there would still be no adequate proof of the extent of damage; and to adopt the arbitrary basis proposed would create an endless chain of departures from the tariff and would extend the effect of the original crime. The law makes the lawbreaker pay a fine to the government, but this does not give a right of action for a private injury. Three decisions in somewhat similar cases are cited in support of the view that the right to recover is limited to the pecuniary loss suffered and proved. A new trial is ordered.

Railway Officers.

Executive, Financial and Legal Officers.

E. W. Beatty, general solicitor of the Canadian Pacific at Montreal, Que., will succeed A. R. Creelman as general counsel on July 1.

Alexander Robertson, whose appointment as assistant to the president of the Missouri Pacific System, with headquarters at St. Louis, Mo., has already been announced in these columns, was born at Albany, N. Y., in 1860, and began railway work in 1885 with the Fitchburg Railroad. He remained with that road until April, 1897, successively as brakeman, conductor, general yardmaster, station master and trainmaster. In November of that year he went to the Wabash, and until August, 1903, was consecutively general yardmaster, trainmaster and superintendent of the Middle division. He then became manager of operations of the Western Maryland and West Virginia Central and Pittsburgh, resigning in January, 1904, to become general manager of the Terminal Railroad Association of St. Louis. In November of the following year Mr. Robertson returned to the Western Maryland and West Virginia Central & Pittsburgh as general manager. In April, 1907, he was made vice-president and general manager of the Western Maryland, which absorbed the West Virginia Central & Pittsburgh, and in May, 1911, he was chosen president of that road, resigning January 1 of this year. His appointment as assistant to the president of the Missouri Pacific, as above noted, took effect June 9.

A. Robertson.

Charles R. Thompson, of the Missouri Pacific, has been appointed assistant to the first vice-president of the Texas & Pacific, with headquarters at New Orleans, La.

It is understood that E. N. Brown, president of the National Railways of Mexico, has tendered his resignation. The board of directors have not as yet taken action on this resignation.

Operating Officers.

John McCraw, acting superintendent of the Central Vermont at New London, Conn., has been appointed superintendent of the Southern division, with office at New London.

W. F. Berger, chief train despatcher of the San Antonio & Aransas Pass, has been appointed assistant superintendent, with headquarters at Yoakum, Tex., succeeding H. E. Jones, resigned.

B. B. Tolson, trainmaster of the Mobile & Ohio at Jackson, Tenn., has been appointed superintendent of the St. Louis division, with headquarters at Murphysboro, Ill., succeeding E. W. Moore, deceased.

S. A. Morrison, trainmaster of the Chicago & North Western at Chicago, has been appointed superintendent of the Wisconsin division, with headquarters at Chicago, succeeding F. O'Brien, who has been appointed superintendent of the St. Louis, Peoria & Northwestern. L. M. Davis, chief train despatcher, succeeds Mr. Morrison.

G. H. Trenary, division superintendent of the Chicago & Alton at Salem, Ill., has been appointed superintendent of the Chicago division, with headquarters at Danville, Ill., in place of E. N. Brown, resigned. J. O. Bell, superintendent of the Evansville division at Evansville, Ind., succeeds Mr. Trenary as superintendent of the Illinois division. F. R. Ghidden succeeds Mr. Bell. J. F. Epler, acting assistant to the general manager, has been appointed assistant to the general manager in charge of maintenance of equipment, with headquarters at Chicago.

George R. Sinnickson, who has been appointed superintendent of the Schuylkill division of the Pennsylvania Railroad, with office at Reading, Pa., was born on December 24, 1874, in Philadelphia, and graduated from Princeton University in the class of 1896. He entered the service of the Pennsylvania Railroad in 1897, as a chainman on the Delaware & Raritan Canal, and later was made rodman. In September, 1897, he was transferred in the same capacity to the Philadelphia & Erie and the Northern Central, and the following year became rodman on the Delaware & Raritan Canal. He returned to the Philadelphia & Erie in April, 1899, and the following month was made rodman on the Sunbury division. In 1900 he was appointed assistant supervisor on the Amboy division, and the following year was transferred to the New York division in the same capacity, becoming supervisor on the Tyrone division in March, 1903, and the following year he went to the Monongahela division. He also served as supervisor on the West Jersey & Seashore and the Philadelphia division, and in March, 1911, he was appointed division engineer of the Susquehanna and Western division. On January 15, 1913, he was made division engineer of the West Jersey & Seashore, which position he held at the time of his recent appointment as superintendent of the Schuylkill division of the Pennsylvania, as above noted.

G. R. Sinnickson.

Noel W. Smith, who has been appointed superintendent of the Middle division of the Pennsylvania Railroad, with office at Altoona, Pa., was born at Williamsport on December 25, 1869, and was educated in the public schools of his native town. He entered the service of the Pennsylvania as a student in telegraphy at Williamsport, and then until September, 1889, was clerk in the division freight agent's office at the same place. He left railway work in 1889, to enter Lehigh University, and after graduation from that university returned to the service of the Pennsylvania as a rodman on the Sunbury division in April, 1893. He was subsequently assistant supervisor on the Baltimore division of the Northern Central; Renovo and Williamsport divisions of the Erie division; Maryland division of the Philadelphia, Baltimore & Washington, and engaged on experimental track work for the chief engineer of maintenance of way at Harrisburg. In January, 1900, he was promoted to supervisor at Williamsport, and was then transferred in the same capacity, first to Middletown and then to Harrisburg on the Philadelphia division. In December, 1905, he was made supervisor in the office of the principal assistant engineer at Altoona, and in May of the following year was promoted to assistant to the principal as-

N. W. Smith.

sistant engineer at Altoona. In April, 1907, he was made division engineer of the Middle division, and on January 15, 1910, was appointed superintendent of the Central division of the P. B. & W., which position he held at the time of his recent appointment as superintendent of the Middle division of the Pennsylvania as above noted.

Traffic Officers.

