WE GUARANTEE, that of this issue 10,850 copies were printed; that of those 10,850 copies, 9,869 copies were mailed or delivered by messenger to regular paid subscribers; 800 copies were distributed among members and guests of The Railway Signal Association and at the Coliseum; 131 copies were mailed to advertisers; and 50 copies were set aside for office use.

CONTENTS:

The attendance at both the morning and afternoon sessions of the association yesterday should be a source of much gratification to the officers and to the membership at large. Even though the morning session began at 9 o'clock, there has been no preceding opening session in the history of the association when so many members were in attendance, and at many times throughout the day many men were standing after all chairs were filled. The large attendance and the interest in the discussions forecast that the fourteenth annual convention will surpass all previous records for interest and value of the work done. The registration yesterday was 315, which is the largest for an opening day in the history of the association.

In marked contrast with its presentation last year, the report of Committee 10 on the Uniform System of Signaling, which has been under discussion for so many years, was unanimously adopted without discussion. This is the same report that met with such a favorable reception from the Signal Association last fall, and was referred to letter ballot at the Quebec meeting by unanimous vote, and also without discussion, and was passed by a vote of 574 to 10. The adoption of this report by both associations will now enable it to be referred to the American Railway Association, probably just in time to be taken into consideration in the revision of the standard code which that organization now has under way. The reports from Committee 10 on the other two subjects were offered merely as information. The one dealing with effects of treated ties on track circuits was interesting, the information having been taken from the experience of a large number of roads, all of which seem to have had such varied results that at this time there is not much upon which to base definite conclusions, although the committee did very well in this respect.

The suggestion made by Mr. Loree at the annual dinner of the American Railway Engineering Association one year ago that in view of the large proportion of the expenditures of the maintenance of way department devoted to labor, the association give more attention to the economics of labor, has borne its first fruit this year. Acting upon this suggestion the board of direction assigned this subject to three committees last spring. The first report embodying definite recommendations is that of the Track Committee, which made three recommendations regarding desirable agencies to obtain a better class of section foremen. Before starting upon this work the committee made an outline of the most essential subjects to be considered, this outline including subjects enough for several years' study. Judging from the very general response to the request for information by the sub-committee having the matter in charge and by the interest shown in the convention yesterday, the members and railway executives in general agree upon the importance of this subject. The fact that the cost of labor in the maintenance department is increasing indicates that the situation is becoming worse. It is frequently the case in associations of this kind for a desire to be shown to avoid reference to labor conditions, especially where any recommendations involve the question of an increase in wages. If an increase in wages is essential to the maintenance or increase of efficiency, it is just as much within the province of an association to recommend it as it is to make a recommendation regarding the selection of material. The subject of economics of labor has been neglected so long and is now such a pressing one that the association is to be congratulated for taking it up even at this late date, and it is to be hoped that the committees will be encouraged to go deeply into the subject and make definite recommendations, even though they may perhaps involve increases in wages or rearrangements of forces

Some of the rules for the organization and guidance of inspectors in the mill, shop and field, presented by the committee on Iron and Steel Structures, seem to be rather a general discussion of the subject of inspection than a series of definite rules for the guidance of an inspector familiar with his work. Many of the qualifications of an inspector outlined in the preamble would be equally desirable in any other line of business. While this information might be valuable to a man unfamiliar with the subject, it is hardly to be expected that such a man will be employed as an inspector without previous mill experience. In one place it is stated that the inspector should "study the operations of the plant and become familiar with the various processes of manufacture." To be qualified as an inspector, a man should have this knowledge of the processes of manufacture before being appointed. Some of the requirements in the rules seem to belong more properly in the specifications furnished to the inspector than in the rules outlined

for his guidance. The minority report calls attention to some of the defects in the present system of inspection which are common knowledge. May not many of these defects be due chiefly to the effects of severe competition? When a railway or other concern lets contracts for the inspection of material upon the basis of competitive bids, the service is pretty sure to deteriorate as the price of the work is reduced. Inspection in many ways is not now as efficient as a few years ago; but the same price is not being paid as in former years. The establishment of a railway inspection bureau by the railways themselves would not necessarily reduce the actual cost of inspection; and if the standard of inspection is to be raised the cost probably will also be increased no matter who does it. The objection that the present inspectors do not gain the advantage of personal contact with the heads of private bureaus is true only to the extent that the inspectors now come in contact with the department head devoting his entire time to one specialty instead of with the general heads.

In commenting upon the amount of study which railway men, and particularly the members of the rail committee, are giving to the rail situation, a prominent student of this subject said a few days ago that nearly all the attention is being given to the manufacture of the rails, which is under the control of the steel makers, and comparatively little organized attention is being paid to the protection of the rails in service, which is under the control of the railways themselves. There appears to be some foundation for this statement. The need for improvement in the manufacture of rails is one of the most pressing affecting railways at the present time. We do not desire to minimize in the least the necessity for the work to get better rails which has been done, or the value of the improvements which have resulted from this work. But, as we have stated before, it does not appear entirely reasonable for the railways to have to provide the funds or the investigators to teach the steel makers how to manufacture their product. Nor is it to be supposed that all the facts brought out in these investigations are new to the manufacturers who have devoted their entire attention to the making of rails for many years. There is no question that the quality of the steel going into the rails leaves much to be desired; but the same is true with regard to the quality of the roadbed and equipment. It is to the defects of the latter, the remedies for which are directly under the control of the railways, that it would seem advisable for the association to devote more attention. It is not commercially practicable to produce rails every one of which will be absolutely perfect, or to maintain the track or equipment in such condition that no broken rails will result. While it is true that almost without exception the rails which give rise to serious wrecks and loss of life and property, are seriously defective, many sound rails were broken last winter because of the unusual climatic conditions and defective equipment and roadbed. Even granting that little danger is due to broken rails of this class, there is some danger, and the financial loss due to the destruction of a large number of rails by a flat wheel is material. It would seem that some concerted study, perhaps by a joint committee of the railway mechanical and engineering associations, should be made of the effects of defective equipment in various degrees of development on the rail under different conditions of roadbed support, temperature, etc. There is also a need of definite information regarding the service which a rail has to withstand in view of the recent statements that the rail is being overloaded. The stresses actually present in the rail, the influences of varying standards of roadbed support, high speeds, heavy wheel loads, low temperatures, etc., are important. In other words, while we are trying to devote a large amount of attention to the study of the manufacture of steel rails it would also appear desirable to devote some attention to the improvement of service conditions, the remedies for which lie directly in the hands of railway officers.

STUDYING THE SCIENCE OF ORGANIZATION.

President Churchill, in his address at the opening of the Engineering Association convention yesterday, dwelt forcibly on the need for more scientific study and handling of engineering and maintenance of way problems, especially that of labor. In the discussion of one of the reports on Rules and Organization, Edwin F. Wendt quoted from the last report of the Block Signal and Train Board the board's statement that "on the large majority of American railroads excellence of administration is nullified by faulty organization, magnification of individual function to the detriment of team work, and by an almost entire absence of a definite system of broad training of subordinates for higher duties." Commenting on the foregoing, Mr. Wendt expressed the opinion that "the study of the principles which underlie organization would be a proper work for this association. I think," Mr. Wendt added, "that this committee should study what is called the 'science of organization.'"

The Block Signal Board, in the sentence quoted by Mr. Wendt, diagnosed the cause of some of the greatest shortcomings of railway operation in this country, and President Churchill and Mr. Wendt suggested the remedy for those shortcomings. Doubtless, Mr. Wendt meant the study he suggested to relate more especially to the improvements in organization needed to increase the efficiency of the engineering and maintenance of way departments; but the same remedy could be beneficially applied to all departments.

There are really two kinds of engineering—the engineering of materials and the engineering of men. The engineering of men includes the best practicable selection, training and supervision of all officers and employes from the top to the bottom; and from a purely financial standpoint it is a more important branch of railway engineering than the engineering of materials. There is plenty of discussion of the proper form of railway organization; but it really is more important to have an organization worked the best way it can be than it is to give it the best practicable form. It is not so important, after all, to whom the roadmaster reports as it is that whomever the roadmasters report to shall select and train them and supervise their work with the greatest practicable care, consideration, intelligence and thoroughness. There is plenty of "rawhiding" in the railway business, but there often is not enough done to get and develop the kind of subordinate officers and employes who will not have to be "rawhided."

The political history of the world shows that democracy is a better form of government than monarchy; but it also shows that some peoples have been very well-governed under monarchy and others very ill-governed under democracy. The same principle applies to industrial organization. The functioning of an organization is even more important than its structure, and study of the "science of organization" as applied to the railways must, if it is to be useful, get below the surface and find out why in many cases organizations of widely different forms fail equally to satisfactorily perform their function. We believe that such a study will show that one main trouble with railway operation in the United States is that the present organizations, whatever their form, usually do not make provision for adequate supervision, including under this head selection, training and direction of subordinate officers and employment of a sufficient number of such officers.

It is a circumstance fortunate and inspiring hope that two men so prominent in the association as the president and

Mr. Wendt have both directed the thoughts of the members along this channel.

PRESIDENT'S RECEPTION AND MR. McNAB'S ADDRESS.

The president and board of direction of the American Railway Engineering Association tendered a reception to the members, ladies and guests in the Gold room of the Congress hotel last night. Although this is the first year that a reception of this kind has been held, the attendance was gratifying to the committee in charge, particularly on account of the number of ladies who were present. It is expected that it may become an annual feature which will be as popular as the banquet and that the ladies may be induced to come to the annual meeting in increasingly large numbers.

President Churchill and the members of the board of direction began receiving the guests about 8 o'clock and as the crowd gathered, they were entertained by vocal and instrumental music. Kloer's orchestra, which has been furnishing music for the banquet for several years, was present, and Sybil Sammis McDermaid, a soprano of note in Chicago musical circles, sang a number of selections, among which was one Scotch air, rendered by request in honor of the speaker of the evening. A baritone solo, with orchestra accompaniment, was also a feature of this part of the entertainment.

The talk on the Panama Canal by William McNab, principal assistant engineer of the Grand Trunk, and past-president of the association, was presented in his usual happy style and was much appreciated. It was illustrated by a number of excellent stereopticon slides, through the courtesy of the government officials in Washington. Mr. McNab is familiar with conditions on the Isthmus as a result of his visits there, and having recently returned from a trip to the canal was able to give recent and authoritative facts concerning the work. His address was full of information of peculiar interest to engineers, although it was presented in such a manner as to hold the interested attention of all the ladies present.

By way of opening his discussion, he expressly disavowed any intention to mention politics, treaties or commerce, preferring to confine himself closely to the engineering features of the work. In his introductory remarks concerning the history of the project, he paid a high tribute to John F. Wallace and John F. Stevens, former chief engineers in charge of the construction, who did much to make possible the successful prosecution of the work under later administrations. Mr. Wallace was the first president of the association and is well known to many of the present members. Mr. McNab gave due credit to the administration of sanitary regulations on the Canal Zone, quoting several verses of the "Song of the Prickly Heat" to show how important these preliminary measures were to make that tropical region safe for the Americans who have gone there to work.

The construction features were divided into three heads, the excavation of Culebra cut, the building of the locks, and the construction of Gatun dam.

The pictures of the big cut made clear the importance of the 400 miles of railway for work trains which were required to remove the excavated material. Recent photographs of the locks served to give an impression of the magnitude of these structures and the work of building the dam which will impound the waters of the Chagres river to form an immense lake was well illustrated by a number of other views.

Mr. McNab, in closing his remarks, advised those who contemplate making a trip to the Canal Zone to go before the water is turned in, as the interesting features will practically all be covered up after that time, and visitors will find, instead of a great engineering project, only a tropical lake with abundant vegetation. He suggested, however, that if any of the members present were so delayed in reaching Panama as to miss the interesting sights there, they can return home by a new transcontinental route, which will be completed in the not very distant future, along which will be found scenery as interesting as any on this continent. By way of proof of this assertion, he had thrown on the screen a number of beautifully colored views of the Canadian Rockies along the new Pacific coast extension of the Grand Trunk. These views had never before been shown and were very much appreciated.

	Annual Dinner at 7:00 P. M.	

ANNUAL MEETING RAILWAY APPLIANCES ASSOCIATION.

At the annual meeting of the National Railway Appliances Association, held Tuesday morning at the Coliseum, there was a larger attendance than usual. President A. P. Van Schaick presided. In his annual report Mr. Van Schaick called attention to the noticeable increase in interest in the exhibits each year on the part of the railway men. He stated that next year the association might be compelled to also lease the new Wilson building, near the Coliseum, in order to provide additional exhibit space to meet the constantly increasing demand.

T. W. Snow, chairman of the nominating committee, reported the following selections for officers of the Association for the coming year:

President, T. R. Wyles, Detroit Graphite Co., Chicago.

Vice-President, N. M. Hench, Carnegie Steel Co., Pittsburgh.

Treasurer, John N. Reynolds, Railway Age Gazette, Chicago.

New members of the board of directors, for three years, J. Alexander Brown, Pocket List of Railroad Officials, New York, and E. H. Bell, Railroad Supply Co., Chicago; for one year, E. E. Hudson, Thomas Edison, Inc., Orange, New Jersey.

Treasurer Reynolds reported that at the end of the fiscal year, April 30, 1912, the Association's assets amounted to $13,225.37, with no liabilities.

1,574 INVENTORS WANT MR. MELLEN'S $10,000.

The $10,000 reward for a successful automatic train stop offered by President Mellen of the New York, New Haven & Hartford a short time ago brought replies from 1,574 inventors. Each applicant was sent a printed list of the conditions which the devices are required to meet. Over 500 replies were received to this circular, and of those who took this second step in the matter, over 95 per cent failed to comply with the very first condition, let alone the other 17.

Altogether there were 1,480 holders of patents among those who sought the reward. They were from all walks and conditions of life and from all grades of intelligence, experience and education—and all grades of a lack of it. Out of the whole number, two devices have been selected for testing, and experimental installations will be made in the near future.

Four replies came from inmates of insane asylums; four

from men serving time in states' prisons; one from a monastery, and one from a man who said he had received a revelation from Heaven in which it was explained to him that anything he took up would be successful. The last-named desired to get a trial of a friend's device, and assured the New Haven that if the said friend secured the $10,000 he only expected $1,000 as commission for the use of his revelation.

Replies came from Panama, Porto Rico, Jamaica, Belgium, France, Ireland, Hawaiian Islands, England, Scotland, Wales, Germany and Denmark, and several other countries.

One inventor's scheme would, in his words, "constitute no source of danger to the passengers, but would probably kill the engineer and fireman. "However," he continued, "since it is to be used on the New Haven, it won't make any difference." Another scheme provided a heavy spring equipped with a hook, which would rise in the center of the track as soon as the train passed. Any following train trying to enter the occupied block would be stopped by the hook firmly grasping the nearest axle and holding the train.

The letter setting forth the 18 conditions to be complied with was answered by one man as follows: "I accept your offer of the $10,000. Please send a check." Another inventor said, "Send me the $10,000, and pay me a retainer's fee and expeness, and I will come down and design you an automatic stop."

The time for filing applications expires on July 1, 1913, and no devices received after that date will be given consideration in connection with the $10,000 reward.

NORFOLK & WESTERN LETS CONTRACTS FOR DOUBLE TRACKING.

The Norfolk & Western has let contracts for double tracking 61 miles of line on its eastern section and for the masonry work on a new double track bridge, to replace the high bridge over the Appomattox river.

BALTIMORE & OHIO ANNUAL DINNER.

The officers of the Baltimore & Ohio in attendance upon the convention will have their annual dinner this noon. This road has maintained a very creditable record for a number of years as regards the large number of men attending the convention, and their dinner in connection with the convention has been an annual event for some years.

CONFERENCE REGARDING DENVER UNION STATION.

A conference of officers of the railways entering Denver, Colo., regarding the matter of the construction of a new union station at that city was held in Chicago yesterday. Among those attending the conference were D. Miller, president of the Burlington; H. U. Mudge, president of the Rock Island Lines; A. L. Mohler, president of the Union Pacific; A. D. Parker, vice-president of the Colorado & Southern; W. B. Storey, Jr., vice-president of the Santa Fe, and E. L. Brown, vice-president of the Denver & Rio Grande.

W. S. DAWLEY TO RETURN TO UNITED STATES.

F. W. Hawks, formerly assistant chief engineer of the Unnan-Fur-Szech-Uan Railway, in Unnan-Fur province, in Southern China, is attending the convention.

Mr. Hawks reports that W. S. Dawley, who is now chief engineer of the Unnan-Fur-Szech-Uan Railway, and who formerly was chief engineer of the Chicago & Eastern Illinois, expects to return to the United States next summer, leaving China in June.

Mr. Dawley, it will be recalled, was treasurer of the Engineering Association for several years. Prior to going to China he was with the Evansville & Terre Haute and before that with the Virginian Railway.

REFERRED TO ARRANGEMENTS COMMITTEE.

One of the incidents which occasionally relieve the strain of a serious discussion was precipitated by C. E. Lindsay, division engineer of the New York Central & Hudson River, during the discussion on the Iron and Steel Structures report. Paragraph 34 of the "Instructions for the Inspection of the Fabrication of Steel Bridges" read, "Have important members so loaded as to be headed in the right direction upon arrival at the site of the work." Mr. Lindsay suggested after the reading of this paragraph that it be referred to the Committee on Arrangements.

NEW FIRM OF CONSULTING ENGINEERS.

C. P. Howard, locating engineer of the Canadian Pacific, and S. S. Roberts, division engineer of construction, Illinois Central, have organized a new firm of civil and consulting engineers, to be known as Howard & Roberts. Both men have had extensive experience in railroad location and construction and expect to specialize in railway surveys, locations, re-surveys, grade revision and terminal developments. The company has offices at room 1662, Transportation building, Chicago.

MEMBERSHIP OF AMERICAN RAILWAY ENGINEERING ASSOCIATION.

The secretary's report showed that the total membership of the association on December 31, 1912, was 1,066, as compared with 1,004 on December 31, 1911. During 1912 there were 5 deaths of members, 12 withdrawals and 23 were dropped for non-payment of dues, while there were 102 additions.

The following table shows the geographical distribution of the membership:

United States	925	Peru	2
Dominion of Canada	91	Philippine Islands	2
Japan	8	Australia	1
China	7	Bolivia	1
Mexico	6	Brazil	1
Cuba	5	Korea	1
Central America	4	Panama	1
New Zealand	4	Porto Rico	1
Argentine Republic	2	Russia	1
Great Britain	2	Uruguay	1
Total			1,066

NEW WORK FOR THE QUEEN & CRESCENT.

Announcement has been made that the Cincinnati, New Orleans & Texas Pacific will build eight new tracks and rearrange its present tracks in the McLean avenue yard at Cincinnati.

B. M. McDade, manager railroad department Detroit White Lead Works, Detroit, Mich., which is attending the convention, announces the appointment of William B. Wise as manager Eastern district at New York.

Proceedings.

The first session of the fourteenth annual convention of the American Railway Engineering Association was called to order at 9:30 a. m. on Tuesday, March 18, in the Florentine room of the Congress Hotel, by the president, Chas. S. Churchill, chief engineer, Norfolk & Western, Roanoke, Va.

The minutes of the last convention were approved as printed.

PRESIDENT'S ADDRESS.

At the last annual convention our membership aggregated 1,004. During the past year there has been an increase of 62, making a total of 1,066. The number of printed pages issued during the year was as follows:

In Bulletins		1,542 pages
In Proceedings		1,364 pages
In Manual	136	
Program, and	56	
Miscellaneous	128	320 pages
Total		3,226 pages
The aggregate to date by this Association is therefore		30,366 pages

CHARLES S. CHURCHILL, President.

EDWIN F. WENDT, First Vice-President.

The various methods reported upon at the last convention for increasing revenues, especially those procurable by economies, have been carried out with the result that on January 1, 1913, our cash on hand was $3,183.11 in excess of what it was on January 1, 1912. The secretary estimates that the proceedings of this convention will be issued about May 1. The credit for this belongs to your secretary, your committee on publication and to your editor, Prof. W. D. Pence.

The American Railway Association has made the following appropriations on account of the investigations of the rail committee: In 1910—$5,000; in 1911—$6,000; in 1912—$10,000, making a total of $21,000, and in November, 1912, a further appropriation of $10,000 was made for the work of 1913, bringing the total up to $31,000. Against this appropriation there had been expended up to November, 1912, $21,011.41.

The Association was invited to be represented at the Fourth National Conservation Congress held at Indianapolis in September, 1912. Messrs. McNab, Atwood, Ferriday, Fink and Young were appointed as delegates to attend that congress.

With the completion of another year in the existence of the American Railway Engineering Association, it is well to review its accomplishments and to point out the work before it.

Its first notable accomplishment has been:

The standardization of materials, designs, specifications and records used in the construction and maintenance of the various parts of a railroad. Progress has been made in the specifications governing the making of such complex materials (so largely used by railroads) as concrete and steel.

While the first of these items relates almost wholly to materials, the proper use of these materials is largely dependent upon labor, skillfully and economically directed; and the second item—namely, the manufacture of such materials as concrete and steel, is very greatly dependent upon the quality of the labor and upon the honest and thorough use of it.

This Association has had before its committees instances of the short life of concrete, due more often to faulty or dishonest labor used, than to the materials themselves composing it; yet so far, more concern has been given by this Association to the materials than to the labor. The discovery of voids in concrete, or of portions where adhesion is lacking, or again of the misuse or damage by laborers of reinforcing materials, has resulted in the gradual increase in the amount of skilled labor and of supervision employed; because, after all, a mass of concrete is only as strong as its weakest part.

The manufacture of steel likewise demands employment of skilled labor in every step of the process. The time was when certain ores of generally known quality when handled and reduced to steel by a method in general practice was all that was necessary; and the product received its name and often its rate value from the record of the individual manufacturers. That time is gone. Labor used instead of

being small in numbers is both large and changeable; so, skillful labor and the efficient use of it, as well as of the extensive mechanisms under its control, is the only surety for a steel that will be uniform in good quality. The rail committee of this Association has brought out this point very forcibly to railroad people and to the manufacturers of rail, as well as to the public.

It has been found that it is those mills which have sought for scientific care on the part of their men, and which have discharged others for carelessness, or for a misguided loyalty to their employer in their effort to produce quantity at the risk of slighting quality, that are to-day producing rails of the more uniform grade. It is by this method of extreme watchfulness that further improvement will be obtained.

The rail committee has shown so far:

First.—That while rail failures in the past have had as many explanations as there were manufacturers, with no means of proving or disproving any of them, now we know the general causes, and the remedies are being worked upon.

Second.—Many negative results of the investigations prove that good or bad mill work produces good or bad rails, and in many cases overcome the advantages or disadvantages of any particular rail section.

Third.—That the amount of discard from the top of ingots does not set a gage on either the high standard of the rail produced, or on the number of rail failures; but rather indicates the relative skill of some mills in controlling the chemical content, casting ingots and rolling rails.

Fourth.—That some mills continuously produce better or more uniform material than others; and that this uniformity is largely the result of greater care and skill at the mills, which has been considerably developed by the publications of this Association.

Fifth.—And now we are finding that the use of thick base rails of the A. R. A.—"B" type is reducing base failures to an insignificant number; and also that care in handling and using rails is productive of both longevity and safety. In fact, that careful labor should follow the treatment of rails until they are removed from main tracks.

To explain one type of watchful labor in detail: About two years ago a broken wheel nicked the rails of over a mile of track on an important railroad. The nicked rails began to break under following trains before their replacement could be completed. It seems important, therefore, that track supervisors should promptly remove rails nicked by broken wheels whenever discovered in main tracks.

It is proper here to place on record the fact that James E. Howard, of the United States Bureau of Standards, has personally complimented the work of this Association on the subject of rails, and it seems well also to call your attention to a recent report of the National Association of Railway Commissioners, by its special committee, to whom was assigned the question of equipment and rails. In this report many quotations are included from the Proceedings of the American Railway Engineering Association, and the following statement is made:

"The best general information obtainable on the subject for the country as a whole will be found in the reports of the rail committee of the American Railway Engineering Association. The care which has been used in obtaining statistics of rail failures by this committee, in analyzing these figures, and in fearlessly reporting its conclusions, justifies high praise."

This problem is a complex and difficult one, but its solution is approaching; and very fortunate will be that mill, or group of mills, that first proves that it is delivering tougher and more uniform rails than are now produced.

This Association should keep up to date in labor-saving machinery and devices, and should discover and compile records of the best practice in handling labor with and without their use. It should also refer to its quality and the economical seasons for its employment, as well as to its best supervision in all branches of railroad construction, maintenance and operation.

One of the best ways for securing efficient results from labor is to freely recognize any improvement that its intelligent use produces. An employer that always points out the fault only, without commending the gain, soon discourages even the most skilled of artisans. Humanity in general needs incentive and encouragement in addition to wages.

We, in America, have made great strides in methods of getting work done; but we cannot afford to overlook the song of the leader of the boat crew on the Mediterranean who keeps the men at vigorous stroke by his frequent exclamation "Glory to Allah." These are both examples of good team work."

Some railroads adopt a prize system in one or more branches of service. There is no single department that will answer more readily to this system than the labor employed upon the maintenance of track. The Pennsylvania, for example, has a special committee of maintenance of way officers to look after the award of premiums for the maintenance of track and roadbed, which award is finally made after an annual inspection of the road by a large number of its operating officers.

The road with which I am connected has used this plan in a modified form for a long period. Its annual inspection awards upon 2,000 miles of railroad last year cost for prizes less than $1,500. This, however, was not a track inspection by officials, but one of roadmasters and track foremen taken from one district to inspect quite another. Not only have these awards been just, but each individual has learned many of the good points found on the other district. Such an inspection is a method of indirect but very effective instruction.

There is an economic cost for putting a new tie in place in the track of every district of a railroad, likewise a corresponding one for putting bridge timbers or steel in place, for laying stone masonry, or depositing concrete. The distribution among the districts of each railroad of the costs secured each month is a great incentive itself in track and other classes of maintenance labor, as also in other departments of railroad service.

If we, for a moment, turn back a dozen years and see how little standardization there existed on railroads as a whole, and how little general information was distributed; and compare that with the mass of valuable information in our Manual and Proceedings, we may realize that there must be likewise a large amount of data as to labor and mechanical appliances for cheapening the use and handling of materials that may be compiled in the same manner. This is of special importance as the unit cost of labor is increasing very rapidly.

The changes in ideas and methods in this branch of economy will be frequent and often great from year to year. Committees can never expect, therefore, to complete this subject. They will, when fully organized in collecting this kind of data, have some new economies to report each year in every branch of the service. The study of this line of economies often leads to what at first thought appears to be bold undertakings.

As examples to be mentioned because of personal knowledge of the details:

The Norfolk & Western has just successfully swung, under the method of cantilever erection, the central and last span, 520 ft. long, being one of a total of five double tracked spans of bridge forming its crossing of the Ohio River. These spans were built around the old spans and rest on the original masonry. The original spans carried the dense traffic until they were replaced. The consideration that led to this novel construction were economy in time and labor combined with the least delays to railroad traffic and none to river traffic.

Another study on similar lines of economy of labor and efficiency mostly, which has been under progress in the engineering department of the same road since 1905, has just culminated in the undertaking of electrification of 27 miles of that portion of its line having the steepest grades and densest business in the heart of the Pocahontas coal field, purely for handling freight traffic most economically.

We should always bear in mind that any saving in cost of labor applying materials is net income to a railroad, just the same as is the saving in overtime charges in handling trains gained either through improvements in grades or in motive power, or through efficient block signals.

In traveling about over various railroad lines, I have observed forces of men employed thereon that do not seem to differ much in number; but there was noticed at the same time a difference in the appearance of the railroads, even to the extent of a large percentage. Close investigations of both the labor employed and the business handled in many cases reveal the fact that for the corresponding amount of traffic the best appearing railroad accomplished its maintenance work at the lower cost. The explanation is simply that it is just as easy and no more expensive to work to a definite line or plan than to a random one; and if this method is followed uniformly on every district of a railroad, any given standard can be acquired without cost.

One of the leading officials of a great concern was heard some time ago to say: "We have let one-fourth of our men go; the other three-fourths have since gotten busy, and we are securing great results." While this did not speak well for the past of that concern, it also proved the fact that there was a large number of unproductive employes, who, if they

had been always well directed, would have added greatly to the stability and value of that property.

A number of years ago we had occasion to have railroad ties condemned as first class because they were of variable lengths and presented a bad appearance in track. Many have been satisfied to condemn only when too short. But I submit it is just as easy to have them cut by the makers practically to the right length.

These illustrations show how we can make our permanent way and track in a period of years things of strength, safety and beauty through uniformity acquired without cost except in the time of skillful directors and in the abundance of standard plans and constructive forms economically followed.

Gentlemen, this is part of our work. We are directors of the economical and efficient expenditure of money. We should hesitate to ask for more till we have shown that we are using that in hand to the best advantage, or until we can prove that we can secure a fair percentage of earning from the additional amount requested. The American Railway Engineering Association can aid in the development of skill in labor efficiency just as it has developed and must continue to improve the standards of materials and specifications.

Summary.

Receipts during 1912		$27,839.91
Expenditures:		
Dec. 1911 vouchers, paid		
Jan. 4, 1912	1,047.68	
Vouchers for 1912	$23,609.12	24,656.80
Excess of receipts over expenditures		3,183.11
		3,183.11
Assets December 31, 1912		10,745.26
Consisting of:		
Six railway bonds	$ 5,206.06	
Cash in bank	5,539.20	
Total		$10,745.26

RULES AND ORGANIZATION.

Last year's report consisted in the presentation of a number of rules regarding the government of employes and the conduct of work of the maintenance of way department.

GEORGE H. BREMNER, Treasurer.

E. H. FRITCH, Secretary.

Reports of Secretary and Treasurer.

Balance on hand December 31, 1911		$ 7,562.15
Consisting of:		
Six railway bonds	$ 5,206.06	
Cash in bank	2,356.09	
Total		$ 7,562.15
Receipts during the year 1912:		
From members		$13,363.25
From others—sales of publications, advertising, etc.		6,111.19
From Am. Ry Assn., Rail Com. fund		7,961.81
From interest on bank balance		123.66
From interest on investments		280.00
Total receipts in 1912		$27,839.91

The subjects assigned the committee for this year were to continue the work of last year, including: the compilation of rules for the government of maintenance of way employes, and the formulation of rules in the nature of specifications or instructions regarding the conduct of work, making use of the recommendations of the various committees dealing with these subjects and of the best practice of railway companies as embodied in their books of rules.

In accordance with the first instruction, the committee recommends that revisions and additions be made in the General Rules for the Government of Employes of the Maintenance of Way Department heretofore adopted by the Association, as follows:

Revise rule No. 8 under "Track Supervisors," "Track Foremen," "Supervisors of Structures," "Bridge and Building Foremen," "Signal Supervisors" and "Signal Foremen" to read as follows:

(8) They shall conform to the prescribed standards, plans

and specifications in the execution of the work under their charge.

Insert under "Track Foremen" a rule to be No. 17 and reading as follows:

They must keep all interlocking pipe lines and trunking free from grass and weeds and all switches, frogs and movable parts of interlocking plants free from snow, ice and other obstructions.

Under "Track Foremen," change rule No. 17 to be No. 18.

Insert a rule under "Track Supervisors" to be No. 17 and under "Track Foremen" to be No. 19 to read as follows:

Any action proposed by county, township, municipal or other authority, which will in any way affect the company, shall be reported immediately to the.....

Insert under General Notice rules to be No. 12 and No. 13 and reading as follows:

(12) The use of intoxicants by employes while on duty is prohibited. Their use, or the frequenting of places where they are sold, is sufficient cause for dismissal.

(13) Employes subject to emergency call shall notify their immediate superior officer and the division superintendent of any change in address, whether temporary or permanent.

In accordance with the second instruction, the committee recommends that the following rules be added to the "Instructions" which were presented and adopted by the Association at its convention of last year. In preparing these rules the specifications have been taken wherever possible from the approved recommendations of the other committees of

J. O. OSGOOD,
Chairman Committee on Rules and Organization.

the Association, the wording only being changed, where necessary, to conform to that of the other rules.

Tie-Plates.

27. Tie-plates must be used wherever ties wear out faster than they fail by ordinary decay. They must be put on so as to get a full and level bearing on the tie and against the rail.

Gaging.

28. Perfect gage is one of the essential features of good track; gage kinks are as detrimental as low joints.

29. The standard gage is 4 ft. 8½ in. Curves 8 deg. and under should be standard gage. Gage should be widened ¼ in. for each 2 deg. or fraction thereof, over 8 to a maximum of 4 ft. 9¼ in. for tracks of standard gage. Gage, including widening due to wear, should never exceed 4 ft. 9½ in.

30. The installation of frogs upon the inside of curves is to be avoided wherever practicable; where this is unavoidable the gage of the track at the frog should be standard.

Curve Easement.

31. On all curves the amount of super-elevation to be given to the outer rail and the proper easement to be provided at the ends shall conform to the standards for "Track" as prescribed by the American Railway Engineering Association and published in the manual, edition of 1911.

Switches.

32. Switches must be placed in accordance with the standard plans and as located by the engineer.

33. Switches and frogs must be kept well lined and in good order. Particular care must be taken to maintain good surface at switches.

34. Switches must be inspected frequently to see that they are in working order and that all nuts, bolts and other fastenings are in place and properly tightened. Broken or damaged parts must be renewed promptly.

35. Switch points must fit closely and accurately to the stock rail, which must be bent to suit the angle of the switch. The bend in the stock rail shall be at such distance ahead of the switch point as will make the gage line continuous.

36. Lead rails in all turnouts must be curved with a rail bender before being laid.

37. All main track switches leading to sidings or branch lines should be protected by switch connected derails.

Switch Ties.

38. Switch ties must be used for all permanent turnouts, crossovers and railroad crossings and placed as shown on the standard plans.

Guard Rails.

39. Frogs must be protected by guard rails, constructed and placed in accordance with standard plans. The tops of the guard rails must be level with the tops of the main rails and must be securely held in place.

40. Guard rails must be so placed that the distance from the gage side of the head of the frog wing rail to the flangeway side of the guard rail shall be exactly 4 ft. 6¾ in., and great care must be taken to preserve this distance.

Track Posts and Signs.

41. All signal posts, whistle posts, mile posts, signal targets, bridge and other standard signs must be kept plumb and in good condition.

42. Whistle posts must be placed so as not to be obscured by fences or other signs.

Care of Track Tools.

43. Tools must not be left standing within 6 ft. of the nearest rail of the track on which a train is approaching.

Road Crossings.

44. Road and street crossings must be constructed as shown on the standard plans and kept in good order.

45. Particular care must be taken to remove as far as practicable all obstacles which obstruct the view of crossing signs and approaching trains.

46. Flangeways must be kept clear of rubbish, snow, ice and other obstructions; defective crossing planks must be repaired promptly.

Platforms.

47. Station platforms must be kept clean, free from rubbish, snow and ice, and in good order.

48. Defective platforms must be promptly repaired or reported.

Fences and Cattle-Guards.

49. Fences and gates along the right-of-way shall be kept in repair and all gates kept closed when they are not in actual use.

50. Cattle-guards must be kept in repair and at all times free from dirt, rubbish and other obstructions.

Track Jacks.

51. Track jacks must not be used between the rails of main tracks, except in unavoidable cases; the track must then be properly protected as in the case of other obstructions.

RULES GOVERNING THE USE OF STOP AND CAUTIONARY SIGNALS FOR THE PROTECTION OF UNSAFE AND OBSTRUCTED TRACK.

Flagging.

52. In case of impassable track, flagging is the first duty, and repairs must wait, if necessary, until signals have been placed.

Flagging Before Obstructing Track.

53. The track must never be obstructed without first displaying stop signals not less than 20 telegraph poles in each direction from the point of obstruction. Stop signals must be in the hands of reliable men. Flagmen must stop all trains and explain to the engineman the nature of the obstruction and its exact location.

Slow Orders.

54. When the track is not in condition for the passage of trains at the usual rate of speed, and this condition will

Convention of the American Railway Engineering Association in Session.

continue over night or for the greater portion of a day, notice must be given immediately to the.....
In such notices the place of danger, its nature, and the speed at which trains may pass must be stated.

In addition to sending this notice, slow (color) signals must be displayed. When repairs have been made the person making them must at once notify the..... that the slow order may be recalled.

Signals to Be Used.

55. The color, hand, flag, lamp and engine steam whistle signals, and the train markers prescribed by and published in the standard code of American Railway Association shall be used. It is suggested that copies of the description and rules for the use of these signals, including diagrams, be inserted in books of rules governing maintenance of way employes.

Time for Obstructing Track.

56. All work which will obstruct the track must be done at such times as will interfere as little as practicable with the passage of trains.

Obstructing Track in Storm or Fog.

57. Except in case of emergency, no work that will obstruct the track shall be done during fogs or storms.

Signals in Obscure Weather.

58. In obscure weather, or on heavy grades or curves, extraordinary care must be taken to make sure that the stop signals are out a sufficient distance in both directions to insure full protection.

Proper Maintenance of Signals.

59. While working under the protection of signals, great care shall be taken that the signals are intact and in their proper location and position. Disregard of signals shall be promptly reported to the .....

Signals for Double Track.

60. In using signals on double track, each track must be considered as a single track railroad upon which trains are likely to be run in either direction at any time.

RULES GOVERNING THE USE OF HAND, PUSH, MOTOR AND VELOCIPEDE CARS.

61. Care must be exercised by foremen and other employes in the use of hand, push, motor and velocipede cars. In order to avoid accident, they must protect themselves with the proper signals, when the view is obstructed. On moving hand cars at least one man must face the rear to look out for approaching trains.

62. Such cars must be protected from the weather and when not in use must be locked.

63. Cars must never be used or left on the main tracks or sidings unprotected. Loaded hand or push cars on the track are obstructions and must be protected by the proper signals.

64. They must not be attached to trains. When following trains, or other moving cars, they must not run closer than ten rail lengths.

65. They must be kept in good order and inspected frequently for loose bolts or other defects.

66. Switches must not be thrown for such cars, unless loaded, and then only under the supervision of the foreman.

NEXT YEAR'S WORK.

For next year's work the committee recommends that it be instructed to review the rules and instructions heretofore adopted by the Association and to recommend such changes and additions thereto as may seem desirable.

Jos. O. Osgood (C. R. I. of H. S.), chairman; G. D. Brooke (B. & O.), vice-chairman; F. D. Anthony (D. & H.), J. B. Carothers (B. & O.), S. E. Coombs (N. Y. C. & H. R.), J. B. Dickson (Erie), C. Dougherty (C. N. O. & T. P.), W. T. Eaton (St. L. S. W.), J. A. Gordon (P. M.), K. H. Hanger (C. R. I. & P.), B. Herman (Southern), Jos. Mullen (C. C. C. & St. L.), E. T. Reisler (L. V.), A. F. Stewart (C. N.), Committee.

Discussion on Rules and Organization.

In the absence of the chairman, Mr. Osgood, the report was presented by Mr. Brooke.

L. C. Fritch (C. G. W.): I would suggest that the "State" be included in the new Rule 18. It covers every subdivision except the state. Very often employes to whom this is directed have information in regard to any state action taken.

The President: The committee would accept that modification, to insert the word state before county.

After considerable discussion it was voted that Rule 27 be changed to read as follows: "When tie-plates are used they shall be applied so as to secure a full bearing upon the tie and for the rail."

L. S. Rose (Big Four): I move that the second half of Rule 28 referring to "gage kinks are as detrimental as low joints" be cut out. It depends on what a gage kink is. I do not believe you can prove that a gage kink is more detrimental than a low joint. (The motion was carrried.)

Albert Swartz (Toledo Rys.): We might say, "Perfect gage is on of the essential features of good track and must be maintained."

The President: The committee is willing to accept the suggestion of Mr. Swartz.

Rule 30.

H. R. Safford (Grand Trunk): Is Rule 30 a proper rule to put under instructions to the section foremen on the theory that the location of the switch is a matter which is not left to the judgment of the section foreman. It is always prescribed by the higher officer, generally the engineer in charge of maintenance on the division.

T. S. Stevens (Santa Fe): I believe that if the standard prescribed by the committee is good the widest publicity we can give to it, is desirable, and it is just as well to have the section foreman know what the standard is, as the division engineer, with the idea that perhaps some time or other the section foreman may be able to check up the division engineer, in some probable error he has been led into by mistake.

The rule was adopted as read.

The last two lines of Rule 31 after the word "standards" was omitted and the rule was changed to read "On all curves the amount of super-elevation to be given to the outer rail and the proper easement to be provided at the ends shall conform to the standards," and a notation in parenthesis will refer to the standards of the Association.

J. A. Atwood (P. & L. E.): I move the adoption of Rule 34 in the form submitted by the committee, the only changes being the addition of the words "and frogs" at the heading of the rule. (The motion was adopted.)

S. S. Roberts (I. C.): Rule 35 as it stands is rather indefinite, and inasmuch as most roads have a specific distance ahead of the switch point for bending a stock rail and as this committee has recommended a certain distance ahead of the stock rail, I move the rule should read "switch points must fit closely and accurately to the stock rail, and the stock rail must be bent in accordance with the standards." Then in parenthesis refer to the recommendations of the track committee of this association. (The motion was carried.)

Rules 36 and 37 were voted to be stricken out.

A. Swartz (Toledo Ry.): Referring to Rule 38, I do not believe it is good practice to use switch ties on railroad crossings. We generally use a heavier timber than switch ties.

G. W. Bremner (C. B. & Q.): I think this ought to refer to the standards of the track committee also.

The President: The committee will accept that and put a note, referring again to the standard practice of this association.

Section 40.

Mr. Brooke: The committee has a communication from Mr. A. M. Shurtleff, suggesting Section 40 should read as follows:

"Guard rails must be so placed that the gage distance from the frog point to the flangeway side of the guard rail shall be at least 4 ft. 6¾ in., and the distance between the flangeway sides of the wing rail and guard rail shall not exceed 4 ft. 5 in."

(The committee accepted this amended reading and it was adopted.)

C. E. Lindsay (N. Y. C. & H. R.): I think that Section 42 should read—"All signal posts, whistle posts, etc., must be placed so that they will not be obscured."

The President: The committee accepts the change to Section 42.

Mr. Lindsay: I think that Section 43 should read, "Tools should not be left where they are liable to be struck by trains." (This was adopted by a rising vote.)

John R. Leighty (Mo. Pac.): I would suggest that we add to Rule 49 as it stands, that a report be made to the proper officer, of all gates which are habitually left open. (The motion was seconded and carried.)

Mr. Lindsay: The latter part of Section 51 is rather indefinite. I would like to substitute for it the words, "and then only under flag protection as per Rule 53," so

that the rule would read, "Track jacks must not be used between the rails of main tracks, except in unavoidable cases; and then only under flag protection, as per Rule 53." (The motion seconded and was accepted by the committee.)

It was voted that Rule 53 read as follows: "The track must never be obstructed without first displaying stop signals in general accord with Rule 99 of the American Railway Association. Stop signals must be in the hands of reliable men. Flag men must stop all trains, and explain to the engine man, the nature of the obstruction, and its exact location."

In Section 57 the words "In case of" were changed to read, "except emergency."

The following is to be added to Section 58: "Displayed at a proper distance."

Mr. Lindsay: In Section 60 I would like to substitute for "signals on double track"—"signals for multiple track," because we have 4 and 6 track-railroads, and I believe the rule would be better if it said, "Each main track shall be considered as a single track railroad upon which trains are likely to be run in either direction at any time, and signals must be displayed accordingly."

The following was inserted in Rule 63, after the word "sidings": "street or public crossings."

Mr. Lindsay: I would like to confine Rule 66 to main track switches, because in yards it is common practice and always will be, to operate the switch by the man in charge of the car, without the foreman being there. (The committee accepted this change.)

Hunter McDonald (N. C. & St. L.): There is an inconsistency between that and 29. It says, "Perfect gage is one of the essential feautres of good track." I do not know of any road that maintains perfect gage. In Section 29, the words in the last part are as follows: "Gage including widening due to wear" if you are going to admit widening due to wear, which we will necessarily have to do, we cannot have perfect gage, and I move therefore that Section 28 be amended to read: "Uniform gage is essential to good track and must be maintained." (The motion was seconded and carried.)

A. G. Shaver (C. R. I. & P.): I want to call attention to one thing that I believe is lacking in the rules for constructing track, and that is the automatic block signal. In some of the territory of some of the roads, they require the section foreman to assure himself that the signal is at "stop" while the change is being made. It would be a good plan to include something of that kind in connection with these rules.

The President: The committee will take that into consideration.

The rules were then adopted as amended, in their entirety.

Edwin F. Wendt (P. & L. E.): Before this committee is dismissed I wish to make a suggestion in connection with the work of next year. Much work has been done in connection with the question of rules, but very little attention has been given to the subject of organization. In reading the final report of the Block Signal and Train Control Board of the United States Government, I was struck with the following statement, "As regards methods, it may be said that on the large majority of American railroads excellence of administration is nullified by faulty organization, magnification of individual function to the detriment of team work, and by an almost entire absence of a definite system of broad training of subordinates for higher duties." It seems to me that our committees might well study the science of organization. Considerable literature has been developed in recent years respecting this question. The study of principles which underlie organization, would be a proper work for this association. I do not refer to those features of organization which give rise to so much discussion. Reference is made to the principles which underlie organization, and I think that this committee should study what is called, "the science of organization."

The President: We will take that up in the committee of the Directory, in assigning subject for the coming year.

Mr. Lindsay: I would like to ask that the committee be asked to prepare and submit to the Association next year, a rule for display of caution signals.

The President: The committee will take that into consideration as part of their instructions for next year.

SIGNALS AND INTERLOCKING.

On Subject No. 1, "Continue investigation of and description of a comprehensive and uniform signal system suitable for general adoption, conferring with proper committee of the American Railway Association," the committee submits the following report:

As a result of several years' study, the committee, in 1907, arrived at the conclusion that the basis of a uniform system of signals should be the control of the train. During the succeeding two years the committee ,after exhaustive study and investigation of the subject, was unable to agree,

First—As to the number of indications that should be given by fixed signals;
Second—As to the wording of the indications;
Third—As to the aspects or forms of the signals that should be used to represent the several indications.

In 1910, the American Railway Engineering Association requested the American Railway Association to bring the matter to the attention of its committee on Transportation for decision. The committee on Transportation heard arguments at a meeting in June of that year and reported as follows:

"MEMORANDUM OF THE ESSENTIALS OF SIGNALING,

"*Incorporated in the Report of the Committee on Transportation of the American Railway Association, May*, 1911.

"The reports of various committees of the Railway Signal Association and of the American Railway Engineering Asso-

A. H. RUDD,
Chairman Committee on Signals and Interlocking.

ciation on the subject of signaling have been submitted to this committee, with the request that the essentials of signaling be outlined or defined for the future guidance of their committees.

"The subject has been carefully analyzed and considered. There are three signals that are essential in operation and therefore fundamental, viz.:

(1) Stop.
(2) Proceed with caution.
(3) Proceed.

"The fundamental, 'proceed with caution,' may be used with the same aspect to govern any cautionary movement; for example, when:

(a) Next signal is 'stop.'
(b) Next signal is 'proceed at low speed.'
(c) Next signal is 'proceed at medium speed.'
(d) A train is in the block.
(e) There may be an obstruction ahead.

"There are two additional indications which may be used where movements are to be made at a restricted speed, viz.:

(4) Proceed at low speed.
(5) Proceed at medium speed.

"Where automatic block system rules are in effect, a

special mark of some distinctive character should be applied at the stop signal.

"The committee therefore recommends:

"*Signal Fundamentals.*

(1) Stop.
(2) Proceed with caution.
(3) Proceed.

Supplementary Indications to Be Used Where Required.

(4) Proceed at low speed.
(5) Proceed at medium speed.

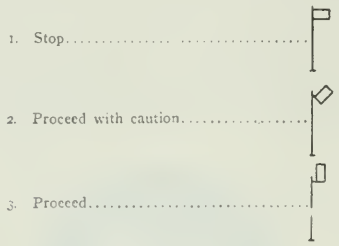
"Stop signals operated under automatic block system rules should be designated by some distinctive mark to be determined by each road in accordance with local requirements."

RECOMMENDATIONS.

The committee submits for approval the following two schemes of signaling in conformity with the recommendations of the committee on Transportation.

Scheme No. 1.

FUNDAMENTALS.

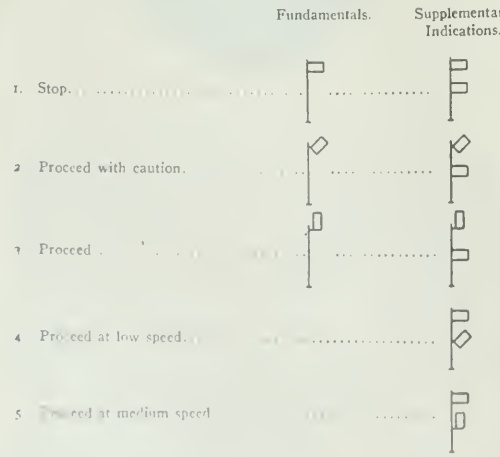


Scheme No. 1.

As means of designating stop signal operated under automatic block system rules, the following are suggested (for all three schemes):

1. The use of a number plate; or
2. The use of a red marker light below and to the left of the active light; or
3. The use of a pointed blade, the blades of other signals giving the stop indication having square ends; or
4. A combination of these distinguishing features.

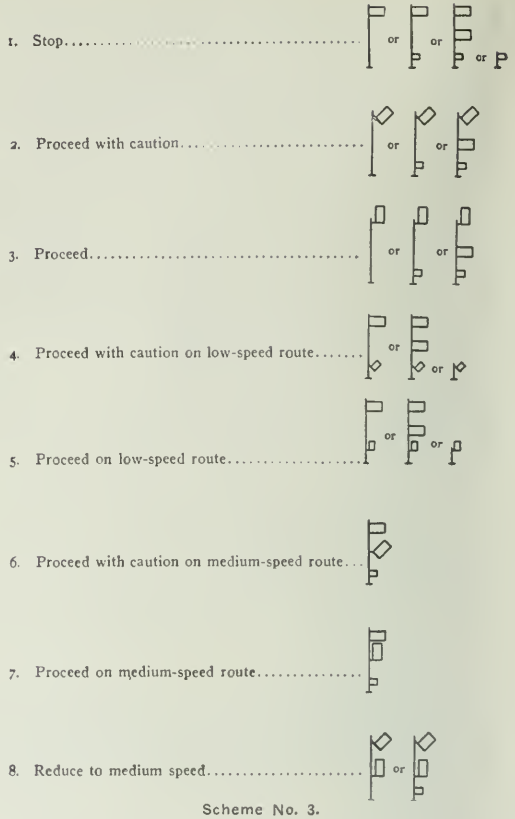
Scheme No. 2.



Scheme No. 2.

Having in view the practice of indicating diverging routes by several arms on the same mast, the committee submits for approval the following to establish uniformity in this practice:

Scheme No. 3.



Scheme No. 3.

The above three schemes are submitted, after an earnest effort to carry out the instructions to "outline description of a comprehensive and uniform signal system, suitable for general adoption," with the idea that each scheme is complete in itself.

CONCLUSION.

That the signal indications and aspects and the means of designating stop signals operated under automatic block system rules, presented above, be adopted, published in the manual and referred to the American Railway Association as information.

EFFECT OF TREATED TIES ON TRACK CIRCUITS.

On Subject No. 2, "Report on the effect of treated and metal ties on track circuits," your committee submits the following report:

Historical.

In 1910 this committee was instructed to confer with the committee on Ties, and report on the effect of treated and metal ties on track circuits. Nothing was acomplished. (See page 128, Proceedings, Vol. 12, Part 1.)

In 1911 instructions were issued to report as above (omitting conference with commitee on Ties). Other subjects were given preference. (See page 70, Proceedings, Vol. 13.)

This is the third year, therefore, that the subject has been assigned to this committee.

Report.

The effect of metal ties is self-evident. Each rail must be completely insulated from its ties to prevent a short-circuit (similar to the action of the wheels and axle of a train). Defective insulation at any point will cause leakage and defective insulation at both ends of only one tie

will throw the track circuit out of service. The effect of creosoted ties is not serious and, with alternating current track circuits, is negligible.

The effect of zinc treated ties is more problematical.

In response to the circular sent to all members on June 1, 126 replies were received, representing 92 railroads—many of them trunk lines. Sixty-nine of these use no zinc-treated ties; four use them to such a limited extent as to render a report valueless, including two which are making the first installation this year; seven use them extensively, but not where track circuits are in service; twelve only use them with track circuits, showing that while the subject is decidedly important to these roads, it does not at the present time, in view of this small percentage, appear to be of great general interest; although, if it could be shown that this treatment did not affect circuits seriously, its use might be extended.

The following extracts from the reports of these twelve roads show that their experiences differ very considerably, due, doubtless, in some measure, to different methods of treatment, but mainly to varying conditions of track, roadbed and especially ballast:

(a) "We are obliged to cut or relay all of our track sections which exceed one-half mile in length, owing to the combined leakage due to treated ties, metal in our ballast and brine drippings. Therefore, none of our track circuits is more tnan one-half mile long, and with sections of this length we have no leakage trouble whatever, even on new lines where all of the ties are freshly treated. New zinc-treated ties undoubtedly increase the leakage at first, but the resistance seems to increase after they have been in service a year or so, and I do not think a 15 per cent. annual renewal would cause serious trouble on any track circuit of reasonable length if the conditions are fairly good otherwise.

(b) "Where track circuits were in operation and renewals were made of some 15 or 20 ties in one location, there was a considerably greater leakage or track circuit current than ordinarily. We had a number of intermittent working track sections. For some time we could not imagine what the trouble was; when finally we did discover it and improvements set in, in several cases the track circuits had to be shortened. It appears that in time the trouble diminished owing, as we believed, to the zinc treatment disappearing from the surface of the tie.

(c) "From our experience the influence of 15 per cent. new zinc-treated ties on a track circuit is not appreciable; where track circuits 4,000 ft. long have been installed on new second track completely equipped with zinc-treated ties, and where ballast and drainage conditions were good. On the other hand, we have found it necessary in some instances to take out zinc-treated ties and replace them with untreated ties where track circuit conditions were unusually bad, and the slight effect of zinc-treated ties was sufficient to overcome the safe operating margin. Such conditions, however, are extremely rare, occurring for the most part through station platforms where the rails are buried in material sometimes having relatively high conductivity.

(d) "A strange coincidence, however, was the fact that in those track circuits in which resistance seemed relatively low to the proportion of treated ties the ties were not uniformly spaced throughout the distance, but were bunched together at only a few points in each such track circuit. On the other hand, in other track circuits in which the resistance seemed relatively high in proportion to the number of treated ties the ties were spaced practically uniformly throughout the length of the track circuit. This would seem to indicate that the effect of a number of treated ties spaced closely is greater than their aggregate effect when spaced with several untreated ties between each two treated ones. In our investigation we also observed the electrolytic action first observed by V. I. Smart, of the Illinois Central, and reported in the *Railroad Gazette* of March 13, 1908. It was noted that the resistance between the two rails, while very low immediately after the installation of a number of treated ties, became appreciably greater after the ties had been in service a short time, due apparently to the insulation of spikes on the positive side of the circuit by the formation of chloride of iron crystals.

(e) "However, when they have been permitted to dry thoroughly before being placed, we have not had any bad effects. We find, if these ties are put in track immediately after treating, or while they are wet, we experience some trouble with leakage in our track circuits.

(f) "We afterward found that we could eliminate this trouble by letting the ties season, and I am quite sure that ties treated with chloride of zinc would be seasoned enough if could put in more than 15 per cent. of them annually without interfering with the block signals. After the ties have been put in the track a sufficient length of time, even though they were not seasoned previously, the trouble will be eliminated. The experience on this road has been that where only a portion of the ties in a section are treated, it is necessary to use considerably more battery than where untreated ties are used, and I believe that if all the ties were zinc-treated, it would be very difficult to maintain a proper track circuit. The track circuit gets better as the ties get older, and in three or four years gets back to almost the same condition as if ties were untreated. In some cases where zinc-treated ties were used on this road, it was found necessary to reduce the length of track sections to 2,000 ft., and with these short sections we still experienced considerable trouble in damp weather. My general experience has been that it is a very hard matter to maintain a proper track circuit in sections where these zinc-treated ties were in use.

(g) "The peculiarity of this treatment is that it causes the most trouble on dry days, and apparently has very little, if any, effect on track circuits in cold or wet weather.

(h) "Where zinc-treated ties are used in all the renewals, and where from 8 to 15 per cent. of the ties are renewed per year, no appreciable effect is produced on the track circuits. In cases where zinc-treated ties are laid continuously, I have found that the length of track circuits would have to be reduced about one-half.

(i) "While we were using the zinc-treated ties we had one case where we had an automatic signal circuit about one mile long. It became necessary to renew a portion of the ties on this part of the track, and in renewing the new ties placed in the track are zinc-treated. The effect of the zinc was very noticeable, especially during wet periods. In fact, the ties caused short circuits so that the signals would not work. The result was that we took out the zinc-treated ties and placed cypress ties. I do not know what per cent. of the total number of ties were renewed, but it would appear that it was possible to ruin a circuit with a very few.

(j) "The ordinary yearly renewals of ties cause no trouble. However, I have experienced cases where on new track all of the ties being treated caused us a good deal of trouble for a period of two or three months. After this time, the leakage stopped, or at least there was not enough of it to prevent the track circuits working. My judgment is that where one is putting in track circuits on zinc-treated ties for new track, the track sections should be made somewhat shorter than otherwise would be necessary.

(k) "We have been using ties treated with chloride of zinc for the last four or five years, and our men advise that they cannot trace any track circuit trouble to the fact that the ties are treated with chloride of zinc. We renew about 15 to 16 per cent. annually.

(l) "With these treatments ('Burnettizing' and 'Card' systems) we find that no difficulty is experienced with track circuits of 3,500 ft. (our standard length), provided that no more than 15 per cent. of treated ties is introduced in one season.

(m) "We have not many zinc-treated ties in our automatic territory; that is, not enough in any one spot to cause very much trouble. We had some trouble with some that were put in last year during the wet season, but it seems that this spring the trouble has disappeared, as we have had no failures on account of wet track so far.

(n) "In some of our zinc-treated ties, which were put in track before being properly seasoned, there was, for a short time, some interference with the circuit, but as soon as the salt on the outside of the tie washed off the trouble ceased. At no time was this trouble serious.

(o) "We have track circuits where practically every tie is treated with this process and find no leakage at all.

(p) "In support of my contention that each tie is a battery, I wish to state that we obtained readings of .003 volt and eight mil-amperes on one of the track circuits, with the track battery and relay disconnected. In other words, the ties alone were producing this much electrical energy. The spikes also appear to have a somewhat shiny surface, such as we would expect from a battery electrode. We are able to pick out all treated ties by means of a voltmeter, by taking readings between one of the rails and a spike driven at random in the tie. On an untreated tie in the track circuit we merely get a slight deflection of the voltmeter needle.

(q) "We now have treated ties in on 19 track circuits

where treated ties are causing trouble. Ten of these circuits are new and nine are old circuits in which treated ties have recently been placed in renewals. Our record of signal failures shows that the trouble commences when the treated ties are put in. The trouble on the treated tie track circuits is due to a weak track circuit; i. e., with a sufficiently powerful track battery at one end of the circuit, the relay at the other end is not energized, due to insufficient current. This condition could be caused by too high resistance of the track circuit or by the track circuit becoming short circuited. The behavior of track batteries shows it is the latter which takes place, the battery being exhausted in five or six days, due to increased current generated. If the trouble were due to increased track circuit resistance, the battery would have longer life. As no change has been made in our track circuits during the last year, other than to put in zinc chloride-treated ties, we feel sure the trouble is caused by the treated ties, as our records now show a large increase in the failures. At a distant signal a year ago the track battery was made up once in every 18 days. One signal failure was reported during 1911. This spring 360 zinc chloride-treated ties were put in on the 5,000-ft. track circuit, and we now renew the track battery once every four days, and even this does not keep the signals working when it rains. At the circuit of another distant signal, 4,600 ft. long, 140 treated ties are causing the same trouble.

"In addition the treated ties are spoiling our track relays. With a variable current at the relay near the amount which causes the relay to pick up, there is considerable sparking at the points, which open and close continuously. This causes the platinum points to burn furrows in the carbon contact points above them. The west-bound distant signal stuck white with a train in the track circuit, August 12, due to platinum points on the relay being caught in the furrows they had burned in the carbon contacts above them. Each time it rains we have a number of failures, and the question should be studied to see what can be done to remedy the trouble. We tried, on one of the track circuits, oiling the ties inside the rail, thinking this might help, but it was not successful. Reports from other railroads show that the trouble disappears in time, but on this division the trouble is now on the increase."

Summary.

The consensus of opinion is:

(1) That track circuits a mile in length are rendered inoperative by the extensive use of zinc-treated ties.

(2) That track circuits 2,000 ft. in length may be operated successfully, even with 50 per cent. or more of ties so treated.

(3) That 10 per cent. to 15 per cent. renewals a year will not materially affect such length circuits.

(4) That, where renewals are made of 15 or 20 adjacent ties, the leakage is much greater than where there are made singly at uniform distances, i. e., with 15 per cent. renewals (every sixth or seventh tie).

(5) That, while the surface salts are present, more leakage occurs during wet weather than with untreated ties, as these wet salts form a better conductor than ordinary wet wood.

(6) That, in dry hot weather, the salts are drawn to the surface and constitute a more or less perfect conductor.

(7) That, after a period varying from three months to a year, these salts disappear and subsequently no interference is noticeable.

CONCLUSION.

That this report be received as information.

On Subject No. 3, "Economics in Labor of Signal Maintenance," your committee begs to state that this subject is being considered with reference to the report in 1914.

A. H. Rudd, chairman; L. R. Clausen, vice-chairman; Azel Ames, C. C. Anthony, H. Baker, H. S. Balliet, W. B. Causey, C. A. Christofferson, C. E. Denney, W. J. Eck, W. H. Elliott, M. H. Hovey, G. E. Ellis, A. S. Ingalls, J. C. Mock, F. P. Patenall, J. A. Peabody, W. B. Scott, A. G. Shaver, T. S. Stevens, H. H. Temple, Edwin F. Wendt, J. C. Young, committee.

Discussion on Signals and Interlocking.

Subjects No. 1 and 2 were unanimously approved. Subject No. 3 will be reported on next year.

IRON AND STEEL STRUCTURES.

The subjects assigned for investigation during the past year were:

(1) Report on rules for instruction and guidance of inspectors in mill, shop and field.

(2) Report on methods of protection of iron and steel structures against corrosion.

(3) Study the design of built-up columns, co-operating with other investigators and committees of other societies.

A final report on rules for instruction and guidance of inspectors in mill, shop and field, accompanied by a general descriptive statement of the qualities desired in an inspector, is given in Appendix A. Mr. Buel presents a minority report in Appendix B. Mr. Schneider desires that the report be referred back to the committee for further study.

A progress report on the design of built-up columns is given in Appendix C.

The recommendations of the committee may be summarized as follows:

(1) That the report on Rules for Instruction and Guidance of Inspectors in Mill, Shop and Field be adopted and printed in the manual.

(2) That the report of the sub-committee on the Design of Built-up Columns be received as a progress report.

A. J. Himes (N. Y. C. & St. L.), Chairman; J. A. Bohland (G. N.), A. W. Buel (W. M.), Charles Chandler (C. G. W.), C. L. Crandall (Cornell Univ.), J. E. Crawford (N. & W.), J. E. Greiner (B. & O.), W. H. Moore (N. Y., N. H. & H.), Albert Reichmann (Am. Br. Co.), O. E. Selby (C. C. C. & St. L.), vice-chairman; C. C. Schneider (Cons. Engr.), G. E. Tebbetts (K. C. Term.), L. F. Van Hagen (Univ. of Wis.), F. O. Dufour (Univ. of Ill.), C. E. Smith (M. P.), I. F. Stern (Cons. Engr.), F. E. Turneaure (Univ. of Wis.), committee.

A. J. HIMES.
Chairman Committee on Iron and Steel Structures.

APPENDIX A.

REPORT OF COMMITTEE ON RULES FOR THE INSTRUCTION AND GUIDANCE OF INSPECTORS IN MILL, SHOP AND FIELD WORK.

The duty of the inspector is to guard the interests of his employer. These interests include the safety of trains, persons and property; the quality of materials and workmanship; correctness of construction, and economy.

Some of the means at his command for protecting these interests are: The careful observance of such instructions as may be received from time to time; reports either received by him, as information concerning the status of the work at distant points, or prepared by him to exhibit the condition of the work under his immediate care; familiarity with the various means of communication between or among the several parties interested in the work and promptness in attending to messages and correspondence; and, by recording daily, in a journal kept for that purpose, the facts concerning all events that may affect the relations between his employer and the contractor, his employer and the public, the contractor and the

contractor and the public. The term "public" is intended to include all third parties. The purpose of such a record is to aid in the settlement of disputes and claims that may arise because of or grow out of the work in hand.

The inspector should have some knowledge of bridge stresses and should be able to read drawings quickly and with accuracy. A knowledge of elementary mechanics and of the mechanics of materials will enable him to understand the reasons for many specifications and the ultimate effect of faults of various kinds. Some knowledge of these branches of bridge building with which he is not directly concerned will be of advantage to him in understanding the work of inspectors employed upon such work. A knowledge of detailed designing is often a help in meeting emergencies or overcoming unexpected difficulties. He should have such knowledge of the relations between the employer and his employes as will enable him to assist in maintaining harmony in the working force.

Temperamentally he should be judicial and diplomatic and not controversial. He should be deliberate in his consideration of new or unexpected conditions, but prompt and decisive in action. When making investigations and reports he should be thorough and exhaustive, in order that the person using the reports may act thereon intelligently and correctly. An inspector's habits should be good, his honesty undoubted, and he should have a loyalty towards his employer that does not come from the payment of a salary. It is too much to expect that any one inspector will have all of these qualifications. His value will, however, be measured by the degree and extent to which he does possess them.

The inspector should be fully provided with the plans and specifications pertaining to the work. Often it is desirable that he should have masonry plans also in order that he may understand clearly the position which the structure is to occupy. He should have a copy of the contract or at least extracts therefrom covering those matters which might possibly need his attention. From time to time during the progress of the work he should be given special instructions covering its various phases. Should any further agreements or understandings be made or arrived at between the company which he represents and the contractor, he should be informed promptly concerning them.

Reports should be made at regular intervals defining the condition of the work and calling attention to matters of especial interest. Special reports should be made upon the happening of some event of more than ordinary interest. The amount of detail or the fulness of the regular reports should be governed by instructions. In general an inspector's time is more valuable when employed upon the site of the work where things are actually being done than in the office tabulating results. If a large amount of clerical work is required it is better to employ a clerk than to permit the inspector to perform duties which would keep him out of sight of the work which he is to inspect.

Instruction for the Mill Inspection of Structural Steel.

(1) Study the contract and specifications and secure such information concerning the proposed structure as will permit a full understanding of the use to be made of the various items of the order.

(2) Secure copies of the mill orders, shipping directions and other information concerning the material to be inspected.

(3) Attend promptly when notified of the rolling of material and so conduct the inspection and tests as not to interfere unnecessarily with the operations of the mill.

(4) Have the test specimens prepared and properly stamped with the melt numbers by the manufacturer. Observe the selection and stamping of specimens and verify the melt numbers when practicable.

(5) Attend and supervise the making of tensile, bending and drifting tests. Make sure that the testing machines are properly handled and that the specified speed of pulling is not exceeded. Note the behavior of the metal and check and record the results of the tests.

(6) Select the bars or other members for full-size tests as specified. Supervise such tests and check and record their results.

(7) Secure from the manufacturer records of the chemical analyses of the melts and accept only those in which the specified contents of impurities are not exceeded.

(8) Secure pieces of the test ingots and test specimens and have check analyses made outside of the manufacturers' laboratory when the analyses furnished by the manufacturer are erratic or for any other reason appear to be incorrect.

(9) Examine each piece of finished material for surface defects before shipment, requiring the material to be handled in a manner that will permit the examination to be thorough and complete. This inspection should detect evidence of excessive gagging or other injury due to cold straightening.

(10) Report promptly the shipment of any material from the mill, whose surface inspection has been waived. Such material should be examined by the shop inspector.

(11) Verify the section of all material by measurement and by weight.

(12) Study the operations of the plant and become familiar with the various processes of manufacture. Cultivate the acquaintance of the mill employes and become familiar with their work so as to have direct knowledge of the mill practice and determine as well as the circumstances permit the correctness of the mill practice in so far as it is covered by the specifications.

(13) Record all tests and analyses on the forms provided.

(14) Keep informed as to the progress of the work in the shop and endeavor to secure the shipment of material at such times and in such order as to avoid delay in the fabrication.

(15) Secure copies of the shipping lists, compare them with the orders and make regular statements of the material that has been rolled and shipped.

(16) Make reports weekly, or as may be directed, submitting complete reports of tests, analyses and shipments and such other information as may be required.

Instruction for the Inspection of the Fabrication of Steel Bridges.

(1) Acquire a full knowledge of the conditions of the contract, such as the time of delivery, the railway company's actual need of the work, the desired order of shipment, and any special features in connection with the delivery such as the position of the girders or truss members on cars at the bridge site.

(2) Study in advance the plans and specifications and see that all provisions thereof are complied with. These instructions are not to be construed as altering the specifications in any way.

(3) Endeavor to maintain pleasant relations with foremen and the workmen and by fairness, decisiveness and good sense interest them in the successful completion of the work.

(4) Attend constantly to the work, making inspection during the progress of the work in the shop, and striving to keep up with the output in order that errors may be corrected before the work leaves the shop. Conduct the inspection so as not to interfere unnecessarily with the routine operations of the shop.

(5) When unusual circumstances require an explanation of the plans or some variation from the specified procedure, take the necessary action promptly.

(6) Study the field connections, paying particular attention to clearances and making notations on the drawings so that they may be checked rapidly.

(7) Check all bevels and field rivet holes.

(8) Give careful attention to the quality of the workmanship, the condition of the plain material, accuracy of punching, care in assembling, alignment of rivets, tightness of rivets, accuracy of finishing of machined joints, painting and general finish.

(9) Make sure that reamed holes are truly cylindrical and that drillings are not allowed to remain between assembled parts.

(10) Watch for bends, kinks, and twists in the finished members and make certain that when leaving the shop they are in proper condition for erection.

(11) Make sure that the webs of girders do not project beyond the flange angles and that the depth of web below the flange angles complies with the specification.

(12) Allow only the material rolled and accepted for the work to be used therein.

(13) Have the fabricated material shipped in the correct order for erection and in accordance with instructions, as far as practicable.

(14) Measure the width of each column and the lengths of all girders between columns when they are to be placed consecutively in a long row so as to insure that the columns and girders will not "build out" in erection to exceed the calculated length.

(15 Check "rights" and "lefts" and make sure that the proper number of each is shipped.

(16) Check base plates of girders before riveting and make sure that the camber is not reversed.

(17) Check the space provided for driving field rivets, allowing sufficient space for the pneumatic riveter.

(18) Examine field connections after riveting to insure proper fitting and ease of erection.

(19) Make sure that shop splices are properly fitted and that matched and milled surfaces to transmit bearing ars in close contact during riveting as specified.

(20) Examine and measure bored pinholes carefully to insure proper dimensions and spacing and smoothness of finish.

(21) Measure the spacing center to center of the end connections for sections of I-beam floors or any similar construction in which the calculated spacing is liable to be exceeded because of the tendency of such work to "grow" as it is assembled.

(22) Make sure that stringers connecting to floor beams beneath the flange have sufficient clearance to care for their possible over-run in depth.

(23) Have the assembling of trusses and girder spans required by the specifications carefully done and, in any case, if a large number of duplicate parts are to be made, insure the accuracy of field connections by having an occasional part assembled with its connecting member. The number of parts to be so assembled should be governed by the workmanship. If errors are found, a sufficient number of parts should be assembled to make it reasonably certain that such errors have been eliminated. Have at least one upper and lower shoe of each kind assembled and make sure that there is no interference.

(24) Make sure that iron templets used for reaming are properly set and held to line.

(25) Secure match-marking diagrams for work which has been assembled and reamed and make sure that the match marks are plainly visible.

(26) Have proper camber blocking used in assembling trusses and secure the desired camber before the reaming is done.

(27) Require that all treads and supports for the drums of draw spans be carefully leveled with an instrument.

(28) Study carefully the machine details and discriminate between those dimensions which must be exact and those in which slight variations are permissible. Determine in advance the desired accuracy of driving fits for bolts or keys and similar parts and make sure that such accuracy is attained.

(29) Examine castings carefully for blowholes and other imperfections and discriminate between such defects as are unimportant and those which render the castings unfit for use.

(30) Make sure that bushings, collars and similar parts are held securely in place.

(31) Make sure that all drum wheels, expansion rollers, turnable rollers and similar parts are exact in size, so as to carry equally the loads which may be placed upon them.

(32) Ascertain in advance that the paint provided complies with specifications. Watch carefully the painting directions and make sure that paint is properly applied and only where intended.

(33) Verify all shop marks and make sure that they are legible as well as correct.

(34) Have important members so loaded as to be headed in the right direction upon arrival at the site of the work.

(35) Try a few countersunk head bolts in the holes where they are to be used to insure a proper fit.

(36) Make sure that small pieces are bolted in place for shipment as shown on the plans and that other small parts are properly boxed or otherwise secured against loss.

(37) Make sure that rivets, tie rods, anchor bolts and miscellaneous parts are shipped so as to avoid delay in erection.

(38) Examine the field rivets to insure that they are free from fins or other defects.

(39) Exercise special care in the examination of all movable structures and particularly their moving parts.

(40) Make reports weekly, or as directed, exhibiting carefully and concisely the actual conditions.

(41) Observe carefully and report such unusual difficulties as may be encountered and the means adopted in overcoming them and endeavor by a study of the details or other means to make recommendations which will prevent their recurrence in future work.

Instructions for the Inspection of Bridge Erection.

(1) Study and observe the plans and specifications for steel construction. Study the masonry plans and check the masonry as built with the steel plans.

(2) Familiarize yourself with the local conditions affecting erection. Make the acquaintance of the principal men engaged upon the work and of local residents whose interests may be affected thereby.

(3) Obtain and study carefully the employes' time table and be well posted concerning the time when regular and extra trains are due and their relative importance. Acquaint yourself with all special traffic arrangements made because of the work in hand.

(4) Secure full information concerning the conditions of the work in the bridge shop and the probable dates of shipment.

(5) Obtain reports of any uncompleted or erroneous work that must be attended to after arrival of the material in the field.

(6) Study the erection program in order to avoid delays and be able to recommend some other procedure in an emergency.

(7) Endeavor to have full preparations made before disturbing the track so that the erection may proceed rapidly and the period of such disturbance be made a minimum.

(8) Keep a record of the arrival of all materials. The contractor's record should be sufficient if available. Strive to anticipate any shortage of material and use all available facilities to hasten delivery of the needed parts.

(9) Study the progress of the work and determine whether it is likely to be completed in the time allotted. If not, endeavor to secure such additions to the force and equipment as will insure such completion.

(10) Make a daily record of the force employed and the distribution of labor, in a way that will assist in following clauses 9 and 23.

(11) Exercise a constant supervision of any temporary structure or falsework and make soundings if necessary with the purpose of discovering any evidence of failure or lack of safety and having it corrected before damage is done. Examine erection equipment with a view to its safety and adequacy.

(12) Be constantly on hand when work is in progress and note any damage to the metal, failure to conform to the specifications, or any especial difficulty in assembling.

(13) Make sure that each member of the structure is placed in its proper position. If match marks are used, examine them with care. Endeavor to have the several members assembled in such order that no unsatisfactory makeshifts need be resorted to in getting some minor member in place.

(14) Prevent any abuse or rough usage of the material. Bending, straining and heavy pounding with sledges are included in such abuse.

(15) Watch carefully the use of fillers, washers and threaded members to see that they are neither omitted nor misused.

(16) Make certain that all parts of the structure are properly aligned and that the required camber exists before riveting. It is possible for a structure to be badly distorted although the rivet holes are well filled with bolts.

(17) Watch the heating of rivets to insure against overheating and to make sure that scale is removed. Examine and test carefully all field-driven rivets and have any that are loose or imperfect replaced. Have cut out and replaced all rivets, whether shop-driven or field-driven, that may be loosened during erection and riveting. Prevent injury to metal while removing rivets.

(18) Present to the contractor at once for his attention any violation of the specifications or contract, and secure a correction or refer the matter to the proper authorities as soon as possible.

(19) Keep informed concerning the use of company material and work trains and assist in procuring such material and trains when needed, and preserve a record thereof.

(20) Secure a match-marking diagram of any old structure to be removed and see that each part of such structure is properly marked in accordance therewith. Make a record of the manner of cutting the old structure apart and report any damage to the members of the old structure. Indicate by sketches or otherwise such repairs or replacements as will be found necessary in re-erection.

(21) Secure photographic records of progress and the important features of the work wherever practicable.

(22) Make a record of all flagging of trains, whether performed for the benefit of the contractor or otherwise, delays to trains, personal injuries, and accidents of every kind.

(23) Make reports as directed, showing the progress of the work, the size of the force and the equipment in use. Make a final report showing the cost of labor of erection per ton of material erected, the cost of labor per rivet in riveting, the cost of correcting errors in design and fabrication and commenting on the design and details; and give such other information as may be useful in planning similar work.

APPENDIX B.

MINORITY REPORT.

At the Buffalo meeting of the committee on September 9, the writer suggested that an effort be made to outline some method or system which would promise some improvement over existing mill and shop inspection, and that a co-operative railroad bureau, combining the good features of "company inspection" with those of "bureau inspection," deserves consideration, particularly on account of the very great advantages which the consolidation of a great tonnage would give, permitting the subdivision and specialization of work to a high degree under competent and experienced resident or district engineers and managers. The chairman of the committee seemed to think that our instructions from the Board to "report on rules for instruction and guidance of inspectors in mill, shop and field," were not broad enough to include anything along the lines of this proposal and the matter was dropped.

Within the past five years the writer had occasion to do personally a considerable amount of shop inspection, and was impressed with the change in conditions and shop practice that had occurred within a comparatively few years. Certainly he had all along an "appreciation" of these new conditions, but that is quite a different thing from the actual, detailed experience of working with them. This recent experience is the basis of the suggestion offered above.

Company inspection is sometimes better, but often worse, than bureau inspection, and even with all the work for a system of allied lines does not consolidate sufficient tonnage to permit such an organization with division of work and specialization as the writer has in mind.

The rules of instruction as drawn may be applicable to "company inspection," but it is not clear how they are going to be applied to bureau inspection, which represents the greater tonnage. They would be entirely inadequate for such a co-operative railway bureau as suggested above. It is the writer's opinion that they will only be useful for company inspection, and that even for this kind they should contain more detail of technical and practical kinds.

The ideas I have suggested with the purpose of improving shop and mill inspection may be expressed as follows:

First.—That the shop and mill inspection of structural steel, to be efficient and satisfactory, should be done on a scale large enough to economically permit the employment at each shop or mill of a corps of men, who may be called checkers, each one of whom is specially fitted and trained for a certain part or detail of the work under a resident inspecting engineer, thoroughly familiar with all details of structural steel and its fabrication, competent to direct the corps of checkers and decide questions calling for the judgment of a man of experience and structural engineering training. Resident inspecting engineers should report to the district chief inspector or manager, who should be an expert in structural steel and its fabrication, as well as a competent bridge engineer, and he in turn should report to the executive head of what may be called the American Railway Inspection Association; except that on technical matters and with proper regulations, he may report to and receive instructions from the chief engineers and bridge engineers of the railway companies which are members of the association.

Second.—That the American Railway Engineering Association use its influence to induce the railway companies to delegate officials to meet and discuss ways and means and, if it appears practicable, to provide for establishing the American Railway Inspection Association as an organization to make a highly improved and standardized shop and mill inspection of structural steel, furnishing the same at cost to the railway companies which are members of or supporting such association. As this can hardly become effective without the support of railway companies representing about 75 per cent of the annual railway purchases of structural steel, it would seem advisable to have the official delegates empowered, under proper restrictions, to pledge the adherence of their respective companies to the support of the project.

Later on such an organization could be expanded to include the inspection of steel rails, but as this would require practically a separate corps—only the district chief and his office and probably a chemist, being common to the inspection of both structural and rail steel—it will no doubt be considered advisable to defer this question to a future time.

The size of each shop corps should include about one man for each 10,000 tons' annual capacity of the shop; the number of independent inspectors at present employed is probably equal to or greater than that. This would require that the inspection of about 50 per cent of the shop capacity be done by the proposed organization, otherwise the cost of inspection would be greatly increased, and my object is to try to show that a very superior inspection method can be devised without greatly increasing the cost.

The district chief, or manager, ought to be a man worth at least $200 to $300 per month, depending on the importance of the district, and could cover a radius of, say, 100 miles from Pittsburgh, Chicago, Philadelphia or Cleveland. Each resident inspecting engineer should be worth not less than $200 or $250 per month at the larger shops, down to a minimum of, say, $150 at the smaller shops. The wages of the other men in a shop corps would range from about $1.00 per day for the scale boy to $4.00 per day for the men checking field fits, templets and laying out. This will work out to between 40 cents and 50 cents per ton for shop inspection in average shops down to 30 cents per ton in the largest shops.

The following is a tentative outline of a shop inspection corps and an estimate of cost for a shop of 100,000 tons capacity per annum, in one unit. For shops of two units a somewhat different arrangement would be required, and in each case the organization of the corps will have to be adjusted to the plan and character of the particular shop concerned:

District chief or manager	$3,600	
District chief, office expense	3,600	
District chief, expense account	1,200	
	$8,400	
25 per cent of $8,400		$2,100
Resident inspecting engineer	$3,000	
Templet checkers, 300 days @ $4	1,200	
Layout and punching checker, 300 days @ $4	1,200	
Assembling and fitting checker, 300 days @ $3	900	
Reaming and rivet checker, 300 days @ $2	600	
Machine and finished work checker, 300 days @ $3	900	
Field connection checker, 300 days @ $4	1,200	
Painting and yard work checker, 300 days @ $3	900	
Scale and weight boy, 300 days @ $1	300	
Clerk, 300 days @ $3	900	
		11,100
		$13,200
Add 15 per cent for general expense		1,980
Total		$15,180
50 per cent of 100,000 tons shop capacity—50,000 tons; 50,000 tons @ 30 36/100c.		$15,180

There would, of course, have to be a general office to which the district chiefs or managers would report, but on technical matters I think the district chiefs or managers should report directly to and receive instructions from the chief engineer or bridge engineer of the railway companies, subject to proper regulations where extra expense is involved.

While it is practically impossible to secure individual inspectors with all the qualifications recommended in the report of committee 15, the desired combination of attributes may be closely approximated in such an organization as that outlined above.

A. W. BUEL.

APPENDIX C.

STUDY OF BUILT-UP COLUMN.

The chairman got into touch with the chairman and secretary of the American Society of Civil Engineers' committee on Columns and Struts and ascertained the nature of the work being carried out under the direction of that

committee so that no duplication of such work would be made.

The chairman then took up with S. W. Stratton, director of the Bureau of Standards, Washington, the question of the possibility of having several series of column tests made by the Bureau in its new 2,300,000-lb. Emery machine then being installed. Director Stratton kindly agreed to have such series made and to begin the tests as soon as the machine was in commission. The sub-committee decided to make detail drawings for a preliminary series consisting of eight sections commonly found in the compression members and struts. A light and a heavy section of each type is to be made up in lengths giving three l/r ratios (50, 85 and 120) and three specimens of each column are to be fabricated, making in all 144 test columns.

The detail drawings were made up by J. E. Crawford and presented to the general committee for discussion at its meeting in Buffalo on Sept. 9, 1912. Ten members having expressed their satisfaction with this preliminary series, with some minor modifications, the chairman arranged with Director Stratton and J. E. Howard to have the 18 columns representing column No. 1, series No. 1, at once fabricated and the tests commenced as soon as the final adjustments of the weighing apparatus were complete. It is hoped that the tests will be under way before Jan. 1, 1913. Before ordering the fabrication of the remaining columns of series No. 1, the committee will examine the results of the first 18 tests representing column No. 1 and will probably then proceed with a subseries on this column, charging one variable at a time in order to determine the best arrangement of details for the section. After the results of these tests are studied, the testing of the remaining columns of series No. 1 will be proceeded with, making such modifications as may be suggested by the results of the tests of column No. 1.

Discussion on Iron and Steel Structures.

A. J. Himes, chairman: The subject of third rail clearance was referred to the committee by the secretary on October 24, 1912, and is still under consideration. There seems to be a general agreement that a change in the diagram should be made. The matter is to receive further study by a subcommittee which will investigate the dimensions of equipment passing over the railroads and propose a new diagram.

At a joint meeting an extended discussion was held and provisions made for a joint committee consisting of two members from Committee XV of the American Railway Engineering Association, two members from the Railway Signal Association and two members from Committee X of the American Railway Engineering Association, provided that Committee X shall elect to co-operate in the work. The following gentlemen were chosen as members of the joint committee: Mr. Chappell, chairman, and Mr. Johnson, of the Railway Signal Association, and Mr. Smith and Mr. Selby of the American Railway Engineering Association.

The committee recommends to the Association that the following subjects should be investigated during the ensuing year:

Methods of Protection of Iron and Steel Structures against corrosion. Design of Built-up Columns. Secondary Stresses. Protection of Traffic at Movable Bridges. Revision of the Bridge Clearance Diagram. Standard Specification for Phosphor Bronze. Riveted Joints and Locomotive Turntables.

Rule 9 under Instructions for the Mill Inspection of Structural Steel was then read.

W. R. Edwards, (B. & O.): It seems to me questionable whether we should insert an instruction of this kind which is entirely contrary to the mill practice at the present day, and which it is impossible for the inspector to carry out.

Mr Himes: The particular question raised by Mr. Edwards is cared for in Section 10, which says, "Report promptly the shipment of any material from the mill, whose surface inspection has been waived. Such material should be examined by the shop inspector."

A. W. Carpenter (N. Y. C. & H. R.): I will read an extract from a letter from our chief mill inspector which may be of interest:

"Owing to the inability of mill inspectors to examine the finished mill product at the mill and before shipment, but little mill inspection is now made along the lines as at first set out. In order to fully comply with this provision it would be necessary to have a number of inspectors at the mill day and night, and who under the present mill arrangement, will have to be stationed at the hot beds beyond the finishing rolls. The mills, if they were required to handle the product for service inspection, for instance at the loading wharfs, or sheds, have not usually provided any room or facilities for laying out and turning over of the structural material. (Rails they have provided for.) They would object strenuously to such an arrangement, and it would certainly make endless contention and confusion. As a stand off, in lieu of this, they have their own inspectors who look after the surfaces and throw out all defective material. The following inspector, accepting the material on test, they then ship forward, and if it is found to be defective on arrival at the shops where it is to be fabricated into the members intended, by the shop inspector, it is thrown out and ordered to be replaced."

The secretary then read "Instructions for the Inspection of the Fabrication of Steel Bridges."

Mr. Carpenter: What does "Camber is not reversed" mean in Rule 16?

O. E. Selby (C. C. C. & St. L.): There is a certain liability of riveting the base plates on the wrong side of the girder, and as some are designed the top flange is just like the bottom flange and they might be mixed up by careless shop work, and the bottom plate might be riveted on the top flange, instead of the bottom flange. I think that is what the clause means in referring to the camber.

T. Earle (Penn. Steel Co.): I would suggest in place of camber that the word "Bevel" be used, and then I think the clause will have a definite meaning. (The suggestion was accepted.)

Mr. Himes: The committee would be willing to make Rule 20 paragraph read: "Examine and measure bored pinholes carefully to insure proper position, dimension and spacing and smoothness of finish."

Mr. Earle: It seems to me it is hardly proper in instructions as Rule 23 to tell an inspector to do something that is not in the contract. It says, even if the contract does not call for the assembling, that the inspector shall require it. That seems hardly proper.

F. W. Wolffe (M. P.): The clause is decidedly objectionable, because it will invite the inspector to ask for an assembling and save himself the trouble of carefully measuring up the connections, which ought to be a part of his duty.

Mr. Cartlidge: I move that the committee be asked to consider this paragraph 23 further. I believe with Mr. Earle and Mr. Wolffe that this clause will cause difficulty. (The motion was carried.)

Mr. Carpenter: It seems to me there is a little redundancy in paragraph 28. Seems to me the driving pit is pretty nearly a definition of accuracy in itself. I would recommend omiting the word "driving."

The President: The committee will accept that.

Mr. Carpenter: There are a few additional clauses which seem to me might be added to this list of instructions that are not as important as most of those mentioned. One of them is to check the dimensions of the material used in each member. I see no reference to that. It seems to me that the fundamental thing is to see that the proper material goes into the members, and if there is anything that we want to call the attention of the shop to it is the checking of the material in the members to see that everything corresponds. I make a motion that we check the material in each member.

O. E. Selby, (C. C. C. & St. L.): Clause 8 seems to cover the question raised by Mr. Carpenter. "Care in assembling," is a somewhat general expression, but "proper attention to the assembling" would include checking the dimensions of the material assembled.

E. A. Frink, (S. A. L. Ry.): In rising to second Mr. Carpenter's motion I would like to say, I think the question of the size of the material is of importance. It is not at all unusual to have members of the same size of varying weights on the same struction. (The motion was carried.)

Mr. Carpenter: In section 20 under Inspection of Bridge Erection, it is not always desired to re-erect old structures. I would suggest after the word, "removed" we insert "which it is desired to re-erect."

The President: The committee will accept that.

Mr. Carpenter: It happens very frequently that a number of parts are bent in erection, especially lattice parts, and compression rivets, and I think a clause requiring the straightening of such parts, especially mentioning lattice parts, would be desirable.

Mr. Lindsay: There are no instructions requiring the inspector to look out for damaged new members, either in the unloading or the erection. I think another point to be guarded against in the unloading and storing of material is to prevent the accumulation of water on members.

The President: It is now in order to adopt these instructions as amended, for insertion in the Manual. Before putting the motion, however, the committee desires to omit

paragraph 23, under fabrication of steel bridges, and it will be taken up as one of the matters for future improvement. If there is no objection we will consider it as referred to the committee in the sense of re-writing it as an additional clause next year, but it will be entirely disregarded in this action of accepting the three sets of instructions for printing in the Manual. Those in favor of adopting these instructions for publication in the Manual, please signify by saying aye. (The motion was carried.)

TRACK.

The committee presents statements of general principles to be followed in the design and manufacture of tie-plates, track bolts and anti-creepers and specifications for steel tie-plates, malleable tie-plates, wrought-iron tie-plates, track bolts, spiral spring nutlocks, ordinary track spikes and screw spikes.

TIE-PLATES.

General Principles to Be Followed in the Design.

The plates shall not be less than six inches in width, and as much wider as consistent with the class of ties to be used.

The length of the plates shall be not less than the safe bearing area of the ties divided by the width of the plate, and, when made for screw spikes, shall be so shaped as to provide proper support for the screw spikes.

J. B. JENKINS,
Chairman Committee on Track.

They shall be not less than ⅝ inch thick along either edge of the base of the rail.

The thickness of the plate shall be properly proportioned to the length.

The plates shall have a shoulder at least ½ inch high. The distance from the edge of rail base to the end of the tie-plate on the outer side must be uniform, and in excess of the projection inside of the rail base.

Where treated ties are used or where plates are for screw spikes, a flat bottom plate is preferable. Where ribs of any kind are used on base of plate, these shall be few in number and not to exceed ¼ inch in depth.

The punching must correspond to the slotting in the splice bars, and, where advisable, may be so arranged that the plates may be used for joints. Spike holes may be punched for varying widths of rail base where the slotting will permit such punching without the holes interfering with each other and when the plate is of such design that the additional holes will not impair the strength of the plate.

SPECIFICATIONS FOR STEEL TIE-PLATES.

Material.

The plates shall be made of Bessemer or open-hearth steel.

Physical Properties and Tests.

The tie-plates shall conform to the following requirements:
Ultimate strength, not less than 55,000 lbs.
Elastic limit, not less than 50 per cent of ultimate strength.
Elongation, not less than 20 per cent in 2 inches.
Reduction of area, not less than 40 per cent.

Plates shall bend cold for 90 deg. without showing any sign of fracture.

A sufficient number of tests will be made to satisfy the inspector that the material meets the specifications in every respect.

Workmanship and Finish.

Subject to the following allowances, the form and dimensions of the plates shall conform to the drawings submitted to the manufacturer.

The length and width shall not vary more than ⅛ inch from the dimensions shown.

The thickness shall not vary more than 1/32 inch from the dimensions shown.

All variations in length shall be left on the inside end of the plate.

The distance from the shoulder to the outside end of the plate must be made uniform.

The spike holes must be punched from the top, clean cut, without burrs, and the plates must not be cracked or bent out of shape in punching the holes.

All plates must be stamped on the top side, outside of the base of rail, with the section and weight of rail.

The plates shall be free from burrs and imperfections.

Inspection.

When required, the manufacturer shall furnish samples of tie-plates from a preliminary rolling before proceeding with the filling of the order and give sufficient notice in advance of the date when they will be ready for inspection.

The inspector representing the purchaser shall have free entry at all times, while the work on the contract of the purchaser is being performed, to all parts of the manufacturer's works which concern the manufacture of the material ordered.

The inspection shall be made at the mill and the manufacturer shall afford the inspector free of cost all reasonable facilities to satisfy himself that the plates are being furnished in accordance with these specifications. The tests and inspection shall be so conducted as not to interfere unnecessarily with the operation of the works.

Tests shall be made of samples of the finished product selected by the inspector from each lot of 50 bundles. Two pieces shall be selected for each test, and if both meet the requirements of the specifications the lot will be accepted. If one of the test pieces fails a third test piece shall be selected and tested; if it meets the requirements of the specifications the lot will be accepted, but if it fails the lot will be rejected.

If, after shipment, any tie-plates are found to be defective, due to material or manufacture, they may be rejected.

Shipping.

Tie-plates shall be wired together in bundles, the weight not to exceed 100 lbs., and shipped with a uniform number in each bundle.

SPECIFICATIONS FOR WROUGHT-IRON TIE-PLATES.

Material.

The plates shall be made of wrought-iron.

Physical Properties and Tests.

The ultimate strength shall be not less than 45,000 lbs.

Plates shall bend cold for 90 deg. without showing any sign of fracture.

A sufficient number of tests will be made to satisfy the inspector that the material meets the specifications in every respect.

Workmanship and Finish.

Subject to the following allowances, the form and dimensions of the plates shall conform to the drawings submitted to the manufacturer.

The length and width shall not vary more than ⅛ inch from the dimensions shown.

The thickness shall not vary more than 1/32 inch from the dimensions shown.

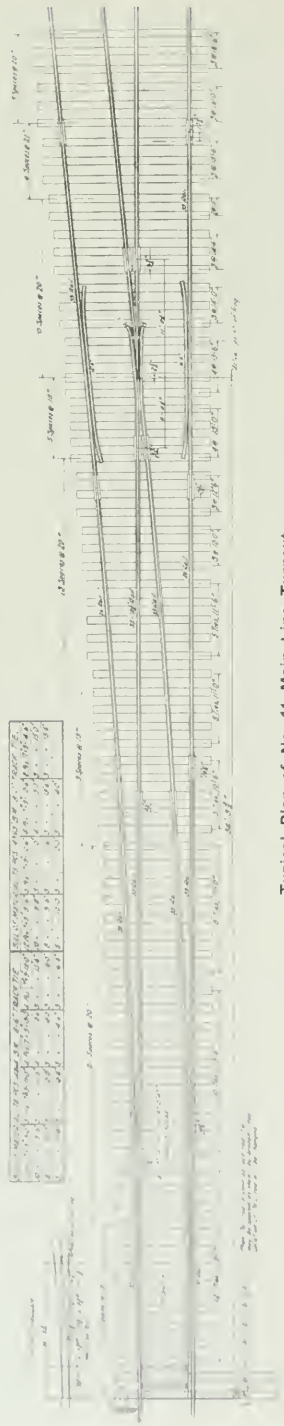
All variations in length shall be left on the inside end of the plate.

The distance from the shoulder to the outside end of the plate must be made uniform.

The spike holes must be punched from the top, clean cut, without burrs, and the plates must not be cracked or bent out of shape in punching the holes.

All plates must be stamped on the top side, outside of the base of rail, with the section and weight of rail.

The plates shall be free from burrs and imperfections.



Typical Plan of No. 11 Main Line Turnout.

Inspection.

When required, the manufacturer shall furnish samples of tie-plates from a preliminary rolling before proceeding with the filling of the order and give sufficient notice in advance of the date when they will be ready for inspection.

The inspector representing the purchaser shall have free entry at all times, while the work on the contract of the purchaser is being performed, to all parts of the manufacturer's works which concern the manufacture of the material ordered.

The inspection shall be made at the mill and the manufacturer shall afford the inspector free of cost all reasonable facilities to satisfy himself that the plates are being furnished in accordance with these specifications.

These tests and inspections shall be so conducted as not to interfere unnecessarily with the operation of the works.

Tests shall be made of samples of the finished product selected by the inspector from each lot of 50 bundles. Two pieces shall be selected for each test, and if both meet the requirements of the specifications, the lot will be accepted. If one of the test pieces fails a third test piece shall be selected and tested; if it meets the requirements of the specifications the lot will be accepted, but if it fails the lot will be rejected.

If, after shipment, any tie-plates are found to be defective, due to material or manufacture, they must be rejected.

Shipping.

Tie-plates shall be wired together in bundles, the weight not to exceed 100 lbs., and shipped with a uniform number in each bundle.

SPECIFICATIONS FOR MALLEABLE TIE-PLATES.

Material.

The plates shall be made from furnace malleable iron.

Physical Properties and Tests.

All plates must be cast with a lug for test purposes. The test lug when broken off must not break easily, as cast-iron, but must bend and show signs of toughness The fracture must show a narrow band of white metal on the surface, the center portion being dark and fiberless.

The plates must bend sufficiently to show thorough annealing.

A sufficient number of tests will be made to satisfy the inspector that the material meets the specifications in every respect.

Workmanship and Finish.

Subject to the following allowances, the form and dimensions of the plate shall conform to the drawings submitted to the manufacturer.

The length and width shall not vary more than 1-16 inch from the dimensions shown.

The thickness shall not vary more than 1-32 inch from the dimensions shown.

All plates must be properly and thoroughly annealed.

All plates must be well cleaned and free from warping, shrinkage, cracks, blow holes, fins, and other imperfections.

Inspection.

When required, the manufacturer shall furnish samples of tie-plates from a preliminary lot before proceeding with th filling of the order and give sufficient notice in advance of the date when they will be ready for inspection.

The inspector representing the purchaser shall have free entry at all times, while the work on the contract of the purchaser is being performed, to all parts of the manufacturer's works which concern the manufacture of the material ordered.

The inspection shall be made at the mill and the manufacturer shall afford the inspector free of cost all reasonable facilities to satisfy himself that the plates are being furnished in accordance with these specifications.

These tests and inspection shall be so conducted as not to interfere unnecessarily with the operation of the works.

If, after shipment, any tie-plates are found to be defective, due to material or manufacture, they may be rejected.

Shipping.

Tie-plates shall be wired together in bundles, not to exceed 100 pounds, and shipped with a uniform number in each bundle.

TRACK BOLTS.

Facts and General Principles to Be Taken into Consideration in the Design.

As a rule, as large track bolts should be used as the rail and splice bars will permit.

Bolts with rolled threads show a greater ultimate strength than those of the same size with cut threads. The elastic limit, however, is not materially different.

A workman pulling on a 33-inch wrench with a pull of 100 pounds will load a ⅞-inch diameter bolt to the extent of 45,000 pounds per square inch, where the threads are in average condition. Therefore, it is easy to see how a bolt with a low elastic limit will readily be stretched in being tightened.

A ⅞-inch bolt with an elastic limit of 45,000 pounds will require the same pull to stretch it as a 1-inch bolt with an elastic limit of 35,000 pounds. Again, a 1-inch bolt with an elastic limit of 75,000 pounds requires over twice the pull to stretch it as a 1-inch bolt with an elastic limit of 35,000 pounds.

SPECIFICATIONS FOR TRACK BOLTS.

Material.

Steel shall be made by the open-hearth or other approved process. If necessary to secure the properties desired, the bolts may be heat treated.

Physical Properties and Tests.

The bolts shall conform to the following requirements:

For carbon steel				
For untreated nickel or other alloy steel				
For heat treated nickel or other alloy steel				
Elastic limit	not less	than	35,000	lbs. per sq. in.
Elastic limit,	"	"	25	per cent in 2 in.
Elastic limit,	"	"	50	per cent.
Elongation,	"	"	45,000	lbs. per sq. in.
Elongation,	"	"	20	per cent. in 2 in.
Elongation,	"	"	40	per cent.
Reduction of area,	"	"	75,000	lbs. per sq. in.
Reduction of area,	"	"	15	per cent in 2 in.
Reduction of area,	"	"	40	per cent.

Elastic limit shall in no case be less than 50 per cent of the ultimate strength.

The elastic limit, elongation and reduction of area may be determined on a test piece ½x2 in. turned from a finished bolt.

The ductility of the bolts shall be determined by the cold bend test, which requires that the material used in the bolts shall bend cold through 180 deg. and flatten itself without fracture on the outside of the bent portion. This bend may be made on the unthreaded portion of a finished bolt, on a blank bolt, or on a test piece of the same size and same grade of steel, in any case, subjected to the same treatment as the finished bolt. It is not necessary that the bolt bend double in the threaded portion.

A sufficient number of tests shall be made to satisfy the inspector that the material meets the specifications in every respect.

Workmanship and Finish.

Subject to the following allowances, track bolts shall conform to the drawings submitted to the manufacturer:

The length shall not be more than 1/16 inch less or ⅛ inch more than the dimensions shown.

The diameter of the bolt shall not vary more than 1-64 inch from the dimensions shown.

The size of the head shall not vary more than 1-16 inch from the dimensions shown.

The outside dimensions of the nut shall not vary more than 1-32 inch from the dimensions shown.

The shoulder of the bolt shall not vary more than 1-64 inch from the dimensions shown.

The heads and nuts shall be free from checks or burrs of any kind. They shall have the U. S. Standard upset thread unless otherwise specified. The threads may be either cut or rolled and shall be full and clean, with not less than two, or more than five, finger threads.

Inspection.

When required, the manufacturer shall furnish samples of bolts from a preliminary rolling before proceeding with the filling of the order and give sufficient notice in advance of the date when they will be ready for inspection.

The inspector representing the purchaser shall have free entry at all times, while the work on the contract of the purchaser is being performed, to all parts of the manufacturer's works which concern the manufacture of the material ordered.

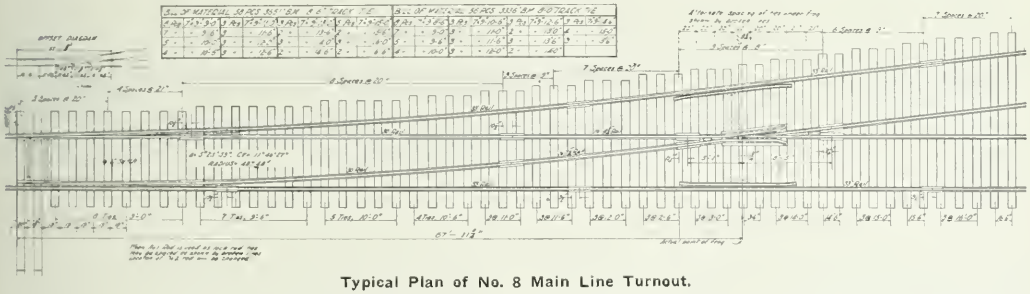
The inspection shall be made at the mill and the manufacturer shall afford the inspector free of cost all reasonable facilities to satisfy himself that the bolts are being furnished in accordance with these specifications. Tests and inspection shall be so conducted as not to interfere unnecessarily with the occupation of the works.

Tests shall be made of samples of the finished product selected by the inspector from each lot of 100 kegs. Two pieces shall be selected for each test and if both meet the requirements of the specifications the lot will be accepted. If one of the test pieces fails a third test piece shall be selected and tested; if it meets the requirements of the specifications the lot will be accepted, but if it fails the lot will be rejected.

If, after shipment, any bolts are found to be defective, due to material or manufacture, they may be rejected.

Marking and Shipping.

When the bolts are shipped they shall have the nuts applied for at least two threads, shall be properly oiled to prevent rusting and shall be packed in serviceable kegs. All kegs must be plainly marked as to material, size of bolts and name of manufacturer.



Typical Plan of No. 8 Main Line Turnout.

SPECIFICATIONS FOR SPIRAL SPRING NUTLOCKS.

Material.

The steel from which the nutlocks are made must be of open-hearth steel, or other approved process, and shall conform to the following chemical analysis:

Phosphorus,	not over	.05	per cent.
Sulphur	" "	.05	per cent.

Physical Properties and Tests.

After the finished nutlock has been subjected to pressure sufficient to compress it flat for a period of one hour, its reaction shall not be less than two-thirds its height or thickness of section, providing thickness is less than width of section. If the section is square, the reaction must not be less than one-half its thickness. If height or thickness of section is more than its width, reaction shall not be less than the width of the section.*

With one end of the finished nutlock secured in a vise, and the opposite end twisted to 45 degrees, there must be no sign of a fracture. When further twisted until

*Note.—The internal diameters naturally affect the percentage of reaction, and the above specifications apply to nutlocks of internal diameters from 13-16 in. to 1 5-16 in. Owing to the difficulty of establishing a common rate of percentage that shall be uniformly applicable to any internal diameter of any nutlock of any section, it has been sought to cover the matter as above. The amount and durability of the reactionary power under constant pressure is the true test of any spiral spring nutlock. The percentage of reaction increases proportionately with the increased internal diameter of any given section.

broken, the fracture must show a good quality of steel.

A sufficient number of tests will be made to satisfy the inspector that the material meets the specifications in every respect.

Workmanship and Finish.

The dimensions and form of the nutlock shall conform to the drawings submitted to the manufacturer.

The nutlocks shall be clean, without burrs or rough edges. The coil and cross-section shall be uniform throughout.

The manufacturer is required to guarantee:

First. That the steel was thoroughly annealed and permitted to assume its proper molecular structure before being made into nutlocks.

Second. That the subsequent heat treatment was scientifically accurate according to the best methods known, to secure uniformity of temper and the highest efficiency attainable.

Inspection.

When required, the manufacturer shall furnish samples of nutlocks from a preliminary lot before proceeding with the filling of the order, and give sufficient notice in advance of the date when they will be ready for inspection.

The inspector representing the purchaser shall have free entry at all times, while the work on the contract of the purchaser is being performed, to all parts of the manufacturer's works which concern the manufacture of the material ordered.

The inspection shall be made at the mill and the manufacturer shall afford the inspector free of cost all reasonable facilities to satisfy himself that the nutlocks are being furnished in accordance with these specifications. The tests and inspection shall be so conducted as not to interfere unnecessarily with the operation of the works.

Tests shall be made of samples of the finished product selected by the inspector from each separate heat treatment. Two pieces shall be selected for each test and if both meet the requirements of the specifications the lot will be accepted. If one of the test pieces fails a third test piece shall be selected and tested; if it meets the requirements of the specifications the lot will be accepted, but if it fails the lot will be rejected.

If, after shipment, any nutlocks are found to be defective, due to material or manufacture, they may be rejected.

Marking and Shipping.

When the nutlocks are shipped they shall be packed in good serviceable boxes. All boxes must be plainly marked as to material, size and number contained therein, and the name of the manufacturer.

SPECIFICATIONS FOR ORDINARY TRACK SPIKES.

Material.

Steel shall be made by the open-hearth or other approved process. If necessary to secure the properties desired the spikes may be heat treated.

Physical Properties and Tests.

The spikes shall conform to the following requirements:

Ultimate strength, not less than 55,000 pounds.

Elastic limit, not less than 50 per cent of ultimate strength.

Elongation, not less than 20 per cent in 2 inches.

Reduction of area, not less than 40 per cent.

The finished spike, when bent back on itself through 180 deg. and hammered down, shall show no signs of fracture.

When the head of the spike is bent backward cold it shall show no signs of fracture.

When the body of the spike is twisted cold 1½ turns it shall show no signs of fracture.

A sufficient number of tests will be made to satisfy the inspector that the material meets the specifications in every respect.

Workmanship and Finish.

Subject to the following allowances, the form and dimensions of the spike shall conform to the drawings submitted to the manufacturer.

The thickness shall not vary more than 1-32 inch from the dimensions shown.

The length shall not be less, nor over ¼ inch more, than the dimensions shown.

The thickness of the head shall not vary more than 1-16 inch from the dimensions shown.

The angle of the hook shall not vary more than one degree from that shown on the drawing.

The spikes must be neatly formed, free from burrs and rough edges, and have well-shaped heads and sharp points.

Inspection.

When required, the manufacturer shall furnish samples of spikes from a preliminary rolling before proceeding with the filling of the order and give sufficient notice in advance of the date when they will be ready for inspection.

The inspector representing the purchaser shall have free entry at all times, while the work on the contract of the purchaser is being performed, to all parts of the manufacturer's works which concern the manufacture of the material ordered.

The inspection shall be made at the mill and the manufacturer shall afford the inspector free of cost all reasonable facilities to satisfy himself that the spikes are being furnished in accordance with these specifications. The tests and inspection shall be so conducted as not to interfere unnecessarily with the operation of the works.

Tests shall be made of samples of the finished product selected by the inspector from each lot of 100 kegs or bags. Two pieces shall be selected for each test and if both meet the requirements of the specifications the lot will be accepted. If one of the test pieces fails a third test piece shall be selected and tested; if it meets the requirements of the specifications the lot will be accepted, but if it fails the lot will be rejected.

If, after shipment, any spikes are found to be defective, due to material or manufacture, they may be rejected.

Marking and Shipping.

When the spikes are shipped they shall be packed in good serviceable kegs or bags. All kegs or bags must be plainly marked as to material, size of spikes and name of manufacturer.

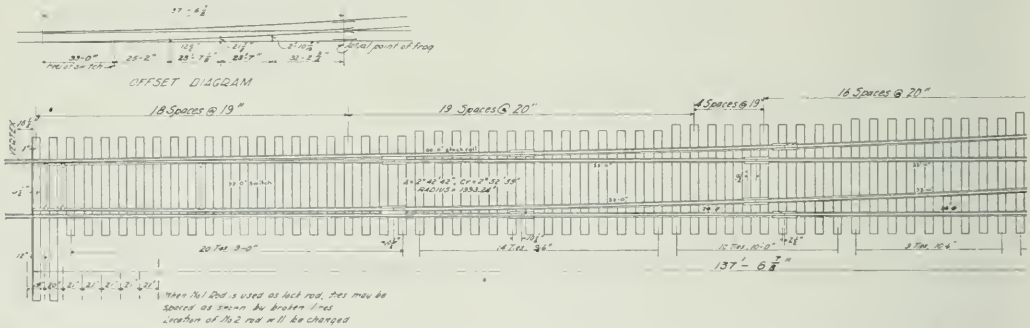
SPECIFICATIONS FOR SCREW SPIKES.

Material.

Screw spikes shall be made of open-hearth steel.

The chemical properties of the finished spike shall conform to the following limits:

Phosphorus,	not over .05 per cent.
Sulphur,	" " .05 per cent.



Physical Properties and Tests.

The finished spike shall conform to the following requirements:

Ultimate strength, not less than 60,000 lbs. per sq. in.

Elastic limit, not less than 50 per cent of ultimate strength.

Elongation, not less than 22 per cent in 2 in.

Reduction of area, not less than 40 per cent.

The material used in the spikes when bent cold through an angle of 180 deg. and hammered down shall show no signs of fracture.

The finished spike when bent cold through an angle of 90 deg. shall show no signs of fracture.

A sufficient number of tests will be made to satisfy the inspector that the material meets the specifications in every respect.

Workmanship and Finish.

The dimensions and form of the screw spike shall conform to the drawings submitted to the manufacturer.

All spikes shall be finished smooth and in a workmanlike manner, having no rough edges. They shall be of exact size, with symmetrical heads the axis of which must be situated in the direct line of the shank axis produced.

Inspection.

When required, the manufacturer shall furnish samples of spikes from a preliminary rolling before proceeding with the filling of the order and give sufficient notice in advance of the date when they will be ready for inspection.

The inspector representing the purchaser shall have free entry at all times, while the work on the contract of the purchaser is being performed, to all parts of the manufacturer's works which concern the manufacture of the material ordered.

The inspection shall be made at the mill and the manufacturer shall afford the inspector free of cost all reasonable facilities to satisfy himself that the spikes are being furnished in accordance with these specifications. The tests and inspection shall be so conducted as not to interfere unnecessarily with the operation of the works.

Tests shall be made of samples of the finished product selected by the inspector from each lot of 100 kegs or bags. Two pieces shall be selected for each test and if both meet the requirements of the specifications the lot will be accepted. If one of the test pieces fails a third test piece shall be selected and tested; if it meets the requirements of the specifications the lot will be accepted, but if it fails the lot will be rejected.

If, after shipment, any spikes are found to be defective, due to material or manufacture, they may be rejected.

Marking and Shipping.

When the spikes are shipped they shall be properly oiled to prevent rusting and shall be packed in good serviceable kegs or bags. All kegs or bags must be plainly marked as to material, size of spike and name of manufacturer.

ANTI-CREEPERS.

General Requirements to Be Met in the Design and Manufacture.

They shall be so designed as to fit two or more different weights of rail and so that they can be readily removed and reapplied.

They must be easy to apply under full-ballasted track.

They must be substantial enough to stand driving to place without chance of breaking.

The least possible number of movable parts is desirable.

When applied they must be in position rigidly enough to carry the tie with them in any kind of ballast without slipping.

They shall be made with sufficient take-up to permit of proper tightening.

They must not loosen when in place, or sufficiently to slip when the rail slacks back.

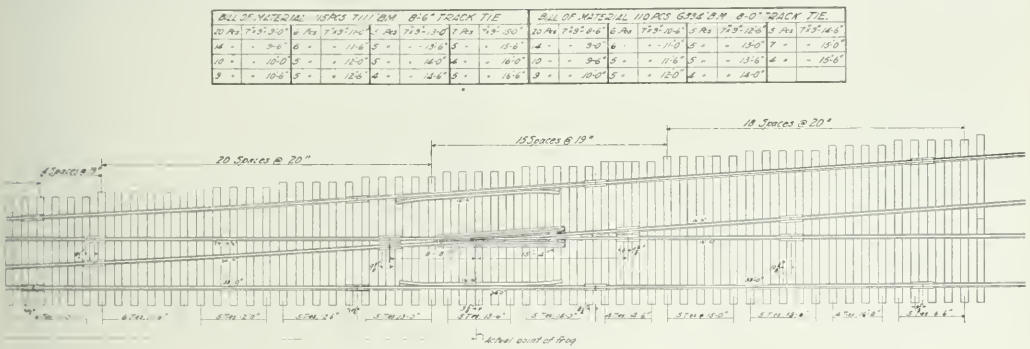
Controlling or delicate parts should be made of non-rustable material.

Anti-creepers made of steel shall be of sufficient size to minimize the destruction by rust.

Anti-creepers made of malleable iron must be from furnace malleable iron properly annealed, and of sufficient weight to prevent breakage and distortion in application or in service.

STUDY OF DESIGN OF MAIN LINE TURNOUTS.

The committee presents typical plans illustrating recommended designs for Nos. 8, 11 and 16 main line turnouts. In addition, it has secured data as to the height of center of gravity of locomotives and tenders recently constructed and has under way a table showing the speed at which trains may be run through various turnouts and various curves with different elevations of outer rail, for publication as a matter of information. This information is not yet in shape for submission. The committee has also begun the preparation of typical plans for cross-overs.



Typical Plan of No. 16 Main Line Turnout.

ECONOMICS IN TRACK LABOR.

The committee adopted the following preliminary outline for future study, the plan being comprehensive and intended to cover the work of several years:

A system of reports to measure the efficiency of gangs for various kinds of work and the efficiency of various kinds of labor with a view to establishing tangible data to correctly measure efficiency.

A system of reports to establish unit costs of work.

The use of a system of work cards and other means of planning work and keeping records to measure progress.

The development of a plan and system for establishing a thoroughly accurate basis of comparison of track conditions as a means for measuring efficiency—equating for various conditions, such as rails, ballast, ties, drainage, length of track, etc.

A study of the use and efficiency of motor cars for track work.

A study of labor-saving devices.

A study of the method best suited to various kinds of track work, particular reference being made to rail, ballast and tie renewals.

A study of the method of renewing ties, as to renewal of ties on every mile of track each year or taking a portion of the track each year to avoid disturbing track too often.

A study of the matter of proper season for various kinds of track work.

A study of the organization best suited to carry on the above work as to extra gangs versus section gangs.

A study of the general suggestion to combine under section foremen such work as ordinary maintenance of signals and telegraph lines, rough carpentry, water station repairs, etc.

Proper size of track supervisors' territory.

The establishment of a labor bureau to better control and secure labor.

Training laborers for track work by specially organized gangs for that purpose.

Rates of pay for section labor.

The matter of obtaining good section foremen.

The education of section foremen.

The rates of pay of section foremen.

The proper basis for providing section houses.

The subjects chosen for immediate investigation were the matter of educating and securing section foremen and method of making program of work and sequence of work.

Two circulars were prepared and submitted to the membership dealing with these subjects. A great deal of information has been received, some of which enables the committee to reach a conclusion with reference to certain matters, and in other instances the information furnished is not in sufficient detail to enable a conclusion to be reached at this time, and these matters will be the subject of further research. Eighty-seven replies were received to this circular, and the following represents the summary of the information received:

"A" Has your company in effect any plan for the systematic education of men to fill the places of section foremen?

"C" Do you have any defined plan of equipping gangs with apprentices and assistant foremen?

Of the total replies received

57 indicated no plan in effect.

23 reported the practice of employing assistant foremen.

6 reported the practice of employing apprentices.

1 reported the use of a "school gang" for the education of foremen.

1 reported no information.

2 reported the practice of using both assistant foremen and apprentices.

"D" Do you have any defined plan of educating foremen as a class by instruction, such as educational bureaus, periodical meetings, etc.?

Of the replies received

72 indicated no definite plan for education.

10 reported the practice of periodically instructing men through meetings.

3 reported the use of educational bureaus.

1 reported education by pamphlet, and

1 reported education by inspection trips to other roads.

"B" From what classes of men do you now select foremen?

The intent of this question was to develop to what extent selections were made for foremen from certain nationalities or classes of labor, but the information received is quite general and not sufficiently specific to enable the sub-committee to give a very accurate opinion upon this matter, and this is to be made the subject of further research with a view to determining the relative efficiency of various classes or nationalities, information showing the number of each nationality employed, their qualifications as to honesty, reliability and general efficiency, and the effect, in employing foreigners for section foremen, in improving the supply of labor for ordinary section work with a view to overcoming the difficulties now existing in foreign labor desiring to work generally in large gangs.

"J" What percentage of your foremen are foreign born?

25 report none employed.

27 report 25 per cent or less.

16 report 50 per cent or less.

8 report 75 per cent or less.

7 report 100 per cent or less, and

4 give no information.

CONCLUSIONS.

The committee recommends for adoption and publication in the manual:

1. As representing good practice:

(a) Tie plates—General principles to be followed in the design.

(b) Specifications for steel tie plates.

(c) Specifications for wrought iron tie plates.

(d) Specifications for malleable tie plates.

(e) Track bolts—Facts and general principles to be taken into consideration in the design.

(f) Specifications for track bolts.

(g) Specifications for spiral spring nutlocks.

(h) Specifications for ordinary track spikes.

(i) Specifications for screw spikes.

(j) Anti-creepers—General requirements to be met in the design and manufacture.

2. As representing good practice:

Typical plans of Nos. 8, 11 and 16 main line turnouts.

3. As desirable agencies to obtain a better class of section foremen:

(a) The application of the principle of apprenticeship for a defined period during which the rate of pay shall be the same as a laborer, following which those men who show the necessary qualities for foremanship to be given an increase in compensation and the title of assistant foreman. From this position those men should be promoted to that of section foreman.

(b) The application of a method of education by periodical instruction in the form of meetings, at which supervising officers should instruct as to practice and encourage discussion between the men.

(c) The application where possible of an educational system, such as is being conducted on several of the larger railways, for which articles are written by supervising officers dealing with the best practices, which articles are printed and sent to foremen and assistant foremen free of cost, following which an examination is conducted and promotions depending on the results of such examinations.

4. The "Table of Functions of the Ten-chord Spiral" as supplementing and completing the table on pages 102-110 of the manual and superseding the table on page 111.

5. The headings "W = Length Theoretical Point to Toe" and "K = Length Theoretical Point of Heel" in place of "W = Length Point to Toe" and "K = Length Point to Heel" in columns II and III, Table of Theoretical and Practical Switch Leads on page 92 of the manual.

The committee recommends that subjects 2 and 3 be reassigned, the former with instructions as to the features to be studied.

Discussion on Track.

Conclusion No. 2 was adopted, the term "timber," replacing the word "material." Conclusions No. 3, 4 and 5 were also adopted.

Mr. Jenkins: I would move the adoption and publication in the Manual of Specification (a) in conclusion No. 1.

Mr. Stimson: I move the third paragraph specifying 5/8 in. thickness be stricken out and that it be considered that the thickness of the plate is covered by the next paragraph, and that there are comparatively few tie-plates now in use 5/8 in. thick. (The motion was seconded and carried.)

The Secretary read the paragraph beginning, "The spike holes must be punched——"

Mr. Jenkins: I wish to announce that the committee by letter ballot amended that specification so as to read, "The spike holes must be punched clean cut, without burrs, and the places must not be cracked or bent out of shape in punching the holes." The committee recognizes in the majority of cases it is best to punch the holes from the top, and that should be the general practice, but there are special cases where the holes should be punched from the bottom, where the punching cannot be successfully done from the top.

Mr. Lindsay: In connection with section relating to the stamping of plates, I think that would be improved if it read, "All plates must be stamped on the top side, outside of the rail seat, with the prescribed mark indicating the section and weight of the rail." I make that suggestion because on many roads we have our standard tie-plate which gives a distinct letter or number for the tie plate that is to be used with certain weights of rails. There are certain letters which are to be used for the tie-plate at the joint, and others at the end of the angle bar. I believe if it is made to read in the form I have suggested, it would be more universally applicable.

The President: The committee will accept that amended reading.

Mr. Lindsay: Under the heading "Shipping" at the end of the specifications for steel tie-plates, I would like to substitute the following: . . . "Tie-plates shall be wired to-

gether in bundles of uniform number, weighing not to exceed 100 lbs. and properly tagged."

Mr. Jenkins: The committee will accept that suggestion.

The President: A motion was made and seconded that the general principles to be followed in the design of tie plates, as amended be adopted for publication in the manual.

The motion was put to vote and carried.

Mr. Jenkins: I move the adoption for publication in the Manual of the Specifications for Steel Tie-Plates, as amended.

The motion was carried.

The secretary then read the Specifications for Wrought-Iron Tie-plates.

L. C. Fritch: I move that the specifications for wrought-iron tie-plates be amended to harmonize with the amendments in connection with the specifications for steel tie-plates, which are substantially the same as the specifications for wrought-iron tie-plates.

The motion was carried.

Mr. Lindsay: I suggest that the Specification for Malleable Tie-Plates be read, caption by caption.

Mr. Fritch: Under "Workmanship and Finish," it is stated that the length and width shall not vary more than 1/16 in. from the dimensions shown, while in the wrought iron and steel specifications it is given as ⅛ in. What is given as the difference?

Mr. Jenkins: The malleable tie-plates can be made to conform better to the dimensions than the steel tie-plates can.

Mr. Lindsay: I move that the shipping articles be changed to agree with the same article under steel tie-plates and wrought iron tie-plates.

The President: The committeee will agree to that.

Mr. Jenkins: I move that the specifications for malleable tie-plates be adopted. (The motion was carried.)

(The Secretary read the Facts and General Principles to Be Taken into Consideration in the Design of Track Bolts, which was adopted.)

The Secretary read the specifications for Track Bolts.

Mr. Lindsay: Under "Workmanship and Finish," I would like a clause somewhat as follows inserted: "Care must be taken to avoid damage to the metal by overheating in manufacture."

Mr. Jenkins: The committee will accept that.

Mr. Jenkins: I move that Specification for Track Bolts be adopted as amended for publication in the Manual. (The motion was carried.)

(The Secretary read the specifications for Spiral Spring Nut Locks, and they were adopted.)

The Specifications for Ordinary Track Spikes were then read.

The President: In connection with these specifications, it is understood that any changes made in the previous specifications that should be made in these specifications to make them harmonize with the others will be made in these specifications.

Mr. Fritch: I think somewhere in the specifications we should show how the length of the spikes should be measured, whether it should be the length over all, or the measurements should be under the head.

Mr. Jenkins: The committee will amend the paragraph just read by having it begin "The length under the head," etc.

The President: That will undoubtedly be acceptable.

Mr. Jenkins: I move the adoption, for publication in the Manual, of the Specifications for Ordinary Track Spikes. (The motion was carried.)

(The secretary read the specifications for screw spikes.)

Mr. Lindsay: Have the committee considered the method of making the thread on the screw spike, or do they think it necessary to specify how the thread should be formed?

G. J. Ray: There is only one way that the thread can be made economically, and that is rolled. When you buy them, you will find that the manufacturer who makes them in any other way will not be able to compete with the markets. I do not think there is any question but what the method of manufacture will take care of itself. You have to roll them to make them economically.

Mr. Lindsay: Many spikes are shipped in boxes. I think the paragraph should read "Good serviceable boxes, kegs, or bags."

Mr. Jenkins: The committee will change that by making it read "Shall be packed in good serviceable packages."

Mr. McDonald: Why was Bessemer steel cut out in connection with screw spikes as well as bolts, and retained in regard to tie plates.

Mr. Jenkins: We think a better quality of material is required in screw spikes and bolts than in tie plates.

Mr. Jenkins: I move the adoption and publication in the Manual of the Specifications for Screw Spikes. The motion was carried.

The secretary read the general requirements to be met in the design and manufacture of anti-creepers.

Mr. Lindsay: I think the clause should read: "They must not loosen when in place sufficiently to render the anti-creeper inoperative when the rail slacks back."

The President: The committee will accept that.

Mr. Jenkins: I move the adoption of the general requirements to be met in the design and manufacture of anti-creepers for publication in the Manual. (The motion was carried.)

E. F. Wendt (P. & L. E.): I want to make a few remarks on the question of "Economics in Track Labor," referred to in this report. A number of the committees have begun the study of economics. This work grows out of the paper of Mr. Loree submitted at the last convention, which showed that about 55 per cent of all of the expenses of a railroad consisted in the cost of labor. The object of our association is the advancement of knowledge pertaining to the scientific and economic maintenance of railways. I submit that we have done well to take up these scientific studies which relate to the economics, and the beginning of this work marks an epoch in the history of our association.

The relation of the cost of labor to the gross revenue of all the railroads in America has risen, as shown by the figures of the Interstate Commerce Commission. During the past 20 years wages to gross revenue have risen from 37.7 to 41.9 per cent. During the same period the ton mile rate, which represents the amount of money the railroad company receives from the public, has declined from 9.3 mills to 7.5 mills, and during the same period the relation of dividends and interest to gross has declined from 28.3 to 24.2 per cent. It is, therefore, apparent that every effort should be made to bring about such economies in labor as are possible.

In our railroad industry there are three interests entitled to a hearing, the capitalist, the wage earner, and the people who use the roads. To show how each of these three interested classes has fared for some time past, here are the percentages of total gross earnings devoted to wages and to interest and dividend payments. How the third party of the contract, the public, as typified by the shipper, has fared can be seen from the average rate per ton per mile:

	Per cent. Wages to Gross	Per cent. Dividends and Interest to Gross	Ton-Mile Rate
1911	41.90 per cent*	24.27 per cent*	0.750*
1910	40.43	23.47	0.753
1909	40.03	24.33	0.760
1907	40.47	20.99	0.759
1905	39.36	23.84	0.766
1903	38.82	24.47	0.763
1900	37.99	25.74	0.729
1895	40.78	30.17	0.840
1890	37.71	28.37	0.930

Since 1890 wages have risen 11.1 per cent, as compared with gross earnings, while dividend and interest payments taken together, notwithstanding the rise of recent years, show a net decline of 14.5 per cent. The general tendency has been to devote a decreasing portion of gross earnings to payments to the capitalist and an increasing portion to wages.

Mr. Lindsay: I ask the committee to study the question of cross-overs. It is a large subject that is in the air, and we are told the recommendations of this committee are all wrong, and that we must have a No. 20 cross-over, to be entirely safe, in order to operate a railroad safely. The committee has considered nothing longer than No. 16 as necessary, and one Public Service commission has gone on record as saying it is entirely safe to run at the normal speeds incident to every day operation through a No. 20 cross-over. I hope the committee in studying this question will give attention to the matter of curvature at the switch angle. I figured roughly with an engine of 17-ft. wheel base on a 15-ft. switch point, with a spread at the heel of 6 in., the curvature is equivalent to 22 deg. and 35 min.; with a 20-ft. switch point, it is 16 deg. and 15 min.; with a 30-ft. switch point, it is 13 deg. and 6 min. Assuming the rigid wheel base of a locomotive as including the distance from the forward pony truck to the rear driver, as 26 ft. with a 15-ft. switch point, the curvature is 14 deg. 34 min.; with a 20-ft. switch point, 10 deg. 55 min., and with a 30-ft. switch point, 8 deg. 30 min. Assuming the rigid wheel base as 34.66, with a 15-ft. switch point, the curvature would be 11 deg. 2 min.; with a 20-ft. switch point, the curvature would be 8 deg. 55 min.; with a 30-ft. switch point the curvature would be 6 deg. 37 min. How fast is it safe to go over the switch point regardless of the curvature of the point, and go by a switch point without any elevation at normal speed?

Mr. Jenkins: The committee has gone ahead with its work

*Estimated.

and has prepared designs for cross-overs which it will submit next year, and the committee has also undertaken to find out the relation of speed to turn-out radius, and the relation of speed to the switch angle, and we have made some progress along that line.

RAIL.

The work outlined by the board of direction for the year was as follows:

(1) Consider revision of the manual; if no changes are recommended, make statement accordingly.
(2) Present recommendations on standard rail sections.
(3) Continue investigation of rail failures and present conclusions drawn therefrom.
(4) Continue special investigation of rails.
(5) Make concise recommendations for next year's work.

REVISION OF MANUAL.

The work of the committee resulted, after several years, in the presentation of a set of specifications for carbon steel rails at the annual convention in 1912, which was adopted by the association.

Since that time, some criticisms of the clearness of the meaning of one or two of the sections have been received, and the committee has made a careful study of all the sections in the specifications, with a view to keeping them up to date

W. C. CUSHING,
Chairman Committee on Rail.

and making them as perfect as possible, with the result that a few revisions are now submitted for adoption by the association, some of them being merely changes in wording and rearrangement, which it is hardly necessary to point out in detail. The principal changes are, however, as follows:

Section 4. *Chemical composition:* The words "of each heat" have been added, so that the section reads, "The chemical composition of each heat of the steel from which rails are rolled, determined as prescribed in section 7, shall be within the following limits."

This change was made because the question arose at one mill as to whether it was necessary for every heat to have its chemical elements within the limits prescribed by the specifications.

Section 14. *Elongation or ductility:* A new paragraph has been added, as follows: "A sufficient number of blows shall be given to determine the complete elongation of the test piece of at least every fifth heat of Bessemer steel, and of one out of every three test pieces of a heat of open-hearth steel."

In measuring the elongation, acceptance or rejection is determined by the amount shown under one or more blows of the tup, but in addition to this, it is advisable to determine the total elongation or ductility of a certain number of test pieces, in order to keep informed on the toughness of the material, by repeating the blows till failure results. It is at present customary to carry on these tests, and it was thought advisable and proper to add the requirement to the specifications in order to make them more complete.

Section 17. *Bessemer process drop tests, clause* (b): The words "does not break and" have been added to the second line, so that the clause reads, "If the test piece breaks at the first blow or does not show the required elongation (section 14), or if the test piece does not break and shows the required elongation, but when broken shows interior defect, all of the top rails from that heat shall be rejected." The words "nicked and" have also been omitted from both clauses (a) and (b). Both the additions and omissions were brought about by discussion as to the precise meaning of the clause. Similar changes have been made in (c), (d), (e) and (f).

Section 18. *Open-hearth process drop tests:* Clauses (a) and (b) have been made to read as follows:

(a) "If two of these test pieces do not break at the first blow, and if both show the required elongation (section 14), all of the rails of the heat shall be accepted, provided that none of the three test pieces when broken show interior defect."

(b) "If two of the test pieces break at the first blow, or do not show the required elongation (section 14), or if any of the three test pieces when broken show interior defect, all of the top rails from that heat shall be rejected."

In clause (a), the changes were the addition of the words "if both," the addition of the words "none of the three," and the omission of the words "nicked and," also "do not."

In clause (b), the additions were the words "three tests" and the omission of the words "that have been tested under the drop" and "nicked and."

The changes were made necessary to abolish any cause for dispute as to the meaning, because, as already explained for section 17 (a) and (b), some were inclined to lay too much stress on the words "nicked and" when considering the rejection of certain rails represented by the test piece which showed interior defect, although it had not been nicked. Similar changes have been made in clauses (c), (d), (e) and (f), for the same reasons.

Section 30. *Straightening:* A new clause (b) has been added as follows: "Rails heard to snap or check while being straightened shall be at once rejected."

It is well known that the present method of straightening rails is undesirable, but it is the one almost universally employed and no other method now known is considered practicable. Sometimes, during this straightening process, rails are heard to snap, indicating that some unusual injury has been done, and it is the object of this clause to make that grounds for rejection.

Section 32. *Finishing:* A new clause (c) has been added, as follows: "When any finished rail shows interior defects at either end or in a drilled hole, the entire rail shall be rejected."

The rejection of such rails at the mills has been a source of dispute for several years, and in order to remove the cause for further contention, this clause has been added.

(*b*) *Revision of rail record forms. "Report of Mill Inspection, Form M. W.* 401." On page 59 of the manual is shown the present standard form of the association, entitled "Report of Chemical and Physical Examination," but since the change in the rail specifications, it is no longer suitable for the purpose, because, in the case of open-hearth heats, three ingots of each heat are tested instead of one, and an elongation or ductility requirement has been added; consequently, it is necessary to have a form on which the additional results can be reported. The name has been changed to "Report of Mill Inspection," because of the similarity of the form name to that of M. W. 407, "Laboratory Report of Chemical and Physical Examination." A new form, to take the place of the old one, is therefore submitted.

"*Certificate of Inspection, Form M. W.* 402." In connection with the new specifications adopted by the association, it has become advisable to make changes in the above form, now printed on page 60 of the manual, and therefore a revised form is submitted. The principal change is the tabulation in two columns of the "Rails Accepted" and the different causes for "Rails Rejected."

"*Laboratory Report of Chemical and Physical Examination of Rail, Form M. W.* 407." The present standard form is illustrated on page 67 of the manual, but, owing to progress in testing, which has resulted in the addition of tests, it has been found advisable to provide for the report of those additional tests; consequently, this form has been entirely revised, and a new blank is presented. The old form provided only for chemical analyses and the usual physical tests of tensile strength, elastic limit, elongation and reduction of area, while the new form provides for the report, in addition, of the drop test, hardness test, and transverse test of base.

"*Tabulation of Results of Mill Inspection of Rails, Form M. W.* 418." Owing to the change in the rail specifications, it will be necessary to revise this form, which is now illustrated between pages 60 and 61 of the manual. A new form, with the necessary additions in columns for entering the observed data, is submitted to you for your approval.

STANDARD RAIL SECTIONS.

The American Railway Association delegated to the Rail Committee of the American Railway Engineering Association the question of sections of rail and other matters connected with them, as well as that of specifications.

The sections used by the various railroads were collected, comparison between them and sections suggested by members of the committee was made, and all of the information as to rail failures in connection with the sections which could be obtained was considered. Some members of the committee submitted sections for consideration where their studies suggested that changes might be made for a better section, the desire being to keep the section within certain lines so that rail joints could be used and have a bearing on the straight portion of the rail both under the head and on top of the base, with as little additional stress on the bolts as possible.

At the meeting of the sub-committee in Pittsburgh it was decided that, while there was some merit in the suggested sections, the committee is not in a position to recommend any new section at the present time, as the sections of the so-called A.R.A. types "A" and "B" had been used by a number of roads, with good results as compared with other sections, but they have only been in use for about three years at the most, and with a great many roads only about two years. It is the consensus of opinion of the sub-committee that it may be advisable to add a little metal to the fillets both under the head and at the base.

The sub-committee, however, has under consideration modified sections, and will continue to study from time to time as it obtains information concerning the weak spots in the present sections. It will also undertake to make a study of rail joints and report at future meetings.

In regard to rail stresses; there is a great deal of indefiniteness regarding the methods by which various parties have estimated them. P. M. La Bach, of the Rock Island Lines, has worked on this problem, and the results have been sent out in sections to the members of the Rail committee. He is now revising the information, and putting it in better shape. The committee will also have other data that it will use in connection with the above, and it may be necessary for some members of the association to make experiments of their own.

The subject of "Stresses to Which Rails Are Subjected in Service" has been under preliminary investigation for the past year by Sub-Committee "D," Mr. Baldwin, chairman.

STATISTICS OF RAIL FAILURES.

The statistics of rail failures for the year ending October 31, 1911, were prepared by Mr. Trimble. The responses have been more complete than ever before, and the information furnished relates to 12,893,007 tons of rail. The report contains a great deal of valuable and useful information, nevertheless, it is proper to call the attention of the members to the fact that it is impossible to make comparisons under similar conditions of traffic, roadbed and weight of rail when dealing with the reports from companies whose problems vary widely, and because it is not feasible to obtain the information which would be necessary to make comparisons accurate, such, for instance, as the tonnage which has passed over rail of equal age and with the same quality of roadbed. The record of comparative wear of special rail, however, is being kept in such a way that comparisons are possible.

SPECIAL INVESTIGATION OF RAILS.

Experiments and Tests.

M. H. Wickhorst, engineer of tests for the committee, has continued his work on experiments and tests under the direction of sub-committee "A" during the past year, and the results of his work are issued in appendices. The cost of this work to the railways has been borne entirely by the American Railway Association, and the total appropriations made since November, 1909, up to November 1912, has been $21,000, while the expenditures to the end of the same period were $21,011.41.

In addition to the above, some of the manufacturers have incurred large expenses through the use of their facilities and material when the investigations were made, the amount of which is not known.

During the year 1912 the engineer of tests made reports to the rail committee on: Abrasion test of rails on a revolving machine; Influence of titanium on Bessemer ingots and rails; Pipeless ingots; Transverse ductility of base of rails, and Influence of silicon on open-hearth ingots and rails.

The first report gave the results of abrasion tests of rails made at several different mills. The tests were made at the South Chicago works of the Illinois Steel Company on a "revolving machine," consisting of a circular track 20 ft. in diameter, on which a heavy beam revolved which could be given additional load by means of springs. Under the conditions of this test open-hearth steel of .74 per cent. carbon abraded more slowly than Bessemer steel of .50 to .54 per cent. carbon, but the tests were not entirely satisfactory and were few in number.

The next study gave the results of an investigation made at the works of the Lackawanna Steel Company at Buffalo, to determine the influence of titanium on Bessemer steel ingots and rails. A series of heats was made with treatments varying from nothing to .6 per cent. metallic titanium added in the form of a cold 15 per cent. alloy. According to the results obtained, the use of amounts of .1 per cent. or more of metallic titanium in the manner mentioned, prevents the "honeycombed" condition of the upper part of the ingot found in plain Bessemer steel, but was also attended with a larger and deeper "pipe." The heavy segregation or concentration of carbon, phosphorus and sulphur found in the interior and upper part of ingots of plain Bessemer steel was largely restrained, but the mild negative segregation found in the interior and lower part of the ingot was not materially altered. The brittle zone found in rail of plain Bessemer steel from the upper part of the ingot, as determined by drop and tensile tests, was avoided, but the properties of the rail from the lower two-thirds of the ingot were not changed. Large internal flaws were found in rail considerably lower down from the top of the ingot in steel treated as mentioned, than in rail made from plain steel. Treatments with .05 per cent. metallic titanium produced the above results only in part, but treatment above .1 per cent. had only little additional influence.

The third report dealt with an investigation of two special ingots made by the Standard Steel Works Company at Burnham, Pa., by a process which prevents the formation of a "pipe" in the interior of the ingot. The steel was acid open-hearth steel treated with titanium. The ingots were shipped to the Maryland Steel Company at Sparrows Point, Md., where they were tested. The main feature of the casting process was a sand core on top of the iron mold. The ingots were cupped down at the top, but contained no interior pipe.

The fourth report described a method for determining the transverse ductility of the bottom of the base of a rail and the load required to break the flanges of a rail supported near the edges of the flanges. The results were given of a few tests made at Buffalo at the works of the Lackawanna Steel Company, of Bessemer and open-hearth rails. The method of making the tests was to support a piece of rail about two ft. long on two supports placed opposite each other near the edges of the flanges under the middle of the length of the rail. The supports were six in. long and placed one-half in. in from the sides of the flanges. The load was applied in the test machine to the top of the rail at the middle. The method may be considered a means of determining the strength of the flange and of determining the transverse properties of the base of the rail, as regards the transverse ductility of the metal in the base and the presence of structural flaws such as seams.

The last report gave the results of an investigation made at the Gary works of the Illinois Steel Company on the influence of silicon on open-hearth ingots and rails. A heat of about .15 per cent. silicon was used and a series of higher silicons in this steel up to above .5 per cent. was obtained by means of mold additions of finely crushed ferro-silicon. With about one-fourth per cent. silicon or more the ingots were free from most of the honeycomb present in the upper third of the ingot with the heat amount of silicon, but they also had larger pipes. The higher silicons also had less concentrated segregation of carbon, phosphorus and sulphur. Silicon had but little influence on the results in the drop test. When tested in the test machine as a beam, the stiffness and breaking load of the rails increased with increase of silicon, while their ductility was not greatly influenced. In longitudinal tensile tests, the yield point and tensile strength increased somewhat with the increase of silicon, while the ductility remained about the same. In tests of the flange, the load required to break the flange increased somewhat as the silicon increased, while the transverse ductility of the base remained about the same.

The above work concerning both titanium and silicon indicate that they tend to restrain segregation of carbon, phosphorus and sulphur, but used as they were in this work they were attended with larger pipes. This suggests the idea that in order to obtain the full benefits of their use, a method of casting the ingots is necessary whereby the pipe is avoided or minimized.

Testing Each Ingot.

The question of testing each ingot has been quite thoroughly considered by correspondence and by discussion, and the committee recommends that no change be made in the specifications in this respect at present, for the following reasons:

(a) The tests now required by the specifications are sufficient to determine the character of the metal in the heat. In

so far as it is intended to discover specific flaws in the rail, additional tests would have relatively little value, as these defects are quite local, and are apt to occur in any part of the ingot, or rail-bar, so that the presence or absence of internal defects in the piece tested is no certain criterion of the presence or absence of similar defects in other parts of the same bar.

(b) The character of the metal in the rails of one heat varies *down* the ingot more than it does from one ingot to another, and in making the complete drop test of an open-hearth heat, the three tests made from approximately the poorest parts of the ingots designate the average of the poorest part of the metal fully as well as if we tested a piece from each ingot.

(c) Careful examination in detail of the many tests of open-hearth rail made in the last two years on the New York Central Lines fails to show any necessity for the testing of each individual ingot.

RECOMMENDATIONS FOR WORK IN 1913.

The subjects recommended for assignment to the committee for 1913 are the same as those already assigned for the year 1912, and in addition the subject of rail joints.

The general line of investigation which the committee has in view for Mr. Wickhorst is submitted below, and embraces a great deal more work than he can cover in any one year. The main point kept in mind in the work of the last two or three years has been to conduct it so as to bring out if possible information useful in improving rails for the purpose of making them uniformly safe, and it is probable that this must continue to be our guiding principle for some time to come. Investigations intended to improve the wearing properties of rails must, it would seem, be considered as secondary to those which have uniform safety as the prime consideration. It soon developed that the type of rail failure which was uppermost in our attention a few years ago, namely, split and mashed heads, was traceable to the interior condition of the ingot and our work has consisted therefore largely of "ingot" studies. Recently, failures classified as broken rails and broken base, have been brought more to our attention, due largely to last winter's crop of broken rails. It seems that such failures are largely attended or perhaps caused by deep seams in the base of the rail and it is now proposed that the work of the immediate future be directed toward throwing light on the cause of such seams and methods for their prevention.

CONCLUSIONS.

The committee makes the following recommendations:

(1) That the revision of the specifications for carbon steel rails be approved for printing in the manual.

(2) That Form M. W. 401, "Report of Mill Inspection," as revised, be approved for substitution in the manual for the present standard form.

(3) That Form M. W. 402, "Certificate of Inspection," as revised, be approved for substitution in the manual for the present standard form.

(4) That Form M. W. 407, "Laboratory Rail Report" be approved for substitution in the manual for the present standard form.

(5) That Form M. W. 418, "Tabulation of Results of Mill Inspection of Rails," as revised, be approved for substitution in the manual for the present standard form.

W. C. Cushing, chairman (Pa. Lines); R. Montfort, vice-chairman (L. & N.); E. B. Ashby (L. V.), J. A. Atwood (P. & L. E.), A. S. Baldwin (I. C.), J. B. Berry (C. R. I. & P.), M. L. Byers (D. & H.), Chas. S. Churchill (H. & W.), F. A. Delano (Wabash), P. H. Dudley (N. Y. C. Lines), C. H. Ewing (Atlantic City Ry.), L. C. Fritch (C. G. W.), C. W. Huntington (C. R. R. of N. J.), J. D. Isaacs (S. P.), Thos. H. Johnson (Pa. Lines), H. G. Kelley (G. T.), C. A. Morse (A. T. & S. F.), G. W. Kittredge (N. Y. C. & H. R.), Jos. T. Richards (P. R. R.), J. P. Snow (Cons. Engr.), A. W. Thompson (B. & O.), R. Trimble (Pa. Lines), M. H. Wickhorst, Committee.

SPECIFICATIONS FOR CARBON AND STEEL RAILS.

Inspection.

1. *Access to Works*—Inspectors representing the purchaser shall have free entry to the works of the manufacturer at all times while the contract is being executed, and shall have all reasonable facilities afforded them by the manufacturer to satisfy them that the rails have been made in accordance with the terms of the specifications.

2. *Place for Tests*—All tests and inspections shall be made at the place of manufacture, prior to shipment, and shall be so conducted as not to interfere unnecessarily with the operation of the mill.

Material.

3. *Material*—The material shall be steel made by the Bessemer or open-hearth processes as provided by the contract.

Chemical Requirements.

4. *Chemical Composition*—The chemical composition of each heat of the steel from which the rails are rolled, determined as prescribed in section 7, shall be within the following limits:

	Per Cent for Bessemer Process	
Elements.	70 lbs. and Over, but Under 85 lbs.	85-100 lbs. inclusive.
Carbon	0.40 to 0.50	0.45 to 0.55
Phosphorus, not to exceed	0.10	0.10
Manganese	0.80 to 1.10	0.80 to 1.10
Silicon, not to exceed	0.20	0.20

	Per Cent for Open-Hearth Process.	
Elements.	70 lbs. and Over, but Under 85 lbs.	85-100 lbs. Inclusive.
Carbon	0.53 to 0.66	0.63 to 0.76
Phosphorus, not to exceed	0.04	0.04
Manganese	0.60 to 0.90	0.60 to 0.90
Silicon, not to exceed	0.20	0.20

5. *Average Carbon*—It is desired that the percentage of carbon in an entire order of rails shall average as high as the mean percentage between the upper and lower limits specified.

6. *Modification of Carbon for Low Phosphorus*—When the material used at any mill is such that the average phosphorus content of the ingot metal used in the Bessemer process is running below 0.08 and in the open-hearth process is running below 0.03, and if it seems mutually desirable, the carbon may be increased at the rate of 0.035 for each 0.01 that the phosphorus content of the ingot metal used averages below 0.08 for Bessemer steel, or 0.03 for open-hearth steel.

7. *Analyses*—In order to ascertain whether the chemical composition is in accordance with the requirements, analyses shall be furnished as follows:

(a) For Bessemer process the manufacturer shall furnish to the inspector, daily, carbon determinations for each heat before the rails are shipped, and two chemical analyses every 24 hours representing the average of the elements, carbon, manganese, silicon, phosphorus and sulphur contained in the steel, one for each day and night turn respectively. These analyses shall be made on drillings taken from the ladle test ingot not less than ⅛ in. beneath the surface.

(b) For open-hearth process, the makers shall furnish the inspectors with a chemical analysis of the elements, carbon, manganese, silicon, phosphorus and sulphur, for each heat.

(c) On request of the inspector, the manufacturer shall furnish a portion of the test ingot for check analyses.

Physical Requirements.

8. *Physical Qualities*—Tests shall be made to determine:

(a) Ductility or toughness as opposed to brittleness.

(b) Soundness.

9. *Method of Testing*—The physical qualities shall be determined by the drop test.

10. *Drop Testing Machine*—The drop testing machine used shall be the standard of the American Railway Engineering Association.

(a) The tup shall weigh 2,000 lbs., and have a striking face with a radius of 5 in.

(b) The anvil block shall weigh 20,000 lbs., and be supported on springs.

(c) The supports for the test pieces shall be spaced 3 ft. between centers and shall be a part of, and firmly secured, to the anvil. The bearing surfaces of the supports shall have a radius of 5 in.

11. *Pieces for Drop Test*—Drop tests shall be made on pieces of rail not less than 4 and not more than 6 ft. long. These test pieces shall be cut from the top end of the top rail of the ingot, and marked on the base or head with gage marks 1 in. apart for 3 in. each side of the center of the test piece, for measuring the ductility of the metal.

12. *Temperature of Test Pieces*—The temperature of the test pieces shall be between 60 and 100 deg. Fahrenheit.

13. *Height of Drop*—The test piece shall, at the option of the inspector, be placed head or base upwards on the supports, and be subjected to impact of the tup falling free from the following heights:

For 70-lb. rail.....16 ft.
For 80, 85 and 90-lb. rail.....17 ft.
For 100-lb. rail.....18 ft.

14. *Elongation or Ductility*—(a) Under these impacts the rail under one or more blows shall show at least 6 per cent. elongation for 1 in., or 5 per cent. each for two consecutive inches of the 6-in. scale, marked as described in section 11.

(b) A sufficient number of blows shall be given to determine the complete elongation of the test piece of at least every fifth heat of Bessemer steel and of one out of every three test pieces of a heat of open-hearth steel.

15. *Permanent Set*—It is desired that the permanent set after one blow under the drop test shall not exceed that in the following table, and a record shall be made of this information.

Section.	Rail Weight per Yard.	Rail Moment of Inertia.	Permanent Set, Measured by Middle Ordinate in Inches in a Length of 3 ft. Bessemer Process.	Permanent Set, Measured by Middle Ordinate in Inches in a Length of 3 ft. Open-Hearth Process.
A.R.A.-A.....	100	48.94	1.65	1.45
A.R.A.-B.....	100	41.30	2.05	1.80
A.R.A.-A.....	90	38.70	1.90	1.65
A.R.A.-B.....	90	32.30	2.20	2.00
A.R.A.-A.....	80	28.80	2.85	2.45
A.R.A.-B.....	80	25.00	3.15	2.85
A.R.A.-A.....	70	21.05	3.50	3.10
A.R.A.-B.....	70	18.60	3.85	3.50

16. *Test to Destruction*—The test pieces which do not break under the first or subsequent blows shall be nicked and broken, to determine whether the interior metal is sound.

17. *Bessemer Process Drop Tests*—One piece shall be tested from each heat of Bessemer steel.

(a) If the test piece does not break at the first blow and shows the required elongation (section 14), all of the rails of the heat shall be accepted, provided that the test piece when broken does not show interior defect.

(b) If the test piece breaks at the first blow, or does not show the required elongation (section 14), or if the test piece does not break and shows the required elongation, but when broken shows interior defect, all of the two rails from that heat shall be rejected.

(c) A second test shall then be made of a test piece selected by the inspector from the top end of any second rail of the same heat, preferably of the same ingot. If the test piece does not break at the first blow, and shows the required elongation (section 14), all of the remainder of the rails of the heat shall be accepted, provided that the test piece when broken does not show interior defect.

(d) If the test piece breaks at the first blow, or does not show the required elongation (section 14), or if the test piece does not break and shows the required elongation, but when broken shows interior defect, all of the second rails from that heat shall be rejected.

(e) A third test shall then be made of a test piece selected by the inspector from the top end of any third rail of the same heat, preferably of the same ingot. If the test piece does not break at the first blow and shows the required elongation (section 14), all of the remainder of the rails of the heat shall be accepted, provided that the test piece when broken does not show interior defect.

(f) If the test piece breaks at the first blow, or does not show the required elongation (section 14), or if the test piece does not break and shows the required elongation, but when broken shows interior defect, all of the remainder of the rails from that heat shall be rejected.

18. *Open-Hearth Process Drop Tests*—Test pieces shall be selected from the second, middle and last full ingot of each open-hearth heat.

(a) If two of these test pieces do not break at the first blow, and if both show the required elongation (section 14), all of the rails of the heat shall be accepted, provided that none of the three test pieces when broken show interior defect.

(b) If two of the test pieces break at the first blow, or do not show the required elongation (section 14), or if any of the three test pieces when broken show interior defect, all of the top rails from that heat shall be rejected.

(c) Second tests shall then be made from three test pieces selected by the inspector from the top end of any second rails of the same heat, preferably of the same ingots. If two of these test pieces do not break at the first blow and if both show the required elongation (section 14), all of the remainder of the rails of the heat shall be accepted, provided that none of the three test pieces when broken show interior defect.

(d) If two of these test pieces break at the first blow, or do not show the required elongation (section 14), or if any of the three test pieces when broken show interior defect, all of the second rails of the heat shall be rejected.

(e) Third tests shall then be made from three test pieces selected by the inspector from the top end of any third rails of the same heat, preferably of the same ingots. If two of these test pieces do not break at the first blow, and if both show the required elongation (section 14), all of the remainder of the rails of the heat shall be accepted, provided that none of the three test pieces when broken show interior defect.

(f) If two of these test pieces break at the first blow, or do not show the required elongation (section 14), or if any of the three test pieces when broken show interior defect, all of the remainder of the rails from that heat shall be rejected.

19. *No. 1 Rails.*—No. 1 classification rails shall be free from injurious defects and flaws of all kinds.

20. *No. 2 Rails*—(a) Rails, which, by reason of surface imperfections, or for causes mentioned in section 30, hereof, are not classed as No. 1 rails, will be accepted as No. 2 rails, but No. 2 rails which contain imperfections in such number or of such character as will, in the judgment of the inspector, render them unfit for recognized No. 2 uses, will not be accepted for shipment.

(b) No. 2 rails to the extent of 5 per cent. of the whole order will be received. All rails accepted as No. 2 rails shall have the ends painted white and shall have two prick punch marks on the side of the web near the heat number near the end of the rail, so placed as not to be covered by the splice bars.

Details of Manufacture.

21. *Quality of Manufacture*—The entire process of manufacture shall be in accordance with the best current state of the art.

22. *Bled Ingots*—Bled ingots shall not be used.

23. *Discard*—There shall be sheared from the end of the bloom, formed from the top of the ingot, sufficient metal to secure sound rails.

24. *Lengths*—The standard length of rails shall be 33 ft., at a temperature of 60 deg. Fah. Ten per cent. of the entire order will be accepted in shorter lengths varying by 1 ft. from 32 ft. to 25 ft. A variation of ¼ in. from the specified lengths will be allowed. No. 1 rails less than 33 ft. long shall be painted green on both ends.

25. *Shrinkage*—The number of passes and speed of train shall be so regulated that on leaving the rolls at the final pass, the temperature of the rail will not exceed that which requires a shrinkage allowance at the hot saws, for a rail 33 ft. in length and of 100 lbs. section, of 6¾ in. and ⅛ in. less for each 10 lbs. decrease in section.

26. *Cooling*—The bars shall not be held for the purpose of reducing their temperature, nor shall any artificial means of cooling them be used after they leave the finishing pass. Rails, while on the cooling beds, shall be protected from snow and water.

27. *Section*—The section of rails shall conform as accurately as possible to the template furnished by the railroad company. A variation in height of 1/64 in. less or 1/32 in. greater than the specified height and 1/16 in. in width of flange, will be permitted; but no variation shall be allowed in the dimensions affecting the fit of the splice bars.

28. *Weight*—The weight of the rails specified in the order shall be maintained as nearly as possible, after complying with the preceding section. A variation of one-half of 1 per cent. from the calculated weight of section, as applied to an entire order, will be allowed.

29. *Payment*—Rails accepted will be paid for according to actual weights.

30. *Straightening*—(a) the hot straightening shall be carefully done, so that gagging under the cold presses will be reduced to a minimum. Any rail coming to the straightening presses showing sharp kinks or greater camber than that indicated by a middle ordinate of 4 in. in 33 ft., for A. R. A. type of sections, or 5 in. for A. S. C. E. type of sections, will be at once classed as a No. 2 rail. The distance between the supports of rails in the straightening presses shall not be less than 42 in. The supports shall have flat surfaces and be out of wind.

(b) Rails heard to snap or check while being straightened shall be at once rejected.

31. *Drilling*—Circular holes for joint bolts shall be drilled to conform accurately in every respect to the drawing and dimensions furnished by the railroad company.

32. *Finishing*—(a) All rails shall be smooth on the heads, straight in line and surface, and without any twists, waves or kinks. They shall be sawed square at the ends, a variation of not more than 1/32 in. being allowed; and burrs shall be carefully removed.

(b) Rails improperly drilled or straightened, or from which the burrs have not been removed, shall be rejected, but may be accepted after being properly finished.

(c) When any finished rail shows interior defects at either end or in a drilled hole the entire rail shall be rejected.

33. *Branding*—(a) The name of the manufacturer, the weight and type of rail, and the month and year of manufacture shall be rolled in raised letters and figures on the side of the web. The number of the heat and a letter indicating the portion of the ingot from which the rail was

made shall be plainly stamped on the web of each rail, where it will not be covered by the splice bars. The top rails shall be lettered "A," and the succeeding ones "B," "C," "D," etc., consecutively; but in case of a top discard of 20 or more per cent., the letter "A" will be omitted. All markings of rails shall be done so effectively that the marks may be read as long as the rails are in service.

(b) Open-hearth rails shall be branded or stamped "O.-H.," in addition to the other marks.

34. *Separate Classes*—All classes of rails shall be kept separate from each other.

35. *Loading*—All rails shall be loaded in the presence of the inspector.

Discussion on Rail.

Mr. Cushing: Apropos of the question of steel rails it is interesting to read the following remarks made by former president John Edgar Thomson in his annual report to the stockholders in 1864, nearly 50 years ago:

"The rapid destruction of iron under the high speeds and heavy locomotives now used upon railways, has become a subject of serious consideration, not only to the managers of these improvements in this country, but also in Europe. When the Pennsylvania Railroad was planned, a locomotive weighing 45,000 to 50,000 lbs. was considered as the extreme limit to these machines, justified by prudence. But the demands of the public for high speeds has compelled the introduction upon all thoroughfares of more powerful engines. These could only be obtained by adding to their dimensions and weight, which has produced its natural result—great wear and tear of iron rails and the superstructure of the road. This evil has been still further increased by the inferiority of the rails now manufactured, compared with those placed upon railways when the edge rail was first introduced. It was then deemed essential that rails should be made from the best refined iron produced from selected ores. The great increase in the demand for iron under the rapid development of the railway systems in England and this country soon caused the substitution of an inferior article, which seemed for a time to answer the purpose, but which experience has proven to be insufficient to resist the causes referred to, as continually operating for its destruction. A return to the quality of iron originally used on railways, would be the natural remedy for this difficulty, but this will require time, as none of the rail mills have the required furnaces to refine their metal. In Europe this subject has been longer considered, and the determination appears to be general, to gradually substitute a still more expensive material—either a rail made wholly of steel—with a steel head only—or the wearing surface converted into steel after the iron rail is made. The present high cost of rails made entirely of steel will probably prevent their general adoption, although the rapid destruction at the terminal and stations, where the iron rail in some positions does not last six months, will fully justify their introduction. For the purpose of testing the relative value of steel and iron rails in such positions, we have procured 150 tons of rails made wholly of cast steel. A trial is also being made of a rail with a steeled wearing surface passed through the rolls, when drawn from the converting furnace, which promises well. It is understood that favorable results have been obtained from rails, the top plate in the pile from which they were made being puddled steel. If the two metals can be firmly welded together, this improvement in railway bars will be generally adopted. This is a subject of such great importance to the company that it will continue to meet the earnest attention of your directors, and if necessary to effect the reformation desired in the quality of rails, it should become important to erect works to effect that object, such a policy will be adopted. The frequent renewal of rails is not only expensive, but it adds to the interruption of the traffic of the line."

The only conclusions we have to offer to the association for adoption this year are in line with proposed revisions of what is already in the Manual. As these changes are due to criticisms made at the last annual convention and those received during the year, it is presumed that they are in line with the wishes of the association, and I make the motion now for their adoption.

(Conclusions 1, 2, 3, 4 and 5 were adopted.)

H. M. Wickhorst: Taking the statistics of rail failures as published in one of our recent bulletins, 90 per cent of the failures can be divided into two general classes. First of all, we have failures of the crushed heads, split heads, and also in that should probably be included most of the web failures. This class of failures is traceable finally to the interior condition of the ingot from which the rails were made; that is, they are a matter of excessive segregation, which produces a brittleness in the interior of the section. Under wheel loads the head spreads sideways. The top metal is always ductile, but the interior metal may not be so, sometimes due to structural flaws or laminations, but most particularly due to excessive carbon and phosphorus, which makes extremely brittle non-ductile material inside, so that when the top of the head spreads sideways a crack develops internally and finally comes to the surface at the under side of the head at its junction with the web. Sometimes, in the case of a badly segregated rail, it will run farther into the web and come out to the surface at the side of the web. So a good many failures, classed as web failures, would come under that head. That would include probably 50 per cent of the failures. Then, second in the class, we have broken bases, and broken rails, which, I will simply state very briefly, we think we can now definitely trace to a seam in the bottom of the base. If the bottom of the base contains a seam, when excessive load comes on, when the load come on, for any reason, or if there is an eccentric bearing, then the seam opens, and if the seam happens to be away from the center a piece of the flange may break out and we get a moon-shaped or crescent break. If, however, as is more generally the case, the seam opens up near the center of the base, the base will open up and a piece of the flange start to break off, and then the break goes through the whole of the section. So what are classed as broken rails (square breaks—angular breaks), and base breaks in general, can be traced to the presence of a longitudinal seam in the bottom of the base. This will probably include about 40 per cent of the rail failures. These two classes will account of about 90 per cent of all the rail failures of the country. Now, to sum up, then, we may say 50 per cent of the rail problems consists in getting sound metal of fairly even composition and 40 per cent consists in so rolling the steel as to avoid the seams in the base.

A vote of thanks was offered to the committee.

The meeting adjourned until 9 a. m. Wednesday, March 19.

FIVE DIRECTORS OF THE A. S. C. E. HERE.

Professor G. F. Swain of Harvard University, president of the American Society of Civil Engineers, is attending the convention. It was interesting to note yesterday that in addition to President Swain and Vice-President C. S. Churchill at least two other members of the board of directors of this society were in attendance—C. F. Loweth and Lincoln Bush.

PRACTICAL MEN AT THE COLISEUM.

Considerable comment was heard at the Coliseum yesterday regarding the number of roadmasters and foremen who are visiting the show. One western road sent in a number of the foremen on its Illinois lines, while a division engineer of one of the large roads running east from Chicago sent a ticket to the Coliseum and a railroad pass to Chicago to each of his foremen with the suggestion that they attend some day this week. The increasing recognition of the value of this exhibit to the practical man is one of the best indications of its real merit.

WARWICK IN OUR MIDST.

William Jennings Bryan, Secretary of State of the United States, came as near being present at a meeting of the Railway Signal Association night before last as he may ever get. He attended the wedding, the preparations for which were begun almost before the Monday afternoon session, in the Florentine room of the Congress Hotel had adjourned. His coming was unheralded, his stay short—and diplomatic—and his departure unostentatious. Few besides those being married and those helping them get married knew he was there. The few stragglers from the R. S. A. meeting who saw him thought he was "Jim" Lorenz. But he was there, all right, and he dispensed silence and smiles, and kissed the bride with as much dignity and eclat as if he were concluding a treaty with the court of St. James. The bride, who was Miss Amy Wessel, is the daughter of an old-time friend and neighbor of Mr. Bryan's.

REGISTRATION—AMERICAN RAILWAY ENGINEERING ASSOCIATION.

After careful consideration for the past year, the American Railway Engineering Association has made application for second-class mail privileges for the bulletins of the association. If this can be secured it will mean a saving of $500 annually in the expenses of mailing.

J. B. BERRY TO BE ASSISTANT TO THE PRESIDENT.

J. B. Berry is to become assistant to the president of the Rock Island Lines, being succeeded as chief engineer, as already announced in the Daily, by C. A. Morse, chief engineer of the Santa Fe.

Mr. Berry has been chief engineer of the Rock Island Lines since 1905. He was for a while, when the Rock Island and Frisco Lines were under the same financial control, also consulting engineer of the Frisco. Before coming to the Rock Island he was for seven years chief engineer of the Union Pacific.

Mr. Berry entered the service of the Chicago & Northwestern in 1878, and was employed in its engineering department until 1893. He then went to Omaha as chief engineer of the Fremont, Elkhorn & Missouri Valley, where he remained until he became chief engineer of the Union Pacific.

Mr. Berry's work in the reconstruction of the Union Pacific was one of the notable pieces of engineering work in the railway history of the country, and he has ever since occupied a prominent place among railway engineers.

NEW COAL HANDLING BRIDGE AT DULUTH, MINN.

A new dock and storage plant for unloading, stocking and reshipping coal has recently been completed at Duluth for the Clarkson Coal & Dock Co. The plant is reached by boat from a slip on one side of the property and provision has been made in the design of the plant for unloading from a second slip, which may be located along the other side of the storage ground in the future. The storage space is 630 ft. wide and has a capacity of upwards of 200,000 tons. It is spanned by two steel bridges placed end to end which are built in duplicate, with the exception that the unloading machinery which will be used to unload boats in the future slip, if this is added, has not been placed as yet. The span of each bridge between the tower leg and the shear leg is 201 ft., with a 68-ft. cantilever outside of the tower leg extending over the slip in the case of one of the bridges, and over a storage pile in the other case. Each bridge also has an 80-ft. cantilever extending over the storage space between the two bridges. The shear legs of the two bridges are 160 ft. apart so that the ends of the two cantilever arms just clear each other. This arrangement allows the two bridges to be operated independently or to be lined up and operated in tandem. The storage piles are about 40 ft. high and the clearance to the underside of trusses is 55 ft.

One of the unusual features in the design of these bridges is the use of single rail trucks under both the tower and shear legs. This feature was made necessary by limitations imposed by the owners and necessitated numerous changes in the design from the type of bridge ordinarily used for this purpose. In order to secure longitudinal stability for the bridge, tower bracing is provided extending back two panel points from the leg, or about 27 ft. The tower leg, the tower bracing and the bridge span are thus rigidly connected. The span is supported on the shear leg by a nest of ball bearings which allows movement in both directions. The single rail trucks have center pins which carry the load from the tower and allow movement of the trucks due to inequalities in the track. Roller bearings are provided at the ends of these trucks.

The coal is unloaded from boats by a 2.5 ton grab bucket operating from the cantilever boom over the slip. This boom is made to swing vertically in order to clear the masts of vessels in the slip. The bucket is operated by Watson's cable rig and remote control from an operator's house on the tower leg of the adjacent bridge. The bucket is able to make two trips per minute, giving it a capacity of 300 tons per hour. The unloading bucket dumps the coal into a 10-ton hopper, supported by the tower bracing, from which it is fed by a

Coal Bridge of the Clarkson

reciprocating feeder to a 36-in. belt conveyor supported from the lower chord of the bridge. This belt conveyor extends nearly to the middle of the bridge span above the storage pile. Coal intended for storage under the main span of this bridge can be deposited at any desired point by the use of a shuttle conveyor, which is supported under the main conveyor, and can be moved back and forth on the bridge to bring its discharge end to any desired point.

If it is desired to carry the coal from the boat to the screening plant at the shear leg of the first bridge, the shuttle conveyor is arranged to receive the coal from the first conveyor and deposit it on a third conveyor, which discharges it into a 40-ton hopper carried by the shear leg. This hopper can feed the mine-run coal directly into standard gage cars on the two tracks adjacent to the shear leg or into the screening plant supported on the shear leg from which the slack and lump coal can be loaded directly or placed in bins for later shipment, as desired. A Christy box car loader is provided below the screening plant in case it is necessary to load the coal into box cars.

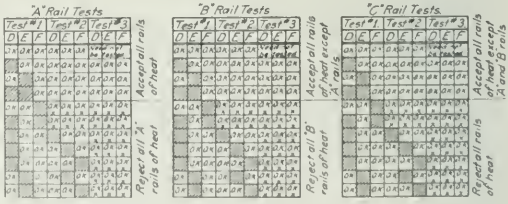
When it is desired to store coal in the pile between the two shear legs under the inside cantilever arms the belt conveyors are so adjusted over the shear leg of the first bridge that the coal is carried past this point instead of being dropped into the hopper. The coal received by the conveyor on the cantilever arm of the first bridge can either be deposited directly into the storage pile under that arm or fed to the conveyor under the cantilever arm of the second bridge when the two are lined for operation in tandem. The latter conveyor carries the coal past the shear leg of the second bridge and deposits it on a shuttle conveyor under the main span of that bridge which can place it either in the storage pile under that span or in the screening and loading plant on the shear leg of that bridge, which is a duplicate of the one described for the first bridge.

This arrangement of belt conveyors is so complete that it is possible to secure almost any combination and by adjustment of the shuttle conveyor under each bridge and the tripping arrangements at the ends of the conveyors, coal can be deposited at almost any desired point. For reclaiming the coal from the storage piles, a 2.5-ton grab bucket is operated on the lower chord of each bridge. These buckets are dumped directly into the large hoppers over the screening and loading plant.

The belt conveyor equipment for the entire bridge was furnished by the Robins Belt Conveyor Co., Chicago. The entire bridge was designed and constructed by the Roberts & Shaefer Co., Chicago, under the direction of E. E. Barrett, chief engineer.

KEY TO 1912 A. R. E. A. OPEN HEARTH STEEL RAIL SPECIFICATIONS.

To simplify the duties of the inspectors at the rail mills and to enable them to know immediately the correct action to take when inspecting rails which are being rolled under the new specifications of the American Railway Engineering Association, adopted last March, Robert W. Hunt & Company have prepared a key for the use of their inspectors which presents the specifications at a glance. Under the new specifications, if the chemical analysis is satisfactory, three test pieces are taken from each heat from the top end of "A" rails made from the second, middle and last full ingot cast. The test may be made head up or base up under the drop test, and if the first two tests are satisfactory in all



Key for the Inspection of Rail.

respects, the third need not be made. To pass the test satisfactorily the specimen must not break on the first blow of the drop, indicated by column D in the diagram, must show 6 per cent. elongation in one inch or 5 per cent. in two consecutive inches as the result of one or more blows, indicated by column E in the diagram, and must show no interior defect or fracture when broken, indicated by column F. A shaded square in the diagram indicates a failure, in which event the inspector's course of procedure will be outlined as

Coal and Dock Co., Duluth, Minn.

shown at the right. A cross in the diagram shows possible unnecessary tests.

Referring to the diagram, the inspector can tell at a glance, for instance, if one specimen failed under the drop test and in elongation, but the other two tests were satisfactory in all details, that all rails of the heat should be accepted, while, on the other hand, the key shows that if the first test specimen fails under the drop test and the second in elongation, all the "A" rails should be rejected. Where the "A" rails are rejected the key shows likewise the action in testing "B" and also "C" rails.

This diagram applies for the proposed revised 1913 American Railway Engineering Association specifications, with the exception that all three test pieces must be broken and must all be free from interior defects to insure acceptance. Therefor, the cross in columns F of tests two and three should be omitted. The new specifications also require that one test piece from each heat must be struck repeated blows to determine the full elongation.

SIGNAL APPLIANCES ASSOCIATION MOVING PICTURES.

The Signal Appliances Association will give an exhibition of moving pictures at 166 N. State street, Chicago, at 3:00 o'clock p. m. on Thursday. The Richmond pictures, some new films on "Keeping the Blocks Open" in the Cascades and some other new pictures will be shown.

THE WEATHER.

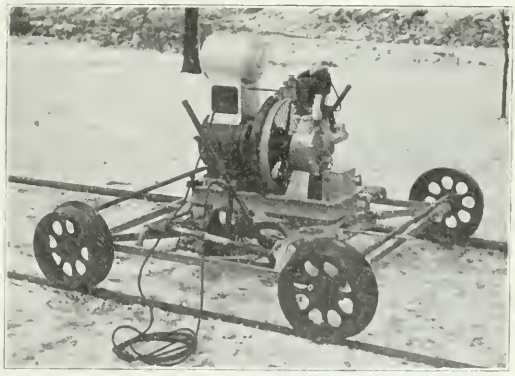
A year ago the convention of the Railway Engineering Association was held in the midst of a severe blizzard. This year's weather has not been exactly all that could be desired, but it has been a marked improvement, and on the whole has been satisfactory, considering that the month is March.

AN ELECTRIC SIGNAL BONDING OUTFIT.

An electric signal bonding outfit has been designed by the Chicago Pneumatic Tool Co. to furnish electric current for the operation of the drills for signal bonding. This apparatus consists of a single cylinder, 4-cycle gasolene engine, direct connected to a 1¼ k. w. generator, wound for 25 volts. The engine and dynamo are direct connected and mounted on a welded steel frame made of 3-in. channel steel. When detached from the truck they can be equipped with two handles so that the entire outfit can easily be carried by two men.

The generating unit may also be mounted on a 4-wheel truck with a welded channel steel frame. This truck has a wheel base of 50 in. The generating outfit is held to the truck frame by two bolts, which may be readily removed if desired. The weight of this 4-wheel truck is 130 lbs., and the combined weight of the truck and generator is about 500 lbs.

The engine develops 5 h. p. at normal speed of 1,500 r. p. m. Both valves are mechanically operated. The hardened steel crank shaft running in ball bearings is entirely



Electric Rail Bonding Outfit.

enclosed and dust-proof. Lubrication is provided by a force feed oiler which takes care of all bearings except those of the dynamo.

Ignition is by means of a Bosch high-tension magneto, and cooling is effected by means of a fan-shaped fly wheel of large diameter. The switchboard has provision for making connections to two electric bonding drills. A fuse block is enclosed in the switch case.

NEW TYPE OF SHEFFIELD STANDPIPE.

A new telescopic spout Sheffield standpipe, recently brought out by Fairbanks, Morse & Co., Chicago, is shown for the first time at the railway appliance show. The Sheffield standpipe was one of the first to make its appearance in the field and it has been constantly improved. The lower

New Sheffield Standpipe.

part of the new No. 11 pipe is similar to the Nos. 6, 7, 8 and 10 Sheffield columns, having the Sheffield water balanced horizontal main valve and regularly provided with automatic relief valve, which takes care of water hammer in mains having high pressure.

The spout is the distinctive feature of the new No. 11 standpipe. In addition to a vertical movement of five ft. at the end of spout, it has a lateral movement of about four ft., and a "cross-track" movement of about three ft. In other words, the end of the spout will describe an oval about three by four ft., so that it is unnecessary to spot the man-hole so exactly as with other types of standpipes. This oval movement feature also lessens the chances for damaging the pipe should the engine move while taking water.

FLASH LIGHT INVENTOR AWARDED NOBEL PRIZE.

The Nobel prize for physics for 1912 was awarded to Gustaf Dalen of Stockholm for his inventions of the flash light and sun valve, both of which have been such great aids to navigation. These devices have been adopted all over the world for marine signaling, and the fact that the inventor was awarded the Nobel Prize for his inventions speaks much for their merit.

The application of the flashlight to railway signaling was described in the Railway Age Gazette of March 7, and in the Signal Engineer for March, 1913. As mentioned the flashlight is being introduced by the Commercial Acetylene Railway Light & Signal Co., New York, and in its first installation in the west was on an automatic block signal near Maywood, Ill., on the Chicago Great Western. The light it produces is visible further than the steady light and the colors are more fully brought out. A tank of acetylene is placed at the foot of the mast and the gas is piped up the mast to the lamp, inside of which the flashing device is placed. The flasher is controlled by a diaphragm valve, and produces 60 flashes per min.

Recent experience shows that the gas is ignited by a pilot flame which burns continuously and that the total consumption, including both the flash light and the pilot flame, is 4-5 of a cu. ft. of gas in 24 hours, and it is therefore, possible to run one of these lights for nine months from one tank without any attention.

SEMAPHORE LONG-TIME BURNING OIL.

The problem of producing a signal oil that will withstand low temperatures is bad enough. The Moloney Oil & Manufacturing Co., of Scranton, Pa., having solved that problem, has tackled one that is even more difficult. The service record of its product during the hard winter of 1911-12 showed that the company's semaphore long-time burning oil will not freeze. But the company recently completed some exhaustive experiments to produce a signal oil that cannot freeze. Service records show that the recent output of signal oil will burn through periods of lower temperatures than 25 deg. below zero. It withstood as low as 30 deg. below zero in 1912, in actual service.

The semaphore long-time burning oil is scientifically refined, contains no sulphur—which causes crustation on lamp wicks—has a fire test of 150 deg., and is designed to burn for from 150 to 170 hours without attention.

It is not generally understood that there is a difference between the requirements for one-day burners in signal lamps and for long-time burners. There is, however; and the semaphore long-time burning oil is designed to satisfy the more rigorous demands of the signal system which requires continuous day and night illumination of the signals with inspection by the maintenance force only at intervals of from one to three days. As the result of three years' trial under service conditions and exhaustive laboratory tests, the company is now offering to submit samples of its signal grade—the semaphore long-time burning oil—for test purposes.

STEEL TIE INSULATION.

One of the objections most frequently urged against steel ties is the difficulty of insulation, especially with reference to signal circuits. To give satisfactory service in track,

Steel Tie Track on Pittsburgh & Lake Erie Insulated with Fibre Shims.

they must not only provide the required insulation when installed, but must maintain it under the wear and load of the rail and other track fastenings regardless of whether the insulation is rivcted or bolted between the rail and the tie. The Pittsburgh & Lake Erie has an installation of

3,000 Carnegie I beam steel ties in the main westbound freight track at McKee's Rocks, Pa., which was put in during the summer of 1907. This track, which is shown in the accompanying photograph, is insulated with 6,000 American Vulcanized Fibre Co.'s fibre shims. This track carries an average daily traffic of 16 heavy freight trains and about 10 trains of miscellaneous freight and about 25 heavy engine movements. It is said that in spite of this traffic not a single signal failure has occurred because of defective insulation since this fibre has been in service.

NEW HEAVY TRACK SCALE.

The Southern Railway has recently installed a new track scale at Granite Quarry, near Salisbury, S. C., which is of an improved type and especially heavy construction. Several features of note are included in the design, which was built in accordance with specifications of the engineering department.

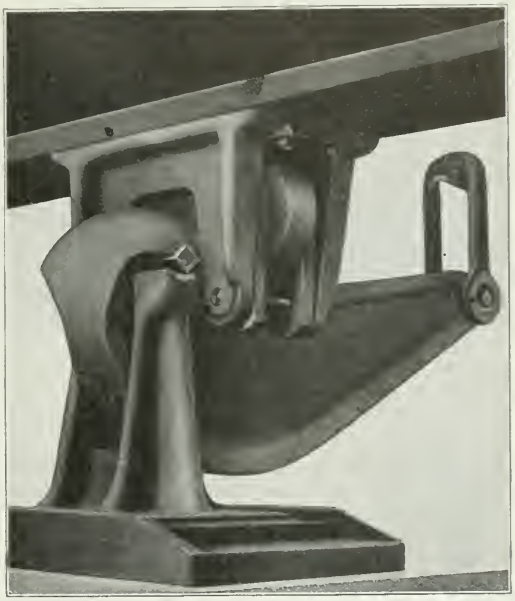
This scale has a Strait suspended platform and is of the four-section extra heavy railroad pattern. It is 54 ft. long and has a capacity of 150 tons, although provision is made for an additional load of 150 tons for impact, so that its strength is sufficient to carry and to weigh a dead load of 300 tons.

The length of knife and pivot edge bearings are also proportionately increased throughout, and are backed or supported by the metal being carried out as shown in the half-tone cut. The excess strength and increased proportions are for the purpose of insuring the utmost accuracy as well as the greatest durability and freedom from breakage under the hardest service.

The scale itself has no action other than that of weighing, not being set in motion by the vibration of the platform. The platform is suspended from "bearing feet" resting on the knife edges, permitting it to vibrate independently. All pivots and knife edges are thereby relieved of unnecessary wear. No check rods are used; the platform being in no way connected with the frame work or any stationary part, is always free, so that inaccurate weights from interference are prevented. The bearing feet are so designed that they cannot shift on the knife edges which prevents change in balance, the cause of much inaccuracy.

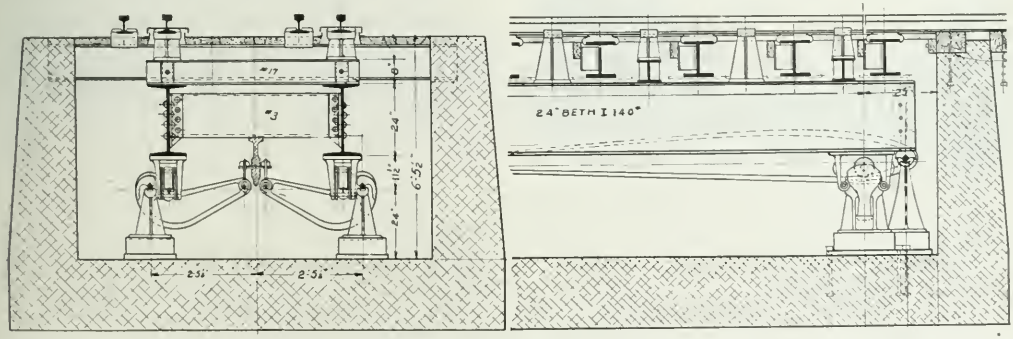
The scale is erected upon "wedge adjustable" foundation plates grouted in the concrete, enabling any lever to be easily brought up to proper level simply by the use of a wrench, should there be any change or settling of the foundation. Bronze adjusting bolts are used so that rust will not prevent operating. No underframing of structural steel is employed, thereby reducing the expense of painting, which is necessary to prevent rust when this material is used in such locations.

The superstructure is what is known as the stationary deck or platform, being supported by crosswise steel beams laid in recesses in the coping wall. The "dead" track rails are carried by cast iron bearing blocks resting directly on the crosswise supporting "H" section Bethlehem beams, these



Main Lever and Suspension Bearing Supporting I Beams of Scale Track.

blocks being of suitable shape to fit over the beams and to receive the rails. The live track is carried by cast iron chairs projecting through openings in the stationary deck. These openings are protected by dirt shields. Each alternate chair rests on the lengthwise main stringers and each other alternate and shorter chair is supported by crosswise "H" section Bethlehem beams riveted to the main stringers.



Cross and Longitudinal Sections Showing All-Steel Construction, with Overhang and Wedge Adjusting Foundation Plates.

Filler blocks are provided in the crosswise "H" section beams under the chairs, giving the same effect as if solid. The main stringers are 24 in., 140 lb. Bethlehem girders, having a flange 13 in. wide, which, in connection with the fillers and lateral bracing, makes an exceedingly stable and

substantial construction. Neither the live nor dead tracks or any part pertaining to the operation and maintenance of the scale is connected to or depends on timbers or any perishable material.

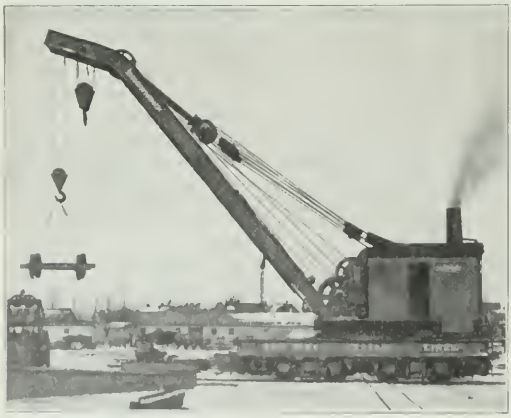
The scale is built with overhang construction or what is sometimes called bridge-ends. The approach tracks are carried over the scale two ft. at each end, leaving a 50 ft. live or weighing track. The load, therefore, is delivered directly over the center of the main levers of the first section, producing no tilting or cantilever effect.

The levers and all active parts are carried up well above any possible interference from accumulating ice or debris. In connection with the fact that no check rods are used, this prevents the scale from freezing up, a cause of much annoyance in cold countries. There is ample room for a man to pass above the main levers in going through the pit, and every part is convenient to inspect. The design of the scale allows any lever to be easily removed without taking out a single bolt or knocking out any pivot. This may be done without even losing the use of the track. The pit has a level floor, making it very convenient to do such work and to keep the pit clean.

A type registering (printing) beam was, of course, furnished with this scale.

NEW YORK CENTRAL CRANE.

The Browning Engineering Co., Cleveland, O., has just shipped a new wrecking and erecting crane to the New York Central which is equipped with a standard goose neck boom for wrecking purposes and also with a 60 ft. boom for use in erection. A special feature of the design of this crane was the necessity for clearing the third rail on the electrified lines



New Wrecking Crane for New York Central Lines.

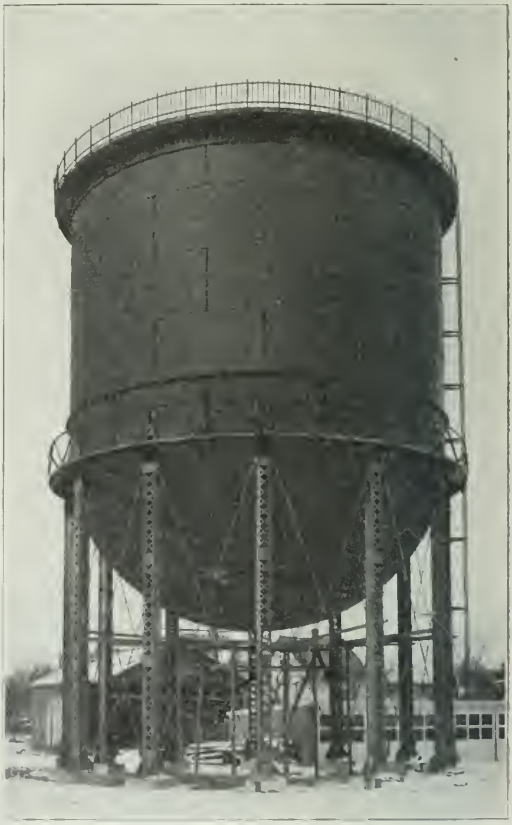
of the New York Central. The car body is 25 ft. 8 in. long and made of 18 in. girder beams. The wheel base is 16 ft. ½ in., the trucks conforming to the M. C. B. standard.

The rotating superstructure is carried on a roller 7 ft. 10 in. in diameter, and the crane is housed in with sheet iron. The goose neck boom is 40 ft. long, with an extension of 10 ft. at the bottom, by means of which it may be used as a 50 ft. boom. There is a main hoist block having a capacity of 45 tons and an auxiliary block of 15 tons capacity. The weight of the crane in working order is about 190,000 lb. The speed of the main hoist block on the six-part line is 20 to 25 ft. a min., and the auxiliary hoist on the two-part line is about 60 ft. per min. The crane is self-propelled through a gear on the inside axle of each truck and has a travel speed on level grade of about 500 ft. a minute.

A LARGE RAILWAY STYLE WATER TOWER.

On account of an error in the make-up of yesterday morning's Daily, by which the illustration of the steel tank at Lakewood, O., was omitted from the description, we are repeating this description below to accompany the cut, as shown herewith.

This tank is believed to be the largest steel tank on a short steel tower ever built and is of a style commonly used by railways. It has a capacity of 560,000 gal. and height to bottom of tank of about 18 ft. The total height is 70 ft. and the diameter 46 ft. The bottom of the tank is constructed of compound curve, the largest radius of



Large Steel Water Tank at Lakewood, O.

curvature being about 24 ft. The twelve columns are each supported by a pier 10 ft. square at base and 6 ft. high. No roof is used on this tank. The two balconies are for ornamentation and also for convenience in inspection. The initial cost of tanks of the size illustrated approximates five cents per gallon.

This structure illustrates the tendency of engineers to abandon the steel stand pipe having a flat bottom resting on a masonry pier. A large portion of the cost of flat-bottom stand pipes is included in the extra masonry required to support them. The water in the lower portion is usually not available for service and failures due to rusting out of metal sometimes occur. The structure shown was designed and built by the Des Moines Bridge & Iron Co., Pittsburgh, Pa.

STRAUSS BASCULE BRIDGE AT SOUTH CHICAGO.

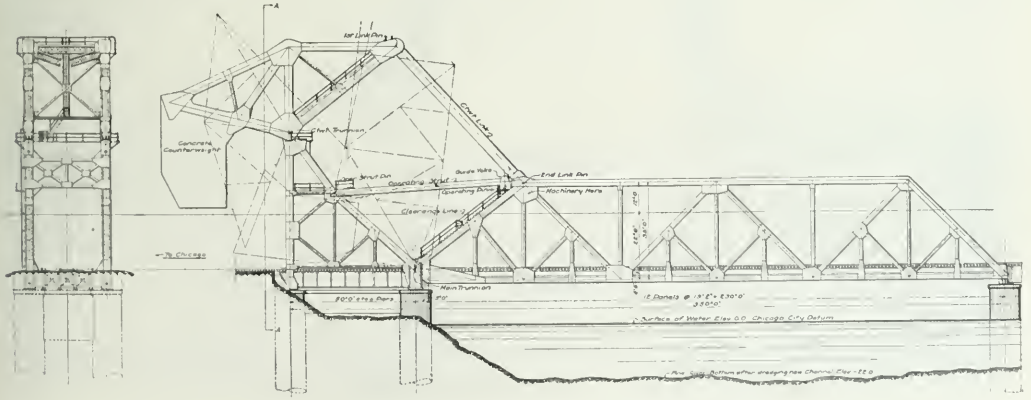
The erection of the Strauss bascule bridge for the Baltimore & Ohio over the Calumet river at South Chicago, which is the longest and heaviest single leaf bascule span in the world, has just been completed. This bridge has a 50 ft. tower span and a 235 ft. single leaf double track movable span. The substructure includes six cylindrical concrete piers about 80 ft. high and 12 ft. in diameter. In the construction of these piers an unusual method of internal bracing was used in the open wells which were sunk to rock in which to build the cylinders. Cofferdams of 3 in. by 12 in. tongue and groove sheet piling were used for about the first 18 ft. of the excavation, which was through quicksand. At this depth a stiff blue clay was reached, which extended down to rock. An open well was driven in the bottom of each cofferdam and was lined with horizontal sections of No. 20 corrugated iron. Commercial sheets about 9 ft. long were bent to a 6 ft. radius, each sheet having riveted to its ends 2 in. by 2 in. angles, with holes in the outstanding legs to allow the connection of abutting sections in the same course to form a solid ring. The courses were placed from the top down, each course overlapping the upper one by a single corrugation. It was found that this construction provided tight joints and only at one point was there any tendency for the sheeting to yield to the external pressure. After the completion of these wells, they were filled with 1:3:5 concrete.

The structural steel in the superstructure of this bridge weighs 1,300 tons and the counterweight 2,000 tons. The bridge is designed for a loading of Cooper's E-50, the trusses differing only slightly from a stationary span of similar dimensions. The trusses bear directly on the river piers and the floor system and top and bottom laterals are the same as those ordinarily used in fixed spans. This bridge, in common with all other heel trunnion bridges of this type, has constant and vertical reactions upon the supporting piers, allowing an economical design of these piers. This was the first bridge of the Strauss design which has been built without side bracing for the towers. It was necessary to omit the bracing in this design on account of the close proximity of the tracks of another road, but after a careful analysis of the stresses in the tower, it was found that this bracing is not in any way essential, and it is expected that in future these structures will in general be built without it. The stability of the tower is increased as the size and weight of the bridge increases, so that it will not be difficult to apply such towers without side bracing to even the largest bridges. The steel work was designed according to Greiner's bascule specifications.

The bridge is designed to move from the closed to the fully opened position in 1.25 min. The operating machinery is located over the end portal at the trunnion end of the movable span. In some of the later designs by this company, the machinery is located on the tower, a feature which has some advantages. Electric power will be used for the operation of the bridge, and an auxiliary gasoline engine plant has been installed, which is capable of operating the bridge in case of any failure of the electric power. The operator's tower is located alongside the bridge, but is built as an independent structure and is so designed that it can serve both the present bridge and a future double track bridge, which has already been contracted for, to be built alongside the present one.

Bridge Shortly After Being Lowered.

The movable span was erected in the open position, which has been found advantageous, and was first lowered on Saturday, February 15. At this time a complete set of tests was made on the operation of the bridge. The tests included observations on the time required for operating the leaf, the power consumption in various positions, and all other features that will have a bearing on its efficient operation. When the structure was first lowered, it was found to be only ⅛ in. out of alinement. The operating time of 1.25 min. was made exactly at the first trial. The bridge is not to be placed in operation immediately, as the swing span of the Lake Shore & Michigan Southern, which is closely adjacent to the new Baltimore & Ohio bridge, swings over the



Elevation and Section of Strauss Bascule at South Chicago.

site of the rest pier of the new trunnion bridge so that this pier cannot be completed up to its full height. The Lake Shore & Michigan Southern is at present replacing its span, however, and when that company's new bridge is complete, the rest pier will be finished and the B. & O. bridge put into operation. In the meantime, the movable leaf will be allowed to stand in the fully opened position.