L. K. Redman has been appointed general agent of the Chicago & Eastern Illinois at Terre Haute, Ind.

A. W. Davis has been appointed industrial commissioner of the Houston & Brazos Valley, with headquarters at Freeport, Tex.

R. P. Buckingham, soliciting agent of the Missouri, Kansas & Texas, at Houston, Tex., has been appointed traveling freight agent, with headquarters at Waco, Tex.

H. A. Fidler, formerly division freight agent of the Detroit, Toledo & Ironton, is now traffic manager of the Big Sandy & Kentucky River Railway, with headquarters at Ashland, Ky.

C. B. Foster, general passenger agent of the Canadian Pacific at Winnipeg, Man., has been appointed assistant traffic passenger manager of the Eastern Lines with headquarters at Montreal, Que.

W. E. Downing has been appointed general eastern agent of the Illinois Central, with office at New York, to succeed L. F. Klein, resigned to accept service with another company, effective July 1.

Robert Burns has been appointed traveling freight agent of the Sunset-Central lines of the Southern Pacific, with headquarters at Waco, Tex., succeeding C. W. Higgins, resigned to go to the Southern Pacific Steamship Lines at Galveston, Tex.

J. T. Burke, traveling freight agent of the Delaware & Hudson, with headquarters at Buffalo, N. Y., has been appointed traveling freight agent, with office at New York, succeeding T. J. Lynch, promoted. H. J. Sheffer, general southern freight agent at Philadelphia, Pa., succeeds Mr. Burke, and W. H. Chase succeeds Mr. Sheffer.

Frank H. Plaisted, assistant to the director of traffic of the Southern Pacific, has been appointed assistant director of traffic with headquarters at New York. He was born on June 9, 1866, at Cincinnati, Ohio, and was educated at Central High School, Kansas City, Mo. He began railway work on October 7, 1884, as a clerk on the Kansas City, Fort Scott & Gulf, now a part of the St. Louis & San Francisco. On March 20, 1889, he went to the Union Pacific at Salt Lake City, Utah, and was traveling freight agent of that road for nine years, from 1892; first at Salt Lake City, then at San Francisco, and from April, 1897, when the Oregon Short Line was segregated from the Union Pacific, again at Salt Lake City. From 1902 to October, 1905, he was district freight and passenger agent at Boise, Idaho, of the Oregon Short Line, and then was promoted to assistant general freight agent at Salt Lake City. On January 1, 1912, he was appointed assistant to director of traffic of the Union Pacific and the Southern Pacific systems. In consequence of the order of the Supreme Court, separating the Southern Pacific and the Union Pacific, he resigned on February 6, 1913, as assistant to director of traffic of the Union Pacific, remaining with the Southern Pacific, which position he held at the time of his recent appointment as assistant director of traffic of the same road as above noted.

Engineering and Rolling Stock Officers.

William Stiles has been appointed roadmaster of the Missouri, Kansas & Texas at Atoka, Okla.

William M. Mitchell has been appointed fuel supervisor of the Chicago Great Western, with office at Chicago.

Joseph Smith has been appointed roadmaster of the Second district of the Northern Pacific, with headquarters at Duluth, Minn.

C. J. Rist, formerly division engineer of the Erie at Huntington, Ind., has been appointed assistant engineer maintenance of way of the Pere Marquette, with office at Detroit, Mich.

F. L. Guy has been appointed division engineer of the Eastern division of the Atchison, Topeka & Santa Fe at Emporia, Kan., in place of M. C. Blanchard. H. J. Moore has been appointed division engineer of the Oklahoma division at Arkansas City, Kan., to succeed Mr. Guy. O. West has been appointed acting roadmaster of the Western division, with office at Dodge City, Kan., succeeding W. E. Bohl. E. B. Dehart has been appointed roadmaster of the Colorado division, with headquarters at Pueblo, Colo., in place of B. A. West.

Thomas Benjamin Kennedy, who has been appointed engineer of the Cumberland Valley, with headquarters at Chambersburg, Pa., was born on September 22, 1870, at Chambersburg. He graduated from Chambersburg Academy in 1887, and then took an engineering course at Lafayette College, and at Princeton University. He began railway work in October, 1890, as a rodman and instrument man on the Great Northern. He went to the Cumberland Valley in November, 1892, as a clerk in the auditor's office, and later was transferred to the superintendent's office. From February, 1894, to January of the following year he was draughtsman and instrument man in the maintenance of way department of the same road, and then was appointed assistant supervisor. In May, 1903, he was made supervisor of division B, and later was transferred in the same capacity to division A. He was appointed freight trainmaster in November, 1906, and two years later was made general trainmaster. In July, 1911, he was appointed assistant to engineer in the maintenance of way department, which position he held at the time of his recent appointment as engineer of the same road as above noted.

Arthur Besore Clark, who has been appointed assistant engineer of maintenance of way of the Pennsylvania Railroad, in charge of roadway and track, with office at Philadelphia, Pa., was born at Green Village, on October 1, 1867. He was educated at Mercersburg College, and in 1891, graduated from Lafayette College, with the degree of C.E. During his summer vacations in 1889 and 1890, he was a rodman on the Pennsylvania. After graduation he was rodman on the Philadelphia division, at Philadelphia, and in July, 1896, was promoted to assistant supervisor on the Altoona division, and later held the same position on the Pittsburgh division. In July, 1900, he became supervisor on the Baltimore division, Northern Central Railway, and one year later was transferred to the Pittsburgh division, at Pittsburgh. He was made assistant engineer of the Middle and Western division, Philadelphia & Erie, on December 15, 1905, and was subsequently transferred in the same capacity to the West Jersey & Seashore, and later to the Maryland division of the Philadelphia, Baltimore & Washington. On January 15, 1910, he was appointed principal assistant engineer of the same road, with office at Wilmington, Del., which position he held at the time of his recent appointment as assistant engineer of maintenance of way of the Pennsylvania, as above noted.