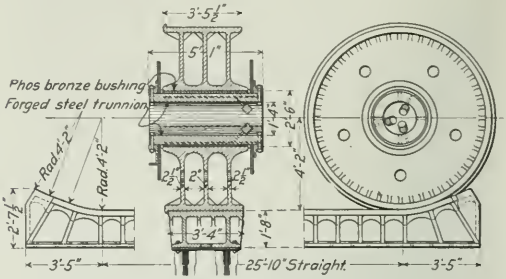
The substructure for this bridge was built by the Foundation Co., New York. The superstructure was designed by the Strauss Bascule Bridge Co., Chicago, and was fabricated and erected by the Pennsylvania Steel Co., Steelton, Pa. The entire work was under the direction of J. E. Greiner, consulting bridge engineer; F. L. Stuart, chief engineer, and W. S. Bouton, bridge engineer, Baltimore & Ohio.

RALL BASCULE BRIDGE AT PORTLAND, ORE.

The two leaf Rall bascule span of the Broadway bridge over the Willamette river, Portland, Ore., is the largest rolling trunnion bridge ever built. The span center to center of piers is 278 ft., and the clear distance at the top of the raised leaves when fully opened is 250 ft. The roadway is 46 ft. 6 in. wide between guards and provision is made for two street car tracks and two wagon ways. On the outside of the main trusses, which are 50 ft. on centers, 9 ft. sidewalks are provided, making the width of the bridge 70 ft. over all.

A special feature of this bridge was that the specifications required the trusses of the bascule span to be in line with the trusses of the approach spans. This necessitated special recesses in the counterweight boxes and their truss supports to enable them to pass between the trusses of the approach spans and also developed many interesting problems in the design of the bracing and other details for adjustment, expansion, etc.

The rolling load of each leaf including the counterweight, is approximately 2,000 tons, each roller, therefore, carrying a load of about 1,000 tons. The rollers are each 8 ft. 4 in. in diameter and 40 in. long. In order to properly distribute the rolling load to the carrying girder a steel track casting 20 in. high is provided, which transfers the load directly to the web section of the supporting girder without depending on rivets for the distribution. The rollers and the bearing castings are of nickel chrome steel. The distributing castings, as well as the rollers, are without cogs or teeth, so



Main Trunnion, Roller and Supporting Track of Rall Bascule Bridge.

that the operation of the bridge is smooth and practically noiseless. When the bascule span is closed, the heel of the river arm bears on a lower support directly over the pier. This support carries all the live load of the bascule span and, if desired, may be adjusted vertically to carry a portion or all of the rolling load.

Ralph Modjeski of Chicago is chief engineer in charge of the general design and construction for the city of Portland. The bascule span was designed by the Strobel Steel Construction Co., Chicago, which controls the Rall patents. The Pennsylvania Steel Co., Steelton, Pa., is the contractor for the superstructure of the entire bridge, including the machinery and electrical equipment for the bascule span. The bridge is nearly completed, and the bascule span has been successfully operated.

Rall Rolling Bascule Span Over Willamette River, Portland, Ore.

United States and Mexico	$5.00
Canada	6.00
Foreign Countries (excepting daily editions)	8.00
Single Copies	15 cents each

Engineering and Maintenance of Way Edition and the four Maintenance of Way Convention Daily Issues, North America, $1.00, foreign (excepting daily editions), $2.00.

Application made at the Post Office at Chicago, Ill., for entry as mail matter of the second class.

WE GUARANTEE, that of this issue 11,000 copies were printed; that of those 11,000 copies, 9,869 copies were mailed or delivered by messenger to regular paid subscribers; 950 copies were distributed among members and guests of the American Railway Engineering Association and at the Coliseum; 131 copies were mailed to advertisers; and 50 copies were set aside for office use.

CONTENTS:

Edwin F. Wendt, who was elected president of the American Railway Engineering Association yesterday, is assistant engineer of the Pittsburgh & Lake Erie, with office at Pittsburgh. Mr. Wendt was educated in the public schools of New Brighton, Beaver County, Pa., and was graduated from Geneva College, Beaver Falls, Pa., in 1888, with highest honors in the classical course. He entered railway service in 1888 as axeman and chainman in the engineering corps of the Pittsburgh & Lake Erie and served continuously with that road in the different positions of axeman, chainman, rodman, levelman and transitman up to October 1, 1898, since which time he has been assistant engineer in charge of maintenance of way, construction and contract work. Since he has been connected with the engineering department of the Pittsburgh & Lake Erie, this road has been extended and reconstructed; second, third and fourth tracks have been built, large terminal and classification yards and the extensive new locomotive and car shops at McKees Rocks have been constructed and the new Pittsburgh station and general office building has been built. Mr. Wendt was elected a member of the Engineers' Society of Western Pennsylvania in 1890; a member of the American Society of Civil Engineers in 1903, and a charter member of the American Railway Engineering Association in 1900. He has been especially active in the work of the latter association, being chairman of the committee on "Records and Accounts" during 1903-4-5; a member of the committee on "Signals and Interlocking," 1906-13, inclusive; a member of the Board of Direction during 1908-9-10; chairman of the committee on "Publications" during 1912-13; second vice-president in 1911 and first vice-president in 1912. He has also been a member of the Board of Trustees of Geneva College, Beaver Falls, Pa., since 1907, and is a member of the University Club of Ptitsburgh. By training, experience, talents and personality Mr. Wendt is fitted for the presidency of the greatest railway engineering association in the world—an association that has numbered among its presiding officers some of the leading engineers of the railways of North America.

In his discourse at the dinner last night on the effect of music on the railways George A. Post suggested to the railway men that they push from the center of the stage those who sing of what is the matter with the railways and themselves trill a few notes about what is not the matter with the railways—about what they have and the creditable things they do. The public seems to need to learn that the music of railway operation and development is more important and necessary than the music of railway regulation—and this is not said to minimize the need and importance of regulation. About the only feasible way of informing the public about the good features of railway management and operation in this country, one of the things that are needed to make them better, is, as Mr. Post indicates, for railway men to sing about them. After a while railway men may be able to get other people to take up the tune; but they will have to teach it to them first.

In the discussion of the first conclusion of the committee on Wooden Bridges and Trestles, that it be recommended as good practice to use guard timbers on all open floor bridges, the legal aspect of the matter should be borne in mind. There is a difference of opinion as to the necessity for guard rails on bridges. Many engineers believe that their installation does not insure the safety of a derailed car. One member went so far as to say that he believed that in many cases a black mark painted upon the tie would be equally effective. This view is not shared by most of the membership of the Association; and many roads place guard rails on all open floor bridges. But if the Association goes on record as recommending guard rails on all open floor bridges as good practice, it places the railroad which does not install them in an embarrassing position in a lawsuit. The recommendations of this important Association have great weight in court; and they should not be made without due regard to this fact.

After working under difficulties in securing information for the past two years, the committee on Economics of Railway Location made a report yesterday which, while incomplete in many ways, presented many points to be considered in the locating of main lines. No other report made at this year's convention has brought out so much discussion; and this fairly measures the interest aroused by it. Many of the statemens of facts and some of the conclusions drawn are open to argument; and probably the committee presented them in the form it did to draw out discussion. It has been unusually difficult to get the data essential to a thorough study of the subject, the principal reason being that very little information regarding the cost of operation of trains

under varied conditions of grade, curvature, temperature, etc., has been kept in such form as to make practicable valuable comparisons. The facts brought out by the committee should serve as the basis for further useful investigation that will call forth data confirmatory of some and contrary to others of the conclusions drawn. In his written discussion W. J. Wilgus points out a number of places in which the conclusions of the committee may be questioned. But the conclusions of Mr. Wilgus are open to some of the same objections as those of the committee. There are not sufficient data in existence for accurate determination of the importance of the various factors to be dealt with; and until this ceases to be true it will continue to be difficult to draw sound conclusions.

It is probably too much to expect that any simple formula regarding railway location can be developed which will be applicable to all conditions. But there are many elements of uncertainty which can be eliminated. The principal business of a railway, from a purely revenue standpoint, is the transportation of freight. The net earnings depend mainly on the economy with which this traffic is handled. Therefore from a business standpoint the subject of this committee is very important; and effective study of it will be productive of large results in the form of net revenue. In a study of the savings which would be made by the construction of a new line on an eastern railway a few years ago, it was found that the old line was not being operated to its best advantage, and as a result of a careful engineering investigation the method of operation was so changed that a very great reduction in the cost of operation on the old line was made. The objection sometimes raised that the association should be careful not to step over into the realm of the transportation department is not weighty, for the function of the engineering department, as of all other departments, is to move traffic. As Mr. Himes aptly expressed it, the engineering department might rather be called the "co-operation department." It is to be hoped that this committee's report and the discussion of it will serve as a means of bringing out much further information. To collect and compile the data essential for a thorough study of the subject will require the continual service of a number of men; and it would seem that the railways either individually or through the American Railway Association could well afford to assume the necessary expense for this.

PRESIDENT WORTHINGTON'S ADDRESS.

The address made by President Worthington of the Chicago & Alton at the annual dinner of the Engineering Association last night was typical of the public utterances now being made by railway executives who are progressive and public-spirited and who clearly recognize the conditions with which railway managers are confronted. Mr. Worthington was optimistic. He expressed the belief that the railway problem in this country can be solved by government regulation; and he implied that government ownership would not solve the present problem but merely substitute for it a much harder one. While he was optimistic, he based his optimism not on the belief that all the present tendencies and methods of public regulation would work out satisfactory results, but that the wisdom of the American public would change some of these tendencies and methods.

Railway managers formerly were reticent. They have become very frank. They are telling their troubles to the public as frankly as Mr. Worthington did last night, not because they especially like to tell them—they would greatly prefer not to have any of them to tell—but because, as the public now regulates and controls railway management, the railway problem can be solved only by co-operation between the managers and the public.

Some railway men at times despair regarding the results of frank and full discussion of the railway situation. They say that spokesmen of the railways have been presenting their case to the public for years now, and that the number of people who have learned very many facts about railway conditions and that believe what the railway managers say is still small. As a matter of fact, the number of people who now have some understanding of the railway situation and a desire to see the railways intelligently and fairly regulated unquestionably is greater than it ever was before. That the number is not still greater is not surprising. The management of railways was not formerly so circumspect in many ways as it is now. Meantime, there was a growing storm of both just and unjust criticism. Railway managers neither did enough during this period to effect needed reforms nor to explain and defend the conditions that were explicable and defensible. The work of years cannot be undone by the work of months. The railways are much better managed and much better defended than they ever were before. But they will have to be thus managed and defended for a long time yet before public opinion regarding railway matters will become satisfactory.

The engineering department has not come so much in contact with public regulation as some other departments. The traffic department now has the rates that it may charge largely dictated to it. The mechanical department must comply with federal and some state laws in inspecting locomotive boilers, installing safety appliances, etc. The operating department has the number of men it must employ in train crews fixed by law in many states, as well as the hours that employes may be kept at work, etc. The engineering and maintenance of way department is quite likely at almost any time to be confronted with measures for the regulation of various details of roadway, track and structures. There are two ways to deal with proposed regulation. One is, if it is right, to do voluntarily the thing it is proposed to require to be done. The other, if the thing proposed is wrong, is to meet the advocates of the proposed legislation squarely and try by facts and logic to prove to their satisfaction and that of the public that their proposals are wrong. Fortunately, the railway engineers of this country understand these things. While, however, the engineering department has not as yet come very directly in contact with public regulation, it has felt its effects. Regulation has tended to hold down and reduce earnings, and this has tended to interfere with adequate expenditures for maintenance and new construction.

There seems to be only one way to improve regulation and its results, and that is constantly to discuss them fully and frankly. Some years ago Edwin Lawrence Godkin, long the editor of the *New York Evening Post*, and of the *Nation*, wrote a paper entitled "The Duty of Educated Men in a Democracy," in the course of which he said: "One hears every day from educated people some addition to the number of things which 'governments' ought to do, but for which any government we have at present is totally unfit. One listens to them with amazement, when looking at the material of which our government is composed, for the matter of that, of which all governments are composed, for I suppose there is no question that all legislative bodies in the world have in twenty years run down in quality. The parliamentary system is apparently failing to meet the demands of modern democratic society, and is falling into some disrepute; but it would seem as if there was at present just as little chance of a substitute of any kind as of the dethronement of universal suffrage. It will probably last indefinitely, and be as good or as bad as its constitu-

ents make it. But this probable extension of the powers and functions of government make more necessary than ever a free expression of opinion, and especially of educated opinion. We may rail at 'mere talk' as much as we please, but the probability is that the affairs of nations and of men will be more and more regulated by talk. • • • So I shall, in disregard of the great laudation of silence which filled the earth in the days of Carlyle, say that one of the functions of an educated man is to talk, and, of course, he should try to talk wisely." Mr. Worthington said in his address that the Engineering Association is "a body of professional men whose fundamental requirement in order to qualify in their calling is a most liberal technical education; gentlemen who, I might say, represent the culture and aristocracy of the railroad profession." The application of Mr. Godkin's remarks to men of the class which Mr. Worthington thus described is obvious. Do the highly-educated, broad-minded and able railway engineers of this country fully live up to their duty as "educated men in a democracy" by discussing the railway business with people outside that business as much as they might?

A. H. RUDD RESIGNS AS CHAIRMAN OF COMMITTEES X AND I.

Committee X on Signals and Interlocking of the American Railway Engineering Association and Committee I on Signaling Practice of the Railway Signal Association had their annual dinner at the Congress Hotel Tuesday evening. A. H. Rudd resigned as chairman of both committees, and the members decided upon T. S. Stevens, signal engineer of the Atchison, Topeka & Santa Fe, as his successor to both of them, subject, of course, to the action of the directors of the two associations. C. C. Anthony, assistant signal engineer, Pennsylvania Railroad, was chosen for vice-chairman. The membership of these committees is practically identical. It is customary to appoint to membership on Committee I of the R. S. A. all members of that organization who also belong to the A. R. E. A., and are members of Committee X.

THIS FROM A RAILROAD MAN!

A well known railroad man was asked this morning what he thought of the exhibit as a whole. His reply was, "It is very artistic."

This coming from a railroad man was more than unexpected, but it is highly expressive at that. The exhibits of some previous years have been some other things than artistic, principally because it is rather difficult to get together a bunch of "stuff" made of iron and steel, concrete and brass, wire and paint, in a shape that has a right to any of the very numerous and elastic applications of the word "artistic."

The show this year, however, is artistic, and the general arrangement is much better, and the exhibits more attractive than ever before—if such a thing is possible.

PENNSYLVANIA IMPROVEMENTS AT PHILADELPHIA.

The board of directors of the Pennsylvania Railroad have authorized the electrification of the main line for suburban passenger traffic from Philadelphia to Paoli, a distance of 20 miles. Involved in the scheme is some six-track improvement work which, with the widening of the Broad Street station, will afford much needed terminal relief. The first work to be undertaken will be that previously announced in the *Railway Age Gazette*, which includes the construction of an eight-track station at North Philadelphia, and the building of additional tracks on the connecting railway, involving a new arch bridge over the Schuykill river at Girard avenue.

BY REQUEST OF COMMITTEE ON ARRANGEMENTS.

The committee on arrangements on being notified through yesterday's Daily of the action of the convention in referring to them paragraph 34 of the "Instructions for the inspection of the Fabrication of Steel Bridges" reading, "Have important members so loaded as to be headed in the right direction upon arrival at the site of the work," delegated L. C. Fritch to advise the convention during yesterday morning's session that the committee would accept this assignment on the condition that members come to them fully loaded and with their headlights burning so that there can be no mistake as to which direction they are going.

J. T. BRANTNER GIVEN MEDAL FOR FIFTY YEARS' SERVICE.

J. T. Brantner, superintendent, Martinsburg shops, maintenance of way department, Baltimore & Ohio, Martinsburg, W. Va., has been awarded a gold medal for the completion of 50 years' continuous service on that road. Mr. Brantner entered the service January 1, 1863, so that his half century of connection with the system was completed December 31, 1912. He is the first man to be awarded a medal for such service. Mr. Brantner is attending the convention of the American Engineering Association.

BALTIMORE & OHIO DINNER.

Sixty-three officers of the Baltimore & Ohio attended the annual dinner yesterday noon of representatives of this road attending the convention. Earl Stimson, chief engineer maintenance of way, presided and gave a short talk, being followed by J. A. Spielman, engineer maintenance of way, Pittsburgh; G. W. Andrews, general inspector of maintenance, Baltimore, and J. T. Brantner, superintendent, frog and switch shops, Martinsburg, W. Va.

HOWARD & ROBERTS.

Through an error, C. P. Howard of the newly organized firm of Howard & Roberts, was referred to in Tuesday morning's Daily as having been connected with the Canadian Pacific. Mr. Howard has been with the Illinois Central for several years and many of his friends no doubt realized the error in the previous notice.

DEAN TURNEAURE HERE.

F. E. Turneaure, dean of the college of engineering, University of Wisconsin, who is in attendance at the convention, has just returned from Europe, where he has been making a study of railway conditions on the European roads.

Proceedings.

PROCEEDINGS.

The Wednesday morning session of the American Railway Engineering Association was called to order at 9:20 a. m. by President Churchill.

ECONOMICS OF RAILWAY LOCATION.

The chairman has made a study to determine the approximate general laws affecting such maintenance of way accounts as are influenced by changes in physical characteristics of locations and presents the results of this study for the consideration of the association. It is not assumed that the analysis of the accounts for the 53 railroads shown in the table gives the correct cost per mile of main track, but it is believed that for the major portion the figures are within reasonable proximity of the truth, and that the individual diagrams show with sufficient accuracy the general law of ratios of increased cost for a fixed unit of traffic to the portion of expense due to age or decay.

The conclusions presented are recommended for adoption, believing that the application of the formulas therein to the normal annual charge for each account will eliminate

A. K. SHURTLEFF,
Chairman Committee on Economics of Railway Location.

considerable of the guesswork of the past. The ratios of cost per mile of side track to mile of main track on any particular line can be estimated without too great an element of guesswork, and in the average case it will not be found far from the suggested value in the table. With these conclusions adopted your committee has a way opened for the further study of questions entering into economics of location.

ANALYSIS OF MAINTENANCE OF WAY AND STRUCTURE ACCOUNTS.

The majority of the problems of economics of railway location deal only with main track questions, although an occasional problem introduces the consideration of side-tracks. It is therefore necessary to analyze and separate certain of the primary operating accounts between costs for main track and costs for sidings, particularly those accounts covering maintenance of way and structures.

Great difficulty has been found in obtaining the necessary information from the railway companies to aid in the proper analysis of the questions. Only three or four railroads out of the many asked for information have attempted to give any data to aid in the digest of this particular question. However, the question has been studied on one large system of nearly 8,000 miles of main tracks and does not vary materially from the ratios of cost per mile of main and side tracks of the other three roads. The figures cover a period of four years and are used in the following analyses, believing them to represent a fair and reasonable average of the relative costs of maintaining main and side tracks for most of the railways of the United States. The figures will not apply to roads lying entirely within a dense manufacturing or mining district where the necessary mileage of side track nearly equals or sometimes exceeds the main track mileage, and the switching mileage is so heavy as to make the tonnage over the side tracks exceedingly large. The methods of this analysis can be followed in such a case, using the ratios of costs that have been found proper for the heavy switching traffic on the industrial sidings.

The following gives only the accounts which are particularly due to both main and side track usage:

Account 1.—Superintendence of Way and Structures. One mile of side track requires practically one-third the cost of one mile of main track.

Account 2.—Ballast. One mile of ballasted side track averages only about one-fourth the cost of one mile of ballasted main track. This factor is a difficult one to reach logically and is a matter of judgment. No detailed figures have been obtainable, as usually only a minor portion of side tracks are ballasted and not all main tracks.

Account 3.—Ties. The number of renewals per mile of side track for four years averaged about 70 per cent of the number per mile of main track. The side track renewals embraced No. 2 ties as well as No. 1, and the average cost per side track tie was about 70 per cent of the cost per ties for main track, making the total charge per mile of side track practically one-half of the cost per mile of main track.

Account 4.—Rails. Main line rail was relaid by new rail, re-rolled rail or good relayer rail of heavier section, in all cases the renewal portion of the charges being only the tonnage equal to the weight of the released rail at the charge per ton for the material replacing it. Side track renewals were from relayer rail only and charged out on the above principle according to the form prescribed by the Interstate Commerce Commission. The arbitrary credit for relayer rail released and charge for same used was practically 75 per cent of the cost of new rail. Scrap released was credited at approximately market value. The average charges per mile of side track for rail renewals was about 25 per cent of the cost per mile of main track.

Account 5.—Other Track Material. Practically 37 per cent of this account was account of frogs and switches, the major portion being to frogs, hence due entirely to side tracks, although many existed in the main track. A careful analysis shows that one mile of side track costs practically the same as one mile of main track for this account due almost wholly to the costs of turnout frogs and switch points.

Account 6.—Roadway and Track. The cost per mile of side track averages about one-third the cost per mile of main track. This is due not only to the lower grade of maintenance of side track, but to the fact that many items charged into this account are principally main track items, for example, ditching, bank widening, track walkers, cutting weeds on right of way, etc.

Account 9.—Bridges, Trestles and Culverts.

Account 10.—Over and Undergrade Crossings. Occasionally a small portion of these two accounts is chargeable to side tracks, but for the majority of cases the amount is so small as to be negligible in economic calculations.

Account 18.—Roadway Tools and Supplies. One mile of side track requires about one-third the cost of one mile of main track.

In the remaining accounts of maintenance of way structures the side track mileage rarely affects the amount of the account and can be neglected in economic calculation. The main track portion of these accounts per mile of main track can be obtained by dividing the total charge to each account by the equivalent main track mileage, the latter being the total main track mileage plus the product of side track mileage by the proper per cent of cost per side track mile for the given account.

The above accounts are all materially affected by volume of traffic except Account 2, ballast, and Accounts 9 and 10, bridges, culverts, over and under grade crossings.

The train mile has been commonly used as a traffic unit in economic studies in the past, but it is illogical to use this unit as a measurement of wear and tear on the track owing to the wide limits in weights of trains that can be handled by the same locomotive in districts of different gradients. A train with gross weight of 2,000 tons will cause about double the wear and tear on the structure that would be caused by one of half the weight. The ton mile would be the best unit considering total weights on

Cost of Maintenance on Accounts Affected by Traffic.

the rails if freight traffic only passed over the track, but passenger traffic also must be considered and owing to the higher velocity of trains the damage done per ton of passenger train is greater and the labor of maintaining track for the higher velocities is increased. With velocities equal, the damage done to track will vary about directly proportional to the load per axle and one ton of locomotive will create more disturbance to track than one ton of car and contents.

The following gives some average axle loads for the heaviest types of modern locomotives and for average loading for cars. It will be many years before the average locomotive loading reaches these figures, while the average car loading will probably increase:

	Average load per axle.
Passenger service.	
Atlantic locomotive	39,100
Pacific locomotive	37,800
10-Wheel locomotive	22,000
Average passenger train car	22,000
Freight service.	
Mikado locomotive	48,500
Consolidation locomotive	44,600
Mallet Comp. locomotive	42,300
50-ton capacity gondola car, loaded one way return empty	22,500
Average 35 tons per car of freight train (above present average)	17,500

The present average of load per axle of freight and passenger locomotives in less than double the average load per axle of train.

In studying average maintenance expenses by divisions for a period of years on the large system previously mentioned it appeared that the best unit of traffic measurement of expense was what we will term the equivalent ton mile. The total equivalent ton miles would be the sum of the following:

Double the freight locomotive mileage times average weight per locomotive.
Four times the passenger locomotive mileage times average weight.
Total freight ton miles (cars and contents).
Double the passenger ton miles (cars and contents.)

This unit considers that one ton of passenger car does double the injury of one ton of freight car, and that one ton of locomotive affects the track as much as two tons of the train back of the locomotive. This unit of measurement even best fits the increase of maintenance of buildings due to increase of traffic and consequent increase in number and size of buildings. Passenger traffic demands a higher type and better grade of maintenance than freight, and even a better type of shop buildings for repair.

With the exception of Account 4, rails, there is a minimum expense for the accounts affected by the volume of traffic due to depreciation and decay. This expense must be met to keep the road in shape for operation. The increase in expense above this minimum is practically directly proportional to the equivalent ton mileage passing over the tracks. There may be a slight loss of rails by corrosion, but its effect on the general account cannot be noticed and the cost can safely be considered directly proportional to the equivalent ton mileage.

Criticism may be made of adopting a traffic unit that involves the estimating of passenger train tonnage. Nothing can be done of value if the work of the committee is to be based in the terms of statistics as kept at the present time. Net ton miles, freight and passenger train

car mileage is kept, also road engine mileage separated between freight and passenger service. Weights of locomotives are a matter of record. The estimating covers the assumption of an average weight for empty freight cars, which at present is about 18 tons, and an average weight per car and load of passenger train cars. At the present time 44 tons per passenger train car of the average train will not lead to great error, and the average passenger train of the United States has approximately 5.3 cars per train. This last figure is not necessary for use where passenger train car mileage is available.

Early in the present year the Interstate Commerce Commission published a pamphlet, "A Preliminary Abstract of Statistics of Common Carriers for the Year Ended June 30, 1911." The information in this pamphlet is more complete with reference to operating data of individual roads than has heretofore been published. The accompanying table showing the items of costs of the maintenance accounts affected by traffic is deduced from data given by the Commission, using the ratios of costs per mile of sidetrack as outlined to reduce to cost per mile of main track only. As only average weights of locomotives, excluding tender, were given, two-thirds of the weight was added to cover weight of tender and the same weight of engine was assumed for both passenger and freight service. The ton mileage was worked from net ton mileage and the mileage of the two classes of cars and road engines.

There is no attempt to place the cost of ties in dollars per mile of track as there is probably no account in which there is a wider variety of materials or unit costs than in ties. Climatic conditions affect the tie question, particularly noticed when comparing the roads of the South with those of the North. It is evident that the roads using either properly treated woods or timber of a high grade, and protecting the ties from mechanical wear by heavy tie plates with good bearing area, are receiving good returns because of the practice.

In all of the accounts it must be recognized that some of the roads were above the normal in the various accounts and other roads below. Taking the data from several years' operation of a railway, the following formula will give the average expense of maintenance due solely to age and decay for the accounts where both decay and mechanical wear enter the question and using the tabular values for the functions as deduced from these statistics for 1911 the average expense for any volume of traffic per mile of main track can be estimated:

A = Total main track mileage.
B = Total side track mileage.
C = Average annual charge to the given account.
P = Proportional charge per mile of side track as compared with charge for main track only.
X = Annual charge per mile of main track to keep in condition for proper operation covering the amount due to age or decay.
R = Proportion of X representing the additional charge per mile of main track for each million equivalent ton miles per annum.
M = Million ton miles traffic per annum per mile of main track.
E = Charge per annum per mile of main track only, for the given account.

$$E = \frac{C}{A + BP} = X + MRX = X\ (1 + MR)$$

$$\text{Then } X = \frac{C}{A + BP + MR\ (A + BP)}$$

The values given for P and R in the tables with conclusions are suitable to determine the average value of X for the great bulk of the railroads of the country, providing a sufficient number of years' data is used to produce a normal average. For the exceptional cases where a large portion of the total track mileage consists of busy industry spurs and sidings, suitable values for P must be ascertained.

The data given for ties is based on a study of renewals on different divisions of the same line with widely varying traffic. On track where ties were of a high grade timber or creosoted and with a large proportion of ties protected by heavy tie plates, the renewals in main track were 6.5 per cent. of the total in the track plus 0.3 per cent. for each million equivalent ton miles traffic. This figure appears to fit very closely the northern half of the United States, where the roads have taken means to properly protect the ties. In the southern portion the percentage due to decay will be greater, but by multiplying the proper percentage by the value 0.46 per million equivalent ton miles, the average renewals can be approximated for cases where proper methods are used to retard mechanical wear. Each locality can determine within reasonable limits the value of the constant renewals required due to decay for the available timbers.

Account 4, rail renewals, apparently costs about $11 per mile of main track for each million ton miles and requires about 1.1 tons of new rail for this traffic. This figure will answer under present conditions of rail renewals and checks very closely with some data gathered on the equivalent ton mileage per mile of track during the life of 80-lb. tangent rail on a busy double track division. The maximum equivalent tons over any of the rail was 147 millions. The tangent rail released was in condition for relaying or for re-rolling and considering 110 million miles the average for this rail would make practically 1.1 tons per million equivalent ton miles.

According to custom the maintenance charges are only for the weight released less the arbitrary credit for the usable released material, although heavier sections may be used for replacements. The relaying rail when used to replace still lighter sections on districts of less traffic will further reduce the maintenance charge, as the rail finally released fixes the final distribution of the total cost between maintenance and betterments. It is apparent that as the average weight of rail approaches the modern heavier section betterments will absorb a less proportion of expense of rail renewals and maintenance charges will be increased. Sufficient data is not at hand to show whether the heavier rail will withstand an equivalent increase in tonnage directly proportional to its weight. It can hardly be expected to do so as head wear determines the necessity of renewals where rail sections are sufficiently stiff for the axle loads. The cost of rail renewals will probably be found to bear a different relation to the volume of traffic in a very few years.

The other maintenance of way and structures accounts affecting main track are for all practical purposes independent of the volume of traffic. Most of them are dependent either on mileage of main track or mileage of road. Tunnels, bridges and culverts and over and under grade crossings are dependent on the topography of the country and materials of construction, and in comparing the relative economy of different locations the amount and character of the tunnels and bridges on each must be considered in estimating the difference in maintenance costs.

The tables in the conclusions give the accounts under their respective headings. Other maintenance of way and structures accounts may be ignored, as they bear practically no relation to location.

Average values for any of these main accounts can be obtained from Interstate Commerce Commission reports for the leading roads in all sections of the country.

The foregoing covers only the foundation of the work for analyzing the effect of changes in physical characteristics on maintenance of way and structures accounts. It can be seen that distance affects nearly all of the accounts mentioned and that the volume of traffic affects only a portion of them. Curvature affects only the rail renewals and roadway and track accounts with a very slight addition to tie renewals, providing that good substantial tie plates having large bearing area are used. It must be assumed that proper details of construction are used in the initial work in estimating relative values of different lines. Future study of the committee should be to determine the effect of curvature on the accounts mentioned and then take up the study with reference to maintenance of equipment and conducting transportation expenses.

The following are the conclusions with reference to the present study:

CONCLUSIONS.

1. The problems of economic location deal only with main track in the majority of cases, side tracks entering into the question only where differences in distance are so great as to necessitate additional side tracks.

2. The annual charge per mile of main track for any account embracing both main and side track can be approximated for any operated line by the following formula:

A = Total average main track mileage.
B = Total average side track mileage.
C = Average annual charge to the account.
P = Proportional charge per mile of side track as compared with charge per mile of main track.
E = Average annual charge per mile of main track only.

$$E = \frac{C}{A + BP}$$

The average value of P is shown in the table, but for roads located almost wholly within dense mining or manufacturing districts requiring an exceedingly large proportion of busy side and spur tracks the values would be higher and should be determined.

3. The accounts covering maintenance of main track do

not all vary by the same general law, but vary most directly according to the following groups:

(a) Affected by both miles of track and volume of traffic.
(b) Affected by miles of main track.
(c) Affected by miles of road.
(d) Affected by local topographical features.

Therefore no single unit of measurement of relative maintenance expense is applicable to all accounts in comparing the relative economies of two locations. The tables show the groupings of the accounts under their proper heading.

4. One ton of passenger train does more damage to track than one ton of freight train and the locomotive creates more disturbance than an equal weight of cars and contents. Until data is available to correctly estimate the relative damage, it is recommended that the following ratios be used in estimating effect of traffic on the accounts in group (a):

One ton of passenger car and contents produces approximately the effect of two tons of freight car and contents.

One ton of locomotive produces approximately the effect of two tons of the balance of its train.

The total ton mileage reduced to terms of ton miles of freight car and contents is termed the *equivalent ton mileage.*

Most of the accounts in group (a) have a constant maintenance expense due to age and decay, plus an additional expense depending on volume of traffic. This additional expense per mile of main track varies most directly with the *equivalent ton mile.* The equivalent ton mileage can be approximated by adding together the following:

Net freight ton mileage.

Double the freight locomotive mileage times average weight in tons.

Freight train car mileage times the average weight of empty cars (at present about 18 tons).

Double the passenger train car mileage times the average weight of car and contents (at present about 44 tons).

Four times the passenger engine mileage times the average weight in tons.

5. The average annual expense per mile of main track due to age or decay for the accounts in which this item enters can be approximated for any road by the following formula:

E = Charge per annum per mile of main track only.
X = Annual charge per mile of main track due to age or decay.
R = Proportion of X covering the additional charge per annum per mile of main track for each million equivalent ton miles.
M = Million equivalent ton miles per annum per mile of main track.

Then from the above and the equation in Conclusion 2.

$$E = X + MRX = X\ (1 + MR) = \frac{C}{A + BP}$$

$$X = \frac{C}{A + BP + MR\ (A + BP)}$$

Average values for P and R are shown in the tables.

ACCOUNTS AFFECTED BY MILES OF TRACK AND VOLUME OF TRAFFIC.

No.	Account.	Avg. Values. P	R	1911. Avg. Values. X	RX	Remarks.
1	Superintendence	0.33	0.44	$ 18	$ 8	
2	Ties (based on number used)	0.7	0.046	Varies	...	Cost, quality and climatic conditions vary widely.
2	Ties (based on cost)	0.5	0.046	Varies	...	Local conditions must determine value of X. Curvature affects charges but lightly where protected by proper plates and fastenings.
4	Rails	0.25		0	...	Present average annual charge per mile of main track is $11 per million ton miles, or 1.1 tons new rails for same traffic. Curvature affects this account.
5	Other track material	1		0	...	Present average annual charge per mile of main track is $10 per million ton miles Affected slightly by curvature.
6	Roadway and track	0.33	0.245	$200	$49	Affected by curvature.
16	Buildings	0.	2.4	10	24	Affected only where distance or increased volume of traffic makes additional buildings necessary.
18	Tools and supplies	0.33	0.40	5	2	

ACCOUNTS AFFECTED BY MAIN TRACK MILEAGE.

No.	Account.	Remarks.
2.	Ballast	For full ballasted track this varies with the quality of ballast and cost laid down at side of track.
7.	Removal of snow and ice	Varies widely, depending on climatic conditions.
13.	Signals (block signals only)	Present average cost $125.00 per mile with average of one signal to the mile. Curvature may necessitate additional signals.
20.	Stationery and printing	

ACCOUNTS AFFECTED BY MILEAGE OF ROAD.

11.	Grade crossings, Fences, cattle guards and signs	Mileage of main track affects this account slightly, but variation is most directly in proportion to miles of road.
12.	Snow fences and snow sheds	Varies widely, dependent on climatic conditions.
14.	Telegraph and telephone lines.	Varies slightly per mile of road, depending on number of wires.

ACCOUNTS AFFECTED SOLELY BY TOPOGRAPHICAL FEATURES.

8.	Tunnels	The expense of these items depends on the number, size and character of the structures on each location.
9.	Bridges, trestles and culverts	
10.	Over and under grade crossings	

REVISION OF MANUAL.

The committee recommends that Conclusion 2, page 436, of the Manual, be changed to read: Numerous tests demonstrate that there is no absolute value for train resistance. For practical purposes freight train resistance can be considered constant between velocities of 7 and 35 miles per hour; that Conclusions 3 and 7 be eliminated and the matter under subhead 1 on page 618 of this report be substituted; also the table on page 615; that for conclusion 4 there be substituted conclusions 1-4 on pages 620 and 621, and that conclusions 8 and 9 be renumbered 7 and 8, respectively.

A. K. Shurtleff (C. R. I. & P.), Chairman; R. N. Begien (B. & O), Vice-chairman; F. H. Alfred (P. M.), A. C. Dennis (Cotr. Engr.), C. P. Howard (I. C.), F. W. Green (La. & Ark.), P. M. LaBach (C. R. I. & P.), Fred Lavis (Cons. Engr.), F. W. Smith (C. C. C. & St. L.), H. J. Simmons (E. P. & S. W.), Walter Loring Webb (Cons. Engr.), M. A. Zook (C. G. W)., Committee.

APPENDIX A.

RATIO OF LOCOMOTIVE EQUIVALENT TON MILEAGE TO TOTAL.

The accompanying table shows the per cent. of equivalent ton mileage that the locomotive bears to the total equivalent ton milage of its class of traffic for the roads given in the table in the body of the report. Owing to the fact that both tables were made on the average weight of locomotives of the road, passenger and freight engines considered the same, the percentage shown for freight locomotives is probably lower than it should be and the percentage for passenger service higher since the average freight locomotive weighs more than the passenger types.

PER CENT. LOCOMOTIVE EQUIVALENT TON MILEAGE BEARS TO TOTAL EQUIVALENT TON MILEAGE OF ITS CLASS OF TRAFFIC.

This table is given as information to show the approximate amount of damage done by the locomotive for each class

of traffic, on the basis of one ton of locomotive doing double the damage of one ton of the balance of its train. The question of the exact ratio of damage is an intricate one and would require more data than the committee has at present. There is no strong probability that the average axle load of locomotive and tender will reach the exceptionally heavy loading given for the extra heavy Mikado type in the report for many years, even if it ever does, and the modern consolidation will, in the majority of cases, represent the average to be considered in estimating values of locations.

It is interesting to note that by the proposed method of equivalent ton miles the passenger locomotive does as much damage as the balance of its train, while the freight locomotive does about one-third as much as the balance of its train on the average. The two extremes of freight service are represented by the Pittsburgh & Lake Erie, which with its low grades averages about 16.5 tons of cars and contents to each ton of locomotive, and the Denver & Rio Grande with its very heavy mountain gradients averages about 3.9 tons cars and contents per ton of locomotive. The extremes in passenger service are the New York, Chicago & St. Louis, averaging 3.15 tons passenger cars to one ton of locomotive, and the Chicago & Eastern Illinois Railroad, average 1.88 tons per locomotive ton.

In former practice the locomotive has been frequently considered as affecting a track in a fixed ratio to the balance of its train, but examples above will show the inconsistency of using such methods. It is to be hoped that data will become available to fix the factor with more certainty than the one assumed in this report.

Discussion on Economics of Railway Location.

W. J. Wilgus, consulting engineer: I have been much interested in reading the report of the Committee, especially the part bearing on the suggested method of segregating certain items of maintenance expenditures between passenger and freight service. It would seem that this point has a vital bearing not alone on economics of railway location, but also on another matter that is at least equally important.

The ascertainment of reasonably accurate costs of transporting passengers and freight is becoming increasingly necessary as a basis for resisting improper rate reductions, and for securing higher rates where their fairness can be proven. While a few of the I. C. C. classification items of maintenance fluctuate in proportion to train mileage handled, the majority of them are, as stated by the committee, directly or indirectly affected by the gross weight ton mileage that rolls over the rails. The question then arises—should the actual tonnage be taken, embracing locomotives, cars and contents, or should an attempt be made, as recommended by the committee, to make allowance through "equivalent ton mileage" for excess damage assumed to be done to track and structures by the higher speed passenger trains and by locomotives as compared with the load they haul?

As regards the comparative effect of passenger and freight trains, it is the opinion of the writer that, generally speaking, there is no appreciable difference, if in considering the higher speeds in passenger service equal attention is paid to destructive agencies peculiar to the freight service, such as drippings from coal and refrigerator cars, imperfections of equipment, heavier wheel concentrations, twisting action of locomotives at slow speeds, littering of roadbed and the fouling and destructive action of the products of combustion of inferior grades of coal used in freight service. Corrosive drippings are detrimental to floor beams and stringers and solid floors of bridges; to track fastenings such as spikes, tie-plates, bolts and splices; and to rails, frogs and switches. Side bearings on freight cars are so stiff as to provide much less freedom of adjustment to varying track conditions than on passenger cars. This has been strikingly shown on tracks used exclusively for freight traffic, where trucks in passing from curve to tangent retain their skewed position and grind the outer rail for considerable distances.

Springs under freight cars are less delicately adjusted than on passenger cars, with correspondingly greater shock to track and structures, especially in the case of eight-wheel coal cars having 18,750 lbs. per wheel as contrasted with 12-wheel passenger coaches weighing but 12,500 lbs. per wheel. Superworn tires, flat spots on wheels, dragging brake beams and draft rigging, and similar imperfections peculiar to freight equipment, cause additional wear and tear. Slowly moving freight locomotives when exerting their maximum tractive force, cause a twisting action from side to side that tends to work track out of line as much or more than higher speed passenger trains.

Droppings from freight trains, such as lumps of coal, rubbish, loose doors and other broken parts, increase the danger and add to the cost of policing. Freight locomotives consume more coal and use a poorer grade of fuel, and the resulting larger volume of cinders, gases and smoke fouls the ballast, corrodes metallic structures, and injures paint on buildings, bridges and signals to a greater extent than with passenger power. Freight locomotives under load stop and start more frequently, causing slipping of drivers that blisters and wears the rail. Local freights do more or less switching on main tracks and at stations, with accompanying wear and tear on track and structures.

On many railroads both "drag" and preferential freight trains on certain divisions are run at high speeds, in order not to interfere with the passenger service, and any fixed rule for calculating "equivalent ton mileage" would have to be varied to meet these frequent conditions.

It therefore seems clear that relative speeds of passenger and freight trains are so variable and the instances in which the latter are more destructive to track and structure so numerous, that any attempt to arbitrarily fix the percentage that one exceeds the other would lead to questionable results. Judgment, which in any event must guide a decision, would seem to lead to the conclusion that, taking all these facts into consideration, the added cost of maintenance chargeable to passenger service by reason of higher speeds is practically offset by many features incident to the slower speed traffic.

As to the comparative effect of locomotives and of the load they haul, it is possibly true that the former cause somewhat more damage per ton than the latter, but not to the extent that might be imagined. For instance, taking two loaded coal cars weighing 150 tons, their smaller diameter wheels, less perfect construction and maintenance, and drippings and droppings, may be said to go far toward equaling the twisting and corrosive effects of a locomotive of the same weight; and in passenger service the smaller wheels and tail-end side swing may be considered as going far toward equaling the destructive action of the locomotive.

To guess that the locomotive, including its tender, creates twice as much destructive action per ton of gross weight as the load it hauls, may yield a result more in excess of the truth than the making of no allowance may understate the truth.

Summarizing, in the absence of precise data, and taking into account the complexity of the problem, is it not fair to say that under average conditions a gross weight ton of passenger train creates the same destructive effect on track and structures as a gross weight ton of freight train; and that an attempt to assign constructive tonnage to portions of the rolling load as the measure of their assumed excess wear and tear on track and structures, will result either in complications and contradictions, or in so many variations in the formula as to make the exceptions prove the rule?

A. K. Shurtleff, committee chairman: It is sometimes supposed that the problems of this committee can be reduced to an exact science and that simple formulæ can be deduced which will be mathematically correct in all cases when applied to the problems regardless of the varying conditions. This is impossible, owing to the fact that, were it possible to determine accurately the proper coefficients for each of the variables under different conditions, the formula would become very complex, and the judgment of the engineer would have to be exercised in selecting the particular value of each coefficient for the condition which he thinks may exist. Such complicated equations would probably lead to no greater accuracy than the approximate simpler formulæ such as this committee is attempting to establish.

We are trying to formulate methods for analyzing the problems of economics with reasonable accuracy. In so doing, we give equations which, to our best knowledge, cover average conditions. We expect that many roads will find the values of certain terms of the equations different under their conditions of operation from those given by this committee. In such cases we believe that by the use of the methods to be proposed by this committee and the coefficient values as they find them, satisfactory results will be obtained in weighing the relative economic values of various locations.

In our present report we have attempted to give a method for analysis of maintenance of way accounts, hoping at a later date to simplify to an equation form of sufficient accuracy for the field engineer. We are attempting to analyze the items which are affected by volume of traffic on the basis of equivalent ton mileage, reducing locomotive tonnage and passenger train tonnage to an approximate equivalent of freight car tonnage, using multipliers for each, which, in our present judgment, appear to represent the relative damaging effects of a ton of each class, as compared to the average effect of one ton of freight car and load.

In this connection I desire to call attention to the criticism of W. J. Wilgus, and his suggestion that actual tonnage be used in dividing between the two classes. The points raised

by Mr. Wilgus showing expenses created by freight service which do not apply to passenger traffic are excellent. At the same time the points brought out about the locomotives can be used as an excellent argument in favor of considering one ton of locomotive as producing greater damage than a ton of car and contents.

There is wide difference of opinion with reference to the relative damage per ton of passenger train when compared to a ton of freight. It is certain that our roads require a much higher grade of maintenance, both in labor and material, to take care of the higher speeds of passenger service than they would if the entire tonnage over the rails was freight. Unfortunately, the tests at St. Louis covering counterbalancing were only made on Atlantic Passenger Locomotives of the so-called balanced compound type, no such tests being made on simple locomotives.

With the exception of the Cole engine, the nosing of these locomotives increased materially with the velocity, and in the Baldwin balanced compound was as great as 0.74 in. per revolution at 240 r. p. m. or 56 m. p. hr. In this locomotive at the same speed the load on each wheel of the first set of drivers became very light through one-quarter of each revolution and returned abruptly in about one-eighth revolution. At 320 revolutions one forward driver left the rails. It is well known that counterbalancing can be most satisfactorily accomplished in four-cylinder locomotives, but statistics show that less than 7 per cent of the Atlantic and Pacific type locomotives have 4 cylinders, the balance being simple. The great bulk of passenger locomotives are of the simple engine type and at the high velocities undoubtedly cause much greater disturbance to the track than the balanced compound cited above.

In view of these disturbing forces at high speeds and the necessity of higher grade of maintenance, it would seem that the costs of maintenance in those accounts affected by the volume of traffic would be greater per ton for passenger service than for freight and that the equivalent ton mileage principle should be used in the analysis of costs for these accounts.

The factors for reducing to equivalent ton mileage may vary somewhat. Data covering several years' operation on a 4-track road having 2 tracks devoted to each class of traffic would help materially in fixing the relative values.

(It was moved and seconded that conclusion 2 under Revision of Manual in the report be accepted.)

L. C. Fritch (C. G. W.): This subject is something that is so much involved that it is very hard to fix any formula or rules that will fit all conditions. I believe some resistances will increase with the speed and others will decrease with the speed, but it looks to me like the limits between 7 and 35 m. p. h. are rather high. The limits ought to be from 5 to 20 m. p. h. The higher limits are really the more practicable for freight train speed, and I think Mr. Begien reaches the conclusion that one is almost forced to reach, that it is almost impossible to establish any formula that will fix the train resistance; that with all the numerous tests that were made, according to his report, it is very hard to get anything that will serve as a guide. Of course, the main difficulty is that there is such a vast difference in equipment, and it is not always possible to fix any definite resistances. My own opinion is that the railroads of this country are going to extremes in tonnage. They are overloading trains. I have always believed that there is an economical maximum tonnage which is very much below the maximum tonnage which locomotives are able to draw. I think that many roads are expending more money in overtime and interference with traffic than would be the case if they established an economic loading, which would be much better than the maximum tractive power of the locomotive; the tonnage could be used in such cases with less delay and interference.

F. S. Stevens (P. & R.): I might say on the question of tonnage it appears to me to be a self-evident fact that the most economical tonnage to handle is that which will enable an engine to deliver the greatest tonnage from one point to another within a given time at the least expense. This holds true, no matter whether you wear your engine out in one month, or one year, or ten years—the quicker you wear it out the better. The whole question is to move the tonnage, the most of it, in the least time, at the least expense; that is the whole thing to be worked out.

C. P. Howard (I. C.): I have recently used this data in calculating the time and fuel consumption and other items for a division of 130 miles. In a case where it would be practicable to haul a 5,000-ton train at about 3.5 m. p. h. over the proposed 0.3 per cent. grade, it was found a 4,000 train would be just about the economical limit. The fuel consumption per ton mile remains practically the same for the 5,000-ton train as for the 4,000-ton train. The time increases a great deal. In fact the time for the 4,000-ton train was about 15 per cent greater than the time for a 2,700-ton train. The fuel consumption for the 2,700-ton train, as calculated from the information given by Mr. Shurtleff in his bulletin checked out very closely with that given by the superintendent in his estimate.

F. S. Stevens: One of the principal questions is interference. The tonnage rating that is worked out absolutely correctly, which will give the best results and move the greatest tonnage in the least time, is indefensible in many cases, because to put that tonnage over the road means that you cannot put anything else over it. The local freight and the passenger service must be put out of commission. The tonnage trains can only move to the limit of the sidings, and they must have a limit of speed, and if they get into a hole in some place on account of the preferred service, they cannot get out. All these things have to be considered.

(Conclusion 2 was then adopted as revised.)

Mr. Shurtleff: We propose to change conclusion 7 of the Manual to agree with Mr. Begien's conclusions from dynamometer tests, presented elsewhere in this issue, except that we desire to omit his conclusion 2, and state under D in conclusion (1): "The following formulae are practicable where train has been in motion at least 15 minutes." Then give the formula for A rating, which is the same as the present formula given in 3, or practically the same; the formula for B rating, the formula for C rating, and the formula for D rating. Those give the ratings for different conditions of temperature. Then insert the table shown on page 615 of the Manual. In that way we cover in the one conclusion what was covered in the two conclusions at the previous meeting.

L. C. Fritch: How are we going to get the train in motion the first 15 minutes? I cannot see that there is any practical use in that. Of course, they could heat up the journals, but they could not put on additional tonnage after the train had been in motion fifteen minutes. So of what use is the resistance at that time? It is probably well enough for information, but I cannot see that it is of any practical value to us.

G. D. Brooke (B. & O.): As I understand the adaptation of this formula to actual practice, a certain speed will have to be assumed and that would be the speed that probably would be attained on the ruling grade after the train had been in motion 15 minutes, in starting, of course, and for the first 15 minutes of the run. If the run during that period is on the ruling grade, the train would proceed at a considerably lower speed than the assumed speed, but that lower speed for a period of 15 minutes would not appreciably affect the running of the train over the division; so the value of the formula would not be affected.

Mr. Shurtleff: The rating is always given as two things that govern the time allowable over the district, and your ruling grade. The time allowable over the district would fix the speed on the ruling grades, and this speed would in many cases not fall below 6 m. p. h., and more often it runs to 8 and 10. At 10 m. p. h. the locomotive has a great deal less tractive power than it has at 5 m. p. h. In spite of the fact that we have in the past assumed that the locomotive could work with the reverse lever down in the corner, up to 8 or 10 m. p. h., we have yet to find a fireman who can fire the modern locomotive under these conditions. Therefore, when you get to working at 7½ or 8 m. p. h., your draw bar pull is much less and during the early few minutes of the run the locomotive has greater power to overcome the starting resistances. I do not think it would make so much difference at mere stop for a signal, where the journals would not have a chance to cool down.

Mr. Sullivan: It is unfortunate in a great many cases that the operating department and the engineering department do not work closer together than they do. I do not think this committee can go too far into the other fellow's department. Take a practical case. Suppose we have a superintendent who wants to load everything up to the very last notch, and we have some 0.4 per cent grades that could possibly be reduced to 0.3 per cent. We do that work and spend thousands of dollars on a division. The next superintendent comes along and says, "We are loading too high; we are going to load at a 10 or 15 per cent reduction." The chances are that the money that you have spent on the grade reduction has been thrown away for the reason that if the former superintendent were loading for the short grades, the loads could be carried over. I am very much opposed to any restrictions of this committee in the way of figuring out economics and going into the costs, and also the method of transportation. That problem would have to be solved by each road itself. They must get together with the operating

and engineering departments, but the general information that this committee can give should not be restricted.

A. J. Himes (N. Y. C. & St. L.): In pursuing the subject along this line, it is primarily the duty of the engineer to be thoroughly posted with the work of the operating department as it is actually done and to learn from it all that he can and to offer his assistance in any case where it appears that the best results are not being secured in the operation of the road. In many cases too sharp a division has been made between the different departments. The particular development of the present generation in all kinds of economic work has to do with co-operation. The great secret of success in large enterprises is to bring about accurate and hearty co-operation between the many units of an organization.

(The recommendation of the committee in the second paragraph of the Revision of the Manual was adopted.)

J. L. Campbell: I believe that a safe rule for a locating engineer to follow is to assume that the operating department will make a proper and efficient use of the plant, that the engineering department gives for the conduct of transportation.

The substitution of conclusions 1-4 under "Tonnage ratings" in Mr. Begien's Appendix B (published elsewhere in this issue) for conclusion 4 of the Manual was next considered.

J. B. Jenkins (B. & O.): There seems to be a considerable difference of opinion based on different results and tests, as to whether degree of curve increases the resistance, per degree, or whether it decreases it. In general it sems if you disregard all other conditions that a 10 deg. curve seems to require less compensation per degree than a 2 deg. curve, but I believe if we consider other conditions we will find the case to be quite the opposite. I think the reason why the 10 deg. curve seems to require less compensation is that, the speed at which the freight train passes over the 10 deg. curve is more nearly that for which the curve is super-elevated, while with a 2 deg. curve, the curve is liable to be elevated for fast passenger service and the freight train goes around it at a much slower speed, resulting in greater friction. The principal factor in changing the rate of compensation should be the relation of the elevation of the outer rail to the elevation required for the average speed of freight trains. Undoubtedly there is more friction in swinging the truck on a 4 deg. curve than there is on a 2 deg. curve. I believe if all conditions were taken into account, that these figures should be more nearly reversed; that it should be more nearly 0.04 for the 2 deg. curve, 2,000 ft. long, and more nearly 0.03 for the 4 deg. curve 1,000 ft. long.

G. D. Brooke (B. & O.): It appears to me that there is confusion here between the degree of curve, and the central angle of the curve. The total compensation will be the same whether it is a 4 deg. curve, or a 2 deg. curve, but the rate per degree will be different. Take the example just cited, with a 2 deg. curve 2,000 ft. long, 40 deg. of central angle; your total compensation would be 1.2 ft. With a 4 deg. curve 1,000 ft. long, your compensation would be at the rate of 1.2 or the total compensation for the whole curve will be the same thing, 1.2. In other words your degrees of central angle would be constant, but your rate of compensation would increase with the degree of curve, while the length of your curve will decrease in inverse proportion.

J. L. Campbell (E. P. S. W.): I ask the committee to state the reasons for making the curve length a factor in determining the rate of compensation.

Mr. Shurtleff: There is only a portion of the train being subjected to the resistance at one time, and the draw bar pull of the locomotive is constant. If the whole train was subjected to the resistance it would mean that each ton of the train was subjected to that resistance, but in cases where only half of the train is subjected to that resistance, work out as Mr. Begien did, we think a less resistance would be suitable in each case.

S. S. Roberts (I. C.): Would it not be better to drop the word "super" in paragraph 3 of the conclusions from the word "Super-elevation?

Mr. Shurtleff: The committee will accept that.

Mr. Brooke: There is one remark I wish to make for the information of the Association and that is that the dynamometer tests referred to in the paper of Mr. Begien embraced almost every conceivable class of line and traffic. The tests were made on lines having from 2 to 2.1 per cent grades, with curves as high as 14 deg., and they were made over 0.3 per cent. lines, with maximum curvature of 4 deg., on which there was no passenger travel whatever. They embraced other high-speed lines having curves of 5 and 6 deg., with mixed traffic, and practically level lines having some curves as high as 9 to 10 deg. curves, on which the speed of passenger trains was high, and the speed of the freight trains was low.

E. Gray, Jr. (C. & O.): It has been suggested that compensation is not necessary in the case of minor grades or very light grades. I think that this view is wrong. Much mischief has been done and the possible train load of railroads cut down by the contrary practice. It often happens that a railroad might have long stretches of very long grades and only a few governing grades and that compensation has been carried out only on those heavy grades, and it occurs afterwards that those stretches of light grade become the governing grade either because helper engines are employed on the heavier grades, or the grades are reduced by changing the route.

M. L. Byers (B. & H.): I want to offer a suggestion to the committee. My idea is that curved resistance depends on three principal factors. The first is the degree of curvature, the second is the relation between the length of the curve and the length of the train, and the other in the super-elevation of the curve. The formula which the committee has offered us seems to agree pretty well, perhaps I should say very well, for the first two factors. I suggest that the committee keep in mind the matter of looking into the question of the effects of variation in super-elevation on the curve resistance in the future.

J. L. Campbell: I do not believe the curve length is the proper element to take into consideration in determining the rate of compensation. I think on a 1 per cent grade, if a properly compensated grade is one-half the length of the curve, that you must eliminate that part of the train which is off the curve.

Prof. W. G. Raymond (Iowa University): I think, from theoretical grounds, the curve resistance varies with the degree. Therefore, the compensation to be theoretically exact, to produce the effect that the chairman of the committee says he wishes to produce, namely, a constant pull on the draw-bar, or at least a constant effort of the locomotive, to produce that as nearly as possible, his compensation should vary with the curve resistance, and I think it is pretty well established that curve resistance must vary with the degree of the curve. I think that is evident, from the fact that a large part of this resistance is due to the twisting of the truck on the track, and that means simply the friction between the wheel and the rail, and that must be largely independent of the degree of the curve. In these days we are devoting a large part of our effort to the betterment of the submerged tenth, and it seems to me the submerged tenth that have four tracks are as well entitled to consideration as the 90 per cent of the roads who have only one track, and therefore it seems to me that in the committee's report, when it is finally made up, that there shall be rules for one track roads and other rules for four-track roads, and I believe the committee should take notice of that fact in making its conclusions.

(The new conclusions 1-4 were then adopted by vote of the association.)

Mr. Shurtleff: The conclusions presented in the main report are in reference to the present matter published in the Bulletin and attempt to lay down an approximate method of analyzing the maintenance of way expenses, particularly those expenses which vary with the volume of traffic. They are presented to aid in the analyzing of the expenses referred to, but this committee cannot feel it has hit the exact method. We believe, however, we have made a long stride toward a proper method of analysis.

Conclusion 1 was adopted.

Conclusion 2 and 3 were adopted as information.

L. S. Rose (C. C. C. & St. L.): Concerning conclusion 4, I do not believe as a general proposition that the passenger train is twice as severe on a track as the freight train. It depends somewhat on the speed. I believe that the passenger cars are kept in better condition than the freight cars and have fewer flat wheels. The damage to the track which causes repairs depends on the speed, and that should be taken into consideration.

L. C. Fritch: I have not any constructive criticism to make in this case, but it does seem to me before we adopt even as information a conclusion that may be as far reaching in its effects as this we ought to get all available data on the subject. We all know that efforts are being made to determine the cost as between passenger and freight service. If we establish a principle here that it costs twice as much to maintain the track for passenger service as for freight service I think we want to be very sure of our ground.

Mr. Shurtleff: The committee did not have any definite information on this subject but studied the question carefully. It is just merely a guess. This committee has got to stop work now on the advance study of this question until we get some means of going ahead and analyzing these accounts. We will be glad to receive all assistance from any of the roads that can be given us, in order to determine this question.

C. E. Lindsay (N. Y. C. & H. R.) We have a 4-track road, two tracks being devoted to passenger traffic, and two tracks being devoted wholly to freight traffic, although the passenger tracks are also used for high-speed freight traffic. If it was my guess, I would reverse the guess of the committee. I think the committee has been misguided by the effect of the train as a whole and the committee has overlooked the question of speed. In my opinion the design and maintenance of passenger equipment is far superior to that of freight equipment. In the passenger equipment we have 6-wheel trucks, with a very superior spring arrangement. In the freight service we have 4-wheel trucks and the spring arrangement is hard and rigid on the track.

Mr. Byers: I do not believe a fast freight train running at 60 m. p. h. is different in its effects from a passenger train running at the same speed, and my experience with the relative cost of maintenance of track under high and low speed traffic is that it depends mostly on the standard of the maintenance of the tracks as to the cost. The cost of track maintenance, as the result of deterioration under train service, is principally for surfacing, that is, the labor cost, and the labor cost of picking up a low joint, ⅛ in. low, is almost the same as picking up a joint ½ in. low. If you had trains running 60 to 70 m. p. h. you must maintain the joints more nearly to a perfect level than on a track where the trains run 30 m. p. h. Any examination of ordinary freight track will show that this element is taken into consideration and that the maintenance is much less perfect in that case than in the higher speed tracks.

Mr. Lindsay: The conditions of our roads are these: Up until 3 or 4 years ago the passenger tracks were sacred, but recently the density of traffic has increased to such a point that it has been necessary, in order to take care of the freight traffic, to run a great many freight trains, both of the slow freights and the fast freights, on these passenger tracks, and the effect on the cost of maintenance has been very marked. Mr. Byers calls attention to the sameness of cost in raising a small low joint or a very bad low joint. That is a question of comfort with relation to passenger trains and does not enter materially into this case.

(Conclusions 4 and 5 were referred back to the committee.)

WOODEN BRIDGES AND TRESTLES.

The Association directed that the outline of committee work for the year 1912 be as follows:

(1) Report on formulæ for use in determining the strength of sheet piling.

(2) Report on fire protection of wooden bridges and trestles.

(3) Complete report on the use of guard-rails for wooden bridges and trestles.

On subject No. 1 the committee reports progress.

On subject No. 2 the committee does not deem it advisable to make any recommendations, but submits its report as information.

On subject No. 3 the committee makes the following recommendations:

(1) It is recommended as good practice to use guard timbers on all open-floor bridges, and they should be so constructed as to properly space the ties and hold them securely in their places.

(2) It is recommended as good practice to use guard-rails to extend beyond the ends of the bridges for such a distance as required by local conditions, but that this length in any case be not less than 50 ft.; that guard-rails be fully spiked to every tie and spliced at every joint, the guard-rail to be some form of a metal guard-rail.

(3) It is recommended that the guard timber and guard-rail be so spaced in reference to the track rail that a derailed truck will strike the guard-rail without striking the guard timber.

(4) The height of the guard-rail to be not over one inch less than the running rail.

The committee recommends that the following subjects be assigned for the ensuing year:

(1) Complete report on formulæ for use in determining the strength of sheet piling.

(2) Report on the subject of docks and wharves.

I. L. Simmons (C., R. I. & P.), Chairman; W. S. Bouton (B. & O.), Vice-Chairman); H. Austill, Jr. (M. & O.), Henry S. Jacoby (Cornell Univ.), F. E. Bissell (A. C. & Y.), P. B. Motley (C. P. R.), R. D. Coombs (Cons. Engr.), D. W. Smith (H. V.), E. A. Frink (S. A. L.), W. F. Steffens (B. & A.), E. A. Hadley (M. P.), H. B. Stuart (G. T.), Hans Ibsen (M. C.), Committee.

APPENDICES.

Illinois Central:

All through bridges and high steel viaducts are being equipped with rerailing devices, especially where a high rate of speed is maintained. Some few high and long wooden structures have been equipped with rerailing devices. These rerailing devices are placed 12 ft. 6 in. from the end of the structure on the roadbed. The inside guard rail is continued out 20 ft. past the rerailing device, running to a point connected by a cast steel casting 2 ft. 3 in. long and bolted to casting with 2¾-in. bolts. The outside guard timber is connected near the rerailing casting with a steel guard rail 18 ft. 7 in. long, turned out at the end near the guard rail point 1 ft. 7 in. from the running rail. The rerailing device consists of two separate castings made of semi-cast steel. The casting between the traffic rail and the outside special guard rail is 5⅝ in. high and shaped in between both rails. The casting has a 10-in., flat-bearing surface. The casting between the traffic rail and the inside guard rail is 5 ft. 8 in. long and 9 31/32 in. wide. It has a rib 3½ in. high at center running down to a flat surface at each end. This rib is 2½ in. at center of casting from ball of main rail, beveling back at the ends of the casting 5½ in. to the guard rail. These devices have proved effective. An engine weighing 100 tons was rerailed on a high viaduct while running at 30 miles an hour. Freight cars have been rerailed on another high viaduct and on a long through truss bridge.

Pittsburgh & Lake Erie:

A rerailing device at the south end of the bridge over the Youghiogheny River at McKeesport has rerailed cars frequently, as evidenced by cut ties approaching the rerailing device and vanishing at that point. Other cars have been rerailed at the device placed at the end of the bridge over the Mahoning River at Lowellville Junction. At both of the above points the absence of the rerailing device would undoubtedly have resulted in the destruction of the bridge.

Philadelphia & Reading:

When a No. 6 frog is used, the guard rails on the approach end are extended 41 ft. 3 in. On the trailing end they are extended 20 ft. and the rails bent until the ends are 18 in. apart. When a No. 8 frog is used, the guard rails are extended 54 ft. 7 in. on the approach end. On the traiing end they are extended 35 ft. and bent as above. When a No. 10 frog is used the guard rails on the approach end are extended 68 ft. On the trailing end the guard rails are extended 50 ft. and bent as above. On single track the frog points shall be used on both ends. On double track the frog is used only on the ends facing traffic.

Lehigh Valley:

On double track guard rails extend 200 ft. from the bridge on approach side and 30 ft. on the leaving side, where the speed is over 35 miles an hour. When the speed is less than 35 miles an hour the guard rails extend only 100 ft. on the approach side. On single track the guard rails extend 100 ft. or 200 ft. from the end of the bridge, depending on whether the speed is low or high.

Chicago, Rock Island & Pacific:

The minimum length for the extension of guard rails beyond the bridge is 60 ft. In cases where the span has a pile or timber trestle approach, the guard rails should extend over this approach and 60 ft. beyond, providing the approach is not more than 300 ft. long. In case the approach is more than 300 ft. long, the guard rail should extend 300 ft. from the end of the bridge.

Lake Erie & Western:

Within the last two years we have had five derailments which we consider would have been considerably more serious if it had not been for the guard rails. In one case the derailed truck struck the point of the guard rails within a few inches of the center of the track and the truck was pulled

over so that the car safely crossed the bridge and the wheels between the running rail and the guard rail.

Pennsylvania Lines West:

We know of cases where derailed wheels have crossed safely over a bridge on which there were guard rails, when the train would undoubtedly have been wrecked had no guard rails been provided. As a specific instance, I abstract from report of a derailment on the Ohio Connecting bridge (Pittsburg), on March 2, 1907:

"This bridge has a total length of 4,520.2 ft., and crosses both channels of the Ohio river, Brunot's island, and about 1,400 ft. of the city, north of the river, at an elevation of 50 ft. above high water level.

"On the above date, a westbound freight train approached the bridge at a speed of about 19 miles an hour. The train comprised 32 cars, and the third car from the rear was a 70,000 lbs. capacity coal car, loaded. About 30 ft. from the east end of the bridge a flange, on the front wheel of the rear truck of the above car broke, on an 11-deg. approach curve, and the car was derailed at a point about 197 ft. on the bridge. From this point the derailed truck ran over the bridge about 740 ft., until the train was stopped by the wrecked floor and separated air hose.

"The running rails on the bridge were 85 lbs. per yard, and in addition to the standard outside timber guards there were inner guard rails of old 85 and 80 lb. rail, placed 8 in. in the clear, inside of the running rails, and spiked to every other tie."

The conclusion of the report stated: "That the presence of the inner guard rails, beginning at the east end of span No. 3 (through span, 416.1 ft. long), undoubtedly prevented a serious accident to this span, which might possibly have been its destruction. That the continuance of the inner guard rails across span No. 3 and the deck spans controlled the movement of the wrecked truck, and had it not been for the old ties on the deck spans, might possibly have prevented further accident.

"On span No. 3 the north wheels sheared the spikes on the north of inner steel guard rail, and the lateral force of the wheels against this guard rail bent over the spikes on the south, moving the rail inward an inch or two. When the train reached the deck spans, the ties on which were nine years old, the inner steel guard rail was moved inward as much as a foot in places.

"Inner guard rails of steel rails are not desirable for bridges of this length or character, because the spikes are sheared by derailed wheels, and guard rails moved inward, even on perfect ties.

"Inner guard rails, consisting of timber, 7x8, laid flat and lock-dapped to the ties, should be used."

Chicago, Milwaukee & St. Paul:

We have had a number of cases of derailments on bridges which have clearly and unequivocally demonstrated the value of the guard rails, and especially of the type we use. Several of these cases have been on important bridges, where the result of a car breaking through or running off the floor would have been a very serious matter. One case was a heavily loaded refrigerator car, which passed over three 200-ft. spans on a 6-deg. curve. Another case was on one of our Mississippi River bridges, where the derailed wheels traveled over several spans, and a considerable distance of the approach, part of which was on a curve. In both of these cases there was no injury to the structure, and no complete wreck of the car. We are firmly convinced that the type of guard rail used was responsible for our escaping with so little damage.

Norfolk & Western:

On one timber trestle, 200 ft. long, we put a gravel floor as a trial three years ago. As this bridge is on a curve, we have had to keep the gravel from shaking down to the low rail. This is done by the trackmen. It is a defect in the plan, and longitudinal obstructions should be placed to prevent the gravel from shaking down. Before fireproofing this trestle we had eight to ten small fires a month and one complete destruction, but have had no fires since it has been fireproofed.

Chicago, Rock Island & Pacific:

In 1909 we started the use of ballasted deck trestles. For the year ending June 30, 1910, we had 368,253 lin. ft. of pile trestles, including approximately 7,500 ft. of ballast deck trestles. During this year we had 88 fires. The statistics for 1911 have not yet been completed, but we now have approximately 10,000 lin. ft. of ballast deck trestles. For the nine months ending March 31, 1911, the fire loss amounted to $6,444.71. We also have a large number of trestles having "fireproof deck," which consists of 1-in. thick boards between the ties, covered with crushed stone, gravel or slag. We have no means of telling just how much the use of fireproof or ballast deck trestles has decreased our fire losses, except that in not a single case since we have adopted their use has a fire been reported on any of them.

Chicago, Milwaukee & St. Paul:

This company uses two methods of protecting the floors of timber bridges from fires originating from locomotives. No method has been adopted for protecting timber floors on steel bridges. One of the methods of fire protection used by this company consists in spreading a layer of gravel over the ties to a depth of about 3 in. The gravel is supported between the ties by nailing 1-in. boards either over the openings or between the ties. The guard timbers are protected by strips of galvanized sheet iron. The other method consists of laying strips of galvanized iron so as to completely cover the ties and guard timbers.

Although no means have been adopted by this company for protecting the timber floor of steel bridges, the danger aris-

FIRE PROTECTION ON WOODEN BRIDGES AND TRESTLES.

ing from fires on timber floors on deck girders has been eliminated on all of the more recent deck girder bridges by the use of either reinforced concrete slab ballast floors or creosoted timber ballast floors.

This company has two instances on record of bridge fires starting on bridges with fire protection. The first instance was on the Pacific Coast extension, where a bridge protected by gravel was destroyed. It is supposed that the high winds prevalent in this particular locality had blown the finer particles of ballast away and had shifted the coarser, thus leaving spots unprotected. The second instance occurred on a bridge which was protected by sheet iron only between the rails. In this case the fire started on the guard timbers.

At the close of the season of 1910 this company had protected 47,417 ft. of timber bridges against fire. At the close of the season of 1911 it is expected to have about 80,000 ft. of timber bridges so protected. In addition to this, all of the timber bridges on the C. M. & P. S. have been protected. During the period between January 1, 1911, and August 25, 1911, there has been about 50 per cent. less fires reported, caused by locomotives, than for the corresponding time during 1910.

Wherever headroom is sufficient, we use a ballasted trestle. No fireproofing of open-deck trestles is provided, but grass and rubbish are kept away from the piles.

Pennsylvania Lines:

On four of the nine operating divisions of this company fire protection is provided on some of their bridges. One division covers stringers between the ties and tops of caps with galvanized iron, projecting 1 in. over each side of the stringers and caps. One division formerly covered the tops of stringers between and under the ties with tin, but has discontinued the practice, as when the tin rusted through or broke and a spark passed through the opening to the dry timber beneath, the fire was difficult to reach, and in putting it out the fireproofing was entirely destroyed. This division has recently fireproofed the floor of one bridge over a street by attaching on top of the plank floor old Winslow car roofing, scrapped at the shops during the repair of cars. This protection has so far been satisfactory.

A third division covers the stringers with galvanized iron. A fourth division covers the deck from guard rail to guard rail with galvanized iron, running the sheeting over the guard rail and 3 in. or 4 in. outside. These sheets do not run under the rail, but lap over the flanges. They have also fireproofed one bridge by covering the tops and sides of each tie between the guard rials and the guard rails themselves with galvanized iron sheeting.

Where only the stringers and caps are protected, the protection of the stringers only applies to wooden bridges. The caps of bents supporting steel bridges are protected. On divisions where the entire deck has been fireproofed, this fireproofing has been done on both timber and steel bridges. We have not suffered any severe fire losses in the decks of bridges fireproofed, but one dangerous fire is reported with several small fires originating in the piling.

Reports from the four divisions on which some fireproofing has been applied show the total length of bridge so protected to be about one mile, or a small proportion of the total number of bridges on these divisions.

The division on which the tops of caps and stringers are covered with galvanized iron, projecting 1 in. over the sides, reports 75 per cent. decrease in the number of fires on bridges so protected. The other divisions report that, on account of the recent adoption of self-cleaning ash pans, which have largely increased the number of fires, statistics cannot be furnished.

The cost of protecting the tops of stringers between the ties and tops of caps with galvanized iron, projecting 1 in. over the sides of each, is reported as 22 cents per linear foot of track. The cost of protecting the deck with old Winslow car roofing is reported at 10½ cents per linear foot of track, for labor only. The cost of protecting the entire deck with galvanized iron sheeting to line 3 in. or 4 in. beyond the outside wooden guard rails varies from 79½ cents to $1.88 per linear foot, depending upon the location and size of bridge. This fireproofing was applied by a contract tinner and roofer.

(Conclusions 4 and 5 were referred back to the Committee.)

Discussion on Wooden Bridges and Trestles.

I. L. Simmons, Committee Chairman: I move that conclusion 1 be adopted as good practice.

J. L. Campbell: Is this report intended to cover the wooden guard rail outside of the track rail only?

Mr. Simmons: This is for the guard timber, and the guard timber is considered as the guard rail on the outside of the bridge.

(Conclusion was adopted.)

Mr. Rose: Is it the recommendation of conclusion 2 to have guard rails on all bridges?

Mr. Simmons: Yes.

Mr. Rose: I think that is going a little too far. Extending that reason a little bit, you will want a guard rail on every fill, and you will have the railroad with a guard rail from one end to the other.

C. E. Lindsay: I suggested the use of the words "guide rail" for this inner rail. Its purpose is to guide derailing wheels past the point of danger. When you look in the Manual for a definition of guard rail you will find it is a longitudinal member, usually a metal rail secured on top of the ties inside the track rail to guide derailed wheels. Our understanding of guard rail is to prevent wheels from being derailed, and I think there should be a definite term to show that the terms "guard timber" and "guard rail" are used indiscriminately and improperly. I am certainly opposed to the using of guard rails at all bridges. The use of a guide rail is to minimize the effect of a derailment in that particular locality. I think that the Dominion of Canada has done a very sensible thing in confining the use of guard rails to openings more than 50 ft., but I think it is necessary to go further. The object of the guide rail is to minimize the effect of derailments at points where there is a structure which might be damaged by the derailed car or where the curvature is excessive, or the speed grade, or where the height of an opening into which a vehicle might fall would be so great as to make a terrible calamity, or where the clearances are close and the speed excessive.

There is no sense in putting in an inner guard rail where there are turnouts at both ends. That would not minimize the result of derailment. Take a point at slow speed where a derailed wheel would do no harm, a guide rail is of no use and I hope the committee will reconsider this action and seriously consider a definition of the term "guide rail."

Mr. Loweth: I am opposed to any recommendation that we should put guide rails or guard rails, whatever they may be termed, on all bridges. It is an unnecessary expense, and is not in accordance with the facts or practice as indicated in the tabulation of the statement of the various roads in the committee's report.

Mr. Campbell: I agree with Mr. Loweth and Mr. Lindsay about the requirement for guard rails on all bridges. Many bridges are only 14 ft. long. Referring to page 664, I think the committee has shown what it intended to say in the recommendation. I raise a question about the necessity—in fact I am of the opinion that the guard rail on the outside of the bridge is a source of danger. I think that any guard rail outside of a rail has a tendency to aggravate the position of the derailed truck and to slew it across the track. I believe the guard rail at the end of the bridge should be removed and that we should depend entirely on the guide rails instead of the running rails.

R. C. Sattley (C. R. I. & P.): As superintendent of bridges and buildings for some 11 years on a railroad, it is my opinion that it is necessary to protect truss bridges with an inner guard rail, and we always advocate the putting of the inner guard rail 150 ft. from the end of the bridge. We have always followed this practice.

C. E. Smith (M. P.): The Missouri Pacific has about 800,000 lineal feet of bridges, and about 10,000 bridges. If guard rails were put across these bridges, and for 50 ft. from each end of each bridge, there would be about 1,800,000 ft. of track to protect, which, at a cost of 75 cents per lineal foot, would be something over $1,250,000, which at 6 per cent would be somewhere around $80,000 a year increased interest charged to the railroad for so protecting the bridge. There have been some derailments that have caused wrecks on bridges and trestles on railroads, but I do not know of a case where an inner guard would have prevented derailments or, if the guard rails had been there, would have eliminated the damage caused by these wrecks. The railroad company would still be away behind on the investment.

Mr. Simmons: I do not see that the recommendations carry the same effect that a state law would. It is not a question whether a railroad can afford to do it or not, but a question whether the damage to the structures in the past has warranted putting them on. So far as the short length of bridge is concerned, you can have as disastrous a wreck on a 15-ft. bridge as on a 500-ft. bridge. The length does not make any difference; the location might make some difference. That is to be determined by the man who has the matter in charge.

Mr. Rose: I think the question of guide rails is pretty largely a matter of sentiment. I have known of some derail-

ments where there was a guide rail and it had on effect. The outer timber did the work. I hope this convention will not rule that guide rails are necessary. I do not believe they are necessary, judged by the amount of good they serve.

Geo. W. Andrews (B. & O.): I take exception to what Mr. Rose has said. I know from practical experience that the inner guard rail is of decided benefit. We have had a number of derailments, and if it had not been for the inner guard rail the engine and possibly a large number of cars would have gone down the embankment.

Mr. Loweth: It seems absurd, on a deck bridge, where the deck girder bridge or deck pile and trestle bridge, that we should put in 10, 30 or 40 ft. long, over a shallow opening, that we should put in guard rails and extend them out 30 to 50 ft. at each end. It means that the protection that we put in at the ends is more than the protection on the bridge. If it is necessary to put in protection of that kind on short, shallow bridges, why don't we put it in over the miles of high embankment that we have, where the consequences of derailment would be much more serious than would be the case in many shallow bridges?

H. T. Porter (B. & L. E.): The inside guard rail was for the purpose of guiding a derailed wheel when the cars were 60,000 lbs. capacity. By putting in guard rails carefully, we did have some confidence in their being able to guide a derailed wheel, but since we have reached an axle-load on cars of from 35,000 to 40,000 lbs., the condition has changed. We have had cases where a derailed truck on an ore car has followed the track over 3 miles and missed but very few spikes and bolts. We have had other cases where the derailed car crossed the track and went down the bank in less than 60 ft. We have had cases where the car tore out a guard rail that was thoroughly spiked, and when the matter was under investigation I told our people that I believed that a black stripe painted along the ties would have done as much good as the guard rail. When your wheel is derailed and comes up against the guard rail, the situation is different from having the weight of the wheel on the rail. Any fastenings that I have been able to use were insignificant when they would have to resist the pressure of a derailed truck, when the load on the axle is 35,000 to 40,000 lbs., and where the truck has a tendency to cross the track.

(The conclusion was referred back to the committee.)

Mr. Loweth: In conclusion 3, I would like to suggest that the committee add after the words "guard rail," in the first line, "when used," so that it will read: "It is recommended that the guard timber or guard rail, when used, be so spaced," etc.

The President: The committee accept that.

(The motion to adopt Conclusion No. 3 was then carried.)

J. B. Jenkins (B. & O.): I move to amend conclusion 4 by inserting "inside guard rail must not be higher, or over one inch lower than the running rail."

The President: The committee accepts that.

(Conclusion 4 was then adopted as amended and the committee was excused.)

UNIFORM GENERAL CONTRACT FORMS.

The Committee was instructed to complete its report and submit the General Construction Contract. In accordance with the suggestions made at the convention in 1912, the secretary of the Association had a draft of the proposed form printed and sent a copy to the senior officer of each railway having membership in the Association with a request for a criticism of the contract by the Legal department. Seventy replies were received, which may be classed as follows:

Number of Replies.	*Nature of Replies.*
One.	Thought it impractical to draw a uniform contract form.
Six	Preferred their own forms and made no other comments.
Thirty-five.	Approved of form, except in a few cases, where the lien clause was criticised.
Three.	Did not criticise, two of these being Canadian roads.
Twenty-five.	Made more or less extended criticisms.

The secretary tabulated the replies, including both the criticisms and the corresponding clauses of other contracts. This information was used by the committee in revising the forms submitted for criticism. Many of these criticisms concerned the detailed wording of the various clauses, and but few of them disapproved of any of the provisions as a whole.

The plan of having an agreement form of two pages to be used by itself for unimportant work and to act as a binder for the "General Conditions, Specifications and Plans," was approved by the convention of 1912. This agreement form as presented was also approved. As the result of legal criticisms received the committee desires to recommend three amendments to this form, as follows:

In the third paragraph insert the words "except as hereinafter specified," making this paragraph read: "The Contractor shall furnish all necessary transportation, except as hereinafter specified, materials, superintendence, etc."

In the first line below the blanks left for the description of the work, insert after the word "attached," the words "identified by the signatures of the parties hereto" and eliminate the word, "as," making this paragraph read: "in accordance with the plans hereto attached, identified by the signatures of the parties hereto, or herein described, and the following general conditions, etc."

Add to the next paragraph the words "time being of the essence of this contract," making this paragraph read: "The work covered by this contract shall be commenced..... .....and be completed on or before the.....day of....., 191...., time being of the essence of this contract....."

The committee presents for approval:

(1) Amendments to form "A" as above.

(2) Form "B" as presented.

RECOMMENDATIONS.

(1) That standing committees which have prepared specifications be instructed to harmonize them with the approved contract form by the elimination of provisions which duplicate or nullify clauses of the contract form.

W. G. ATWOOD,
Chairman Committee on Uniform General Contract Forms.

(2) That the special committee on uniform general contract forms be discharged on account of the completion of the work assigned to it.

W. G. Atwood (L. E. & W.), chairman; J. C. Irwin, vice-chairman; C. Frank Allen (Mass. Inst. of Tech.), E. F. Ackerman (L. V.), Thos. Earle (Penn. Steel Co.), John P. Congdon (Cons. Engr.), R. G. Kenly (M. & St. L.), E. H. Lee (C. & W. I.), C. A. Paquette (C. C. C. & St. L.), H. C. Phillips (A. T. & S. F.), J. H. Roach, (L. S. & M. S.), C. A. Wilson (Cons. Engr.), H. A. Woods (G. T. P.), committee.

CONSTRUCTION CONTRACT.

A—AGREEMENT.

This Agreement, made this.....day of..... in the year.....by and between.....party of the first part, hereinafter called the Contractor, and .....party of the second part, hereinafter called the Company.

Witnesseth, That, in consideration of the covenants and agreements hereinafter mentioned, to be performed by the parties hereto, and of the payments hereinafter agreed to be made, it is mutually agreed as follows:

The Contractor shall furnish all the necessary transportation, except as hereinafter specified, materials, superintendence, labor and equipment, and shall execute, construct and finish, in an expeditious, substantial and workmanlike man-

ner, to the satisfaction and acceptance of the Chief Engineer of the Company.....
.....
in accordance with the plans hereto attached, identified by the signatures of the parties hereto, or herein described, and the following general conditions, requirements and specifications, forming part of this contract.

The work covered by this contract shall be commenced.....and be completed on or before the .....day of.....191...., time being of the essence of this contract.....
.....

And in consideration of the completion of the work described herein, and the fulfillment of all stipulations of this agreement to the satisfaction and acceptance of the Chief Engineer of the Company, the said Company shall pay, or cause to be paid, to said Contractor the amount due the Contractor, based on the following prices: .....
.....

This agreement shall inure to the benefit of and be binding upon the legal representatives and successors of the parties respectively.

In Witness Whereof, The parties hereto have executed this agreement in.....the day and year first above written.

Witness:

B—GENERAL CONDITIONS.

Bond.

1. The Contractor agrees, at the time of the execution and delivery of this contract and before the taking effect of the same, to furnish and deliver to the Company a good and sufficient bond of indemnity to the amount of.....dollars, as security for the faithful performance, by the Contractor, of all the covenants and agreements on the part of the Contractor contained in this contract. The security in such bond of indemnity must be satisfactory and acceptable to the Company.

This bond shall remain in force and effect in such amount, not greater than that specified, as shall be determined by the Chief Engineer, until the final completion and acceptance of the work.

Contractor's Understanding.

2. It is understood and agreed that the Contractor has, by careful examination, satisfied himself as to the nature and location of the work, the conformation of the ground, the character, quality and quantity of the materials to be encountered, the character of equipment and facilities needed preliminary to and during the prosecution of the work, the general and local conditions, and all other matters which can in any way affect the work under this contract. No verbal agreement or conversation with any officer, agent or employe of the Company, either before or after the execution of this contract, shall affect or modify any of the terms or obligations herein contained.

Intent of Plans and Specifications.

3. All work that may be called for in the specifications and not shown on the plans, or shown on the plans and not called for in the specifications, shall be executed and furnished by the Contractor as if described in both these ways; and should any work or material be required which is not denoted in the specifications or plans, either directly or indirectly, but which is nevertheless necessary for the proper carrying out of the intent thereof, the Contractor is to understand the same to be implied and required and shall perform all such work and furnish any such material as fully as if they were particularly delineated or described.

Permits.

4. Permits of a temporary nature necessary for the prosecution of the work shall be secured by the Contractor. Permits for permanent structures or permanent changes in existing facilities shall be secured by the Company.

Protection.

5. Whenever the local conditions, laws or ordinances require, the Contractor shall furnish and maintain, at his own cost and expense, necessary passageways, guard fences and lights and such other facilities and means of protection as may be required.

Rights of Various Interests.

6. Wherever work being done by Company forces or by other Contractors is contiguous to work covered by this contract the respective rights of the various interests involved shall be established by the Engineer, to secure the completion of the various portions of the work in general harmony.

Consent to Transfer.

7. The Contractor shall not let or transfer this contract or any part thereof (except for the delivery of material), without consent of the Chief Engineer, given in writing. Such consent does not release or relieve the Contractor from any of his obligations and liabilities under the contract.

Superintendence.

8. The Contractor shall constantly superintend all the work embraced in this contract, in person or by a duly authorized manager acceptable to the Company.

Timely Demand for Points and Instructions.

9. The Contractor shall not proceed until he has made timely demand upon the Engineer for, and has received from him, such points and instructions as may be necessary as the work progresses. The work shall be done in strict conformity with such points and instructions.

Report Errors and Discrepancies.

10. If the Contractor, in the course of the work, finds any discrepancy between the plans and the physical conditions of the locality, or any errors in plans or in the layout as given by said points and instructions, it shall be his duty to immediately inform the Engineer in writing and the Engineer shall promptly verify the same. Any work done after such discovery, until authorized, will be done at the Contractor's risk.

Preservation of Stakes.

11. The Contractor must carefully preserve bench marks, reference points and stakes, and in case of wilful or careless destruction, he will be charged with the resulting expense, and shall be responsible for any mistakes that may be caused by their unnecessary loss or disturbance.

Inspection.

12. All work and materials shall be at all times open to the inspection, acceptance or rejection of the Engineer or his duly authorized representative. The Contractor shall provide reasonable and necessary facilities for such inspection.

Defective Work or Material.

13. Any omission or failure on the part of the Engineer to disapprove or reject any work or material shall not be construed to be an acceptance of any defective work or material. The Contractor shall remove, at his own expense, any work or material condemned by the Engineer, and shall rebuild and replace the same without extra charge, and in default thereof the same may be done by the Company at the Contractor's expense, or, in case the Chief Engineer should not consider the defect of sufficient importance to require the Contractor to rebuild or replace any imperfect work or material, he shall have power, and is hereby authorized, to make an equitable deduction from the stipulated price.

Insurance.

14. The Contractor shall secure in the name of the Company and for its benefit policies of fire insurance on such structures and in such amounts as shall be specified by the Chief Engineer not exceeding.....

Indemnity.

15. The Contractor shall indemnify and save harmless the Company from and against all claims, demands, payments, suits, actions, recoveries and judgments of every nature and description brought or recovered against it, by reason of any act or omission of the said Contractor, his agents or employes, in the execution of the work by or in consequence of any negligence or carelessness in guarding the same.

Settlement for Wages.

16. Whenever, in the opinion of the Chief Engineer, it may be necessary for the progress of the work to secure to any of the employes of the Contractor any wages which may then be due them, the Company is hereby authorized to pay said employes the amount due them or any lesser amount, and the amount so paid them, as shown by their receipts, shall be deducted from any moneys that may be or become payable to said Contractor.

Liens.

17. If at any time there shall be evidence of any lien or claim for which the Company might become liable and which is chargeable to the Contractor, the Company shall have the right to retain out of any payment then due or thereafter to become due, an amount sufficient to completely indemnify the Company against such lien or claim, and if such lien or

claim be valid, the Company may pay and discharge the same, and deduct the amount so paid from any moneys which may be or become due and payable to the Contractor.

Work Adjacent to Railroad.

18. Whenever the work embraced in this contract is near the tracks, structures or buildings of this Company or of other railroads, the Contractor shall use proper care and vigilance to avoid injury to persons or property. The work must be so conducted as not to interfere with the movement of trains or other operations of the railroad; or, if in any case such interference be necessary, the Contractor shall not proceed until he has first obtained specific authority and directions therefor from the proper designated officer of the Company and has the approval of the Engineer.

Risk.

19. The work in every respect shall be at the risk of the Contractor until finished and accepted except damage or injury caused directly by Company's agents or employes.

Order and Discipline.

20. The Contractor shall at all times enforce strict discipline and good order among his employes, and any employe of the Contractor who shall appear to be incompetent, disorderly or intemperate, or in any other way disqualified for or unfaithful to the work entrusted to him, shall be discharged immediately on the request of the Engineer, and he shall not again be employed on the work without the Engineer's written consent.

Contractor Not to Hire Company's Employes.

21. The Contractor shall not employ or hire any of the Company's employes without the permission of the Engineer.

Intoxicating Liquors Prohibited.

22. The Contractor, in so far as his authority extends, shall not permit the sale, distribution or use of any intoxicating liquors upon or adjacent to the work, or allow any such to be brought upon, to or near the line of the railway of the Company.

Cleaning Up.

23. The Contractor shall, as directed by the Engineer, remove from the Company's property and from all public and private property, at his own expense, all temporary structures, rubbish and waste materials resulting from his operations.

Engineer and Chief Engineer Defined.

24. Wherever, in this contract, the word Engineer is used, it shall be understood as referring to the Chief Engineer of the Company, acting personally, or through an assistant, duly authorized, in writing, for such act by the Chief Engineer, and wherver the words Chief Engineer are used it shall be understood as referring to the Chief Engineer in person and not to any assistant engineer.

Power of Engineer.

25. The Engineer shall have power to reject or condemn all work or material which does not conform to this contract; to direct the application of forces to any portion of the work which, in his judgment, requires it; to order the force increased or diminished, and to decide questions which arise between the parties relative to the execution of the work.

Adjustment of Dispute.

26. All questions or controversies which may arise between the Contractor and the Company, under or in reference to this contract, shall be subject to the decision of the Chief Engineer, and his decision shall be final and conclusive upon both parties.

Order of Completion; Use of Completed Portions.

27. The Contractor shall complete any portion or portions of the work in such order of time as the Engineer may require. The Company shall have the right to take possession of and use any completed or partially completed portions of the work, notwithstanding the time for completing the entire work or such portions may not have expired; but such taking possession and use shall not be deemed an acceptance of the work as taken or used, or any part thereof. If such prior use increases the cost of or delays the work, the Contractor will be entitled to such extra compensation or extension of time, or both, as the Chief Engineer may determine.

Changes.

28. The Company shall have the right to make any changes that may be hereafter determined upon in the nature or dimensions of the work, either before or after its commencement, and such changes shall in no way affect or void this contract. If such changes make any change in the cost of the work, an equitable adjustment shall be made by the Chief Engineer to cover the same.

Extra Work.

29. No bill or claim for extra work or material shall be allowed or paid unless the doing of such extra work or the furnishing of such extra material shall have been authorized in writing by the Engineer.

The price for such work shall be determined by the Chief Engineer, who may either fix a unit price or a lump-sum price, or may, if he so elects, provide that the price shall be determined by the actual cost, to which shall be added ..... per cent, to cover general expense and superintendence, profits, contingencies, use of tools, Contractor's risk and liability. If the Contractor shall perform any work or furnish any material which is not provided for in this contract, or which was not authorized in writing by the Engineer, said Contractor shall receive no compensation for such work or material so furnished, and does hereby release and discharge the Company from any liability therefor.

If the Contractor shall proceed with such extra work or the furnishing of such extra material after reciving the written authority therefor, as hereinbefore provided, then such work or material, stated in the written authority of the Engineer, shall be covered, governed and controlled by all the terms and provisions of this contract, subject to such prices as may be agreed upon or fixed by the Chief Engineer.

If the Contractor shall decline or fail to perform such work or furnish such extra material as authorized by the Engineer in writing, as aforesaid, the Company may then arrange for the performance of the work in any manner it may see fit, the same as if this contract had not been executed, and the Contractor shall not interfere with such performance of the work.

Property and Right of Entry.

30. The Company shall provide the lands upon which the work under this contract is to be done, except that the Contractor shall provide land required for the erection of temporary construction facilities and storage of his material, together with right of access to the same.

The Contractor shall not ship any material or equipment until he has received written notice from the Engineer that he may proceed with said work or any part thereof.

Unavoidable Delays; Extension of Time on Parts of Work.

31. If the Contractor shall be delayed in the performance of the work from any cause for which the Company is responsible, he shall, upon written application to the Chief Engineer at the time of such delay, be granted such extension of time as the Chief Engineer shall deem equitable and just.

Suspension of Work.

32. The Company may at any time stop the work, or any part thereof, by giving ten days' notice to the Contractor in writing. The work shall be resumed by the Contractor in ten days after the date fixed in the written notice from the Company to the Contractor so to do. The Company shall not be held liable for any damages or anticipated profits on account of the work being stopped, or for any work done during the interval of suspension. It will, however, pay the Contractor for expense of men and teams necessarily retained during the intervals of suspension, provided the Contractor can show that it was not reasonably practicable to move these men and teams to other points at which they could have been employed. The Company will further pay the Contractor for time necessarily lost during such suspension at the rate of .....per cent. per annum on the estimated value of all equipment and fixtures owned by the Contractor and employed on the work which are necessarily idle during such suspension, said rate of.....per cent. per annum being understood to include depreciation, interest and insurance. But if the work, or any part thereof, shall be stopped by the notice in writing aforesaid, and if the Company does not give notice in writing to the Contractor to resume work at a date within .....of the date fixed in the written notice to suspend, then the Contractor may abandon that portion of the work so suspended, and he will be entitled to the estimates and payments for such work so abandoned, as provided in Section Thirty-eight (38) of this contract.

Expediting Work, Correcting Imperfections.

33. If the Chief Engineer of the Company shall at any time be of the opinion that the Contractor is neglecting to remedy any imperfections in the work or is not progressing with the work as fast as necessary to insure its completion within the time and as required by the contract or is other-

wise violating any of the provisions of this contract, said Engineer, in behalf of the Company, shall have the power, and it shall be his duty, to notify the Contractor to remedy such imperfections, proceed more rapidly with said work or otherwise comply with the provisions of this contract.

Annulment.

The Company, if not at fault, may give the Contractor ten days' written notice, and at the end of that time if the Contractor continues to neglect the work, the Company may provide labor and materials and deduct the cost from any money due the Contractor under this agreement; and may terminate the employment of the Contractor under this agreement and take possession of the premises and of all materials, tools and appliances thereon, and employ such forces as may be necessary to finish the work. In such case the Contractor shall receive no further payment until the work shall be finished, when, if the unpaid balance that would be due under this contract exceeds the cost to the Company of finishing the work, such excess shall be paid to the Contractor, but if such cost exceeds such unpaid balance, the Contractor shall pay the difference to the Company.

Company May Do Part of Work.

Upon failure of the Contractor to comply with any notice given in accordance with the provisions hereof, the Company shall have the alternative right, instead of assuming charge of the entire work, to place additional forces, tools, equipment and materials on parts of the work for the purpose of carrying on such parts of the work, and the cost incurred by the Company in carrying on such parts of the work shall be payable by the Contractor and such work shall be deemed to be carried on by the Company on account of the Contractor, and the Contractor shall be allowed therefor the contract price. The Company may retain the amount of the cost of such work, with.....per cent. added, from any sum or sums due or to become due the Contractor under this agreement.

Annulment Without Fault of Contractor.

34. (a) The Company shall have the right at any time, for reasons which appear good to it, to annul this contract upon giving thirty (30) days' notice in writing to the Contractor, in which event the Contractor shall be entitled to the full amount of the estimate for the work done by him under the terms and conditions of this contract up to the time of such annulment, including the retained percentage. The Contractor shall be reimbursed by the Company for such expenditures as in the judgment of the Chief Engineer are not otherwise compensated for, and as are required in preparing for and moving to and from the work; the intent being that an equitable settlement shall be made with the Contractor.

Notice; How Served.

(b) Any notice to be given by the Company to the Contractor under this contract shall be deemed to be served if the same be delivered to the man in charge of any office used by the Contractor, or to his foreman or agent at or near the work, or deposited in the postoffice, postpaid, addressed to the Contractor at his last known place of business.

Removal of Equipment.

(c) In case of annulment of this contract before completion from any cause whatever, the Contractor, if notified to do so by the Company, shall promptly remove any part or all of his equipment and supplies from the property of the Company, failing which the Company shall have the right to remove such equipment and supplies at the expense of the Contractor.

Failure to Make Payments.

35. Failure by the Company to make payments at the times provided in this agreement shall give the Contractor the right to suspend work until payment is made, or at his option, after 30 days' notice in writing, should the Company continue to default, to terminate this contract and recover the price of all work done and materials provided and all damages sustained, and such failure to make payments at the times provided shall be a bar to any claim by the Company against the Contractor for delay in completion of the work.

Monthly Estimate.

36. So long as the work herein contracted for is prosecuted in accordance with the provisions of this contract, and with such progress as may be satisfactory to the Chief Engineer, the said Chief Engineer will, on or about the first day of each month, make an approximate estimate of the proportionate value of the work done and of material furnished or delivered upon the Company's property at the site of the work, up to and including the last day of the previous month. The amount of said estimate, after deducting ..... per cent., and all previous payments, shall be due and payable to the Contractor at the office of the Treasurer of the Company on or about the 20th day of the current month.

Acceptance.

37. The work shall be inspected for acceptance by the Company promptly upon receipt of notice that the work is ready for such inspection.

Final Estimates.

38. Upon the completion and acceptance of the work the Chief Engineer shall execute a certificate over his signature that the whole work provided for in this agreement has been completed and accepted by him under the terms and conditions thereof, whereupon the entire balance found to be due to the Contractor, including said retained percentage, shall be paid to the Contractor at the office of the Treasurer of the Company within ..... days after the date of said final certificate. Before the time of payment of said final estimate the Contractor shall submit evidence satisfactory to the Chief Engineer that all payrolls, materials, bills and outstanding indebtedness in connection with this work have been paid.

Discussion on Contract Forms.

W. G. Atwood (Committee Chairman): The statement of the committee covers about everything that they have to say. Thirty-five legal departments approved the form as it stands, except for the lien clause. That lien clause we changed as a result of their criticism.

V. K. Hendricks (St. L. & S. F.): I would like to ask, as a matter of information, how the blank space after "time being of the essence of this contract" in Form *A* is to be filled in.

Mr. Atwood: That is for qualification or specification and description that will fit in the different cases, and the blank is left to be used for any of those purposes.

Mr. Fritch: I believe it would be an improvement if "all the necessary transportation, except as herelnafter specified," would follow after equipment. Then it would be sure to cover everything—labor, material and equipment.

Mr. Atwood: The committee will accept that change.

Mr. Rose: I do not quite understand that permit arrangement in paragraph 4, Form *B*. I think in many cases it would be better for the company to get the permit than the contractor.

Mr. Fritch: This refers simply to temporary permits. Any permanent permit should be secured by the company.

Mr. Rose: I would like to know if it is possible to carry out this section 14, taking out insurance in the name of the company for property the company does not own and has not accepted? I think it would be necessary to assign that portion of the work that is covered by insurance to the company in order to collect the insurance.

Mr. Atwood: It is the opinion of the committee that structures erected or material furnished to the company on the right-of-way under this contract, which provides for certain definite payments, is the company's property when it is so erected and furnished. And that the contractor has a lien on it, but the material or structure is the property of the company.

L. C. Fritch: Referring to paragraph 26, one thing that has not been quite satisfactory to me is the arbitration clause, the chief engineer representing the railroad company alone being the judge of the disputes between the company and the contractor. I do not believe that that would be sustained in the courts.

Hunter McDonald: My experience with respect to the matter of arbitration clauses is that they are entirely useless. You can go into court and get your controversy settled by a judge in a much more expeditious manner and with much more fairness and with about the same expense that you can by arbitration.

C. A. Wilson (C. E.): I was retained in a case where there was a suit brought for damages by a contractor. The suit was a jury case. The attorneys for the railway contended that this was not a suit in damages; that by the contract the engineer had been constituted the arbitrator between the two parties, and he had rendered his decision as arbitrator, and that therefore it was an appeal case from the arbitration of the engineer.

C. P. Howard (I. C.): I have been in some law suits in which these questions have been brought up. I don't remember the courts having passed on it, but my recollection of comment of eminent attorneys on the subject is that the

decision of the chief engineer in authority as an arbitrator would stand, unless it could be clearly proven that he had acted from fraudulent motives or had clearly made a mistake.

Mr. Atwood: An appeal can be carried either to a court or to an arbitration board after the completion of the work by agreement; but we feel it is necessary that the chief engineer have this power during the progress of the work to see that it is carried on.

L. C. Fritch: I would like to have a blank left in the third line, paragraph 29, before "engineer," so that if any company wishes to have the extra work controlled entirely by the chief engineer, that might be inserted.

The President: The committee will accept that.

Robt. Ferriday (Big Four): I would recommend that the time of giving notice be left blank in paragraph 32. A little job of grading would not amount to anything, but if a man has a one million dollar building, ten days would be pretty short notice.

L. C. Fritch: It does not seem to me that the clause is quite consistent. In one place it refers to equipment and fixtures; in another place to men and teams.

Mr. Gifford: The word "Owned" might be changed to "equipment and fixtures owned by the contractor." Frequently the contractor rents the equipment. We might change the word owned or leave it out entirely and make it read, "The value of all fixtures and equipment furnished by the contractor on the work."

The President: The committee will accept that.

The President: The committee will insert a blank instead of the figures "10" in paragraph 33 under the title of annulment, to agree with the other cause.

Mr. Rose: I move that "20th" be left blank in paragraph 36.

The President: The committee accepts that.

Edward Gray, Jr. (C. & O.): It seems to me there might be some ambiguity in the last clause of paragraph 15 "Negligence in guarding the same," seems to exclude everything outside of it, as now written and punctuated. If that was intended it seems to me we would have to use "guarding" in a too general sense. I would suggest that it read "By reason of any act or omission of said contractor, or in consequence of any negligence or carelessness in guarding same."

Mr. Atwood: The committee will accept that.

Mr. Rose: This will not save the company from suits for patents. I do not think that is covered.

Mr. Atwood: That has been referred to the legal departments of several of the roads represented on the committee, and they have all ruled that it did cover patents.

Mr. Hendricks: I move that the last line of paragraph 1, reading "The final completion and acceptance of the work" be stricken out, and that it read "After the expiration of the time in which liens can be filed."

Mr. Atwood: The committee would suggest as a substitute for that, the words "Until the final completion or acceptance of the work" be struck out, and that it be replaced by blank, to be filled in as desired.

Mr. Hendricks: I will accept that.

Mr. Lloyd: Clause 36 says the materials shall be paid for. I do not understand why he should get additional compensation for the materials.

Mr. Atwood: Materials delivered prior to the first of the month during which the suspension might take place, would be paid for under the estimate. If we add the word "materials" in this clause it would cover interest on materials after that time and during suspension.

(The committee was discharged, their work having been completed.)

WOOD PRESERVATION.

The board of direction assigned the following subjects:

(1) Continue investigation of proper grouping of different timbers for antiseptic treatment.

(2) Investigate the merits of various preservatives, giving special attention to oil from water-gas tar, and to the use of refined coal-tar in creosote oil.

In addition to the subjects specifically assigned, the committee continued investigations on the following two subjects assigned in previous years, but on which no final report was made:

(3) The advisability of revising the specifications for fractionation of creosote oil.

(4) Recommend forms for the inspection of preservative processes.

GROUPING OF TIMBERS FOR ANTISEPTIC TREATMENT.

In the report last year the committee stated the fundamental principles governing the grouping of timbers for treatment, which were adopted by the association for publication in the manual. It was the consensus of opinion that further recommendations could not be made until an extensive series of experiments had been conducted, which would indicate the proper practice at stated locations, and with timber from specific regions. An outline of the points to be covered by experimental work in different regions was prepared and sent out to the members of the sub-committee on grouping, and some investigative work has been in progress during the year. However, owing to the long time required to reach definite conclusions and because of the difficulty of arranging for sustained experimental work along uniform lines, no data are available which would justify changing or adding to the fundamental principles outlined last year.

Some of the best authorities express the opinion that, owing to the variations in the character of the same kind of wood in different regions, the problems of grouping must be worked out at each individual treating plant, and that statements regarding detail practice which would have general application cannot be made. Another view of the matter, which has been expressed, is that the next step is to determine the laws governing the penetration of creosote, from which the grouping of timbers according to natural resistance may be made. As the committee has no facilities for studies of this kind,

EARL STIMSON,
Chairman Committee on Wood Preservation.

and since the wood-preserving industry looks to the U. S. Forest Products Laboratory and other institutions devoted to technical investigations for reports along this line, it is recommended that the attention of the United States Forest Products Laboratory be called to the desirability of a study of the regional variation in wood structure by species, in reference to the absorption of preservatives.

The committee will continue its investigations along these lines during the coming year.

THE MERITS OF PRESERVATIVES.

The Use of Refined Coal Tar in Creosote Oil.

The sub-committee to which this subject was assigned made an exhaustive research for facts pertaining thereto upon which the committee might base a report and definite recommendations. The result was such that the committee was not able to reach a conclusion and is not in position at this time to present a report with recommendations to the association. The committee, therefore, reports progress, and will continue the consideration of this subject.

The Use of Oil from Water Gas Tar.

So far as the committee has been able to learn, water-gas creosote has not been extensively used under its own name as a wood preservative, and there is very little information to be found as to its efficiency. A few piles treated with it are driven in the harbor of Norfolk, Va. These waters are badly infested with Teredo, and the piles are said not to have been attacked, although they have been there about three years. Professor Allen[illegible] a tie at Swarthmore which was treated

with water-gas creosote and was in service nine years at Porto Rico. This tie is still sound. The Public Service Corporation of New Jersey has been using water-gas creosote for several years for treating ties. These ties should show in about two years whether the treatment is good or not. They are now treating a large number of pine ties with straight water-gas creosote furnished by the United Gas Improvement Company of Philadelphia. One of the large creosoting companies has recently obtained a patent for treating wood with a mixture of water-gas creosote and coal-tar creosote, and one of the large railroad companies is contemplating the use of a mixture of water-gas creosote and coal-tar creosote for ties. The United States Forest Service has some specimens treated with water-gas creosote placed at West Pascagoula and Gulfport, Miss.; the latter put in the water in March, 1912. None of the specimens has been there long enough to give any results. It seems that the principal objection to water-gas creosote has been to its unauthorized use as an adulterant in coal-tar creosote. Its use, however, is now increasing in legitimate mixtures, and, while it is too early to get any results, it seems that a number of people favor using at least a mixture of this oil with coal-tar creosote.

It is recommended that the investigation of this subject be continued for another year.

CONSIDERATION OF THE SPECIFICATIONS FOR FRACTIONATION OF CREOSOTE OIL.

For some years past the committee has had under consideration the relative merits of the flask and retort for the fractionation of creosote oil. For the purpose of obtaining information on this point, and on which to base consideration of further revisions in the specifications for fractionation, the committee sent samples of various creosote oils to different railroads for fractionation by the various methods. Based on these examinations, the committee recommends that no change be made in the adopted specifications for fractionation of creosote oil.

FORMS FOR REPORTING INSPECTION.

Two forms for reporting inspection of treatment are submitted. Form "A" provides a record of the treatment and the determination of the absorption of the preservative by gage readings. Form "B" provides a record of the determination of the absorption by weighing. These forms are intended as a general guide for reporting and keeping records of the inspection of the treatment of timbers, and may be varied to suit any special kind of treatment.

The following is explanatory of the gage readings, designated by letter on Form "A":

Reading "A"—Is the reading of the measuring tank gage before the oil is put into the cylinder.

Reading "B"—Is the tank gage reading when the cylinder is completely filled.

Reading "C"—Is the tank gage reading when the pumping of the oil into the cylinder is stopped.

Reading "D"—Is the tank gage reading after all the oil from the charge is returned to the measuring tank.

Reading "A" minus "D," corrected for temperatures, gives the number of gallons used in the charge.

Reading "B" minus "C" gives the number of gallons pumped into the timber after the cylinder is filled and is used to give the gross absorption for light processes where oil is taken out of the timber by an initial air pressure, or by a final vacuum, or both. There will be a discrepancy in this gross absorption, due to the amount of oil absorbed by the timber while cylinder is being filled.

RECORDS FROM SERVICE TESTS.

In Appendix "B" to this report was given the record from service tests, brought up to date and extended to include a number of additional tests not shown on the records submitted with the report of last year.

CONCLUSIONS.

It is recommended:

(1) That no change be made in the adopted Specifications for the Fractionation of Creosote Oil.

(2) That the forms "A" and "B" for reporting the Inspection of Treatment of Timbers, and the notes explanatory of the gage readings on Form "A," as given under the subhead "Forms for Reporting Inspection," be adopted for insertion in the manual.

OUTLINE OF WORK FOR 1913.

The committee recommends:

(1) Continue investigations of the merits as a preservative of oil from water-gas and the use of refined coal-tar in creosote oil.

(2) Continue the compilation of available information from service tests.

(3) Continue the investigation of the proper grouping of the different timbers for antiseptic treatment.

(4) Report on methods of accurately determining the absorption of creosote oil.

(5) That the board of direction assign the work of drawing up a standard specification for timber for treatment to a joint committee of the committee on wood preservation and the committee on grading of lumber.

Earl Stimson, chairman (B. & O.), E. H. Bowser, vice-chairman (I. C.), G. M. Davidson (C. & N.-W.), H. B. Dick (B. & O. S. W.), C. F. Ford (C. R. I. & P.), Dr. W. K. Hatt (Purdue Univ.), V. K. Hendricks (S. & L. & S. F.), George E. Rex (A. T. & S. F.), E. A. Sterling (Cons. Engr.), C. M. Taylor (P. & R.), Dr. H. von Schrenk (Cons. Engr.), T. G. Townsend (Southern), Committee.

Discussion on Wood Preservation.

Earl Stimson, Committee Chairman: Under the heading "Consideration of the specifications" for fractionation of creosote oil," I will ask Dr. Von Schrenk to present the subject.

Dr. H. von Schrenk: The experiments to which the chairman refers were made as a result of a number of inquiries which came to the committee last year, as to whether the standard practice now printed in the Manual for fractionating coal-tar creosote was the best method for conducting this operation, and in order to secure fuller data on the subject, two separate creosoted oils were sent out, by the sub-committee to a number of railroads, with the request that they analyze or fractionize these samples according to the standard methods now printed in the Manual, and according to a suggested method of using a flask instead of a retort which had been presented by a sub-committee of this committee two years ago. The oils were labeled respectively A and B. The samples all come from the same cans, and the methods prescribed by the Manual and by the recommendation made to the committee two years ago were followed by various operators for various companies. The results have been tabulated in the report this year. A careful study was made. First as to the variations in results between the two methods per se and then a study of the variations due to the fact that different individuals were using one and the same method. After a careful tabulation of these variations, the committee came to the conclusion that the present method as printed in the Manual, showed a variation which was slightly less from the personal standard than that obtained in the fractions made with the suggested method, and we could find no evidence of any improvement which could be obtained by the suggested method, over the one which we have standing in the Manual at the present time, and in order that these results might once and for all be available to those interested in the subject, we have presented in full the actual results submitted by the individual operators.

Mr. Stimson: I will say in explanation of Form "A" that it provides a record of the treatment and the determination of the absorption by gage readings. Form "B" provides a record for the determination of the absorption by weighing. Form "B" provides a check against Form "A." I move that this be adopted for insertion in the Manual. (The motion was seconded and carried.)

TIES.

The board of direction assigned the following subjects to the committee:

(1) Report on the effect of design of tie-plates and track spikes on durability of ties.

(2) Continue study of the stresses to which cross-ties are subjected, and determine size required.

(3) Report on economy in labor and material effected through use of treated ties compared with untreated ties.

(4) Continue the compilation of information as to the use of metal, composite and concrete ties.

The report on the effect of the design of tie-plates and spikes on the durability of ties is given in appendix A, and is submitted as information.

The report on the subject of stresses to which cross-ties are subjected is given in appendix B.

The committee also reports progress on the subject of economy in labor and material effected through use of treated ties compared with untreated ties.

In appendix C was given a compilation as to the use of metal, composite and concrete ties.

CONCLUSIONS.

The committee has given the subject of stresses to which cross-ties are subjected an exhaustive study, covering a period of two years, and after conferences with a number of leading members of the Association, finds no reason to change its conclusions submitted in 1912, and given on page 331 of Volume 13, and resubmits them for adoption:

The conclusions of the committee are as follows:

(1) It is impracticable to perform experiments to determine size of cross-ties, for the following reasons:

The character of the subgrade varies radically on the same road and in different parts of the country. The kind of ballast varies widely. The necessary depth of ballast varies with the weight of axle loads as well as density of traffic. The necessary distance between face of ties varies with the weight of axle load, as well the density of traffic. The kinds of timber used for ties vary in different sections of the country. The width of base of rail (or weight of rail) and use of tie-plates. Treated or untreated ties, crushing stress and durability. Amount of labor spent on track maintenance and drainage.

(2) It is recommended that the report on the effect of design of tie-plates and track spikes on durability of ties be received as information.

(3) It is recommended that the report on metal, composite and concrete ties be received as information.

L. A. Downs (I. C.), Chairman; G. W. Merrell (H. & W.), Vice-Chairman; H. W. Brown (Pa. Lines), W. J. Burtin (M. P.), L. C. Hartley (C. & E. I.), E. D. Jackson (B. & O.), H. C. Landon (Watauga R. R.), F. R. Layng (B. & D. E.), E. R. Lewis (D. SS. & A.), R. J. Parker (A. T. & S. F.), L. M. Perkins (H. P.), J. G. Shillinger (Rutland), G. D. Swingly (B. & O.), D. W. Thrower (I. C.), H. S. Wilgus (P. S. & H.), Louis Yager (M. P.), E. C. Young (N. Y., P. & H.), Committee.

L. A. DOWNS,
Chairman Committee on Ties.

APPENDIX A.

The Effect of the Design of Tie-Plates and Spikes on the Durability of Ties.

A circular letter requesting information relative to this subject was sent to members of the Association. The following is a list of the questions asked:

(1) Do you use flat, longitudinal flange, transverse flange, pronged or corrugated tie-plates?

(2) Please send plan of your standard tie-plate, and give method of applying.

(3) Do you use screw or cut spikes?

(4) In your opinion, how far should tie-plate extend outside base of rail to overcome side thrust, and what should be total bearing area? Give reasons for your conclusions.

Replies were received from 61 railroads. The number of roads using only one design of tie-plate and the kind of plate used, are:

Longitudinal flange	16
Transverse flange	8
Flat	5
Pronged	4
Corrugated	11

The number of roads using two designs of tie-plates and kind of plates used, are:

Longitudinal flange and flat	3
Longitudinal flange and pronged	1
Longitudinal flange and corrugated	1
Transverse flange and pronged	1
Transverse flange and corrugated	1
Flat and pronged	1
Pronged and corrugated	1

The number of roads using three designs of tie-plates and kind of plates used, are

Longitudinal flange, transverse and flat	1
Longitudinal flange, transverse and corrugated	2
Longitudinal flange, flat and corrugated	1
Longitudinal flange, pronged and corrugated	1
Transverse flange, flat and pronged	1

The number of roads using four designs of tie-plates and kind of plates used, are:

Longitudinal flange, transverse, pronged and corrugated	1

The committee was unable to obtain any definite information bearing on the relative effect of the different designs of tie-plates and spikes on the life of ties, but it is thought that experiments, which are now being conducted, will throw some light on this subject in the near future.

APPENDIX C.

Study of the Stresses to Which Cross-Ties are Subjected.

The assigned topic resolves itself into two parts:

Continue the study of the stresses to which cross-ties are subjected, and determine the size required.

In order to have an expression of opinion as to the best method for handling the topic, a letter was sent to 27 members of the Association and 15 replies were received which show quite a divergence of opinion. "Track Deformation," by Cuenot, covers very well many of the suggested methods mentioned in said letters for solving the second half of the topic.

The first part of the assigned topic may be touched upon to the extent of spacing of the ties. The preponderance of the mileage voting is in favor of twelve-inch face to face; the next in favor is ten-inch; the next thirteen-inch. The recommendation of this committee for 1912 was ten to twelve-inch, and the above table substantiates its recommendation.

The Ballast committee published a translation of "Gravel as Ballast," by C. Bräuning in the proceedings for 1912, Vol. 13. Mr. Bräuning's conclusions, which are in accord with the committee's recommendations, are as follows:

"Of greater importance than the width of the tie is the spacing of the ties. As the spacing is decreased two advantages are derived: first, the unit pressure is decreased; secondly, the carrying capacity of the roadbed is increased. It is just within the limits of tie spacing usually considered that the relation a-b (a = distance face to face to tie; b = depth of tie) ranging from 3½ to 2 (spacing 35-inch and 19½-inch center to center) that the carrying capacity increases at a high rate. The limiting feature of decreasing tie spacing is the ability to tamp the ties properly. Ties 6½ in. in height can still be tamped with convenience when separated 13½ in. But this 23-inch from center to center is the lowest limit. This is the one most effective and simplest means of increasing the strength of the roadbed and to utilize it to the fullest advantage, especially on roadbeds which are fully loaded, is urgently recommended."

Mr. Byers, Vol. 1, 1911, International Railway Association, says "20-inch center to center of ties small as practicable." With an 8-inch tie the spacing face to face is 12 in. Therefore the committee feels that its conclusions are fully in line with Mr. Bräuning's recommendations, though prepared without knowledge of either Messrs. Bräuning's or Byers' conclusions.

	Percentage here represented, 23.			

Vol. 13, pp. 306 and 307 of the Proceedings for 1912 give a table of the different number of ties per 30-ft. rail, the percentage of roads using 6 x 8 x 8 and a table giving the different sizes of cross-ties in current use. The divergence of practice is undoubtedly largely due to varying conditions in different localities and to a tendency to "follow the leader." The latter is probably nearer the mark, as the tendency in American railroading has been in the past, and only now is being broken away from, for the railroad heads always to compare the engineering department recommendations with practice on other roads, with the result that in many lines our progress has been slow.

Report was received as information without discussion.

SIGNS, FENCES AND CROSSINGS.

The following subjects were assigned for consideration:

(1) Report on the relative advantages of the different kinds of fence posts, with definite recommendations.

C. H. STEIN,
Chairman Committee on Signs, Fences and Crossings.

(2) Report on the best form of track construction and flangeways at paved street crossings and in paved streets, with definite recommendations.

(3) Continue the investigation of ways and means for securing a proper quality of fence wire to resist corrosion and secure durability.

RELATIVE ADVANTAGES OF THE DIFFERENT KINDS OF FENCE POSTS.

Replies were received from 44 railroads, with the following information as to kind of post used, cost, life of same, etc.:

It will be observed from the foregoing that the various roads use the different kinds of timber indigenous to their geographical position as follows:

Cedar	32	Oregon Flr	1
Chestnut	7	Juniper	1
Locust	9	Tamarack	1
Oak	9	Burnettized Pine	1
Bois D'Arc	5	Mulberry	1
Catalpa	1		

There are certain species of each of the above woods that are not suitable for fence posts, but doubtless must be used because they are cheap and native to the locality. This is indicated by the following summary:

Life of Posts.

Red Cedar	7 to 25 years	Black Locust	10 to 25 years
Cedar	10 " 30 "	White Oak	7 " 15 "
White Cedar	12 " 17 "	Bois D'Arc	12 " 45 "
Chestnut	10 " 15 "	Catalpa	10 " 25 "
Locust	7 " 20 "	Juniper	15 "
Yellow Locust	15 " 30 "	Mulberry	15 " 20 "

Doubtless some give little heed to the particular species of such timber that they use, and assume that any species of that genus has about the same life. This is manifestly incorrect, as is demonstrated by the oak family. The inferior grades of oak have only a life of from two to four years, while a good white oak has a life in our northern climates of from 10 to 12 years at least. Certain classes of oak last much longer in their native regions than in other localities to which they are transported for use. This principle applies with equal force to every other class of timber.

In reviewing the replies of the various roads, we find that the consensus of opinion, based upon the experience of the users, is that the different classes of timber have an average life as indicated below:

Red Cedar	18 years	White Oak	10 years
White Cedar	15 "	Bois D'Arc	25 "
Chestnut	12 "	Catalpa	15 "
Yellow Locust	20 "	Juniper	15 "
Black Locust	20 "	Mulberry	15 "

Climatic influences have an important bearing upon this phase of the case, and may lengthen or shorten the life of a particular kind of wood, dependent upon locality in which used. It is not feasible in most cases to recommend any particular kind of timber for a given territory, as the source of supply may be so distant as to preclude its use economically. According to information received, the cost of the various kinds of wood posts is:

	Range.	Average.
Red Cedar	15c to 25c	22c
Cedar	7c " 20c	14c
White Cedar	12c " 15c	14c
Chestnut	10c " 27c	20c
Locust	15c " 40c	25c
Yellow Locust	20c " 38c	30c
Black Locust	15c " 25c	20c
White Oak	11c " 40c	20c
Bois D'Arc	13c " 17c	15c
Catalpa	15c " 25c	20c
Juniper	6c " 10c	8c
Mulberry	13c " 17c	15c

It will be observed that the relative cost to life of post ranges from one-half cent to two cents per year of life, the Bois D'Arc and the Juniper being the cheapest posts, but so rare that a more general use is impossible.

It was of interest to know to what extent wooden posts were subject to destruction by fire. Replies received indicated that this varied by from 1 per cent. to 5 per cent., with the exception of one road which reported a loss of 30 per cent. from this cause. We think it fair to assume that the average loss by fire is around 3 per cent.

Only two roads so far as we can learn make mention of having used any metal posts, and then only to a limited extent. In the one case bar iron ¼ in. x 2 in. was used, and in the other, old boiler tubes. We have reason to believe, however, that quite a number of roads, not replying to our circular, are trying out a proprietary metal post. Several styles of steel right-of-way fence posts are on the market. Their exploitation has just begun in the last year or two, and any statement as to their efficiency and economy could be but vague and from the manufacturers' standpoint alone. Greater experience may demonstrate their utility, but thus far we have no data upon them, and can only give some computations from one of the manufacturers, which might be of interest for study from the viewpoint of railroad economy. These figures, while prepared for a certain style of post only, if reliable, will no doubt be equally accurate for any other style of metal post, built along similar lines, and others are generally so designed. In order that the membership may have the manufacturers' explanation of the merits of the steel post for their further consideration, we give the statement of the case in substance according to one with whom we have had the matter under discussion:

Steel posts cost	23.03 cents
Cost of setting	1.30 "
Total	24.33 "
Estimated life	30 years

Based upon above figures, steel posts set one rod apart cost .81 cent per year.

The cost of setting wood posts is estimated at 5.8 cents each. The following table is based on wood posts costing from nothing up to 20 cents each, and is intended to show what the life of wooden posts must be at different first costs to be as cheap as the steel post:

Cost of post.	Cost of setting.	Total cost.	Years it must last to be as cheap as steel.
0 cents	5.8 cents	5.8 cents	7.1 years
5 "	5.8 "	10.8 "	13.3 "
8 "	5.8 "	13.8 "	17. "
10 "	5.8 "	15.8 "	19.5 "
12 "	5.8 "	17.8 "	21.9 "
15 "	5.8 "	20.8 "	25.6 "
17 "	5.8 "	22.8 "	28.1 "
18.53"	5.8 "	24.33 "	30. "
20 "	5.8 "	25.8 "	31.2 "

The above figures would indicate that wood posts costing 15 cents would have to have a life of 35.6 years and those costing 20 cents a life of 31.8 years to be as cheap as steel.

The first steel posts are said to have been manufactured about fifteen years ago at Bloomfield, Ind. Others, doubtless, of different design unknown to the committee were manufactured as long ago and perhaps longer, but only during the past 12 years have they been given any serious study with a view to placing them on the market for ordinary right-of-way fencing. Hundreds were taken up and examined to discover signs of rust, and deterioration at the ground line or elsewhere. They have been in use at Spencer, Worthington, Bloomfield, Ind., and elsewhere in all kinds of soil and under all conditions. The investigations have resulted in placing them on the market during the past year or so.

To be of economic worth for right-of-way protection, a fence post must possess the following qualities: durability, practicability, efficiency, and the price must be right. Inquiry develops that one man can set in a day from 15 to 35 wooden line posts. To be conservative, 30 posts per day per man is assumed as the unit of work. Estimating wages at $1.75 per day places the cost of setting a wood post at 5.8 cents. The cost of post is estimated at 12 cents, resulting in an entire outlay of 17.8 cents. Experience is said to have demonstrated that three men can readily set from 390 to 640 steel posts per day, or 130 to 213 per man—130 posts per man is taken as the basis of calculation with wages at $1.75 per day. This places the cost for setting a steel post at 1.3 cents. Cost of steel post 23.03 cents, plus cost of setting 1.3 cents, resulting in entire outlay, 24.33 cents.

Comparative Cost of Steel and Wood.

Entire cost of steel post 24.33c; estimated life 30 years.
Money worth 6 per cent.
Entire cost of wood post 17.80c; estimated life 12 years.
Expenditure for steel posts.....24.33 cents
Expenditure for wood posts.....17.80 "

Difference ..... 6.26 "

Compound interest on 6.26 cents for 12 years amounts to 13.06 cents. At the expiration of 12 years wood posts have failed and need renewal. 13.06 cents has been saved over cost of steel posts. This is equivalent to purchasing 8.8 years more protection with wood. In other words, 24.33 cents expended for steel give 30 years of protection, while same amount expended for wood gives 12 years original life, plus 8.8 years interest on investment, or 20.8 years, a balance in favor of steel of 9.2 years. Viewing the matter from another angle, assuming that posts are set one rod apart, track protection costs per year as follows:

Steel Posts.		Wood Posts.	
Per rod	$ .0081	Per rod	$ .0117
Per mile	2.59	Per mile	3.74
Per 100 miles... ..	259.00	Per 100 miles.....	374.00

Balance in favor of steel posts of
$ .0036 per rod per year.
1.15 per mile per year.
115.00 per 100 miles per year.

Other advantages claimed are no staples used; right-of-way may be burned over from time to time without injury to posts. No loss from accidental fires and no renewal on that account. Special end, corner and gate posts must be used in connection with the steel line post. No means are provided for bracing them so as to use them as end or corner posts. There is not enough steel in them to stand the strain of stretching a heavy wire fence. The minimum amount of steel necessary is used to meet the requirements of a right-of-way fence. The line and end posts are treated as distinct problems. In this they are not unlike posts made of other materials.

Comparative Cost of Steel and Wood End and Corner Posts.
Cost of End Post.....$1.62
Cost of Corner Post..... 2.30

Assuming it fair to say that twice as many end posts will be needed as corner posts, it places the average of the stretching post at $1.84 each. If $1.84, the cost of the steel corner post, bears the same relation to the cost of a good wooden corner post that the price of the steel line post bears to the price of the wooden post, then the economy is demonstrated. In order to determine whether or not this relation maintains, we resort to the following equation:

$$\frac{12c \text{ (cost of wood line post)}}{23.03c \text{ (cost of steel line post)}} \times \text{(cost of wood corner post)} = \$1.84 \text{ (cost of steel corner post)}$$

We find $\times = 96$ cents, cost of wooden corner post, which appears to be a conservative estimate of the cost of a good wooden corner post. From a mathematical and perspective point of view, the manufacturer of the steel fence post appears to have made out a case that is worthy of continued and further close investigation. Time alone, under practical service conditions, can demonstrate if the figures are based upon substantial premises, and subject to corroboration. To be efficient and adequate, the steel posts must resist corrosion, must be sufficiently strong to withstand ordinary and accidental hard usage, must not heave from the ground in winter, must remain firm and not loosen up, permitting the fence to get out of proper alignment. The speedy extinction of our forest lands and the failure on the part of all concerned to encourage the practice of reforestation, caused the users of wooden fence posts to seek some efficient substitute. The steel fence post has not yet proved its merit in practice and at this time concrete with suitable reinforcement seems to offer the only solution to the problem.

It is recognized as a primary proposition in the design of a concrete fence post that in order to secure a post of such weight that it can be readily handled, it must not be too heavy; hence, reinforcement is necessary to reduce the bulk of concrete. This reinforcement must bear a co-ordinate relation to the concrete and act in harmony with it. To produce this result it must be properly placed, and make a proper mechanical bond with it. It has been demonstrated that while concrete posts are not as strong as wooden ones, they are sufficiently strong to meet all practical conditions.

The committee has gotten into touch with the various manufacturers of concrete fence posts, as well as with the various railroads that are experimenting with them, so far as has been possible, and will endeavor to present some data relating to them. Not more than a dozen railroads are using concrete posts in large quantities at this time, but a large number are pursuing the subject with a view to their extensive use.

In reviewing the methods employed by the various manufacturers and railroad companies who have given this subject careful investigation, we find that they accord very closely with practices recommended by the United States Department of Agriculture in Bulletin 403, and we, therefore, present certain extracts from that bulletin with some additional notes.

On account of the variations in the size of the sand grains and in the unfilled spaces between the particles of sand, stone and gravel, the quantities of concrete made, according to certain proportions may vary. For the same reasons the quantity of water may or may not be sufficient to make the concrete wet enough. Water should always be measured by the bucket to have uniform results.

Different pockets of sand and gravel and different crusher-run rock vary in size and consequently in the unfilled spaces or voids between the grains or pieces. If unscreened bank run gravel is decided upon, it should be used in the proportion of one part of cement to four parts of gravel. For crushed rock or screened gravel (which is much better than bank run gravel) the concrete should be used in the proportion of one part of cement, two parts sand and four parts of rock or gravel. Also one part cement to four parts chats makes good concrete. All measurements should be made with the material poured loosely into the measuring box and the box when full should be leveled smooth.

The amount of moisture in sand, gravel and stone varies so much with weather conditions that the quantity of water for a cubic foot of concrete cannot be fixed exactly. During the mixing of the cement with the sand and rock sufficient water should be used for the concrete to be wet enough when the mixing is complete to tremble under a blow from the shovel. This amount of water causes a rich mortar to flow to the outside of the post and insures a smooth finish.

In general, where crushed rock or screened gravel is used, the full amount of sand is spread out upon the board and

upon it the necessary cement is evenly distributed. The whole is turned dry until the cement no longer shows in streaks, and the color of the batch is uniform. The mixture is then spread out flat, just as the sand was, and upon it the crushed rock or screened gravel is distributed evenly. Three-fourths of the water required is added and the mixing is continued. In dry, hot weather it is a good plan to throw water on the pile of crushed rock before mixing.

Concrete has a tendency to stick to either steel or wood. In order to yield a smooth finish to the post, it is customary to give the inside of the molds a coating of oil. Soft soap or crude oils used sparingly serve the purpose well. Too much oil will destroy the setting qualities of the cement and will give a face roughened with pockmarks. A small amount of oil, poured into a pail of water and applied with a mop or stiff broom in scrubbing out the molds after they have been used five or ten times, or as often as necessary, will prevent the concrete from sticking.

After the molds, which, as a rule, lie flat, have been oiled or soaked, the concrete should be placed in them at once. If for any reason the concrete stands thirty minutes after mixing, it should be thrown away and a new batch mixed, for cement, if it has once partially set, makes weak, dangerous concrete, even though it is retempered by turning or adding water. If wooden molds are used, they should be well soaked in water so that the concrete post will not cause them to swell and thus crack the post.

Reinforcing should be placed near the outside wall, where it is reasonable to expect that cracks will open. For reinforcement, metal slightly rusted is as good if not better than metal that is not rusted. In placing the reinforcing rods in position it is a wise precaution to bend them back at the ends. This takes only a little more time, but, if it is done, the reinforcement must be two in. longer to allow the metal to be turned back one in. at each end of the post. New barbed wire should not be purchased for reinforcement, for while it costs more than plain reinforcement, the bond between it and the concrete is no stronger than between smooth wire and concrete. The danger section, or the point where posts are liable to break, is at the surface of the ground. For fences for lots and other places where posts may be subject to rubbing and crowding, short extra reinforcing pieces two ft. long are sometimes placed in the post to lap this danger section.

It is a great mistake to believe that, when the molding is done, a concrete post is finished. The quality of the post must be determined by curing. The green post should be left in the mold until thoroughly hardened; usually for two or three days. During the first two days of the life of a post it must be kept wet and covered with canvas, burlap, carpet, or any clean material. Sand will serve after the concrete has become hard, but manure will stain green concrete and otherwise affect it. The sprinkling should be continued up to the eighth day. After the tenth day, if the space is needed, the post may, with care, be placed on end in the same manner that wooden fence rails were formerly piled. A drop of only 6 in. often breaks a green post. The jar in hauling to the field over rough, frozen roads or in a wagon bed with a very uneven bottom has seriously injured posts which were not well seasoned. Concrete posts gain rapidly in strength for the period of one year; they should, therefore, be made as long as possible before it is necessary to set them in the fence. No post should be used until it is at least 3 months old, and, to meet any contingency, a supply of well-seasoned posts should be kept on hand.

There are numerous methods of attaching wire fencing to concrete posts. Some makers place staples or wire loops in the green concrete; others make holes in the posts. The former method is not desirable, because the fastener cannot be located exactly where the wire of the fencing will come when the post is set in the ground; then, too, the fastener will eventually rust or break off and will thus injure the looks of the post. On the other hand, holes through the posts weaken them and therefore this method is, in general, unsatisfactory.

The simplest, easiest and cheapest way of fastening a wire fence to a concrete post is to encircle the post with a wire one size less than the corresponding wire in the fence proper, and to twist this wire around the strand of the fence. This is done in two ways. The fastening wire is placed around the post, twisted upon itself and then to the fence wire; or one end of the fastening wire is twisted around the fence wire, and the free end is then carried around the post and twisted on the other side to the same wire. Either plan is good, but care must be taken to draw the fastening wire tight, or else stock trying to get through the fence may raise or crush down the fencing with their heads. If any trouble is experienced, the post should be roughened at the fastening point with a cold chisel.

Expansion and contraction of the fence, due to heat and cold, are cared for by the tension curves of "kinks" in the woven wire fencing, and no fear may be felt in drawing the fastening wires as tight as necessary. Wooden nailing strips should never be embedded in the posts, for moisture will swell the wood and crack the concrete.

In the early stages of concrete post making it was the opinion of some that posts need not be tapered from base to top, but it has now become the almost unanimous judgment that taper is necessary for many good and essential reasons. It has been definitely demonstrated that it almost entirely if not absolutely prevents heaving in winter. A fence post acts as a cantilever and the post is therefore largest toward the ground line, where it is the most severely stressed. It also reduces the amount of concrete required, lessening the quantity toward the top of the post, where the full section, as at the base, is not required. The tapered post lends itself most naturally to the fastening of the fencing wire by means of the loop around the post, the taper preventing displacement of the loop.

Conclusions.

(1) Concrete posts are practical, economical and a suitable substitute for wood.

(2) Reinforcement should be placed as near to surface of post as possible; ½ in. from surface is best location.

(3) Post should taper from base to top.

(4) Post should not be less than 5½ in. at base and 4 in. at top.

(5) Concrete mixture should consist of one part cement to four of run of pit gravel; or one part cement, two parts sand and four parts crushed rock or screened gravel. Gravel or crushed rock not to be smaller than ¼ in. in size, nor larger than ½ in. Concrete should be of a quaking consistency.

(6) Molds should have a jogger or vibratory motion while the concrete is being introduced to compact it and smooth up the surface of post.

(7) Posts should not be made out of doors in the freezing weather. They should not be exposed to sun, and should be sprinkled with water the first eight or ten days after being made to aid curing.

(8) Molds should be carefully oiled or soaped to provide a smooth finish and to prevent concrete sticking to mold.

(9) Posts should be cured for not less than 90 days before being set or shipped.

(10) Posts should be carefully handled and be packed in straw, sawdust or other suitable material for shipment.

Recommendations.

(1) We recommend the adoption of conclusions 1 to 10 relative to concrete fence posts.

(2) We recommend that the foregoing conclusions be substituted for those in the 1911 manual, page 210, upon the subject of concrete fence posts.

We recommend to the board of direction that the committee be directed to endeavor to have a series of tests conducted to determine the comparative strengths of the different forms of concrete fence posts and method of reinforcing, with a view to ascertaining the most suitable form, these tests to be performed, if possible, at one or more of the university or government laboratories.

TRACK CONSTRUCTION AND FLANGEWAYS AT PAVED STREET CROSSINGS AND IN PAVED STREETS.

This subject has been under consideration for several years past, and the committee has studied the practice in European countries as well as our own.

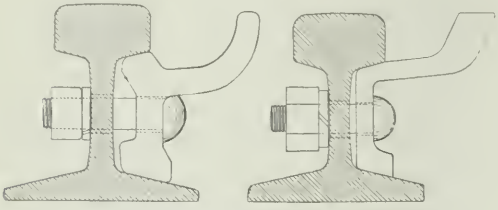
In both this and foreign countries, asphalt, bitulithic, wood block, brick, granite and trap rock paving have been tried. It has been exceedingly difficult to keep the paving along the rails in good condition where asphalt, asphalt blocks or bitulithic was used. In most cases where tried, these materials were removed from between the tracks, and for a distance of 2 ft. outside of rails, and replaced with wood or stone blocks. This has not only resulted in economy, but has also reduced the long interruptions to traffic due to the frequent repairs. The substance of our investigations would seem to indicate that granite or trap rock specification blocks make the most suitable material for this purpose.

It seems from plans sent us to have been accepted, as a matter of fact, beyond the pale of argument, by most of the steam and street railway lines, that a concrete bed of thickness varying from 4 in. to 12 in. is the proper form of construction for the track substructure. The committee, however, believes that this is not conclusive and that it is still open to question, particularly in the case of steam roads with extremely heavy cars and heavy axle loads of motive power, whether a concrete base will not have a train of evils

to follow in its course, even more serious than those to be met with in using a foundation of hard rock ballast, or other suitable material, with proper drainage provisions.

In a consideration of the various types of construction thus far tried, it is thought that the same design should be used at paved street crossings as through paved streets. The 141-lb., 9-in. girder rail appears to meet the general conditions of each case in the most satisfactory manner. It will not permit of widening gage on curves, however. Ordinary tee rails (on chairs of various designs if necessary to obtain depth for paving), have been used; a special rolled form of flangeway or an old rail laid on its side for flangeway opening is frequently employed, usually the latter, but this cannot be considered as the best form of construction.

In previous committee reports upon the subject of the best form of flangeway, the idea of a special rolled filler to provide flangeway opening has been referred to. This feature has been given some study and we find two or three roads using such an arrangment. It is our opinion that such a form of flangeway is suited to road crossing construction



Rolled Flangeway for Paved Streets.

where paving is not required, but is not well adapted to street crossings where rigid laws are in effect in regard to paving requirements, or through paved streets. The steel companies can roll these special forms, but they are very expensive because of the little tonnage that would be used. They are not mill stock, because a different section is needed for each weight of rail, and because of frequent changes in rail section.

The 9-in. girder rail can be very readily compromised to the ordinary tee rail with which the track is generally laid on each side of the crossing or at the end of the paved street. It is not the intention of the committee to state that there are not other styles of construction that will give, or do give, good results; nor is it of the opinion that a more permanent form will not be devised in the future, but it believes that for the amount of money expended that the design submitted already tried out under heavy service will be best adapted to meet the most general requirements from the standpoint of durability, high standard and economy of maintenance.

Conclusions.

(1) Specifications for best form of track construction and flangeways at paved street crossings and in paved streets:

Treated ties should be used, laid on a bed of crushed rock gravel or other suitable material, not less than 8 in. nor more than 12 in. in depth, placed in about 3-in. layers, each to be thoroughly rammed to compact it.

Vitrified tile drains not less than 6 in. in diameter, with open joints, leading to the nearest point from which efficient drainage may be obtained, or with sufficient outlets to reach sewers or drainage basins, should be laid on either side of and between tracks, parallel with the ballast line and outside of ties.

One hundred and forty one-lb., nine-in. depth girder rail, or similar section, with suitable tie plates and screw spikes should be used. Track should be filled in with crushed rock, gravel or other suitable material, allowing for a 2-in. cushion of sand under finished pavement.

The ballast should be thoroughly rammed as it is installed for paving foundation to settle it. Two-in. of good sharp sand should be placed on top of the ballast.

Paving must conform with municipal requirements, granite or trap rock blocks preferred. Hot tar and gravel should be poured into the joints as a binder.

(2) The inclusion in the Manual of the plan for flangeway.

Recommendations.

We recommend the adoption of conclusions 1 and 2, Specifications and Plan of Best Form of Track Construction and Flangeways at Paved Street Crossings and in Paved Streets.

WAYS AND MEANS FOR SECURING A PROPER QUALITY OF FENCE WIRE TO RESIST CORROSION AND SECURE DURABILITY.

The committee has been continuing its investigations into this subject during the past year and has endeavored to obtain all available information as to the most recent practice, but it is compelled to state that the developments have been very few.

It is the opinion of one of the large manufacturers that the most practical solution of the problem of securing greater durability is by what is known as the "special galvanizing" process. The fence is made from wiped wire which will withstand four one-minute immersions in the standard copper sulphate solution for both the horizontals and stays. It is claimed that such a wire should compare favorably with unwiped wire, which will pass the same test. The committee thinks, however, that this is open to question, although we understand that large tonnages of this special galvanized wire is being supplied according to specifications of foreign railway companies.

We believe that the method of weaving the wire is one of supreme importance and that the brutal treatment that the wire receives during the course of weaving at some plants might be responsible for the quick deterioration of the wire. So far no satisfactory method has been devised of galvanizing the fence fabric after it has been woven, although many attempts have been made, but the expense appears thus far to be practically prohibitive from a commercial standpoint.

It is open to doubt in our minds whether the asbestos process of wiping the wire is as productive of good results as that of the old form of charcoal wiping. The asbestos wipers cannot at all times be adjusted with care and accuracy, so that one strand may carry a fair coating, while another will be wiped so closely as to almost entirely denude the steel.

In taking the matter of fence fabrication up with an expert in wire making, he stated that there were two accepted methods of fabricating the wire fencing. The ordinary and most generally used is the custom of selecting a very soft wire as the cross wire, first winding it on a bobbin so that it can be handled properly in wrapping it about the line wire of the fence. This process is extremely hard on the galvanizing, and there is practically no wire that will stand the treatment without showing material injury to the coating. A modification of this practice is to feed the cross wire in short lengths, and where the ends of the sections pass one another at the crossing of the line wire of the fencing, they are seized by a twister and wound together about the lateral strand.

The other method is that of applying a straight single piece cross bar the full width of the fabric and attaching it to the line wires by a separate and distinct section of wire known as a tie. This process undoubtedly results in the least injury to the wire used in the fabric, although it is impossible to get away from the wrapping of the ends about the selvage wires when using the straight stiff stay.

There is another process of electric welding, but it is an open question whether this does not change the structure of the steel and destroy the coating at the point of contact.

The committee is not prepared at this time to offer any additional information on this subject, nor is it warranted in reaching any conclusions. It believes that it is incumbent upon the railroad companies, in the light of past experience and with the information that has been imparted from time to time by the Association, to pursue their own investigations, and that investigation of this subject by the Association should be discontinued for the present.

Recommendations.

(1) We recommend to the Board of Direction the discontinuance for the present of the instructions to investigate ways and means for securing a proper quality of fence wire to resist corrosion and secure durability.

(2) We recommend to the Board of Direction that they assign to the committee the investigation of the various kinds of signs for railroad purposes as applicable to both employe and the public.

C. H. Stein (C. R. R. of N. J.), chairman; G. E. Boyd (D. L. & W.), vice-chairman; R. B. Abbott (P. & R.), H. E. Billman (M. P.), E. T. Brown (B. & O.), J. T. Frame (C. G. W.), C. M. James (A. C. L.), L. C. Lawton (A. T. & S. F.), G. L. Moore (L. V.), J. B. Myers (B. & O.), F. M. Patterson (C. B. & Q.), C. H. Splitstone (Erie), W. F. Strouse (B. & O.), W. D. Williams (Cin. Nor.), committee.

Discussion on Signs, Fences and Crossings.

Richard L. Humphrey: The committee recommends that the reinforcement be about one-half inch from the surface, and also recommends, not the mixed gravel, which is excellent, but says "gravel or crushed rock." I think it will be

found where the crushed stone is rather soft or is a stone with high absorptive qualities, that there may be trouble encountered by having that material in a fence post. The gravel or crushed rock used in the post should be a hard, dense material with slight absorptive qualities, or it will cause the destruction of the post.

Mr. Stein: I move the adoption of conclusions 1 to 10 under Fence posts and that the conclusions and recommendations be substituted for those in the 1911 Manual of Recommended Practice.

Mr. Humphrey: I suggest that we put in the fifth conclusion "gravel or crushed rock of low absorption."

The President: The committee will accept that.

S. A. Jordan (B. & O.): I ask why, in conclusion 9, the posts should be cured for not less than 90 days before being sent or shipped?

Mr. Stein: It is the opinion of manufacturers of concrete posts, and I say this with the support, I believe, of every manufacturer of concrete posts, that under all circumstances they should be cured for not less than 60 days. That means a seasoning process, and while it would appear that a small mass of concrete like a post would dry out or season and cure within a comparatively short period of time, it has been found by experience that is not the fact and that it really requires at least 60 days, and the statement is made that 90 days is preferable in every case before the concrete post reaches its full strength, and even after that it continues to grow in strength, and that is the experience with respect to other forms of concrete. We thought we would be on the safe side and specified 90 days. If the users desire to cure the concrete for only 60 days, that is a matter within their own control and they can substitute 60 days for the 90 days.

Mr. Humphrey: The committee might consider the question of steam curing, which is a matter of accelerating the interval between the making and use of the post. With the use of a proper system of steam curing the time can be reduced.

E. V. Smith (B. & O.): In conclusion 7 the committee say that the posts should not be exposed to sun. Why should that not read, "should not be exposed to sun or artificial heat"? Why not have that apply to artificial heat also, in extreme weather.

Mr. Stein: Some manufacturers of concrete posts cure their posts by steam—that would be the application of artificial heat. The committee thought it would not be well to make any change in that conclusion at this time. The object of not exposing the posts to the sun is to prevent the cracking or alligatoring of the posts. There is also a provision in conclusion 7 that the posts should be sprinkled. That is to allow for the complete absorption of the moisture and the compacting of the material and the seasoning of it.

Mr. Humphrey: I think conclusion 9 should have some explanatory note. That 90 days applies to natural curing. Where steam curing is used the time should be less. As this is to go into the Manual there should be some explanatory note.

The President: What would you suggest, Mr. Humphrey?

Mr. Humphrey: I would suggest a note be added reading, "90 days when cured naturally."

The President: The committee will accept that.

(The motion to adopt the recommendations of the committee, covering conclusions 1 to 10 and also the publication of the conclusions in the Manual, was adopted.)

Mr. Stein: The second subject referred to the committee was, "Track Construction and Flangeways at Paved Street Crossings and in Paved Streets." We secured all available data and it was our conclusion that the form of track construction and flangeway at paved street crossings and in paved streets should be as given here.

E. V. Smith: Why should we specify, in the first paragraph, a maximum depth of not "more than 12 in."? I think that should be omitted.

Mr. Stein: There may be some remote cases where more than 12 in. are necessary, but where you have fairly good supporting ground and you put in more than 12 in. you may have to resurface the track more frequently on account of the gradual settlement or compacting of the balance. I realize that the investigations of the Ballast Committee have shown that the greater the depth of ballast the more evenly the load is distributed, but this is the result of the experience of those roads which have tried it, and we have felt that from 8 to 12 in. was a proper margin.

J. S. Campbell: I am surprised that even 8 in. of ballast will properly support a railroad track across a paved street, without a degree of settlement which will interfere with the traffic on the track. I ask if the committee has any information as to what extent the city will permit that form of construction. In El Paso they require a solid concrete foundation and on our own account, we have found it very desirable, at least, if not absolutely necessary, to have the track in perfect surface, so that they will not have to repair the crossing frequently, and for that reason we make a solid concrete foundation.

F. P. Patenall (B. & O.): I would suggest that the note specifying the "concrete packing" be left blank, and another note put there "as specified."

Mr. Stein: One of the members of the committee calls attention to the fact that one of the points we have been talking about is covered in the text of the report. If members had read this paper they would have learned something about it in better form than I can express it.

Mr. Patenall: Under "Recommendations" we are asked to have this included in the Manual, and I suggest that if there are other parts of the report which refer to concrete packing that the matter should be cleared up.

Mr. Stein: The committee will withdraw the note "Concrete packing" and just say "form of packing."

Mr. Ferriday: It seems to me that it is unnecessary and contrary to what we know about ballast to specify that there shall not be more than 12 in. of ballast. The Pennsylvania Railroad made tests, and I think the committee on Ballast made some report, in which they showed that an increase of the ballast to a thickness of perhaps 18 to 24 in., reduced the cost of maintenance. In explanation of why that is given as a maximum of 12 in. in the specifications before us it is said that some of the New York Central track settled where they had 12 in., but did not settle where they had 4 in. I think in the case of any fresh track put down we would have to wait some time until it settled and that might possibly take longer time with a deeper ballast than 12 in., but it does not seem to me that it is desirable to go on record and put in the Manual that 12 in. should be the maximum. I therefore make a motion to omit the words "not more than 12 in." in the second paragraph.

The President: The committee will accept that.

Mr. Jenkins: I suggest changing the plan to conform. There is a note, "8 to 12 in. for ballast." That should not be less than 8 in.

(Motion to adopt the specifications as read was carried.)

Mr. Stein: The third subject to be considered is "Continue the investigation of ways and means for securing a proper quality of fence wire to resist corrosion and secure durability." Unfortunately, the tests which were being conducted at Carnegie Institute, at Pittsburgh, were abandoned some time ago. We, therefore, recommend to the Board of Direction the discontinuance of this subject.

MASONRY.

The work assigned by the board of direction was as follows:

(1) Report on waterproofing of masonry and bridge floors, including methods, cost and results, with definite recommendations.

(2) Report on the effect on concrete structures of rusting of the reinforcing material.

(3) Report on the principles of design of plain and reinforced concrete retaining walls, abutments and trestles.

As the subject of waterproofing is a large one, in which materials and new methods are coming into use all the time, it has been found impossible to submit a satisfactory report at this time.

The sub-committee has done a great deal of work during the summer and fall on the principles of design of plain and reinforced concrete walls, abutments and trestles in the way of investigation and gathering together information as to their design. They also made some effort to get some money from the board of direction and individual subscriptions in order to make a test of a section of a large size retaining wall, but were unable to obtain the necessary money to make this test. It is hoped the board of direction will see their way clear to authorize this test this coming year. Other than this, the committee has no report to make.

During 1912 the joint committee on concrete and reinforced concrete has revised its previous report, to which has been added some new matter and the whole brought up to date. The report will be available to the various societies represented, including the American Railway Engineering Association, in the near future.

During the year meetings of the joint committee on Standard Specifications for Cement were held in an effort to harmonize the differences between the American Society for Testing Materials and the Government Engineers, and acting upon a resolution, representatives from the American So-

ciety of Civil Engineers, the United States Government, and the Society for Testing Materials were requested to confer relative to these differences. This conference had its initial meeting October 24, 1912, organized, and has been carrying on such investigation work as may lead to an agreement on Uniform Methods of Tests and Standard Specifications for Cement.

G. H. TINKER,
Chairman Committee on Masonry.

G. H. Tinker, chairman (N. Y. C. & St. L.), F. L. Thompson, vice-chairman (I. C.), Robert Armour (G. T.), G. J. Bell (A. T. & S. F.), C. W. Boynton (Univ. Port. Cem. Co.), T. L. Condron (Cons. Engr.), J. K. Conner (L. E. & W.), L. D. Crear (Erie), L. N. Edwards (G. T.), A. H. Griffith (B. & O.), G. W. Hegel (C. J.), L. J. Hotchkiss (Found. Co.), Richard L. Humphrey (Cons. Engr.), W. H. Peterson (C. R. I. & P.), Philip Petri (B. & O.), J. H. Prior (C. M. & St. P.), F. E. Schall (L. V.), G. H. Scribner, Jr. (Contr. Engr.), A. N. Talbot (Univ. of Ill.), Job Tuthill (K. C. Term.), J. J. Yates (C. R. R. of N. J.), Committee.

APPENDIX A.

Disintegration of Concrete and Corrosion of Reinforcing Metal.

In cases where disintegration of concrete and corrosion of reinforcing metal are under investigation attention should be directed to the quality of the concrete, to the concrete materials, and to the workmanship before any conclusions can be drawn as to the effect upon good concrete of the deteriorating agencies present. In deciding upon preventive measures again due, attention to materials and workmanship will usually prove to be the most effective.

The failures of concrete structures most commonly reported are those due to faulty design, including details, use of improper materials, poor workmanship and neglect of proper precautions in removing forms and applying loads and otherwise overstressing new concrete structures.

While the subject of failures due to these causes is not considered to be included under the committee's assignment, they are sometimes wrongly supposed to be due to the disintegration of concrete. Failure to properly provide for shrinkage of concrete due to hardening in air, and for expansion and contraction due to temperature changes, is a common cause of cracks which may lead to failures.

The requirements for good materials have been described in numerous texts, specifications and reports, together with the methods of determining whether or not the materials meet the requirements. However, the proper precautions are not usually observed in choosing materials, especially aggregates. Although good concrete can be made with crushed stone screenings as fine aggregate, the results of laboratory tests on this material are likely to be misleading, and tests on specimens made to reproduce as nearly as possible field conditions of mixing, placing and hardening are especially desirable when screenings are used.

To obtain good work, competent and ample supervision is necessary, and no expedient can be resorted to that lessens the requirements for workmanship. In practically all cases where failures have been investigated it has been found that the workmanship could have been improved with profit. Probably the most common cause of failures of concrete structures has been the premature removal of forms. It has been definitely established that low temperature retards the hardening of concrete, and in work done during cold weather, precautions should be taken accordingly.

Investigations concerning the effect of sea water on concrete immersed for periods up to fifty years or more; of the relative merits of standard Portland cement and Portland cement made with varying contents of SO_3, MgO, CaO, Fe_2O_3, Al_2O_3, SiO_2, etc., in resisting the disintegrating effects of sea water; of the effect of varying the proportions of cement in the mortar and concrete; of the addition of various finely ground materials to the cement after burning; of the relative durability of concrete cast in place as compared with concrete blocks allowed to harden before placing in the sea; and of the effect of various materials added to the concrete mixture to produce impermeability and consequent increased durability have been made in various European countries and in America.

Regarding the chemical composition of the cement, the following conclusions are presented: Cement containing up to 2½ per cent. of SO_3 resist the action of sea water fully as well as cement with lower SO_3 content. While all the hydraulic cements now in use are liable to decomposition in sea water, Portland cement is the one to be preferred in every respect. High iron Portland cement and puzzolan cement have failed to show superiority over standard Portland cement in resisting the disintegrating effect of sea water.

Regarding the effect of varying the proportions of cement in the mortar and concrete, in general the richer mixtures have been found to offer better resistance to the attack of sea water. Proportions recommended for mortars are those with one part cement to one part of sand up to one part cement up to two parts sand. The bad condition of mortars leaner than the above, after exposure in sea water, stands out prominently. In the use of reinforced concrete for maritime works, it is advisable to employ larger proportions of cement than are usual for similar works in fresh water.

Concerning the addition of finely ground material to the cement after burning, it has been found that the addition of ground puzzolan or furnace slag to Portland cement increases the resistance of the resulting mortar or concrete to the disintegrating effect of sea water. Allowing the concrete to harden under favorable conditions before exposure to the action of sea water greatly increases its resistance to attack by the sea water and is recommended wherever possible.

When concrete is deposited under sea water such precautions should be observed as will prevent the washing of the cement from the mixture. Forms should be so tight as to prevent the entrance of sea water after depositing the concrete in order that a smooth surface may be obtained sufficiently rich in cement to be impermeable after properly hardening, and with the forms removed.

Where the effect of sea water on concrete has been other than mechanical, it is believed that disintegration is caused by the substitution of MgO from the sea water in the place of the CaO of the cement, as well as to the decrease in the proportion of silica and the increase in SO_3.

The making of a dense, impermeable concrete by the use of a well graded aggregate, rich mixture, proper consistency, and good workmanship, and allowing the concrete to harden under favorable conditions before being exposed to the action of sea water, are generally conceded to be efficient means of satisfactorily insuring the preservation of concrete in maritime works.

Investigations concerning the effect of ground waters which contain acids or alkalies on concrete drain tile, sewers, tunnel linings, etc., and of the effect of sewage on concrete used in sewers and disposal works, have disclosed several instances of apparent disintegration. The following points have been demonstrated in regard to the resistance of concrete to these agencies. Drain tile which, due to the use of poor aggregates, improper methods of manufacture or the use of lean mixtures are porous, may be affected by the soil acids found in some localities or when required to carry strong alkali seepage common in many irrigated sections of the western United States. The aggregate should be composed of materials inert to the acids or alkalies present in the water. A chemical examination of the sand from country known to contain alkaline soils is to be recommended.

Water containing substances known to react with the elements of the cement should be kept from coming in contact with concrete until the latter has thoroughly hardened. Care should be taken to provide a smooth surface and sufficient slope to the extrados of the arch of tunnel linings and sewers when the ground water level lies below the tunnel grade to facilitate the flow of seepage water to the sides. It is believed that the back filling over the arch ring should consist of porous material, such as coarse, crushed stone, for the same reason. It is also believed that side drains should be

provided where necessary and connected with an under drain, which should be provided in all cases. The alkalies which are most active in causing disintegration of concrete when allowed to penetrate into the interior of the mass are the sulphates of sodium, magnesium and calcium.

The measures to be used in making concrete which is to be exposed to the action of these deteriorating agencies in order to prevent disintegration are the same as recommended for sea water construction. Impermeability is the prime requisite and the results of experimenta and practical tests indicate that plain concrete, carefully prepared, is just as resistant, if not more so, than concrete mixed with foreign materials or special preparations.

Disintegration of concrete in sewers and sewage disposal works, whether due to the use of poor materials, poor workmanship, or insufficiently rich mixtures, has been found to take place above the normal surface of the liquid contained. The following explanation is advanced for this action. Quantities of hydrogen sulfid are evolved from the sewage. This sulfid is produced in two ways: (a) By the bacterial decomposition of sulphur-containing-proteins and related compounds, and (b) the reduction of sulphates which are contained in unusual amounts in some water supplies. Of the two, the second seems to be the more important. The hydrogen sulfid which escapes as gas from the sewage is partially dissolved in the moisture on the under side of the roof and concrete walls. Here it is oxidized to sulphuric acid partly by atmospheric oxidation and partly by bacterial action. The sulphuric acid acts upon the calcium compounds in the concrete forming calcium sulphate and breaking down the concrete.

Cinders with much sulphur are likely to give unsatisfactory results in concrete, especially if there is much coke or porous material present. Such cinders may be improved if allowed to weather, with occasional washing, until the ferrous iron and sulphur have been oxidized and bleached out. Porous cinder concrete in roofing slabs exposed to the action of locomotive gases does not form an efficient protection for reinforcing metal, which has been found to corrode and cause the disintegration of the slab. Freshly made concrete surfaces in contact with smoke gases at temperatures below 45 deg. F. have failed to harden properly, and experiments indicate that under such conditions the cement is acted upon by some of the gases. It has therefore been recommended that when heating is done by means of open fires, higher temperatures should be maintained.

Laboratory experiments furnish most of the information which exists concerning the effect of electrical currents on concrete and reinforcing metal. The discrepancy between the conditions in these experiments and field conditions seems to be greater than is the case in other laboratory tests on structural materials, and the information obtained up to this time is difficult of application to field conditions. It has not been shown that the strength of plain concrete is affected by the passage of an electric current through it. It is generally accepted that if an electric current passes into concrete through steel which is tightly embedded in it, the steel is corroded and the expansion of the metal, due to corrosion, disrupts the concrete. Corrosion takes place at the anode. The cathode is not affected by oxidation.

Results of experience up to date have shown no reason for changing the conclusions presented in the progress report of the joint committee on concrete and reinforced concrete, 1908: "Tests and experience have proved that steel embedded in good concrete will not corrode, no matter whether located above or below fresh or sea water level. If the concrete is porous, so as to be readily permeable to water, the metal may be corroded in the presence of moisture."

Discussion on Masonry.

Mr. Thomson: The chairman of the committee, Mr. Tinkar, has been ill practically all of the year, and the work of the committee has been handicapped on this account, and the report of the committee, while it is in good shape, is not in proper condition for publication, and the committee expects to get the matter in better shape by the next meeting. The committee also desires to state that the Appendix A has been printed without the consent of the committee and requests that it be withdrawn.

(The report of the committee was received as a report of progress.)

FOUND.

A Masonic emblem was found yesterday at the Coliseum. It is now in the office of the secretary of the N. R. A A. at the Coliseum, where it can be claimed by the owner.

THE ANNUAL DINNER.

The fourteenth annual dinner of the American Railway Engineering Association was given last night in the gold room of the Congress hotel. President Charles S. Churchill was toastmaster and the speakers and their subjects were: B. A. Worthington, president of the Chicago & Alton, "Looking Into the Future"; Rev. R. W. Dickie of Montreal, Canada, "Internationalism"; George A. Post, president of the Railway Business Association, "The Effect of Music Upon Railways;" and P. G. Rennick of Peoria, Ill., "The Twentieth Century Pattern." Mr. Rennick is connected with the Columbia Bureau of Lyceum Talent.

The dinner was one of the most successful in the history of the association. The attendance was unusually large. The addresses of Messrs. Worthington and Post both dealt with the public relations of the railways. Mr. Worthington's was a serious discussion of the situation, and Mr. Post's was a mixture of the facetious with the serious, and both were listened to with great attention and enthusiastically received. Rev. Mr. Dickie talked on "Internationalism." He discussed the relations between Canada and the United States, indicating his belief that annexation would never come, but that the two countries could draw closer and closer together with advantages to both.

The addresses of Messrs. Worthington, Dickie and Post were as follows:

Mr. Worthington on "Looking into the Future."

It is needless for me to say that I fully appreciate the high honor of addressing your association at its annual banquet; but it is with some degree of hesitancy that I assume to appear before a body of professional men whose fundamental requirement in order to qualify in their calling is a most liberal technical education; gentlemen who, I might say, represent the culture and aristocracy of the railroad profession; and I might also say with sincere candor, gentlemen who, as we all know, represent the only branch of railroad service where the rules and practices are based upon exact science. Of course, I will admit that sometimes a premise may be wrong, but the conclusions of our engineers are always based upon sound formulae—or empirical deduction.

With the permission of the chairman of your entertainment committee, I have selected for the subject of my address "Looking into the Future," and with your kind indulgence, I shall take as my text an article appearing in the March issue of the World's Work, entitled "What I Am Trying to Do," by the Honorable Franklin K. Lane, late chairman of the Interstate Commerce Commission, recently appointed Secretary of the Interior, in which article Mr. Lane says: "We are seven, but we work as one."

In the concluding paragraph he states:

"The men who actually operate our railroads, who keep the intricate wheels of this mighty machine constantly in motion and always at our service, receive too little public acknowledgment for the work they perform. They are among the most skilled, capable and honest of our business and professional men. They have an enthusiasm in their work and a loyalty to their companies that is a constant satisfaction, and their delinquencies too often may be traced to policies which purely as railroad men they would not countenance. With these men we can work, and through them we may hope for the realization of a national system of railroads that will be fair as to rates, profitable as to income, and adequate as to service."

As many of you know, I am a native son of the Golden West, having been born and raised in California, and I have had the honor of a personal acquaintance with Mr. Lane for over a quarter of a century. While he was once an earnest advocate of government ownership of the railroads, in the fifth paragraph of the article above mentioned he says:

"Our primary object must be to prove the efficacy of the machinery devised by law for bringing the policy of our railroads into conformity with the policy of the law—to make private capital serve public need and yet conserve the interest of the railroad owner. The public wish the best of service at the lowest possible rates; the owners desire the highest return consonant with the fulfillment of their undertaken duties. This may be an *impasse*—a situation so impossible of resolution that we are destined to join *those nations who are experimenting with governmental ownership*

and operation. That stage of despair, or of resolution—dependent upon the viewpoint—we, however, have not yet reached. In fact, I believe we are far from it, for we have only entered upon the experiment of regulation by commission, and students of this subject from other lands have said that their countries would not have sought refuge in governmental ownership had they in time discovered the American method of dealing with the railroad problem."

Briefly reviewing the situation, taking a back sight into the past to establish a foresight into the future, let us summarize the known quantities with which we have to deal, formulate our equations and theories and project them into the future as best we may.

Commerce is defined as the taking of things from the place where they are plentiful to the place where they are needed, and it has been well said that the degree of civilization enjoyed by a nation may be measured by the character of its transportation facilities. This is true not only of modern nations, but of all nations of which we have authentic history. The most advanced nation has always excelled in commerce and wealth, and the economic measures adopted for the furtherance of these interests have evolved civilization, which in itself is merely improvement in arts and learning.

B. A. WORTHINGTON.

COMMERCE THE FORERUNNER OF CIVILIZATION.

Among the first great nations of which we have positive knowledge were the Phoenicians, who for nearly two thousand years enjoyed the commercial supremacy of the world. Out of the necessities of their expanding commerce they invented numerous devices, many of which, withstanding the severe test of time, have been preserved for us, indispensable to modern civilization. They invented, for instance, an alphabet of their own representing sounds, because the picture writing of their neighboring nations could not be adapted to the needs of commerce, and their alphabet has been handed down to us of today as the greatest of all inventions. Before the Phoenician alphabet came into general use, history is dark, save for the flickering sparks of civilization commemorated by representations of visible objects, the meaning of which so often is conjectural.

Each subsequent nation which has risen to prominence has contributed its share to civilization, but only because of the exigencies of commerce and that indispensable factor of commerce—transportation. Wherever we may look, we shall find that commerce is the hand that shapes the destiny of nations, the agency which most needs and best utilizes the factors of civilization—art and learning.

China, with her yet primitive transportation facilities and necessarily restricted commerce, is an up-to-date object lesson in this respect. The accredited inventors of printing and explosives, those wonderful agencies of progress and defense, the principles of which have been known to the Chinese for over one thousand years, yet in all that long period not one Chinaman out of a total of three hundred million living population had even the faintest conception of the value of their inventions—because the spurs of commerce were unknown to them, and their simple defenses were best accomplished by stone walls of commercial isolation. It is of peculiar interest that the Chinese worship a fabled dragon, an object of terror, while our own forefathers worshipped their sacred bull, the carrier of their burdens, an emblem of progress.

Within the past few years, however, China has been awakened by the shrieking locomotive and the rumbling wheels of commerce, the introduction of modern business facilities marking the end of long centuries of domestic slavery, appalling pauperism, and thieving hordes which for generations have thrived upon their depredations—the theory of the ancient Chinese government being exploded with the gun powder of their own making.

NEW THEORIES OF GOVERNMENT.

In America independence, having its birth in the memorable events which led up to the activities of the Boston tea party, an open rebellion against the restraints which England sought to impose upon American commerce—has advanced new theories of government. In the application

of these theories many new conditions have been encountered and many perplexities have arisen to tax the wisdom and the courage of our most learned and capable men. In the past we have surmounted all these obstacles because we have always been able to find amongst us somewhere a man of the hour with conviction and courage of conviction equal to the occasion—and we have passed through some crucial tests. The nation has been torn asunder, the North and the South have faced each other with dripping swords, but we have never before encountered a situation so insidious of growth and so seriously affecting the bone and sinew of our strength, yet so full of promise, as the railroad situation of today. We are again wintering Valley Forge, internal discontent and conflicting elements adding to the difficulties of a seemingly impossible task. Let us hope with Mr. Lane that with the men who will answer the call final results may be realized which will be fair and adequate for all.

REBATING INEVITABLE UNDER KEENLY COMPETITIVE CONDITIONS.

During the past half century the railroads have been developing the resources of this country in a perfectly natural way. That certain abuses have crept into their methods is not at all surprising, for wherever active competition exists we shall always find abuses of a more or less serious nature; and when the apparently ideal methods of small business are applied by a sensitive, active, alert organization to a business having a net capitalization of $14,000,000,000, relatively unimportant shortcomings are wonderfully magnified and assume unusual significance. Yet during this period of rebating, discrimination and kindred evils, the wealth of the United States increased from $7,000,000,000 in 1850 to $107,000,000,000 in 1904, $65,000,,000,000, or over half of this enormous wealth, having been developed during the last twenty-four years of this period, while the pernicious practices so often referred to were under full sway. From this point of view the matter of rebating, etc., dwindles to relative insignificance, for we must bear in mind that this enormous wealth is *substantial* wealth, invested in the gilt-edged securities of farm lands, city property, industrials and public utilities, all enhancing in value dependent entirely upon future development of railroads.

But I hold no brief for the rebating system or discriminatory practices. No right-thinking railroad man in the country is but thankful that these days of extortion are passed forever. Nor do I claim that railroad business methods or conditions are yet perfected, but in justice to the sensitive economic features involved, I do plead for the most careful premeditation, and that should doubt arise in regard to any features, it should be carefully hedged in with all the proper safeguards of public welfare, bearing in mind the all-important lessons of history, and that economic and natural laws are always superior to statutory enactments and must not be disregarded.

MEETING CONDITIONS OF THE FUTURE.

The railroad situation at the present time is as delicate as it is complex. In the decade 1890 to 1900 the volume of freight traffic handled by the railroads was doubled, and in the following decade it was doubled again—and still the end is not in sight. Our farms are yielding but a small proportion of the crops that are possible by intensive cultivation. The density of our population is less than 31 persons to the square mile, while the population of the United Kingdom is 373 and that of Belgium 660 to the square mile; and if we project a line into the future from the point which we have established in the past, we cannot misapprehend the further development which lies directly before us.

But whether the volume of business increases or whether it decreases are speculative conditions, alike threatening to the railroad situation. An increase in the volume of business is an absolute necessity under present conditions of reduced net earnings per unit of service, but to provide facilities to handle an increased volume of business is a financial impossibility unless new capital can be induced to enter the field of railroad investment.

In referring to this phase of the question, Howard Elliott, president of the Northern Pacific railway, a man who has fought his own way from the humblest ranks to this position of eminence, stated in a recent address that there should be $1,700,000,000 new capital put into the transportation business of the United States each year for the next five years—a total of $8,500,000,000, or 60 per cent of the present calculated value of all our railroad property. This practically amounts to reconstruction throughout in order to handle the business now offered and make suitable provision for what we *know* is ahead of us. This means the replacement of obsolete equipment, the elimination of grades, double-tracking, safety appliances, also innumerable non-productive improvements, such as the elimination of grade crossings, modern station facilities, etc., demanded by the public—in short, better and safer transportation throughout.

The expenditure of $1,700,000,000 new capital each year for the next five years would not mean that the wealth of this country would be decreased to this extent. Far from that! It would mean that this amount of money would be spent for labor and materials right here at home, and every cent of it would revert to the people in the most satisfactory forms acceptable to them. What a glorious vision of prosperity this presents!

GOVERNMENT REGULATION NOT OBJECTIONABLE.

The original founders of our railroad systems, visionary though they may have been and doubtless were, could never have thought possible the wonderful development and the amazing prosperity of the past twenty years. History presents no precedent, simply because the possibilities of transportation have never before been so thoroughly exploited. Neither could this development have been possible, save for the acute business instincts of private ownership of railroads and the widest freedom of individual initiative, neither of which could survive government ownership or government operation.

Government control is not at all objectionable to the railroads; in fact, it is a necessity; and its restraining influences are entirely wholesome. In many respects the government has already produced results which the railroads could never hope to accomplish—such, for instance, as the elimination of rebating and other discriminatory practices inherent to active competition, all of which practically have been abolished from the sphere of railroad operation.

But in paring down the claws of this alleged monster, the railroads—a regular Chinese dragon to those less familiar with their economic and strategic uses, still the same sacred carrier of burdens and the emblems of progress that our ancestors worshipped forty centuries ago—they have cut into the quick, and until the wound heals by natural processes, progress will be crippled. In taking away from the railroads the prerogative of rate making and by prescribing numerous restrictive conditions of operation which tend to reduce revenue and increase expenses, they have taken away from the railroads their natural weapons of offense and defense, and have left the railroads apparently at the mercy of an unsympathetic public, which, laboring under grave misapprehension, sees nothing but misdeeds, naturally, artificially and oftentimes maliciously, magnified.

RAILROAD FACILITIES INADEQUATE TO MEET REQUIREMENTS.

Owing to this unfortunate state of affairs, the railroads of the United States have now reached a stage where they are unable to provide adequate terminal facilities where they are most urgently required, and where congestions recur annually, lasting for months at a time, regardless of the extreme shortage of equipment. The steadily decreasing margin of safety in railroad operation, amounting to substantially 28 per cent in the past ten years, has made it compulsory upon the part of the railroads to cut maintenance charges, and accordingly the physical property—roadway and rolling stock—has in many instances been sacrificed to produce even these results, and visions of the future have become obscured by the run-down conditions of today.

RAILROAD VS. INDUSTRIAL RETURN ON INVESTMENT.

Turning from this unpleasant aspect, in the shadow of gloom which has fallen upon the railroad situation the investing public looks askance at the red figures in income account, like fire destroying property values, and turns reluctantly to industrials, where obscurity seems to promise security, where the net return upon capital invested is more than twice as great as in railroads, where the public is not a factor to consult, and where the government is in no wise sponsor for results.

That the railroads should expect to share in the general prosperity of their own making is not surprising—excepting that the railroads yield by 5.7 upon investments, while manufactures yield over 12 per cent, and the value of farm land and city property is appreciating in value so rapidly that comprehensive data is not available. In view of the risks assumed in railroad undertakings, the developments which they have always encouraged, and the excellent service which they are rendering to the public even under the present restrictive conditions, it would appear that more encouraging results should be possible along this line of investment, as a more substantial guaranty of public safety, financially and commercially. The suggestion that railroad investments should earn as much as investments in manufactures, for instance, is not out of order, because the right to earn a reasonable profit upon legitimate investment is

all that is asked for, and the improvement of railroad property and the enlargement of its facilities is a matter of urgent public necessity. This menace of financial impossibilities thrust upon the railroads should be speedily removed as a restraint to commerce, which, in fact, it is, and in no small measure.

DIVIDENDS ON RAILROAD STOCKS.

In the matter of dividends on railroad stocks, the impression seems to prevail that a dividend of, say, 7 or 8 per cent stock would be equivalent to throwing that much wealth into the sea, when, in fact, it would merely revert to the people—to the widows, orphans, business men, financial and endowed public institutions, where it would be reinvested immediately in one highly desirable form or another. Certainly this would be no crime. It would be an economic condition much to be preferred to the closed shop, with roundhouses standing full of crippled locomotives, yards filled with bad-order cars, roadway neglected because of financial stringency, and wasteful congestions prevailing—all resulting in unsatisfactory service to patrons, unsatisfactory results for the railroad managers, and a passing of dividends for the shareholders. The question is who *does* get any benefit from this condition of affairs?

RAILROAD SECURITIES HELD ABROAD.

Another phase of this question, one which should cause the deepest reflection, is the fact that from 20 to 25 per cent of our railroad securities are held abroad. With private ownership of railroads as it exists today, it is useless for the government to attempt to evade the responsibility for the depreciating values of these securities, which are being returned to us under protest. Our "commerce laws" originally were enacted for the protection of bona fide investors in railroad securities and to prevent practices that could not be measured by a strict code of business justice, and if we would avert national dishonor, more undesirable than anything else that could happen, we should be ever conscious of this delicate situation and leave nothing whatever undone to satisfy in the fullest measure our pledges of faith held abroad.

The armies and navies of the world have always existed primarily for the protection of commerce. Relentless wars have been waged, and shall yet be waged, because of conditions that affect national wealth and national welfare, and nothing affects national wealth and national welfare as do conditions of commerce.

No individual has ever knowingly sought to destroy a source of his income, but he will fight, and fight to the death, to preserve it. Nations are merely groups of individuals, none the less sensitive and responsive to these same conditions, and as long as foreign capital invested in American railroads yields just and satisfactory returns to the strong financial institutions of Europe, their dogs of war will ever remain chained up at home, American railroad securities will be our national security—not the misnomer they seem to be today—and the International Peace Conferences at The Hague will be merely a waste of effort so far as America is concerned.

This condition of affairs is peculiar to America alone. It is one of our most valuable assets, the most formidable defense that any nation has ever erected. Let us not tear it down with our own hands.

Moreover, we are now approaching the time when it will be possible to materially strengthen this position, when securities must be floated for the $8,500,000,000 which should, and must, be put in our transportation system within the next five years, and we cannot afford to ignore the opportunity that is now knocking at our door.

JUDGE KNAPP AND COMMISSIONERS LANE AND PROUTY AGREE.

In this tangled web of conflicting conditions now lying before us, I believe that the ends have finally been gotten together. I believe the crisis is passed—even perhaps as our eminent authority, Mr. Lane, expresses the thought respecting government ownership: "That stage of despair, or resolution, we have not yet reached."

In his fine, deliberate, cautious manner, possibly the question of government ownership and operation of our railroads may have slipped by unobserved and into oblivion with the changing of his own attitude upon this point. Let us hope that it has.

In the beginning of his article to which I have referred, Mr. Lane states in regard to the personnel of the Commission:

"It would be hard to find seven men who differ more in temperament, in training, or in type of mind, than the present commissioners. We differ as one leaf from another in our political sympathies. Often we do not arrive at our conclusions from the same strategic angle."

Yet it is worthy of note that Mr. Lane's predecessor, the Honorable Charles A. Prouty, ex-chairman of the Interstate Commerce Commission, a man who, like Mr. Lane, has made a life-long study of the perplexing railroad problems, has stated:

"If the time does come when railroad property is sacrified to public clamor, when the public demands its confiscation and the regulating tribunal concedes that demand, no property will be of much value. The day will have come when the obligation of private rights is no longer observed."

The Honorable Martin A. Knapp, likewise an ex-chairman of the Interstate Commerce Commission, a tireless student of the railroad situation, and one of the most profound thinkers in this country, expresses his thoughts as follows:

"I should regret to see the government take up the business of owning and operating our railroad lines."

It would, therefore, seem that these three able analysts, individually and by different methods, have arrived at about the same conclusion—that the square of commercial condition cannot be made to fit satisfactorily into a theoretically perfect circle of public ownership.

When this question is finally and definitely disposed of, we may proceed more understandingly and along more scientific lines to pursue the cause of higher civilization.

RAILROAD MEN MAY BE RELIED UPON TO AID COMMISSION.

The clarifying of the railroad situation may yet take years to accomplish, for it must necessarily be a slow and careful procedure; and in the efforts of the commission to untangle this web of misunderstanding and misdirected efforts no right-thinking railroad man, no public-spirited man, whatever may be his calling, should withhold his fullest support and his warmest encouragement. The railroads, having nothing to fear, I am sure will, as a unit, welcome and enthusiastically embrace the opportunity to work in full harmony with the commission and for the common cause of the people, including not only patrons of railroads and railroad employes, but also the holders of railroad securities and the public generally—a happy solution which in itself will contain all that is desirable in government ownership or operation, and yet will maintain the constitutional rights of private property and preserve the spirit of industrial freedom and the incentive for individual initiative which in the past twenty-four years have wrought a stupendous wealth, regardless of all our shortcomings.

LOOKING INTO THE FUTURE.

That we are nearing a satisfactory solution of this entire railroad problem, I am convinced. The fact is clearly demonstrated by the three opinions herein cited, those of the three ex-chairmen of the Interstate Commerce Commission, each arrived at entirely independently of the others and very probably from entirely different strategic angles.

Furthermore, in stating his views before the Traffic Club of Pittsburgh less than a year ago, the Honorable Charles A. Prouty used the following language:

"No form of investment today is, and no form of investment in the future will be, more certain than railroad stocks and bonds. . . . The worst that could happen to the stockholder of any of our great railway systems would be a temporary suspension of dividends, and even this could occur only under very unusual circumstances."

In view of the unanimity of opinion and the unqualified assurances emanating from an undisputed authority, the Interstate Commerce Commission, I feel confident that the reins of the situation are in careful hands and that we will yet be able to demonstrate the truth of the assertion that "the degree of civilization enjoyed by a nation IS measured by the character of its transportation facilities."

Therefore, with a full knowledge of what we are trying to do, conscious of the tremendous task before us, and the wonderful possibilities that are contingent upon the *correct* solution of the present-day railroad problem, now is not the time to lament what has happened, or what may have happened in the past, but with unwavering faith in the wisdom and integrity of our able Interstate Commerce Commissioners, generals of the greatest army that ever entered a field of conquest, let us set about to build our bridges into the future—bridges big enough to span any depression which we might encounter in the commercial conditions before us, bridges strong enough to withstand the test of prosperity which we have already sighted over the established points of the past.

"Internationalism," by Rev. Robert W. Dickie.

I suppose I shall have to note this as the great day of my life so far—my first visit to Chicago. I don't see how I have managed to live [illegible] on this continent without seeing Chicago and [illegible] life. I assure you, gentlemen, now

it has come to pass, I like it very much. I suppose I have to thank your ex-president, Mr. McNab, for this pleasant experience. For the past few years Mr. McNab has been bringing you over a series of distinguished Canadians. I think you have had the Hon. G. W. Ross, ex-premier of Ontario; the Hon. Geo. P. Graham, ex-minister of railways, and the Hon. F. D. Monk, ex-minister of public works. They are a fair sample of our distinguished men. Now that you may know that we are not all distinguished over the line, he has brought me along. I may also add I am acting in the capacity of chaplain to your worthy ex-president.

I have been announced to speak on the question of "Internationalism," a question which I know you are all interested in in a practical way, for it is your work to build and maintain these great steel highways that bind people together. The highways of a nation make possible a common interest and a community of life in the nation. They conquer sectionalism and provincialism as nothing else can, and in the great world movement of bringing the nations of the world closer together, of integrating them into a greater solidarity of life, the railways must play an important part. Without them the thing is impossible.

REV. R. W. DICKIE.

GEORGE A. POST.

In both Canada and the United States we have abundant evidence of the work that railways can do in bringing people together with a real community of life. In the United States at the beginning of your history you were a string of states along the Atlantic coast. The great highway between them was the sea. That natural highway made possible that intermingling of life and interest which is the ground of national life. The history of the development of the American nation has been the history of her railways. From a fringe of small communities along the seaboard, you have grown to almost a hundred million, stretching from the Atlantic to the Pacific, and from Mexico on the south to the Land of Promise in the north. Of course, your railways opened up the country to settlers. But I rather suspect they would have come anyway though not in such great numbers. Even if you had not had railways, the people of Europe would have been drawn by your rich lands and free institutions as by a great world magnet. Instead of the railroad train, the prairie schooner would have carried the people westward. But how would you have preserved the Union? The interests of communities, such as California and New England, Texas and Dakota, without communication, would inevitably have grown apart. I am afraid the "just consent of the governed" would not have been maintained. But the railways bound these diverse states together in a community of life and interest. They are the arteries through which the life of a nation pulsates back and forth. Such free inter-communication of different communities standardizes life and inter-relates interests. If your union is one and indissoluble, it is because your railways have made a real solidarity of life possible. Even the work of Lincoln could not have insured its perpetuity had it not been for the great builders of highways who have laid 200,000 miles of railway since his day.

What the railways have done for the nation on the south of the line they have done for the nation on the north. We date our national history in Canada from the year 1867, which we call the year of confederation. Before that date there had been in Canada a number of Canadian provinces or colonies, as they were then called, each independent of the other, under the British Crown. They got together and after a while they got the British North America Act, the charter of our nation, establishing a Federal government for the Dominion. But we could not make a nation out of these isolated communities by act of Parliament and royal charter. The great desideratum was to get the life and interests of these communities mixed up. So one of the first acts of the government of the Dominion was to build the Intercolonial Railroad, connecting Ontario and Quebec with the Maritime Provinces. The road has never paid its way in cash earnings, but it has done better—it has mixed the life of Ontario and Quebec with the life of the Maritime Provinces. And then we got wise to the fact that these provinces were but a fraction of our great country. We commenced to realize that we had an immensely extensive and immensely rich country on our western plains, to which

people were already going, and also the Province of British Columbia on the Pacific Coast. Then the Canadian Pacific Railway was projected—one of the greatest railway enterprises ever undertaken, if you remember the difficulties of the task and the fact that then Canada only had 5,000,000 people. Unlike the intercolonial, it has paid fairly good dividends on its investment, but it, too, has made a united Canada possible. It bound together this string of communities stretching across a continent and made them one people. Two other transcontinental railways will soon be helping in the great work of mixing Canadian life and standardizing it throughout the length and breadth of the land. In Canada we honor the Fathers of Confederation who drew up the plan and constitution of the nation, but we honor not one whit less our railway engineers, these builders of highways which have become the arteries of our national life.

Now, sir, we are two nations on this continent—two independent nations. We in Canada are bound to Britain by many ties—ties of blood, of affection, of interest which we all want to see maintained. This solidarity of interest and affection we designate by that high-sounding word, "imperialism"—a sort of a charmed word with us these days. But Canada has long since got past the stage of a colony or a vassal state. We have absolute control of our own domestic affairs. Another charmed word with us is "national autonomy," and we have the reality. Britain has not meddled in our domestic affairs since confederation. We have power to make commercial treaties with other nations—we were going to make one with you two years ago—and it was not Britain that upset our apple cart, but it was from another source that the trick of jolting the cart was done, that furthered the upset. A few years ago we made a commercial treaty with France. Well, with our internal affairs in our own hands and our foreign relations, there we have the substance of our independence, if not the name. But what of the power of the crown? We own the same thing as Britain does, just as Scotland did before the union. But our King has not a tithe of the power of your President. He is a constitutional monarch, who acts only on the advice of ministers directly responsible to the people. To all intents and purposes the nation to the north is as independent as the republic to the south.

Like you, too, we in Canada are very proud of our country and its institutions. We have unbounded confidence in the future of our country. We are but a small people yet—only about eight millions—but we believe that our great national wealth will bring the peoples. That wheat field of ours in itself—900 miles by 300 miles in area—will bring people, to say nothing of the wealth of forest and mine, and we have a larger potential water power than any other country—about twice that of the United States—and the people are coming to us just as fast as we want them—as fast as we can assimilate them into our national life. As it is, in proportion to our population, they are coming faster than they ever came to your shores. Last year we received over 350,000, 75 per cent English-speaking and 25 per cent foreign-speaking. You sent us about the same number as Great Britain. Send us more. These men from the Middle West states are the equal of the best that we get in our west. There are some timid souls among us who fear what they call the American invasion of our west. I am not at all afraid of it; I will trust the average American citizen to be loyal to the institutions of the land where he is making money, and I am glad to say most of them are making money out on our plains.

And we are proud of our institutions.

Your republic has been spoken of as the great experiment in democracy. You are past the experimental stage long since and have abundantly justified the experiment. But we, too, are making an experiment in democracy, and we hope to profit by your great experiment. We are laying the foundations of our national life under the most favorable circumstances. We are comparatively unhampered by old-world traditions and we learn both from America and Europe. In a word, our experiment in the Canadian democracy is to secure the freedom of a republic and the stability of a monarchy, and up to date I think we are succeeding.

Gentlemen, we are two peoples on this continent. Our histories, our traditions, our institutions are not the same. The destinies of the two are not yet manifest. But one thing is certain, annexation is out of the question. The thing is as dead as a door nail. So far as I know, there are only two annexationists on this continent. One in the United States and one in the Province of Quebec. But, honestly, I think he of the United States was only joking, and I believe the Province of Quebec man has recently gone back on the idea. Goldwin Smith, Erastus Wiman and Elgin Myers and Edward Farrar have no successors and we might as well give the thing a decent burial.

Two nations, but two nations at peace as brethren laboring for the advancement of civilization on this continent and in the world, is our ideal. The signs are favorable. Next to the loyalty of our two countries to their respective traditions and institutions, I admire their international relations. Three thousand miles without a gun or fort or soldier—that is splendid. Next year we are taking steps to celebrate one hundred years of peace. That, too, is splendid. Let us make it a thousand. I contrast this with the unfortunate conditions obtaining among the European nations. How different the boundary between France and Germany and that between us. Guns, fortresses, marching men everywhere there; here on either side of our unguarded boundaries citizens plying the useful arts of peace, each so busy with his own tasks that he has no time or inclination to prepare for the brutal trial by combat.

Our happy international relations on this continent are due, I think, chiefly to two things. First, we have no old scores to wipe out. We have a hundred years of peace behind us. That is our international tradition. And then both belong to the industrial type of civilization. Herbert Spencer used to say that we move naturally in the course of social evolution from a military to an industrial type of society. We in these two countries have, I think, gone further than the European countries. At any rate, the military temper is not so strong among us. I know that you have the school of General Homer Lea in the states that are always expecting some terrible power to drop down upon your country with destruction, and hysterically calling for more military and naval preparation. We have some of the same kind in Canada—military jingoes, we call them over there. But the men do not represent the genius of either Canada or the United States. Our genius here is to attend to business and play fair and believe that industry and fair play don't need big guns and dreadnoughts to back them up.

If we are to extend this hundred years of peace to a thousand, the railways and the railway builders must play an important part. I have said the railways are the arteries of the great social fabrics. They have bound the states together, and they have bound the Canadian provinces together. Let them continue the great work of social integration and bind together these two nations with bands of steel. Let them run north and south, as well as east and west. These highways of the people have mixed up life from east to west; let them mix it up from north to south. There is no reason why the life of Ontario should not mix as freely with the life of Michigan as with the life of Quebec, or why the life of Manitoba should not mix as freely with the life of Dakota as with Saskatchewan. We are of one stock; we breathe the same American air; our traditions are largely the same. There is no reason why we should stand apart. The mixing of life and interest among our people makes for peace. These 130,000 men you sent over to our plains last year are a pledge of good feeling, and so are the 75,000 Canadians living in Chicago. Every business connection between the two binds us closer together.

It is a great blessing to have a boundary line without a gun. The only thing we have on these boundaries is tariff walls. They are great hindrances to the mixing of life and interest. But, happily, we seem to have seen the worst of them. I do not hear any voices crying to build them higher, and I hear from both sides of the border a cry rising in volume and strength each year to have them lowered. Of course, an economic life which has been nourished behind tariff walls cannot at once throw them down without serious complications. But the encouraging thing is that both peoples are looking that way. Then again your interest is our interest, and our interest is your interest. Even tariff walls can not keep the prosperity of one country from being felt by the other or hold back the hard times of one country from stalking forth into the other. You want things that we have, and we want things that you have. Why should not the exchange of them be without let or hindrance?

You are road builders, and roads are for the freest and easiest possible communication. If you are to build roads north and south and integrate these nations as you have these states with a real solidarity of life, more important for your purposes than tunneling the St. Clair river or spanning the Niagara, is the lowering, and eventually the destruction, of these tariff walls which are separating into two parts an economic life which naturally is one and indivisible. I have no desire to go beyond the hundred mark, yet I hope to see the day when not only shall there be no warships on our lakes, but no tariff walls on our boundaries, when the life of these two peoples shall move freely back and forth over the great highways which you and your successors shall construct.

Gentlemen, we are two separate nations, but we are sprung of the same stock. Your interests are our interests, and our interests are your interests. Carry on your noble work of

making railways and highways, breaking down the spirit of provincialism and sectionalism, integrating these two nations into a greater solidarity of life and interest, until we become among the nations of the earth an example of international common sense and good will.

Mr. Post on "The Effect of Music Upon the Railways."

Does anyone doubt that there has been "music in the air" surrounding our railroads for the past several years? If our railway officials have not for a long time been pupils in the music which portrays public emotion, it would be difficult to understand what they have been doing. But there is not any doubt about it, and they have been apt pupils, too. They know the difference between a solo and a chorus. They have heard them. And the way they have been waltzed around by legislative "Willies" until they were out of breath and dizzy, has been a caution.

Our railways have become practiced listeners to the orchestration of popular desire. Before the regulatory conservatory of music was opened it might be truly said that apparently railway men did not know one note from another. But they do now. Their ears have become skilled to discern whether the theme is dignified or important or trivial. They have become honest and earnest listeners. They can now quickly perceive the skill of the performer in building up an orchestra ao convey to the public the idea of a wrathful composer. They appreciate how effectively the feelings of the public may be played upon when the composer of the theme has recognized the force of the law of "distribution of repetition." The master musician knows that the subject matter of a movement must be repeated again and again in order that it may be firmly fixed in the mind. That is why so many composers of anti-railway movements constantly play up the "wrongs" they want made right, paying no attention to the magnificent line of "rights" that are observed by the railways and which the public really enjoy. In a movement dedicated to woe there is no room for the rapturous note of joy.