A. B. Clark.

The following supervisors on the Pennsylvania Railroad have been transferred: W. T. Hanly from the Pittsburgh division to the Middle division at Newport, Pa.; H. C. Bolenius from the Maryland division to the Pittsburgh division at Conemaugh; Robert Faries from the Trenton division to the Maryland division of the P. B. & W. at Washington, D. C.; E. O. Wood from the Sunbury division to the Trenton division at Trenton, N. J.; J. O. Hackenburg from the Baltimore division to the Pittsburgh division at East Liberty, Pa.; John Atlee from the Buffalo division to the Baltimore division of the P. B. & W. at Parkton, Md.; R. R. Nace from the Cresson division to the Buffalo division at Buffalo, N. Y.; M. W. Clement, su-

pervisor in the office of assistant to the general manager, to the Manhattan division at New York City; B. O. Hultgren, supervisor on the Monongahela division, to the office of assistant to the general manager at Broad Street Station, Philadelphia; M. de K. Smith, Jr., from the Bedford division to the Monongahela division at West Brownsville Junction, Pa.; J. C. Smith, from the Central division to the Bedford division at Bedford, Pa., and Frederick Evans, assistant supervisor on the Middle division, has been appointed supervisor on the Sunbury division of the Northern Central, at Sunbury, Pa.; F. D. Davis, assistant supervisor on the New York division, has been appointed supervisor on the Cresson division at Barnesboro, Pa.; E. C. Silvius, assistant supervisor of the Pittsburgh division, has been appointed supervisor on the Central division of the P. B. & W. at Media, Pa. The following assistant supervisors have also been transferred: E. C. Smith from the Conemaugh division to the Middle division at Huntingdon, Pa.; J. H. Cooper from the Tyrone division to the Conemaugh division at Blairsville; N. D. Vernon from the Maryland division of the P. B. & W. to the New York division at Jersey City, N. J.; J. D. Archibald from the Baltimore division to the Maryland division of the P. B. & W. at Chester, Pa.; W. T. Bevan, from the Monongahela division to the Baltimore division of the P. B. & W. at Baltimore, Md.; E. L. Koch from the Conemaugh division to the Pittsburgh division at East Liberty, Pa.; R. L. Kell from the West Jersey & Seashore to the Conemaugh division at Freeport, and the following transitmen in the office of the engineer maintenance of way, have been appointed assistant supervisors: G. L. Hoffman, of the Monongahela division at Dravosburg, Pa.; C. W. Leach, of the West Jersey & Seashore, at Millville, N. J., and W. G. McNees, of the Tyrone division, at Tyrone, Pa.

John H. Tinker, acting superintendent of motive power of the Chicago & Eastern Illinois, at Danville, Ill., has been appointed superintendent of motive power and machinery, with headquarters at Danville. He was born in August, 1864, at Altoona, Pa., and received a high school education at Altoona and began railway work in July, 1881, as machinist apprentice with the Pennsylvania Railroad. He was made vise shop foreman of the Meadows shops in June, 1896, and in December of the following year was appointed roundhouse foreman at Jersey City, N. J. He again returned to the Meadows shops in December, 1898, as erecting shop foreman, and in January, 1900, was promoted to master mechanic at South Amboy, N. J. He resigned the latter position in November, 1902, to go to the Baltimore & Ohio as master mechanic of the Chicago division, leaving in November, 1903, to become connected with the Model Gas Engine Works as machine foreman. In May, 1904, Mr. Tinker went to the Illinois Central as general foreman at Mounds, Ill., and in May, 1905, left that road to accept the position of assistant master mechanic of the Louisville & Nashville at South Louisville, Ky. Four months later he returned to the Illinois Central as master mechanic at Danville, Ill., and in February of this year he was appointed acting superintendent of motive power. He now becomes superintendent of motive power and machinery, as above noted.

J. H. Tinker.

Purchasing Officers.

J. H. Beggs, maintenance equipment accountant of the Chicago & Eastern Illinois, has been appointed purchasing agent, with headquarters at Chicago, succeeding T. J. Powell.

OBITUARY.

E. W. Moore, superintendent of the St. Louis division of the Mobile & Ohio, with headquarters at Murphysboro, Ill., died in the latter city on June 17. Mr. Moore was born in 1862 at Keokuk, Iowa, and began railway work in 1877 as brakeman on the Keokuk & Des Moines Valley. He was subsequently until October, 1890, brakeman and conductor on the Cairo & St. Louis and the Mobile & Ohio. From the latter date to August, 1902, he was trainmaster of the St. Louis division of the Mobile & Ohio, and was then made superintendent of that division.

Edwin Tracy Jones, auditor of revenue of the Southern Railway, with headquarters at Washington, D. C., died in the Garfield hospital in that city on June 16. He was born at Decatur, Ala., and was educated in the public schools of his native town. He began railway work at the age of 16, as a messenger on the Memphis & Charleston, now a part of the Southern, and then to 1885 held various clerical positions, including that of ticket agent. In 1885 he was in the local office of the same road at Memphis, Tenn., and subsequently was chief clerk and cashier of the Chesapeake & Ohio Southwestern at Memphis, returning to the service of the Memphis & Charleston in 1888, as assistant agent at Decatur, Ala. The following year he entered the auditor's office of the same road at Memphis, and then to 1895 was consecutively cashier of the Louisville, New Orleans & Texas, now a part of the Yazoo & Mississippi Valley, and agent of the Tennessee Midland, now a part of the Nashville, Chattanooga & St. Louis, at Memphis. From 1895 to 1898, he was with the Mallory Steamship Company at Galveston, Tex., and in October of the latter year, was made a clerk in the freight auditor's office of the Southern Railway. In June, 1901, he was appointed auditor of freight accounts, and since July, 1904, was auditor of revenue of the same road. Mr. Jones was in good part responsible for the unusually efficient organization of the Southern Railway auditor of revenue's office.