The music of railway regulation may be said to be both classic and romantic. The classic has come from the soul of the public in deep tones, registering the fiat of the people that wrongs in morals and equities must be righted The romantic has not been so lofty in impulse, but querulous as to details. The romantic is aimed at the intensity of passion rather than the depths of emotion.

There has been in the composition of regulatory music a strong tracing of the fine Italian hand, if we can depend upon musical writers who tell us that "Italian composers were given to resorting to the easy processes of tickling the ear without regard to the fitting of the melody to the text." There certainly has been a great deal of "ear tickling" done in the scheme of regulation.

It must be admitted in fairness that a very large proportion of the regulatory music to which our railways have listened has adhered closely to the fundamental requisites of proper musical form, as it has contained propositions of themes suitable for development. Chief among these has been the idea of the establishment of railway commissions. As a matter of fact, the railways have become so accustomed to this movement by its frequent repetition that they have entirely overcome their original aversion for it and have come to enjoy many of its harmonic advantages. It is true that they still cannot be said to be enraptured of the drum beats and loud trumpets, which suggest war, and to which they are forced to march, not as volunteers, but as conscripts. But they are marching right along and they keep step with remarkable precision, considering that they were so recently members of the awkward squad. Besides, the histories of the world's wars tell us that many a conscript became a valuable soldier and won encomiums as a patriot.

We all of us know when at the theater a tune is played and words are sung by a masterful singer, we unconsciously begin to hum the tune and then to softly whistle it, and finally when we have packed the words into our memory, we burst forth and sing it ourselves. Well, that is just what has happened to our railway managers. They are now humming the tune of railway regulation. There are some of the notes that bother them because they are so fearfully high in register as to strain their throats; some that are so syncopated that they cause them to stumble, while some of the bass notes are so low that in their efforts to reach them they make a noise like a grouch. There are staccato measures so abrupt, detached and disconnected as to cause them bewilderment in keeping to the tune. Regulatory composition ought to be made more simple for universal rendition, and it is hoped that the theme will be simplified by wise composers who will see that the interpolated bars and movements that really impair the harmony and are not truly germaine to the general theme, are useless and confusing and ought to be cut out.

One of the most important requisites of music, a form has been utterly neglected by the composers of regulatory music, and that is the interpolation of needed points of repose. There is too much of the clarion blast of the reveille, the waves of tumultuous fervor lash too high and continuously and the delirium of power is too rampant. There is too little of the sweetened accents of peace as delineated by the flute, not enough of the nerve quieting legato during which the railroads can take their bearings, find out where they are, and what they can do about it, and whether they understand the motif of the composer.

People cannot stand it to be worked up to the pitch of frenzy all the time. The loud pedal was not intended for constant use. There is nothing so exhaustive and wearisome as the continuous exhibition of sheer power.

I was deeply impressed a few nights since by an incident that occurred in a theater in New York. The bill of the play had provided a series of performances varied in scope. Thrilling feats by acrobats caused the audience to be breathless in amazement at the terrible risks of life and limb taken by the performers and elicited salvos of applause as in safety they concluded their perilous undertakings. Prima donnas electrified their hearers by touching high notes that seemed beyond the reach of human throat. Giants with a muscular development super-human gave startling exhibition of what strength can endure and accomplish. Magicians mystified by their legerdemain and won our resounding plaudits. Comedians convulsed us with their drollery. But it was not until a couple who were billed as man and wife, who must live together day after day, gave a skit in which connubial felicity was the keynote, that the audience rose to its highest point of enthusiasm. The voices of the couple were not remarkable, but they sang of love. Their actions were those of intense mutual admiration and their asseverations were that they could not live without each other. They embraced with an ardor that was infectious, and, as they billed and cooed and hugged and kissed with sympathetic unction and sincerity, with the air of those who were thoroughly enjoying themselves and meant every word they were singing, the audience seemingly forgot that they were simply doing a theatrical turn and simply went wild over them. Compared with their appeal to the heart side of the people there assembled all the tricks, skill, daring, fun and art of those who had preceded them was as nothing. All the world loves a lover. The world is at its best when manifesting appreciation, consideration and tenderness. The sweetest, most inspiring, most ennobling music of all the ages is the harmony of the heart.

Within the proper limitations of an after-dinner speech I cannot do more than warble a few notes of all the emotions that well up from my heart to my lips as I am stirred by the contemplation of the effects of harmony when it shall resound throughout the corridors of human endeavor.

I have touched lightly, and I fear not impressively, upon the effect that the music of regulation has had upon our railways. With all its false notes, strident bars, crashing of brass and impulses of unrestrained fervor, the railways are better for it, and they have learned to make responses thereto —hesitatingly at first—but increasing in strength and in appreciation of its underlying motive.

The point I wish to make by my incursion into the field of musical metaphor is that, having realized how they have been impressed by the concert of the public voice making clear to them the emotions of those who have composed the statutory measures, conceived the movements that have carried conviction of the necessity for governmental supervision of railway operation, the railway managers have shown a disposition to bestir themselves to compose the "music of the rails." Many of our railway executives are appearing in public and upon social occasions to tell the story of the railroads. This is what must be done, and done continuously and effectively. Those who have sung of what they want have had too much of a monopoly of the stage center. It is up to the railroad men to sing to them of what they have. The railway managers have been too long the audience and it behooves them to become performers themselves. Those who do not exercise their vocal chords by framing language are seldom understood. True, there is a lot of talk that nobody can understand, and that perhaps does not mean much, if anything, but the fact remains that it is the fellow who talks who gets an audience. Some who hear him think they understand and act accordingly. There must be borne home to the consciousness of the public the story of the wonderful things that railroads are doing for them. Place in juxtaposition the blessings that railroads confer upon our land and what the public wants them to do in addition, and the blessings are as a mountain of joy overshadowing a molehill of discontent.

Once get the people of the United States to cease brooding

over their few real ills and many imaginary ones and hold up to them (they cannot be exaggerated) their manifold advantages vouchsafed by their marvelously equipped and managed transportation facilities; show them by your daily walk, conversation and achievements that their real ills are the subject of your serious thought for their proper remedy, and their frowns will be changed to smiles; their imprecations will be changed to words of praise.

So I say to you, my friends of the railways, SING! Sing to the public of mountains tunneled to reduce grades and distances. Sing to them of the waters spanned by steel and of embankments upheld by granite eternal. Sing of the luxury of modern travel and of the sleepless vigils kept for the safety of those who must absent themselves from their home firesides. Sing of the annihilation of distance by the celerity of train movement. Sing of the spacious and majestic terminals in our great cities, with every heed for their creature comfort and convenience. Sing of the doubling and quadrupling of tracks for the handling of our nation's traffic.

EDWIN F. WENDT, President-Elect.

Sing of the higher wages and lower rates of American railroads when compared with other countries. Sing to the populace of your comprehension of their needs, and when from the choir of the people you hear the prayer, "Oh, Promise Me!" in answering song tell them that the vow is made and will be kept.

Thus shall we as a people move steadily up the mountainside which leads to the great Plain of Amity, where athwart the vaulted heaven above shall be displayed in letters of living light the memorable words of Grant, "Let us have peace."

Then as the multitude of those who must be served by the railways approach the hosts of those who serve them, who are moving with radiant faces to meet them, the air will be vibrant with a song from the people:

"Our railroads are our joy and pride;
No more their conduct we deride
We're boastful of their usefulness
And they our rights do not transgress."

And with a zest, bespeaking a glee that maketh the heart glad, shall come the response from those who carry:

"See, our patrons, an army great,
Our service they appreciate!
Our dealings square, from wrath we're clear,
And they are now our friends sincere."

Having come within close touch, when hands may be clasped in cordial grip, in splendid unison, making the welkin ring with the melody of friendship, all will join in singing:

"Together we, in harmony,
Will weave our country's destiny,
In field and mart, in mine and mill,
And, on the rails, there'll be good will."

NEW OFFICERS OF THE A. R. E. A.

The result of the election of officers of the American Railway Engineering Association for the ensuing year was announced by President Churchill just before the close of the afternoon session yesterday. The new officers are:

President—E. F. Wendt, assistant engineer, Pittsburgh & Lake Erie, Pittsburgh, Pa.

First Vice-President—W. B. Storey, Jr., vice-president, Santa Fe System, Chicago, Ill.

Second Vice-President—Robt. Trimble, chief engineer maintenance of way, Northwest System, Pennsylvania Lines, Pittsburgh, Pa.

Treasurer—Geo. H. Bremner, engineer Illinois District, Chicago, Burlington & Quincy, Chicago, Ill.

Secretary—E. H. Fritch.

Directors for Three Years—

A. K. Shurtleff, office engineer, Chicago, Rock Island & Pacific, Chicago, Ill.

C. A. Morse, chief engineer, Santa Fe System, Topeka, Kans.

John G. Sullivan, chief engineer, Western Lines, Canadian Pacific, Winnipeg, Man.

Members of the Nominating Committee—

H. R. Safford, chief engineer, Grand Trunk System, Montreal, Que.

A. O. Cunningham, chief engineer, Wabash, St. Louis, Mo.

R. L. Huntley, chief engineer, Union Pacific, Omaha, Neb.

R. N. Begien, assistant general superintendent, Baltimore & Ohio, Baltimore, Md.

A. F. Robinson, bridge engineer, Santa Fe System, Chicago, Ill.

REGISTRATION—AMERICAN RAILWAY ENGINEERING ASSOCIATION.

MEMBERS.

Alfred, F. H., Gen. Man., P. M. R. R., Detroit, Mich.
Bailey, A. R., Instructor Surveying, Univ. of Mich., Ann Arbor, Mich.
Barnard, R. C., Supt., Pennsylvania Lines, Cincinnati, O.
Batchellor, F. D., Asst. to Gen. Supt., B. & O. S. W. R. R., Cincinnati.
Bates, Onward, Con. Eng., Chicago.
Beahan, Willard, Assistant Engineer, L. S. & M. S. Ry., Cleveland
Beye, John C., Loc. Eng., C., R. I. & P. Ry., Chicago, Ill.

SUPERVISORS AT THE CONVENTION.

The Bessemer & Lake Erie is well represented at the convention and the exhibition. All five of this company's track supervisors and both of its supervisors of structures are spending two days each in the sessions of the convention and at the Coliseum.

The three supervisors of the St. Louis division of the Vandalia are visiting the convention and the exhibition to-day.

APPLICATION OF B. & O. DYNAMOMETER TESTS TO TONNAGE RATING.*

By R. N. Begien,
Assistant General Superintendent, Baltimore & Ohio.

Many miles have been run with dynamometer cars, but few real results have been obtained which give reliable data concerning train resistance. The number of formulæ in use only serves to inspire a serious doubt as to the accuracy of any of them. It is true that some dynamometer charts have not been properly studied, but there are many unknown factors which make the interpretation of the charts difficult. Facilities for making these tests properly are rarely had. It is an expensive matter to make the tests and an equally expensive one to analyze the charts. The results obtained seldom agree with the preconceived notions of those who use them, causing modifications and amplifications of a more or less "practical" nature. The verdict is, generally, that the only way to make a rating is to try different loadings until the correct one is found, and then use it.

This method would be all right if the loading adopted as the result of such trials was a proper one for all conditions of cars and condition of track and weather. There is also a difference of opinion as to what constitutes a correct rating. It is a mistake to suppose that proper ratings depend entirely on the power of the locomotive and the grade; yet the ideal condition is realized when such facilities for handling trains are supplied that those two factors control the rating. The tests described below have demonstrated that with the wide variation of working conditions on a railroad, there is no such thing as an absolute value to train resistance. It is, however, possible to establish a practical base which is on the safe side and will give good working results. Since the object of tonnage rating is to establish a standard by which performance may be measured, it is better to predetermine that standard than to allow each one to make its own. The inevitable result of the establishment of standards is good, since uniformity of performance approximating a proper standard always yields a higher average than a mixture of high and low grade performance. In other words, good results may be obtained by doing well all the time.

DYNAMOMETER TESTS.

During the months of October, November and December, 1910, and January, 1911, dynamometer tests were made on the Baltimore & Ohio, with trains made up as naturally resulted from traffic conditions. The tests extended over all the main lines and more important branches of the road, thus embracing a wide variety of conditions. The profiles of many of the divisions were specially run for these tests. The dynamometer used was of the direct pull oil cylinder type, with piston rod connected to the drawbar of the car. The recording apparatus of the car was described in the *Railway Age* of April 13, 1906, page 655.

Graphical charts were made by the recording apparatus showing continuous records of the following items of information: (a) Location of the test car upon the road; (b) time elapsed since beginning of test (½-min. intervals); (c) mile posts; (d) speed in miles per hour; (e) drawbar pull of locomotive; (f) injector in use or shut-off; (g) coal fired (number of scoops); (h) boiler pressure; (i) train line (air) pressure. Notations of temperature and weather conditions were made as often as change occurred. Data of train consist, weight and length were entered on the charts. On the engine, "log books" were kept preserving tabulated records of: Position of reversing lever, position of throttle lever, use of injector, boiler pressure, scoops of coal fired, water consumed, and other data relating to the tests.

CALCULATING RESULTS.

The purpose of the calculation was to determine the total frictional train resistance at intervals of one-half minute throughout each test run. To do this, it was necessary to calculate the resistances due to grade, curvature and acceleration at each half-minute interval, and to subtract the sum of these resistances at each such point from the total drawbar pull developed by the engine at that point. The remainder, being the total frictional train resistance, was divided by the weight of the train in tons, thus obtaining the frictional train resistance in pounds per ton. This method gives the momentary values of "train resistance" at the points considered.

The speed of the paper travel used on the recording machine throughout the tests was such as to make the graphical charts on a scale of three inches to the mile. A distinctive mark on the time record line shown on the charts was made to indicate the expiration of each half-minute interval. The points so indicated will hereinafter be spoken of as "half-minute points." It was necessary to determine for each half-minute point the speed of the train, the difference in feet of elevation between the rear of the tender and the rear of the caboose, and the degree of curvature of the section of track on which the train was located at that instant.

To determine the speed at each half-minute point, the average speed during the half-minute interval preceding was added to the average speed during the half-minute interval succeeding and the sum having been divided by two, the result was considered as the speed at the point under consideration.

The average speed during each half-minute interval was determined as follows: Through each half-minute point a vertical line was drawn, cutting the drawbar pull record line, the distance record line and the location record line. Having selected on the chart some well-established point such as a signal tower, it was given the mileage designation corresponding to its mileage on the track profile. The distance from this point to each half-minute interval was scaled and the resulting mileage figure assigned. This mileage was then reduced to terms of hundred foot stations, corresponding to the stations on the track profile by multiplying by 52.8. The difference between the mileage figures at two adjacent half-minute points multiplied by 120 was then the average speed for the interval between these points. This speed was checked by scaling between the half-minute points with a 40 parts to the inch scale, reading one "mile per hour" for each 1/40 inch.

The calculations were tabulated in columns headed, "Time"; "Miles from Starting"; "Hundred Foot Stations"; "Grade Factor" (i. e., difference in feet of elevation between rear of tender and rear of caboose); "Speed"; "Speed Difference" (i. e., increase in speed during the half-minute interval); "Speed Force" (i. e., pounds of available drawbar pull consumed in acceleration); "Grade Force" (i. e., pounds of available drawbar pull consumed in overcoming the resistance due to grade and curvature), and "Speed Force plus Grade Force" (i. e., the sum of the two items next preceding and the total amount to be subtracted from total drawbar pull, leaving as remainder total "Train Resistance"). The "Speed Difference" was deduced from the "Speeds" by subtraction, and shows the average acceleration in miles per hour for half-minute intervals. The "Speed Force" was obtained by use of the formula given by G. R. Henderson, in his "Locomotive Operation:"

(1) $Pt = C\frac{V_2^2 - V_1^2}{S}$, where Pt = energy in lbs. per ton. C = constant V_1 and V_2 = velocities considered in miles

*Abstract of Appendix B to the Report of the Committee on Economics of Railway Location.

per hour. S = distance in feet. For a constant time interval of 30 seconds.

$$(2)\quad S = \frac{5280}{120} \cdot \frac{V_2 + V_1}{2} = 22\ (V_2 + V_1) = \text{feet per half minute.}$$

Substituting (2) in (1).

$$Pt = \frac{C\ (V_2^2 - V_1^2)}{22\ (V_2 + V_1)} = \frac{C}{22}\ (V_2 - V_1).$$

The revolving wheels tend to increase the effective inertia in a horizontal direction in a loaded car by three per cent., and in an empty car by eight per cent.

Applying these percentages to 66.76 (given by Henderson):

$C = 1.03 \times 66.76 = 68.76$ for loaded cars.

$C = 1.03 \times 66.76 = 68.65$ for loaded cars.

Then $Pt = \frac{68.65}{22}\ (V_2 - V_1) = 3.12\ (V_2 - V_1)$ for loaded cars.

$= \frac{72.1}{22}\ (V_2 - V_1) = 3.28\ (V_2 - V_1)$ for empty cars.

$= 3.20\ (V_2 - V_1)$ for partly loaded.

The total force of acceleration for a train, for an interval of 30 seconds, is:

$$P = KT\ (V_2 - V_1),$$

when P = total force of acceleration (+ when speed is increasing, and — when decreasing).

K = constant varying from 3.12 to 3.28 as above.

T = actual tonnage of train behind tender.

$V_2 - V_1$ = change of velocity in miles per hour.

$V_2 - V_1$ was taken to the nearest tenth mile and tables prepared for each train consist to show P for any change of velocity appearing in the speed difference column.

The "Grade Factor" was scaled from the profile and shows the difference in elevation in feet between the rear of the tender and the rear of the caboose at the half-minute point, the length of the train having been computed from the train consist, and laid down to scale on the track profile, according to the position of the head end of train, shown in the "Station" column. A (+) "Grade Factor" indicates an ascending grade, and a (—) "Grade Factor" indicates a descending grade in the direction in which the train is moving.

Curvature was allowed for in the "Grade Factor" by adding a (+) quantity to the difference in elevation between the ends of the train, at the rate of .04 ft. for each degree of central angle occupied by the train for curves of over 1,000 ft. in length, and shorter curves when the tangent track between them was so small that the train may be taken to be entirely on curve. For curves less than 1,000 ft. in length, the compensation was taken at .03 ft. per degree of central angle.

The force consumed in overcoming the resistance due to grade and curvature is:

$$F' = \frac{G \times 20}{L},$$ where F = force in lbs. per ton (+ when grade is ascending, and — when descending). G = "Grade Factor" in feet. L = length of train behind tender expressed in "Stations" (units of 100 feet).

$$F' = T \frac{G \times 20}{L} = \text{Total "Grade Force" for train of (T) tons (L) 100-ft. stations in length.}$$

$\frac{20}{L}$ T — is a constant for each train consist and F was tabulated for different values of G to tenths of a foot.

"Speed Force + Grade Force" at each half-minute point was subtracted from the drawbar pull shown on the chart at that point, leaving as remainder the total train resistance, which divided by the total tonnage of the train gave the momentary resistance in pounds per ton at that point.

Record books were used to preserve a tabulated record of the half-minute readings for each run, classifying the readings by speed ranges (1-5, 5-10, 10-15, 15-20, 20-30, 30-40 and 40-50 miles per hour), temperature ranges (20 to 35 deg. and 35 deg. up) and ranges of car weight (below 20, 20 to 30, 30 to 40, 40 to 50, 50 to 60, 60 to 70, and over 70 tons). A chart was made for each run, plotting "resistance" and "time" vertically against "distance from start" horizontally. The legend showed "average car weight," "temperature ranges" and "speed ranges" and for each point plotted a note was made of the number of half-minute readings averaged to give the value plotted. Each value plotted was the average of ten or less half-minute readings. From the "run charts" were selected all stops of sufficient length to cause an increase of 3 lbs. per ton in resistance, the increase in resistance caused by a stop being determined by averaging all half-minute readings for 15 minutes before the stop and subtracting from the average of all half-minute readings for 15 minutes after the stop. These selected stops were plotted on the charts as "zero distance." Resistance was plotted vertically against "distance from stop" horizontally. For each R value plotted, the number of half-minute readings averaged to secure the value was indicated.

The "final charts" were obtained by classifying the "stop charts" by "average car weight" and "temperature range" groups. The points on charts which could be so classified into one group were replotted into a series of charts varying from each other only in the "speed range" covered by each. A curve was then drawn on each chart so classified and replotted, which indicated the "resistance" value for that particular "average car weight," "temperature range" and "speed range."

"Final charts" from fourteen test runs have been worked up according to the preceding outline. These test runs have been grouped into three sets as follows:

Group No. 1.
(Temperature Range, 20 to 35 deg.) (Average Car Weight, 30 to 46 tons.)

	Temperature.	Average Car Weight.	Total Tons.
Run No. 1	32-35 deg.	46 tons	1,693
Run No. 2	33-35 deg.	35.3 tons	954
Run No. 3	29-35 deg.	30.1 tons	1,084
Run No. 4	22-35 deg.	39.0 tons	1,246
Run No. 5	23-35 deg.	33.5 tons	1,071
Run No. 6	31-35 deg.	37.1 tons	1,225
Run No. 7	27-35 deg.	38.6 tons	1,159

Group No. 2.
(Average Car Weight, 10 to 30 tons.) (Temperature Range, 20 to 35 deg.)

	Temperature.	Average Car Weight.	Total Tons.
Run No. 8	26-35 deg.	18.6 tons	874
Run No. 9	27-35 deg.	24.7 tons	839

Group No. 3.
(Average Car Weight, 30 to 50 tons.) (Temperature Range, 20 to 35 deg.)

	Temperature.	Average Car Weight.	Total Tons.
Run No. 10	50-60 deg.	27.6 tons	382
Run No. 11	36-40 deg.	50.7 tons	1,370
Run No. 12	35-38 deg.	35.6 tons	1,244
Run No. 13	48-56 deg.	35.2 tons	914
Run No. 14	35-47 deg.	34.6 tons	1,108

It will be observed that in each of the three groups the range of average car weight, and in Group No. 3 the temperature range, is greater than contemplated in the outline. This modification of the outline was adopted in order to get as many points as possible in each set, from which to draw curves, it having found that if the original outline were strictly adhered to there would not be enough points in each group to indicate any definite results. Even under the modified plan the results are meager, Groups Nos. 2 and 3 not having enough points to give satisfactory indications. Group No. 1 is fairly satisfactory.

Study of the final charts shows that the plotting points fall at widely varying distances above and below the curve of average value, and, while the curve may readily be drawn, there is no close aggregation of points immediately along the curve. Although other investigators have exhibited charts, resulting from studies of similar tests, which do show the points all practically falling on the curves, the conclusion reached in the present instance is that under service conditions the different items entering into train resistance are continually varying through such wide ranges that the total resistance, even under conditions considered constant, cannot be determined to be any very constant quantity. Nor can it be concluded that a curve may be drawn which will represent more than an average of widely varying values.

In the Manual of Recommended Practice of the American Railway Engineering Association is given the adopted formula for train resistance on a level grade: $R = 2.2\,T + 122\,C$. The tests made do not show any results which would change that formula. It is probably as practical as necessary, and will give results which are close enough for service conditions. Absolute accuracy is not essential, since the train resistance must be equated with the engine tractive power, and the latter must have a large factor of safety to make up for the varying capacity of the crew, the differences in fuel and the condition of the machine.

DEVELOPMENT OF FORMULÆ FOR OTHER TEMPERATURES.

Using the charts in Groups Nos. 1 and 2, a formula for resistance in pounds per ton has been derived for "B" rating at temperatures from 20 to 35 deg. Averaging all readings shown at more than 10 miles from start, on charts in Group No. 2, in which the average car weight is 21 tons, gives $R = 9.5$ lbs. per ton. Averaging all readings shown at more than 10 miles from start, on charts in Group No. 1, in which the average car weight is 37 tons, gives $R = 6.7$ lbs. per ton.

In the resistance formula $R = K\,(T) + K'\,(C)$, in which $T =$ tons per car, $C =$ number of cars, and K and K′ are constants solve for the value of K, as follows:

21-ton car: 21×9.5 lbs. $= 199.5 = K\,(21) + K'\,(1)$ (1)

37-ton car: 37×6.7 lbs. $= 247.9 = K\,(37) + K'\,(1)$ (2)

Substituting (1) from (2). $48.4 = K\ 16$

$K = 3.0$

Substituting K in (1) and solving for K′,

$199.5 = 3.0 \times 21 + K'$

$K' = 136.5.$

Substituting these values of K and K′ in the resistance formula, $R = 3.0\,T + 136.5\,C.$

Investigations made from data not as good as the preceding have enabled the completion of formulæ for other temperatures. It is arbitrarily assumed that the ratings are called A, B, C and D, as follows: A rating for temperatures over 35 deg. F., B rating for temperatures between 20 and 35 deg. F., C rating for temperatures between 0 and 20 deg. F. and D rating below 0 deg. F. Without going into detail, the formulæ deduced are:

A rating: $R = 2.2\,T + 122\,C.$

B rating: $R = 3.0\,T + 137\,C.$

C rating: $R = 4.0\,T + 153\,C.$

D rating: $R = 5.4\,T + 171\,C.$

Ratings made on the basis of these formulæ have stood the test of practice. They should be used as a basis to work on and should be tempered by the judgment of the operating officer in charge on the ground.

In practice, the drop from A to B is usually made by giving trains A rating minus 50 tons or minus 100 tons, and gradually following the temperature rather than by changing suddenly. It should be understood that decreased ratings are used for other conditions of weather than those caused by temperature, high wind being a frequent cause of reduction. When the frost comes in the fall its effect begins to show up in increased transportation expense. The slow freights catch it first. For a while an effort is made to hold up the ratings, but the frost gets into the journals and the time of the run drags out until the items "Crews relieved" and "Exceeded 16 hours" cause a cut in the ratings. Fast freights which make almost continuous runs without stops are not much affected by cold weather unless it is very severe. High winds, however, are very hard on both fast freights and passenger trains. The combination of high winds and cold weather should be amply compensated by reduced ratings, as not only is the train resistance increased, but the loss of power on the engine affects its hauling capacity.

It is difficult to always "size up" the conditions a train is going to meet throughout its run so as to give it the proper tonnage. The following items should be considered: Trains leaving terminal in the afternoon will have the lower night temperatures to meet. Trains starting at night under severe cold may often pick up tonnage after the sun is up. Trains starting a run in the low altitudes will find colder weather in the mountains. Trains starting in the mountains may often take on tonnage in the low lands. Trains having many stops and starts will be affected by cold more than trains running continuously. Trains starting up-grade leaving terminal may haul larger ratings if helped leaving terminal for at least 20 minutes until the journals become warmed. Position of passing sidings plays an important part in rating trains in winter. If sidings are in such positions that a train starts out of siding on a down-grade or on a grade substantially less than the ruling grade, larger ratings may be handled than is the case where sidings are located on ruling grades. If trains can get out of terminals promptly and put in the time on the road instead of standing in yards, better rating may be handled than when a large part of the allowable time is consumed in doing nothing.

The temperature has the following effects on expense and on the revenue train load: Increased overtime, increased yard expense, increased enginehouse expense, increased fuel for locomotives and for heating, increased damage to equipment on road, increased snow and ice account, increased other expense, and decreased train load. As the revenue train load decreases, all of the expenses which vary with the train load increase. Since from 25 to 30 per cent of all transportation expense varies directly with the train load (depending on the proportion of the road expense to all expense), it is evident that the effect of temperature is heavy.

Of all the tonnage hauled on a railroad whose train load is above 300 revenue tons, only the slow freight maintains a train load constantly above the average. Manifest trains rarely carry more than 50 cars, and do not average that much. The car load is light—five tons is fair—and 250 revenue tons is a high revenue train load. Local freights make very low train load and haul freight at high expense for wages. They are often back hauls in local freight, which are a loss as far as revenue train load is concerned. The effect of both local freights and fast freights, therefore, is to hold down the revenue train load. Since temperature ratings affect slow freights principally, and fast freights and local freights up to a lesser degree, it is evident that its effect on the revenue train load is quickly apparent.

In Middle Atlantic states the train load will decrease from 15 to 30 per cent in winter, depending on conditions. When the proportion of heavy slow freight to the total business decreases, the drop in the train load is especially great. On account of cold weather troubles at engine terminals, steam failures on the road, and for other reasons, locomotives make less mileage in winter than in summer. There is always trouble on long grades where the fireman has to work continuously for [illegible] an hour. Firemen do not like to perspire in the [illegible] and they usually wear more clothes than necessary [illegible] are exerting themselves. The en-

gineer on his seat box is dressed for sitting still and not for helping out a fireman with a dying fire. So a drag engine with a heavy tonnage train often fails in the winter when it would be all right in summer.

The freezing of coal and ore in cars is a cause of great delay to the movement of cars, which often means light trains to get faster movement. The ordinary method of building fires under cars to thaw them out and pounding the hoppers with hammers results in increased expense apart from the delay to the cars. It takes men to build fires under cars and it costs money to furnish fuel to burn. It also takes extra force to beat hoppers.

If cold weather comes at a time when business is brisk, as in the winter of 1911-12, the expense in all departments is bound to be heavy. It pays, therefore, to know something about effect of temperature on train haul. In practice there are two ways of allowing for variations of temperature: (1) Keep the rating constant and vary the adjustment for each temperature, and (2) keep the adjustment constant and vary the rating for each temperature. They both amount to the same thing in determining the actual tons hauled, but in practice it is probably better to follow the second plan. By so doing, train crews readily see that a reduction in tonnage has been made, whereas, if the "Wheel Report" shows full tonnage and merely a change in the adjustment, they often think they are hauling "A" ratings in "C" weather.

The formulæ developed above for B, C and D rating on level grade should be used to represent the resistance of a train that has been in motion at least 15 minutes. It is practical to assume that the resistance will be constant up to 30 miles per hour. With reasonable ratings of the power, starting resistances are negligible in warm weather. The engine must have a greater margin in cold weather, and when starts have to be made on ruling grades (especially when they follow long stops) extra allowance should be made.

TONNAGE RATINGS.

Proper tonnage rating is that load which can be hauled by the engine under consideration over the road at an economical speed. Owing to factors which are, in a measure, indeterminate, it is not an exact science. Strictly economical tonnage rating would be different for every train. This can readily be seen, since no two engines are in the same condition. In a like manner, some cars are in a better condition to be hauled than others. Road conditions differ on different parts of the same division and some men are better and more uniform performers than others. Perfect uniformity of mechanical and roadway conditions would result in large economies in the way of a decreased number of trains due to increased tonnage per train. Where it is impossible to secure perfection, uniformity pays well, even if it costs money to get it.

The object of adjusted tonnage rating is to give an engine the same amount of work to do regardless of whether a train is made up of heavy loads, light loads, empties, or any combination of them. If all cars of the same weight had an equal resistance to traction, this would be possible. Different kinds of cars and varying conditions of track, weather and wind make it possible only to approximate the desired result. The adjustment is an arbitrary amount added to the weight of each car, whether loaded or empty, to qualize the pull on the engine under conditions of hauling loaded, empty or mixed trains. Adjustments are functions of the rate of grade and the resistances of the train. Practically they vary only with the rate of grade.

Most operating divisions have broken profiles and different rates of grade, so that the ruling grade should be first determined, the ruling grade being the grade which governs the train load. The adjustment for that grade should be used. If train loads are adjusted correctly for limiting conditions, there will be no trouble with the other parts of the railroad as far as tractive power is concerned. When helpers are in use, the adjustment should be for the single engine ruling grade. This procedure will establish an adjustment which will be too large for helper grades, but the error is on the safe side.

When possible, the grades should be established from recent profiles. If there are none, it is a good plan to run them. Railroad profiles change in the course of years. It is a well-known fact that fills settle, causing deep sags in the grade line. The raising of tracks through cuts is cheaper than ditching, but is responsible for summits in the cuts. On some lines, where the profile has been checked, it has been found that stretches of 0.3 per cent. grade have become 1 per cent. If places of this character occur near a point of heavy resistance, an immediate effect on the tonnage of a train is the result. When an engine is working with its bar well forward, with the fireman tired out, the fire dirty, and the steam pressure dropping, such places will cause the stalling of a train, and in a short time the frequent delays will result in decreased tonnage rating.

Raising tracks is not as economical as the section foreman and supervisor would lead us to believe. While better drainage is undoubtedly secured, it is generally better practice to clean the ballast, and widen cuts to secure a ditch, and to raise track only when it becomes necessary to put roadbed to a proper line and surface. On such occasions, grade stakes should be used to establish the grades. On many railroads an effort has been made to place permanent monuments, so that the track could be kept at a constant elevation. The difficulty of maintaining monuments along a roadbed is well known. They are likely not only to be a menace to the lives of the trainment, but they are constantly settling, and being knocked by sectionmen, and occasionally by derailments. However, the importance of placing permanent monuments cannot be overestimated.

In the early days of railroading, compensating for curvature was practically unknown. For many years it was probably unnecessary. Compensation for curvature is not vital to small trains running at speed. The resistance due to curvature is principally felt by heavy tonnage trains on ruling grades where the engine is rated at a high percentage of its cylinder tractive power. Various experiments have been made to determine how much reduction in grade would compensate for the added resistance of curvature. It has generally been the practice to compensate this at a stated amount, and, while this method is not as accurate as could be desired, it is very much better than no compensation at all. From considerable observation of the influence of curvature and an examination of numerous tests of its effects, it is felt that the following rules would improve the present practice.

Conclusions: Compensate .03 per degree: When the length of curve is less than half the length of the longest train, when a curve occurs within the first 20 ft. of rise of a grade, or when curvature is in no sense limiting. Compensate .035 per degree: When curves are between ½ and ¾ as long as the longest train, and when the curve occurs between 20 ft. and 40 ft. of rise from the bottom of the grade. Compensate .04 per degree: When the curve is habitually operated at low speed, when the length of the curve is longer than ¾ of the length of the longest train, when super-elevation is excessive for freight trains, and at all places where curvature is likely to be limiting. Compensate .05 per degree wherever the loss of elevation can be spared.

The effect of curvature on low grades is generally greater than on heavy grades, provided the length of train is what would be justified by the low grade. In speaking of low grades, levels, 0.1 per cent, 0.2 per cent and 0.3 per cent grades are referred to. On double track railroads, particular attention should be paid to curves, whether uphill, downhill, or level, at places where steam is being taken by the engine in

moving in either direction. On virtual level grades each track should have its tangents slightly raised and its curves slightly sloping down hill, so that the pull by the engine may be uniform, and the resistance of the line constant. The value of keeping the line resistance constant becomes more important as the length of the train increases. One of the prime objections to hauling a long train is the danger of parting, and in this danger curvature plays an important part. If the line is crooked, having many short curves, it is usual for the slack of the train to be constantly taken up and let out. If the engine runs out on a bit of straight track, when the rear of the train is bunched on the curves, it will accelerate faster than the other end of the train. Unless the engineer is watching, and using the brakes slightly, he may pull out a drawbar. If, on the other hand, the front end of the train is on a curve, and the rear end on straight track, the tendency is for the rear end to run in on the front end, and break a knuckle. It should not be supposed that it is impossible to have different classes of compensation on each track of a double track railroad.

From a scientific standpoint, although not always from a financial view, it is evident that a six-track railroad is the most desirable for a road that handles a three-speed service. This will give a passenger track, a fast freight track, and a slow freight track in each direction. Without attempting to discuss what will be gained by the operation of a six-track railroad, it should be said that as many tracks as possible are justified if a standpoint of super-elevation alone is considered. Of course, it becomes necessary for a train to stop occasionally on a curve, and for that particular case the super-elevation is always wrong. Inasmuch as no super-elevation at all is necessary at very low speeds, it may be eliminated entirely on tracks that are used exclusively for standing cars, and very low super-elevation, if any, should be used for yard tracks.

On a single-track railroad carrying more than one class of traffic, there are two ways to treat super-elevation: (1) Make the freight tonnage rating as great as possible, and in accordance with the ruling grade. In this case, it will be necessary to elevate the curves for freight speed, and run the passenger trains slowly over ruling grades. (2) Use a higher super-elevation for passenger speeds, and decrease the tonnage rating to make up for the increased resistance caused by the wheels of the freight trains binding against the lower rail.

Single-track railroads which are crooked can rarely haul as high a percentage of rating as double-track railroads, on account of the super-elevation being wrong. It is easy to see that every down-grade becomes an up-grade for movements in the opposite direction on a single-track road. Inasmuch as the movement downhill is likely to be faster than it is uphill, the super-elevation must be made for the downhill movement or introduce speed limits on downhill trains. On single lines that are exclusively for freight, super-elevation on ruling grades should be made for not over 15 miles per hour. It is less expensive to slow down the descending movement than to reduce tonnage rating on account of excessive super-elevation.

Without discussing the theory of the spiral as affecting railway grades, it should be said that the object of the spiral is twofold: To afford a run-off and a run-on from a level cross-section to a super-elevation cross-section, and to ease the horizontal passage from a straight line to a curve. It is evident that in passing from a level position to a super-elevated position, when the inner rail of the curve is laid at grade, the center of gravity of the mass of the train must be raised through a distance equal to one-half the super-elevation. This is generally a minor rise, but in order to haul uniform tonnage this minor point should be carefully observed, especially where limiting conditions are found, such as places near the end of a long-continued effort. It has been proposed in the past that the inner rail be depressed a distance equal to one-half of the super-elevation, and the outer rail be raised the same amount. While this has been objected to by some railroad men, it can certainly be done and so maintained, and from a tonnage standpoint it is desirable. It is submitted that the railway of the future, which is scientifically operated, will find conditions such as these limiting their tonnage unless care is taken. While it might be said that refinements in the track are unimportant, it should be borne in mind that, in order to realize the full value of improvements, these matters must be taken into consideration. A combination of correct conditions results in the most effective operation.

Curves that reverse without any tangent between them mean operating expense. Not only must the super-elevation change abruptly, but the trucks must change their position in the same manner. It is considered good practice to leave room between the points of spiral for four freight cars to straighten up after they change direction. On most new construction, provision is made for at least 1,000 ft. between curves, and this practice is recommended unless great expense is involved.

In exactly the same way that a horse can haul a wagon better on an asphalt pavement than on a cobble stone road, so can a locomotive haul tonnage more easily on a good track than on a poor track. Without going very far into the discussion of track maintenance, it may be stated that from a tonnage standpoint good track consists of the following things: Mathematical alinement, super-elevation conforming to the speed, an unyielding sub-grade, heavy enough rail so that the depression under the ruling grade is small, enough ties beneath the rail to transmit the load uniformly to the sub-grade, deep enough ballast to secure good drainage and distribution of loading, and as much strength as is necessary. It is easy to see that if a train is hauled along a roadway that is constantly pressing down the rails, it is literally climbing a hill all the time.

Many railroads are suffering today on account of the fact that during the early days of construction it was not thoroughly realized that a tunnel might be a limiting factor in tonnage rating. The following are the causes of the limiting effect of tunnels: A tunnel is dark, making the engine crew less confident; a derailment in a tunnel is almost sure to result in serious damage and loss; the heat in long tunnels, especially if of small section, is intense; the track conditions, such as line and surface, are never as good as on the outside; the rail is generally damp, causing either the excessive use of sand, or the slipping of drivers; drainage in tunnels is usually bad, and difficult to improve; there are usually speed restrictions in tunnels. It was formerly the practice to carry maximum grades through tunnels in order to shorten them. This serious defect in many cases makes tunnels the ruling points. In tunnels of small section the use of helper engines is undesirable on account of the heat; the smoke and gas add to discomfort of operation; the impracticability of firing in long tunnels causes a drop in steam pressure.

There have been many plans devised for tunnel ventilation. Most of them are successful under some circumstances, but none is successful under all conditions. Long tunnels are generally built by means of shafts, and these shafts are sometimes left open to aid the ventilation. If the heat in the tunnel is greater than that outside, shafts will help when the atmosphere is low in humidity. When the humidity is high, shafts make but little difference in tunnel conditions. This is unfortunate, as tunnels at such times are very foul. Disc fans used in the shaft will operate satisfactorily sometimes, but their efficiency seems to vary about the same as the open shaft. Pure air blown down shafts is successful at times, but if the shaft is near the center it generally happens that

only one end of the tunnel is cleared out, the air remaining stationary at the other.

The Churchill system of ventilation, by which pure air is blown through the tunnel from one end through nozzles fitted at the sides of the tunnel, is successful, if the enginemen operate the locomotive so that the smoke is blown ahead of the engine. If two engines are used ahead on a train, and it is necessary to work the second engine, the position of the front engineer is unbearable. If one engine is used in the rear and one in front, and the smoke and gas from the second engine reaches the first one, the front engine crew are in the same position as in the case of the double-header, but if the train is skilfully handled, the smoke and gas of the rear engine will not reach the head engine. In tunnels where the grade inside is considerably less than the ruling grade, it is sometimes found possible to shut off one engine entirely, and in that case there is no difficulty, provided that the train does not move faster than the air current.

The natural tendency is to drive the engine as hard as possible through the tunnel on a heavy grade in order to get through quickly. The speed of the air currents in the Churchill system of ventilation in a tunnel a mile long usually averages about 8½ miles an hour over the whole distance. If the tunnel is being worked to anywhere near its capacity, the additional time in the tunnel may seriously limit the number of trains that may be put through it. It has been found, however, that if the tunnel is cleaned out by the ventilating apparatus before the passage of each train, there is little difficulty in getting through. As a rule, the engine crews prefer this method.

Double-track tunnels are of sufficient section so that there is little discomfort in a tunnel a mile long, even if the locomotive is fired all the way through. The practice in Europe has always been much better than that in the United States in that even with single-track tunnels their section has been large enough so that they are less uncomfortable than those in this country. Tunnel ventilation in Europe is largely restricted to the dilution of locomotive gas with plenty of fresh air, rather than driving the smoke and gas ahead of the engine.

In the construction of new tunnels, an effort should always be made to reduce the grade in the tunnel considerably below the ruling grade, so that there may be no need of touching the fire during the passage through the tunnel. Ample section to secure good conditions is essential. In this connection it should be noted that the effect of long single-track tunnels of narrow section on the ruling grade is to reduce the tonnage rating in the tunnel by 10 per cent at least.

Primarily it should be said that the effect of the length of a ruling grade depends entirely on what speed it is necessary to make up that grade. Hardly any operating division has more than 40 per cent of ruling grade in either direction. It is generally computed that a train must average ten miles an hour over a division of 100 miles in order to secure the best economy.

Assume a division with 40 miles of ruling grade, and 60 miles of either downhill or less than ruling grade. If eight miles per hour is averaged on the ruling grades, and 12 miles per hour on the down grades and less than ruling grades, the run may be made in ten hours. If a grade is very short, following a stretch of either downhill or less than ruling grade, sufficient speed may be had at the bottom to carry the train over the top, even though the ascending grade be considerably more than the ruling grade. As the train goes up the hill, its speed will constantly decrease. The speed at the top of the hill must be such that the engine still has some margin between its maximum tractive effort and what is required of it. This result depends entirely on the speed of the train at the foot of the grade. Such a grade is called a "momentum grade," and, while most railroad men will say it is not safe to depend on momentum, it is probable that there is not an important railroad in the country where the locomotive engineers cannot tell of portions of the line that are operated in that manner, even though the officers of the railroad do not know it. Were it not for momentum, it is likely that many curves would prove to be stalling points that are now passed around with little, if any, trouble. We are learning more every day about handling trains and power at low speeds, but it must be understood that these low speeds are only for use for short periods of time, and not for general practice over a whole run. When the grade is long enough for the train to become stretched out fully upon it, or, in other words, when the engine settles down to a constant speed with its maximum tonnage, the rating speed for that particular train becomes fixed. Without a rise in the steam pressure, the train cannot accelerate as long as the grade remains the same. If there is a large percentage of this character of line on the division, the rating speed must be considerably higher than if there are only one or two places. For instance, it may be possible to average seven miles per hour over one piece of grade, if that is the only piece on the division, because the difference in time should be made up on the rest of the division, but it would be manifestly improper to load an engine so that such a low speed would be made over the whole run. Not only the low speed, but the constant demand on the engine would be such that the fireman would play out, and a failure would be the result.

PROPER PERCENTAGE OF RATING.

It has been stated that a locomotive standing on a dry steel rail should be capable of exerting a pull on a spring balance equal to approximately ¼ its weight on drivers. This amount can be increased by the application of some medium to increase the co-efficient of friction, such as sand, to about 35 per cent. (for momentary purposes only). This same pulling power can be used to haul a train, including, of course, the engine and the tender itself.

Ratings in use are never as great as could be pulled by the locomotive utilizing a tractive power of ¼ the weight on drivers. The reason is apparent. Time is the essence of rating, just as it is the prime factor in all railroading. The governing question is: For how long a time must the locomotive be required to exert its maximum pull during any particular run? If it is required to exert a maximum effort for only about five minutes at a time, the rating might be established for a maximum effort, provided that time for rest of man and recuperation of fire elapses between the periods of maximum effort.

If maximum ratings were established for divisions where the ruling grades were long enough to require maximum effort for some time, the following conditions would have to be combated: Poor draft, owing to slow exhaust; poor fire on account of poor and intermittent draft; dirty fire on account of imperfect combustion; tired fireman on account of heavy work for a long time; steam failure, and stalling. It will be understood that, if an engine is adjusted to working under such conditions, an improvement may be had compared with an engine which is utilized on general service. The practical problem then is: How long can the ordinary fireman keep his fire in shape to deliver steam at full stroke? At what rate does his capacity deteriorate? At what rate can he maintain a steady and consistent performance for long periods of time?

In order to secure as uniform working conditions as possible, it is necessary to assign values as closely as possible to the rates mentioned. The accompanying plat will represent about what is considered fair practice. In order to apply the chart, find out how long a time it is feasible and practical for the locomotive to consume in ascending the ruling grade, and taking that time on the chart, follow up the line and see what percentage of full rating may be given the engine. It

is evident that when the percentage of rating gets as low as 60, it would pay to keep a full rating for the ruling grade with an assisting engine to avoid penalizing all the rest of the run improperly.

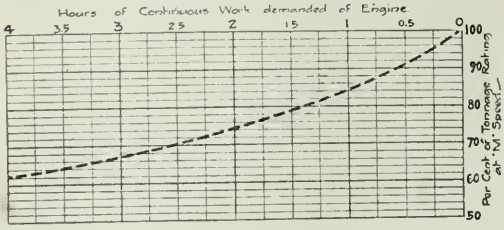

Diagram Showing Amount Rating Should Be Reduced on Account of Continued Work.

When the ruling factor in the operation is to conserve power, the greatest number of ton miles per engine mile is the figure to work for. This, however, will not always produce the lowest cost per ton mile. At times there is a shortage of train crews and a surplus of power. In this case it becomes imperative to make the greatest number of ton miles per train mile. This nearly always shows the greatest economy of movement.

Ratios of Resistance and Car Weights Including Adjustment.

An engine cannot do work and overcome train resistance unless it can transmit its cylinder work to the rail by means of adhesion due to the weight of the engine and the friction between wheel and rail. The adhesion of the wheels to the rails may be reduced by a number of circumstances as follows: Moisture acting as a lubricator, frost, grease, poor rail surface, manganese or other metals in the steel, excessive super-elevation, throwing too much weight on one side, and inability to use sand.

Assuming that, for rating purposes, the resistance formula, $R = 2.2\ T + 122\ C$, is correct, the resistance of a 20-ton car and a 70-ton car on different grades is shown in the accompanying table. Without a knowledge of train resistance under different conditions of car weight, it might be supposed that gross tonnage multiplied by the distance hauled would form the most accurate measure of work accomplished. The cost per gross ton mile would then be a measure of efficiency of operation. However, this is not true since it takes 60 per cent of the power to haul a 20-ton empty car on a level that it does to haul a 70-ton loaded car, while the empty car is less than 30 per cent of the weight of the loaded car. It, therefore, follows that as a measure of the cost of performed work the gross ton mileage alone is not an adequate basis of comparison. If, however, the adjustment figures are added to the weight of the car, the results become comparative at once, as shown in the second table.

ATTENDANCE AT THE COLISEUM.

There were more railway men at the Coliseum yesterday afternoon than at any previous time since the exhibition was opened last Saturday. The rules governing admission, by excluding those who were not directly interested in railways and have heretofore attended the show more as sightseers than anything else, resulted in confining the attendance practically altogether to railway officers and employees. The wisdom of this method of handling the attendance was demonstrated on several occasions when the crowds of railway men became so large that if they had been swelled by hundreds of mere sightseers there would not have been room enough for such a comfortable opportunity to inspect exhibits as the members of the Appliances Association have a right to expect and as railway officers enjoy. In a word, the exhibits have undoubtedly been more thoroughly inspected by railway men this year than ever before, principally because these men could take their time and were not crowded.

NEW SIGNAL INSTALLATIONS.

The Nashville & Gallatin Electric Railway (Tenn.) has installed a new signal system on its entire line, covering 25 miles of single track, which will be put in service before the end of this month. The Indianapolis & Cincinnati Traction Company has extended its signaling system to 45 miles of its lines in Indiana and Ohio. The new installation provides for complete switch protection and several new features of separate directional control of train movements are embodied in the dispatching apparatus. The Mesaba Railway Company has contracted for an installation of signals on 36 miles of line. Work will be commenced immediately. All of these installations will use the Simmen signal system.

RAILWAY BUSINESS ASSOCIATION DIRECTORS MEET.

The quarterly meeting of the directors of the Railway Business Association was held in Chicago yesterday. There were in attendance the president, George A. Post, president Standard Coupler Company; Col. H. G. Prout, vice-president and general manager Union Switch & Signal Co.; A. M.

Kittredge, president Kay & Ess Company; George W. Simmons, vice-president Simmons Hardware Company; F. T. Heffelfinger, president Peavey Grain Co.; Irving T. Hartz, president Morden Frog & Crossing Co.; J. C. Bradley, president Pratt & Letchworth Co.; James S. Stevenson, vice-president Berry Brothers, Ltd.; W. G. Pearce, vice-president American Brake Shoe & Foundry Co.; E. B. Leigh, president Chicago Railway Equipment Company; W. W. Salmon, president General Railway Signal Co. W. E. Clow, president James B. Clow & Sons; and F. W. Noxon, secretary of the Association.

The principal speeches made at the Association's last annual dinner in New York on December 19 were James J. Hill and W. L. McKenzie King, former Minister of Public Works of Canada. There has been such a demand for their addresses that the Association has sent out 56,000 copies of Mr. Hill's address and 55,000 of Mr. King's. The Association has also ascertained that these speeches were reported in newspapers and other publications having a total circulation of 9,000,000.

SIGNAL COMPANY SOLD.

The Federal Signal Company, Albany, N. Y., has completed negotiations for the purchase of the American Railway Signal Company of Cleveland, O.

ARRANGEMENTS COMMITTEE OF THE RAILWAY SIGNAL APPLIANCES ASSOCIATION.

The arrangements committee of the Railway Signal Appliance Association will hold a meeting at the Congress Hotel at 1 o'clock this afternoon, to make further arrangements for the annual convention to be held at Nashville, Tenn., next October

STEEL RAILS FOR CONCRETE REINFORCEMENT.

W. K. Hatt, professor of civil engineering, Purdue University, will deliver an illustrated lecture in the Florentine room, Congress Hotel, at 7:30 o'clock tonight in which he will present the results of tests on rolled steel rails for concrete reinforcing bars. As this lecture is to be informal and will be withheld from publication, the officers of the association are anxious to have a good representation of the members present to hear Dr. Hatt.

ALL-STEEL COALING STATION.

The accompanying cut illustrates an all-steel locomotive coaling station of 300 tons capacity arranged to coal on two tracks. While many of the mechanical devices for controlling and operating these stations are covered by patents, the type of bin with supports is made to suit the individual choice of the railway engineer in each case. The more common materials of construction—wood, concrete and steel—are all used, but wood is being abandoned in most of the newer structures where permanency is considered most important. In the all-steel structures the bottom is curved or conical, which causes all of the coal to move whenever the spouts are opened. This prevents spontaneous combustion. The roofs are also of conical steel. This form of bottom is not so easily made of wood or concrete as with steel because the curved and conical steel bottom is suspended and not supported except at its connection to the cylinder. It is probably the cheapest construction in many cases and is certainly more permanent than wood. It also occupies a minimum space, and has a very handsome appearance. The tank is tightly enclosed and objectionable dust or waste can be reduced to a minimum.

The structure here illustrated was built by the Des Moines Bridge and Iron Co., Pittsburgh, Pa., for Roberts & Shaefer

All-Steel Coaling Station.

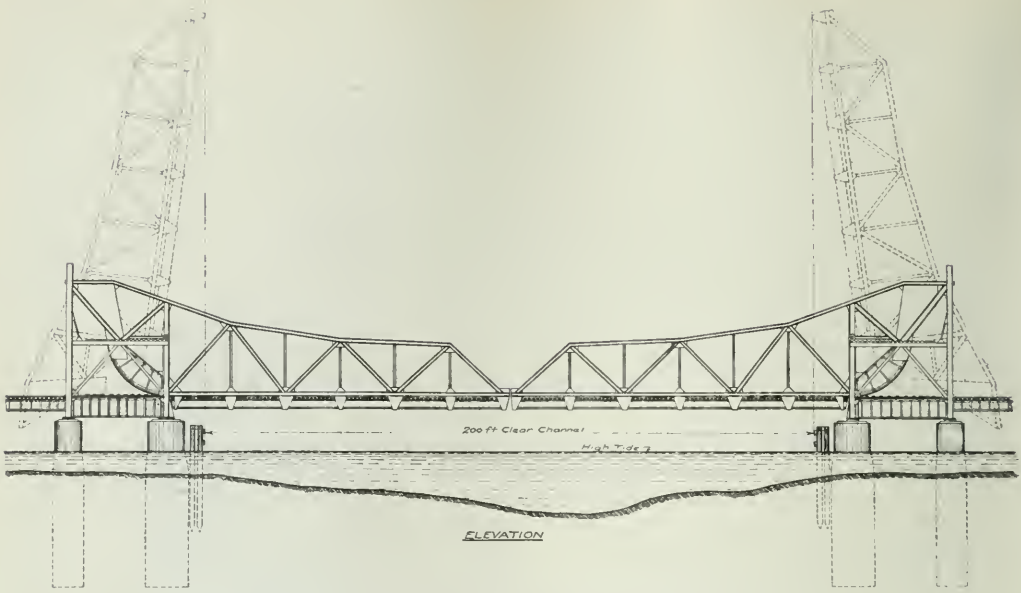
contracting engineers, Chicago. It is located on the Elgin, Joliet & Eastern at Rossville, Ill.

SCHERZER ROLLING LIFT BRIDGES.

The first Scherzer rolling lift bridge built for the Metropolitan West Side Elevated Railway across the Chicago river nearly 20 years ago has been and is now carrying continuously a traffic of more than 1,500 trains daily, which is thought to be a record for movable bridges. Although it is operated frequently to allow river vessels to pass, the maintenance charges have been small and the bridge is still in excellent condition. The structure consists of two double track bridges side by side.

The accompanying cut shows the double leaf cantilever Scherzer rolling lift bridge under construction across Pamban Channel, on the extension of the South Indian Railway lines from Southern India toward the Island of Ceylon. This structure will consist of a number of deck plate girder spans in combination with the through Scherzer rolling lift bridge across the navigable channel. The cantilever trusses of the movable span are similar to the double leaf bridge of this type constructed in 1908 for the Burma Railways across the Ngawun river, Burma.

The movable span of the South Indian Railway bridge is 225 ft., center to center of bearings, being 5 ft. longer than the Burma bridge. The clear channel for navigation is 200 ft. wide. When the bridge is open, it provides an unlimited vertical clearance, so as not to obstruct the highest



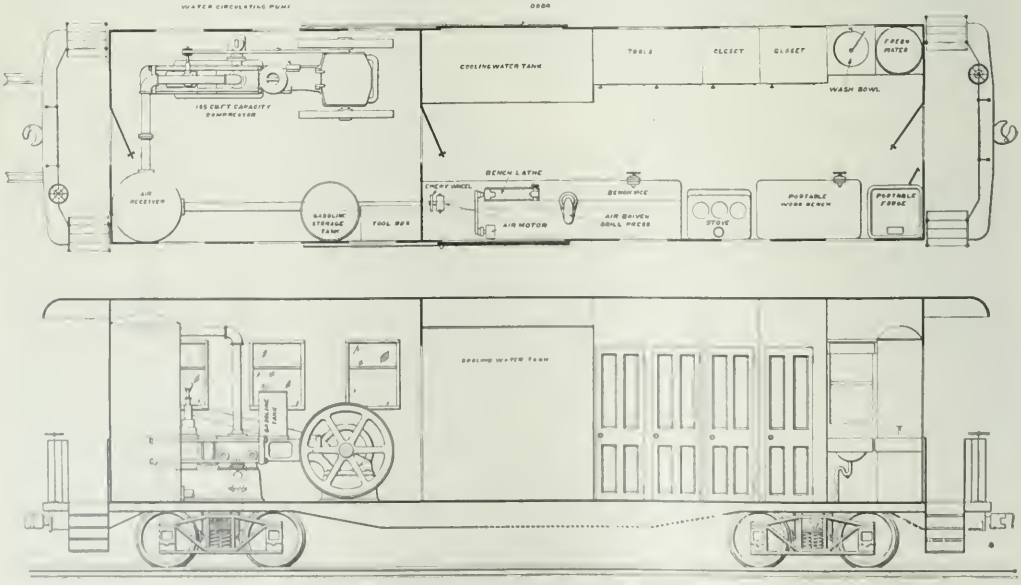
Scherzer Double Leaf Rolling Lift Bridge Across Pamban Channel, India.

masted vessels. Each bridge leaf is operated by one 25 h. p. motor. The foundations have been completed, and the approaches to the lift bridge are now nearing completion. This Scherzer bridge was fabricated in England, and erection will be completed within three or four months.

The Scherzer Rolling Lift Bridge Co., Chicago, prepared the designs, plans and specifications for the superstructure, operating machinery and power equipment and is acting in a consulting engineering capacity on the bridge, in co-operation with the engineers of the South Indian Railway.

RAILWAY REPAIR CAR.

The accompanying cut illustrates an installation of stationary and portable air tools operated by a gasoline engine driven compressor. The tools include drills, riveting and chipping hammers, painting machines and an air hoist. The arrangement of the car is such that it can be very conveniently used for bridge work either on new construction or repair work. The complete equipment for this car is furnished by the Chicago Pneumatic Tool Co., Chicago.



Chicago Pneumatic Tool Company's Railway Repair Car.

Subscriptions, including 52 regular weekly issues and special daily editions published from time to time in New York, or in places other than New York, payable in advance and postage free:

United States and Mexico	$5.00
Canada	6.00
Foreign Countries (excepting daily editions)	8.00
Single Copies	15 cents each

Engineering and Maintenance of Way Edition and four Maintenance of Way Convention Daily issues, North America, $1.00; foreign, $2.00.

Entered at the Post Office at New York, N. Y., as mail matter of the second class.

WE GUARANTEE, that of this issue 8,250 copies were printed; that of those 8,250 copies, 6,798 were mailed to regular paid subscribers and 145 were provided for counter and news companies' sales; that the total copies printed this year to date were 105,639 copies—an average of 8,755 copies a week.

VOLUME 54. MARCH 21, 1913. NUMBER 12.

CONTENTS

*Illustrated.

THE time is ripe for the adoption by the railways of the United States of a standard box car. This type of car, designated by the commission on car service which was recently appointed by the American Railway Association as "legal tender equipment," is so generally interchanged and the practice of the home route is so wasteful that the commission has made the suggestion that all box cars be placed in a pool which can be governed by regulations that will insure the best service being obtained from such cars by the railroads generally. Such a movement, which would naturally lead to the adoption of a general standard box car, if suggested a few years ago, would have had little chance of being put through—and it is possibly just as well that it was not attempted. At the present time, however, sufficient experience has been gained from the different types and designs of box cars to enable a standard box car to be decided upon which should give excellent results from the construction, maintenance and service standpoints, and should thus receive the support of the mechanical and operating officers. The splendid returns which have been received from the publication of the car balances and performances by the American Railway Association and the results which have already been accomplished by the commission on car service and the recommendations which it has made would seem to insure the hearty support of the executive officers to such a movement. It would not be surprising if the American Railway Association should ask the Master Car Builders' Association to present its recommendations for a standard box car in the very near future.

THE twenty-sixth annual report of the Interstate Commerce Commission for the fiscal year ending June 30, 1912, contains a number of tables relating to the causes of accidents, and among them is a special compilation of those that have been caused by wheel failures. In 1912, for example, there were 3,847 accidents due to defective equipment, of which 984 were caused by broken wheels, and of these 627 were broken flanges. The report contains a tabulation of such wheel failures for eleven years, 1902 to 1912 inclusive. Comparing the first two years of this period with the last two, we find that for 1902 and 1903 there were 1,011 accidents caused by wheel failures as against 1,800 for 1911 and 1912, showing an increase of 78 per cent. in the total number. These figures cannot be taken, by themselves, to present an accurate statement of the case, because they take no account of the increase in traffic that has occurred between the two dates. In 1902 and 1903 the total ton-mileage of the United States was nearly 331 billion; in 1910 and 1911 it was nearly 509 billion. (The figures for 1912 have not yet been compiled.) This shows an increase of 54 per cent. in tonnage carried, or 24 per cent. less than the increase of wheel failures. If the comparison is to be made on the basis of car mileage, figures for the whole country are not available for later than 1910; but taking those from four representative railways, the Pennsylvania, Union Pacific, Illinois Central and Chicago, Rock Island & Pacific, we find that the empty car mileage increased 44 per cent. and the loaded car mileage 58 per cent. in the eleven years covered by the report. At the same time, the car loads increased 9 per cent. From the operating standpoint, then, wheel failures have increased faster than ton mileage, car mileage or car loading. If wheel failures had increased at the same rate as loaded car mileage the failures for 1911 and 1912 would have been 1,597 instead of 1,800, which is an increase of 12.7 per cent. above what would have been a normal increase; and it seems fair to attribute a part, at least, of this to the 9 per cent. increase of average wheel loads.

THE Pennsylvania Railroad has decided to electrify its line from Broad street, Philadelphia, west, 20 miles, to Paoli—a beginning which probably means, ultimately, a very extensive change, for the company's lines centering at Broad street extend in five different directions; to New York, to Reading, to Pittsburgh, to West Chester and to Washington. It is about two years since a committee was appointed from among the officers of the several departments of the road to consider the subject of the enlargement of the facilities in Philadelphia and some of the preliminary details were decided on some months ago, including the remodeling and enlargement of the North Philadelphia station, and the construction of eight main tracks at that point, a "detail" which will cost $1,000,000. Now, the board of directors has authorized the electrification of the main line, as above noted, for suburban passenger traffic. No further

details than the mere fact of the decision have been given out, because none have been decided. The problem is an exceedingly complicated one, involving, as it does, as great a provision for future growth and traffic as possible, in which even an outlook of twenty years ahead is too short a time to be considered. The question must be viewed not only in the light of the immediate and coming needs of the twenty miles to be corrected, but as to its influence on and inter-relationship with the other developments suggested. For these reasons the system to be used has not yet been decided. While it is expected that this particular improvement may be completed in 1914, it is, to a great extent, dependent upon the expedition with which negotiations can be carried on with the city as to the land that will be required and the acquisition of the property on Filbert street, which bounds the present terminal on the north, all of which will take considerable time. Involved in the scheme is some six-track improvement work, which, with the widening of the Broad street station, will afford the much needed terminal relief. Of all of this work, the first step to be undertaken will be, as previously announced, the construction of an eight track station at North Philadelphia coupled with the increased tracking of that section of the road, the Connecting Railway, which includes a new arch bridge across the Schuylkill river at Girard avenue.

SCIENTIFIC MANAGEMENT.

MORE meetings or forums should be held throughout the country like that of the Western Economic Society at Chicago last week, when for two days the subject of scientific management was discussed from the standpoints of the employer, the employee, the engineer and the social worker. As we have said repeatedly in the past, there is undoubtedly much merit in the principles of scientific management, but the application of these principles is so little understood, and their introduction requires so much careful and painstaking investigation, as well as a radical change in the relation of employer and employee, and their attitude toward each other, that it will require years—possibly a generation or two—before they can with success be generally introduced; and this is particularly true in those fields where they are not so susceptible of application as in certain classes of manufacturing establishments and machine shops. Meanwhile it will be necessary to conduct a vigorous and systematic campaign of education to bring both the employer and employee to see their value and to co-operate with each other in their introduction. And this is a most vital point, for unless the principles are rightly applied, much harm may be done, and in the words of one of the speakers at the conference, "Scientific management may become a nuisance."

One of the most effective addresses was that by Morris L. Cooke, director of public works of Philadelphia—and it was effective because of the big-hearted, broad-minded conception of scientific management which he is striving to work out as a public officer. He spoke of scientific management as a means of ameliorating the condition of the toiling classes, and this thought was emphasized time and time again during the conference by those who have been notably successful in using it. Attention was directed to the fact that although F. W. Taylor has developed and used the principles of scientific management for many years, and has presented papers on his work before our great engineering societies, still, until two years ago, he was hardly known, even in his own city. At that time the awakening of the public to the necessity of the conservation of energy and material had made the time ripe for an announcement concerning it. Louis D. Brandeis, in the hearing of the freight rate advance cases, startled the country with it, and in a way made unfair use of it, for industrial organizations, schools, the management of the home, and almost everything else done by human agency was just as inefficient from the standpoint of scientific management as were the railways—and in many cases probably more so.

It was, therefore, of special interest to hear a man like Mr. Cooke, who had worked with Mr. Taylor, say that in spite of the fact that many thousand men were working under scientific management the number was so relatively small that it might truthfully be said that almost 100 per cent. were not working under it, and that probably as much as two generations would be required to educate the public to adopt it generally.

From the statements of the representatives of the labor interests who were present, and especially of John P. Frey, editor of the *International Moulders Journal*, whose arguments and personality made a strong impression on those in attendance, it is evident that organized labor is bitterly opposed to the new methods and that much hard and patient work must be done to bring its representatives to see that the men will not be imposed upon, but that as one speaker said: "There is a vast difference between strenuosity and efficiency." And it must be apparent to any close observer that just as piece-work and bonus systems have failed of securing the best results where they have been abused by the employer, so any other system must fail if the men are not given a square deal.

One thing is going to delay the general introduction of the new principles for many years, and that is that so few men are actually fitted to introduce them and that so many fakirs have rushed into the field. Carl Barth expressed it well when he said that it often made him so heartsick that he sometimes felt like giving the whole thing up. To develop a trained leader in this field should require at least as much time as to train a first class physician, and yet look at the number of so-called "efficiency experts" who have sprung up like mushrooms in a night! Near the close of the session one factory manager who had introduced scientific management with good results asked if there was no way in which these fakirs could be driven from the field; no one could suggest a solution of the problem.

The last session on Saturday afternoon was in the nature of a summary and a questionaire, and in the absence of F. W. Taylor, who was detained because of illness, F. B. Gilbreth and Morris L. Cooke answered the questions which had been presented. It proved to be a most interesting session and because of the ability and thorough training of these two gentlemen and the evident sincerity of their efforts in trying to better the condition of the laboring classes, produced a profound impression on those present which was not even dissipated by a fiery and equally sincere attack on scientific management by the well-known anarchist, Emma Goldman, which, by the way, gave a good idea of the patient effort which it will be necessary to exert in dealing with organized labor along these lines. In this connection it may be of interest to know that Mr. Gilbreth has published a book* entitled "Primer of Scientific Management" which is based on answers to questions and objections which have been made by workmen in criticizing scientific management.

Another notable incident during the meetings was an address on "The Selection of Employees" by Dr. Katherine M. Blackford, which briefly sketched the study that is made of each man's personality before he is hired by the Rumely Company, in order that he may be assigned to the work for which he is best suited. Among the nine characteristics which are examined is that of color. As an illustration Dr. Blackford noted that on the Pittsburgh & Lake Erie the chief despatcher was a brunette, and upon inquiry found that blondes were seldom employed in that capacity, the present staff on that road being composed entirely of brunettes, except for one red head. Other characteristics examined are size; shape of profile of head; structure; consistency; expression as shown by voice, gesture, walk, clothing, etc.; proportion as to energy, vitality and endurance; experience; and texture or quality, i. e., fine or coarse. Men should be so selected as to harmonize with the job and the characteristics of the boss. Necessarily Dr. Blackford could only cover the subject superficially, although a speaker at a later session mentioned a book on the subject by Dr. Blackford which may shortly be issued. Altogether the meeting proved to be a great success, and the example of the Western Economic Society should be followed by similar organizations in other parts of the country.

GOVERNMENT REGULATION AND RAILROAD STANDARDS.

STATE regulation, as related to railroad service, implies an improvement of that service. It is on the expectation of more completely satisfying the reasonable demands of the public that legislators are induced to adopt regulating laws. Even the grafting legislator, when he prepares a "strike" bill, means to recommend something that will at least seem to better the service. If railroad service had always been first class, everywhere, the legislatures, no doubt, would have turned their attention to other things.

When the federal government, in 1893, by an Act which only clumsily fitted the situation, standardized the Janney car coupler and the Westinghouse air brake it improved railroad service; this by compelling dilatory companies to catch up with the more enterprising. The standardizing was accomplished indirectly, for the statute did not specify either of those two devices; but it was effective standardization, nevertheless. That law was justified only because it aimed to make the best practice the universal practice. The same may be said of the boiler inspection law of 1911. We are not prepared to say that the boiler inspectors are worth what they are costing—$200,000 a year—but no one can find fault with the fundamental principle of the law.

But a government, in following railroad standards, is not always so sure of doing the right thing. The question of what is the best railroad practice is not always found to be so clearly settled in advance. In Connecticut, last week, the engineer of the State Public Utilities Commission, reporting on a collision which occurred at Warehouse Point, January 10, recommended that enclosed disk signals be superseded by semaphores. This officer of the state would be able, no doubt, to quote the opinion of competent railway officers in support of this view. It would not be the first time that a state commission has gone too far, justifying itself in that way. But what we wish to point out is that the trouble at Warehouse Point was not ascribed to the type of signal. The report makes no suggestion that a semaphore would have been any better. The collision occurred at night, and at night semaphores and disks, for every practical purpose, are all the same. It may be admitted that semaphores are very generally favored by signal engineers; but this opinion is not universal, and large numbers of disk signals still give satisfactory service; why should the state lend its influence in favor of throwing away all the automatic signals on 60 miles of road? Quite likely the New Haven company could spend its money to better advantage on some section of road which has no block signals at all. No good purpose would be served, probably, by requiring state officers, reporting on accidents, to refrain entirely from making general observations concerning safety; but, surely, in going outside the subject in hand it is desirable to keep on very solid ground. (The real causes of this collision are given in another column.)

Another case where a government officer has acted on railroad officers' standards and in so doing has missed his point, is that of the collision at Dresden, Ohio, December 3, last, when 11 persons were killed. The inspector of the Interstate Commerce Commission, reporting on this case, says that the time interval between trains (passenger trains) should be more than five minutes. A passenger train was unexpectedly stopped, because of trouble with air brakes, and the flagman did not have time to get back far. This view is correct, if the time interval is to be used. If the interval were to be made 10 minutes or more, the government could get the indorsement of many railroad rule books. If it were made 20 or 30 minutes, universally, it could be plausibly recommended as a safe rule, with some exceptions. (The present recommendation does not say how much greater the time interval should be.) But the best railroad standard demands the use of the space interval; the time interval has been proved inadequate. Governmental authorities cannot fairly approve the time interval, simply because it has railroad approval. To merely lengthen the time interval is not making rational use of the lesson of those eleven deaths. The Interstate Commerce Commission has repeatedly recommended the use of the space interval system, because no other system is adequate; in issuing this report the commission ignores its own former declarations. The justification of governmental action in the matter of air brakes was that the railroads did not properly live up to their own best standards; the same consideration applies in the case of the block system.

In passing, it may be noted that the inspector follows another bad example, set by some railroad men, when he refers to the failure of the air pipe on the engine as one of the chief causes of the Dresden collision. That failure was not a cause at all; it was only the occasion. It caused the stoppage of the train; but what kind of a theory is that which makes it unsafe to stop a train? Where is the superintendent who is willing to ride over his own division unless he can feel perfectly safe in stopping at any place, at any time?

In one of these two reports, we see, the inspector went too far, and in the other not far enough; and with reputable railroad backing in both cases. In a third case, a collision at Bowerston, Ohio, December 13, the inspector of the Interstate Commerce Commission, attacking the flagging rule of the Pennsylvania Lines, sets out to say what a perfect flagging rule should be; but he stops at the end of the sixth line! (We shall not complain at brevity, *per se*, for those who go farther may fare worse.) The form criticised is that of the well known Rule 99, of the American Railway Association, which leaves everything to the judgment of the flagman. Says the report: "When considered in connection with safety in the movement of trains, the flagging rule is of paramount importance, and its requirements should be as absolute as it is possible to make them. It should be incapable of more than one construction, entirely free from uncertainty or indefiniteness, leaving no room for error of judgment by a flagman when such error may prove disastrous."

Here is a case where a state officer may well pause, for the rules of the railroad companies are of all sorts. If the United States government, or any power on earth, could frame a workable flagging rule, railroad officers surely would hail it with joy. But everybody knows that the beautiful ideal here outlined by Mr. Belnap has been striven after by innumerable committees, during the past 30 years, and that they have all given up in despair. A rule entirely free from indefiniteness, leaving no room for error of judgment, would either be (*a*) so long that half the brakemen could not be taught to comprehend it, or (*b*) would necessitate the employment of a half dozen flagmen on every train, and cause very frequent delays, to say nothing of the cost and the uncertainties of constant dependence on torpedoes and fusees. The conclusion of the American Railway Association, after years of discussion, that the flagman must be trusted to use his judgment, is a virtual confession that a complete and workable flagging rule cannot be made. The Association leaves every road free to amplify the rule to any extent desired, and many books do still specify distances and other details; but where is the superintendent who is satisfied with his rule, except under favorable circumstances and light traffic? This is not the first time that governmental authorities have attempted to give us a satisfactory flagging rule. The Louisiana State Railroad Commission recently prescribed a long one. But with the best rule ever written, the railroad officer who aims at a reasonable degree of safety—we will not say perfect safety—still finds himself left with many conditions not satisfactorily provided against; and he turns to the block system as the only escape from an impossible situation.

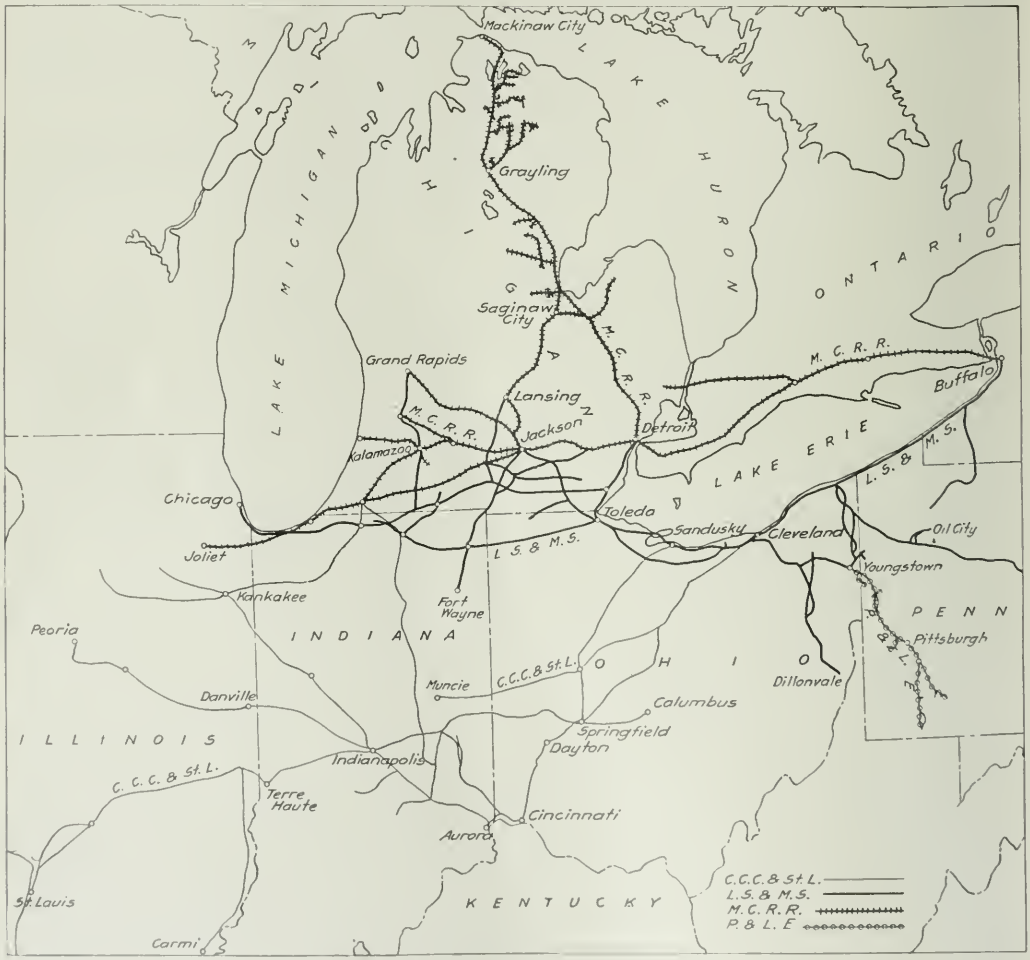
As we have already intimated, government can sometimes promote good railroading by prescribing the best standards of practice. This last report contains some salutary truths, forcibly expressed. But experience has taught that there is danger both of going too far and of not going far enough. When it comes to formulating a satisfactory flagging rule for general adoption there is a thirty years' history that cannot be ignored.

LAKE SHORE AND MICHIGAN SOUTHERN.

THE results of operation of the Lake Shore & Michigan Southern in 1912 are like a renewed pledge that earnings wisely turned back into a railroad property will, under good management, bear fruit in a reduction in *transportation* costs. In 1912 the cost of transportation; exclusive of any expenditures on the maintenance of property or equipment, per revenue ton mile moved was less by over 7 per cent. than in 1911. The Lake Shore carried the greatest amount of traffic in its history and earned a total from operation of $54,284,000, or 12.25 per cent. more than in 1911. Despite liberal increases in maintenance expenditures, the company had an operating income of $17,093,000 in 1912, as against $14,212,000 in 1911.

In a good many ways the Lake Shore & Michigan Southern is comparable to no other railroad in the United States. In natural advantages it is second to none. The company operates 1,872 miles of road, by far the greater part of which is main line, with almost no grades, through a territory in which fuel is cheap and where the nature of the traffic permits of very heavy car and train loading and of a comparatively small percentage of empty car mileage. These natural advantages account in part for the heavy train load, low operating ratio and great earning capacity of the Lake Shore when compared with other roads; but a decrease of 7 per cent. in transportation costs in 1912 as compared with 1911, in the face of an increase in labor costs, is the result of a policy of betterment from earnings that has been one of the characteristics of the management of the Lake Shore for a good many years.

A heavy expenditure for betterment of railroad property will often appear to have little, if any, direct effect in reducing transportation costs as long as the volume of traffic remains the same. When, however, the volume of traffic shows a material increase, as was the case in 1912 on the Lake Shore, the real advantages of former expenditures become apparent. In 1912 the Lake Shore carried 41,081,000 tons of revenue freight, which is more by 6,194,000 than was carried in 1911. The average haul was 167 miles in each year, so that the ton mileage totaled 6,874,000,000 in 1912, as against 5,841,000,000 in 1911. The Lake Shore has a freight traffic density of 3,813,000 tons carried one mile per mile of road. In addition to this quite remarkable freight density, the road



The Three Principal New York Central Lines West of Buffalo.

carried 402,000 revenue passengers one mile per mile of road.

Of the total 41,082,000 tons of freight, bituminous coal furnished 10,807,000 tons; ores, 5,621,000 tons; and stone, sand and like articles, 4,048,000 tons. The increase in the tonnage of these three commodities was for bituminous coal, 1,695,000 tons, for ores, 917,000 tons; and for stone, etc., 890,000 tons. The Lake Shore furnishes a good example of how profitable it is on most roads to carry a large proportion of low grade freight which, although it takes a low ton mile rate, permits of large economies in cost of handling. The Lake Shore can almost be compared with the Delaware, Lackawanna & Western as a net revenue earner; but whereas the Lackawanna gets an average ton mile rate of well over 7 mills per ton per mile, the Lake Shore gets but 5.29 mills. This was the average in 1912 and was only slightly lower than the 1911 average.

The operating ratio in 1912 was 65.46 per cent. as compared with 67.09 per cent. in 1911. There was spent for maintenance of way and structures 12 per cent. of total operating revenues in 1912 and 12.79 per cent. in 1911; for maintenance of equipment, 17.11 per cent. in 1912 and 16.69 per cent. in 1911; for traffic expenses, 1.77 per cent. in 1912 and 2.12 per cent. in 1911; and for general expenses, 1.79 per cent. in 1912 and 1.91 per cent. in 1911. Transportation expenses consumed but 32.79 per cent. of total operating revenues in 1912, as against 33.58 per cent. in 1911.

A good indication of how the company was able to reduce its transportation costs by 7 per cent. is afforded by a comparison of equipment mileage and car and train loading figures. The train load of revenue freight in 1912 was 693 tons, as against 635 tons in 1911, and the total train load, including company freight, which is an even better criterion of operating conditions, was 731 tons in 1912, as against 666 tons in 1911. Another way of stating the same thing is that while ton mileage increased by over 17 per cent., freight train mileage increased only 7.81 per cent., and freight locomotive mileage increased less than 7 per cent. With an increase in passengers carried one mile of a little over 1 per cent., the mileage of passenger locomotives showed a decrease, which although slight in itself is remarkable, in that the majority of other roads showed increases in 1912 in passenger train mileage quite out of proportion to the increases in passengers carried one mile.

Nearly all of the common stock of the Lake Shore & Michigan Southern is owned by the New York Central & Hudson River and deposited under Lake Shore collateral trust bonds. The 18 per cent. dividend, amounting to $8,904,000, which was paid by the Lake Shore both in 1912 and 1911, figures as "other income" on the New York Central's income statement. Whereas, however, the parent company had less than 2 per cent. surplus on its stock after paying 6 per cent. dividends to its stockholders, the Lake Shore had a surplus in 1912 of $7,584,000, or 15 per cent., on its own stock, and this surplus is properly an equity for New York Central stockholders.

In 1912 the Lake Shore spent $3,239,000 for additions and betterments and added net to its equipment $2,178,000, although as a matter of bookkeeping it credited road and equipment account with $1,506,000 for equipment trust installments paid in 1907, 1910 and 1912. The Lake Shore's balance sheet makes a very strong showing. With working liabilities amounting to $18,916,000, there are working assets of $134,332,000. The very strength of the showing possibly indicates that at no very distant future time the company hopes and expects to do some permanent financing. Included in working liabilities are $11,648,000 one-year notes, part of which fell due on February 24 of this year and part on March 2. The notes were temporarily refinanced by the sale last week to J. P. Morgan & Company of $12,000,000 one-year 4½ per cent. notes. The Lake Shore's credit is so high that it can get short term loans on very reasonable terms and can therefore well afford to wait for permanent financing until the bond market is to the liking of its bankers. One-year notes, however, are probably only a temporary expedient even for a road with credit like the Lake Shore. Included in working assets are $107,119,000 marketable securities and $9,329,000 loans and bills receivable from subsidiary or affiliated companies. Cash on hand at the end of 1912 amounted to $6,235,000.

The following table shows the principal figures of operation in 1912 as compared with 1911:

	1912.	1911.
Average mileage operated	1,872	1,775
Freight revenue	$36,371,244	$31,101,335
Passenger revenue	11,835,199	11,350,096
Total operating revenues	54,283,617	48,360,997
Maint. of way and structures	6,516,212	6,187,623
Maint. of equipment	9,283,833	8,069,393
Traffic expenses	961,762	1,026,317
Transportation expenses	17,797,334	16,245,052
General expenses	975,504	924,489
Total operating expenses	35,534,644	32,443,875
Taxes	1,771,098	1,673,940
Operating income	17,093,279	14,212,105
Gross income	27,442,055	24,496,694
Net income	16,584,384	14,268,365
Dividends	9,000,000	9,000,000
Surplus	7,584,384	5,269,365

MICHIGAN CENTRAL.

LIKE the Lake Shore & Michigan Southern, although, of course, on a smaller scale, the Michigan Central had a substantially larger surplus after the payment of dividends in 1912 than in 1911. After the payment of 6 per cent. dividends in 1912 there was a surplus of $1,602,000, or $610,000 more than the surplus in 1911 after the payment of the same dividends. As in the case of the Lake Shore, this surplus forms in large part an equity for stockholders of the New York Central & Hudson River.

The Michigan Central operates 1,817 miles of road. The greater part of its stock is owned by the New York Central & Hudson River, and its lines form the northern part of the New York Central Lines west of Buffalo. While its main line between Buffalo and Chicago has a heavy density of both passengers and freight, a considerable portion of its mileage runs up into the State of Michigan, where traffic is comparatively light. The average ton miles per mile of road amounted to 1,794,000 in 1912, and to 1,701,000 in 1911, and passenger miles per mile of road amounted to 233,000 in 1912, and 220,000 in 1911. No such large preponderances of total tonnage carried is bituminous coal, ores and stone on the Michigan Central as on the Lake Shore. The total tonnage of revenue freight carried in 1912 was 21,100,000, as against 18,729,000 in 1911, and of this total tonnage in 1912, 3,893,000 tons were bituminous coal and 2,105,000 tons were stone, sand and like articles. The bituminous coal tonnage showed an increase over 1911 of 601,000 tons, and the stone of 318,000 tons.

The M. C. carries a quite large tonnage of products of agriculture, grain alone furnishing, in 1912, 1,235,000 tons. A large tonnage of manufactures is carried consisting of a great variety of articles, the movement of the greater number of which is, of course, intimately connected with the prosperity of the country served. Manufactures other than those usually listed separately, such as petroleum, sugar, iron, agricultural implements, household goods, etc., amounted to 2,672,000 tons in 1912, an increase over 1911 of 356,000 tons. The generally prosperous condition of the country is not reflected, however, in increased local passenger business. The total number of interline passengers amounted to 1,214,000, an increase of 150,000 over 1911; but local passengers decreased in number, as did also commutation passengers, so that the total number of revenue passengers carried amounted in 1912 to 6,000,000, or only about 1 per cent. more than was carried in 1911.

Total operating revenues amounted to $32,912,000 in 1912, an increase of $2,747,000 over 1911. Operating expenses did not mount up in quite the same proportion as revenues, so that the operating ratio in 1912 was 69.91, as compared with 70.76 in 1911. Total expenses amounted to $23,009,000, an increase over the

previous year of $1,663,000. The following table shows the ratio of each class of expenses to total operating revenue:

	1912.	1911.
Maintenance of way and structures	11.03	11.77
Maintenance of equipment	14.32	14.58
Traffic expenses	2.32	2.60
Transportation expenses	40.45	39.94
General expenses	1.79	1.87

Only very slightly more was spent for maintenance of way in 1912 than in 1911, and this increase was entirely accounted for by larger track forces at higher wages. Total maintenance of way cost $3,630,000 in 1912, which is $81,000 more than was spent in 1911. This includes the expenditure for roadway and track, which is largely made up of the cost of track labor, and amounted in 1912 to $1,411,000, as against $1,177,000 in 1911. The annual report does not make it entirely clear as to why so much smaller sums are shown as having been spent for ties and rails. In 1912 the expenditure for ties was $595,000, or $234.000 less than in 1911, and the expenditure for rails was $86,000, or $133,000 less than in 1911. President Brown, in his comments, mentions the decreased prices in rails and ties. The detailed figures accompanying Mr. Brown's report show that a greater tonnage of 100-lb. rail was laid in 1912 than in 1911, and that more ties were put in track in 1912 than in 1911. The average price per ton of rail is given at 31.17 in 1912 and at 30.22 in 1911, and the average price of ties at distributing points at 71 cents in 1912 and 68 cents in 1911.

Maintenance of equipment cost $4,712,000 in 1912, or $312,000 more than in 1911; and although steam locomotives averaged 34,152 miles apiece in 1912, as against 32,588 miles in 1911, repairs per locomotive mile cost 7.08 cents in 1912 and 6.11 cents in 1911.

The Michigan Central, with its higher grade traffic, has no such heavy train load as the Lake Shore, but with the increases in tonnage of various commodities was able to show a revenue train load of 455 tons in 1912, as compared with 424 tons in 1911 The gain in train loading was entirely in revenue freight, company freight averaging one ton less per train. Not only did car loading increase (from 15.71 tons per loaded car in 1911 to 16.52 tons in 1912), but there was a notable reduction in empty car mileage. Total freight car mileage amounted to 271,478,000 miles in 1912, and of this total mileage, 194,513,000 was made by loaded cars, an increase over 1911 of 692,000 car miles, and 70,202,000 was made by empty cars, a decrease of 10,513,000 car miles. The very considerably heavier ton mileage was handled with 8,127,000 freight locomotive miles, which is less by 69,000 than the locomotive mileage in 1911.

The balance sheet of the Michigan Central at the end of 1912 showed cash on hand of $3,201,000, comparing with $3,311,000 at the end of 1911. Loans and bills payable remained the same throughout the year, namely, $4,500,000. The Michigan Central is not a heavily capitalized property, and although it used its credit to help finance the Detroit river tunnels and to guarantee the principal and interest of Canada Southern 50-year 5 per cent. bonds, of which $22,500,000 have been issued, it should under favorable bond market conditions not have any trouble in permanently financing its loans and bills payable.

The following table shows the principal figures for operation in 1912, as compared with 1911:

	1912.	1911.
Average mileage operated	1,817	1,817
Freight revenue	$21,218,205	$19,538,604
Passenger revenue	8,250,336	7,607,052
Total operating revenues	32,580,853	29,872,566
Maint. of way and structures	3,629,732	3,549,205
Maint. of equipment	4,711,843	4,400,291
Traffic expenses	764,733	783,599
Transportation expenses	13,313,059	12,049,103
General expenses	5,859,388	563,552
Total operating expenses	23,008,756	21,345,755
Taxes	1,366,985	1,322,621
Operating income	8,564,111	7,505,023
Gross income	9,674,774	8,675,980
Net income	2,726,333	2,116,364
Dividends	1,124,280	1,124,280
Surplus	1,602,053	992,084

CLEVELAND, CINCINNATI, CHICAGO & ST. LOUIS.

COINCIDING as it does with the demands of the firemen for higher wages now being heard before the arbitration committee, the publication of the annual report of the Cleveland, Cincinnati, Chicago & St. Louis for the calendar year 1912 gives a bit of unpremeditated evidence that is rather interesting. Total expenses on the Big Four were $1,674,000 more in 1912 than in 1911. Of this increase, $1,049,000 was due to increases in the payrolls in the maintenance and transportation departments.

The Big Four did a record business in 1912. Its total earnings amounted to $32,714,000, an increase over 1911 of $2,282,000. The road (2,012 miles operated) carried 4,084,231,000 revenue ton miles, an increase over 1911 of 458,864,000. Passenger revenue and business were somewhat smaller in 1912 than in 1911, but only about a quarter of the total operating revenues of the C. C. C. & St. L. are furnished by passenger revenue. With the increases in traffic handled, an increase of $1,674,000 in expenses is not excessive. The operating ratio on the Big Four is high, but was slightly less in 1912 than in 1911. It was 74.46 per cent. last year and 74.55 per cent. the year before. The increase in expenses, due to larger payments to employees, seems out of proportion to the total increase in expenses.

The C. C. C. & St. L. is controlled by the New York Central & Hudson River. It competes with the Pennsylvania Lines West and, as will be seen from the map published with the comments on the Lake Shore & Michigan Southern's annual report, its lines have somewhat the characteristics of a network. It is probably largely due to the fact that it has so much larger proportion of what may be called branch line mileage that its operating ratio is so much higher than that of the Lake Shore.

The Big Four carries a large proportion of low grade traffic, and while it gets a low average ton mile rate—5.43 mills in 1912—this is true also of the Lake Shore. Of the total tonnage carried, which amounted in 1912 to 25,817,000 tons, 11,139,000 tons were bituminous coal and 1,548,000 tons were stone, sand and like articles.

The class of expenses that seems high when compared with the Lake Shore transportation expenses. The following table shows the per cent. of total operating revenue that was consumed by each class of operating expense in the years 1912 and 1911:

	1912.	1911.
Maintenance of way and structures	11.97	11.07
Maintenance of equipment	17.95	17.81
Traffic expenses	2.63	3.00
Transportation expenses	39.84	40.40
General expenses	2.07	2.27

The revenue trainload on the Big Four increased from an average of 445 tons in 1911 to 474 tons in 1912. Car loading was better by about 5 per cent. The average number of tons of all freight per loaded car was 21.3 in 1912, and 20.2 in 1911. While there was a large decrease in empty mileage, there was an even larger increase in loaded car mileage, so that notwithstanding the heavier train load, the mileage of freight trains increased from 8,105,000 in 1911 to 8,580,000 in 1912. Loaded freight car mileage last year totaled 201,578,000, an increase over 1911 of 11,877,000; and empty freight car mileage amounted to 79,329,000 in 1912, a decrease from 1911 of 10,714,000.

The Big Four is not a heavily capitalized road. The total stock and bonds outstanding average about $72,400 per mile of road operated; but it is paying dividends only on its preferred stock, which totals $10,000,000, calling for $500,000 in dividends. There is $47,056,000 common stock outstanding which is receiving no dividends. After the payment of 5 per cent. on its preferred, the C. C. C. & St. L. had a surplus in 1912 of $1,844,000, as against $1,302,000, the corresponding surplus in 1911. The company readjusted through its profit and loss account its general balance sheet statement so as to correspond to the requirements of the Interstate Commerce Commission, and in so doing debited profit and loss with $1,385,000 for property abandoned from 1905 to 1912 inclusive. The company spent and charged

to capital account $1,395,000 for additions and betterments to roadway and structures and $2,782,000 for new equipment, crediting the equipment account, however, with $1,129,000 for equipment trust instalments paid in 1907, 1910 and 1912, and for the balance in the equipment replacement fund. At the end of 1912 the company had on hand $3,537,000 cash, with total working assets of $10,573,000, and working liabilities of $8,235,000, of which $2,745,000 was loans and bills payable.

The following table shows the principal figures for operation in 1911 and 1912:

	1912.	1911.
Average mileage operated	2,012	2,012
Freight revenue	$22,168,002	$19,933,296
Passenger revenue	7,778,136	7,819,255
Total operating revenues	32,714,238	30,431,915
Maint. of way and structures	3,915,421	3,370,476
Maint. of equipment	5,872,422	5,418,645
Traffic expenses	860,666	912,751
Transportation expenses	13,033,333	12,293,691
General expenses	677,902	690,144
Total operating expenses	24,359,745	22,685,708
Taxes	1,190,243	1,062,512
Operating income	7,135,769	6,637,608
Gross income	7,892,577	7,345,340
Net income	2,344,352	1,801,616
Dividends	500,000	500,000
Surplus	1,844,352	1,301,616

NEW BOOKS.

Car Builders' Dictionary. 1912 (Seventh) Edition. Compiled and edited for the Master Car Builders' Association by Roy V. Wright, managing editor of the *Railway Age Gazette* and editor of the *American Engineer*, assisted by Andrew C. Loudon. Illustrated. 953 pages, 9 in. x 12 in. Published by the Simmons-Boardman Publishing Company, New York, and distributed by the McGraw-Hill Book Company, 239 West 39th street, New York. Price, leather bound, $6; cloth bound, $4.

This dictionary is too well known to require any description. The new edition cannot be properly designated as a revision of the last edition, since it is to all intents and purposes an entirely new book. The progress in car design and construction has been so great during the past three years that a large part of the illustrated section of the 1909 edition was found to be obsolete.

The designs illustrated in the present edition have been most carefully selected and represent approved modern practice in every particular. The smaller and lighter equipment has by no means been overlooked, but recent improved designs have been chosen as examples. The utmost care has been used to make the book complete and to cover the full range of rolling stock. This has resulted in a material increase in the size of the volume, in spite of the fact that the machine tool section given in the previous edition has been eliminated. The drawings are fully dimensioned, and all of the more important details are shown separately. Cross references giving the location of the drawings of associated parts accompany many of the captions and are one of the new features which will be fully appreciated. One of the most valuable parts of the book is that containing the standards of the Master Car Builders' Association, which are given complete, and in each case have been redrawn on a larger scale, making them much more legible than those furnished by the association.

In the definition section, all of the new terms that have come in general use during the past few years have been included, and their meaning made clear. Definitions of other terms have been completely revised, and in many cases entirely reworded. Among the new features are the complete details and specifications for postal cars as required by the United States government. The section on electric motor cars has been greatly extended, and an entirely new section on wrecking equipment and tools has been added. Typographically the book presents a much more pleasing appearance than former editions, and the reproduction of the photographs in the book is particularly well executed.

Letters to the Editor.

JAMES J. HILL'S STATISTICS.

Baltimore, Md., March 15, 1913.

To the Editor of the Railway Age Gazette:

Will you give me space to correct a momentary aberration?

In a letter which you were good enough to publish for me in your issue of March 14, in relation to Mr. Cunningham's criticism of James J. Hill's statistics, I made the statement that "all incomes are from 50 to more than 100 per cent. lower in Europe than here." Obviously this is an incorrect statement. What I intended to say was that "all incomes are from 50 to 75 per cent. lower in Europe than here." I may add that the statement has received very recent confirmation in so far as it applies to Germany in a statement by Dr. Gustav Stresemann in the *Manufacturers Record* of February 27. Dr. Stresemann says "the purchasing power of the dollar is scarce more than 2 to 2½ marks." This would make the scale for Germany from about 40 to 53 per cent. lower than income and prices in the United States. As Germany pays higher wages than the majority of the countries on the continent of Europe, it will be seen that my statement, as I intended to make it, is fully supported by quite recent evidence from Germany.

M. B. Wild,
Statistician, Baltimore & Ohio.

DEFLECTABLE HEADLIGHT.

Chicago, Ill., March 3, 1913.

To the Editor of the Railway Age Gazette:

In your issue of February 28, 1913, W. F. Schaphorst sets forth the need of a deflectable headlight to illuminate the right of way on curves. Such a device was developed on the Missouri, Kansas & Texas, two years ago by J. R. Pratt, electrician, in which the parabolic reflector is revolved through a slight angle about a vertical axis passing through the focal center of the reflector. The reflector is operated by the engineer in the cab pulling a small lever which connects through a system of rods to the headlight. The headlight casing itself is in no way affected, the parabolic reflector shell alone moving. Since the reflector is revolved about its own focal center, there will be no change in the effectiveness of the beam of light as deflected on rounding a curve.

This design has been used to some extent on the M. K. & T., and is very popular with the locomotive engineers themselves.

Edward Wray,
Publisher, *Railway Electrical Engineer.*

MORE PUBLICITY.

Chicago, March 8, 1913.

To the Editor of the Railway Age Gazette:

Railroad men quite generally appreciate the value of the right sort of publicity. It has often seemed to me that they have long overlooked an opportunity for effective publicity, especially in the smaller communities. Any traveler who has had occasion to wait for a train in a station situated in a town of 5,000 people or less has probably read and reread the few flyspecked and age-worn public notices that adorn the walls of the waiting room. Occasionally a picture may be found in the better class of stations, and at rare intervals some special advertising matter may be in evidence. As a general proposition, however, the traveler who has no book or paper to read is confronted with the necessity of passing the time before the arrival of his train, in idleness.

There are four classes of people that may be found in the waiting room at such a time, the loafer down to see the train go through; the townspeople who are there to meet friends; the professional traveler, and the casual traveler. At a time such as this in a station of the character previously indicated, an oppor-

tunity is presented to the railroad company to make a specific advertising appeal to at least three of the four groups previously suggested. The value of such an opportunity has been recognized in other lines of business. The practice of calling the attention of the customer to particular features that may be of mutual interest is universally followed in the better classes of merchandising establishments. Particularly, increasing emphasis is placed upon the character of the service offered.

It would seem that a weekly bulletin service would constitute a comparatively inexpensive, but entirely adequate, method of utilizing this opportunity. An attractively designed and printed bulletin placed upon the wall of the waiting room upon which appeared a number of items of general interest pointedly stated could be made a most effective factor in the interest of the right kind of publicity. Upon this bulletin attention could be called to improvements in service, records in safety, traffic handled, expenditures to make facilities more adequate and other features pertaining to the railroad company which would be of interest and a matter of local pride to the people of each community. Such a bulletin service could also be made of value in calling attention to sectional needs in an agricultural, commercial and industrial way. It would also afford an opportunity for pressing home to the reader each week that the business of the company was to serve his interests in every possible manner. A high standard of service is, of course, the first and most essential factor in the relation of the railroad to the public. A persistent policy of tactfully calling attention to various features of the service is equally important. Persistent repetition of even self-evident facts has a definite advertising value. A bulletin service of the type suggested would afford a convenient and comparatively inexpensive method of accomplishing this result.

The expense connected with such a service would be very nominal as compared with many forms of advertising which are very commonly employed. The three items of expense would be, a writer to produce the copy—this is not office boy work—the expense of printing the bulletins and the expense incident to the distribution of them.

In summary there are three essential considerations with reference to this suggestion: (1) a large number of people in a receptive mood, (2) an abundance of interest and valuable data for company customers, (3) an advertising medium that has the merit of comparatively slight expense.

Such a service would be welcome to at least one casual traveler.

George A. Clark.

PRIZES FOR ALERTNESS.

Buffalo, N. Y., March 18, 1913.

To the Editor of the Railway Age Gazette:

I have read with much interest your article, in the last issue, on the order which has been promulgated on the Pennsylvania Railroad instructing passenger trainmen to freely convey information to passengers; and particularly with your suggestion that where this information has to come through the office of the despatcher everybody interested ought to be on the alert to receive and give out information in the shortest possible time.

Why would it not be a good plan to give "merits" for quick action in matters of this kind? This could be done in the same way that some of the roads, where the Brown system of discipline is in effect, give station men and others commendatory notices when they discover a broken wheel or a loose brake-beam. Or, to make the matter more business-like, why not offer a definite prize, perhaps only a small one, to be awarded every six months to the despatcher or station agent or conductor, who makes the best showing of alertness in this matter?

I recall that on some road in Indiana, I think it was the Wabash, some time ago mention was made of how, by a little friendly rivalry between crews, the time taken to gather a wreck and start out a derrick car had been very greatly reduced. If men take pride in thus clearing the road when it is obstructed, why can we not also school ourselves to take pride in clearing up passengers' troubles, when they are anxious because of a blockade on the line?

G. H. M.

SEE AMERICA FIRST?

Philadelphia, January 20, 1913.

To the Editor of the Railway Age Gazette:

Your request, some time since, for my views on the subject of "See America First," has not been overlooked, but this is my first opportunity.

Undoubtedly the novelty of a sea voyage and the sight of foreign lands is a strong attraction to the would-be traveler, with money to spend, for his first trip; and it is not so strange that his patriotism should succumb, especially after hearing what his more experienced friends can tell him of comparative costs. But just at this point patriotism succumbs a second and many more times. Europe affords many districts where one can find more than enough to interest him for all summer, with but a few miles of railroading, and almost every night one may rest comfortably in a clean bed, after a well cooked and carefully served dinner, and all for a very modest price. Great hotels in great cities are much the same the world over; but rarely in this country can one find real comfort devoid of extravagant elegance, or for a moderate price.

And the question of railroad comfort is not so one-sided as is often asserted. The American is quite likely to look with scorn on European railroads and their methods, but let him learn those methods, fit his ways to them, and he will find an ease and comfort of travel which cannot be surpassed in this country, if it is often equaled.

Another point of no little moment in the life in Europe is the generally greater respect shown for law and order. (I have always been most deeply impressed, on my return to this country, by its absence.) I have never found even German police regulations oppressive, but on the other hand, have felt a calm comfort in joining in the uniform obedience, for the common good. City street traffic affords an ample field for observation on this point. After all, there is little difference in the habit of mind which sends the careless teamster past the traffic officer's raised arm at a crowded crossing, and that which sends a locomotive engineer past a stop signal. Both are more frequent in this country than in Europe.

The difficulty lies deeper than the individual; it lies in the laxity of public opinion, which is ready to excuse and condone the invitation provided disaster does not accept it.

Another element which affords much comfort and pleasure to the traveler in Europe, and the frequent lack of which causes much discomfort here, is the cheapest thing in the world—courtesy. That it is often superficial makes it no less effective, and the film, however thin, is vastly better than none at all. The hotel manager who, at our departure, came to our cab door, bowing his thanks for our patronage, and presenting Mrs. Busch with a bouquet of roses, left with us a sense of pleasure and a desire to return, which I have never experienced on leaving any hotel in this country. Many Americans will laugh at this excess, but it is very pleasant; and it pays, as the transatlantic passenger lists will show.

A German gentleman whom I met last summer, said one morning, as we were steaming up a Norwegian fjord: "Tell me why I should go to your country; what more can I see there? My home is in Mannheim. In two hours and for a few marks I can be in Switzerland; or, it is not so much further to this northern country, where I can live well for six kröner ($1.27) a day. I know you will tell of your great cities, but I mean apart from them; I am thinking of a place to spend my vacation pleasantly. The Yellowstone? How far? What would it cost? Five hundred marks and more for railroad alone from New York there and back. Think what I can do for that sum here. Why should I go? What can I see there? Tell me."

I was at a loss. What answer would convince him that he should see America at all?

Henry Paul Busch.

STUDIES OF OPERATION—THE B. R. & P.

Increased Transportation Costs Per Gross Ton Mile Offset by Moving Traffic in Such a Way as to Get Competitive Business.

By William E. Hooper,
Associate Editor *Railway Age Gazette.*

The Buffalo, Rochester & Pittsburgh is an independent road in highly competitive territory with an excellent credit, operating about 568 miles, with a heavy freight traffic density and a fairly large passenger business. The fact that it is independent, in highly competitive territory, and being very successfully managed, indicates that a highly efficient organization must have been developed and most progressive policies must have been adopted.

If we study any large railroad system like the Chicago, Rock Island & Pacific, or the Pennsylvania as a whole, we get a great number of averages which are the result of any number of variables, each variable being in many cases itself an unweighted average. Weather conditions, material costs, labor costs, traffic conditions, standards of operation, all are radically different in Minnesota and in Texas. The Buffalo, Rochester & Pittsburgh is, in respect to operating conditions, a unit, and a study of these conditions has the further advantage that the B. R. & P. does not have its problems and its conditions of traffic forced on it by some outside considerations which have little, if anything, to do with that particular property. Its problems and conditions are those of an individual, not of some incomplete part of an individual.

The road is divided into four main line divisions, the Rochester division from Rochester to Ashford, the Buffalo division from Buffalo to Salamanca, the Middle Division from Salamanca to DuBois, and the Pittsburgh Division from DuBois to Butler Junction, including joint tracks to Pittsburgh and New Castle, at each of which points independent freight terminals are maintained.

Until eight or ten years ago the road depended almost entirely on coal tonnage, but notwithstanding the fact that the B. R. & P. has to meet competition of strong lines both for through and local business on nearly the entire length of its line, a very good business in general freight traffic other than coal has been built up. At the end of 1912 more than 50 per cent. of its earnings was from sources other than the transportation of coal, and more than 50,000,000 passengers were carried one mile, the passenger revenues alone amounting to over 11 per cent. of the total revenue from all sources. The B. R. & P. has had to depend, for its development of passenger and general freight traffic, largely on the quality of service which it can offer to shippers and travelers. Under circumstances such as these, the efficiency of operation cannot be judged solely, or in fact primarily, on the reduction in operating costs. The B. R. & P. itself figures that it loses 5.42 mills per mile on each passenger that it carries. As a matter of fact it probably makes money on its passenger business as well as on its freight business, but in both branches if the B. R. & P. is to handle the business at all, quality of service must be the first consideration. The study of operation of this road then divides itself into an exposition of operating methods and an analysis of costs.

To develop service that will be satisfactory to both the shipper and the traveler, and to perform this service economically, it is first of all necessary that all departments of the road act in close conjunction with each other. In other words an organization must be developed which will act as a unit. The word unit has become associated with divisional organizations; the B. R. & P., however, is organized on a strictly departmental basis.

All of the general officers report directly to the president, and acting as a board of management, it results in a compact, thoroughly competent and thoroughly loyal unit whose energies have been directed with extraordinarily good results toward the solution of a rather difficult problem. It is not intended to go into a discussion here of the financial results that have been obtained on the Buffalo, Rochester & Pittsburgh. It is sufficient to say that in the fiscal year ended June 30, 1912, the company earned $1,770,895 after the payment of all fixed charges, and was able to increase its dividend from an annual 5 per cent. to 6 per cent. A study of how these results have been obtained is a study of innumerable details; each detail, however, attacked along certain definite lines. It is impossible to *define* the principle that has governed this development. It is possible, however, to suggest these principles by describing the way certain particular problems are handled.

Coal and coke traffic originates on branch lines joining the main line near Indiana Junction and DuBois. The greater part of this traffic moves north to Rochester, where it is either shipped to Canada and St. Lawrence river territory via Lake Ontario or turned over to connecting eastern lines. Trains are moved solid from these junctions to Salamanca yards, and since the B. R. & P. is not a low grade line, a great deal of double-heading is necessary. The greater part of the coal and coke equipment sent north loaded returns south empty, and of course, it is necessary for power used in double-heading to be sent south under light rating. Furthermore, the empty cars must be distributed to the mines promptly and on the proper basis. Since almost the entire merchandise and manufacturers' business is highly competitive, this business must be moved promptly; but here again the most important factor in getting the business lies in having equipment available at once at the points where it is wanted.

It will be seen, therefore, that there are two factors which must be considered in determining expenditures for power, schedules for freight trains, etc. The nature of traffic permits of heavy loading, while the exigencies of the traffic and of competition necessitate prompt movement. Furthermore, it is not considered as expensive to send power south that is able to maintain a fairly high speed with light rating as it would be to send heavier power south with a light rating that would not permit of as rapid movement. In other words, the Buffalo, Rochester & Pittsburgh has a traffic and a profile northbound that would suggest the use of Mallet locomotives, but other conditions modify the situation to such an extent that Mikado locomotives are being used on the heavier grades and in pusher service, displacing lighter power. On the heavier grades, where a Mikado is used in pusher service, it is taking the place of two consolidation locomotives, so that now a consolidation and a Mikado are used where previously three consolidations were used.

The object aimed at in passenger traffic development is to afford comfort rather than speed, this same tendency is consistently carried out in all expenditures made on account of the passenger department. It is safe to say that little, if any, additional expenditure is put into maintenance of roadbed to provide for high speed passenger trains, while on the other hand a considerable amount of money is being spent for passenger stations that are comfortable and attractive for the towns in which they are built. In this regard a detail of passenger operation is worth mentioning. Cafe cars are being operated on local passenger trains. It is a rather interesting experiment, and is mentioned here because it is an indication of how particular

operating problems are being met and because the fact that a cafe car is being carried on local trains has a decided effect on the cost of operation.

It has already been suggested that the measure of the efficiency of operation in the freight department is the promptness and adequacy of car distribution. The method of keeping track of this car distribution and of the movement of loaded and empty cars on the line is not different materially from that in use on quite a number of other lines. On its face it is the ways in which the ordinary methods of operation are used rather than the methods themselves that are of special interest. A situation report, such as is made up at 6 a. m. and 6 p. m. on the B. R. & P., is shown herewith. The situation report, of course, goes to the general manager, superintendents, superintendent of car service, trainmasters and despatchers, and also goes to the president. In addition to this situation report, there are six other important reports that are used by the despatchers, trainmasters and superintendent of car service.

It may be said that these six other reports are elaborations of the report on the situation. This report tells what has been done the day before and what has to be done during the next succeeding 12 hours. The other reports show what cars are available to do this work, and it is through the manipulation of these cars that the despatchers and the superintendents do their most important work. The situation is further complicated by the fact that the B. R. & P. is an originating road, nearly 90 per cent. of the total traffic carried originating on its own lines and a very large percentage of this traffic being shipped off the lines.

Since 1908, up to and including the entire calendar year 1912, the B. R. & P. has supplied its coal shippers with 100 per cent. of their requirements for cars. This is not an average situation; that is, the shipper has not received eventually 100 per cent. of his requirements—he has received it day by day, even during the period of rather severe car shortage in the latter part of 1912. In 1909 1,244,946,097 ton miles and 44,914,997 passenger miles were carried, and in 1912 1,704,307,001 ton miles and 51,101,188 passenger miles were carried. To obtain this result, one or both of two things must have taken place. Facilities have been increased or the organization has been perfected so as to make materially greater use of the same facilities, or—and this is what has actually happened—there has been some increase of facilities with a marked increase in the efficiency of their use.

In 1909 $560,630 was spent for additions and betterments to roadway, and all of these may properly be charged to additional facilities for use of the transportation department; in 1910 $906,496 was spent for additions and betterments, of which $824,081 may properly be charged for new facilities for the transportation department; in 1911 $1,117,282 was spent for additions and betterments, of which $1,045,724 was properly chargeable to improved facilities for the transportation department; and in 1912 $633,664 was spent for additions and betterments, of which $556,111 was properly chargeable to increased facilities for the transportation department. It has been the practice of the B. R. & P. to make special appropriations each year from income to the sinking fund under equipment agreements, a portion of which is used for the purchase of new rolling stock, and the balance to retire a part of the equipment truts bonds falling due each year. These appropriations amounted to $315,000 in 1910, $371,500 in 1911 and $375,000 in 1912. Further there was a net addition of $2,820,438 to the equipment account provided for from current assets and the issuance of equipment bonds. This is a total of $2,986,546 spent on roadway and track and $3,195,438 spent on new equipment.

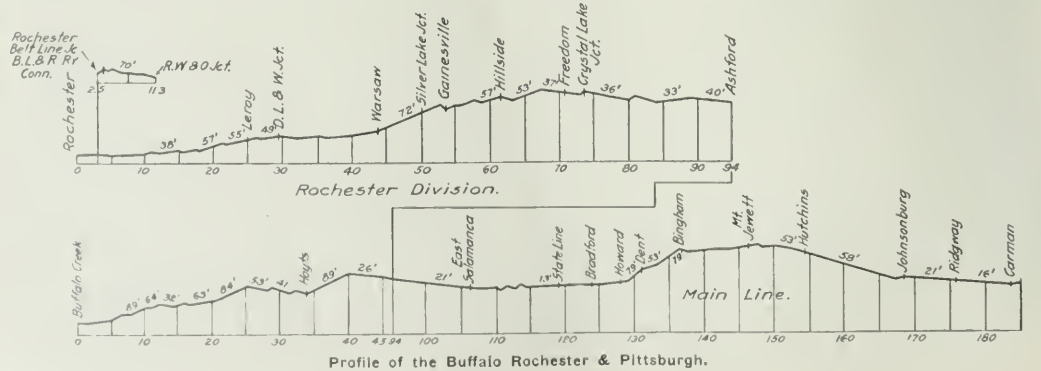
It is interesting to note that by far the larger proportion of the sums spent for additions and betterments, other than equipment and double tracking, was spent to avoid waste of material and labor, such, for instance, as water storage reservoirs, mechanical coal and ash handling facilities, and creosoting plant where ties, piles, bridge timber and other structural lumber is creosoted.

In 1909 the company's locomotives had an average tractive effort of 30,995 lbs., in 1912 this had been increased to an average tractive effort of 33,180 lbs. Freight service cars had an average capacity in 1909 of 36.62 tons, and in 1912 an average capacity of 40.23 tons, with less than 1 per cent. out of a total of more than 16,000 cars out of service for repairs, and 90.69 per cent. of locomotives out of a total of 300 in service in good condition.

The provisions for water supply are very important as an added asset of the company, but, for the purpose of our study, are only one of the many details that go to explain the results that the operating department has obtained, and their importance is more a question of farsighted investment for the future than immediate moment to the operating department, although the latter advantage should not be overlooked.

The total ton mileage moved behind the drawbar, including passengers and freight and weight of equipment in 1909, was 2,202,189,301. In 1912 this ton mileage was 2,994,457,899. Car loading per loaded car was 12 per cent. greater in 1912 than in 1908.

Trainload is often taken as a measure of the efficiency of *operation* as between different railroads. As a matter of fact trainload is often more nearly a criterion of traffic conditions than of operating conditions. Take an extreme example; a road having freight mainly made up of merchandise and bulky commodities, such as dry-goods and furniture, may show a trainload of 300 tons, while a road with a large proportion of its tonnage furnished by products of mines and heavy manufactures, such as originate in the Pittsburgh district, may show an average trainload of 600 tons, and yet the road with the low grade tonnage may not actually be operated with as great economy as the road with the high grade tonnage. Even as an indication of greater



Profile of the Buffalo Rochester & Pittsburgh.

or less efficiency from year to year. On the same road the trainload is not a sure guide to conditions of operation. Too much emphasis cannot be laid on this consideration because it is seldom given due weight in discussions of operating efficiency.

Total empty car mileage is largely a matter that is a concern of the traffic department rather than of the operating department. A gain of 50 per cent. in operating efficiency on a road like the B. R. & P. would reduce empty car mileage to an almost negligible degree. It is true that with heavier power, elimination of grades, etc., the average trainload can be increased, but these things are only two of numerous handles by which the management of a railroad grasps the problem of reducing operating costs and of increasing operating efficiency. The B. R. & P. has in use tonnage rating machines at important terminal yards that have helped materially in giving engines their full rating. Operation is a continual game in which new conditions have to be met, and in the last analysis the best measure of whether or not the operating department is working to the best advantage lies in the answer to the question: Is the shipper receiving the service which will induce him to use this particular road, rather than another, at a cost that leaves the railroad a gainer from his traffic and not a loser?

This means in the first place that the road must have sufficient equipment to handle the business which it can under the most favorable operating conditions originate. This equipment must be utilized to its fullest possible capacity under the conditions that occur from month to month. Train despatching, car loading, motive power, organization, all play their part, and organization is not the least important of these factors.

The conclusion from all this is that it is not so much increased facilities that have enabled the B. R. & P. to obtain the results that have been obtained as increased efficiency in the use of these facilities. Now comes a question as to what has been the trend of costs of performing this additional service. We know that the scale of wages paid employees has materially increased during the four years 1909 to 1912. Has the cost of doing business on the B. R. & P. increased in anything like the proportion that the business done has increased? In other words, making full allowance for the increased scale of wages, has the management been able to show anywhere near the same increases in efficiency as has been shown in the use of the physical plant? The B. R. & P., like every other road in the country, has shown materially larger labor costs.

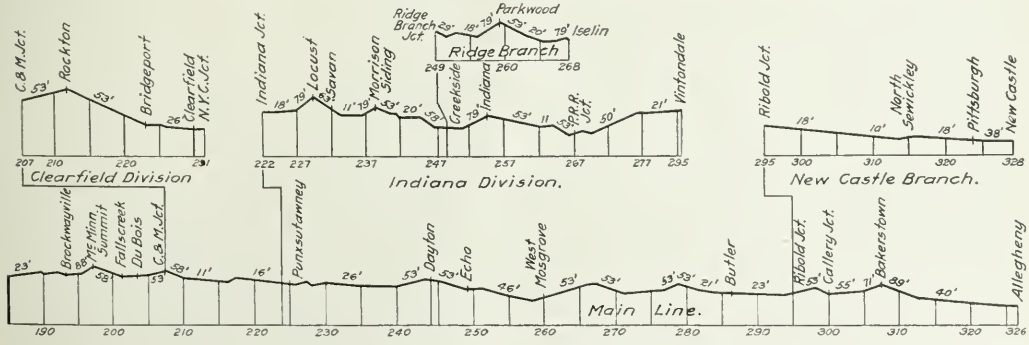
Reducing this cost to a gross ton mileage* basis, transportation expenses in 1909 per gross ton passenger mile cost 0.2837 cents and in freight service transportation cost 0.0810 cents per gross ton mile. In 1912 the cost in passenger service for transportation expenses was 0.3135 cents and in freight service, 0.0906 cents. This is an increase in cost of moving passenger business of 10.5 per cent. and in cost of moving freight business of 11.9 per cent. During these four years the scale of wages on the Buffalo, Rochester & Pittsburgh for all classes of employees in train service has increased approximately 12 per cent.

While transportation expenses can be so accurately divided as between passenger and freight, it is not possible to divide maintenance of way expenses except on some arbitrary basis. Maintenance of way, however, can be fairly accurately divided. The question of dividing these expenses as between passenger and freight is not one which can be solved in any general way. Each road is a different problem. On the Buffalo, Rochester & Pittsburgh there is no very fast passenger service. It is strictly accurate to say that the roadbed, bridges, etc., would be kept in just as high a state of repair and the standard of upkeep would be the same whether or not there were any passenger trains running. Rails, ties and ballast wear out on such a road in proportion to the tonnage hauled over them where there is no complicating factor of high speed. If we divide, therefore, all the maintenance of way expenses on a ton mileage basis, with the exception of those expenses such as freight and passenger station maintenance, which can be divided directly, we would get for the B. R. & P. a fairly accurate apportionment of these expenses as between the two classes of service. Maintenance of equipment can largely be charged directly either to freight or passenger equipment, according to the object of the expenditure, and it is fair to divide the other expenses under the head of maintenance of equipment on the same ratio as between freight and passenger as are the expenses under this head that can be charged direct.

General expenses must be divided on some arbitrary basis. On a road like the B. R. & P. a ton mileage basis seems a fairer basis than a train mileage basis. Using this method, namely, to divide transportation expenses on the basis on which they are actually made and the remainder on a train mile basis; to divide maintenance of way expenses on a ton mileage basis, with certain exceptions; maintenance of equipment on the basis of actual expenditure or on this proportion; and general expenses on a ton mileage basis, we find that the cost per gross ton mile for all expenses for freight in 1909 was 0.194 cents and in 1912, 0.199 cents. For passenger business the cost was 0.445 cents in 1909 and 0.464 cents in 1912. Since the receipts for freight are on a net ton mileage basis and for passengers on a passenger mile basis, it is interesting to divide costs on this same basis. The cost per revenue ton mile in 1909 was 0.320 cents and in 1912, 0.328 cents. The receipts per revenue ton mile, including receipts for switching service, were 0.488 cents in 1909 and 0.486 cents in 1912. The cost per passenger mile in 1909 was 1.526 cents and in 1912, 1.534 cents, while the receipts per passenger mile in 1909 were 2.225 cents and in 1912, 2.387 cents. The company figures its expenses on a train mile basis and shows a loss on passenger business and a profit on freight business; but, as was previously suggested, on the basis on which expenses are divided here, there is a profit shown on both freight business and on passenger business.

The gross ton mile is a better basis on which to estimate costs

*By "gross ton miles" throughout is meant total of lading and equipment, passenger weights being estimated.



Profile of B. R. & P. (Continued).

of repairs of locomotives than any other that the writer knows of, when the object to be attained is the comparison of cost as between different years on the same road. Of course, where one road is to be compared with another the effect of grades is so great that this unit of comparison loses much of its meaning; but over a period of four years on the same road where the grades have not been materially changed, the cost of repairs of locomotives per gross ton mile is an accurate measure of the efficiency of the motive power department. Increases in labor cost have affected the cost of repairs of locomotives so that if we were to find no higher cost in 1912 than in 1909 it would be fair to assume that there has been an increased efficiency in this department. As a matter of fact, however, the repairs of passenger locomotives cost 0.0466 cents per gross ton mile in 1909 and 0.0457 cents in 1912, and the repairs of freight locomotives per gross ton mile cost 0.0181 cents in 1909 and 0.0138 cents in 1912. This is a remarkably good showing.

It should be borne in mind that this study of cost was for the years 1909 to 1912, inclusive. The Mikado locomotives, which have been put into freight service, and the Pacific type locomotives, which have been put into passenger service, were not in use in the fiscal year 1912, so that the effect of their use cannot be shown in this discussion. This is true of other improvements which the B. R. & P. has made or is making in the present fiscal year. Telephone train despatching, which has been in use on the Rochester division for some time, is being extended to the Middle and Pittsburgh divisions. Automatic block signals are being installed this year on the Rochester division, but none of these things had an effect on the cost or in the quality of service in the four years 1909 to 1912.

The B. R. & P. has recently put into effect a new system of applying discipline, and while this new system, of course, did not affect costs of service in the four years we are studying, it is one of numerous indications of the policy which has been pursued in perfecting the organization during these four years. Discipline on the B. R. & P. is decided on by a court presided over in the case of trainmen either by the trainmaster or the superintendent. Heretofore a man was disciplined by being suspended for a certain number of days. Under the new system, discipline is decided on in the same manner as before, but its application is withheld unless there should be cause for further discipline within a specified period of probation. A man who has committed some fault which the court decides should be visited with a suspension is put on probation for six months, a decree of suspension of over ten days and less than 30 days makes the period of probation nine months, and a decree of suspension of 30 days or over calls for a period of probation of one year. If an employee keeps a clear record during this period of probation, at the end of that time his slate is wiped clean and he starts over again. Should, however, the employee get into trouble during his period of probation, he must at once serve the suspended sentence which the court found him liable for, and in addition a new period of probation is started. This system has been in effect since October 1 and is working satisfactorily. It is saving money both to the company and to the employees and is saving a very considerable hardship on the part of the employee's family.

The spirit that lies behind this form of discipline is the spirit that has been the key-note of the management of the property during the four years under review. This is the spirit of co-operation. Co-operation to be successful must assume on the part of all those who participate in it a degree of intelligence and a desire for fair play that will make it possible to eliminate to a certain extent hard and fast rules.

It is this spirit of co-operation that more than anything else explains the results that have been obtained in the last four years. It explains the effectiveness of the methods that are used to run the service and in so doing meet competition. It explains the elimination of red tape and correspondence that is one of the noticeable features in the conduct of business on the B. R. & P., and it explains the remarkable lack of friction between the different departments. We can point to specific instances and tell how co-operation was secured, but under different circumstances

Form of Situation Report.

the method of securing this co-operation would be different, although the final result might be the same. The nearest that one can come to a definition is to say that the treatment of officers and men alike is based on the assumption that they will recognize fair treatment, and that they are at heart working for the best interests of the service as a whole.

One of the best ways to eliminate misunderstanding is to avoid unnecessary correspondence. This fact is recognized on nearly every railroad in the country. It is one of the underlying principles of the Hine system of unit organization. It is on the Buffalo, Rochester & Pittsburgh an accomplished fact, and it is an accomplished fact because each department is made an intelligent part of a complete organization. Not only are a few heads of departments permitted to come together in discussion of common problems, but all the officers of each department are made to understand that the great majority of their problems are problems common to other departments. This co-operation is not attained in a mechanical way and therefore does not lend itself easily to description or analysis. The fact that discipline is administered by a joint court, composed of officers from different departments; the fact that there are frequent and informal meetings between officers of different departments for discussion, or that every three months an inspection trip is made of the entire road, in which the heads of all the departments join and during which there is absolutely free discussion, does not do more than tell part of the story. All of these things are aids to the development of this spirit of intelligent co-operation. All of them together would be comparatively weak aids were they not backed up by faith founded on experience. This faith is more effectually engendered by the fact that to the common knowledge of employees and officers, an employee who has met with misfortune through no fault of his own is treated by the company not as a tool which is no longer useful, but in a spirit of real generosity, better than by any elaborate merit system that has yet been devised.

There are certain conclusions that may be drawn from this study of operation on the Buffalo, Rochester & Pittsburgh. Passenger business, even on a road handling a heavy density of freight traffic, can be made a profitable branch of operation. Despite increased costs of operation, competitive business can be profitably developed if enough attention is paid to the development of the service. A loyal and efficient organization can be built up despite competition in the labor market and despite the modern tendency to regard the interests of labor and employer as antagonistic, without endangering the financial results which the management owes to the stockholders of a railroad.

TICKET ISSUING MACHINES ON THE LONG ISLAND.

The Long Island Railroad has in use in Brooklyn, N. Y., a number of machines for simultaneously printing and issuing tickets, and recording the number and value of the tickets issued, and they are working in a very satisfactory manner. The machines look somewhat like the familiar cash registers, seen in retail stores, and were made by the National Cash Register Company, Dayton, Ohio.

Machinery is provided in the metallic case for printing tickets of denominations from 5 cents to 35 cents, inclusive; they are for use only on the local electric trains. The printing mechanism is synchronized with the recording mechanism which shows the number and value of all tickets issued. Four different men can sell from the same machine, the tickets themselves and the automatic recording apparatus indicating by a designating letter the identity of the person making each sale. Each seller may lock the machine so that none of the others can disturb his tickets or his records. A mechanical counter shows the opening and the closing numbers of the tickets issued each day. The counting apparatus also shows the total sales for any given period; and the agent has no reports to make, except a brief statement of the totals. The machines are operated by an electric motor and are capable of printing 100 tickets a minute.

ARBITRATION OF THE FIREMEN'S WAGE CONTROVERSY.

The entire first week of the arbitration proceedings in the Eastern firemen's wage demands was devoted to taking the testimony on the firemen's side and in cross-examination by Elisha Lee, representing the railroads. On Thursday, March 13, W. S. Carter, president of the firemen's brotherhood, called to the witness stand A. H. Hawley, secretary of the organization. Mr. Hawley, whose testimony followed that reported in the *Railway Age Gazette*, March 14, page 479, gave statistics of firemen killed and injured and figures pertaining to the insurance features of the brotherhood. He said that the membership had grown from 48,500 in 1903 to 85,300 at the end of the last fiscal year; that in 1911 and 1912 about 20,000 members had resigned or been dropped and 250 had died. Of the 20,000, less than 5,000, he claimed, joined the Brotherhood of Locomotive Engineers, the others entering other employment. From 1904 to 1912 there were 4,437 deaths, of which 2,124 were from railroad accidents.

Dr. Walter B. Cory, general medical examiner of the brotherhood, the next witness, gave it as his opinion that a fireman's work is extra hazardous and that exposure, heat, and other things weaken the men so that they are more subject to disease. He gave insurance companies' regulations to show that firemen are not considered good risks.

James Kirby, president of a carpenters' union, gave testimony regarding the wages paid in the building trades as compared with those paid firemen. Mr. Carter asked him if it was contrary to rules for a building-trades man to take a drink, either on or off duty, and Mr. Kirby replied that it was not. Mr. Lee interrupted to ask Mr. Carter if he was in favor of a fireman taking a drink while on duty, and the latter replied that he was not. In cross-examining, Mr. Lee brought out that carpenters and other artisans lost considerable time, due to bad weather, and that they furnished their own tools. Mr. Kirby had stated that no examination as to sight, hearing, etc., is required of a building trades man, and Mr. Lee asked him if he thought a color-blind painter would be much of a success. Mr. Kirby thought not.

S. T. Steinberger, of the brotherhood's general offices, gave statistics regarding the number of times firemen had worked over 16 hours, as shown in reports made by the railroads under the law, to the Interstate Commerce Commission. Mr. Carter was careful to bring out that he considered these as unavoidable and not infringements of the law. In cross-examining, Mr. Lee showed that, although a fireman gets paid overtime for time worked in excess of ten hours, the railroads get no increase in ton-miles.

D. B. Robertson, Youngstown, Ohio, a locomotive engineer on the Erie, followed with statistics purporting to show that a fireman's wages will buy much less of the necessaries of life now than in 1907.

Mr. Lee informed the board on Thursday that he had a communication from the Toledo, St. Louis & Western, asking to be permitted to withdraw from the proceedings. Judge Chambers, chairman of the board of arbitrators, refused permission, and when, on Friday, the matter was again brought up Judge Chambers said that the board had power to punish for contempt by certifying to the circuit court for the district, and he believed the Toledo, St. Louis & Western would be in contempt in withdrawing from the arbitration without the board's consent.

W. J. Lauck, a statistician of Washington, D. C., was the next witness. He had prepared tables, which, Mr. Carter stated, had cost the brotherhood $18,000. They dealt with the capitalization, train loads, revenue, etc., of the roads concerned in the arbitration and tended to show that the stockholders were receiving much more benefit from the increases in revenue than the firemen. Tables and statements were given for individual roads and a number of these were dealt with in considerable detail. In dealing with the Baltimore & Ohio, Judge Chambers

calculated that wages had been increased about 48 per cent. in 11 years. Mr. Carter said this was misleading, as Mr. Lauck had been compelled to accept the figures filed by the railroads with the Interstate Commerce Commission, and that these were "absolutely erroneous." Mr. Lee immediately objected to Mr. Lauck's giving any further testimony if the figures were based on erroneous information. Mr. Carter then objected to any testimony along the same lines being introduced by the railroads. He claimed that members of the Interstate Commerce Commission had informed him that the railroads falsified their reports as to employees, and said that if they would falsify under oath to the Interstate Commerce Commission they would falsify to the arbitration board. He claimed that the enginemen got themselves into trouble in their arbitration by using the railroads' reports. Mr. Lee said he did not admit that the figures were false, but as Mr. Carter contended they were, he must persist in objecting to the admission of the tables based on them. Judge Chambers ruled that such a condition did not entirely invalidate the testimony. In the case of the New York, New Haven & Hartford, Judge Chambers asked why, in the face of the figures given, it should be necessary to reduce the dividend rate, which, according to press reports, Mr. Mellen, president of the New Haven, says will have to be done. Mr. Lauck replied that if the financial management had been as efficient as the transportation management, there would be no such necessity.

In cross-examining Mr. Lauck, Mr. Lee made it plain that he disagreed with a great many of his conclusions. One of Mr. Lauck's tables, using as a basis the revenue train mile, showed that operating revenue on the roads concerned had increased from $1.90 to $2.46, while the cost of firemen has increased only from 3.89 cents to 5.64 cents. Mr. Lee, calculating percentages, showed that this meant an increase in revenue of 29 per cent., while the cost of firemen had increased 45 per cent. Judge Chambers asked whether, if some roads could afford to pay more than others, the firemen would ask an increase only on those roads that could afford to pay it. Mr. Carter said if they were doing the work they certainly would ask an increase; and he compared the case with that of two buildings being erected, one by a wealthy contracting firm, and the other by a firm that had difficulties in making ends meet. He contended the workmen should get the same wages on both buildings; but Mr. Lee disagreed, saying that it is a question of demand and supply; that one family would pay a servant seven dollars a week while another paid $10; they paid according to their means.

Mr. Carter was very much afraid that by some of his replies Mr. Lauck was giving the impression that he repudiated some of his previous statements, but Mr. Lauck said he did not; that whatever objections he admitted as being fair, his general conclusions, that the firemen were doing more work, were correct. He admitted to Mr. Atterbury that he was not a practical railroad men and was competent only to pass on the question from the standpoint of an accountant. Mr. Lee again brought in the fact that in comparing the amount of coal handled, etc., for 1902 and 1912, Mr. Lauck had used percentages, and contended that the same method should have been used in other comparisons. Mr. Lauck said that revenue had increased 40 times as much as the cost of firemen, but Mr. Lee stated that increased operating expenses had absorbed a very large percentage of the increase. Mr. Lauck thought the firemen should be paid the same on two similar competing roads, even if one had a surplus and the other a deficit. Mr. Carter here brought in the question of weight on drivers, saying that payment on that basis meant payment according to productive capacity. He made a comparison between firemen and steel rail manufacturers, saying that if the railroads are prosperous the rail makers make a profit, and that when the mills cannot make a profit they stop making rails. Mr. Lee replied that, unfortunately, when the railroads do not make a profit they have to go on operating just the same. Mr. Carter again brought up the question of falsified reports made to the Interstate Commerce Commission, and repeated his previous statement regarding them. Mr. Lee replied that they were not false and that they were made according to the commission's requirements. He read from a statement of the commission in the railroad rate case, which said that railroad labor was paid as well as, and sometimes better than other forms; and that an increase in rates could not be permitted for the purpose of paying extravagant wages.

REPORT ON COLLISION AT BOWERSTON, OHIO.

The Interstate Commerce Commission has issued a report by Chief Inspector H. W. Belnap, on a rear collision of freight trains, causing the death of one employee, which occurred on the Pittsburgh, Cincinnati, Chicago & St. Louis, near Bowerston, Ohio, December 13, last. The line at this point is worked by the manual block system. A west bound freight, Extra, No. 8020, unexpectedly stopped when its rear car was about 1,500 ft. west of O B tower, and 1,000 ft. west of the home signal connected with this tower, was run into by a following freight, Extra, No. 8188. The collision occurred at 5:12 p. m., and the second train had been running at about 51 miles an hour from the last preceding station. Engineman Stocker, of this train, was killed. The flagman of the standing train had gone back and placed a red fusee on the track immediately in front of the tower, 1,500 ft. in the rear of his train. He was called in and had got back to his train a few minutes before the collision.

Freight trains are run under permissive block signals, and after the passage of train 8060 the signalman at O B had set his home signal at 45 degrees, indicating that the block section was occupied. With the signal thus set, he was able to give a clear distant signal, and this he did; this being the usual custom. As train 8060 had passed out of sight, the signalman acted in accordance with the prescribed methods, in displaying a clear distant signal to No. 8188. This, says the inspector, is not adequate protection. Moreover, the spectacles on the distant signal are so arranged that when the signal arm stands at 45 degrees, as it might if the connections were out of adjustment, a passing train would find no light at the distant signal, and might easily miss it; and thus would approach the home signal at an unsafe speed. Although the freight was running at about 50 miles an hour, there is a rule limiting the speed on this part of the road to 40 miles an hour. This rule had been in effect only 19 days. The inspector finds that it has been habitually disregarded, the train sheets showing many violations between November 24 and December 31.

Though the signalman did not disobey any rule, he is criticized for using bad judgment, especially when there was a red fusee burning directly in front of his cabin. The traffic on this division, says the inspector, is heavy enough to justify the use of block signals its entire length. A number of short sections are already thus equipped. Concerning the excessive speed of the freight train, the inspector says: "That the enginemen on this division pay no attention to the established speed restriction is a matter of daily record, and their failure to observe the rule must have been known and acquiesced in by the operating officers. Such dereliction of duty by those who are charged with the enforcement of regulations cannot fail to weaken respect for all rules and render nugatory all efforts to maintain really effective discipline. Rules that are not intended to be enforced have no proper place in a railroad company's code of regulations, and when the operating officers of a railroad permit rules that have been enacted to secure safety to be violated with impunity, they cannot reasonably expect to escape responsibility for the consequences of such violation." The inspector calls for a flagging rule entirely free from uncertainty or indefiniteness; one which would leave no room for error of judgment by a flagman.

POSTAL CAR ILLUMINATION TESTS.

Results of Extensive Tests Made by the Baltimore & Ohio, and Used as a Basis of the New Government Specifications.

The character of the visual work performed in the railway postal car requires a high quality of illumination, and the long hours during which artificial light is required, make the problem of furnishing a reliable and economical supply a difficult one. For the purpose of obtaining more adequate data on this subject the Baltimore & Ohio, through its electrical department, made an extensive series of tests during the fall of 1912 in Washington, D. C., on one of its latest types of steel postal cars. The standardization of the construction and of the arrangement of this type of car makes it possible to draw conclusions from these tests that will generally apply to cars built under the present government specifications.

Although the tests were carried out on a broad engineering basis, covering all practicable methods of car illumination available at the present time, the investigation was confined solely to the question of providing proper and adequate illumination. The questions of maintenance, of the most desirable kind of illuminants, and of the operating problems connected with the generation of light were not considered further than with respect to their influence upon the quality of illumination provided. In detail, the phases of the subject covered were the relative suitability of: first; Pintsch gas and electricity, representing the most important types of primary illuminants, as far as their influence upon the quality of illumination produced was concerned; second, the different types of reflectors and diffusers; and third, the different types and arrangements of lighting units. The investigation consisted of illumination tests to ascertain efficiency and uniformity data as well as shadow effects obtained with the various types of lighting units and spacing arrangements; also, visual intensity tests to ascertain the intensities of illumination required in the different sections of the car by the character of the visual work performed in those sections.

Two important features brought out by the investigation were; that adequate illumination may be provided with the amount of light that is at present generally provided by most railroads, the unsatisfactory illumination frequently obtained being largely due to the improper arrangement of the light units and unsatisfactory types of reflectors; and that the amount of illumination required for the work in the postal service has been considerably over-estimated.

In the direct system of illumination the correct location of the light is determined by absence of the shadows. In the bag rack section of the car the light units should be located along the center line of the car and the mounting height should be 7 ft. 7 in. from the floor to the center of the lamp filament or gas mantle in order to produce the least objectionable shadow effects as well as to eliminate shadows on the rear bag rack label. At the letter cases adequate illumination can be provided for only by light units independent of those used for illumination of the body of the car, and such light units should be located as far in front of the case as possible without shadows being thrown on the work by the body of the mail distributor. With the standard design of letter case having a 17 in. table this distance is 20 in. from the front of the letter case.

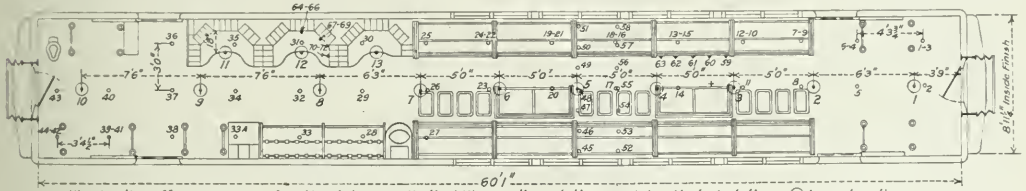

Fig. 1—Location of Stations and Lamps with 5-ft. Spacing.

In determining the best types of reflectors for postal car service four qualities were considered; the effect of the resultant illumination upon the eye; the relative efficiency; the cleaning consideration; and the liability to breakage. As these are not of equal importance the following relative values of these qualities were chosen after considering the question from several different points of view. Out of a total of 100 points an importance represented by the following figures was assigned to each of the qualities under consideration:

Effect on the eye	44
Efficiency	30
Cleaning	18
Breakage	8
Total	100

On this basis the relative suitability of the various types of reflectors for postal car lighting was found to be as follows:

Class of Reflector.	Make of Reflector Represented in Tests.
Aluminumized metal	Holophane D'Olier No. 18460 body of car; Holophane D'Olier No. 18470 at letter case.
Heavy density opal glazed reflecting surface (specially designed for car lighting service)	Holophane No. 18626 redesigned.
Medium density opal glazed reflecting surface	Phoenix CL-50.
Porcelain enameled metal	Holophane D'Olier No. 18461.

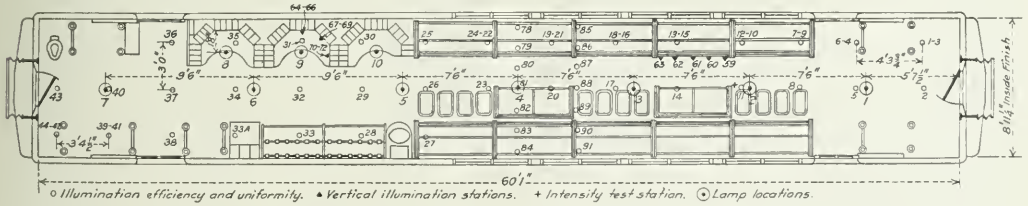

Fig. 2—Location of Stations and Lamps with 7½-ft. Spacing.

Class of Reflector.	Make of Reflector Represented in Tests.
Medium density opal depolished reflecting surface	Macbeth-Evans Alada No. SF-1623.
Indirect lighting with enameled reflectors for gas lighting	Experimental enameled reflector.
Mirrored glass (direct lighting)	X-Ray 555.
Prismatic clear	Holophane No. 18226.
Prismatic satin finish	Holophane No. 18226-SF.
Reflecting and diffusing globes	Safety Corona No. 8026.

Extensive tests to determine the amount of illumination required for comfortable reading indicated that there was an appreciable difference in the character of the illumination afforded by different types of equipment. Certain types gave an illumination of such a character as to leave the eye in a less satisfactory condition for vision, thus requiring an increased intensity of illumination for adequate vision. For practical purposes it was found that with direct lighting systems the equipment could be divided into two classes relative to the character of illumination produced; one in which the specular element was considerable, such as was obtained from direct lighting systems employing mirrored glass, porcelain enameled, heavy density opal reflectors with glazed reflecting surface; and one in which the illumination was largely diffused, such as was obtained from direct lighting systems using diffusing globes, opal reflectors of all classes ex-

cept heavy density opal with a glazed reflecting surface, aluminumized metal, and prismatic reflectors. This class of reflectors required approximately 80 per cent. of the illumination of the first class. Extensive tests made to ascertain the intensities of illumination required, showed that 2.25 foot candles on the reading plane was a safe value for minimum satisfactory intensity for continuous close visual work under illumination derived from lighting units of the second class. On the same basis it was found that 3.5 ft. candles was ample illumination and that higher values were unnecessary for adequate service. It was further found that about one-half or slightly less of this minimum intensity value was required at the mouth of mail bags in the bag rack portion of the car, on the face of the letter cases and in the storage section. The results of the illumination tests with the principal types of electric and gas units tested are given in the accompanying table. Figs. 1 and 2 show the plans of the test car giving the location of the lighting units and of the test stations. The table gives the average, maximum and minimum foot candle values obtained in the car as a whole, the bag rack section, the letter case section and the storage section. The efficiency of the system is given as the ratio of light falling on the working plane to the total light generated by the lamps.

The importance of using proper types of reflectors in car lighting service for all classes of cars is shown in the comparison of the illumination obtained with the most efficient type of reflector tested, the mirrored glass, with the bare lamps, in which the illumination obtained on the working plane where the reflector was used was practically 220 per cent. of that obtained with the bare lamps, the number of lamps installed being the same in each case. The ceiling of the car had been freshly painted a dead white, which gave more favorable conditions for the bare lamps than would generally be obtained in service. Further, the glare effect obtained from the bare lamps is such as to render the eye much less efficient as well as more susceptible to severe eye strain than where reflectors are used.

The minimum and maximum initial illumination values, as well as the service illumination values required under the Post Office Department specifications, revised to December 28, 1912, were determined upon as a result of these tests in this connection, and they constitute the only authentic data thus far available on this subject.

So far as the question of illumination is concerned the investigation showed that when proper location of lamps and proper types of reflectors are provided, equally satisfactory results may be obtained with Pintsch mantle gas lighting and electric lighting. In conducting the tests the assistance of illuminating experts of the leading reflector, car lighting fixture, and incandescent lamp manufacturers was obtained, and in order to insure the greatest accuracy of the test results the National Bureau of Standards extended its co-operation by calibrating the instruments, rating the lamps used, and making photometric curves of all the light units tested.

Acknowledgment is made by the railway company to the Holophane Works of General Electric Company, Safety Car Heating & Lighting Company, Adams & Westlake Company, National Electric Lamp Association, General Electric Company, Westinghouse Lamp Company, Macbeth-Evans Glass Company, National X-Ray Reflector Company, Phoenix Glass Company, Opalux Company, and the National Bureau of Standards for their co-operation in conducting this research.

Proposed Spanish Railroad.—The *Gaceta de Madrid* of a recent date contains a notice inviting plans for the construction of a secondary 17-mile railway from Haro to Ezcaray, province of Logrono. The minimum rolling stock of the company will consist of 4 locomotives, 5 mixed first and second class cars, 5 third-class cars, 3 mail cars, 4 baggage cars, 12 box cars, and 23 flat cars. The capital necessary for the construction is calculated at $542,833. The Spanish government will guarantee 5 per cent. per annum on the capital invested.

WHAT I AM TRYING TO DO.*

By Franklin K. Lane.

What are we of the Interstate Commerce Commission trying to do? We are seven, but we work as one. It would be hard to find seven men who differ more in temperament, in training, or in type of mind than Mr. Clements of Georgia, Mr. Prouty of Vermont, Mr. Clark of Iowa, Mr. Harlan of Illinois, Mr. McChord of Kentucky, Mr. Meyer of Wisconsin, and the writer. Yet I believe that no other group of men labors for the Government with more singleness of purpose than does this commission. There is, of course, a flat-footed way of stating our purpose—one transcribed from the letter of the statute: We are attempting to regulate and control the rates, rules, and practices of our railroads, and of other public utilities engaged in interstate commerce. (Herein, however, I shall deal only with railroads.) I recognize that such a statement is about as luminous as to say that the President of the United States is trying to enforce obedience to the nation's laws and give direction to its policies. Succinctly and suggestively put, it may be said that the object of each day's work—the investigations made, the rulings and orders issued—is to insure fair play as between the public who need transportation service and the carriers who furnish it.

In a very real, though not perhaps a strictly legal, sense we legislate within fixed limitations. The effectiveness of our work has been made possible only by the liberality of the Supreme Court in the construction of this law and of the powers of the commission.

It is entirely within the truth to say that this commission has no policy other than that which is expressed from day to day in the rulings that it makes. At the same time it would be idle to say that we are without consciousness of direction.

Our primary object must be to prove the efficacy of the machinery devised by law for bringing the policy of our railroads into conformity with the policy of the law—to make private capital serve public need and yet conserve the interest of the railroad owner. The public wish the best of service at the lowest possible rates; the owners desire the highest return consonant with the fulfilment of their undertaken duties. This may be an *impassé*—a situation so impossible of resolution that we are destined to join those nations who are experimenting with governmental ownership and operation. The stage of despair, or of resolution—dependent upon the viewpoint—we, however, have not yet reached. In fact, I believe we are far from it, for we have only entered upon the experiment of regulation by commission, and students of this subject from other lands have said that their countries would not have sought refuge in governmental ownership had they in time discovered the American method of dealing with the railroad problem.

In this experiment we are trying above all to be practical; to work with facts. If wise we are not to be terrorized by our own precedents or those of the railroads themselves; less than a century of experience is too short a time within which to say the final word upon any problem of railway economics. And constantly there is this all-important factor to be safeguarded; the self-respecting, self-asserting, risk-taking, personal initiative of the railroad man whose imagination and experience must be sympathetically brought into public service if the whole scheme of regulation is to become more than a flat code of lifeless rules.

In earlier days railroad men accepted uniformly the current law of competition as a full code for the government of their conduct. It was their business as practical men to make their properties as profitable as possible. They did not understand the philosophy which distinguished their properties from other business enterprises. Regarded from this standpoint, their practices became entirely reasonable.

To be sure, railroad policies differed. This was because railroad men differed. Some had larger imaginations than others

*From an article in the March issue of *World's Work*. This abstract is reprinted by kind permission.

and comprehended more perfectly the import of their conduct. But railroading was to all an industry. Its product was tons of freight hauled or passenger miles made. To cut a rate to secure traffic was thought to be no more offensive to good morals or fair dealing than for one contractor to underbid another in the selling price of a house.

In superimposing restraint upon these carriers—a restraint which the law had always recognized as possible—and in attempting to enforce the regulations now imposed, it is not to be overlooked that our railroads were built in large part upon this private industry theory. As a nation we took no more concern as to where a railroad was to be built or how it was built than we did as to where a man should live or how he lived. It was any one's privilege to build a railroad. Given a financier of underwriting reputation, a road could be projected from Dan to Beersheba without any one knowing the location or the traffic-producing possibilities of either place. The result was as pretty a system of unscientifically planned railroads as might well be imagined, and not only unscientifically planned, but illy and uneconomically built. Originally they were erected to serve local needs. Many of them were later connected into nation-serving carriers by the strength and synthetic genius of a few men. But as a whole they were without large plan, built upon a speculative and competitive basis, and operated as rival industries. Logically, therefore, and perhaps inevitably, they fought their way to the edge of bankruptcy, or beyond. Then, to save themselves, they took refuge in combinations, pools, and agreements under which they raised rates and reduced service.

It would be difficult, I think, to find a self-respecting railroad man who would presume to say to the American people that he would prefer to return to the order of things that prevailed before the government undertook regulation of railroads.

It is said that railroad regulation restricts railroad building. No doubt this is true in part. This commission has no power to permit a railroad to be built or to deny it that right. Nevertheless, the powers that we do exercise doubtless have an influence in limiting the building of certain types of roads, notably those whose primary purpose is not public service but a species of blackmail upon other roads or those whose rails are laid as a foundation for wildcat speculation. Let us be frank, however, and inquire why, the country over, we are not building railroads with that same feverish activity that characterized the '70's and '80's. Manifestly one reason is that there is not the opportunity. The railroad map of the United States in 1861 showed about 35,000 miles of railroad; that of 1910 nearly 250,000 miles. The greater part of this development took place in the two decades following the Civil War. There are now few large spaces on that map which remain unsupplied with the major transportation facilities. Nor have the people so much to give by way of bounty as they had in earlier days when they donated to the railroads of the country a tract of land amounting in the aggregate to seven times the superficial area of the State of Pennsylvania. Naturally this condition could not continue indefinitely. There followed a period of reaction in which many lost all that they had ventured in these properties, and now, out of the welter of building, organizing, and reorganizing, we have come upon a period of greater stability in which we are making fuller use of the utilities we have, placing them upon a sounder basis and in fitter condition.

There is to my mind another, perhaps a minor, reason for the comparative decrease in railroad building during later years. The promoter has been engaged in other business. The industrial corporation has been the great speculation of the last few years. Our financiers had fairly well saturated the market with railroad securities, but industrial corporations had never felt the buoyant effect of an aggressive policy of exploitation for speculative or investment purposes. The industry of selling securities is a special psychology. It depends upon impression and suggestion. It hopes not to throw two ideas into the mind of the purchaser at the same time. And so for some years we have found the energy of the interested press and of the "street" devoted to suggesting this most profitable single thought: "Industrials are the things now." With the result that in ten years we have uttered and sold more industrial securities than had been sold upon all the bourses of the world—perhaps more than were ever issued before. But while we know that the wise promoter plays upon a harp of a single string we also know that he sometimes changes that string. So it may come to pass that upon the slightest provocation or excuse his present sad song as to railroad securities may yet turn into a gladsome outburst whenever this shall become advisable.

It is probably true that as a speculative industry railroading in the United States will not flourish in the future as it has in the past. As a basis for sound investment, however, the hope of the American railroad rests in successful regulation.

And because of the very protection now granted under the law there are some who would urge, with reckless disregard of their own history and experience, an increasing rate of toll with every new rise in value. These unwise and too precipitate gentlemen ask that the government shall by force of law do for them what they could not have done for themselves under the private industry theory, and do it possibly to the demoralization of industry. Wisdom would seem to teach that the transition from the one theory to the other must, for the very welfare of the roads themselves, carry with it no conditions that are onerous and not plainly justifiable before the court of public opinion.

What that future shall be is one of those great problems which must necessarily engage the minds of those who think at all upon this most perplexing and many-sided question, and it is one that turns to no slight extent upon the policy which the government adopts toward the railroads, and upon the policy which they adopt toward the government. This country can not grow without adequate transportation facilities. The railroad is our common highroad; it is not a luxury; it is not a concern in which the farmer and the manufacturer alone are interested; it is an essential to the commercial life of our people, almost as necessary as the land itself. The freight rate determines where we shall mine and how we shall mine; where we shall manufacture and how we shall manufacture; where we shall plant and what we shall plant; what we shall eat and wherewithal we shall be clothed.

Should rates be made merely to meet the needs of the day and every new investment come from a new increment of capital, or should the shipper of today be taxed in some part for the benefit of the shipper tomorrow? To whom belongs the broad margin of profit arising out of superior efficiency, and what should be the standard from which to measure up or down? What share should the community itself have in the growth of values which it in part creates? Questions like these are hidden in the often ingenuous inquiry, "What is a reasonable rate?" And their answer cannot be found in the books but must come from a prescient study of the whole railroad problem.

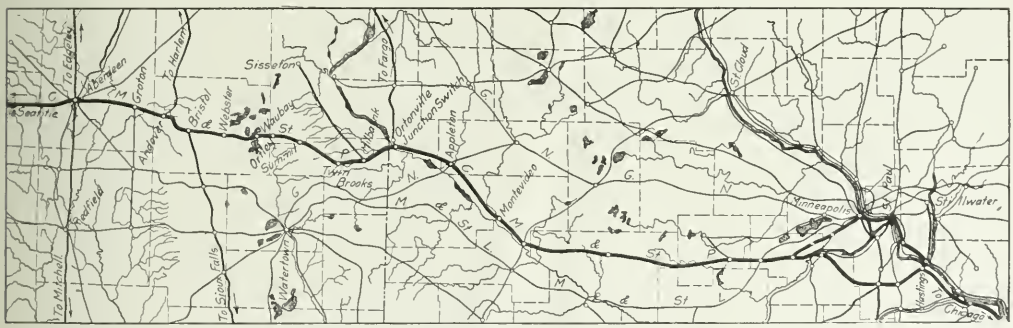
To make regulation a success we must have coöperation—a sympathetic understanding of the direction that must be taken by the shipper, the government, and the railroad man. With the new theory we may hope to see an increasing number of railroad directors who represent the money of the real investor and who give their time to its protection, and of railroad presidents who live at least part of their time upon the line of their own railroads and know the needs of the country they serve and are in touch with its people. In all charitableness it can be said that there has been too close an identity between railroad policies and Wall Street policies. The men who actually operate our railroads, who keep the intricate wheels of this mighty machine constantly in motion and always at our service, receive too little public acknowledgment for the work they perform. They are among the most skilled, capable, and honest of our business and professional men. They have an enthusiasm in their work and a loyalty to their companies that is a constant satisfaction, and their delinquencies too often may be traced to policies which purely as railroad men they would not countenance. With these men we can work, and through them we may hope for the realization of a national system of railroads that will be fair as to rates, profitable as to income, and adequate as to service.

IMPORTANT IMPROVEMENT WORK ON C. M. & ST. P.

Second Track and Grade Revision Between Aberdeen, S. D., and Montevideo, Minn.—Drag Line Excavators Used Extensively.

In line with the policy of the Chicago, Milwaukee & St. Paul of getting its line in readiness for the heavy traffic which the Puget Sound extension and the western feeders are producing in rapidly increasing volume, double tracking and grade and line revision have been undertaken at a number of points on the main line west from St. Paul. On the Hastings and Dakota division about 96 miles of double track east from Aberdeen, S. Dak., have been built during the past season. Work is still under way on other sections between Aberdeen and Montevideo and a short section west of Montevideo was placed in service last year. Between Minneapolis and Montevideo considerable work is under contract. Plans have been made for double tracking the entire distance between Montevideo and Aberdeen. This line was handling during the past summer from 40 to 50 trains per day over single track, and there are abundant indications that the traffic this year will be much heavier than this.

The grades and curves on the old line limited the rating eastbound on this division to 1,600 or 1,700 tons, and only slightly higher than this westbound. The new double track line will be operated with .5 per cent. maximum grades and 1 deg. maximum curves between Aberdeen and Montevideo, and .4 per cent. between Montevideo and Minneapolis. The old line on the hill between Twin Brooks and Summit had 34 curves, some of which were as sharp as 3 deg. 30 min. In the reconstruction work 29 of these curves have been eliminated and the maximum curvature of 1 deg. has been held to. In most cases the new line follows the old very closely, the revisions being confined principally to substituting long tangents for a number of curves. At one point, however, just east of Andover, the new eastbound track has been built on a long loop in order to secure the desired grade. This rather unusual arrangement for a line in a prairie country is shown in the accompanying sketch.



Portion of the C. M. & S. P. Between Aberdeen and Minneapolis Which Is Being Double Tracked and Otherwise Improved.

USE OF DRAG LINE EXCAVATORS IN GRADING.

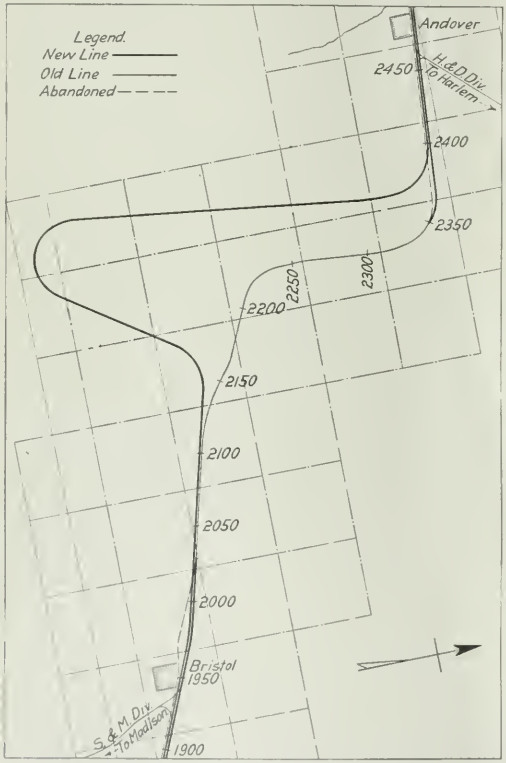
The grading on the section between Aberdeen and Milbank was not exceptionally heavy, amounting to about 4,000,000 yds. The principal interest in this portion of the work is in the fact that the contracts which were handled by drag line excavators were in the aggregate probably the most extensive ever undertaken with these machines in railway construction. The heaviest piece of drag line work was a continuous fill about 4.5 miles long requiring about 900,000 yds., located between Groton and Andover. This work was handled by the general contractors, Morris, Shepard & Dougherty, of St. Paul, using a class 24 and a class 20 Bucyrus drag line. These machines were chosen for this work principally because there was no borrow pit within easy reach where steam shovels could be operated, and also because the material along the line under the top soil was too hard to be handled with elevating graders. The material for the first 4 to 6 ft. consisted of prairie soil, but below this there was an extremely hard grade of shale and hard pan. When the shale was first excavated it was so hard that when struck with a hammer it gave out a ringing tone, but after a few days exposure to the elements it rapidly deteriorated and formed a sticky mud when wet.

The fill was 37 ft. wide at subgrade and varied in height up to 32 ft. As it was necessary that the work be hurried as much as possible, an elevating grader was used to remove the top soil in the side borrow pits which extended 200 ft. from the slope stakes on either side of the fill. The material excavated by these graders was hauled in wagons to the fill and used for building the base to a depth of 10 ft. The smaller drag line then followed on one side of the fill, building up the near slope and filling in the center. This machine was equipped with a 3 yd. bucket and an 85 ft. boom. The larger drag line followed on the other side of the fill, building the other slope and finishing off the grade. It had a 3.5 yd. bucket and a 100 ft. boom, which was long enough to reach the opposite slope of the fill without difficulty.

A small grader, which is ordinarily used for highway work, was kept on top of the fill for leveling and crowning the subgrade. This little machine, which cost only $75, and could be operated with four horses, proved very effective and economical for handling this work. The grader could be set at any height and any angle so that the top of the fill could be very accurately finished. The fills so made were about as clean cut and accurate as are ever seen on railway construction work in this class of material. Both drag lines were required to leave a 5 ft. berm between the toe of the fill and the top of the borrow pit slope. The borrow pits had an average depth of 15 ft. The surface of the ground was level and hard enough to allow the machines to be moved very easily and the width of the pits made it unnecessary to move ahead very far each day; conditions which were very favorable to the economical handling of material by these machines. The only trouble experienced in the moving of the machines was in crossing a 500 ft. ravine which had been filled in with vegetable matter leaving a very soft and boggy surface. To make this unstable foundation safe for the machines, they first filled in about 2 ft. of dry earth as far as they were able to reach, and on this surface was placed a cribbing of ties and 6 in. x 8 in. skidway timbers 14 ft. long. To move the machines ahead the bucket was anchored at an angle of 45 deg. from the direction of

travel in order to prevent cutting up and softening the foundation. By properly placing the rollers the travel of the machine was maintained in a straight line.

When the work was first started the machines were operated with two 10 hour shifts, but later the smaller one was put on three 8 hour shifts. During the early stages of the work the two machines averaged about 1,000 yds. each per shift, but this output was materially increased later. During the month of July, which contained 26 working days, the small machine moved 73,000 yds., and the large machine moved 84,000 yds. During the 18 working days in August, the two machines together handled 130,000 yds. The larger machine averaged 65 swings per hour for an entire month, and for the month of July it made a total of 33,480 swings, the smaller machine



Loop Line Between Bristol and Andover Adopted to Secure 0.5 per cent. Grade East Bound.

making 26,800 swings in the same time. The 900,000 yds. in this fill were handled between June 10 and August 21, about 10 days of that time being lost in getting the machines into operation.

In addition to the engineer and fireman on each machine, there were required from two to six laborers, but there were rarely over ten men employed on both machines. Each machine burned about 6.5 tons of coal in 24 hours, the coal being hauled from a siding near the middle of the section and piled along the line of the work. Water was obtained from artesian wells ranging from 1,000 to 1,200 ft. deep, which delivered it at a head of 30 ft. Considerable trouble was experienced with foaming in the boilers, which an examination showed was due to the large amount of citrate of magnesia contained in this artesian water. The trouble was overcome by mixing crude oil with the water. For introducing this crude oil into the boiler a Detroit lubricator was attached to the boiler in the rear of and below the dome. The steam line leading out of the dome was tapped for the lubricator pipe and the boiler was tapped just above the water line. The condensed steam thus served to force the oil into the boiler. About 3 qts. of oil were used every 24 hours.

Both drag lines were equipped with 3,400 c. p. regenerative arc lights suspended from the boom and eleven 16 c. p. incan-

Class 24 Bucyrus Drag Line Making Fill from Side Borrow.

descent lights on the machine. The power for these lights was supplied by a 2.5 k. w. 110 volt generator direct connected to a reciprocating engine mounted over the main engine.

Paget buckets were used on both machines, but it was found that they worked better when the stiff bails were removed and chains substituted. The loose chain seemed to allow the bucket to adjust itself more easily to the surface of the material in which it was working, and it was possible to handle the buckets fuller than with the stiff bail.

Near Waubay another large piece of drag line work was handled by the Callahan Construction Company with a 90 ton drag line equipped with a 90 ft. boom. Most of this work was in a slough, and in order to get rid of the water ahead of the drag pan a ditch ¾ of a mile long, 80 ft. wide and 15 ft. deep

Filling Cars from Hopper Which Was Fed by the Drag Line.

was dug. An 8 in. centrifugal pump was installed to handle the water that collected. Hoy & Elzy handled a sub-contract near Summit with a drag line excavator which dumped the material into cars. Their machine was of their own make, being entirely of wood, and was equipped with a 45 ft. boom and 1.5 yd. bucket. The engine had 7 in. x 10 in. cylinders and the circle on which the machine swung was 12 ft. in diameter. The material was dumped into a wooden hopper holding about 4 yds., from which it could be dropped to horse-drawn cars of one yard capacity. The bottom of the hopper was just high

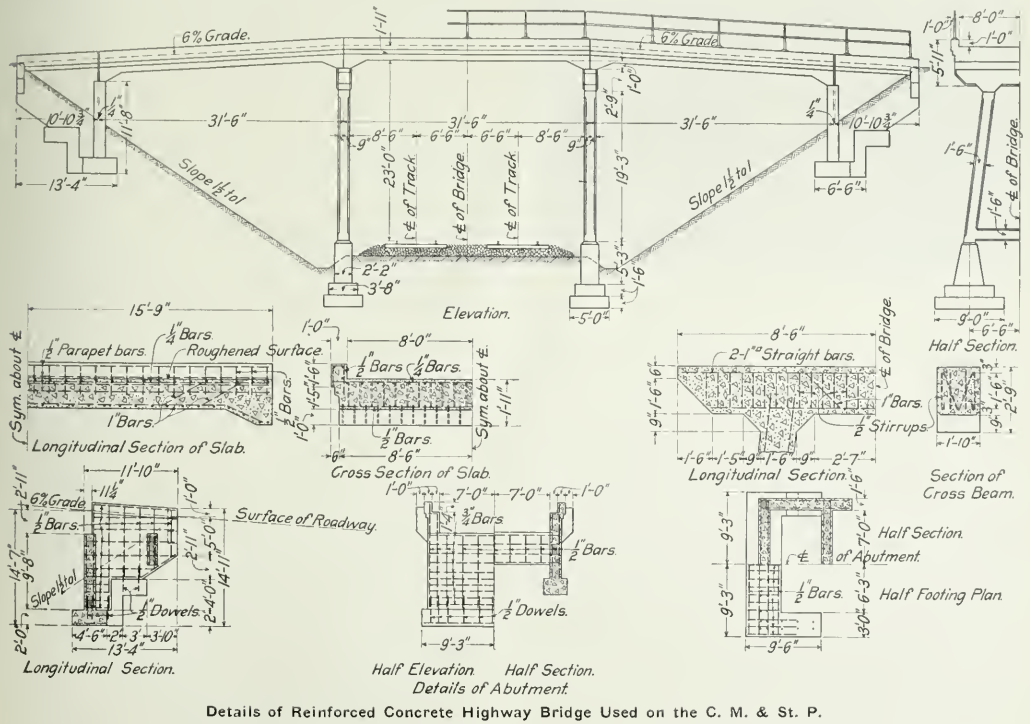
enough to allow a team of horses to walk under it. During the progress of the work it was desired to change the horses for dinky engines pulling longer trains. The clearance of the hopper was not sufficient to operate an engine under it, and on account of the extremely high lift that would have been required to raise the material into a hopper which would clear the engines, it was decided to drop the material directly into the cars. This practice proved very satisfactory, and it was found that the buckets could be dumped closer to the top of the cars than is usual with steam shovels, thereby reducing the drop of the material and lessening the damage to the equipment. Cars of 1.5 yd. capacity were substituted for the 1 yd. cars when the use of the engines was decided upon.

Drag Line Excavator Dumping Directly into Cars.

This machine was handling a very hard cemented gravel which was overlaid with about 2 ft. of loam. Similar material in a steam shovel cut near Ortley was handled without blasting, but it was found necessary in the drag line work to loosen the material with light charges. This drag line worked two 10 hour shifts, using only seven men. One of the best records made was the handling of 68,000 yds. in 30 days. The same contractor operated a Bucyrus drag line of steel construction with a 26 ft. circle, 76 ft. boom and 2.5 yd. bucket, which handled material from a side borrow directly to the fill.

Considerable Light Grading Was Handled by Grading Machines, in this Case Pulled by a Traction Engine.

There were a number of steam shovels used on the work, and the rest of the material was handled by grading machines and team outfits. No unusual features were developed in the handling of these plants.



Details of Reinforced Concrete Highway Bridge Used on the C. M. & St. P.

BRIDGE AND TRACK WORK.

There was no unusual bridge work to be handled, the principal structures being a plate girder bridge over the James

river and a concrete trestle bridge to take care of the overflow of the James river. This trestle is of the standard type used on the Milwaukee lines, having four 16 ft. spans carried on bents of 10 hexagonal concrete piles capped with a reinforced concrete cap 2 ft. 10 in. wide and 3 ft. 6 in. deep. The slabs had a uniform thickness of 3 ft. 6 in. Cast iron or concrete pipe was used for culverts in sizes up to 48 in. Concrete box culverts were used for larger drainage openings. All of the concrete work was handled by company forces under the engineering department. One typical 6 ft. x 8 ft. box culvert, 80 ft. long contained 200 yds. of concrete. Although most of the concrete was mixed and placed by machinery, this particular concrete was hand mixed, being placed in four working days by a foreman and 15 men. The labor cost for the structure was $700.

Wherever possible, separate grades for highways were provided. In most of these cases the road is carried under the tracks in slab top concrete structures varying in size from 20 ft. x 13 ft. to 28 ft. x 16 ft., the barrels being limited in length to 35 to 40 ft. When overhead structures were required they were usually built of timber, but in some cases where the locations were permanently established and there were no changes likely to be made, concrete structures were used. The reinforced concrete bridge which has become standard on the Milwaukee for such overhead crossings consists of three floor slabs of 31 ft. 6 in. spans carried on two column bents and two especially designed abutments. The two column bents of reinforced concrete have 1 ft. 6 in. square columns battered about 1 to 7.5 and tied together just above the footings by a reinforced concrete tie 1 ft. 6 in. square. The floor slabs have a minimum depth of 1 ft. 11 in., and can be used on grades up to 6 per cent.

Trestling for One of the Highest Fills.

At Andover, Bristol and Summit, small yards to care for 200 or 300 cars each, are being provided. Andover and Bristol are junction points with branch lines, and Summit is at the top of the grade where it will still be necessary to store a considerable number of cars at times. A new terminal yard is being built at Montevideo, with a capacity of about 1,000 cars and a yard with fifteen 3,500 ft. tracks; a 30-stall roundhouse, and shops are already in service at Aberdeen. Passing tracks 4,000 ft. long are being provided for both eastbound and westbound trains at about every other station, or at intervals of 15 to 20 miles.

The standard roadbed width for fills is 35 ft., for heights up to 20 ft., and 37 ft. for greater heights. The corresponding widths in cuts are 39 and 43 ft., using 1.5 to 1 slopes in both cases. The new tracks will be laid with 90 lb. rail on fir ties with tie plates. Gravel ballast, obtained from a pit near Wauby is being used.

This construction work is being handled under the direction of C. F. Loweth, chief engineer, W. H. Penfield, assistant to the vice president and formerly assistant chief engineer, and T. H. Strate, construction engineer in direct charge of the work, to all of whom we are indebted for courtesies extended in connection with the securing of the above information.

REPORT ON WAREHOUSE POINT COLLISION.

The Public Utilities Commission of Connecticut has issued a report dated February 8, giving the conclusions of C. C. Elwell, chief engineer of the commission, on the causes of a collision which occurred on the New York, New Haven & Hartford, at Warehouse Point, January 10, about 8 p. m. A north-bound express train was flagged near Windsor Locks. The flagman belonged to extra freight No. 368; and when he reached the next side track and saw a freight standing there, he got off from the engine of the express, and then signalled to the engineman that all was clear. But this proved to be another train, No. 368 having gone forward to the next station. At that station, before it could be set off, the freight was run into by the passenger. One person was injured slightly. The conductor of the freight ran back to stop the passenger train but was not soon enough, there being a sharp curve in the line. The immediate cause of the collision was the failure of the engineman of the express to watch carefully for an automatic block signal which stood on this curve. There is no distant signal for this block signal, and as the curve turns to the left it is customary to depend on the fireman to read the signal. It is visible to him for only a few seconds. A switch, quite near the signal, is visible about the same time. The fireman in this case thinks that he must have mistaken the switch light for the signal light. The inspector says that neither of the two freight trains had lights burning in the cabooses to illuminate the indicator showing the number of the train, and this he calls the primary cause of the accident. The block signal so near the switch is declared to be blindly located. He recommends more careful attention to the indicators in the cabooses; that a distant signal be provided for the home signal referred to, and that prompt consideration be given by the railroad to the removal of all banjo signals on the main line.

REPORT ON DRESDEN COLLISION.

The Interstate Commerce Commission has issued a report made by Chief Inspector Belnap, dated February 18, on the rear collision at Dresden, Ohio, on the Pennsylvania Lines, December 3, last, when passenger train No. 43 ran into the rear of passenger train No. 125 which had been unexpectedly stopped; and 9 passengers and two employees were killed and seven persons injured. The collision occurred about 6 p. m., when it was quite dark, but clear. The trains had left the last preceding station five minutes apart, which is the minimum time interval prescribed by rule 91. The flagman of No. 125 is said to have gone back promptly, walking a part of the time, and part of the time running; and he probably reached a point about 1,000 ft. to 1,200 ft. back of his train when he was passed by train 43. The engineman of train No. 43 could see but a short distance, but the fireman could have seen the tail lights of the standing train about 1,500 ft. off, had he been looking out, but he had been putting coal into the fire just then. Train 43 was running about 50 miles an hour, or faster, though a rule on the time table limits the speed of trains on this part of the road to 40 miles an hour.

The inspector calls the inability of the flagman to get back a sufficient distance the direct cause of this collision, and he says that the time interval should be greater than five minutes. The brakeman is held responsible, however, for not taking fuses with him. These he keeps in his train box, in the smoking compartment of the car, instead of having them at the rear end of the car, where they would be quickly available. Had he put down a fusee the engineman of No. 43 might have seen its reflection in time. The conductor is blamed for not seeing that the flagman had all of his stop signals ready for use in case of emergency. The engineman of No. 43 is held responsible for running too fast, but on evidence of employees it is decided that this speed limit rule is not generally observed. The trouble on the leading train was the breaking of the pipe which supplies air to the air whistle signal. This pipe had been reported, the day before, as needing repairs, and the inspector censures the road for not keeping the engine in proper condition

IMPRESSIONS OF EUROPEAN RAILWAY PRACTICE.

Training of Employees and Careful Selection and Design of Material Are Given More Attention Than in This Country.

By Henry W. Jacobs.

To the motive power man the railroad systems of Europe present an aggregate of about 100,000 locomotives of all sizes and kinds, compared with 60,000 in the United States, and operating over a railroad mileage somewhat less than the mileage of the United States. Railroads have been in existence in Europe even longer than in this country, and, naturally, in the development in each country, the special genius of each people has developed particular excellence in one respect or another; many of these features are pregnant with examples that America might well follow, or at least study and consider most carefully.

The superiority of European railroad mechanical methods generally may be classed into divisions, training of personnel, and selection and design of materials.

In the treatment of the employees in the shops and in locomotive running service, the training is longer and more thorough and careful than it is with us; and this training has as its objective a more definite preparation for the predetermined vocation of the man.

APPRENTICE TRAINING.

For the service of the locomotive and car shops, for instance, apprentice courses and schools in connection with the works or shops are established in all of the countries, with the result that each succeeding generation of mechanics finds men not less skilled than their fathers, but on the contrary, equally as well trained in practical work and with a far better understanding of the technical aspects of the continued improvement in mechanical methods.

The apprenticeship courses are almost equivalent to some of our institutes of technology in the technical groundwork of instruction imparted; and at the same time, by having the young men devote the majority of their time to practical shop work, often in shops especially set aside for the purpose where certain classes of material, such as small locomotive parts and shop tools are made requiring the most accurate workmanship, they become practical skilled mechanics. Such pioneers as George M. Basford in this country, who gave much time and effort in trying to awaken a similar interest in our shops, cannot be too highly commended.

In America we cannot be said to train men that they may be fitted as mechanics. The young man does not set out consecrated, as it were, to the high calling of producing work mechanically and beautifully without flaws. He sets out rather with the desire to get through his journeyman and mechanic days as hastily as possible that he may the sooner be an inventor or a shop superintendent, instead of the consummation of his ambition being the perfection of his skill; such skill as he might acquire is consumed by his ambition. This is a price we are paying for democracy, and our industrial efficiency is footing the bill. We must admit that in this aspect they do things better abroad, where the devotion of a life to the service of a (mechanical) calling is still a live and honored tradition.

The enginemen receive similar careful training for their posts, having to go through a certain amount of shop experience, which gives them a knowledge of the machine they are to run and influences their attitude toward the careful nursing and treatment of that machine when it is entrusted to their care. The result of this attitude is on the one hand to keep the engine at all times in the best working condition, and on the other hand to get from it the maximum possible efficiency. By these methods of training, and also by the provident welfare and benevolent institutions, which find their highest development in Germany, the men fit naturally into a life work and position, and in these positions they are given opportunity to remain.

When the men are in the service their moral welfare continues to be the subject of a kindly paternalistic administration. The soda fountain established in the Budapest shops has been mentioned and furnishes the germ of an idea which may well be adapted to our uses in America. Whether we belong to a prohibition or total abstinence movement or not, we are all agreed as to the evil effects of alcoholism, as to the benefits of temperateness, and it is interesting to note in this connection that American railroads have probably done more (by stern discipline in enforcing Rule G) in the cause of practical temperance than have the political movements to this end. In the extirpation of an evil, we should seek its root. Why is a saloon? The saloonkeeper long recognized that he could not alone draw his trade by selling alcoholic drinks, but to keep and hold his customers he would have to give them good service. For that reason he gives the whole and hearty cheer, the wayside warmth and companionship to the lonely shop or workmen, as in the inn of old, and with practical concession to modern business needs, uses, etc. In the saloon the quickest and cheapest of lunches may be had. Every saloon is (for men) a public comfort station. The barkeeper is the working shopmen's banker, in many instances where his pay-check is cashed without inconvenient red tape, and if the workman is his customer in good standing and needs a dollar or five, he gets it. The saloon in America has made itself a public service institution—not confined to the hours 10 to 3.

How different might our workmen's life here be if the soda fountains had set themselves to give the same service as the bars—if they were such representative servic institutions. In this we have the idea of our R. R. Y. M. C. A.'s—the true way, as the writer has already elaborated in an earlier book, to confirm men in moral habits; and when we add to the moral influences the growing utility of these Y. M. C. A.'s and recreation clubs such as Mr. Ripley of the Santa Fe has instituted, the railroads are developing a public service of the highest order, one deserving even of being fostered by government support, as is done in similar instances abroad.

Not only are the employees carefully prepared for their respective trades, but the engineers who are to design the locomotives, machinery and other paraphernalia of railroad operation are trained with a view to close working limits of the materials employed. Attention is paid to the quality of the material—that it should be of the best for the purpose in view, and that all parts, for instance of a locomotive, shall be as light and small as is consistent with strength because of the limitations as to wheel loads and clearances. For these reasons greater attention is paid to the nature of the metal entering into cylinder and other castings, into rod and other forgings, and to the reduction of the thickness of the walls and other sections to a minimum; and also to the most careful heat treatment and subsequent testing of all parts so as to eliminate internal stresses in the material.

In view of this great care both in design and in selection of material, the locomotive parts are not generally subject to such heavy working stresses and fewer engine failures take place due to breakages of frames, rods, blowing out of cylinder heads, etc.

FISCAL POLICY.

The fiscal policy of the roads abroad with respect to the personnel, particularly of the shops, is such as to provide an

even average of working hours and working output. The necessary financial reserves are maintained for this purpose irrespective of the current high or low tide of traffic receipts. The general policy of a great many of our railroads is to curtail the shop forces and hours whenever a business depression sets in, which has unfortunate results in the disorganization of the working forces, bringing about the loss of many good workmen, and tending to make our mechanics unsettled and causing them to drift from one branch of work to another.

None realize the drawbacks of this policy better than our operating officials themselves, and the necessary financial support should be given to the changes in this procedure that they would be only too eager to bring about. The annual result would increase the net earnings of the roads as compared with the losses entailed by the present practice, as well as give better service and operating conditions. I have been told by men in charge that in the last two years the policy of retrenchment which is very frequently followed to curtail expenses at the close of the fiscal year, had the same effect on the momentum of the work in progress as the continual stopping and starting of a flywheel would have on the even running of a steam engine.

CONSERVATISM OF EUROPEANS.

I had often heard of the ultra-conservatism of Europeans in adopting changes, but I must confess that my personal observations inclined me rather to the opposite view. I found European engineers and shop officers only too ready to accept changes in existing practice that could be shown to be an improvement. For instance, their new shop layouts are well designed and the most modern machinery is installed, some of it, as stated, coming from America. Roundhouses are modern in construction, such details as power driven turntables (even with the smaller locomotives used abroad), efficient ventilation, etc., being given attention. In modern improvements in locomotive design, we must give Europe credit for making the fullest practical use of superheaters, compound and multi-compound engines, tank engines for all classes of service except the heaviest long-distance through express and freight trains; and we should not ignore the practical conservation resulting from the general use of briquetted fuel.

MANUFACTURE OF MATERIALS AND EQUIPMENT.

In another respect, however, a tendency that was not so good, considered economically, either with reference to the railroad operation or the welfare of the industrial community, impressed me very strongly. I refer particularly to conditions obtaining in England. This tendency was towards the manufacture of all kinds of material used in railroad construction and operation at the company's shops, turning the railroad into a very large manufacturing concern. The result of this policy on the part of the English roads is that the locomotive building industry there has received so little encouragement that it is placed at a great disadvantage in maintaining plants for the supplying of engines for the British colonies and for export to other countries in competition with some of the great continental locomotive works. The same condition holds true with regard to the rolling of steel rails, the building of cars etc. This is a policy we should avoid following to too great an extent in America, as railroads are, and should primarily confine themselves to being, a transportation enterprise.

The manufacturing business presents entirely independent and different problems, and can be handled quite as well, if not better, by individuals or companies devoted to the special kind of manufacture in question than is feasible by the large organization of a railroad whose directors and principal officers are primarily concerned with the securing and handling of traffic and the financial problems involved.

A manufacturer of an individual article, such as a bolt for example, has to devote the greatest attention to that article to see that both its quality and its price enables it to survive as a product under competitive conditions. The manufacturer of bolts must make each bolt produce its share of profits or dividends; a railroad company, on the other hand, being organized for the production of transportation and not for the manufacture of materials, has no direct or competitive incentive to make each bolt pay a dividend or be of such design and quality that it may compete (in its efficiency as a bolt) with the kinds of bolts used by other railroads. Marked and indirect advantages accrue from leaving manufacture to concerns especially equipped therefor, since not only can the work be produced as cheaply or more cheaply, with all the overhead charges included, and as well or better than can be done by the railroad shops; but also the employees' families, and the financial supporters of these factories, are drawn into an attitude sympathetic with the railroad enterprises instead of being indifferent as to its welfare. Also the labor position of the railroads is much improved, since an association of employees, that can make a simultaneous demand for an entire railroad system, will be split up among the different manufacturers and trades supplying railway materials, leaving to each industry the handling of its own special labor problems and requirements.

It is well recognized in America that some of our stupendous organizations, employing tens or hundreds of thousands of men, have become unwieldy in their handling of questions relating to the personnel, owing to the physical impossibility of a single man at the head deciding upon all matters; and on the other hand a tendency to take away the power of decision from subordinate officers and officers in direct relation with the men and the questions concerning them. In the past, in smaller concerns, where the employer was in direct touch with his men and with the conditions of the industry, the working condition of the men and the attention given to the character of the product was more satisfactory and gave rise to less discontent, both on the part of the workers and on the part of the users of the materials, than is wont to be the case where the activities are carried on as part of a vast corporation.

Our Railway Business Association has done much to calm popular clamor for the unreasonable in railroad legislation and to counteract a tendency toward drastic rate cutting by government commissions. This organization, although unasked, took the side of the railroads in the recent period of stress, and by its makeup was able to accomplish much that the railroads themselves could not do. Its membership is made up of the largest and strongest, as well as numerous minor concerns, scattered over the land from coast to coast. All members are active allies of the railroads. Their influence through their thousands of employees, permeates and affects public opinion in a way impossible for any other organization. When one considers what this one organization, friendly to the railroads, has done, the advisability of taking work from such concerns and performing it in railroad shops becomes questionable; in fact it seems as if railroad friendships should be built up even more among outsiders by increasing the list of those from whom we purchase and the list of articles purchased. Some roads, however, seem to be going in the other direction and are inclining toward the English practice in this matter.

OPERATION OF EQUIPMENT.

Besides the conditions under which the equipment and other materials of a railroad are produced, there is much that is instructive to us in Europe's example in the operation of this equipment. Reference has already been made to the few engine failures, which, for instance on the Prussian state system, are of such rare occurrence that it is not necessary to make of them a matter of daily or hourly report with continual irritating criticism of officers and men. Of course, reports are made of engine failures when they occur, but these are due almost entirely to some exceptional and unavoidable accidental cause, failures due to wear or weakness of the locomotive parts being corrected as to causes before a failure on the road can take

place. This precaution is exercised by the most careful roundhouse inspection, both on the part of the engine crew to whom the engine is assigned, and on the part of the inspectors charged with this duty. This care in keeping the engine in condition results in a smoothness and reliability of working that is indeed enviable.

OPERATING ECONOMY.

Mention has also been made of the economy of the European locomotives in fuel and steam, this economy commencing with the design of the locomotive and ending with the personal interest of the engineer and fireman and the supervision given to their individual performances by the motive power and transportation officers. Despite our abundance of cheap but excellent coal in America, our fuel bill constitutes such a large percentage of railroad operating cost that we surely should be no more sparing in pains and effort to bring this fuel consumption to a minimum than have been the Europeans.

In view of the several respects in which the European railroads are excellently maintained and operated with closest regard to excellence of service and detailed attention to economy in repair and operation, it may be wondered why European railroads are not more profitably run than are the American roads. While abroad I gave my attention to the practical shop and locomotive aspects of the roads, rather than a comprehensive study of their financial and fiscal arrangements and conditions, but as far as I could gather from the published statistics available in these latter respects, and from conversations with the higher railroad officials, the greater first cost of the railroads in Europe, due to their having originally been built through thickly settled regions where the right-of-way had to be acquired at a high price from private concerns, has imposed upon the roads abroad fixed charges much greater in proportion to the volume of traffic than obtains with us. Another influence is the small clearance of locomotives and cars, and the consequently short train lengths, these limitations having their origin in the fact that the early railroad equipment comprised carriages and wagons transferred from the highways to the metal railed tracks by providing them with flanged wheels and pulling them by a steam locomotive instead of animal traction. With the extension of lines, the early wagon wheel gage, distance between double tracks, sections of tunnels and cuts (often walled so that the least width of strip of land necessary would have to be purchased) were not increased, and it was not considered necessary in view of the greater cheapness of steam railroad haul compared with the previous traffic for the roads. The reason we have employed larger clearances in America is that we were fortunate in building our railroads through a thinly settled and comparatively undeveloped country where the land cost was not so serious a problem.

Since coming back to my native home, I have wondered over the contrasts, the differences that have arisen in so many details in Europe and America, and I am most weighed down by the difference in the way the European and the American view the human aspects of the rail transportation problem. We have dealt with certain aspects of the employee—his selection, his formative period, his security in the enjoyment of the fruits of years of service. These methods are in distinct contrast to "the individualistic shift for yourself free American melee," which has finally crystallized in making our unions so strong—strong because they furnish the channel through which workmen have become more secure in their positions. How often have we seen workmen lose their positions due to the fact that [illegible] foreman was tyrannical and wished to exercise the [illegible] which he had recently been promoted.

The contrast in the attitude toward and by the public is equally striking. Rates and bases for them typify such relations. In England and America rates have arisen almost entirely out of competitive activities between either routes or localities. Certain maxims have been established by law. On the Continent, and particularly in Germany, an attempt at a scientific kilometric-plus-terminal charge classification has been attempted, governmental control of this matter being similar to the aim of our own Interstate Commerce Commission legislation and decision today. The result in Germany has been devious, as exceptions to the flat or zone tariffs; certain commodity rates existed when the new scientific plan was adopted. Under these exceptions or "Ausnahme" tariffs most of the German freight of today moves more pliant to traffic growth than with the rigid so called scientific method, which has correspondingly diminished in proportion to traffic moved.

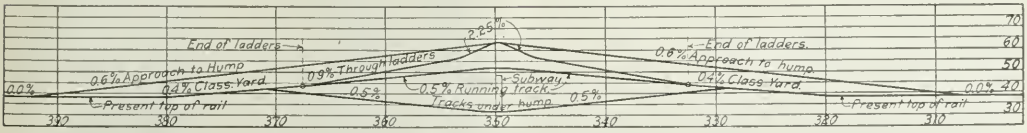
Strangely enough, however, nowhere abroad do we see any indication of an attempt to base rates upon physical valuation of the property used to effect transportation. This is a new shibboleth that has raised its head in our land, and that is destined to wander a tortuous course; we cannot but wonder what will be the effect on two roads of different construction standards between the same termini, or two roads of similar construction, but different operating conditions?

NEW CLASSIFICATION YARD AT CHICAGO.

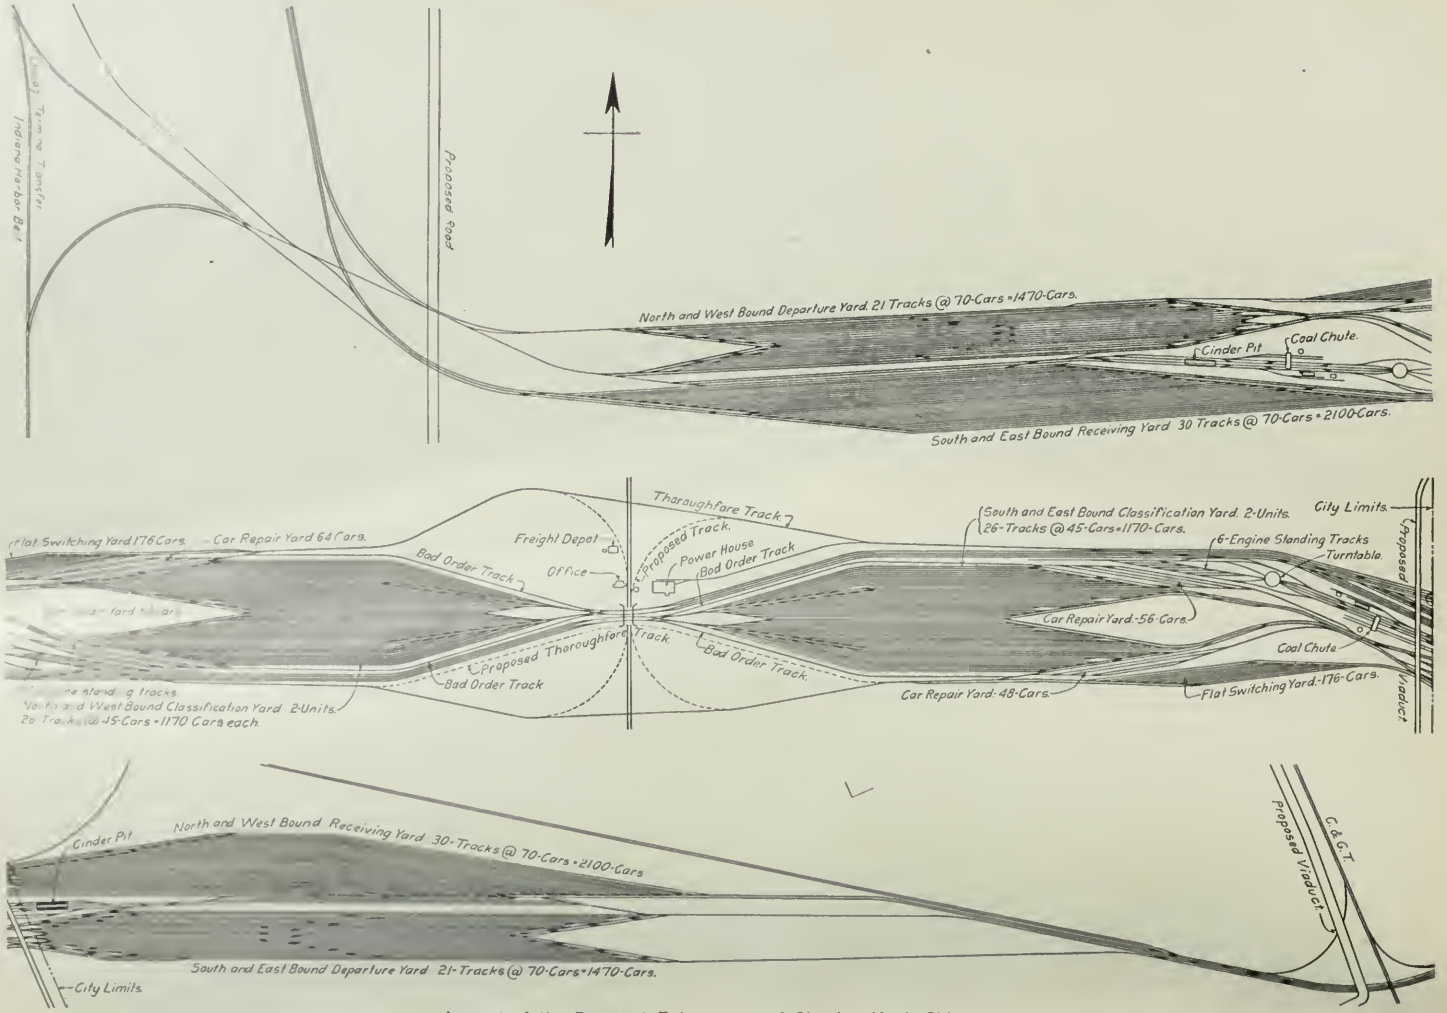
Preliminary plans have just been announced by the Belt Railway of Chicago, showing the nature of the improvements and additions to be made to the Clearing yard, located in the southwest portion of Chicago, as outlined in our news column last week. The original Clearing yard was constructed about 12 years ago by the Chicago Union Transfer Railroad Company, and at the time it was built it was the largest of its kind. Two classification yards were built, one on each side of the hump over which were carried two tracks, one for use in each direction. Small receiving yards were located on the lower level at each side of the hump, but no departure yards were provided, the classification yard serving also as a departure yard. The approach tracks to this yard were so located as to cross each other at grade. This feature combined with others, resulted in considerable delay and interference with train movements, although the old yard has only been used to a very limited extent.