Propose Chinese Line.—It is understood that a party of engineers, Chinese and foreign, left Shanghai recently with northern Kiangsu as their objective. The visit is in connection with the projected railway from Hsuchowfu to Tsingkiangpu, and it is reported that their intention is to make the necessary purchases of land for the line if this can be done.

Railway Construction in India.—The Southern Shan States Railway is now open for traffic as far as Kywedatson, about 16 miles from Thazi. It will be open before long to Yinmabin, 22 miles; and it is hoped to get up to Kala by next year. Were the line pushed on to Kentung and the Chinese frontier it would mean another 300 miles beyond Taunggy; and the cost would be very heavy. A line, however, continued right through the Southern Shan States would open up a wonderfully rich country.

Baggage Subways in Paris.—There has recently been provided at the Gare du Nord in Paris, France, a subway to facilitate the transfer of baggage from cabs to departing trains. The barrows with baggage descend by seven elevators placed near the ticket offices, baggage registration bureaus and weighing machines, to a subway which passes under five tracks. The empty barrows are brought up by separate elevators, four in number, in the booking hall. The 15 elevators are worked by electricity and are capable of lifting a load of 2,000 lbs., including the weight of the barrow, a distance of 1 ft. 6 in. per second.

Pekin Kalgan Line, China.—The Pekin-Kalgan Railway continues to prove its value to the Chinese government as a profit-earning medium. It is the pioneer of railways built with Chinese capital and operated by Chinese engineers and that its business continues to increase, considering the heavy grades and great cost of negotiating the Nankou Pass, speaks volumes for the capacity of those who are in control. The unusually high gradients not only compel a heavy fuel consumption but also demand good train crews. The total distance now covered by the line is 141 miles. It was originally built more with a view of its strategic value than with the idea of developing commerce, but its effectiveness in opening up the rich grain producing area of the table-land has surprised even the most sanguine of its original advocates.

Equipment and Supplies.

LOCOMOTIVE BUILDING.

The Gulf, Texas & Western has ordered 1 ten-wheel locomotive from the Baldwin Locomotive Works.

The Birmingham & Southwestern has ordered 1 ten-wheel locomotive from the Baldwin Locomotive Works.

The New York Central Lines have ordered 1 Mallet locomotive from the American Locomotive Company.

The Haslam Lake Timber & Logging Company has ordered one locomotive from the Baldwin Locomotive Works.

The Detroit & Toledo Shore Line has ordered 3 consolidation locomotives from the Baldwin Locomotive Works.

The Boston & Albany has ordered 6 Pacific type locomotives and 14 mikado locomotives from the American Locomotive Company.

CAR BUILDING.

The Grand Rapids & Indiana is in the market for 85 flat cars and 60 gondola cars.

The Southern Railway has ordered 250 hopper cars from the Pressed Steel Car Company.

The Atlantic Coast Line has ordered 100 flat cars from the American Car & Foundry Company.

The Great Northern is said to have ordered 1,000 coal cars from the American Car & Foundry Company. This item has not been confirmed.

IRON AND STEEL.

General Conditions in Steel.—A large number of consumers are holding back orders in the belief that prices will be reduced in the near future. It is not probable, however, that there will be any general reduction in prices for several months, as the mills are in a strong position with a large number of orders on their books. If there is any price cutting it will most likely be on the part of the smaller independent companies. The mills are operating at full capacity and it is expected that the ingot production this month will establish a new high record. A reduction in the output of pig iron is looked for and this will be followed by a shrinkage in the production of steel later on. Many producers feel that the productions of steel in the last half of the year will show a shrinkage, compared with the first half.

A Railway in Iceland.—The Consul-General at Copenhagen reports that a railway six and one-half miles long is to be built around the harbor of Reikiavik, Iceland, the first railroad in that country.

Australian Railway Proposals.—A short time ago the Queensland Premier said he had not heard anything definite as to the proposal to link up New South Wales and Queensland railways, via Kyogle and Beaudesert, but there had been some talk of establishing connection between Kyogle and Killarney, via Acacia Creek. The government did not intend to consider any railway proposals this year, but when some of the railway problems now in hand were disposed of, it would be time enough to deal with interstate linking up.

Railways in Sumatra.—The Dutch Indies government now has in Sumatra a line known as the West Coast of Sumatra Railway, which is 152 miles in length, of 3 ft. 6 in. gage, and equipped with 65 locomotives, 74 passenger coaches, and 634 freight cars. This line serves only a very small portion of the west coast of the island, connecting the port of Padang with Fort de Kock, and having three short branches. The only other existing railway in Sumatra is the Deli Railway, a private line on the northeast coast in the rich tobacco-growing district of Deli. This railway radiates in several directions from the capital city of Medan, and comprises about 80 miles of 3 ft. 6 in. gage.

Supply Trade News.

The Isthmian Canal Commission will, until July 9, receive bids on miscellaneous supplies, including switch stands, tie plates, track bolts, track spikes, valves, etc. Circular No. 781.

Judge Snediker, on June 23, appointed Charles L. Harrison receiver and H. M. Estabrook co-receiver for the Barney & Smith Car Company, Dayton, Ohio. Mr. Estabrook is president of the company. The receivers were appointed on the application of Joseph Brothers & Co., Cincinnati, Ohio, creditors to the extent of $11,139. E. F. Platt, a stockholder of the Barney & Smith company gave out a statement that the company was perfectly solvent and that the trouble had been caused by the recent floods

C. A. Coffin has resigned his position as president of the General Electric Company, Schenectady, N. Y., and has been made chairman of the board of directors. Edwin Wilbur Rice, Jr., senior vice-president and a director of the company, has been made president, succeeding Mr. Coffin. Mr. Coffin was one of a group, who, in 1882, bought control of the American Electric Company, New Britain, Conn., which had been founded in 1880 by Professor Elihu Thomson. This company made arc-lighting apparatus under the Thomson-Houston patents. The plant was moved to Lynn, Mass., and the name of the company was changed to the Thomson-Houston Company. The company grew rapidly under the administration of Mr. Coffin. In 1892, the Thomson-Houston Company was consolidated with the Edison General Electric Company under the name of the General Electric Company, with Mr. Coffin as president. It was he who brought about the agreement between the Westinghouse Electric & Manufacturing Company, Pittsburgh, Pa., and the General Electric Company in regard to the exchange of licenses under their respective patents, by which a long struggle over patents was avoided and large sums of money saved. Mr. Coffin foresaw that a large amount of capital would be necessary for the growth and expansion of electrical undertakings and was largely responsible for the education of investors to a correct appreciation of the value of securities of electrical enterprises. For this reason the present development of electrical public utilities is largely due to the efforts of Mr. Coffin.