Until recently the Belt Railway has been owned by the Chicago & Eastern Illinois, the Erie, the Grand Trunk, the Wabash and the Monon. As mentioned in the issue of March 22, 1912, page 693, seven other roads, the Burlington, the Chesapeake & Ohio, the Illinois Central, the Pennsylvania, the Rock Island, the Santa Fe and the Soo, have each purchased an interest in this road. The Belt Railway has also recently purchased the Chicago Union Transfer Company, including its real estate and the present hump yard at Clearing. New plans have been prepared for the rearrangement and extension of this yard, as shown in the accompanying drawing.

In order to take advantage of the property already owned and to utilize as far as possible the work already done, the classification yards on each side of the hump have been re-



Profile Over Hump.



Lay-out of the Proposed Enlargement of Clearing Yard, Chicago.

tained, but each has been separated into two yards, each yard leading to its own track over the hump. This yard will serve as a clearing or interchange yard between the various owning roads, and the interchange traffic of each road will, in most cases, be practically all in one direction, although some of the southern roads, as the Illinois Central, for instance, will deliver cars to this yard for connecting lines both east and west. Cars delivered by the eastern lines will be brought into the yard from a connection with the Belt near the Grand Trunk crossing at Hayford. Traffic from the western roads will be delivered at the western end of the yard over the four-track connection from the north, which will swing around parallel to the yard and connect with the Belt about a half mile north of the yard. In this way all traffic will pass through the yard in the direction of its final travel, eliminating reverse movements. This interchange business will all be brought into the yard by the individual roads with their own power, moving over the tracks of the Belt Railway from their various connections.

The receiving and departure yards at both ends will be entirely new. Each receiving yard will consist of 30 tracks of 70 cars capacity each, while each departure yard will have 21 tracks of the same length. The classification yards will each contain 52 tracks holding 45 cars each. One unusual feature worked out in the design of this yard is that providing for four tracks over the hump, enabling this number of trains to be classified at one time. Each hump track is provided with two approach tracks, while the two hump tracks in each direction are connected with crossovers, enabling cars from either track to be sent to any classification track. Arrangement is made for communication between the two sides of the yard by a track passing under the hump.

It is proposed to operate the switches at the ends of the classification yards next to the hump from an interlocking tower placed on the hump. Provisions will be made to light the yard by electricity and to provide means for the proper return of the car riders to the hump. Compressed air will be carried into the departure yards as well as into the repair yards. All power required for various purposes will be generated at the powerhouse, already completed and located near the hump. A coal chute, water tank, cinder pit and turntable will be provided between the classification and the receiving and departure yards at each end.

Work has already been started on this extension and it will be pushed as fast as weather conditions permit. It is aimed to have the yard completed for service late in the present season. Over 1,000,000 cu. yd. of grading will be required to provide for the additional tracks.

When completed, the yard and its approaches will contain about 150 miles of track, while the car capacity in the receiving, classification and departure yards, exclusive of ladders and thoroughfare tracks, will be between 11,000 and 12,000 cars. The plan shown is considered as a first unit and has been designed with a view to the construction of additional units with a minimum interference at any time when the business demands.

In designing this yard the principal ideas kept in mind were: to separate incoming and outgoing business at each end as far as practicable; to provide receiving and departure yards so located with reference to the classification yards that the progressive movements of the cars tended to move them in the direction of their final destination; to bring the points where inbound engines cut off into close proximity with engine terminal facilities and convenient to the departure yards, and, in fact, to enable all movements within the yard to be performed by yard engines so that the transfer engines may be enabled to depart with the least delay and interference to yard movements.

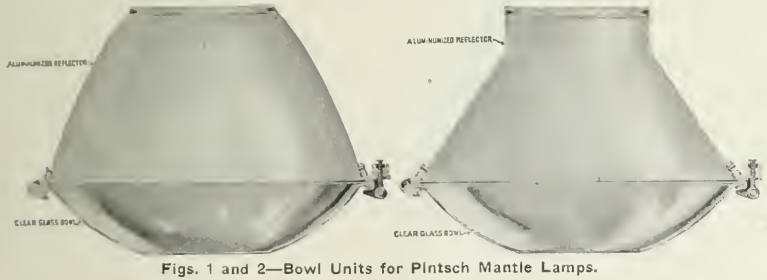
This work has been designed and will be carried out under the direction of E. H. Lee, chief engineer, Chicago & Western Indiana and Belt Railway, who is chairman of an advisory committee of engineers of the proprietary lines, the other members of which are A. S. Baldwin, chief engineer, Illinois Central; J. B. Berry, chief engineer, Rock Island; W. L. Breckenridge, engineer maintenance of way, Burlington, and R. Trimble, chief engineer, maintenance of way, Pennsylvania lines west.

LIGHTING FIXTURES FOR POSTAL CARS.

The results of the exhaustive tests made on a Baltimore & Ohio postal car at Washington during the latter part of last year and the recent specifications for lighting postal cars issued by the post office department are described elsewhere in this issue. The Safety Car Heating and Lighting Company has developed a new line of fixtures for this class of service.

Where the Pintsch lighting system is used, it was found desirable to use a type of metal reflector that would distribute the light properly on the letter cases, bag-racks and paper boxes without a wasteful use of the light on the ceiling and other parts of the car where it was not needed in the distribution of mail matter. Two types of aluminumized steel reflector units have been developed, one for letter case lighting and the other for bag-rack, paper box and storage lighting. Both of these reflector units are made to fit the standard Pintsch mantle lamp, and not only give the required illumination at all points in the car but, by a careful distribution of the light, economize on the gas consumption. The reflector unit shown in Fig. 1 is designed for use on Pintsch lamps in the center of the car to light the bag-racks and paper boxes as well as for general illumination in the car. The characteristic light distribution curve of this reflector is such as to make the labels at all points in the bag-rack and storage portions of the car very distinct.

The reflector unit shown in Fig. 2 is designed for use at the letter cases and its characteristic light distribution curve is such as to insure ample illumination on the horizontal reading plane as well as on all the letter case labels. The conditions of letter case lighting are such as to require careful study in the design of a reflector to meet the requirements, and without extreme care the lighting at some points on the letter case labels is very apt to fall below or above the specifications.



Figs. 1 and 2—Bowl Units for Pintsch Mantle Lamps.

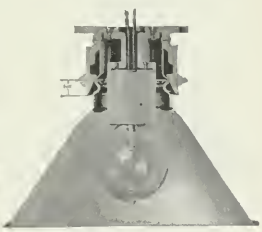


Fig. 3—Shade Holder and Adjustment for Electric Lamp.

This reflector meets these requirements in all cases and allows an ample margin for depreciation. With the standard postal car construction adopted by the post office department, the mounting height of Pintsch mantles should be 7 feet 7 inches from the center of the mantle to the floor of the car, and two different types of mantles are recommended for use with these reflectors.

For electric lighting the government has allowed a wide latitude in the use of lamps and reflectors, and the development of a universal type of lighting fixture has necessitated careful study of all conditions. With different spacing of the light units, any of the standard electric train lighting lamps can be successfully used. Considering the metal reflectors alone, it is necessary to provide a fixture that will give a variety of mounting heights considered in the relation of the top of the reflector to the base contact of the electric lamp. A reflector is designed to meet certain lighting requirements by providing a characteristic light distribution curve when the center of the light source is in a certain fixed relation to the reflector, and it is on account of the variable position of the filament, in different types of electric lamps of different shapes and different wattages, that different heights of the base contact of the lamps in relation to the top of the reflector must be provided for in any universal lighting fixture. As in the case of the Pintsch mantle lamp, the light should be distributed where it is needed for the distribution of mail, and not wasted to light the ceilings of the car. It is claimed that the aluminumized and enameled steel reflectors are most satisfactory for this purpose, since they distribute the maximum light downward and in addition are practically free from the danger of breakage. The Safety Car Heating and Lighting Company has selected five types of steel reflectors for postal car lighting, of which that for letter case lighting is shown in Fig. 3. This is intended for all types of electric lamps used at the letter cases. To provide for the use of these different types of lamps and reflectors, six different positions of the base contacts of the lamps in relation to the top of the reflector must be available, and a shade or reflector holder has been developed on the principle of the safety shade holder, wherein a practically universal adaptation to any of these types of reflectors or lamps is obtained. The variable mounting height of the lamp filament in the reflector is taken care of by an extension member or socket support inside of the shade holder, while all the other parts of the shade holder are interchangeable for all conditions of postal car lighting. These shade holders are made to attach to the base and stem of a fixture designed to give the correct height from the center of the lamp filament to the floor of the car according to the requirements in the government specifications. The bases of these fixtures are made with either one or two outlets for either ½-in., ¾-in. or 1-in. conduit, and provide for an easy and accessible method of conduit wiring inside the car. This universal type of shade holder is also adapted, without change in its construction, to the many types of Crouse-Hinds condulets occasionally preferred by the engineer in installing his electric wiring.

The feature of universally adapting a fixture for every requirement in postal car lighting is of immense advantage to the operation of car lighting, since it provides for future developments in electric lamp manufacture or for a change in the standard types and sizes of lamps in use on the railway having these fixtures already installed. These fixtures use the most approved type of electric lamp sockets having a substantial spring base contact and heavy insulation. For the convenience of railways ordering lighting fixtures for postal cars, the Safety Car Heating and Lighting Company has prepared a table of the lamps, reflectors, and types of holders which may be used to meet the government specifications.

Construction of Light Railways in Argentina.—The government inspector supervising the construction of the light railways in the province of San Juan has reported to the government that progress on the construction of these lines is very slow. He states that the branch to Marquesado is finished and that with respect to the circuit from San Juan to Santa Lucia the buildings, earthworks, sidings, and telegraph have been finished to Santa Lucia, and this branch has just been opened. The branch from Caucete to Albardon is progressing very slowly, earthworks are finished to kilometer 18, and wiring on both sides of the line is complete to that distance. He states that this branch is of great importance for the commercial and agricultural development of this important zone.

General News.

A message by wireless telegraph sent from Key West, Fla., recently was heard at Cairo, Egypt, about 7,000 miles away.

The United States district attorney at Chicago filed a bill in the district court on March 13, to recover $6,200 in penalties from the Illinois Central for violations of the federal hours of service law.

The Department of Agriculture reports that the losses by fire in the national forests during the year 1912 were lower than for many years. The total is estimated at $75,290. The aggregate number of acres burned over was 230,000, as compared with 780,000 acres in 1911.

A letter from the president of the Pennsylvania Railroad to the governor of New York, protesting against the adoption of a full crew law, is given in another column. The presidents of the New York, New Haven & Hartford, the New York Central and the Erie have sent similar letters to the governor.

The postmaster general reports that the number of parcels carried in the mails during the month of February was about fifteen million, or 50 per cent. in excess of the number carried in January. The number mailed in Chicago was 5,167,540 ,more than a million greater than the number sent from New York, which showed the next largest record.

About five hundred men working in the track repair department of the Pennsylvania Railroad in New Jersey struck and left their work last week. Two hundred electrical workers of the New York, New Haven & Hartford struck March 17, demanding higher pay and better conditions. These men are repair and maintenance men on the electric-traction section of the road, west of Stamford.

Another new passenger train is to be put in service on April 1 by the Chicago & North Western and the Union Pacific between Chicago and San Francisco in addition to the new extra-fare "Overland Limited." It will be called the San Francisco Limited, and will leave Chicago daily at 8:30 p. m., arriving at San Francisco at 8:50 p. m., the third day. Eastbound it will leave San Francisco at 11:40 p. m., arriving in Chicago at 8:30 a. m.

A press despatch from Washington, purporting to give the utterances and views of Interstate Commerce Commissioner McChord, says that orders have been issued to safety appliance inspectors to be more rigid in the inspection of railroad equipment; and that the commission intends henceforth to impose maximum instead of minimum penalties. This increase in vigilance is for the purpose, we are told, "to avert the usual spring crop of wrecks."

The Pennsylvania Railroad has increased the pay of 2,700 telegraphers, despatchers, agents and signalmen an average of 10 per cent. The employees were represented in negotiations by a committee of 28, headed by C. M. Giles. The readjustment will add $75,000 to the payroll of the company and will affect 790 offices and towers on the lines east of Pittsburgh. The question of a general increase for men of these classes throughout the system is now being considered. The question of granting two relief days a month will be taken up later.

The mayor of Youngstown, Ohio, has ordered the Erie railroad to cease running trains through the city faster than six miles an hour. This enforcement of an old city ordinance follows a long campaign in which the city has called on the Erie to abolish five grade crossings in the heart of the business section. The final crisis arrived on March 13, when an eastbound Erie passenger train crashed into a street car on one of the crossings, demolishing the car, seriously injuring 22 persons and killing two outright. The state railroad commission will investigate the case, and the city officers think the commission will order the road to abate the crossings. The cost of such a change would be very high, probably $1,000,000.

New Jersey Grade Crossing Law.

The law which has been passed in New Jersey to abolish grade crossings of highways and railroads is chapter 57 of the public laws of 1913. It gives the Board of Public Utility Commissioners authority to order railroads at their own expense to abolish a crossing whenever it shall appear that [illegible] or that public travel is impeded. The entire expense is to be borne by the railroad, except that (1) a street railway may be required to pay 10 per cent. of the direct cost; (2) the expense of relaying sewers, pipes, paving, etc., is to be borne by the city or town, and (3) wires, pipes, etc., belonging to corporations or private parties must be moved by their owners.

Passenger Train Equipped with Automatic Connectors.

A train on the Cincinnati, New Orleans & Texas Pacific, consisting of locomotive, mail, baggage and express car, combination coach, day coach and parlor car and operating between Cincinnati, Ohio, and Danville, Ky., has been equipped with automatic connectors for steam heat, brake and signal pipes, as well as a telephone line. According to officers of the railway the device has been in service two weeks with good results, the train covering 230 miles daily. The connector is manufactured by the Durbin Automatic Train Pipe Connector Company, St. Louis, Mo.

Speed Recorders on the Baltimore & Ohio.

The through passenger trains of the Baltimore & Ohio are now equipped with two speed recorders, two to a train; one in the baggage car and one in the locomotive. In the baggage car the "Haushalter" speed tape is used, while on the locomotives the Boyer speed recorder is used. Both of these machines make records on tapes. At the end of each trip the tape is taken out by the local inspector, who makes a suitable record of the date, time, etc., and sends the whole to the office of the general inspector of transportation, where a permanent record is kept. The information given on the tapes is checked against the rates of speed prescribed in the results limiting speed at different points on the road, so that excessive speed is at once brought to notice. The maximum speed of passenger trains on the Baltimore & Ohio, except between Philadelphia and Washington, is 60 miles an hour, and the officers require a rigid observance of the limit. On the Philadelphia-Washington line the limit is 65 miles an hour.

Railway Legislation, Passed and Proposed.

The Utah senate has rejected a bill providing for the creation of a public utilities commission.

The governor of Indiana has signed a bill passed by the legislature giving the railroad commission power to order the separation of grades at crossings in the state.

Both houses of the Missouri legislature have passed bills requiring all railways, electric railways, street railways and terminal companies to incorporate under the laws of Missouri. The senate bill prohibits such companies from transferring freight or passengers within the state, unless so incorporated, and imposes a penalty of $2,000 to $10,000 for each violation.

New York City Subways.

After exasperating delays in the courts and elsewhere extending over more than two years, the New York State Public Service Commission First district, on Wednesday of this week signed contracts with the Interborough Rapid Transit Company and the Brooklyn Rapid Transit Company for the construction and operation of new subways, designed to complete the system of underground rapid transit in the boroughs of Manhattan, Bronx, Brooklyn and Queens. The city government has appropriated $88,200,000 for this work, the estimated amount which will be necessary to pay for the share of the improvement which is to be paid for by the city.

Railroad Valuation and Rates.

It is not surprising that "members of the Interstate Commerce Commission are said to be staggered by the problem of physical valuation of railroads, telephone and telegraph lines, laid upon them by a recent act of Congress." It is said that "a huge corps of engineers and accountants and writers will be required for the valuation" and that "this is the most gigantic task ever imposed on any government." It may also be said that the task will cost an enormous sum and cannot possibly be accomplished with any approximation to accuracy. Such a result as may be reached will be absolutely worthless.

The man more responsible than any other for getting this

absurd requirement through Congress is Senator La Follette, of Wisconsin, and it is amazing that a majority of both parties should have been brought to its support. The only excuse for it is the contention that the Interstate Commerce Commission cannot determine what a reasonable rate is without knowing the actual value of the railroad property. This is the height of absurdity. It is certain that a reasonable rate cannot be determined by any such method as that proposed. The value of any property in use, that for which it can be bought or sold now and upon which its owners are entitled to a return, depends upon many considerations besides what it originally cost. A rule for rate-making, of the kind proposed, would throw into confusion the whole system of traffic and shift lines of communication all over the country, leaving many of them in ruins. If this task of the Interstate Commerce Commission should be prosecuted for a series of years at great cost to the government and the railroads, all paid for in the end by the people of the country, the result would be found to be utterly useless for the ostensible purpose. Congress ought to put a stop to the ridiculous farce.—*Journal of Commerce, New York.*

Argument for Government Valuation.

On the subject of valuation of railroads by the government, Chairman Clark of the Interstate Commerce Commission is quoted as follows:

The law requires that the rates of the carriers shall be reasonable. Manifestly the fair return upon the value of the property cannot be determined until the value of the property is known. In one important case involving advanced rates on a commodity that moves in large volume the carriers presented to the commission voluminous testimony as to the value of their properties. This testimony was uncontradicted, as no one aside from the carriers themselves had any reliable information on that subject. Advanced rates prescribed by the commission were established by the carriers, but the validity of the order was challenged in the courts. Exhaustive testimony was presented before the court in which the carriers again proved the value of their properties, and, strangely, those values for each of two carriers were something like $100,000,000 more than those which had been proved before the commission a comparatively short time before. And it was not because of additional investment or improvement in the interim. The commission was finally upheld by the Supreme Court of the United States. But suppose that the carriers had proved the value of their properties to have been much greater than they did. Who could have disproved the claim? Who knows the value of the property of a single carrier? Congress has provided a means for securing reliable authentic and exhaustive information on which to base a determination of the cost, the present, and the reproductive value of these properties that exist under public franchises and perform public functions. The owners of the properties are guaranteed a hearing upon any objections which they may desire to present against valuations proposed by the commission. The work is one of great magnitude, but the commission is not, as has been suggested, staggered or dazed by the duties that have been placed upon it. The work will be approached and proceeded with in a business-like, impartial and thorough way. The amount of available funds, the number of available, competent men, and the time necessarily spent in securing reliable information as to financial matters in the past, all bear directly on the question of how soon the work can be completed.

New Haven's Experience with the Automatic Stoppers.

The New York, New Haven & Hartford announces that since Mr Mellen made his ten-thousand-dollar offer, published a few months ago, 1,574 automatic train stops have been presented to it; and that two of the devices submitted are going to be tried. The names of these two are not given, being withheld, evidently, for the purpose of breaking the news gently to the friends of the other 1,572. Proposals came from Panama, Porto Rico, Jamaica, Belgium, France, Ireland, Hawaiian Islands, England, Scotland, Wales, Germany, Denmark and a few other places. This list should make the government at Washington a trifle jealous, for in the list of applicants before the Block Signal Board, Panama, Porto Rico and Ireland do not appear. The New Haven people have searched the patent office records, and find there 1,483 patents on automatic stops and cab signals. The 91 devices not patented are, doubtless, so full of merit that they have no need of such adventitious protection as a patent.

Describing his experiences, an officer of the New Haven says: "Many of the devices submitted were ingenious, if not practical, but only about 5 per cent. of them were worthy of consideration. One device consisted of a heavy spring hook which it was claimed would automatically raise up from the roadbed when a train passed a signal and catch hold of an axle on one of the cars, thereby stopping the train. [Described in *Scientific American* about 30 years ago.] The competitors represent nearly every walk of life, from clergymen to jail birds. Four of them are in jail and one has recently been indicted in Canada for attempting to sell stock on false pretences [and has been sentenced to imprisonment in the United States]."

The New Haven road must henceforth be classed as a benevolent institution—anything but a soulless corporation. Merely to classify and acknowledge these 1,574 communications must have required a lot of work, and the statements of the officers indicate that they expect to test the two devices at the road's expense. Mr. Mellen's offer may be taken as one more demonstration of the power of money, for the number of inventions presented to him is more than double the number brought before the Block Signal Board at Washington during its four years' existence. A large share of the 1,146 schemes presented at Washington had to do with other elements of railroad operations; ties, rails, rail joints, brakes, life-saving cushions, health-promoting apparatus, etc.

Annual Report of Bureau of Explosives.

The annual report of Colonel B. W. Dunn, chief inspector of the Bureau for the Safe Transportation of Explosives and Other Dangerous Articles, shows that 14,609 inspections were made by the bureau during the last calendar year. The total number of packages condemned as unsafe for transportation was 5,197; 4,798 boxes of high explosives and 399 kegs of black powder. These figures show a decided reduction, the totals for the preceding year having been 6,591 boxes of high explosives and 1,205 crates of black powder. The number of cars in transit found to seriously violate the regulations was very much larger last year than the year before; 456 in 1912 and 210 in 1911.

The number of railway companies belonging to the bureau has steadily increased, and now aggregates 290; and the mileage of these lines is 249,751. The aggregate losses caused by accidents in transportation of explosives during the year 1912 was $10,200, which is very much less than in any preceding year of the record, except 1909, when the total was only $2,673. A table is given showing accidents occurring in the manufacture, storage or use of explosives, which during the year aggregated 56 accidents; persons killed 80; persons injured 93; property loss $2,136,428.

The inspectors of the bureau, reporting on cases of rough treatment of cars, have not been able to find any improvement over preceding years. Investigation of instances of rough handling of cars almost always brings from the operating officer of the railroad the reply that he finds no evidence of rough treatment. The train men do not attend the inspectors' lectures as often as do other employees. The inspectors have tried to instruct trainmen and yardmen by going into the yards at night; and they find that most of the men respond readily to instruction. Commenting on the difficulty of securing the interest of all employees in the instructions which are given by the inspectors, looking to safeguarding lives and property, Colonel Dunn says:

"The only cheap way to get valuable experience is to learn of the misfortunes of others. It is true unfortunately, that the maximum interest in our work is taken by those who have suffered from explosions. If a car of dynamite were to explode about once a year on the lines of each of our members, our lecture halls could not contain the audiences, and the reports of our inspectors would be on the top of every pile of correspondence awaiting action."

A general meeting of the bureau will be held in New York City in the month of May.

Thirty pages of the report are devoted to detailed accounts of accidents, eight pages to a report from the chemical laboratory, and twelve pages to lectures.

Full Crew Law: Cost $783,917.

President Samuel Rea, of the Pennsylvania Railroad, has sent to Governor William Sulzer of New York a protest against the proposed full crew law in that state, the bill for which has been passed by the Assembly and favorably reported to the Senate. Following a strong statement of arguments with which our readers are already familiar, Mr. Rea says:

"This measure lays down an arbitrary rule. There must be the same number of men on a passenger train, for example, whether it is a continuous run of 100 miles or a run involving stops at every way station. Such a rule adds an extra and unnecessary brakemen, arbitrarily, to a large number of trains. If he contributes to the safety of passengers or other train employees, by all means put him on the train. But no additional security is obtained. Advocates of similar legislation have been repeatedly and successfully challenged to name any serious accident resulting from insufficient train crews.

"Bills similar to that now pending in New York were vetoed by Governors Hughes and Dix, and also by Governor Foss of Massachusetts and Governor Harmon of Ohio, on the very proper ground that the public service commission should deal with all such questions. The decision in different cases should be left to the railroad manager, unless there is an inadequate or improper practice, in which case public service commissions should have power, after hearings, to prescribe the practice to be followed. As a matter of fact, there are runs on our own road calling for even more men than are stipulated in the unvarying rule of this bill. In other cases, a smaller number of men is quite sufficient.

"If then there is no additional safety and no increased efficiency in a superfluous crew, and if the public interests are adequately safeguarded through the Public Service Commission, why place upon the railroads, and ultimately upon the public, the burden of a heavy and fruitless expenditure?

"How will the unnecessary extra employees advantage the men already working for our company, especially our lines in New York state which do not now fully earn their fixed charges, let alone any dividends; or how will this unnecessary expense help these lines to provide the high character of service required by the public?

"Our records show that the Pennsylvania Railroad has already wasted $783,916.84 in complying with the extra crew law which is now being contested before the courts of Pennsylvania. How will a similar waste benefit the people of New York?"

In connection with Mr. Rea's letter the reader will be interested in the following extract from the *Wall Street Journal* of December 11, 1912:

"On November 3, two days before election, the legislative representative of the Brotherhood of Railroad Trainmen sent the following letter to all members of the organization in New York state: . . .

"Sirs and Brothers:

"Believing that the most important subject concerning our organization today is the full crew bill, and being anxious to secure the passage of said bill, I considered it my duty to learn the attitude of the candidate for governor who is most likely to win out, so I called upon the Hon. William Sulzer and requested that he state his position on this most important measure.

"Mr. Sulzer said to me, 'If I am elected I will sign the full crew bill, and I will aid you in securing its passage.' He also requested that I notify the lodges of the state as to his position. Continuing, he said: 'I would come out openly for the bill, but if I did the railroads would spend a barrel of money to defeat me. . . .'

"Fraternally yours,
"John Fitzgibbons, Leg. Rep. B. of R. T."

President W. C. Brown, of the New York Central, sent to the governor a letter similar to Mr. Rea's and adding certain other points. Mr. Brown said:

The placing of an additional man on all trains is not only not an additional source of safety but may prove otherwise. No accident in this State has ever been laid by a proper authority to undermanning of trains. Since the Public Service Commission has been in office it has not reported that a single one of the many accidents which have been investigated by it was caused by the undermanning of trains. It is estimated that if this legislation should become a law the increased cost to the railroads of the State would be $2,000,000 a year. The increased cost to the New York Central will be $750,000 a year. In the event of the railroad managers the expenditure of this vast amount of money will be a pure waste. It will in no sense tend to greater safety or greater efficiency of operation. It is a vast, unreasonable and unnecessary economic waste. The overmanning of a train causes the excess man or men to idle away their time, and thus detracts from the efficiency of the service performed.

If, however, there is any necessity for an increase of the number of men upon any trains, the Public Service Commission has jurisdiction to entertain a complaint and to make an authoritative decision. It has already exercised it in two cases, one being against the New York Central.

This particular bill and bills of a kindred nature are a direct and serious blow to the farmers of the State.

The State of New York consumes approximately $1,200,000,000 worth of farm products each year, but of this amount it produces only about $300,000,000 worth.

During the ten years from 1900 to 1910 the acreage of improved lands in the State of New York fell from 16,000,000 to 15,000,000, or a loss of 1,000,000 acres.

During the same period the production of butter fell from approximately 75,000,000 pounds in 1900 to 25,000,000 pounds in 1909.

The most discouraging obstacle in the way of agricultural improvement is the absolute inability to secure help. Dairy farmers are selling their cows, producers of cereals, vegetables and fruit are having their operations curtailed every year on account of the inability to obtain efficient help.

This bill, if it becomes a law, will draw from the present inadequate equipment of help on the farms of New York approximately 2,000 men, and will to that extent further cripple the farmers and discourage the efforts now being made in the interest of agricultural improvement in the State.

The railroad draws on the rural communities along its lines for nearly all its employees. There is no other source from which they can be recruited, and this bill, compelling the railroads to employ men for which there is not the slightest necessity, is an economic mistake and a direct blow at every farmer in the state now struggling desperately to keep help to run his dairy and maintain his farm.

American Society of Mechanical Engineers.

The railway committee of the American Society of Mechanical Engineers has arranged for the discussion of the subject of Steel Passenger Car Design in its various phases at a meeting to be held April 8, as mentioned in the *Railway Age Gazette* of March 7. The final list of papers and authors is as follows: Introduction to General Discussion of Steel Passenger Cars, H. H. Vaughan (C. P.); Interior Steel Finish, Felix Koch, Pressed Steel Car Company; Roof Structures, C. A. Seley (Rock Island Lines); Corrosion and Protection of Steel Passenger Cars, C. D. Young (Penna. R. R.); Problem of Steel Car Design, W. F. Kiesel, Jr. (Penna. R. R.); Suspension of Steel Cars, E. W. Summers, president, Summers Steel Car Company; Truck for Steel Passenger Cars, J. A. Pilcher (N. & W.); Provision for Electric Lighting in Steel Cars, H. A. Currie (N. Y. C. & H. R.); Provision for Electrical Equipment on Steel Motor Cars, F. W. Butt (N. Y. C. & H. R.); Special Ends for Steel Passenger Cars, H. M. Estabrook, president, Barney & Smith Car Company; Draft Gears for Steel Passenger Cars, S. P. Bush, Buckeye Steel Castings Company; Cast Steel Double Body Bolster and End Frames for Steel Cars, C. T. Westlake, Commonwealth Steel Company.

Railway Signal Association.

Secretary Rosenberg has announced that all of the propositions submitted to letter ballot at the last annual meeting have been adopted by the required two-thirds affirmative vote. The specifications, drawings, etc., thus adopted are printed in the March issue of the *Journal* of the association.

The proceedings of the association for the year 1912, including these newly adopted standards, will be issued about April 1, making volume 9. Bound in cloth, these proceedings will be sold to members of the association at $1.50, and to non-members at $2. Orders should be sent in to the secretary at once.

Secretary Rosenberg announces that Vandyke negatives or

blue prints of any one of the 124 standard drawings of the association will be furnished by him, full size, at the following prices: Vandyke negatives, 50 or over, 40 cents a copy; less than 50, 50 cents a copy: blue prints 18 cents each. The drawings are 8½ in. x 13 in.

American Society of Engineer Draftsmen.

The Boston members of the American Society of Engineer Draftsmen have made arrangements to hold a general gathering of draftsmen at Franklin Union, Boston, on March 25, with the idea of determining the advisability of forming a branch of the society. The New York office of the society has been moved from 116 Nassau street to 74 Cortlandt street where larger space has been secured. Walter M. Smyth is secretary.

Machinery and Supply Convention.

A triple joint convention of the National Supply & Machinery Dealers' Association, the Southern Supply & Machinery Dealers' Association and the American Supply & Machinery Dealers' Association will be held at Indianapolis, Ind., April 10-12. F. D. Mitchell, 309 Broadway, New York, is secretary of the American Supply & Machinery Dealers' Association.

American Society of Civil Engineers.

At the meeting of the American Society of Civil Engineers, March 19, a paper by E. J. Schneider, M. Am. Soc. C. E., entitled Construction Problems, Dumbarton Bridge, Central California Railway, was presented for discussion and illustrated with lantern slides. This paper was printed in the *Proceedings* for January, 1913.

New York Railroad Club.

The ninth annual electrical meeting of the New York Railroad Club will be held March 21. There will be no set papers, but addresses will be made by men actively engaged in the electrical field.

MEETINGS AND CONVENTIONS.

The following list gives names of secretaries, dates of next or regular meetings, and places of meeting.

Air Brake Association.—F. M. Nellis, 53 State St., Boston, Mass. Convention, May 6-9, St. Louis, Mo.

American Association of Demurrage Officers.—A. G. Thomason, Boston, Mass. Convention, May 20, Chicago.

American Association of General Passenger and Ticket Agents.—W. C. Hope, New York.

American Association of Freight Agents.—R. O. Wells, East St. Louis, Ill. Annual meeting, June 17-20, Buffalo, N. Y.

American Association of Railroad Superintendents.—E. H. Harman, St. Louis, Mo., 3d Friday of March and September.

American Electric Railway Association.—H. C. Donecker, 29 W. 39th St., New York.

American Electric Railway Manufacturers' Assoc.—George Keegan, 165 Broadway, New York. Meetings with Am. Elec. Ry. Assoc.

American Railway Association.—W. F. Allen, 75 Church St., New York. Next meeting, May 21, New York.

American Railway Bridge and Building Association.—C. A. Lichty, C. & N. W., Chicago. Convention, October 21-23, 1913, Montreal.

American Railway Engineering Association.—E. H. Fritch, 900 S. Michigan Ave., Chicago. Convention, March 18-20, 1913, Chicago.

American Railway Master Mechanics' Association.—J. W. Taylor, Old Colony building, Chicago. Convention, June 11-13, Atlantic City, N. J.

American Railway Tool Foremen's Association.—A. R. Davis, Central of Georgia, Macon, Ga.

American Society for Testing Materials.—Prof. E. Marburg, University of Pennsylvania, Philadelphia, Pa.; annual, June, 1913.

American Society of Civil Engineers.—C. W. Hunt, 220 W. 57th St., New York; 1st and 3d Wed., except June and August, New York.

American Society of Engineering Contractors.—J. R. Wemlinger, 11 Broadway, New York; 2d Tuesday of each month, New York.

American Society of Mechanical Engineers.—Calvin W. Rice, 29 W. 39th St., New York.

American Wood Preservers' Association.—F. J. Angier, B. & O., Baltimore, Md. Next convention, January 20-22, 1914, New Orleans, La.

Association of American Railway Accounting Officers.—G. P. Phillips, 143 Dearborn St., Chicago. Annual meeting, May 28, Atlantic City, N. J.

Association of Railway Claim Agents.—J. R. McSherry, C. & E. I., Chicago. Next meeting, May, 1913, Baltimore, Md.

Association of Railway Electrical Engineers.—Jos. A. Andreucetti, C. & N. W. Ry., Chicago. Semi-annual meeting, June, 1913, Atlantic City, N. J.

Association of Railway Telegraph Superintendents.—P. W. Drew, 112 West Adams St., Chicago. Annual, May 20, 1913, St. Louis, Mo.

Association of Transportation and Car Accounting Officers.—G. P. Conard, 7 Church St., New York.

Association of Water Line Accounting Officers.—W. R. Evans, Chamber of Commerce, Buffalo, N. Y. Annual meeting, October 8, Philadelphia, Pa.

Bridge and Building Supply Men's Association.—H. A. Neally, Joseph Dixon Crucible Co., Jersey City, N. J. Meeting with American Railway Bridge and Building Association.

Canadian Railway Club.—James Powell, Grand Trunk Ry., Montreal, Que.; 2d Tuesday in month, except June, July and Aug., Montreal.

Canadian Society of Civil Engineers.—Clement H. McLeod, 413 Dorchester St., Montreal, Que.; Thursday, Montreal.

Car Foremen's Association of Chicago.—Aaron Kline, 841 North 50th Court, Chicago; 2d Monday in month, Chicago.

Central Railway Club.—H. D. Vought, 95 Liberty St., New York; 2d Thurs. in Jan. and 2d Fri. in March, May, Sept., Nov., Buffalo, N. Y.

Civil Engineers' Society of St. Paul.—L. S. Pomeroy, Old State Capitol building, St. Paul, Minn.; 2d Monday, except June, July, August and September, St. Paul.

Engineers' Society of Pennsylvania. E. R. Dasher, Box 704, Harrisburg, Pa.; 1st Monday after 2d Saturday, Harrisburg, Pa.

Engineers' Society of Western Pennsylvania.—E. K. Hiles, Oliver building, Pittsburgh; 1st and 3d Tuesday, Pittsburgh, Pa.

Freight Claim Association.—Warren E. Taylor, Richmond, Va. Next convention, June 18, Bluff Point, N. Y.

General Superintendents' Association of Chicago.—E. S. Koller, 226 W. Adams St., Chicago; Wed. preceding 3d Thurs., Chicago.

International Railway Congress.—Executive Committee, 11, rue de Louvain, Brussels, Belgium. Convention, 1915, Berlin.

International Railway Fuel Association.—C. G. Hall, 922 McCormick building, Chicago. Annual meeting, May 21-24, Chicago.

International Railway General Foremen's Association.—Wm. Hall, 829 West Broadway, Winona, Minn. Next convention, July 22-25, Chicago.

International Railroad Master Blacksmiths' Association.—A. L. Woodworth, Lima, Ohio. Annual meeting, August 18, Richmond, Va.

Maintenance of Way Master Painters' Association of the United States and Canada.—W. G. Wilson, Lehigh Valley, Easton, Pa.

Master Boiler Makers' Association.—Harry D. Vought, 95 Liberty St., New York. Convention, May 26-29, 1913, Chicago.

Master Car Builders' Association.—J. W. Taylor, Old Colony building, Chicago. Convention, June 16-18, Atlantic City, N. J.

Master Car and Locomotive Painters' Assoc. of U. S. and Canada.—A. P. Dane, B. & M., Reading, Mass. Annual meeting, September 9-12, Ottawa, Can.

National Railway Appliance Assoc.—Bruce V. Crandall, 537 So. Dearborn St., Chicago. Meetings with Am. Ry. Eng. Assoc.

New England Railroad Club.—W. E. Cade, Jr., 683 Atlantic Ave., Boston, Mass.; 2d Tuesday in month, except June, July, Aug. and Sept., Boston.

New York Railroad Club.—H. D. Vought, 95 Liberty St., New York; 3d Friday in month, except June, July and August, New York.

Northern Railroad Club.—C. L. Kennedy, C., M. & St. P., Duluth, Minn.; 4th Saturday, Duluth.

Peoria Association of Railroad Officers.—M. W. Rotchford, Union Station, Peoria, Ill.; 2d Thursday.

Railroad Club of Kansas City.—C. Manlove, 1008 Walnut St., Kansas City, Mo.; 3d Friday in month, Kansas City.

Railway Business Association.—Frank W. Noxon, 2 Rector St., New York. Annual dinner, second week in December, 1913, New York.

Railway Club of Pittsburgh.—J. B. Anderson, Penna. R. R., Pittsburgh, Pa.; 4th Friday in month, except June, July and August, Pittsburgh.

Railway Electrical Supply Manufacturers' Assoc.—J. Scribner, 1021 Monadnock Block, Chicago. Meetings with Assoc. Ry. Elec. Engrs.

Railway Gardening Association.—L. S. Butterfield, Lee's Summit, Mo. Next meeting, August 12-15, Nashville, Tenn.

Railway Development Association.—W. Nicholson, Kansas City, Southern, Kansas City, Mo.

Railway Signal Association.—C. C. Rosenberg, Bethlehem, Pa. Meetings, March 17, Chicago; June 10-11, New York; convention, October 14, Nashville, Tenn.

Railway Storekeepers' Association.—J. P. Murphy, Box C, Collinwood, Ohio. Annual convention, May 19-21, Chicago.

Railway Supply Manufacturers' Assoc.—J. D. Conway, 2135 Oliver bldg., Pittsburgh, Pa. Meetings with M. M. and M. C. B. Assocs.

Railway Tel. and Tel. Appliance Assoc.—W. E. Harkness, 284 Pearl St., New York. Meetings with Assoc. of Ry. Teleg. Sups.

Richmond Railroad Club.—F. O. Robinson, Richmond, Va.; 2d Monday except June, July and August.

Roadmasters' and Maintenance of Way Association.—L. C. Ryan, C. & W. Sterling, Ill. Convention, September 8-12, 1913, Chicago.

St. Louis Railway Club.—B. W. Frauenthal, Union Station, St. Louis, Mo.; 2d Friday in month, except June, July and Aug., St. Louis.

Signal Appliance Association.—F. W. Edmonds, 3868 Park Ave., New York. Meetings with annual convention Railway Signal Association.

Society of Railway Financial Officers.—C. Nyquist, La Salle St. Station, Chicago.

Southern Association of Car Service Officers.—E. W. Sandwich, A. & W. P. Ry., Montgomery, Ala. Next meeting, April 17, Atlanta, Ga.

Southern & Southwestern Railway Club.—A. Merrill, Grant bldg., Atlanta, Ga., 3d Thurs., Jan., March, May, July, Sept., Nov., Atlanta.

Toledo Transportation Club.—J. G. Macomber, Woolson Spice Co., Toledo, Ohio; 1st Saturday, Toledo.

Track Supply Association. W. C. Kidd, Ramapo Iron Works, Hillsburn, N. Y. Meeting with Roadmasters' and Maintenance of Way Association.

Traffic Club of Chicago. Guy S. McCabe, La Salle Hotel, Chicago; meetings monthly, Chicago.

Traffic Club of New York. C. A. Swope, 290 Broadway, New York; last Tuesday in month, except June, July and August, New York.

Traffic Club of Pittsburgh.—D. L. Wells, Erie, Pittsburgh, Pa.; meetings monthly, Pittsburgh.

Traffic Club of St. Louis. A. F. Versen, Mercantile Library building, St. Louis, Mo. Annual meeting in November. Monday meetings October to May.

Train Despatchers' Association of America.—J. F. Mackie, 7042 Stewart Ave., Chicago. Annual meeting, June 17, Los Angeles, Cal.

Transportation Club of Buffalo.—J. M. Sells, Buffalo; first Saturday after first Wednesday.

Transportation Club of Detroit.—W. R. Hurley, L. S. & M. S., Detroit, Mich.; meetings monthly.

Traveling Engineers' Association.—W. O. Thompson, N. Y. C. & H. R., East Buffalo, N. Y. Annual meeting, August, 1913, Chicago.

Utah Society of Engineers. R. B. Ketchum, University of Utah, Salt Lake City, Utah. 3d Friday of each month, except July and August.

Western Canada Railway Club.—W. H. Rosevear, P. O. Box 1707, Winnipeg, Man.; 2d Monday, except June, July and August, Winnipeg.

Western Railway Club.—J. W. Taylor, Old Colony building, Chicago; 3d Tuesday of each month, except June, July and August.

Western Society of Engineers.—J. H. Warder, 1735 Monadnock block, Chicago; 1st Monday in month, except July and August, Chicago.

Traffic News.

The Magnolia Petroleum Company is to construct a pipe line, eight inches in diameter, from Cushing, Okla., to Alvord, Tex., where it will connect with another line to the Gulf coast. The length of the new line will be about 210 miles and it will cost about $2,000,000. With the completion of this line, there will be four oil pipe lines connecting the Oklahoma fields with Texas.

Oliver Garby, of the Garby Produce Company, was arrested on March 13, at Los Angeles, Cal., on a complaint filed by an examiner of the Interstate Commerce Commission, charging him with having misrepresented the weight of a carload of vegetables shipped from Los Angeles to Goldfield, Nev., via the San Pedro, Los Angeles & Salt Lake. According to the complaint, Garby billed the carload at 25,000 lbs., and paid $255.63, while the correct weight was 31,500, for which the charge would be $322.09.

Traffic Club of New York.

At the regular meeting of the Traffic Club of New York, to be held March 25, Honorable John Barrett, director general of the Pan-American Union, will deliver an address on the Commercial Aspect of the Panama Canal.

INTERSTATE COMMERCE COMMISSION.

Long and Short Haul Rates on Southeastern Roads.

In a hearing at Washington this week, the Interstate Commerce Commission listened to arguments presented by railroads of the southeastern states objecting to the requirement of the commission that the long and short haul rule of the law be strictly complied with in that territory. Freight rates to all important points are determined by water competition, and also by a good deal of competition between markets of distribution, and the present adjustment of rates is necessary to the business prosperity of the region. Statements were presented showing estimates of losses which would be sustained if the commission's rule were to be adopted, the aggregate annual loss on shipments from the west being over $12,000,000, which is about 7 per cent. of the total gross freight revenue of the roads interested.

Weighing Cars; Hearings at Philadelphia and New York.

The Interstate Commerce Commission's investigation of weighing practices on the railroads of the country, which was the subject of hearings at Chicago last month, was continued in Philadelphia, March 10, and in New York, March 17.

The principal complainants at Philadelphia were retail coal dealers receiving anthracite coal over the Reading and the Pennsylvania roads. Numerous statements were made to the effect that cars falling short 2.5 per cent. were frequent, and that larger shortages were common. Robert H. Large, general coal freight agent of the Pennsylvania Railroad said that allowances of 1 to 2 per cent. were made for water when coal was shipped wet; but some of the individual coal operators refuse to declare their coal wet, and will not allow for the water loss to the receiver.

William H. White, president of the Pennsylvania Retail Coal Men's Association, suggested that the government should compel all shippers to notify the carrier when shipments are wet, and should require a uniform allowance for moisture. Mr. White said that weighing cars while in motion over the scales was not a sufficiently accurate method; and if a car gets by him, the weighmaster is liable to guess at its weight.

W. C. Dunning, a Philadelphia merchant, exhibited details of a claim which he had made against the Pennsylvania Railroad for shortages of coal amounting to $154,000. On this statement the average shortage was 2.5 per cent. James C. Tattersall, of Trenton, said that 20 per cent. of the cars of coal received by him weighed more than they were billed and 80 per cent. weighed less.

William C. Bister, chief of the police department of the Philadelphia & Reading, said that considerable coal was stolen from cars in yards; but the thieves are mostly women and children and convictions are hard to obtain.

At the hearing in New York, Arthur E. Rice, representing the New York Coal Dealers' Association, said that his clients had no complaints to make. They were getting all the coal they bought. Officers of the Erie and of the Central of New Jersey were questioned as to shortages of coal, coming from the anthracite regions over their lines, but they said that cars were carefully reweighed at tidewater, and that losses were not more than 1 per cent. Testimony was given by James Carr, scale inspector of the Delaware, Lackawanna & Western. W. J. Richards, general manager of the Philadelphia & Reading Coal & Iron Company, testified that coal was weighed on railroad scales, and explained in detail how the different kinds of coal are sorted at the mines.

Baggage Regulation.

In re regulations for fixing the dimensions of baggage. Opinion by Chairman Clark:

Prior to 1910 no restrictions existed as to the dimensions of baggage containers. The carriers were experiencing a difficulty, however, in handling the so-called "wardrobe" trunks and other trunks of freak shapes, which were of large, irregular and unwieldy dimensions, and which were used by traveling salesmen for the transportation of their samples. After a series of conferences, the western roads filed tariffs, effective July 1, 1912, which provided that where any dimensions of any piece of baggage exceeded 45 in. there would be an additional charge for each additional inch of each dimension exceeding 45 in. equal to the charge for 10 lbs. of excess baggage. This tariff also provided that on July 1, 1914, extra charges should be collected on the same scale on baggage any dimension of which exceeded 40 in.; also commencing July 1, 1912, no piece of baggage of any class the greatest dimension of which exceeded 70 in. would be transported in baggage cars. The rule adopted by the eastern lines contained substantially the same provisions, except that no declaration was made of intention at a future time to reduce the 45 in. limitation; also the charge for each additional inch above 45 in. is the same as for 5 lbs. of excess weight instead of 10 lbs. This rule does not apply to sample whips contained in flexible cases of leather or canvas, or to public entertainment paraphernalia. The tariffs containing these rules were suspended by the commission. The carriers maintained that it was necessary to preserve aisle space down the center of the car between the piles of baggage, and that this space should not be less than 23 in. wide. It was further shown that if this aisle space were 23 in. wide, only 40 in. would be left on either side of the aisle. This was why the western carriers proposed to make 40 in. the limit of dimension. The commission found that the question related not to the matter of revenue but primarily to the physical limitations of carrying facilities and to the conditions under which the baggage men must work; also that replacement of space is one of the essential factors in which carriers must necessarily give consideration in the furnishing of facilities required by law. Whips in flexible cases were exempted from the proposed limitation in the rule of the eastern lines, but because they exceeded 70 in. in length they were excluded by the western lines' rule from transportation as baggage in the future. Whip manufacturers proposed to pack their sample whips in single flexible canvas or leather cases not exceeding 12 in. in diameter at the base, which is the widest diameter, and not exceeding 90 in. in length or 100 lbs. in weight. As sample whips could not be carried in shorter cases, and as the weight of the cases was only 100 lbs., the carriers agreed to carry whips as baggage under the conditions stated free from other limitations as to dimensions. The commission consented to this exception. The commission found that the rule of the western lines was unreasonable, but decided that carriers could provide for an extra charge for the transportation of pieces of personal or sample baggage having dimension or dimensions exceeding 45 in., but that the extra charge per inch in excess of 45 in. should not exceed the charge for 5 lbs. of excess baggage. As there are now many trunks 72 in. long or over in service, and as it was shown that when placed on end they would not take up much more space than 70 in. trunks, the commission decided that the carriers could reasonably provide that a piece of baggage exceeding 72 in. in any dimension should not be accepted for checking as baggage. The commission found that trunks or rigid containers with more than two bulging sides, or with two bulging sides that are not opposite to each other, were inconvenient in tiering. A number of such

trunks are now in service, so with the idea of protecting the owners, the commission decided that, upon notice of not less than one year, carriers could provide that trunks or rigid containers of this character should not be accepted for checking as baggage. Carriers' definition of sample baggage should permit including salesmen's catalogs. At present the minimum overcharge for excess weight is 25 cents, and the commission decided that where the charges for excess weight and excess dimensions do not exceed this minimum charge, the single minimum charge of 25 cents shall apply. The commission ordered that new rules be adopted in accordance with these conclusions. (26 I. C. C., 292.)

STATE COMMISSIONS.

The New York State Public Service Commission, Second district, has called on the Erie to show cause for not complying with the law of New York, requiring that drinking cups be provided in cars for passengers. The road defends itself by calling attention to the federal law prohibiting the use of common drinking cups.

The New York State Public Service Commission, Second district, has rescinded its order made last November requiring the Boston & Albany to run a passenger train regularly from Chatham to Albany, 23 miles. The train has been run since November 24, and the average number of passengers has been only 11½ per day; and the commission decides it is not justified in directing the continuance of the operation of the train.

New Public Utilities Law in Indiana.

The legislature of Indiana has passed a law creating a Public Utilities Commission which will supersede the present state railroad commission. The law gives extensive power, like those of New York and Wisconsin. The number of commissioners will be five, or two more than the present railroad commission, but the intention seems to be that the present railroad commissioners shall hold over and be members of the new commission. The salaries of the commissioners and of the commission's counsel will be $6,000 a year each; secretary $3,600; and clerk $3,000. The commission is directed to value every public utility in the state.

COURT NEWS.

The government will appeal to the supreme court of the United States against the decision of the commerce court in granting an injunction which forbids the Interstate Commerce Commission to treat as common carriers certain pipe lines used only by their owners, for their own oil.

The federal court at Charleston, W. Va., has decided against the Norfolk & Western in the suit of the state to enforce a passenger tariff based on the uniform rate of two cents a mile. During the pendency of the suit the old rate of two and one-half cents has been collected, but with rebate checks, which will enable passengers to reclaim a half cent a mile, if the law is finally sustained.

The Supreme Court of Wisconsin has rendered a decision suspending a decision of the Dane county circuit court, and declaring constitutional the Wisconsin law of 1911, requiring railways running four trains each way daily, passing a given station, to stop at least two trains daily each way at that station. The Chicago, Burlington & Quincy had appealed from an order of the state railroad commission ordering the road to stop an additional train at Columbus, Buffalo county.

The Delaware, Lackawanna & Western has filed in the federal court at Trenton, N. J., its answer in the suit instituted against it by the government to compel a separation of the railroad company from the Lackawanna Coal Company. In general the charges made by the government are denied, the claim being made that the amount of traffic done, and the influence of the company as related to competitors, had been much overstated. The road denies that the coal purchased by it from independent mines has constituted almost the entire production of the mines; it is declared that the coal thus bought constitutes only a small part of the whole. The company denies that its financial ability or its power or its facilities have been used to the disadvantage of competitors.

In the case of the Southern and other railroad companies against the United States, the Commerce Court last week sustained the Interstate Commerce Commission. The railroad companies asked the Court to annul an order of the commission which had been made in 1912, requiring the carriers to refrain from collecting higher rates for carrying freight to and from Newport News than were collected from the southeastern territory to and from Norfolk. The Chamber of Commerce of Newport News contended that the carriers discriminated in favor of Norfolk and the commission held that the discrimination was unjust. The Commerce Court decides that it was for the commission to determine what the actual conditions surrounding the transportation were, and that it was for the commission to determine the method of service, the relative location of the two cities, how the interchange of freight is made, what the markets for traffic are, the extent of the competition, and other matters pertaining to the welfare of the communities affected. The court says that the commission was amply justified in finding as a fact that the City of Newport News was unjustly discriminated against by the carriers, and that the court would not disturb the finding of the commission.

Are All Pipe Lines Common Carriers?

The Commerce Court on March 12 granted a temporary injunction against the enforcement of the order of the Interstate Commerce Commission requiring certain private pipe lines to file tariffs.

The commission in this case accepted the law of Congress, passed in 1906, making such pipe lines common carriers. Being common carriers they become, when doing an interstate business, subject to the Interstate Commerce law. The Commerce Court, however, holds, evidence, that Congress in this legislation had exceeded its constitutional authority.

The lines involved in the present decision are the Prairie Oil & Gas Company, the Uncle Sam Oil Company, Robert D. Benson and others, the Ohio Oil Company, Standard Oil Company of New Jersey and the Standard Oil Company of Louisiana. In the summer of 1912 the commission, after an extended investigation, made an order requiring certain pipe lines to file tariffs showing their rates to the public for the transportation of oil. Six pipe line companies brought suits to enjoin the order of the commission and applied for preliminary injunctions. Some of these companies are Standard Oil companies, but others are independent companies in strong competition with the Standard.

It was claimed that the amendment in question applied only to such pipe lines, of which there are a considerable number, as are in fact common carriers, and hold themselves out to the public as such; and that if the amendment applied to all pipe line companies, whether public or private, and Congress thereby undertook to make common carriers of such pipe line companies as used their pipe lines solely for carrying their own oil in their own private business, the amendment was unconstitutional, because its necessary effect was to take private property without process of law and without compensation.

The commission held that the amendment of 1906 applied to all pipe line companies, but did not discuss its constitutionality, leaving the question to be decided by the courts. Judge Mack, while agreeing with the majority of the court as to the construction of the statute, dissented on the ground that Congress, in the exercise of its power to regulate interstate commerce, could regulate pipe line owners and pipe lines by prohibiting their use in interstate commerce until they permitted a like use to the public, on the payment of reasonable compensation; that the act did not involve an unlawful taking of property, and that even if the property would be held to be taken, the provision for reasonable compensation for its use met the constitutional requirement.

These six cases arose in as many different states; and the facility and expedition incident to their trial in the Commerce Court affords an illustration of the wisdom of Congress in establishing a single court for the hearing of interstate commerce cases. Under the old procedure these cases would have been tried in various circuits extending from New Jersey to Louisiana, necessitating six different trials and the additional expense in records and travel occasioned by each case being tried by itself rather than all being grouped in one court.

Railway Officers.

Executive, Financial and Legal Officers.

Henry B. Hull, assistant chief claim agent of the Illinois Central, has been appointed chief claim agent, with headquarters at Chicago, to succeed Charner T. Scaife, deceased.

W. P. Newton, assistant general auditor of the St. Louis & San Francisco, at St. Louis, Mo., has been appointed general auditor, with headquarters at St. Louis, succeeding T. B. Dixey, resigned.

E. B. Pierce, auditor of the Ft. Worth & Rio Grande and the St. Louis, San Francisco & Texas, with office at Ft. Worth, Tex., has been appointed auditor of the Missouri, Kansas & Texas, with headquarters at St. Louis, Mo., to succeed T. O. Edwards, resigned.

J. W. Taylor, assistant comptroller of the Chicago, Milwaukee & St. Paul, has been appointed assistant to President Earling, with headquarters at Chicago, and the former position is abolished. B. A. Dousman, assistant auditor, has been appointed general auditor, with headquarters at Chicago.

J. B. Berry, who has been appointed assistant to the president of the Chicago, Rock Island & Pacific, has been chief engineer of the C. R. I. & P., since the year 1905, and during this time has for a considerable period been consulting engineer of the St. Louis & San Francisco. Before going to the Rock Island road, he was for some years chief engineer of the Union Pacific.

J. A. Jordan, vice-president of the St. Louis & Hannibal, the Green Bay & Western, the Ahnapee & Western, the Kewaunee, Green Bay & Western, and the Iola & Northern, with headquarters at Green Bay, Wis., has been elected president of all these roads, with headquarters at Green Bay, succeeding Stephen S. Palmer, deceased, and Edgar Palmer has been elected vice-president, with headquarters at New York, succeeding Mr. Jordan.

Operating Officers.

William Coughlin has been appointed general superintendent of the Missouri, Oklahoma & Gulf, with headquarters at Muskogee, Okla.

Charles Forrester, who has been appointed superintendent of the Stratford division of the Grand Trunk, with headquarters at Stratford, Ont., as has been announced in these columns, was born on March 5, 1876, at Wanstead and was educated in the public school of his native town and at the high school at Petrolea. He began railway work on July 15, 1891, with the Grand Trunk, and has been in the continuous service of that road ever since. He was an operator at various stations on that road until August, 1899, and was then made train despatcher at London. From August, 1906, to October of the following year, he was night chief despatcher, and in October, 1907, was promoted to chief despatcher. He remained in this position until July, 1910, when he was made trainmaster at Stratford, which position he held at the time of his appointment on January 22, as superintendent of the Stratford division of the same road with headquarters at Stratford.

C. Forrester.

Patrick K. Hanley has been appointed trainmaster of the Clinton, Havana and Decatur districts of the Illinois Central, with headquarters at Clinton, Ill., to succeed William Lamb, transferred.

C. E. Brower, trainmaster of the Atlanta, Birmingham & Atlantic, at Manchester, Ga., has been appointed superintendent of the Brunswick division, with headquarters at Fitzgerald, Ga., succeeding Adolph Moritz, resigned.

Owing to the death of A. W. Moss, superintendent of the Schuylkill division of the Pennsylvania Railroad at Reading, Pa., the duties of that position, until further notice, will be performed by G. W. Creighton, general superintendent of the Eastern Pennsylvania division, with headquarters at Altoona.

John C. Muir, whose resignation as division superintendent of the Chicago & Eastern Illinois, with office at Danville, Ill., was recently announced, has been appointed general superintendent of the Chicago, Terre Haute & Southeastern, with headquarters at Terre Haute, Ind., to succeed M. W. Wells, assigned to other duties.

J. F. Hickey, division superintendent of the Missouri, Kansas & Texas at McAlester, Okla., has been appointed superintendent of the Smithville district, with headquarters at Smithville, Tex., to succeed F. R. Blunt, resigned. It is reported that Mr. Blunt has accepted a position with a railroad in Brazil, South America.

Traffic Officers.

Joseph J. Brignall, traveling passenger agent of the Canadian Pacific at Toronto, Ont., has resigned.

J. C. Carey has been appointed commercial agent of the Toledo, St. Louis & Western, with headquarters at Memphis, Tenn.

H. C. Strohm has been appointed traveling passenger agent of the Baltimore & Ohio, with headquarters at Omaha, Neb., in place of Edward Emery, resigned.

Wm. Henderson has been appointed soliciting freight agent of the Georgia Southern & Florida, with office at Macon, Ga., succeeding W. B. Dewberry, assigned to other duties.

L. W. Mosher has been appointed commercial agent of the Missouri, Kansas & Texas at Oklahoma City, Okla., succeeding J. F. Reily, who has been transferred to Sedalia, Mo., as commercial agent in place of Mr. Mosher.

Walter Sorrell has been appointed assistant live stock agent of the Southern Railway, with headquarters at Greensboro, N. C., and C. D. Lowe has been appointed assistant live stock agent, with headquarters at Chattanooga, Tenn.

C. E. Horning, city passenger and ticket agent of the Grand Trunk, at Toronto, Ont., has been appointed district passenger agent, with office at Toronto, succeding A. E. Duff, resigned, and Charles E. Jenney, traveling passenger agent at Pittsburgh, Pa., succeeds Mr. Horning.

W. M. Campion has been appointed commercial agent of the Carolina, Clinchfield & Ohio, with headquarters at Cincinnati, Ohio, to succeed R. D. T. Hollowell, resigned to engage in other business. Frank P. McEwen, traveling freight agent, with office at Cincinnati, has been appointed commercial agent at that place, and the former position is abolished.

Engineering and Rolling Stock Officers.

B. G. Horton has been appointed superintendent of locomotive fuel service on the New Orleans, Texas & Mexico, with headquarters at De Quincy, La.; Fred Hooker and O. Tefteller have been appointed superintendents of locomotive fuel service of the St. Louis, Brownsville & Mexico, both with headquarters at Kingsville, Texas.

S. W. Mullinix, mechanical superintendent of the second district of the Rock Island Lines at Topeka, Kan., has been appointed superintendent of shops at Silvis, Ill., succeeding G. W. Seidel, resigned. C. M. Taylor, mechanical superintendent of the third district at El Reno, Okla., succeeds Mr. Mullinix, and L. A. Richardson, master mechanic at Chicago, succeeds Mr. Taylor.

John D. Isaacs, formerly consulting engineer of the Harriman Lines at New York, has resigned from that office on the Union Pacific system, and remains as consulting engineer of the Southern Pacific Company. E. E. Adams, formerly assistant consulting engineer of the Harriman Lines at New York, succeeds Mr.

Isaacs as consulting engineer of the Union Pacific system, both with offices at New York.

Charles Adelbert Morse, chief engineer of the Atchison, Topeka & Santa Fe system, with headquarters at Topeka, Kan., has been appointed chief engineer of the Chicago, Rock Island & Pacific, with office at Chicago, succeeding J. B. Berry, who has been appointed assistant to the president. Mr. Morse was born on January 1, 1859, at Bangor, Me., and was educated at the University of Maine. He began railway work in 1880 as chainman, instrument and office man on the Chicago, Burlington & Quincy, remaining with that company until 1884. He was then division engineer of the Mexican Central, and for about a year and a half again in the service of the Burlington. From January, 1886, to July, 1901, he was with the Atchison, Topeka & Santa Fe as transitman, division engineer and resident engineer at Fort Madison, Ia., and at Pueblo, Colo.; and then until the following February was assistant chief engineer of the same road at Topeka. He was then principal assistant engineer at La Junta, Colo., until March, 1903, and the following five months was engineer of the Eastern Grand division at Topeka. In July, 1903, he was made acting chief engineer of the Atchison, Topeka & Santa Fe at Topeka, and one year later became assistant engineer. On September 1, 1905, he was appointed acting chief engineer of the company's Coast Lines, and in August, 1906, was made chief engineer of the Atchison, Topeka & Santa Fe proper, with headquarters at Topeka. He was later made chief engineer of the entire system, the position he now leaves to go to the Rock Island.

C. A. Morse.

OBITUARY.

Edward H. Eden, commercial agent of the Delaware, Lackawanna & Western, with headquarters at Minneapolis, died in that city on March 12, aged 43 years.

C. T. Scaife, chief claim agent of the Illinois Central, with headquarters at Chicago, died March 8, aged 65 years. He had been in the employ of the company continuously since December, 1872, and was appointed chief claim agent in June, 1910.

Reuben F. Smith, president of the Cleveland & Pittsburgh, with office in Cleveland, Ohio, died in the latter city March 11, aged 92 years. He had been connected with the Cleveland & Pittsburgh since 1855, when he was made paymaster. He became auditor six years later, and in 1869 was chosen vice-president. Later, under lease of the property to the Pennsylvania Railroad, he was appointed assistant general manager of the Cleveland & Pittsburgh division of the Pennsylvania Lines west of Pittsburgh. Subsequently he was elected president of the Cleveland & Pittsburgh Railroad.

Double Tracking in Spain.—The single-track railway from Barcelona to Villanueva y Geltru, province of Barcelona, is being double tracked. The line, which is 30 miles long, has already been double tracked 16 miles, from Barcelona to Castelldefels, and construction work has been commenced on the prolongation of the second track up to Villanueva y Geltru. This work will necessitate construction of several tunnels through the Sierra de Garraf, to run parallel to the ones now in existence. The total cost of the work is estimated at about $1,080,000.

Equipment and Supplies.

LOCOMOTIVE BUILDING.

The Havana Central is in the market for 8 consolidation locomotives and 4 Pacific type locomotives.

The Union Railroad has ordered 5 consolidation locomotives from the Baldwin Locomotive Works.

The Pennsylvania Railroad has ordered 144 consolidation locomotives from the Baldwin Locomotive Works.

The American Smelting & Refining Company has ordered one six wheel switching locomotive from the Baldwin Locomotive Works.

The New York, New Haven & Hartford advises that it has just ordered 85 freight locomotives, 25 switching locomotives and 12 electric locomotives.

The Lakeside & Marblehead has ordered 1 six-wheel switching locomotive from the American Locomotive Company. The dimensions of the cylinders will be 21 in. x 28 in., and the total weight in working order will be 162,000 lbs.

The Keesville, Ausable Chasm & Lake Champlain has ordered 1 mogul locomotive from the American Locomotive Company. The dimensions of the cylinders will be 16 in. x 22 in., and the total weight in working order will be 96,000 lbs.

The Ohio & Kentucky has ordered 1 mogul locomotive from the American Locomotive Company. The dimensions of the cylinders will be 19 in. x 24 in., the diameter of the driving wheels will be 50 in., and the total weight in working order will be 112,000 lbs.

The Chesapeake & Ohio has ordered 12 Mallet (2-6-6-2) locomotives from the American Locomotive Company. These locomotives will be equipped with superheaters, will have 22 in. and 35 in. x 32 in. cylinders, 56 in. driving wheels, and in working order will weigh 425,000 lbs.

The St. Louis National Stock Yards have ordered 1 six-wheel switching locomotive from the American Locomotive Company. The dimensions of the cylinders will be 19 in. x 24 in., the diameter of the driving wheels will be 51 in., and the total weight in working order will be 121,000 lbs.

CAR BUILDING.

The Great Northern is making inquiries for 500 box cars.

The Grand Trunk is making inquiries for 3,000 forty-ton box cars and 1,000 fifty-ton coal cars. This road will soon order about 10,000 cars.

The New York, New Haven & Hartford advises that it has just ordered 50 coaches, 50 baggage cars, 25 postal cars and 11 dining cars, all of steel construction throughout.

The Havana Central, Cuba, mentioned in the *Railway Age Gazette* of February 14 as being in the market for 740 freight cars, is now in the market for 450 flat cars, 250 box cars, 50 coal cars and 12 passenger cars.

The Pennsylvania Lines West have ordered 42 coaches, 31 combination passenger baggage cars, 5 baggage cars, 5 dining cars and 2 mail cars. This order was divided between the American Car & Foundry Company, the Pressed Steel Car Company and the Standard Steel Car Company.

SIGNALING.

The Illinois Traction System will this season extend automatic block signaling so as to have the main line between Springfield and St. Louis entirely equipped. The new signaling will cover about 60 miles of road, the signals, style B, being furnished by the Union Switch & Signal Company.

The Buffalo, Rochester & Pittsburgh has contracted with the General Railway Signal Company, Rochester, N. Y., for automatic signal equipment for 85 miles of its road; 48 miles single track and 37 miles double track. The signals will be upper quadrant, three-position. The same road has bought telephone train despatching apparatus for 178 miles additional, and with this improvement will have the entire length of the road equipped with telephone despatching lines.

Supply Trade News.

Joseph K. Choate has been made a vice-president of the J. G. White Management Corporation, New York.

F. W. Hubbard, secretary of the Kilbourne & Jacobs Manufacturing Company, Columbus, Ohio, died on March 2.

Edgar N. Easton has associated himself with the railroad sales department of Joseph T. Ryerson & Son, with headquarters at New Haven, Conn.

George W. Greene has been appointed resident manager for Morgan T. Jones & Company, with headquarters at 213 Wabash building, Pittsburgh, Pa.

C. J. Morrison has resigned his position with Suffern & Son, and with others has organized Froggatt, Morrison & Company, 149 Broadway, New York, efficiency engineers.

Rex Gay, formerly with the Ajax Forge Company, Chicago, has resigned to accept a position with the Verona Tool Works, Pittsburgh, Pa., with headquarters in the Karpen building, Chicago.

John H. Craigie, formerly associated with the mechanical department of the Boston & Maine, is now associated with the railroad sales department of Joseph T. Ryerson & Son, with headquarters at Boston, Mass.

The Canton Culvert Company, Canton, Ohio, advises that J. H. Schlafly, president of the company, has been granted patent No. 1,055,800 on corrugated metal culverts of spiral construction and that in future it will protect its interests in this patent which it now controls.

The Asbestos Protected Metal Company, Beaver Falls, Pa., has acquired an additional tract of land adjoining its present main plant at Beaver Falls, upon which it is planning to build a special steel treating plant, a storage building, and a new single story steel and concrete factory for the manufacture of an architectural roofing tiles and asbestos shingles.

Judge Kohlsaat, of the United States Circuit Court at Chicago, on March 3, rendered a decision sustaining patents granted to George F. Colmer and George C. K. Colmer, now owned by the Standard Asphalt & Rubber Company, in the case of the Standard Asphalt & Rubber Company *vs.* the American Asphaltum & Rubber Company, for infringement, and issued an injunction restraining the latter company from further infringement of the patents.

The Pedrick Tool & Machine Company, 3640 N. Lawrence street, Philadelphia, Pa., has been formed by A. D. Pedrick and H. A. Pedrick, who have recently resigned from the firm of H. B. Underwood & Co. The new company will make and sell the Pedrick portable tools, including cylinder boring bars, cylinder and dome facers, crank pin turning machines, driving box planer tools, pipe benders, milling machines, radius planing attachments, and valve seat rotary planers. D. W. Pedrick has also resigned from H. B. Underwood & Co.

Among the bridges for which the Strauss Bascule Bridge Company has recently received orders are the following: A three-track bridge for the Boston Elevated over Mystic river, Boston, Mass.; a bridge for the Chicago, Burlington & Quincy across the Illinois river at La Salle, Ill.; a bridge for the Northern Pacific across Steilacoom creek, Wash.; a bridge for the Baltimore & Ohio across the East Chicago canal, near East Chicago, Ill.; a 160-ft. single-leaf bridge for the Department of Public Works, Canada, across the Cataraquia river at Kingston, Ont.; two bridges for the city of Green Bay, Wis., one across the East river and the other across the Fox river; a 202-ft. double-leaf bridge for the Sanitary District of Chicago over the south branch of the Chicago river at Jackson boulevard, Chicago; a highway bridge for Snohomish county, Wash., over Eby Slough; a 171-ft. double-leaf highway bridge across the Red river for the city of St. Boniface, Man. The bridges for the Northern Pacific and the Chicago, Burlington & Quincy are of the Strauss direct lift type, and are similar in design to the two bridges of this type already being constructed by the Grand Trunk Pacific and by Van Buren county, Ark. The Strauss direct lift type operates without flexible connections.

Railway Construction.

Billings & Eastern Montana.—An officer writes that the company is building a line with its own forces from Billings, Mont., northeast about 15 miles. The principal commodity to be carried on the line will be sugar beets. R. E. Shepherd, president; F. J. Egan, engineer, Billings. (See Billings & Central, March 14, p. 528.)

Buffalo, Rochester & Pittsburgh.—An officer writes that contracts have been given to the Miller Construction Company, Lock Haven, Pa., for grading a three-mile branch at Craigsville, Pa., and a two-mile branch near Homer City.

Canadian Pacific.—According to press reports contracts for double-tracking 135 miles of the Lake Superior division, and 30 miles of the Ontario division, immediately west of Toronto, Ont., have been let as follows: Lake Superior division, Cartier sub-division, 29 miles, to Cook Construction Company, Sudbury; Chapleau sub-division, 13 miles, also on White River sub-division 33 miles, and Schrieber sub-division, 13 miles, to Dominion Construction Company, Toronto, Ont.; Schrieber sub-division, 22 miles, to Chambers, McQuaig, McCaffrey & Cochrane; Nipigon sub-division, 25 miles, to Dominion Construction Company. Ontario division—London subdivision, 30 miles, from Guelph Junction east to Islington, to Jones & Girouard, Ottawa. The contracts include the grading, bridge and culvert work, and track laying. (March 7, p. 459.)

A grading contract has been given to Janse Brothers, it is said, for work on 118 miles of the Bassano-Swift Current line from Bassano, Alta., east, and the work on 90 miles has been sub-let as follows: Ten miles out of Bassano, to Clifford & Company, Bassano; 30 miles to Frank Jackson, Calgary; 12 miles to David Fitzgerald, Carstairs; five miles to F. Brandenberg, Minneapolis; four miles to Cailawait Bros. & Batter, Brooks; seven miles to W. Pearson, Dillon, Mont.; and 22 miles to Noeherne & Mannix, Edmonton.

Chinook Railway.—Application is being made to the Alberta legislature to incorporate this company to build from the Chinook Coal Company's mines at sec. 12, tp. 10, range 22, west 4th meridian, to the Crowsnest branch of the Canadian Pacific near Kipp, Alberta. Shepard & Dunlop, Lethbridge, Alberta, are solicitors for applicants.

Cincinnati, New Orleans & Texas Pacific.—Extensive improvements are to be made in the McLean avenue yards in Cincinnati. Eight new tracks are to be constructed and the present tracks will be rearranged.

Cleveland, Cincinnati, Chicago & St. Louis.—The report of this company for the year ended December 31, 1912, shows that additional main tracks were laid from Miamisburg, Ohio, to Middletown; from Indianapolis, Ind., to Dix., and from Sharonville, Ohio, to Kyles; a number of sidings were also put in and a connection with the Erie constructed from Dayton to Cold Springs. Yard improvements were carried out at Beech Grove, Ind.; at Bellefontaine, Ohio, and at Harrisburg, Ill.

Cleveland Short Line.—See Lake Shore & Michigan Southern.

Dallas & Cleburne Interurban.—This company, which is being promoted by E. P. Turner, Dallas, has not yet completed its organization. Mr. Turner owns franchises granted by the city of Dallas, also a right of way from Dallas southwest to Cleburne, and from Dallas north to Gainesville. Application has not yet been made for a charter, as it has not been definitely decided when the line will be built. It is expected that work will be started during 1913.

Edmonton, Dunvegan & British Columbia.—Contracts have been let for grading 170 miles, and work is now under way clearing the right of way. Track has been laid to Sunniebend, about 70 miles north of Edmonton, Alta., and this portion is to be ballasted at once. The plans call for building from Edmonton northwesterly via Dunvegan to Fort George, B. C. (November 15, p. 973.) J. D. McArthur & Co. are the general contractors.

Gananoque, Perth & Lanark.—The Ontario legislature is being asked to incorporate this company, to build from Gananoque to Lanark, with a branch from Morton northerly to

Portland, and other branches. J. C. Judd, Ottawa, Ontario, is solicitor for applicants.

Lake Shore & Michigan Southern.—The report of this company for the year ended December 31, 1912, shows that on the Sandusky division additional main tracks have been provided, and considerable progress was made on the grade separation work, particularly in the Chicago territory, and in connection with the change of line at Port Clinton. The Cleveland Short Line was opened for operation in July, 1912, between Marcy, Ohio and Collinwood, 9.56 miles, and the entire belt line is now in operation around the city of Cleveland from Rockport on the west to Collinwood on the east, 19.64 miles. An agreement in conjunction with the New York Central & Hudson River has been made with the Lehigh Valley for a share of the land bought from the city of Buffalo, N. Y., known as the Hamburg strip, for enlargement of terminal facilities. The important improvements carried out during the year included additional main tracks from Elyria Junction, Ohio, to Amherst, and from Martin to Millbury; the separation of grades at Port Clinton and track elevation from Grand Crossing to Englewood. The freight yard at Ashtabula Harbor was enlarged and considerable dock improvements were carried out at that place. At Air Line Junction the yard improvements included additional tracks and subways. Between Toledo and Detroit double-tracking work and renewal of bridges was carried out, and at Buffalo a new draw-bridge was built over Buffalo creek. A locomotive and car repair shop was built at Elkhart, and at Englewood, the improvements included a new roundhouse, and power plant, also a car repair yard. A large amount of industrial and passing sidings, new signals, bridge and culvert renewals, additions and improvements to various station buildings and other structures were carried during the year.

Long Island.—The report of this company for the year ended December 31, 1912, shows that on the Bay Ridge improvement the tunnel section between Atlantic avenue and Central avenue, in Brooklyn, N. Y., and the filling in between streets and bridges of the section between Central avenue and Fresh Pond Junction was started in December, and this work will be carried on during 1913. Satisfactory progress has been made on the Jamaica improvement, and on the elimination of grade crossings through Richmond Hill. The platforms and station in the new location at Jamaica, will be put in operation in March, and the whole improvement will be finished during 1913. The North Side division improvement covers the elimination of grade crossings on the Fort Washington branch through Flushing, the laying of second track between Flushing and Great Neck, and the electrification of the lines to Port Washington and Whitestone Landing. This work calls for the elimination of 12 grade crossings. The line to Whitestone Landing was electrified and put in operation in August, and the line to Port Washington will be electrified by September, 1913. It is planned to let contracts and have work well under way in 1913, on the Woodside-Winfield cut-off. This improvement involves the elimination of 11 grade crossings. When this work is completed there will be no highway crossings at grade between New York City and Jamaica. A great deal was accomplished in beginning new work and completing work begun in the previous year on the elimination of grade crossings at 13 other points. The most important crossings are at the South Country Road, at Great River, at Oakdale, and Eastport and at Good Ground. The New York Public Service Commission has ordered the elimination of several crossings on the Montauk division at Bushwick Junction, and on the main line at Queens. Negotiations are now under way with the authorities of New York City in connection with crossings at Hollis on the main line. Work on these improvements will be pushed during 1913. The extension of main tracks during the year consisted of completing the second track on the Oyster Bay branch to Locust Valley; completion of third and fourth tracks to Lynbrook, and a small amount of work in connection with second track between Oakdale and Patchogue.

Louisville & Nashville.—See Tennessee Western.

Michigan Central.—The report of this company for the year ended December 31, 1912, shows that work was carried out on third and fourth main tracks from Junction Yards to Detroit, and on improvements at South Bound Yard, Detroit. Considerable work was carried out on the grade separations at Detroit and at Joliet, Ill.; also on additional yards at Windsor, Ont., at Graling, Mich., at Wenona and at River Rouge. Improvements were made to the yards, North Detroit and Belt Line Junction; double track was laid at Detroit, and miscellaneous siding, yard tracks and logging branches were constructed.

Missouri, Kansas & Texas.—An officer writes that surveys are now being made for an extension of the Wichita Falls & Southern south and west from New Castle, Tex. (March 14, p. 529.)

New York, New Haven & Hartford.—The Public Utilities Commission of Connecticut will give a hearing on March 26, to consider the application of this company in reference to the double tracking of the Berkshire branch, including all line changes incident to the double tracking, between Berkshire Junction, Conn., and New Milford, 13½ miles.

Norfolk & Western.—An officer writes that the company has completed arrangements for double-tracking work on 51 miles of the eastern section as follows: From the present end of the second track at Suffolk, Va., work on 15½ miles has been started, one-half of the work is being carried out by the company's forces, and the other half by the Luck Construction Company, Roanoke; from Disputanta, west eight miles, contract let to W. W. Boxley & Company, Roanoke; from Wilson, 16 miles to connect with a section of completed second track, one-half of this has been let to the Vaughan Construction Company, Roanoke, and the other half to Rinehart & Dennis Company, Charlottesville; from Elam west to Evergreen, 11½ miles, contract let to David W. Flickwir, Roanoke. A new double track structure is to be built to replace High Bridge over the Appomattox river. A contract for the masonry work has been given to W. W. Boxley & Company, Roanoke, and contract for the superstructure to the Virginia Bridge & Iron Company of the same place.

Orange Northeastern.—An officer writes that the plans call for building from Orange, Tex., in a general northeast direction via Vinton oilfield, La., and through Vinton, Starks, Fields, Merryville and Leesville to Natchitoches, about 135 miles. A branch is projected from Merryville northwest to Nacogdoches, Tex., about 90 miles. The company has absorbed the Nacogdoches Railway, a lumber road, and the Lutcher Moore lumber road running east from the Sabine river, 30 miles, will also form part of the system. This latter road is now being laid with heavy rails, and grading work is under way on a 6-mile extension to a connection with the Southern Pacific at Vinton. M. Tansey, Mount Pleasant, Tex., has the contract for the work. The company expects to develop a traffic in lumber, oil, cotton and grain. Edward Kennedy, president, Houston, Tex., A. B. Thurston, chief engineer, Orange. (February 7, p. 271.)

Oregon Short Line.—An officer is quoted as saying that an extension of the Twin Falls branch is to be built to a connection with the Central Pacific, probably at Wells, Nev.

Tennessee Western.—An officer writes that the plans call for building from Iron City, Tenn., northwesterly about 18 miles to a point in the center of Wayne county. No track has yet been laid. Contract for grading has been let to Lacy-McDowell & Company, Brentwood, Tenn. The grading work is about one-third completed, and it is expected that the line will be opened for business about September of this year. It will be operated by the Louisville & Nashville. The company expects to develop a traffic in forest products, iron ore, and agricultural products. C. N. Brady, president, Washington, Pa., W. W. Olney, chief engineer, Iron City, Tenn.

Wichita Falls & Southern.—See Missouri, Kansas & Texas.

RAILWAY STRUCTURES.

Aitkin, Minn.—The Northern Pacific has announced that it will build a new passenger station to cost approximately $30,000.

Beech Grove, Ind.—The report of the Cleveland, Cincinnati, Chicago & St. Louis for the year ended December 31, 1912, shows that repair shops were put up at Beech Grove, Ind., also that bridges were renewed at various points, and engine houses were built at Sharonville, Ohio, at Bellefontaine, at Carey, at Hillsboro, Ill., at Elkhart, Ind., and at Duane. At Harrisburg an engine house annex and coaling station, also a freight house were constructed, and a coaling plant was constructed and other im-

provements were made at Bellefontaine. New passenger station and water facilities were added at Carmi, Ill., and at various points other buildings were constructed during the year.

Dallas, Tex.—Amended plans for the proposed Dallas station have been adopted, and it is announced that work will be started within four months, to be completed within a year or a year and a half after that time. The following officers of the Dallas Terminal Company, which will build the station, have been elected: President, F. G. Pettibone, of the Gulf, Colorado & Santa Fe; first vice-president, W. B. Scott, of the Southern Pacific; second vice-president, W. W. Webb, of the Missouri, Kansas & Texas; secretary, M. L. Buckner; treasurer, R. P. Roach.

Detroit, Mich.—The report of the Michigan Central for the year ended December 31, 1912, shows that a large amount of money was spent for the increase and improvement of terminal facilities in and about Detroit, Mich. Work upon the extensive terminal station has progressed rapidly and it is expected that it will be completed and ready for use before January, 1914. The improvements to stations and other structures included a roundhouse, etc., at West Detroit; roundhouses and facilities at Bay City, North Yard, North Toledo, and at Wolverine, and a freight house and facilities at Lansing. A bridge was built at Fort street, Detroit, and some smaller structures were put up at various points.

High Bridge, Va.—See Norfolk & Western under Railway Construction regarding construction of a new bridge over the Appomatox river.

Houston, Tex.—The Texas & New Orleans has begun work on the construction of a new blacksmith and boiler shop building of re-inforced concrete construction, 314 ft. x 120 ft.

Jamaica, N. Y.—The report of the Long Island for the year ended December 31, 1912, shows that in addition to the Jamaica improvements on which work is expected to be finished during 1913, the company has material for sub-stations, etc., on the ground for the line to Port Washington. It is expected that this work will be completed by September. At various points improvements were made to the passenger service facilities including new passenger stations at Bayshore, at Arverne, at Flushing Main street, at Murray Hill and at Hempstead, and work was started on new stations at Grand street, Newtown, and at Garden City. In addition high platforms in electrified territory, shelter sheds, passing sidings, platform extensions, etc., were built at 18 different points, and in connection with the freight service additional sidings, warehouse tracks, freight yards and additions to freight houses were built at 22 points. Improvements were also made to the company's shops, including the installation of new machinery, additions to buildings, etc.

Marquette, Mich.—The Duluth South Shore & Atlantic is preparing to build a new 15-stall roundhouse.

Slaton, Tex.—The Gulf, Colorado & Santa Fe has appropriated $30,000 for the erection of a three-story passenger station and office building.

Youngstown, Ohio.—The new freight house of the Baltimore & Ohio has been completed and it was put in use March 17. This structure, which, with surrounding improvements cost $500,000, is fireproof, and has a basement equipped for cold storage.

Railway Development Needed in British East Africa.—For some time there has been a congestion of traffic on the Uganda Railway of British East Africa owing to a deficient supply of rolling stock. With the general development that is going on so rapidly in the country, the capacity of the cars and engines has been taxed far beyond their power to respond to the economic demands of an extensive and a variously productive region. The completion of some branch lines and the projection of others make the demand for railway equipment increasingly imperative. Considering the agricultural possibilities of this region, the extensive timber resources, the mineral prospects, the facilities for communicating with Europe and America, and the climate so conducive to European colonization, British East Africa must, for years to come, appeal to the railroad builder as a profitable field for the investment of capital.—*Consular Report.*

Railway Financial News.

Asherton & Gulf.—This company has asked authority of the Railroad Commission of Texas to issue $550,000 bonds on 32 miles of its completed lines.

Boston & Maine.—See New York, New Haven & Hartford.

Chicago & North Western.—The property of the Des Plains Valley, a subsidiary of the Chicago & North Western, has been merged with the parent company, the North Western having assumed the guarantee of the subsidiary's bonds.

Denver, Laramie & North Western.—The Bankers Trust Company, New York, as trustee of the first mortgage bonds of 1910, of which about $1,500,000 have been issued, has brought suit in the United States district court at Denver to foreclose this mortgage and to have an additional receiver representing its interests appointed for the D. L. & N. W.

Des Plains Valley.—See Chicago & North Western.

National Railways of Mexico.—E. N. Brown, president, in a recent interview in New York City, said in part in speaking of the effect of the revolution in Mexico: "Now as to the position of the National Railways of Mexico . . . grossly exaggerated statements have been published recently regarding our property losses. Since January 1 they have not exceeded $100,000. This amount includes the damage to or destruction of buildings, cars, locomotives and track. Our losses in earnings have not been so much from the destruction of property as from the necessity of using circuitous routes in order to keep traffic moving."

New York, New Haven & Hartford.—The Boston News Bureau intimates that as a result of the expected discontinuance of dividends on the Boston & Maine, directors of the N. Y. N. H. & H. will consider the question of reducing the New Haven dividend from 8 per cent. to 6 per cent.

Pere Marquette.—The Guaranty Trust Company, New York, as trustee under the collateral indenture of March 1, 1911, is to offer for sale on March 20, $16,000,000 improvement and refunding mortgage 50-year 5 per cent. bonds. These bonds are held as collateral for $8,000,000 5-year 6 per cent. notes on which interst has been in default since September 1, 1912.

Southern New England.—This subsidiary of the Grand Trunk, which was to have built a line from Palmer, Mass., to Providence, R. I., has been the subject of a special investigation by a committee of business men appointed by Governor Pothier, of Rhode Island, and this committee has decided not to recommend that the state lend its guarantee for $6,000,000 bonds.

Union Pacific.—The California railroad commission, having failed to agree to any modification suggested of the plan for the dissolution of the Union and Southern Pacific, and the time for underwriting the sale of Southern Pacific stock held by the Union Pacific having expired on Saturday of last week, the plan has been abandoned, and it is understood that a new plan is being worked out by Southern Pacific and Union Pacific directors, and will in time be submitted to the new attorney general for his approval.

Western Maryland.—The Western Maryland Terminal Company has applied to the Maryland Public Service Commission to issue $700,000 stock, and the Western Maryland has asked permission of the commission to buy this stock. The stock is to pay for land recently secured for terminals at Port Covington.

Railroad Construction Syndicate.—Negotiations are being conducted between a group of French capitalists headed by the Russo-French Commercial Bank and the representatives of a number of Russian banks in regard to the organization of a syndicate for railway construction. According to their plan, they will finance railway companies that are already organized, purchase concessions, make investigations, etc. Special attention is to be paid to the east and south of Siberia, the Caucasus, and Turkestan. One of the participators of this syndicate is already taking part in construction of railways.

ANNUAL REPORTS.

FORTY-THIRD ANNUAL REPORT OF THE LAKE SHORE AND MICHIGAN SOUTHERN RAILWAY COMPANY.

To the Stockholders of

THE LAKE SHORE AND MICHIGAN SOUTHERN RAILWAY COMPANY:

The Board of Directors herewith submits its report for the year ended December 31, 1912, with statements showing results for the year and the financial condition of the company.

The mileage embraced in the operation of the road is as follows:

	Miles
Main line and branches	871.00
Proprietary lines	289.32
Leased lines	521.90
Trackage rights	190.08
Total road operated	1,872.30

An increase of 97.23 miles in road operated is due to the acquisition through lease of the Lake Erie, Alliance and Wheeling Railroad and to the opening for operation of 9.56 additional miles of the Cleveland Short Line Railroad extending from Marcy, Ohio, to Collinwood, Ohio. There is a reduction of .36 miles due to remeasurement and adjustment of mileage of the Lake Erie and Pittsburg Railway. The net total increase in miles operated over 1911 is 96.87 miles. A statement showing in detail the miles of road and track operated will be found upon another page.

There was no change in capital stock during the year, the amount authorized and outstanding December 31, 1912, being $50,000,000.00.

The mortgage, bonded and secured debt outstanding on December 31, 1911, was		$168,172,482.57
It has been increased during the year by pro-rata liability for certificates under the New York Central Lines Equipment Trust agreement of 1912		2,974,961.25
		$171,147,443.82
It has been decreased during the year as follows:		
January 1, pro-rata of second installment 1910 equipment trust	$918,071.04	
November 1, pro-rata of fifth installment 1907 equipment trust	447,226.18	
By reduction of liability for certificates outstanding under 1910 trust, account transfer of 25 locomotives to Michigan Central Railroad Company	375,979.50	1,741,276.72
Total mortgage, bonded and secured debt outstanding December 31, 1912		$169,406,167.10

SUMMARY OF FINANCIAL OPERATIONS AFFECTING INCOME.

OPERATING INCOME.	1912.	1911.	Increase or Decrease.

Amount to credit of profit and loss (free surplus), December 31, 1911		$36,154,623.35
Balance to credit of profit and loss for the year 1912		7,584,384.06
		$43,739,007.41
Deduct:		
Initial payment of ten per cent on New York Central Lines equipment trust of 1912	$330,551.25	
New equipment purchased from the company's proportion of profit from operations of the Pittsburgh McKeesport and Youghiogheny Railroad	777,311.07	
Expenditures for additions and betterments, equipment, etc., on account The Lake Erie Alliance and Wheeling Railroad Company	582,594.75	
Value of property at Ashtabula Harbor and other locations abandoned during the year	408,939.39	
Commissions and expenses on sterling and franc notes	80,108.44	
Commission and expenses (net) on New York Central Lines equipment trust certificates of 1912	48,545.87	
For adjustment of sundry accounts including uncollectible items	323,788.75	2,551,839.52
Balance to credit of profit and loss (free surplus), December 31, 1912		$41,187,167.89

The revenues from rail operations for the year were the largest in the history of the road, amounting to $54,283,616.52, an increase of $5,922,619.39, or 12.25% as compared with the previous year.

Freight revenue was $36,371,244.49, an increase of $5,269,909.87. The revenue freight carried amounted to 41,081,573 tons, or 6,193,876 tons more than last year. With the exception of products of animals, each group of commodities shows a greater tonnage carried than in 1911. The notable increases are, anthracite and bituminous coal 2,218,874 tons; ores 916,501 tons; stone, sand and other like articles 890,269 tons; other castings and machinery 296,208 tons; bar and sheet metal 263,226 tons, and other manufactures 490,393 tons. There was a slight decrease in the average rate per ton mile due to reduction in lake coal rates effective May 1, 1912.

Passenger revenue amounted to $11,835,198.83, an increase of $485,103.16 over last year, attributable to additional business. There was an increase in local passengers carried of 144,232, a decrease in interline passengers carried of 92,932, resulting in a net increase of 51,300 passengers.

Revenue from transportation of mails was $1,974,227.76, a decrease of $204,405.87, being the result of a reweighing of mails commencing September 1, 1911, when the United States Post Office Department inaugurated the transportation of magazines and periodicals by freight service at freight tariff rates, since which time the earnings from that class of matter have accrued to freight revenue.

Revenue from express traffic was $1,985,690.32, an increase of $239,754.48, attributable to the additional business handled during the year.

Other transportation revenues amounted to $1,626,784.00, an increase of $143,197.60, principally due to larger revenue derived from switching service.

Revenues other than from transportation were $490,471.12, a decrease of $10,939.85. The principal decrease is in rents of buildings and other properties, due to cancellation of leases of the company's coal and ore unloading machinery at Ashtabula Harbor, which have been taken over for direct operation by the company.

Operating expenses for the year, by groups, were:

		Increase.	Per Cent
Maintenance of way and structures	$6,516,211.90	$337,588.59	5.46
Maintenance of equipment	9,283,832.83	1,214,439.89	15.05
Traffic expenses	961,761.66	*64,555.63	6.29
Transportation expenses	17,797,334.45	1,552,282.23	9.55
General expenses	975,503.52	51,014.19	5.52
Total	$35,534,644.36	$3,090,769.27	9.53

*Decrease.

The increase in maintenance of way and structures was occasioned largely by the very heavy volume of traffic moved over the road during the year. To maintain the roadbed and track in first class condition, additional track men were employed and owing to the scarcity of laborers of that class, it was necessary, in order to secure and hold a sufficient force, to grant a higher scale of pay, which in itself added $95,000. to roadway and track expense. Severe weather conditions during the first three months of the year caused a large expense for removal of snow, sand and ice. Several large bridges were renewed during the year. There were increased payments for the use of other companies' tracks under trackage right agreements. The expense for maintenance of signals and interlockers was not so large as in 1911, owing to unusually heavy expenditures in that year for renewal of various interlocking plants.

The great [illegible] company's equipment to transport the large volume of traffic [illegible] the year, made necessary increased charges to maintenance [illegible] expenses. In order to keep equipment in service [illegible] standard, [illegible] more locomotives received general repairs than in the previous year and 85,6[illegible]5 more freight cars were repaired than in 1911. [illegible] renewal of equipment were occasioned by a larger number of old and obsolete locomotives and freight cars having been disposed of [illegible] during the year.

Traffic expenses [illegible] compared with the previous year. Participation of the company in the expenses of fast freight lines was considerably [illegible] to some withdrawals and reductions in assessments.

In transportation expenses [illegible] all items affected by the volume of traffic handled [illegible]. This is clearly attributable to the fact that the company [illegible] 6,193,876 more tons of freight than in 1911. Although increased expenses are shown, there was a considerable saving in the cost of [illegible] particularly in consumption of fuel. Tonnage

moved during the year increased 17.75 per cent. over the previous year, while freight train miles increased only 7.81 per cent. and freight locomotive miles 6.7 per cent. Demand made upon the company by enginemen for increased scale of wages was submitted to arbitration, resulting in an award granted to this class of labor, which added to the cost of transportation expenses subsequent to May 1, 1912. Expenses growing out of personal injury claims were large, there having been serious crossing accidents at 105th Street, Cleveland, and Ashtabula, Ohio. Furthermore, the personal injury compensation laws passed in various States through which the company operates, has materially affected this item of expense.

General expenses show an increase of $51,014.19. Of this increase $11,408.88, represents additional disbursements to retired employes for pensions.

Net revenue from auxiliary operations for the year increased $146,481.62, through the taking over for direct operations by the company, of the unloading machinery on its docks at Ashtabula Harbor, Ohio.

Railway tax accruals amounted to $1,771,097.88, an increase of $97,158.34 over the previous year, and is attributable to higher valuations placed upon the company's property by various State Tax Commissions.