E. W. Rice, Jr., who has just been elected president of the General Electric Company, Schenectady, N. Y., as mentioned above, was born at La Crosse, Wis., May 6, 1862. After graduating from the Central High School of Philadelphia Mr. Rice became associated with Professor Thomson as assistant and confidant in the American Electric Company, New Britain. When this company was moved to Lynn in 1882, Mr. Rice went with it. In 1884 he was made superintendent and soon after technical director in charge of manufacturing. Shortly after the organization of the General Electric Company Mr. Rice was promoted to the position of chief engineer of that company. He was made third vice-president in 1896, having charge of the technical and manufacturing departments. In 1903 he was made a director and subsequently became senior vice-president of the company. Over one hundred patents have been issued in his name. Mr. Rice was instrumental in the development of high tension apparatus, the successful transmission of power at extra high voltages, and did much to improve the design of the rotary convertor and the revolving field generator, as well as electric traction equipment. Mr. Rice is a member of the American Institute

E. W. Rice, Jr.

of Electrical Engineers, the Institution of Civil Engineers, the Institution of Electrical Engineers of Great Britain, and a member of the Engineers' Club of New York. After the Paris exposition in 1900 he was created Chevalier of the Legion of Honor. In 1903 the degree of A. M. was conferred on him by Harvard University, and in 1906 he was given the degree of D.Sc. by Union College, Schenectady.

The Canadian General Electric Company, Ltd., which owns and controls as subsidiary companies the Canada Foundry Company, Ltd., and the Canadian Allis-Chalmers, has decided to consolidate the selling organizations of the two latter companies, dropping the name Canada Foundry Company, Ltd., and conducting the selling organizations of both companies under the name of Canadian Allis-Chalmers, Ltd. Hereafter all sales of electrical apparatus and supplies will be in the name of the Canada General Electric Company, Ltd., and all general engineering contracts and sales of mechanical appliances in the name of Canadian Allis-Chalmers, Ltd.

John L. Nicholson, who has been southern sales manager of the American Locomotive Equipment Company, has been elected director, vice-president and general sales manager of the Locomotive Arch Brick Company, with headquarters at 1201 Chamber of Commerce building, Chicago. Mr. Nicholson was connected with the Chicago & North Western for 13 years as fireman, engineer and road foreman of engines. He entered the employ of the American Locomotive Equipment Company in 1904, after that company had purchased the Wade-Nicholson Hall Arch, of which he was one of the inventors, and he has had a great deal of experience in the development of the brick arch to its present state of efficiency. When the American Arch Company was formed and took over the business of the American Locomotive Equipment Company, he was appointed southern sales manager, which position he held to May 1, this year.

TRADE PUBLICATIONS.

Trap Doors and Fixtures.—The O. M. Edwards Company, Syracuse, N. Y., has published catalog H, giving illustrations and descriptions of its various types of steel trap doors and fixtures for cars.

Pneumatic Tools.—The Chicago Pneumatic Tool Company, Chicago, has issued bulletin No. 127, describing its pneumatic drills, reamers, wood borers, flue rolling and packing machines, and grinders.

Fountain Drawing Pens.—The Keuffel & Esser Company, New York, has published an illustrated leaflet describing the Smith fountain drawing pen, which has just been patented and put upon the market.

Air Brake Hose.—The Sprague Electric Works of General Electric Company, New York, has published an illustrated booklet on its Sprague steel armored air brake hose. The illustrations show this hose fitted to cars.

Terminal Facilities.—The Bush Terminal Company, New York, has published an illustrated booklet entitled How to Reduce Overhead Expense, pointing out the advantages to be derived from the use of its terminal facilities.

Industrial Lighting.—The Cooper Hewitt Electric Company, Hoboken, N. J., has published an illustrated booklet entitled Industrial Lighting. This booklet deals with the theory and practice of the artificial illumination of factories, shops and works.

Locomotive Cranes.—The Brown Hoisting Machinery Company, Cleveland, Ohio, has published catalog No. 1 of Brownhoist locomotive cranes. The catalog is devoted largely to excellent photographs of these cranes in action but contains also some interesting descriptive matter.

Blue Printing Machinery.—The C. F. Pease Company, Chicago, has issued an illustrated catalogue entitled "Everything for Blue Printing," which describes and illustrates all its latest and most improved automatic machinery for blue printing work and various accessories used for this work.

Lubricators.—The Detroit Lubricator Company, Detroit, Mich., has published catalog No. 36L, of the Detroit bullseye locomotive lubricators and locomotive specialties. The bulletin includes dimension tables and valuable information on the care and cleaning of the lubricators.

Steam Couplers.—The Gold Car Heating & Lighting Company, New York, has published an illustrated folder, pointing out the advantages of Gold's Wedge Lock steam coupler, and a comparative diagram on a separate sheet, showing the action of the Gold steam couplers' oscillating gasket and the non-oscillating, soft gasket.

Locomotives.—The Baldwin Locomotive Works has issued in pamphlet form an illustrated article on the "Recent Development of the Locomotive," by George R. Henderson, consulting engineer of the Baldwin Locomotive Works, reprinted from the journal of the Franklin Institute; also an attractive illustrated booklet on gasolene industrial locomotives.

Mikado Locomotives.—The American Locomotive Company, New York, has devoted bulletin No. 1013 to its mikado locomotives, which are designed to combine increased train loads, sustained high speeds, and a high degree of economy in fuel consumption. The bulletin gives a table, showing the results of comparative service tests of mikado and consolidation locomotives, and another table showing the principal dimensions and specifications of mikado locomotives built and building by the company. Illustrations of 16 different mikado locomotives are also shown, together with train tonnage figures for each at different speeds and on different grades.

Swiss Railway Employees.—There are employed on Swiss railways 42,000 persons, 35,200 of whom are with the state lines and 6,800 on private roads. This does not include tramways or funiculars, the majority of which are owned by municipalities or Cantons.

High Price of Oil Fuel in Austria.—It is only a very short time ago that, at the instance of the petroleum producers of Galicia, the Austrian authorities agreed to have the locomotives on a considerable mileage equipped to burn oil. Now the price of oil has gone up so much that the Austrian government is preparing to change back to coal again on part of these engines.

Rosario-Mendoza Line, Argentina.—The financing of the first 175 miles of the line from Rosario to Mendoza has been arranged by the original holders of the concession with the Banco Frances del Rio de la Plata. The bank will issue stock and bonds to cover an estimated expenditure of $3,000,000. The cost of the entire line is calculated at about $25,000,000. The national congress has approved the construction of numerous branches from the line authorized by the original concession.

Electric Railway Construction in Switzerland.—Electric railway building has been active during the past few years, this being particularly noticeable in the Lugano district. The lines completed and put into operation in the Canton of Tessin within the past twelve months are: Locarno-Bignasco, 17 miles; Bellinzona-Mesocco, 16 miles; Biasca-Acquarossa, 9 miles; Capolago-Chiasso, 8 miles; Lugano-Ponte Tresa, 8 miles; Lugano-Tesserete, 5 miles; Lugano-Cardo-Dino, 5 miles.

New Railways for Sumatra.—In 1908 the surveys were made for two railway systems to be built by the Dutch Indies government, which together would extend from Telok Betoeng, at the extreme southern end of Sumatra, through the very middle of the island to Medan. These surveys have since been approved, and money allotted by the government to begin the work. Although these railways will actually form one continuous line, they are nominally divided, for construction purposes into two distinct systems, as follows: The South Sumatra Railway, extending from Telok Betoeng to Petanang, with a branch to Palembang, near the east coast; and another branch to Benkoelen, on the southwest coast. This system, with branches, will total 840 miles. It is to be of 3 ft. 6 in. gage, and the estimated cost of construction is $43,200,000, to be extended over a period of 21 years. In other words, about 40 miles will be built, and $2,050,000 expended each year on this system alone. The Middle Sumatra Railway will extend northward from Petanang, the north end of the South Sumatra system, to Medan.

Railway Construction.

ASHLEY, DREW & NORTHERN.—Regular service is now in operation between Crossett, Ark., and Ladelle, 33 miles, and between Ladelle and Monticello, 10 miles, there is irregular tram service. The plans call for building from Crossett, north via Whitlow, Fountain Hill and Monticello to Gillett, about 90 miles. (November 15, p. 936.)

CENTRAL OF MARYLAND.—This company has been granted permission to build from Keymar, Md., east to Union Bridge, about 10 miles. B. T. Scott, president. W. J. O'Brien, Jr., Calvert building, Baltimore, and C. R. Foutz, Westminster, are interested.

CHESAPEAKE & OHIO.—The Coal River district of the Huntington division has been extended from Helen, W. Va., to Sovereign, 5 miles.

CHICAGO, MILWAUKEE & ST. PAUL.—A new branch has been opened for business on the Columbia division, known as the Moses Lake line, from Tiffis, Wash., west to Neppel, 15 miles. On the Puget Sound lines the Beverly-Hanford extension has been opened for business, and the Montesano line has been opened for freight traffic from South Montesano to Montesano.

CHICAGO & NORTH WESTERN.—An officer writes that a contract has been given to Winston Brothers Company, Minneapolis, Minn., for the grading and bridge work on an eight-mile coal spur from Benld, Ill., south to Staunton, thence southwesterly into Madison county. The work is now under way.

COLORADO & SOUTHERN.—The former Denver & Eastonville line of the Northern division has been extended from Eastonville, Colo., to Falcon, 10 miles.

DALLAS, FAIRFIELD & GULF.—Incorporated in Texas with $105,000 capital and headquarters at Fairfield, to build from Dallas southeast via Ferris and Fairfield to Jewett, about 110 miles. The incorporators include: W. F. Storey, Fairfield; T. E. Alexander, Teague; W. J. Hall, Corsicana, and J. W. Wright, Ferris

DELAWARE, LACKAWANNA & WESTERN.—A contract has been given to C. W. Reynolds, New York, for double-tracking work on seven miles between Jamesville, N. Y., and Syracuse.

DULUTH & IRON RANGE.—The main line has been extended from Ely, Minn., northeast to Winton.

GREAT NORTHERN.—An officer writes regarding the reports that a new line is to be built in British Columbia, that the Great Northern has had negotiations under way for a joint line with the Kettle Valley from Hope, B. C., to Coquihalla Summit, but the negotiations have not been completed, and no contracts have been let for the work.

LEXINGTON & EASTERN.—See Louisville & Nashville.

LOUISVILLE & NASHVILLE.—According to press reports the Lexington & Eastern is locating a 10-mile branch from Mason, Ky., up Mace's creek on the Letcher-Perry border to tap extensive coal and timber lands. It is understood that construction work on the branch will be started at once.

MANSFIELD RAILWAY & TRANSPORTATION.—This company which operates a line from Mansfield, La., southwest to Hunters, 14 miles, is planning to build an extension, it is said, east to Naborton, about 12 miles.

MOTLEY COUNTY.—Incorporated in Texas with $100,000 capital and headquarters at Matador. The plans call for building from a point 3½ miles north of Roaring Springs, on the Quanah, Acme & Pacific, north through the counties of Motley, Hall and Childress, to Memphis, on the Fort Worth & Denver City. The incorporators include J. N. Gaines, J. E. Russell, T. E. Leckie, R. P. Moore and A. C. Traweek, all of Matador.

NATCHEZ, COLUMBIA & MOBILE.—This line has been extended to Tilton, Miss.

NEW YORK SUBWAYS.—The Dock Contractor Company, New York, submitted the lowest bid, $2,578,000, for the construction of section No. 4 of the Broadway-Lexington avenue rapid transit railroad in the borough of Manhattan. This section extends from a point about midway between Houston and Bleecker streets, northeast under Broadway and Union Square to a point about 390 feet north of the southerly building line of Fourteenth street. It will include half of the express station to be built in Union Square and there will also be a local station at Eighth street. The subway is to be a four-track line. The contractor will not be required to lay tracks, ties or ballast, or to do the interior work in stations. (May 29, p. 1205.)

PEORIA, CANTON & GALESBURG (Electric).—An officer writes that contracts will probably be let in July, to build the line from Peoria, Ill., west to Farmington, thence northwest to Galesburg, 52 miles. The line is to have maximum grades of 2 per cent. and 6 deg. curves. There will be one 850 ft. steel bridge, and another of 120 ft., also about 6,000 ft. of trestle work. Horace Clark, president, Peoria, and L. L. Summers & Co., engineers, Chicago. (June 6, p. 1245.)

SAN ANTONIO, UVALDE & GULF.—An officer writes that a grading contract has been given to Ward & Lee, Mathis, Texas, for work on the extension south from Pleasanton, via Mathis, to Corpus Christi. (May 9, p. 1053.)

VANCOUVER ISLAND HYDRO-ELECTRIC & TRAMWAY.—This company it is understood is planning to build an electric railway at Lady Smith, Vancouver Island, B. C., with an interurban extension to Nanaimo via Chemainus, Duncans and Nanoose. Montaque Yates, Victoria, B. C., is interested in the company.

VIRGINIA-CAROLINA.—This company has given a contract to the Callahan Construction Company, Knoxville, Tenn., to build 40 miles of railroad from Abingdon, Va. Arrangements are being made by the contractors to sublet the work. The plans call for building southeast through Ashe county, N. C., to Jefferson, thence southwest to Todd. (May 9, p. 1053.)

RAILWAY STRUCTURES.

CARLETON POINT, PRINCE EDWARD ISLAND.—Bids are wanted by L. K. Jones, assistant deputy minister and secretary, Department of Railways and Canals, at Ottawa, Ont., on July 2, 1913, for a car ferry terminal at Carleton Point.

CHRISTIE, ONT.—See Hornby.

DALLAS, TEX.—Stone & Webster announce the construction in the near future of an interurban terminal station in Dallas. The building will be nine stories high and, with its yard, will occupy an entire city block. The new terminal will cost $2,000,000, and will be used by all of the interurban lines running into Dallas.

FREEPORT, TEX.—The Houston & Brazos Valley Terminal Company has been organized with a capital stock of $300,000 to build railway terminals at Freeport. Directors, C. E. Schaff, president of the Missouri, Kansas & Texas; W. A. Webb, general manager of the Missouri, Kansas & Texas; Felix Jackson, Jas. A. Baker and F. R. Cobb.

HORNBY, ONT.—The Railway Commissioners of Canada have authorized the Canadian Pacific to build bridges on the Ontario division, London sub-division, as follows: One near Hornby; two near Christie, and one over Etobicoke river, near Summerville.

LOCKPORT, N. Y.—The New York Central & Hudson River expects to build in the near future a brick freight house and a team yard at Park avenue, at a cost of between $50,000 and $100,000. The building will be 400 ft. x 40 ft., one story high, except at the eastern end, where a second story for offices will be added.

MUSKOGEE, OKLA.—The Missouri, Oklahoma & Gulf has let a contract to Rooney & Culp for the foundation, and to the Central States Bridge Company for structural work, for its new shops to be built at this point. The main building will be 148 x 200 ft.; the car repair shed 46 x 180 ft.; the carpenter shop 32 x 38 ft.; and the store room 52 x 80 ft.

NONCONNAH, TENN.—It is announced that the Yazoo & Mississippi Valley will at once begin work on construction of two roundhouses in connection with plans that provide for the ultimate construction of car and machine shops at this point.

SUMMERVILLE, ONT.—See Hornby.

Railway Financial News.

Atchison, Topeka & Santa Fe.—The Kansas railroad commission has approved of the lease of the Dodge City & Cimarron Valley for 10 years, at an annual rental of $120,000. The Dodge City & Cimarron Valley runs from Dodge City, Kan., to Elkhart, Okla. (See Railroad Construction, September 27, 1912, page 599.)

Atlantic Northern & Southern.—A decree of sale of this property has been entered providing for the sale of the north end for $87,000 to J. A. McWaid, representing the bondholders, and of the south end for $98,000 to Ables & Taussig, preferred creditors.

Boston & Albany.—This company has applied to the New York Public Service Commission, Second district, for permission to issue $2,015,000 bonds.

Buffalo & Susquehanna.—The New York Supreme Court has authorized the receiver to issue $500,000 six months' receiver's certificates to provide for the $500,000 5 per cent. receiver's certificates matured June 1. Of these certificates, $105,000 6 per cent. certificates have been sold and £69,000 ($345,000) certificates have been discounted. The remaining $50,000, which may be issued either as sterling certificates or as interest bearing dollar certificates, have not as yet been sold.

Canadian Pacific.—The company has called for redemption on July 1 the £7,161,500 ($35,807,500) first mortgage 5 per cent. bonds which are due July 1, 1915. The company is to pay £102 ($510) for each £100 ($500) bond.

Chesapeake & Ohio.—See Kanawha & Michigan.

Delaware & Hudson.—This company has applied to the New York Public Service Commission, Second district, for permission to issue $5,000,000 first and refunding mortgage bonds.

El Paso & Southwestern.—The Arizona Corporation Commission has granted permission to the El Paso & Southwestern to consolidate with it the six roads which form the El Paso & Southwestern system.

Kanawha & Michigan.—The semi-annual dividend of 2½ per cent. and an extra dividend of 1 per cent. have been declared on the $9,000,000 stock, of which $8,054,500 is owned jointly by the Chesapeake & Ohio and the Lake Shore & Michigan Southern. The annual rate in 1912 was 5 per cent., and in June, 1911, the first dividend of 4 per cent. was declared.

Kansas City, Mexico & Orient.—In ruling on the application for a final decree of foreclosure sale, Judge Pollock has held that before this decree can be granted the bankruptcy proceedings of the International Construction Company and the Union Construction Company, which companies built the K. C. M. & O., must be disposed of.

Lake Shore & Michigan Southern.—See Kanawha & Michigan.

Lehigh Valley.—The *Railway* company has applied to the New York Public Service Commission, Second district, for permission to issue $717,000 debenture bonds to the *Railroad* company for improvements.

Mobile & Ohio.—The plan for the exchange of St. Louis & Cairo collateral 4 per cent. bonds for bonds of a new issue of $3,000,000 Mobile & Ohio St. Louis division 5 per cent. bonds of August 1, 1913, has become effective, a sufficient number of old bonds having been deposited with Lehman & Co., New York, and deposits of the remaining bonds are asked for.

New York Central & Hudson River.—The supreme court of New York has upheld the legality of the New York Central Lines equipment trust issue of 1913. The legality of this issue, which had been approved by the New York Public Service Commission and by the Michigan Railroad Commission, was made the subject of a suit by a minority stockholder on the ground that the agreement under which the equipment certificates were issued should be condemned as a violation of the Sherman law.

New York, New Haven & Hartford.—The stockholders' protective committee has named a sub-committee of five to confer with a sub-committee of directors. Thus far the stockholders' committee has received proxies for about 250,000 shares of stock.

See New York, Ontario & Western.

New York, Ontario & Western.—A dividend of 2 per cent. has been declared on the $58,113,982 common stock, payable August 14. No dividends were paid in 1912, but annual dividends of 2 per cent. were paid in 1911 and in previous years, including 1906. The New York, New Haven & Hartford owns $29,160,000 of the stock.

J. P. Morgan and Edward Milligan have been elected directors, succeeding J. P. Morgan, deceased, and L. C. Ledyard, resigned.

Omaha, Ralston & Papillion.—This interurban road, which runs for 18 miles out of Omaha, has been sold under foreclosure for $110,000 to William B. McKinley.

St. Louis & San Francisco.—The receivers are, it is understood, making arrangements with Judge Sanborn, at St. Paul, for the payment of the July interest on the St. Louis & San Francisco refunding mortgage 4 per cent. bonds. Up till Wednesday no action had been taken by the Interstate Commerce Commission in regard to any investigation of the St. Louis & San Francisco receivership.

St. Louis, Iron Mountain & Southern.—The temporary directors who were elected to comply with the Arkansas law that directors of a corporation filing a new mortgage must be residents of Arkansas, have resigned, and J. Gould, F. J. Shepard, James Speyer, J. G. Metcalf, E. L. Marston and E. T. Jeffries have been elected to fill the vacancies.

Union Pacific.—Judge Lovett, chairman of the board, in testifying before the lobby investigation committee of the United States Senate, said that the lawyer whom he was advised to employ if he wished to make the carrying out of the Union Pacific-Southern Pacific dissolution as easy as possible, and to avoid any adverse legislation, was Edward Lauterbach, of New York. Judge Lovett said that he had not been approached directly by Mr. Lauterbach, but a man had called him up on the telephone and made the above suggestion to him.

Railroad Construction in Cuba.—A recent presidential decree grants to the North Coast Railway a subsidy of $9,500 per mile of road to be built between Carbarien and Nuevitas, and also between Camaguay and Santa Cruz del Sur.

Swiss Railway Earnings.—The receipts of the Swiss State Railways for 1911 were as follows: Passenger traffic, $15,001,890; freight traffic, $21,263,988; other receipts, $1,458,926, a total of $37,724,804. Expenditures were $22,664,762, making a balance in favor of the government of $15,060,042.

Passenger Car Ventilation in Germany.—The rule as to windows in passenger cars in Germany has been that they must not be opened on both sides of the car without the consent of all occupying the compartment. Now on city and suburban trains in Berlin neither window in the front compartment of each car may be opened without such unanimous consent.

Motor Car Service in Bavaria.—In Bavaria the administration which operates the railways maintains also an automobile service on 53 routes permanently, and on 8 more during the summer, carrying passengers and mail and parcels. The service has been profitable, the expenses per motor car mile being 15 cents and the earnings nearly 20 cents, and the net for all the lines amounting to $88,000.

New Railway in Rhodesia.—The railway from Mazoe to Shamva, in Rhodesia, to connect the Shamva goldfield at Abercorn with Salisbury and the Rhodesia, Mashonaland and Beira Railway systems, has been completed and opened to traffic. The line is constructed on the standard South African 3-ft. 6-in. gage, and is about 50 miles in length. It is constructed with 60-lb. rails and steel sleepers. There are 24 plate girder bridges varying from 6 ft. to 20 ft. in span, and one of 75 ft. span, in addition to a lattice girder bridge of 100 ft. span. Over 90 culverts from 2 ft. to 4 ft. in diameter have been built. Stations have been provided at Concession Siding, Glendale, Mazoe River, Pimento Park, Kimberley Reefs and Shamva.