Other income for the year amounted to $10,348,776.66, an increase of $64,188.40 as compared with the previous year. Additional income was derived from hire of equipment and separately operated properties due to a greater excess of the company's equipment having been in use on foreign lines and to the larger surplus for the year of the Pittsburgh McKeesport and Youghiogheny Railroad in which the company has a one-half interest. The increase shown in income from funded securities is accounted for by the full year's interest received on bonds of The Cleveland Short Line Railway Company and The Lake Erie and Pittsburg Railway Company, acquired by The Lake Shore and Michigan Southern Railway Company last year in reimbursement of notes of those companies. The retirement of the notes mentioned caused a decrease in the unfunded securities which practically offset the increase in income from funded securities. Income from dividends on stocks owned by the company decreased $974,499.11, due to reduction of extra dividends by The Pittsburgh and Lake Erie Railroad and The Mahoning Coal Railroad Companies.

Deductions from gross income for the year were $10,857,671.42, an increase of $630,343.06, due to following causes:

Deductions for lease of other roads increased $132,157.69, due to a full year's rental paid to The Cleveland Short Line Railway Company as compared with nine months last year, and to rental paid through lease of The Lake Erie Alliance and Wheeling Railroad, effective July 1, 1912.

Joint facility rents increased $324,464.86, principally due to payments covering the entire year for trackage rights acquired over the Pennsylvania and Baltimore and Ohio Railroads in connection with operation of the Lake Erie and Pittsburg Railway.

Separately operated properties—loss, increased $69,068.70, owing to participation by the company in the guarantee in connection with the Merchants Despatch Transportation Company.

Interest for funded debt increased $110,634.26, due to a full year's interest having been accrued on $5,720,000.00 of gold bonds of 1906 issued in 1911, as against a partial year's accrual for that year, and also to interest accrued on the company's pro-rata of equipment trust certificates of 1912, there being no corresponding charge in 1911.

From the net income of the company for the year, amounting to $16,584,384.06, there were paid three dividends on both the guaranteed and common capital stock, aggregating 18 per cent or $9,000,000.00 leaving a balance of $7,584,384.06, which was transferred to the credit of profit and loss.

There was expended during the year for additions and improvements to the property $3,238,615.21, all of which was charged direct to capital account. For the increased train movement on the Sandusky Division, additional main tracks have been provided. To facilitate the movement of traffic and to meet municipal requirements, it has been necessary and desirable to extend the work of grade separation, upon which substantial progress has been made during the year, particularly in the Chicago territory and in connection with the change of line at Port Clinton. The company has also provided additional yard, station, enginehouse and shop facilities to meet the requirements of the increase in business. Details of such expenditures will be found on a following page.

The company as owner of the entire outstanding capital stock of The Lake Erie Alliance and Wheeling Railroad Company, entered into an agreement and lease effective July 1, 1912, whereby it acquired the right to use for the term of its corporate existence, the railroad and properties of The Lake Erie Alliance and Wheeling Railroad Company, extending from Phalanx, Ohio to Dillonvale, Ohio, a distance of 87.67 miles. The Lake Shore and Michigan Southern Railway Company will keep and maintain at its own expense the railroad and properties leased, and is to receive all revenues derived from the operation thereof. As rental it agrees to pay an amount equivalent to four per cent per annum on the outstanding capital stock, interest on the outstanding obligations, and all taxes and assessments of that company.

The opening for operation on July 1, 1912, of that part of the Cleveland Short Line Railway between Marcy, Ohio, and Collinwood, Ohio, a distance of 9.56 miles, has placed in operation the entire belt line around the city of Cleveland, Ohio, extending from Rockport on the west, to Collinwood on the east, a distance of 19.64 miles.

The company issued on March 2, 1912, notes payable February 24, 1913, for 25,000,000 francs equivalent to $4,827,898.55 and sterling notes payable March 2, 1913, for 1,400,000 pounds or $6,819,889.50, making a total of $11,647,788.05, from the proceeds of which the company retired its one year franc notes that matured March 4, 1912, amounting to 60,000,000 francs.

The company purchased from The Michigan Central Railroad Company 30,000 shares of the common stock, par value $3,000,000.00 of the Chicago Indiana and Southern Railroad Company, and also demand promissory notes issued by the latter company, amounting to $495,000.00. Through the acquisition of this stock the company became possessed of all of the outstanding capital stock of the Chicago Indiana and Southern Railroad Company. In the consummation of this transaction it was stipulated that The Michigan Central Railroad Company would be released from its obligation under a contract dated January 15, 1908, by which that company agreed to hold The Lake Shore and Michigan Southern Railway Company harmless from liability on its guaranty of $3,825,000.00 of the fifty year gold mortgage bonds of the Chicago Indiana and Southern Railroad Company.

There were also acquired during the year by purchase, 27,998 shares of stock, par value $1,399,900.00 of The Pittsburgh McKeesport and Youghiogheny Railroad Company, 47,881 shares of stock, par value $2,394 050 00 of The Pittsburgh and Lake Erie Railroad Company, 25 shares of stock, par value $2,500.00 of the Kanawha and Michigan Railroad Company, $1,000,000.00 of The Cleveland Cincinnati Chicago and St Louis Railway Company general mortgage four per cent bonds and $97,000 00 of The Toledo and Ohio Central Railway Company, St. Mary's Division, first preference income bonds.

The Board has authorized the cancellation of the agreement dated November 1, 1907, between the Merchants Despatch Transportation Company, The New York Central and Hudson River Railroad Company, The Lake Shore and Michigan Southern Railway Company, The Michigan Central Railroad Company, The Cleveland Cincinnati Chicago and St Louis Railway Company, The Pittsburgh and Lake Erie Railroad Company, The Peoria and Eastern Railway Company, Rutland Railroad Company, The Lake Erie and Western Railroad Company and the Chicago Indiana and Southern Railroad Company, covering the use of Merchants Despatch Transportation Company refrigerator cars by those companies, to be effective January 1, 1913, and has further authorized the purchase, in conjunction with The New York Central and Hudson River Railroad Company, at its present value, of the Merchants Despatch Transportation Company's refrigerator equipment, consisting of 5,388 owned cars and 1,000 leased cars covered by Merchants Despatch Transportation Company Equipment Trust of 1911. Apportionment between the purchasers is to be on the basis of their respective stock ownership in the Merchants Despatch Transportation Company. Through this division of the equipment, The Lake Shore and Michigan Southern Railway Company will acquire 2,520 of the owned cars and an equity in 468 of the equipment trust cars. The Board has also on behalf of the company, given consent to a reduction of the capital stock of the Merchants Despatch Transportation Company from $5,000,000.00 to $1,200,000.00, under which authority this company will sell, at par, 17,772 shares of its present holding in that company.

All agreements with various dock companies for the lease of ore docks owned by the company at Ashtabula Harbor, and for the handling of ore at that point were terminated as of May 1, 1912, and new agreements were made providing for the handling of ore from vessels to cars by the company through the agency of contractors. In this connection, the company purchased the machinery owned by the Pittsburgh and Conneaut Dock Company located on the company's property at Ashtabula Harbor, agreeing to pay therefor the sum of $775,672.61 in five equal installments.

During the year the company acquired under contract about 76,000 acres of coal lands in Christian, Montgomery, Fayette, Saline, Franklin and Williamson Counties, Illinois, at a cost of approximately $2,500,000.00. Deeds for 16,300 acres have already been delivered and $728,309.98 paid by this company therefor. These coal lands are on or near the line of The Cleveland Cincinnati Chicago and St Louis Railway Company, the majority of whose stock is owned by this company, and the said lands are tributary to the Cleveland Cincinnati Chicago and St Louis Railway and the Chicago Indiana and Southern Railroad, which latter is subsidiary of this company. Contracts have been entered into by The Cleveland Cincinnati Chicago and St Louis Railway Company for the purchase of these lands from this company at cost, plus 5% interest, payable July 1, 1917, and it has made an initial payment of $150,000.00 on account thereof. The Guaranty Trust Company of New York has acted as agent for The Lake Shore and Michigan Southern Railway Company in the making of these purchases and contracts.

Under an agreement dated February 1, 1912, the company has granted to The Bessemer and Lake Erie Railroad Company the right to use the tracks of The Lake Shore and Michigan Southern Railway Company between Dock Junction and Wesleyville, Pennsylvania. The company has also, as lessee of the Jamestown Franklin and Clearfield Railroad Company, granted to The Pennsylvania Southern Railroad Company, under an agreement dated December 30, 1912, the right to run over the tracks of the Jamestown Franklin and Clearfield Railroad Company between Sutton and Franklin, Pennsylvania, one passenger train each way per day.

Under date of August 22, 1912, this company in conjunction with The New York Central and Hudson River Railroad Company, entered into an agreement with the Lehigh Valley Railroad Company for a share in its purchase from the City of Buffalo of a tract of land known as the "Hamburg Canal Strip," for enlargement of terminal facilities, at a cost of $500,000.00, of which The Lake Shore and Michigan Southern Railway Company's proportion will approximate $150,000.00.

In the operation of the pension Department 61 employes were retired and placed upon the pension rolls. Of these retirements, 34 were authorized because of the attainment of seventy years of age and 27 because of total and permanent physical disability. Twenty-four pensioners died during 1912 and at the close of the year 346 retired employes were carried upon the pension rolls. The average monthly pension allowance to these men was $23.33 and the total amount paid in pension allowances during the year was $99,528.28.

By an arrangement made with the Guaranty Trust Company, Trustee of the New York Central Lines Equipment Trust of 1910, the company assigned and delivered during the year to The Michigan Central Railroad Company twenty-five class G-6 locomotives acquired by the company under the terms of that trust, The Michigan Central Railroad Company assuming payment of the remaining unpaid installments applicable to the locomotives so assigned.

On November 20, 1912, the Board of Directors authorized The Lake Shore and Michigan Southern Railway Company, together with The New York Central and Hudson River Railroad Company, The Michigan Central Railroad Company, The Cleveland Cincinnati Chicago and St Louis Railway Company, The Pittsburgh and Lake Erie Railroad Company, and The Toledo and Ohio Central Railway Company to enter into an equipment trust agreement, to be dated January 1, 1913, for the purpose of establishing the New York Central Lines Equipment Trust of 1913. This agreement will provide for an issue of $24,000,000.00 of equipment trust certificates, bearing interest at the rate of 4½% per annum: being not to exceed 90% of the total cost of the equipment to be furnished under the terms of the said agreement. The certificates are to be paid in fifteen annual installments, the first installment being payable January 1, 1914. Out of the $24,000,000.00 of certificates authorized there will be issued, early in 1913, $12,540,000.00. The cost of the equipment to be assigned to this company in connection with the issue of these latter certificates will be approximately $1,006,000.00, and the pro-rata amount of the certificates, representing not to exceed 90% of the cost, will be approximately $879,000.00. Full particulars as to the character of the equipment to be acquired will be set forth in the report to the stockholders for 1913.

Cost of road and equipment on December 31, 1911, was..... $131,078,914.00

It has been increased during the year as follows:

Expenditures for additions and betterments to the property as shown in detail elsewhere.	$3,238,615.21	
Cost of equipment received during the year under the equipment trust of 1912.....	3,305,512.50	
Cost of 1,000 box cars purchased from the company's proportion of profit from operation of Pittsburgh McKeesport and Youghiogheny Railroad for years 1909, 1910 and 1911	777,311.07	7,321,438.78
		$138,400,352.78
Value of equipment retired from service during the year	$866,253.67	
Less amount charged for new equipment acquired, consisting of 7 passenger cars, 3 dinging cars, 10 steel smoking cars, 1 pile driver, 1 coaling machine, 5 steam shovels and cost of applying superheaters to 41 locomotives..	444,726.90	
	$421,526.77	

Credit adjustment in connection with trust equipment to cover profit on parts and accessories, freight and inspection charges, etc...	222,767.30	
Value of twenty-five class G-6 locomotives acquired under 1910 equipment trust and transferred to The Michigan Central Railroad Company	483,524.95	1,127,819.02
		$137,272,533.76

Amount credited in 1912 for account of 1907, 1910 and 1912 equipment trust installments	1,505,784.97
Cost of road and equipment, December 31, 1912	$135,766,748.79

Grateful acknowledgment is made of the faithful, efficient performance of duty by employes in every department of the service during the year.

WILLIAM C. BROWN,
President.

SIXTY-SEVENTH ANNUAL REPORT OF THE MICHIGAN CENTRAL RAILROAD COMPANY.

To the stockholders of

THE MICHIGAN CENTRAL RAILROAD COMPANY:

The Board of Directors herewith submits its report for the year ended December 31, 1912, with statements showing the results for the year and the financial condition of the company.

The report covers the operation of the same mileage as the previous year, as follows:

	Miles
Main line	270.07
Proprietary lines	343.31
Leased lines	1,110.20
Lines operated under trackage rights	93.18
Total road operated (as shown in detail on another page)	1,816.76

There was no change in capital stock during the year, the amount authorized and outstanding being $18,738,000.00.

The funded debt outstanding December 31, 1911, was		$41,269,055.01
It has been increased during the year as follows:		
Pro-rata liability for certificates under the New York Central Lines Equipment Trust agreement of 1912	$2,275,663.50	
Additional liability for certificates outstanding under 1910 trust, account transfer of 25 locomotives from Lake Shore and Michigan Southern Railway Company	375,979.50	2,651,643.00
		$43,920,698.01
It has been decreased during the year as follows:		
Pro-rata of installment on New York Central lines equipment trust certificates of 1910, paid January 1, 1912	$339,098.22	
Pro-rata of installment on New York Central lines equipment trust certificates of 1907, paid November 1, 1912	260,4[illegible]5.45	
Michigan Central Jackson, Lansing & Saginaw three and one-half per cent gold bonds of 1951 purchased and cancelled by the Trustees of the Land Grant Fund of the Jackson, Lansing & Saginaw Railroad Company	5,000.00	604,5[illegible].6[illegible]
Total funded debt December 31, 1912 (detail on another page)		$43,316,174.34

The changes in the road and equipment account during the year were as follows:

Amount charged against main line to December 31, 1911 ...			$48,361,257.59
Charged for additions and betterments in 1912, as shown in detail on another page:			
Against capital account:			
For road	$325,054.78		
For equipment	2,475,653.36	$2,800,708.14	
Against income account (appropriated surplus):			
For equipment	$482,909.55		
Less: For road (adjustment) ..	171.70	4[illegible]2,737.85	
		$3,[illegible]8[illegible],445.[illegible]	
Less: Equipment replacement fund	$30[illegible],042.31		
Equipment trust installments	780,156.07	[illegible],089,[illegible]8.38	2,194,[illegible]47.6[illegible]
Total main line			$50,555,505.[illegible]0
Amount charged against leased lines to December 31, 1911		$17,16[illegible],727.53	
Charged for additions and betterments in 1912, as shown in detail on another page:			
To capital account.			
For road	$181,018.15		
To income account (appropriated surplus):			
For road	367,098.94	548,117.[illegible]9	
Total leased lines			16,618,610.44
Total December 31, 1912. .			$67,174,115.64

On June 19, 19[illegible] this company purchased the entire railroad and property of the Buchanan & St Joseph River Railroad Company for a [illegible] consideration, all of the stock of the latter company being [illegible] by The Michigan Central Railroad Company, the railroad purchased [illegible] of a spur line 1 77 miles in length, situated in Buchanan, [illegible] County, Michigan.

On November 1, 1912, this company subscribed to 1785.6 shares of the [illegible] capital stock of the Toronto Hamilton & Buffalo Railway Company and paid for the same at par. The Toronto Hamilton & Buffalo Railway Company also liquidated its indebtedness to this company, amounting to $[illegible].

Under an agreement dated October 1, 1912, between The Michigan Central Railroad Company, The Canada Southern Railway Company and the [illegible] Trust Company of New York, this company guarantees the payment of the principal and interest of $40,000,000.00 of Canada Southern fifty year five per cent gold bonds, of which $22,500,000.00 have been [illegible] the proceeds to be used in the redemption of $14,000,000.00 of first mortgage bonds of The Canada Southern Railway Company maturing January 1, 1913, $6,000,000.00 of its second mortgage bonds maturing March 1, 1913; and to pay for improvements to the property of The Canada Southern Railway Company made and contemplated.

On November 20, 1912, the Board of Directors authorized The Michigan Central Railroad Company to enter into an equipment trust agreement, to be dated January 1, 1913, for the purpose of establishing the New York Central Lines equipment trust of 1913. The cost of the equipment to be [illegible] to this company in connection with the issue of these latter certificates [illegible] approximately $1,099,000.00, and the pro-rata amount of the certificates [illegible] not to exceed 90% of the cost, will be approximately $960,000.00. Full particulars as to the character of the equipment to be acquired will be set forth in the report to the stockholders for 1913.

On October 21, 1912, and in accordance with agreement dated October 1, 1912, supplemental to lease dated February 15, 1912 establishing the New York Central Lines Equipment Trust of 1910, the Lake Shore & Michigan Southern Railway Company transferred to this company twenty-five freight locomotives, in consideration of which this company assumed the remaining indebtedness on these locomotives amounting to $375,979.50, and made a cash payment of $103,679.75 for the value of the Lake Shore Company's equity in the equipment, less depreciation while in the service of the latter company.

The Detroit Delray & Dearborn Railroad Company, December 5, 1912, increased its capital stock from $50,000.00 to $375,000.00. The unissued portion of the original amount authorized and such amount of the additional issue as may be necessary to be issued and sold, will be used to pay for extensions and improvements to the property.

On December 17, 1912, this company disposed of its holdings of 30,000 shares of the common stock, and a promissory note amounting to $495,000.00 of the Chicago Indiana & Southern Railroad Company, to The Lake Shore & Michigan Southern Railway Company for a consideration of $1,000,000.00. As part consideration the Lake Shore Company also released this company from its guaranty of the principal and interest of $3,825,000.00 of fifty-year gold bonds of the Chicago Indiana & Southern Railroad Company.

The sale of two of the three Detroit River ferry boats, belonging to The Canada Southern Railway Company, and the one ferry boat belonging to this company, to the Wabash Railroad Company for a consideration of $200,000.00, was consummated November 15, 1912, the proceeds being apportioned between the two companies on basis of an impartial appraisal.

Under date of June 12, 1912, this company authorized a contribution of $82,000.00 to the Mackinac Transportation Company for its one-third proportion of the estimated cost of a new steel car ferry, the advances made on this account from time to time to be covered by the promissory notes of Mackinac Transportation Company.

SUMMARY OF FINANCIAL OPERATIONS AFFECTING INCOME.

RAILWAY OPERATING INCOME. RAIL OPERATIONS—	1912. 1,816.76 *miles operated*	1911. 1,816.76 *miles operated*	Increase or Decrease.

Ten per cent payments account equipment trust of 1912	$252,851.50	
For abandoned property	107,972.09	
Discount, commission and expenses equipment trust certificates of 1912, and one-year four per cent notes	52,051.81	412,875.40
BALANCE TO CREDIT OF PROFIT AND LOSS (FREE SURPLUS) DECEMBER 31, 1912		$13,228,542.28

The total operating revenues were $32,911,753.07, an increase of $2,747,262.91 as compared with the previous year.

The freight revenue was $21,318,204.50, an increase of $1,779,520.50. This was due to the increased movement of nearly all commodities, the largest increases being in the tonnage of grain, fruit, bituminous coal, stone, timber, bar and sheet metal, and miscellaneous commodities.

The passenger revenue was $8,250,336.10, an increase of $643,284.14. A large increase in the number of immigrant and other interline passengers more than offset the decrease in the number of local passengers carried, and is reflected in the increase in the average distance each passenger was carried. This additional interline business, together with the discontinuance, to a large extent, of the low-rate excursion travel, caused a slight increase in the average revenue per passenger per mile.

The express revenue was $1,610,393.82, an increase of $131,944.67 compared with the previous year, due to an enlarged volume of business.

The revenue from the transportation of mails was $434,330.74, an increase $2,630.19 due to an under estimate of $16,586.00 in 1911, and additional compensation effective July 1, 1911, of $6,044.19 allowed by the United States Government, based on re-weighing of mails.

The operating revenue from all other sources increased $169,883.41 over the previous year; the principal items of such increase being in switching $103,105.09, car service $30,676.76, other passenger train $20,899.95, excess baggage $6,941.83, storage freight $6,106.01 and milk (on passenger trains) $5,506.52, partly offset by a decrease in rents of buildings and other property $4,579.08.

The total expenses of operation were $23,008,755.63, an increase of $1,663,000.78, as per detail on following pages. By groups and principal fluctuations they were as follows:

Maintenance of way and structures $3,629,732.27, an increase of $80,527.60, caused principally by larger force employed at higher rate of wages in maintenance of roadway, and removal of snow and ice; increased expenditure for track material, and for renewal of signals and buildings, offset by decreased prices in rails and ties, and decrease in bridge work caused by delay in obtaining material.

Maintenance of equipment $4,711,843.11, an increase of $311,547.10, caused principally by heavy repairs to locomotives, partly offset by decreased charges in car repairs.

Traffic expenses $764,733.21, a decrease of $18,865.93, due principally to decreased charges account of East Freight Lines, and in the cost of advertising; offset by increased cost of supervision and maintenance of outside agencies, and by large increase in expenditures for stationery and printing, due to tariff requirements.

Transportation expenses $13,313,058.72, an increase of $1,263,955.38, principally due to handling increased business and to higher wages paid to station employes, telegraphers and towermen. Expenses were abnormally large during the first four months of the year owing to unusual weather conditions and inadequate facilities at important terminals, which brought about a congested condition of transportation that lasted into the middle of the year.

General expenses $589,388.32, an increase of $25,836.63.

There was an increase in the revenue from outside operations of $[illegible]9,189.67 over the previous year derived principally from dining car service and restaurants, and operation of stock yards.

The operating income was $8,564,111.07, an increase of $[illegible]7.73.

Other income was $1,060,663.18, a decrease of $110,293.91 as compared with the previous year, of which $339,135.36 was due to a smaller return in interest on unfunded securities, caused principally by the liquidation of promissory notes of the Detroit River Tunnel Company, and also to a decrease in rentals of $30,455.29 and in miscellaneous income of $12,018.43, offset by an increase of $271,315.17 in dividends on stocks owned.

Deductions from income amounted to $6,898,441.37, an increase of $338,845.35. The principal fluctuations were increases of $189,507.33 in rental of the Detroit River Tunnel, $446,910.08 in hire of equipment, $76,250.89 in interest on equipment trust certificates, $72,838.39 in operating guarantee of Merchants Despatch Transportation Company, $11,286.84 in miscellaneous taxes, partly offset by decreases of $431,475.70 in interest on unfunded debt and $26,559.20 in rentals.

The profit from operation for the year, after payment of six per cent in dividends upon the capital stock, was $1,602,052.88 which has been carried to the credit of profit and loss.

The credits for retired equipment during the year amounted to	$367,745.00
The charges against this account for cost of one cafe coach, new bridge derrick, one caboose car and superheaters, betterments, etc., aggregated	58,702.69
	$309,042.31
Credit balance equipment replacement fund December 31, 1911	32,194.36
Total credit balance December 31, 1912	$341,236.67

During the year $1,067,500.00 was expended for the increase and improvement of terminal facilities in and about Detroit.

The tunnel under the Detroit River has been in constant use during the year, and has proved to be an unqualified success from every point of view.

The work upon the extensive terminal station has progressed rapidly and favorably, and unless some unforeseen obstacle prevents, it is expected that it will be completed and ready for occupancy before January 1, 1914.

During the year this company issued its one-year promissory notes due March 1, 1913, for $4,000,000.00, bearing interest at the rate of four per cent per annum.

An arrangement was made with the Lake Shore & Michigan Southern Railway Company, effective November 24, 1912, for the reciprocal grant of running rights over the single track railroads of the two companies between Detroit and Toledo, whereby the two roads will be operated separately and independently as before, but with the greater safety, efficiency and convenience of double track operation.

In the operation of the Pension Department 44 employes were retired and placed upon the pension rolls. Of these retirements 30 were authorized because of the attainment of seventy years of age and 14 because of total and permanent physical disability. Twelve pensioners died during 1912 and at the close of the year 194 retired employes were carried upon the pension rolls. The average monthly pension allowance to these men was $22.37 and the total amount paid in pension allowances during the year was $50,953.53.

Grateful acknowledgment is made of the faithful, efficient performance of duty by employees in every department of the service during the year.

WILLIAM C. BROWN,
President

TWENTY-FOURTH ANNUAL REPORT OF THE CLEVELAND CINCINNATI CHICAGO AND ST LOUIS RAILWAY COMPANY.

To the stockholders of

THE CLEVELAND CINCINNATI CHICAGO & ST LOUIS RAILWAY COMPANY:

The Board of Directors herewith submits its report for the year ended December 31, 1912, with statements showing the results for the year and the financial condition of the company.

The mileage embraced in the operation of the road is as follows:

	Miles
Main line and branches owned	634.86
Proprietary lines	994.49
Leased lines	248.27
Trackage rights	134.02
Total road operated	2,011.64

A statement showing in detail the mileage of road operated will be found on another page.

There was no change in the capital stock during the year, the amounts authorized and outstanding on December 31, 1912, being as follows:

Preferred stock authorized		$10,000,000.00
Common stock authorized		50,000,000.00
Total preferred and common stock authorized		$60,000,000.00
Preferred stock issued and outstanding	$10,000,000.00	
Common stock issued and outstanding	47,056,300.00	57,056,300.00
Balance common stock authorized but not issued, December 31, 1912		$2,943,700.00

The funded debt outstanding December 31, 1911, was $87,357,685.34

It has been increased during the year as follows:

C C C & St L Ry general mortgage bonds, issued for additions, improvements, double tracking, equipment, etc.	$1,000,000.00	
C C C & St L Ry general mortgage bonds, issued for retirement of prior lien bonds	579,000.00	
To place upon the general books of the Company its pro rata liability in connection with the certificates issued under the New York Central Lines Equipment Trust Agreement of 1912	2,398,353.00	
Real Estate mortgage, Cincinnati, Ohio, Rachel G. Holmes	9,000.00	3,986,353.00
		$91,344,038.34

It has been decreased during the year as follows:

I & St L Ry first mortgage bonds retired	$500,000.00	
Pro rata equipment trust certificates due January 1, 1912	199,625.82	
Pro rata equipment trust certificates due November 1, 1912	246,689.81	
C I St L & C Ry Co first mortgage bonds retired	6,000.00	
C I St L & C Ry Co general first mortgage bonds retired	73,000.00	
C C C & St L Ry Co 5% Gold notes retired	12,000.00	
C S & C R R Co bonds eliminated from funded debt, the interest thereon being treated as rent paid for lease of that property	2,571,000.00	3,608,315.63
Total funded debt outstanding December 31, 1912		$87,735,722.71

On November 20, 1912, the Board of Directors authorized The Cleveland Cincinnati Chicago and St Louis Railway Company to enter into an equipment trust agreement, to be dated January 1, 1913, for the purpose of establishing the New York Central Lines equipment trust of 1913. Out of the $24,000,000.00 of certificates authorized there will be issued, early in 1913, $12,540,000.00. The cost of the equipment to be assigned to this company in connection with the issue of these latter certificates will be approximately $1,258,000.00, and the pro rata amount of the certificates, representing not to exceed 90% of the cost, will be approximately $1,098,000.00. Full particulars as to the character of the equipment to be acquired will be set forth in the report to the stockholders for 1913.

SUMMARY OF FINANCIAL OPERATIONS AFFECTING INCOME.

OPERATING INCOME.	1912.	1911.	Increase or Decrease.
RAIL OPERATIONS—	2,011.64 *miles operated*	2,011.64 *miles operated*	
Revenues	$32,714,238.27	$30,431,914.86	$2,282,323.41
Expenses	24,359,744.53	22,685,707.81	1,674,036.72
NET REVENUE RAIL OPERATIONS	$8,354,493.74	$7,746,207.05	$608,286.69
Per cent of revenue	(74.46%)	(74.55%)	—(0.09%)
AUXILIARY OPERATIONS—			
Revenues	$378,302.75	$355,626.95	$22,675.80
Expenses	406,785.17	401,713.41	5,071.76
NET DEFICIT AUXILIARY OPERATIONS	$28,482.42	$46,086.46	$17,604.04
NET OPERATING REVENUE	$8,326,011.32	$7,700,120.59	$625,890.73
RAILWAY TAX ACCRUALS	1,190,242.60	1,062,512.28	127,730.32
OPERATING INCOME	$7,135,768.72	$6,637,608.31	$498,160.41

OTHER INCOME.			
Joint facility rent income	$341,589.44	$319,639.86	$21,949.58
Miscellaneous rent income	219,016.81	207,988.31	11,028.50
Dividends on stocks owned	40,967.17	72,764.90	—31,797.73
Interest on bonds owned	35,040.00	46,120.00	—11,080.00
Interest on notes, loans, etc.	73,645.08	52,769.25	20,875.83
Miscellaneous income	34,490.00	8,448.94	26,041.06
Interest on sinking fund bonds owned	12,060.00	.....	12,060.00
TOTAL OTHER INCOME	$756,808.50	$707,731.26	$49,077.24
GROSS INCOME	$7,892,577.22	$7,345,339.57	$547,237.65
DEDUCTIONS FROM GROSS INCOME.			
For lease of other roads	$301,362.02	$132,500.00	$168,862.02
Hire of equipment—debit balance	505,122.44	763,307,31	—258,184.87
Joint facility rent payable	482,920.65	526,794.42	—43,873.77
Miscellaneous rent payable	140,960.66	141,710.61	—749.95
Miscellaneous tax accruals	2,970.00	.....	2,970.00
Separately operated properties—loss	71,710.76	42,014.85	29,695.91
Central Indiana Ry—deficit	54,245.00	56,300.00	—2,055.00
Interest on funded debt	3,820,898.87	3,747,347.55	73,551.32
Interest on unfunded debt	154,439.39	80,324.24	74,115.15
Amortization of discount on funded debt	.....	53,425.00	—53,425.00
Miscellaneous deductions	1,535.68	.....	1,535.68
Appropriation of income to sinking fund	12,060.00	.....	12,060.00
TOTAL DEDUCTIONS FROM GROSS INCOME	$5,548,225.47	$5,543,723.98	$4,501.49
NET INCOME	$2,344,351.75	$1,801,615.59	$542,736.16
Dividends preferred, four, aggregating 5%	500,000.00	500,000.00	.....
SURPLUS FOR THE YEAR	$1,844,351.75	$1,301,615.59	$542,736.16

Amount to credit of profit and loss (free surplus) December 31, 1911		$2,169,152.60
Surplus for the year 1912		1,844,351.75
		$4,013,504.35
DEDUCT:		
Discount on C C C & St L gen mtg bonds	$100,000.00	
Commissions on 1910 and 1911 gold deb bonds	273,371.53	
Income November 1890 to May, 1912, from St Louis Div sinking fund bonds (adjustment)	341,500.00	
Interest January 1, 1883 to July 1, 1888 on Kankakee & Seneca 1st mtg bonds (uncollectible)	117,000.00	
Accumulated advances to Mount Gilead Short Line Ry Co (uncollectible)	26,864.29	
Adjustment of Chicago Indianapolis & St Louis Short Line Ry—advance account	167,624.89	
Value of property abandoned 1905 to 1912	1,385,110.00	
Adjustment of sundry accounts	104,093.67	2,515,564.38
BALANCE TO CREDIT OF PROFIT AND LOSS (FREE SURPLUS) DECEMBER 31, 1912		$1,497,939.97

The gross operating revenues for the year, $32,714,238.27, were the largest in the history of the company, showing an increase over the preceding year of $2,282,323.41, of which amount $2,215,691.44 was in transportation revenue and $66,631.97 in revenue from operations other than transportation.

The freight revenue for the year was $22,168,002.10, an increase of $2,234,706.23, or 11.21 per cent. There was moved an aggregate of 25,816,649 tons of revenue producing freight, an increase of 2,477,059 tons over the previous year, of which 1,594,932 tons was in the products of mines, 181,829 in the products of forests, the remainder of the increase being distributed among the other commodities. The average receipts per ton per mile were 5.43 mills, as compared with 5.50 mills in the previous year, a decrease of .07 mills. The average haul per ton increased 2.9 miles and the average number of tons of revenue freight per train mile increased 29 tons, while the average number of freight cars per train mile decreased 1.7 cars.

Passenger revenue decreased $41,119.12, there being a decrease in interline business of $44,868.34 and an increase in local business of $3,749.22. The average amount received from each passenger increased 1.1 cents and the average receipts per passenger mile increased from 1.825 cents to 1.902 cents, or .077 cents. There were 122,684 less passengers carried in 1912; the average distance carried decreased 1.7 miles and there was a decrease of 19,532,803 in passengers carried one mile.

Of the decrease of $67 128.25 in mail revenue, $32,070.11 was the result of decrease in mail compensation allowed by the Government, the balance of the decrease resulting from adjustment made in the mail revenue accounts for the previous year.

The increase in express revenue, $63,5 3.84, represents this company's proportion of the earnings from increased express traffic as compared with the preceding year.

Revenue from milk traffic carried on passenger trains increased $16,880.14 and reflects the efforts made to levelop this character of traffic during the year, together with the improved facilities for handling same, afforded by the new baggage cars received during the year.

Revenues from operations other than transportation increased $66,631.97, which $34,750.94 is from car service (demurrage) and $30,777.56 in miscellaneous revenue.

The operating expenses for the year aggregate $24,359,744.53, an increase of $1,674,036.71, detail of which by groups is as follows:

Maintenance of way and structures increase	$544,914.06
Maintenance of equipment repairs increase	320,750.34
Maintenance of equipment renewals increase	133,076.85
Traffic expenses decrease	52,084.89
Transportation expenses increase	739,641.38
General expenses decrease	12,241.92
Net increase	$1,674,036.71

The increase in maintenance of way and structures, while general through all of the accounts results principally from the increased expenditures for ballast, ties and other track material, and in roadway and track, the latter account increase $761,82 .62. Included in this amount is an increase of nearly $180,000.00 in the pay rolls of the various divisions and approximately $59,800.00 covering abnormal expenditures for labor and material growing out of flood conditions in the vicinity of Cairo. The aggregate increase in pay rolls of this department was $373,495.25.

The increase in maintenance of equipment repairs is distributed to substantially all of the accounts, pay rolls of this department increasing $281,252.94.

Of the increase in charges to renewals of equipment, amounting to $133,026.85, $30,171.05 is in passenger cars, of which there were 10 retired this year against 3 last year, $198,546.05 in freight cars, of which there were 901 retired this year against 642 last year, and $18,047.04 in work equipment, of which there were 65 units retired in 1912 against 57 in 1911. These amounts are partially offset by a decrease of $113,737.29 for locomotive retirements, there having been retired but 14 locomotives this year, as compared with 39 in the preceding year.

The decrease in traffic expenses was $52,084.89, the important decreases being in superintendence, advertising, fast freight lines and stationery and printing.

Transportation expenses increased $739,641.38, of which $394,513.49 was in pay rolls and is due to increased force in this department, together with increased compensation paid certain classes of labor due to changes in rates of pay. The increases extend to practically all of the accounts in this group and reflect the increases in tonnage, locomotive, car and train mileage. The principal item of decrease $88,602.18 is in injuries to persons, due to abnormal payments in the preceding year.

General expenses decreased $12,241.92, the principal items of decrease being law expenses $17,173.11, salaries and expenses of general officers $5,635.94, stationery and printing $4,460.05, partially offset by increase in pensions $10,684.73, insurance $10,484.80 and salaries of clerks and attendants $5,112.51.

The net deficit from auxiliary operations decreased $17,604.04, practically all of which is in the dining car service, from which the revenues increased $25,514.65 while expenses increased but $7,540.14.

Taxes increased $127,730.32, of which $64,619.40 is on real estate in Ohio, $27,565.19 on real estate in Indiana, $31,970.13 on real estate in Illinois, the balance being fluctuations in taxes of other character.

Operating income for the year was $7,135,768.72, an increase of $498,160.41 over the preceding year. Other income was $756,808.50, an increase of $49,077.24, due to increased joint facility and miscellaneous rent income and increased interest on deposits, partially offset by decrease of $31,797.73 in dividends on stocks owned. Gross income was $7,892,577.22, an increase of $547,237.65 over previous year.

Deductions from gross income increased $4,501.49, of which the more important items are: increased interest on general mortgage bonds $43,152.99, on gold debenture bonds $105,625.00, interest on equipment trust certificates—1912 $106,726.70, increase in interest on notes $74,115.15, partially offset by decrease of $258,184.87 in hire of equipment debit balance and decrease of $43,873.77 in joint facility rent payable.

The surplus for the year after paying a dividend of $500,000.00, representing 5% on the preferred stock, was $1,844,351.75, an increase of $542,736.16.

There was expended during the year for additions to the property, improvements, double tracking, equipment, etc., and charged to cost of road and equipment, the sum of $3,048,573.13, a detailed statement of which will be found upon another page.

Action was taken during the year by the stockholders and the directors of the several companies authorizing the conveyance to this company, under the Ohio statutes, of the entire properties of the Cincinnati & Springfield Railway Company, Columbus Springfield & Cincinnati Railway Company, Harrison Branch Railroad Company and Findlay Belt Railway Company; also the conveyance to this company, under the laws of Illinois and of Indiana, of the entire properties of the Cairo Vincennes & Chicago Railway Company and Chicago Indianapolis & St. Louis Short Line Railway Company.

Upon the execution of the several deeds of conveyance so authorized the properties of the six companies mentioned above will become a part of the property of this company as completely and effectually as if the several companies had become merged with this company, but subject, nevertheless, to the liens upon said property severally at the time of such conveyances.

At the annual meeting of the stockholders of the company, held at Cincinnati, Ohio, October 30, 1912, a resolution providing for the guarantee, by the Cleveland Cincinnati Chicago & St Louis Railway Company, of the payment of principal of five million ($5,000,000.00) dollars, par value, of the fifty year first mortgage gold bonds of the Evansville Mt Carmel & Northern Railway Company, and interest thereon, to be issued from time to time under the mortgage executed by that company to the Guaranty Trust Company of New York, Trustee, dated November 1, 1910, maturing July 1, 1960, and bearing interest at the rate of four and one-half per cent (4½%) per annum, received an affirmative vote of more than two-thirds of the entire capital stock of the company issued and outstanding, and having been consented to by more than a majority interest of the holders of the preferred stock, was duly adopted.

During the year an agreement was entered into with the Guaranty Trust Company of New York, providing for the purchase by the Trust Company, for the benefit of this company, of approximately 76,000 acres of coal lands in the State of Illinois, upon which advance payments of $150,000.00 were made by this company, the balance of the cost to be paid July 1st, 1917, at which time the deed or deeds of such lands are to be delivered by the Trust Company. Preliminary expenditures to the amount of $54,243.84 have been made for drilling, etc.

On March 12, 1912, this company entered into an agreement with the Erie R. R. Co., whereby each company uses the main track of the other between Dayton, O., and Cold Springs, O., a distance of about 19.5 miles, thereby making a double track arrangement which became operative October 15.

To enable the passenger traffic of this company to reach a connection with the tracks of the Cincinnati, Hamilton & Dayton Ry. Co. and to operate such trains to and from the Union Depot at Toledo, this company, on April 8, 1912, entered into an agreement with the Toledo & Ohio Central Ry. Co. providing for the use by this company as a tenant of the latter company of about 3,700 feet of the main track of the Pennsylvania Co.

A careful analysis of the Property Investment account of this company has resulted in several adjustments affecting the Road and Equipment, Securities and Advances Accounts, to conform to the accounting requirements of the Interstate Commerce Commission, and involving the charging off against profit and loss of the value of certain property abandoned, all of which adjustments are reflected in the balance sheet, shown elsewhere in this report.

In the operation of the Pension Department 44 employees were retired and placed upon the pension rolls. Of these retirements, 25 were authorized because of the attainment of seventy years of age and 19 because of total and permanent physical disability. Nineteen pensioners died during 1912 and at the close of the year 192 retired employees were carried upon the pension rolls. The average monthly pension allowance to these men was $20.32 and the total amount paid in pension allowances during the year was $46,617.28.

Grateful acknowledgment is made of the faithful, efficient performance of duty by employees in every department of the service during the year.

WILLIAM C. BROWN,
President.

Subscriptions, including 52 regular weekly issues and special daily editions published from time to time in New York, or in places other than New York, payable in advance and postage free:

United States and Mexico	$5.00
Canada	6.00
Foreign Countries (excepting daily editions)	8.00
Single Copies	15 cents each

Engineering and Maintenance of Way Edition and the four Maintenance of Way Convention Daily Issues, North America, $1.00, foreign (excepting daily editions), $2.00.

Application made at the Post Office at Chicago, Ill., for entry as mail matter of the second class.

WE GUARANTEE, that of this issue 10,475 copies were printed; that of those 10,475 copies, 9,869 copies were mailed or delivered by messenger to regular paid subscribers; 425 copies were distributed among members and guests of the American Railway Engineering Association and at the Coliseum; 131 copies were mailed to advertisers; and 50 copies were set aside for office use.

CONTENTS:

The Committee on Buildings deserves much credit for the report on Roof Covering, which was presented yesterday. Beginning with practically no accurate information some three years ago, the committee has devoted much time to this subject and brought out a very valuable comparison of the various materials. Roofing materials are largely trade products made under highly competitive conditions and by patented processes. Because of this the makers have been unwilling to give out information regarding their products, and the committee has labored under serious difficulties. The report is especially valuable, as it deals with materials which the average engineer is called upon to specify to a considerable extent and which, as a rule, he knows little about. It should, therefore, be of great assistance in determining the relative merits of the various products for specific purposes. The bringing out of much of this information should largely eliminate unfair competition and put the roofing business upon a higher basis where the purchaser may better know that when he orders a certain product he will receive it.

The methods of graphical analysis of the throat and station track capacity of large passenger terminals presented by the Yards and Terminals Committee yesterday morning, brought out information which should be highly useful in the design of large passenger stations or in the study of traffic conditions for the purpose of locating and relieving congestion. While a study of this nature is of direct value to only a small proportion of the railway engineers, it is of very great value to that small proportion having in charge the design or operation of large terminals. The three methods outlined for studying this special problem should form a basis on which such studies can be readily made and should also be of considerable assistance in making comparisons upon the same basis of traffic conditions at different terminals.

The directors of the Railway Business Association, following their meeting in Chicago on Wednesday, gave out a statement strongly advocating the amendment of the Erdman act at the special session of Congress which has been called by President Wilson. The association favors broadening the provisions of the law so as, among other things, to include mediation and arbitration of disputes among railways and their track employes. It will be recalled that the law now applies only to controversies between the roads and employes concerned directly with the operation of trains. The Railway Business Association believes it should be made applicable to trackmen, clerks, freight-handlers, machinists, boiler-makers, blacksmiths, car-repairers, etc. It also favors the creation of a board in which "the proportion of the neutral arbitrators to partisans will bring more minds to bear upon the many questions arising in large areas and tend to promote equity in decisions." Under the law as it now stands the arbitration board consists of one representative of the railways, one of the employes and an umpire, the last-named of whom really always decides the controversy. The defects of the existing law are conceded by practically all who have studied its workings. The country recently has very narrowly escaped several bad strikes, and something should be done speedily to remove the constantly recurring menace of serious interruptions of transportation service. There are few, if any, more important matters demanding attention by Congress.

In a number of ways the fourteenth annual convention of the American Railway Engineering Association, which closes to-day, has been better than any of the previous meetings. The number of members in attendance is greater than ever before, as shown by the official registration figures. In 1911, 351 members registered; in 1912, 386, and this year 434. This year's registration is more than 40 per cent of the total membership of the association, which was announced by President Wendt in his inaugural address to have reached 1,115. The attendance in the meetings has been uniformly good, even at the opening of the sessions. The meetings have been carried through on schedule time and the final adjournment of the sessions for hearing reports and discussions was made at the unusually early hour of 12:35 yesterday. One reason for the very large attendance at the sessions of the convention is that the association has this year, for the first time, officially recognized on its programme the exhibition at the Coliseum. The programme included four days, Friday being devoted to a "visit to the National Railway Appliances Exhibition

In the Coliseum and Armory." The officers of the Appliances Association notified all exhibitors that the exhibition would close officially at 10:00 o'clock to-night (Friday), and that exhibits must be left intact up to that time. The knowledge that this was the case has caused many of the members of the engineering association to postpone their visit to the exhibition until Friday, which has allowed them to spend all of their time in the meetings of the convention. The attendance has also been augmented by a very general interest in the reports presented this year. Some of these were among the most important which the association's committees have yet prepared. The Track Committee had a long and detailed report, including much important matter. The Yards and Terminals Committee presented some very valuable data concerning the study of operating conditions of large passenger terminals, and also presented a good report on some features of the operation of hump yards. The report of the Iron and Steel Structures Committee covered the very important matter of inspection; the Committee on Buildings completed the report on roofing materials, and the Rail Committee maintained the very high standard that its previous reports have set. The retiring president, Mr. Churchill, and all the officers and committees of the association, are to be congratulated on the successful conclusion of the year's work.

The report of the committee on Electricity brought up a subject the importance of which is not generally realized by those not fully conversant with the subject of steam road electrification. Many consider that when the electrification of the tracks is completed, the only remaining problems are those of an operating nature. The elaborate precautions taken to guard against the attacks of electrolysis in the Grand Central terminal show that engineering problems of magnitude also remain to be solved. While the subject of electrolysis has required attention ever since street cars have been operated by electricity, and it has been found that stray currents have been the cause of frequent destruction of conduits and water pipes, the full effects of this destructive action have not always been realized when the advisability of the use of electricity in steam railway terminals has been discussed. Difficulties of this nature from the surface lines in many cities have been pronounced, and, notably in Chicago, have given rise to many complaints and careful study within the past year. With the much larger amounts of power required for heavy railway service, these troubles may be greatly intensified and care will be necessary to avoid damage to private property as well as to the railway structures themselves. The committee on Electricity has an interesting subject, which will become increasingly important to steam railroad men as the mileage of electrified tracks increases.

NEED FOR DATA REGARDING TRACK CONSTRUCTION.

An examination of the reports of the committees studying the various elements of the track structure indicates that there is a very general sentiment that the time has come when more accurate data should be collected regarding the stresses to which the track is subjected and the strength of the individual parts singly and together. The Ballast committee reports that as a result of its study "a further test in track under regular traffic is desirable," and has outlined in some detail how such a test should be conducted to determine the proper depth of ballast of various kinds to insure uniform distribution of loads on the roadway. The Roadway committee renews the recommendation made by it a year ago that a special committee consisting of members of the Roadway, Ballast and Track committees be appointed to make experiments to determine the magnitude and distribution of the load transmitted to the roadbed and the bearing power of various materials ordinarily found in the construction of the roadway. Because of the close relation between the roadbed, ballast, ties and rail, such an investigation must cover the entire track structure, for it is impossible to study the action of any one part alone. The use of a heavier rail decreases the load upon the individual tie by distributing it over a greater number of ties. Likewise, an increased depth of ballast distributes the load more evenly upon the roadbed. The Tie committee bears this in mind when it reiterates the statement made a year ago that it is impracticable to make successful experiments to determine the size of crossties because of the influence of these other variables.

The rapidly increasing cost of maintenance of track shows plainly that it is less able to withstand the demands made upon it from year to year, and some remedy is necessary. In spite of the many years that railway tracks have been built and maintained there is practically no data regarding the actual service track can withstand. A number of excellent theoretical analyses have been made and some elaborate experiments have been carried out, notably those of the Pennsylvania at Altoona and of Director Schubert in Germany. These experiments, however, have been conducted largely under artificial conditions with the track equipment especially constructed and with assumptions more or less accurate regarding the loads, climatic and other conditions, so that the results only approximate those secured under traffic.

Before the track structure can be intelligently designed, the forces acting on it must be known. The track of to-day is not the result of such a design, but rather of a gradual development along more or less arbitrary lines. As it is becoming more evident that the limit of this development along the present lines will soon be reached, if indeed it has not already been reached, a series of tests carried on in a main track under actual traffic conditions should be extremely valuable in indicating the weak points in the present construction and showing wherein it may be strengthened. Aside from the necessity of securing a track structure of sufficient strength to meet present traffic conditions, it should be possible, with such tests, to determine the most economical construction to withstand given loads, so that one could determine, for instance, whether it is more economical to use a greater depth of ballast or larger ties to secure the desired resistance. One road is now making a careful study along this line, paying particular attention to the influence of the subgrade on the track structure above. It aims to divide the roadbed into four general classifications, depending upon its degree of solidity. Then, with a certain grade of foundation, one depth of ballast and one size and spacing of ties could be recommended to give a strength equal to that of another depth of ballast on another roadbed. A series of experiments to cover all the variables entering into track construction would necessarily be extensive and expensive, but when one considers the amount of money spent annually for track maintenance it should be well worth the cost. Because of these numerous variables, it is not to be expected that a section of track can ever be designed with the mathematical exactness that a bridge can, but a good series of tests should go a long way towards removing many of the uncertainties and bring us nearer to an exact solution.

MISSOURI PACIFIC-IRON MOUNTAIN DINNER.

The officers of the Missouri Pacific-Iron Mountain system who were present at the convention held their annual dinner Tuesday noon. The representatives of the system who were present included Messrs. Hadley, Leighty, Hale, Carpenter, Dorley, Curd, Burton, White, Rickert, Buckholz, Walker, Simons, Butterworth and Bishoff.

Proceedings.

The Thursday morning session of the American Railway Engineering Association was called to order at 9:20 a. m. by President Churchill.

YARDS AND TERMINALS.

The Board of Direction has assigned the following subjects to this committee:

(1) Report on typical situation plans of passenger stations, of both through and stub types, with critical analysis of working capacity, and include a review of the different methods of estimating their capacity.

(2) Report on developments in the handling of freight by mechanical means.

(3) Report on developments in the design and operation of hump yards.

TYPICAL SITUATION PLANS OF PASSENGER STATIONS.

In the development of the subject the committee presented situation plans and description of the business handled at the following passenger stations: Baltimore, B. & O.; Baltimore, Pennsylvania; Boston, South Station; Philadelphia, B. & O.; St. Louis, Union Station; and Washington, Union Station.

C. H. SPENCER,
Chairman Committee on Yards and Terminals.

In arriving at a description of the business handled at each station, the following outline has been used:

Handling of mail, handling of express, handling of baggage—individual, theatrical; passengers, through, local and suburban.

Each item should be considered apart from any other, particularly as to that which fixes the maximum capacity in a certain unit of time, say, one hour. This would be followed by consideration as to whether this speed or maximum capacity could be sustained for a longer period. Finally the four headings would be considered as applied to each layout.

The committee offers three methods of graphical critical analysis of working capacity of throat and station tracks at a station. The first method has been used by the Belgian state railway and is shown in article by Messrs. Weissenbruch and Verdeyen in Bulletin of International Railway Congress, for September, 1908. The second method has been used by the Pennsylvania railroad in studies of the Broad Street (Philadelphia) station. The third method has been designed for the committee work this year.

A method devised for the Dirschau Passenger station and described in Bulletin of International Railway Congress, for February, 1909, is, after consideration, not recommended.

The essentials to be shown on diagram for analysis of working capacity of a passenger station are:

(1) Occupation of station tracks—
  (a) Capacity of each track;
  (b) Time of occupation;
  (c) Make-up of trains;
  (d) Movements, if any, on internal crossovers in station.
  (e) Number of trains and route arriving and departing and direction of movement.

(2) Movements on throat tracks—
  (a) Arbitrary time over route;
  (b) Whether scheduled trains, drafts, road engines or switch engines;
  (c) Route used before entering and after leaving and direction of movements;
  (d) Interference from cross movements.

Each of the three methods submitted has stood the test of application to extremely heavy traffic conditions.

Diagram of Train Movements at Camden Station, Baltimore, Md., Using Belgian Diagram.

A diagram was presented showing train movements at the Camden station of the Baltimore & Ohio, which was an application of the diagram used on the Belgian State railways, and worked out by officers of that system. It was explained by L. Weissenbruch and J. Verdeyen in the Bulletin of the International Railway Congress issued in September, 1908.

In applying this diagram to Camden station there were certain minor features added to those given in the above bulletin, especially the table showing the capacity of tracks and the symbols used to designate the number and kind of cars occupying the platform tracks. This was for the purpose of showing whether or not two trains could occupy the platform track at the same time.

In the diagram of Camden station two hours were selected in which the number of movements was at a maximum. Many of these movements were switching movements, and during the particular time chosen the station platforms were not utilized to their full capacity for inbound and outbound main line trains. This period was selected and the diagram prepared to show especially the possibility of representing internal switching movements as well as the movements of trains and light road and switching engines.

The diagram as applied to Camden station showed its use both for a terminal station and a through station, since tracks 1 to 7 inclusive are stub tracks in the train shed, while tracks 8 and 9 are on a lower level entering the Belt Line tunnel on the main line between Philadelphia and Washington, constituting a through station.

The fundamental idea of the Belgian diagram is to select a certain number of platform tracks, access to which is secured over one track, or a short stretch of a track, which can be called the "running line" of the group selected. Tracks 8 and 9 show in reality a through station, and therefore, have two running lines. In order to represent routes and to immediately detect movements which would foul each other, numbers are selected to indicate the different routes.

The value of the diagram depends entirely upon the selection of the running lines and the numbers representing routes. The route numbers and the station platform numbers can be made different in design, and running lines should be shown in dotted and broken lines or in lines of different colors. There may be several selections of running lines and routes, but after one or two trials the arrangement that gives the greatest station capacity will be easily determined.

This diagram covered the five essentials which had been submitted by the committee as necessary for a graphical analysis of working capacity of a passenger station in regard to the occupation of station tracks. In the table at the right-hand side of the diagram the capacity of each track could be ascertained. It showed the composition of the train or cut of cars occupying the track and the length of time that the different trains or cuts occupied that track, and whether cars were taken off or added to those on the track. It showed internal movement, also the number and route of arriving and departing trains with their direction. As applied to the movement through throat tracks or fouling points, the numbers were placed at these fouling points and showed the route, the arrows the direction of movements, and the symbols as noted in the legend the class of movements, such as trains, light load or switching engines, or switching engines with a cut of cars. The time taken by a movement on any track was shown by the length of the heavy movement line as drawn on the line representing that track on which the movement is taking place.

All diagrams at first seem quite complicated, but after giving a little time to thoughtful study and becoming

thoroughly familiar with the meaning of each symbol, it is very easy to read them, and they can then be used correctly and quickly.

The make-up of the diagram would depend considerably upon the purpose for which it might be employed. A superintendent or station master, in making a study for rearranging station movements to secure greater capacity, would not need as large a diagram, nor possibly the same kind of a diagram, as would be needed by a towerman, or a train dispatcher, who must handle an emergency movement. It is possible that we might have a station used practically to its maximum capacity, and a certain train might come in late, or on some days there might be unexpected heavy excursion movements, and a diagram to fulfill this purpose should show at a glance at what time, on what track and by what route the different trains could be received. A towerman who has been working for any length of time in a certain tower would probably not have occasion to refer very frequently to this diagram, but a new man would use it constantly, until he became thoroughly steeped in the knowledge of the facilities which he has to handle.

The Belgian diagram gives a very complete picture at a glance, and concentrates on one chart all fouling points and tracks so that the whole situation is shown on the same sheet. It is complete in its representation; it can be spread out if the number of train movements are large, and after a knowledge is had of the fundamental principles it is very simple and can be read without hesitation. It is most important, however, to secure full value of the diagram, that we make a careful selection of the running lines and the numbers representing routes and fouling points.

Diagrammatical Method of Showing Actual Occupation and Working Capacity of Station and Throat Tracks, Broad Street Station, Philadelphia, Pennsylvania Railroad.

For a number of years past, it has been apparent that the track layout of the station and approaches at Broad Street station, Philadelphia, is seriously congested by the train movement incident to handling the service of that terminal. This condition is most in evidence during the rush hours, or peak load periods of the morning and evening, at which time any interference with the normal movement of traffic, such as occurs during severe weather, results in disorganization of the service and consequent delays to trains, from which recovery is slow.

The need for additional relief led to the appointment about two years ago of a board of engineers to study the whole situation, and prepare plans and submit a report for additional facilities. In considering the problem, the committee's first thought was to devise some means of showing graphically the conditions actually existing at the station and on the track approaches, during the peak load periods, or hours of maximum train service; the train movements handled during such hours requiring the maximum demand on the facilities provided. It was necessary that these diagrammatic studies, to be of practical service, should be of such a nature that the results obtained through any change in operating methods could be clearly indicated on the original charts. The charts fully met expectations, and were indispensable in studying the overcrowded condition of the terminal and the resulting changes that would ensue from electrification.

An analysis of the station and throat track layout developed the fact that there are six route or throat tracks at 18th street connecting the eight elevated approach tracks to the sixteen station tracks, over which all passenger train movements are made. A movement over any given route will, of course, block such route for other movements from the moment the route through the interlocking is set up until the movement in question clears the fouling point. It is also evident that when such a movement involves the use of switches which are necessary to the movement of train units over one or more of the five remaining routes, the routes so fouled are blocked until the movement in question clears.

It was apparent from these facts that with the proper data at hand, graphical charts could be prepared that would show all movements actually made over the throat tracks, including blockade of routes, and would indicate the extent to which these facilities were used. This method was, therefore, adopted and the necessary data obtained.

In preparing the throat track charts, the six routes were plotted as adjacent parallel spaces of convenient width and length, on which time was indicated by perpendicular lines. Each individual movement made over the different routes was plotted as a solid line rectangle, cross-hatched with solid lines to show the direction of movement and covering the time included between the actual setting up of the route and its clearance by the movement in question. The blocking of routes other than the one actually in use by any given movement was shown by rectangles, cross-hatched with dotted lines. The character of each train unit handled was indicated on the charts, and, where blockades of other routes resulted, the actual movement made was shown.

The station track diagram showed by means of rectangles, the equipment properly designated, occupying the different station tracks during the busy hours, and the time of arrival or departure of each train unit. The width of track spaces and train diagrams were drawn to scale, and the relative amount of track room occupied by each train unit was, therefore, indicated.

Examination of these diagrams or charts indicated very clearly the congestion now existing, and showed conclusively that the tightest place was at the throat of the station, and that the six routes in their capacity for handling movements were not evenly balanced. This condition is due to the character of the track layout.

These different charts are well adapted to the study of the results to be obtained from electrification; the elimination of shifting movements that would follow the use of multiple-unit electric traction for certain groups of trains being readily indicated on the original diagrams.

The re-plotting of trains can be done without introducing unknown factors, as it is only necessary to adhere to the figures obtained in actual practice, as given in the tower records and plotted on the original diagrams. If new trains are to be introduced, a glance at the station chart will show what platforms are available at any particular time, and, by referring to the throat track chart, one can easily ascertain whether the movement can be made at the desired time without interference with existing conditions.

The daily number of scheduled trains when the tower record was taken in January, 1912, was 543; the number of scheduled trains in the busy two-hour period from 4:00 to 6:00 p. m. was 78, and 286 movements were made in both directions past "A" tower in the same period.

In addition to suburban and long distance passenger trains, a large amount of baggage, mail and express must be cared for. The handling of theatrical scenery and some full carload lots for periodicals is undertaken at West Philadelphia.

Graphical Diagram Devised by Committee for Use in Analyzing Working Capacity of Passenger Stations.

The purpose of the graphical diagram showing the working capacity of a passenger station is twofold: To make clear the necessity for changes in design in the way of revision of or additions to the track layout, and to lay out a working time card.

It is desirable to be able to see at a glance for each station track relatively for any instant: The capacity and the space yet available, the make-up and the amount of equipment occupying, the scheduled time of arrival and departure of such equipment, the switching movement required on any connecting internal crossover and the route arriving and departing, and the direction of the movement.

The diagram should show clearly what throat tracks directly serve the various station tracks without interference with other routes, also, similar information as between the throat tracks, and the different main or running tracks outside of the station; the arbitrary time consumed by a movement over a throat track from the time the route is set up until it is cleared, whether the movement is a scheduled train, draft road engine or a switch engine, the route used before a movement enters a throat track and after it leaves, the direction of the movement and any interference from cross movements.

The method of graphic analysis designed for the committee contemplates satisfying each of these requisites. It has been applied on the diagram presented by the committee to the Broad Street (Philadelphia) station, for which data was available covering approximately 150 movements that are regularly made in the two-hour interval, 8:00 a. m. to 10:00 a. m. Such heavily congested traffic was selected so as to thoroughly test the method.

On the diagram heavy lines plotted as coordinates represented, respectively, the abscissa or horizontal lines the station track, the ordinate or vertical line the throat track, and a second abscissa the main running track. A line

was provided for each unit in these three classes of tracks A scale representing hours and minutes was plotted on each of these lines. For clearness, no less than 1-20 in. should be allowed for each minute.

The capacity of each station track may be shown by a number placed against the station track line to show its length in cars. Each station track line was also marked to show the number of track which it represents. The amount of space available on any track at any instant is the difference between the number of cars shown in any movement or movements occupying the track, and the total capacity of the track. Each occupying movement was shown by a relatively thin line paralleling and alongside of the station track line, and marked as to the character and make-up, both in cars and engines. The time of arrival and departure of any movement was shown by the minute on the scale at which the movement line, now extending vertically, crossed the track line. The heavy horizontal scale lines representing the station tracks jointly served by any certain throat tracks were assembled in a parallel group. The switching movements required on any internal crossover connecting with station track may be shown by drawing thin movement lines from the proper point, as to scale, on the occupation line on one track, through the proper point on the scale of the track to which the crossover connects, paralleling the latter during the time of occupation, and returning vertically again to the original occupation line on the first track. The route arriving and departing for any movement was shown in order by the figures and letters plotted on each movement line near the point of origin or ending on the station tracks, and denoted the respective station tracks, throat tracks and running tracks occupied. The direction of the movement is shown by an arrow.

The relative position of the vertical lines representing the throat tracks, and the horizontal lines, representing respectively the station tracks and the running tracks, showed the grouping as to direct connection one with the other. The arbitrary time consumed by a movement over a throat track from the time the route was set up until it was cleared was measured by the minimum space allowed between the crossing movement lines on the vertical scale line representing the throat tracks, and could also be shown by a number representing the minutes and placed at one end of the throat track line. The scales used should be no less than 1-20 in. to the minute for clearance sake. The vertical lines representing the throat tracks were respectively marked with the letters used to designate each throat track. The conventional movement lines, in addition to being designated at the points of origin and ending by figures and letters denoting as to whether they were trains, drafts, road engines or switch engines, and also as to the route used before a movement enters a throat track and after it leaves, could also be distinguished as to classification of movement, by the use of different colors, just as is customary in the use of strings or lines denoting on an ordinary railroad district time-card chart somewhat similar classification. The direction of a movement was given by the arrows at the points of origin and ending, and the interference of a movement on any throat track was shown by the fact that the movement line passed across each and every throat track line that might be blocked by the movement.

Should it be desired at any terminal to use this method in laying out a working time card, chart boards of a size sufficiently large to suit the purpose could be provided, on which could be permanently plotted the scale line conventions for the station tracks, throat tracks and running tracks. The movements would be indicated temporarily by lines of different colors and would be shown upon the chart by means of strings fastened by pins, as is done on the ordinary railroad district time chart. Tags properly marked and attached to the pins at the originating and terminating point of the movement would give the detail information required, so that after the movements are plotted to meet requirements of the proposed new time card, the information could be checked and called off in the customary way for making up the printed working list, showing arrival and departure of trains and tracks used for each. Should certain movements during any interval of time appear to create an undesirable congestion of traffic, a rearrangement of the strings on the chart may be studied and put into effect, and the possible interference brought about by any such change anticipated and avoided. Should one or more station tracks appear to be handling more than their share of the traffic, similar attention to the chart or diagram can be given, and if no other solution develops, the necessary slight changes in track connections may be made.

Where congested traffic demands, the working charts or diagrams need only be limited in size by the space on the wall available and within reach, and as a rule, where the traffic is as congested as in the Broad Street station, extra sets of charts may be required to satisfactorily cover the day's work. One possible good feature of this method is that it may be handled personally by transportation men, making use of the colored strings, and may be revised and rearranged by them quickly to suit any change in traffic conditions. The make-up of the trains may, if desired, be shown on the diagram also by conventions, representing arbitrarily each style of equipment, placed in order on a line at right angles with each station track scale line and against the time of arrival or departure, indicating the mail, express, baggage, coaches, dining cars, sleeping cars and parlor cars.

In General.

The committee recommends that for the design of a large passenger terminal there should be considered the situation plans submitted to the association in 1911, eliminating the notation 1-7 as applied to the angle of the ladder. These layouts would be expanded or multiplied in such a way as to best meet the requirements of the real estate owned at any particular location.

The committee also desires to emphasize the possibility of the substitution of inclines or ramps in place of stairways in busy stations. In all such stations where the track level is above or below street level, stairway connections have the objection of interrupting and checking the flow of travel at busy hours. This is especially the case where much suburban traffic is handled. It is of interest to note, therefore, that in the new Grand Central terminal at New York inclines have been adopted at several points, presumably because they were considered safer and more expeditious than stairways. The grade of these inclines seems to be eight per cent. Experiments have been made to determine the grade best adapted for convenience. In many places there is not space available for such inclines, but in designing new stations this feature might well be studied.

Conclusions:—In the design of a large passenger terminal the committee presents for adoption the following conclusions:

(1) A holding yard should be directly connected with the platform tracks to provide for a quick emptying and refilling of the latter.

(2) At passenger terminals, where large quantities of baggage and express must be handled, and it does not appear expedient to provide intermediate platforms to be used exclusively for this service, it is recommended that, where conditions permit, baggage and express be received, delivered and handled below or above the train floor (as grade conditions demand) and raised and lowered by elevators, conveniently located, to avoid interference with the movement of passengers.

(3) To provide for proper coupling of cars a maximum curvature for storage and loading tracks of six deg. is recommended.

(4) For safe, efficient and economical operation on station throat tracks the curvature through switches should not exceed that of a No. 8 slip on tangent.

The committee presents as a progress report, without recommendation as to relative merits, the three methods of graphical analysis of working capacity of a passenger station.

DESIGN AND OPERATION OF HUMP YARDS.

Circular letters were sent out during the year to a number of large railways, and as far as the committee was able to ascertain, the only large hump yards built during the last year were the Centralia, Ill., yard of the Illinois Central and the Godfrey, Ill., yard of the Chicago, Milwaukee & St. Paul. A small hump yard has been partially constructed by the Kentucky & Indiana Terminal railway near Louisville, Ky., but as some changes are to be made in plant, it will not be possible to make any report on the yard at this time. (The report then described the Centralia and Godfrey yards, which were described in the *Railway Age Gazette* of Aug. 9, 1912, and April 14, 1911.)

The committee feels that a careful study should be made of the operating conditions of all hump yards and results tabulated to see if improvements cannot be made in some of these yards to secure better efficiency.

Conclusions.

Where tracks are set aside for holding empty cars, the grade leading to such empty tracks should be increased so

that empty cars will move with the same velocity as loaded cars switched to adjoining tracks.

The committee has investigated the "Cut List" system of handling cars on the hump and recommends it as being safe and efficient. This system is briefly described as follows: The yard clerk makes up a list of cars to be switched and tracks they are to be placed on in receiving yard, cut No. 1 being the first car to go over the hump. Cut list form is perforated on three vertical lines, so the list may be divided up into four parts, each part being a duplicate of the other.

Where switches are thrown from a tower, one copy of the list is given to the towerman and one to the man cutting off cars on the hump. Where switches are thrown by hand, each

DEVELOPMENT IN THE HANDLING OF FREIGHT BY MECHANICAL MEANS.

During the past year the committee has made considerable study of the mechanical handling of freight, especially as to the work carried on at the freight house of the Missouri, Kansas & Texas at St. Louis; the Baltimore & Ohio, Pier No. 8, Locust Point, Baltimore, Md.; the Wabash Pittsburgh Terminal freight house at Pittsburgh, Pa. It has also made further study of the use of electric trucks and other appliances.

Commenting on the M. K. & T. freight house, which was described in the *Railway Age Gazette* of June 23, 1911, the committee reports as follows: The daily duty required at this station is approximately as follows:

(1) To handle one million pounds of outbound freight per day for loading into 77 cars.

(2) To handle a considerably less amount of inbound freight, the outbound freight being mostly handled in the afternoon and the inbound freight mostly handled in the morning.

The cost of maintenance of the telpherage system is considerable. In this particular case, however, it was due to the first installation of the overhead rail being soft, necessitating its renewal with a harder grade of steel. Along with the rapid wear of the rail originally installed it was noticed there was more or less injury to the eyes of the employes on account of fine particles being ground off the rail and falling through the air. It has further been found that considerable damage to freight is likely to result—more than results from the ordinary handling of freight, due to crushing by heavy loading on the trucks and on account of the motorman dropping loads with too great force. It has been found in practice that the trucks cannot generally be loaded to their full capacity without frequent rehandling, which is impracticable on account of not sufficient freight destined to a particular car being assembled for loading in its immediate vicinity.

There has been greater difficulty in preventing freight going astray as the result of two sets of men handling the freight on the two floor levels and no check between them. It is further impracticable to avoid a great many empty runs with the telphers to bring back empty trucks, by reason of the fact that when a loaded truck is deposited through a hatchway no empty truck can be placed at the same point to be picked up at that time, and the telpher has to return later to pick up the empty truck from that same hatchway. There is a hazard of personal injury to truckers compelled to work under the trucks while being conveyed, due to the liability of packages falling therefrom. It has developed that there is likely to be considerable idle time of employes, resulting from difficulty in so distributing the freight as to have trucks at all times at the several cars ready for unloading as soon as the trucks previously delivered have been emptied. There is more supervision required to check against idleness and also against pilferage. A repair force at considerable expense is required for the maintenance of the electrical equipment, even at the present time, when the installation is comparatively new, and the cost of maintenance is expected to increase in considerable measure as the equipment becomes older and more worn. The manual labor required in the handling of freight has been demonstrated by experience to be necessarily about as great as the handling of freight on one level without any intermediate mechanical handling, as the result of which the cost of handling freight by this system is materially, and apparently unavoidably, increased, rather than decreased.

It is probably true that the design of the building and of the telpher equipment could be improved, involving less first cost and less maintenance cost. It is naturally to be expected that this would be the case on account of this undertaking being entirely novel as applied to the handling of less-than-carload freight. While the working of this plant seems to indicate that the practicability of handling less-than-carload freight is questionable, there is no question but that the use of the telpher for any certain commodity can be successfully and economically worked where elevation and distance are factors to be considered, or where, regardless of classification, freight is to be delivered at a common point, as for the loading of a vessel. This is further borne out by the fact that a successful telpher system is in use by the Baltimore & Ohio Railroad on its Pier No. 8, Locust Point, Baltimore, Md., where miscellaneous freight is transferred from cars to vessels.

It was expected that the capacity of this St. Louis freight house, with its equipment, would be greatly in excess of the present demand for handling freight, or at least could be made capable of handling a greatly increased amount of freight simply by the addition of telphers and men. But it has been demonstrated by experience that the present volume of traffic about measures the capacity of this plant for handling classified freight, which is a disappointment.

The Missouri, Kansas & Texas was forced to quick action in the nature of providing facilities and was limited as to space in order to obtain desirable location. It is to be complimented for making the bold experiment at a very heavy cost of installation, and it is to be hoped that it may yet find a way of attaining economy in its operation.

Electric Trucks.

Four-wheeled platform motor trucks have been introduced in a number of cases to replace the ordinary two-wheel trucks,

the former having greater carrying capacity and higher speed than the latter. The truck system has the advantage of flexibility of movement with no fixed routes, as where carrier or teipher systems are used, and no investment for fixed plant, while it may be tried and introduced in existing freight houses without trouble.

The Delaware, Lackawanna & Western Railroad is using several storage battery one-ton trucks of this kind (Sprague and General Electric systems) at its transfer station at Secaucus, N. J., where freight brought in cars from various collecting stations in New York is transferred to cars for the outbound local and through trains. The transfer station has two pairs of tracks for the transfer cars, two for local cars, and two for through cars, these being separated by three platforms 900 ft. long (23 cars) and about 22 ft. wide. The trucks are 72x44 in., with the floor 22 in. above the rail and a motorman's platform at one end with controller, brake and steering gear. They have electric bells to warn the truckers and other men, and can move at a speed as fast as ten miles per hour. The trucks are run directly into the cars, over steel bridge plates placed at the doors, and in this way pass to cars on the second track from the platform. Current is supplied from a line supplying the yards and is converted to the necessary voltage by a small plant on one of the platforms. This transfer house with electric truck service is described in further detail in the Engineering Record of September 21, 1912.

Abstracts of papers presented before the New England Railroad Club on February 13, 1913, were also given. (See Railway Age Gazette, November 8, 1912.)

Another type of storage battery truck, built by the Cleveland-Gallon Motor Truck Company, has been used experimentally in the freight station of the Lake Shore & Michigan Southern Railway, at Cleveland, Ohio. This is described in the Railway Age Gazette, October 11, 1912.

In addition to the above, we find some roads and steamship companies are using inclined elevators, overhead jib cranes, stacking or elevating conveyors, briefly described as follows:

Inclined Elevators.

There is a somewhat extensive use of inclined elevators at piers to assist the moving of loaded hand trucks on the inclines between ships' decks and the pier floor. Some of these are traveling platforms, which carry the men and the trucks. Others are simply endless chains which have lugs to engage the axles of the trucks and push them forward, the men walking the ordinary way. The Otis Elevator Company has built a number of installations of the latter class and some of the former class (all on the Reno patents). The installations of the chain type include piers of the Boston & Maine at Boston; the New York, New Haven & Hartford at Bridgeport, Conn.; the Merchants' & Miners' Transportation Company at Savannah, Ga., and the Metropolitan Steamship Company at Boston. Each of these has two electrically operated machines, except that the last has three machines. It is stated that the last named company estimates a saving of $33,000 in handling its freight for one year, which is approximately six times the cost of the machines. Each machine can handle from 600 to 1,900 trucks per hour, according to the speed of the chain.

Overhead Jib Cranes.

A type of crane which is used extensively in freight houses in Great Britain is a combined traveling and revolving overhead crane. Instead of the usual hoisting trolley on the bridge of the crane, the trolley has suspended from it a frame which carries a horizontal boom or jib, and this frame can be revolved through a complete circle. The freight house of the Great Western Railway at Cardiff, Wales, has a Babcock & Wilcox electric crane of this type; its bridge has a span of 50 ft., and the boom on the traveling trolley has a working radius of 18 ft. The hoisting capacity is one ton, and the speeds are as follows:

Bridge travel.....250 ft. per minute
Trolley travel.....120 ft. per minute
Swinging .....230 ft. per minute (at end of boom)
Hoisting ..... 30 ft. per minute

The new freight station of the North British Railway at Glasgow, Scotland, has 15 overhead traveling cranes for unloading cars. These are of the revolving jib type mentioned above, the jib being 23 ft. long, but the trolleys run on narrow parallel runways instead of upon a traveling bridge. Two of these are three tons and the other 1½ tons hoisting capacity. Each of the latter has a 17 h. p. motor for hoisting at 100 ft. per minute, one of 2 h. p. for swinging at two-thirds of a revolution per minute, and one of 4½ h. p. for traveling at 360 ft. per minute. For hoisting freight from cars to the upper floors of the warehouse, there are two traveling trolley hoists on each floor, with three wells or shafts for interior hoisting, while the top floor has a 1½-ton trolley carrier or helper. There are also six elevators at one side of the house. For handling heavy freight, there is a gantry crane, having one end of the bridge supported by a leg with wheels riding on a rail laid on the ground level, while the other end is carried by wheels on a runway built on the freight-house wall. The bridge is of 50-foot span, and carries a traveling hoist of 40 tons capacity. The bridge has a travel of 200 ft. along the front of the freight house and into the yard.

Stacking or Elevating Conveyors.

In pier sheds, cotton sheds, storage warehouses, etc., it is often desirable to stack goods (in bales, sacks, boxes, etc.) to a considerable height, in order to save floor space. Sometimes an overhead traveling crane, or traveling bridge with hoisting trolley, may be installed for this purpose. In many cases, however, a portable machine would have a greater range of usefulness, and several portable elevating and conveying machines of this kind have been installed by the Brown Portable Elevator Company. These installations include the stacking of grain and sugar in sacks, stacking hay in bales, and also handling miscellaneous materials and freight. One installation is for the Central Railroad of Georgia, at Savannah, Ga., for piling bags of material on a pier. The conveyor is carried on a steel frame mounted on a wheeled truck, on which is mounted also the motor and driving mechanism, and this frame can be adjusted to any desired inclination and height. In some machines there is a separate carrier on each side of the truck, so that one may be inclined to raise material from the floor to the heel of the other conveyor, this latter being adjusted to a horizontal or inclined position, according to the point to be reached.

Some freight handling installations at piers have been mentioned above, but in crane equipment for handling ship cargo American ports are notably behind European ports. At the former, reliance is placed mainly on the ship's winches and cargo booms, which can handle material only directly alongside. In European practice there are usually numerous traveling cranes along the quays and sheds. The tower type of crane is a jib crane on a tower mounted on wheels to run on tracks along the piers or docks. The portable type of crane is mounted on a steel tower traveling on a track of wider gage than that of a railway track, and made open so that cars can run beneath the crane, and the crane can move from point to point, without interfering with car on the track which it straddles. A semi-portal or semi-gantry crane may span the width of quay between the freight house and water; the outer end of the bridge is supported by a leg traveling on a rail near the edge of the quay, while the inner end is carried by wheels riding on an elevated runway on the freight house, like a traveling crane. On the tower or bridge is a revolving jib crane, which may be fixed in position or may traverse along the bridge. In many modern installations, the cranes travel on the roof of the pier or warehouse, so that they handle cargo between ship, car or warehouse without obstructions to the tracks or driveways between the house and the ships.

The rail and water terminals at Texas City, Tex., on the mainland side of Galveston Bay were described in the Railway Age Gazette of July 12, 1912. The main pier is 1,400 ft. long and 1,000 ft. wide, with four parallel warehouses: 80x1,120 ft., 118x520 ft., and two 100x750 ft. On shore there are four warehouses in line: One 75x1,000 ft. and three 100x250 ft. One warehouse is equipped with three overhead traveling cranes and an electric conveyor along the floor extending the full length of the building. On one side of the dock are two traveling gantry cranes about 120 ft. long, with hoisting trolleys on the bridge. The inner end of the bridge extends over the warehouse roof, the alternate panels of which are removable so as to form hatchways. The outer end of the bridge projects beyond the dock line, so that freight can be handled directly between the ship's hold and the warehouse.

C. H. Spencer, Chairman; E. B. Temple, Vice-Chairman; W. G. Arn, Hadley Baldwin, W. C. Barrett, G. H. Burgess, A. E. Clift, H. T. Douglas, Jr., A. C. Everham, Geo. P. Johnson, D. B. Johnston, H. A. Lane, L. J. McIntyre, B. H. Mann, A. Montzheimer, W. L. Seddon, E. E. R. Tratman, W. L. Webb, J. G. Wishart, Committee.

Discussion on Yards and Terminals.

Mr. Fritch: I would like to know what the committee means by "holding yard" in the first conclusion under the heading "In General."

B. H. Mann (M. P.): A reservoir yard, you might say, for empty equipment in advance of placing the cut at the station platform.

Mr. Fritch: I believe "storage yard" is a preferable term.

Mr. Mann: "Storage yard" does not correctly represent the meaning of the committee. A storage yard may be a yard in which the empty equipment is placed after the receipt of the train. The wording here is intended to cover the condition where, as the equipment comes from the storage yard, it comes up to the mouth of the station, so as to have that draft, all ready to be pushed into the station just as soon as the track is empty. "Storage yard" has a broader meaning. The "holding yard" has a more limited and a narrower meaning.

Mr. Spencer: The committee wish to change conclusion 2 on page 401 of the Manual, to read as conclusion 2 in the report.

William McNab (Grand Trunk): It seems to me the recommendations would read better if we reverse the wording slightly: "It is recommended that, wherever conditions demand, baggage and express be received, delivered and handled, below or above the train floor (as grade conditions permit)," etc.

The President: The committee will accept that.

Hunter McDonald (N. C. & St. L.): There seems to be some question about the wording regarding the receiving of baggage and express. In most cases that must be done at grade and then the baggage and express is lowered or elevated to platforms. You receive it and deliver it at grade, but you lower it in order to deliver it to the trains or elevate it in order to deliver it to the trains.

Mr. Spencer: I presume in the larger number of smaller stations that may be true. In a large number of our stations, however, baggage is received below the grade. For instance, in Washington, the baggage is received below the grade and elevated to the train floors by means of elevators. In the New York Pennsylvania station the baggage is received above and is lowered. It is to meet these varying conditions and to bring out the best arrangement possible for handling baggage with the least interference with the movement of passengers that the committee made this conclusion.

C. E. Lindsay (N. Y. C. & H. R.): I move the omission of the word "safe" in conclusion 4. (The motion was seconded.)

Mr. Spencer: The committee rather objects to the omission of the word "safe." We had a great deal of discussion in the committee meeting as to entering into questions of safety, but we have taken this position; the Eastern roads, and I think it is spreading out into the West, are putting the question of safety first. I think that is illustrated by the New Year's address sent out by President Willard to the employes of the Baltimore & Ohio Railroad. The time has come when this department has got to enter into questions of safety, and I believe it is the province of every committee to enter into these questions and to recommend what appears to it to be the safe and efficient method. In regard to "No. 8 slip switch on a tangent," a great deal of the trouble experienced in curves is in switches, and it has been found by experience that the curvature through a No. 8 slip switch, although that varies on the different roads, is about the maximum of what should be used.

L. C. Fritch: I think the word "safe" is unfortunate in that connection. By adopting that we practically say that anything greater than that, or, say, a No. 7 or No. 6 slip switch, is unsafe. We have many installations in this country that have a curvature where it exceeds that of a No. 8, and to make the change would involve very large expenditures. The operation through them, if it is conducted properly, is just as safe as it is through a No. 8.

The President: Your idea is that safety can be secured by proper control of the speed?

C. E. Lindsay: A road that adopts a No. 8 turnout for its equipment may be entirely justified, whereas another road, with other equipment, may be entirely justified in using a frog as low as No. 6. We have just about completed the Grand Central Terminal, in which 6½ frogs are used. We think it is perfectly safe under the operating conditions and the equipment that we have.

S. S. Roberts (I. C.): I agree with the committee in regard to the statement of the curvature. To my mind, it is a warning against placing a slip switch on a curve. Very frequently, if you say the curvature shall not be greater than the curvature of a No. 8 slip switch, some man may thoughtlessly place a slip switch so that part of it will be on the inside of a curve, and then he increases the degree of curve in the slip. This statement conveys to me the idea that the curvature in a No. 6 switch upon a tangent is the maximum curvature that you desire to use. If this slip switch were placed on a curve some other number would have to be used in order to attain the degree of curve you would want.

The President: The committee will accept the proposition to remove the word "safe" in that paragraph.

C. Dougherty (C. N. O. & T. P.): In connection with this it seems to me the proper design of connections with slip switches in terminal stations involves so many surrounding conditions, such as the class of engines used or equipment, the speed with which trains are expected to move over the switches and the cost of providing rights of way sufficient to put in frogs of a lower number, that it makes it impossible for this association to adopt a general statement in regard to such matters.

Mr. Lindsay: On our road we have had a great many derailments of a certain type of locomotive on No. 7 slips and turnouts. The No. 7 slip is in general use, but we have had so many derailments of engines supposed to be designed for use around No. 7 slips, it came to be a question whether we would have to throw away the engines or rebuild the slips. We secured the co-operation of the motive power department and tested out those engines, and we have shown to that department the error in the design of the locomotives. They have corrected it, and made it perfectly possible for that engine, a big one, to go around those slips without any danger of derailment. I believe firmly it is perfectly desirable to limit the No. 8 where it is possible to do so, but to say it must be done is going too far.

J. L. Campbell: There may be a question as to the interpretation of the words "efficient and economical." I suppose the committee had in mind the things involved only in running the train around those curves. However, if all of the elements are taken into consideration the substitution of sharper curves in some cases cited might show that it will not be either efficient or economical to do that. I would ask the committee to modify that to read as follows: "Where practicable on station throat tracks the curvature through switches should not exceed that of a No. 8 slip on tangents."

The President: The committee will accept that.

Mr. Spencer: Mr. President, I move the adoption and insertion in the Manual of the 4 conclusions as modified. (The motion was seconded and carried.)

Conclusions under Hump Yards were next considered.

Mr. Spencer: We wish to change conclusion No. 2 from the way that it reads now to read as follows: "The cut list system of handling cars on the hump is recommended as being safe and efficient and is briefly described as follows: 'The yard clerk makes up a list of cars to be switched and tracks they are to be placed on in receiving yard, cut No. 1 being the first car to go over the hump. Cut list form accompanies this report. It is perforated on three vertical lines, so the list may be divided up into four parts, each part being a duplicate of the other. Where switches are thrown from a tower, one copy of the list is given to the towerman and one to the man cutting off cars on the hump. Where switches are thrown by hand, each switch tender has a copy of the cut list, as well as the man cutting off cars on the hump.'"

G. W. Kittredge (N. Y. C. & H. R.): I would like to ask if it is necessary to put the word "safe" in that second conclusion? It carries with it the insinuation that any other process is unsafe.

Mr. Spencer: Not necessarily so. The committee visited a number of hump yards this year. We saw several methods of marking the cars going over the hump. We did not mention the ones that we felt were decidedly unsafe. We saw men running in front of cars chalking on the ends. We saw men running along the side of the cars, taking hold of the grab iron, reaching around the ends and putting figures on the end. This cut list system is in use on the Pennsylvania Railroad. In the work of marking up the cars as done with this list there is no occasion for a man to get injured in any way in giving information to the towerman or to the switchman as to where those cars should go.

S. S. Roberts: The use or the lack of use of this cut list will have some effect on the design of the yard. If you adopt the method of marking on the ends of cars to meet the classification track on which the cars go, it necessitates a very much more complete and much more careful design on the hump than if you adopt this list, because it is necessary then, if the switch is thrown by hand, and to the towerman, if the switch is operated by power, to see the numbers on the cars by night as well as by day, so they can properly set the switches. A good many yards have had difficulty, and some roads have spent a good deal of money because they do not use a switch list. I think the word "safety" in this list is entirely proper. I have visited a number of yards, operated in different ways, and I have seen men dancing around moving cars, putting numbers on the ends of those cars. I would not consider such a job as that for five minutes, no matter what they pay for it. I think safety is entirely proper in this association. An-

other thing, about the lighting, if you have sufficient light on your hump to indicate the number of the car to the towerman or to the switchman, you have got so much light that your car riders are almost blinded, and they get off away down the yard before their eyes become accustomed to the darkness, and you are apt to have more trouble on account of the cars coming together.

Mr. Mann: Just for information, it was the thought of the committee as well that the cut list is a splendid help in O. S. & D. work. The man who handles the cut list keeps a record of the rider, and if there is any damage to the car or the freight in the car, it can be directly traceable to one individual, the rider, provided we file away the cut list. It is a splendid help in the operation of the yard in keeping down damages.

G. D. Brooke (B. & O.): I would inquire from the committee if they consider that these methods which they state were unsafe were efficient? It seems to me that the word "efficient" covers the matter of safety well enough; but a method of operation which is inherently unsafe is at the same time inefficient, and I will be very glad to see the word "safe" omitted.

The President: The committee will accept that amendment. It is also understood that the word "efficient" takes the place of "safe."

Mr. Spencer: The recommendation No. 2 now reads:

"The committee has investigated the 'cut list' system of handling cars on the hump and recommends it as being efficient, and the system is briefly described as follows:

"The yard clerk makes up a list of cars to be switched and tracks they are to be placed on in receiving yard, cut No. 1 being the first car to go over the hump. Cut list 4 accompanies this report. It is perforated on vertical lines, so that it may be divided into multiple parts, each part being a duplicate of the other. Where switches are thrown from a tower, one copy of the list is given to the towerman and one to the man cutting off cars on the hump. Where switches are thrown by hand, each switch tender has a copy of the cut list, as well as the man cutting off the cars on the hump."

The President: Unless there is objection, these two recommendations are approved.

W. I. Trench (B. & O.): I believe, in addition to giving this information to the four persons listed here, that the car rider should also have the information, and this can only be given efficiently by chalking on the ends of the first car or cut. If the car rider does not know on which track his car is going he has no means of determining just what amount of breaking should be done.

Mr. Mann: This matter is subject a good deal to the state of the weather. The yard has to be operated in a pouring rain and the design of the yard is such that the car moves at a certain speed from the top of the hump to the end of the ladder, and after it reaches the ladder it is designed, presumably, to be at such speed that the rider has the cars under control. Each track is presumably marked by a light on the first car so that the rider has all the information necessary without this, and it would be a serious handicap to hold the rider responsible for anything which you would give him on a sheet of paper, bearing in mind that he is out in a good hard rain.

Mr. Trench: I did not refer to giving the information on a sheet of paper. The method which I have seen used successfully is to mark on the first car of the cut "five cars, track 18," or some such notation as that. It is not possible for the man who is cutting off the cut to give the car rider this information, because he is on the opposite end of the cut. I believe it to be true that it is necessary for the car rider to apply the brakes because we see it done on almost every cut. If it is necessary, to avoid a collision, to apply the brakes at the first end of the track into which he is entering, he should have this information.

Mr. Spencer: There is no end to the extent to which this cut list might be carried. It is a matter of how the different roads may want to operate it. There is no objection giving the car rider one of these lists or anyone else who might have use for it. We have provided in our recommendation, as last presented, a multiple cut list which would furnish sufficient copies to extend the system as far as it is desired.

Mr. Roberts: In watching the operation in the use of the cut list, it seems to me entirely necessary to mark on the car where the cut is going to. The foreman tells the rider where to take the cars—he says, for instance, "Take five cars to track No. 4." That is all the information the rider needs, and he should have memory enough to know to what track he is going while he rides through the yard.

Mr. Spencer: I move the adoption of the conclusion as revised. (The motion was carried.)

Mr. Spencer: The last subject assigned to the committee is entitled "Development in the mechanical handling of freight by mechanical means." We present a further report on this subject for information only.

The President: The committee has presented a very complete and enlightened report that will be useful in all branches of railroad work, relating to the operation of yards and passenger stations. The committee is relieved, with the thanks of this convention.

ELECTRICITY.

CLEARANCES.

The committee submits the following report as one of progress and information. It has considered a communication calling attention to interference with the bridge clearance line of the association by the recently adopted third rail, permanent way structures and rolling equipment clearance lines, and has made a recommendation to the committee on Iron and Steel Structures that as much of the bridge clearance diagram as interferes with the third rail and permanent way structures clearance line be eliminated, and in place thereof the clearance line for permanent way structures be substituted on roads where electric equipment is likely to be used.

GEORGE W. KITTREDGE,
Chairman Committee on Electricity.

The committee on heavy electric traction of the American Electric Railway Association submitted a report at the annual meeting held at Chicago in October, 1912, which report recommended clearance lines for third rail, permanent way structures and rolling equipment identical with the lines adopted by this Association at its last meeting, and also submitted for information and guidance a suggested clearance diagram for automatic stops, with the recommendation that the matter be continued to allow the committee time to confer with similar committees of this Association and the American Railway Association. The American Railway Association at its meeting in May, 1912, adopted a clearance diagram for third rail, permanent way structures and rolling equipment identical with the diagram adopted by this Association.

The committee has been following up the progress made during the year on third rail installation and has had the table which accompanied last year's report brought up to date. It is urged on the members of this Association that they try and induce their companies to conform to the clearance diagram on all new work and gradually change over their present installation so that ultimately there can be a free interchange of electric equipment between the various roads.

The committee has been collecting data during the year in regard to overhead clearances and is studying same with a view of taking up this question during the coming year with committees of the American Electric Railway Association and the American Railway Association, so that joint recommendations for overhead clearance lines may be made by the respective committees of each Association.

Summary of Data Regarding Third Rail Location.

The committee is not prepared at this time to take up the question of clearance lines for automatic stops, but as soon as a device that is adapted to conditions obtaining on roads operated in the open has been perfected, the question of established clearance lines will be further considered.

TRANSMISSION LINES AND CROSSINGS.

The committee desires to report progress on the consideration of modifications of the specifications for overhead crossings of electric light and power lines adopted by the Association at the last convention for Transmission Lines and Crossings as will be necessary to cover voltages over 70,000 and also the consideration of the revision of the specifications in paragraphs Nos. 10, 13, 18, 24, 29, 31, 32, 34, 45, 49 51, 55, 60 and 61, which were adopted by the Association with the understanding that the revision of these particular paragraphs would be considered this year. The committee, however, is not prepared at this time to make any further recommendations for the reason that more time is required to study the development of the art in respect to voltages over 70,000, and further because of the fact that the committees of all the various engineering associations have not as yet arrived at an acceptable joint specification.

ELECTROLYSIS.

An invitation has been received from the American Electric Railway Association to unite with them in jointly considering the subject of "Electrolysis," and the chairman has appointed Messrs. Katte, Gibbs and Brumley to serve on this joint committee.

The committee submits the following report with recommendations that it be printed in the Proceedings of the Association as information.

Introduction.—The effect of electrolysis upon steel and iron structures, including water, gas and electric conduit pipes, also on the lead sheaths of insulated cables, has been a matter of serious concern ever since the first street car was operated electrically by means of a grounded return, but not until the advent of electrification on steam railroads did the subject become one of much interest to railway engineers. The matter is receiving the careful consideration of electrical engineers in conference with structural engineers and representatives of various municipal departments, but up to the present time there is no unanimity of opinion as to the best methods of preventing electrolysis, or for protecting metal structures adjacent to the path of grounded return circuits.

Nature.—Electrolysis as referred to in the Electric Railway discussions may be described as the wasting away or corrosion of a metal which is caused by an electric current passing from one metallic conductor to another conductor where both are buried in damp earth, or other semi-conducting medium.

Causes and Effect.—In direct current railway circuits the electric current passes from the power station or substation to the trolley wire or third rail, then through the motors of electric cars or locomotives and back to the station by the track rails. Owing, however, to the fact that it is practically impossible at all times to insulate the rails adjacent to the ground, part of the current leaks into the earth and finds its way back to the station through the ground, and in doing so, if pipes, cable sheaths or steel work are under or adjacent and parallel to the tracks, some of it may return by these metallic structures. At some point or points this current must leave these metallic structures and usually does through the earth in the neighborhood of the power station or substation, causing electrolytic effects in the underground structure or conductor at the points in question, unless precautions have been taken, as later indicated.

There is less opportunity for current to escape from the tracks on electrified roads where the rails are above ground and rest on wooden ties in ballast and there is no opportunity for such escape where the return circuit does not enter the running rails, but is conducted back to the power station by independent and insulated contact rails or wires. Examples of this method of construction are found in slot conduit street railways and those having double overhead trolleys; also in those using a separate insulated return conductor rail.

It is common practice to connect the negative bus-bars in the power station or substations with the running rails by copper cables at the points nearest to the stations. Leakage of current from the rails to the adjacent water pipes along the line may thus occur, and the current flowing in these pipes leaves them and returns to the rails in the neighborhood of the power station, causing electrolysis at the points where it passes from the pipes through the earth.

Prevention.—It is possible to prevent electrolysis by precluding the escape of electric current from the return conductors, but frequently this is not practically possible, as in the case of buried rails carrying return current. Several methods of meeting this latter condition have been employed, briefly described as follows:

Drainage System.—In order to prevent this escape of current into the earth, negative cables are sometimes run from the power station or substation to adjacent pipes or metal work so that the current will leave these structures through metallic paths, thus preventing electrolysis at such points. This system is successfully used in connection with continuous cable sheaths or pipe lines having screw joints, although it results in inducing a larger volume of flow by these paths. joints, as frequently, however, in water pipe lines having lead joints, as frequently electrolysis is induced at the pipe joints.

Insulated Negative System.—Another system employed is to provide insulated cables which are connected to the rails at points remote from the station. It is largely employed in

Europe and is beginning to be specified in connection with the American systems. This has the effect of maintaining a more uniform and lower negative potential and largely prevents the current from leaving the bonded rails. The objection to this system is the high cost of the insulated copper cables, which must be relatively very large and which do not carry current to their full capacity.

Booster System.—A modification of the above system devised to compel the cables to carry current to their full capacity is known as the Booster system. In this system the cables carrying return current are connected to a low potential generator of large capacity which acts like a pump placed in a pipe line of low flow head to increase the volume of flow.

Other Systems.—There are sometimes peculiar local conditions of which advantage can be taken by an electrical engineer, but usually one or the other of the above systems, or combinations of them, are employed to safeguard metallic structures adjacent to the path of the return current.

The first heavy electric traction system in New York City was installed on the Brooklyn Bridge. The power was used principally to switch trains into position to grip a propelling cable. The current demand was usually small and no serious electrolytic problem arose. When, however, the trolley cars and electrified elevated trains crossed the bridge, the situation changed. The return current leaked to the bridge structure and streamed back to Brooklyn by all metallic paths, some even returning through the water of the East River. In 1900 sixty observation stations were established and as a result the bridge structure, particularly the cables, were heavily bonded to the traction tracks at the Brooklyn end and the voltage of the structure at the danger end was reduced.

Grand Central Terminal—New York City.

General.—In the Grand Central Terminal there are thousands of columns supporting terminal yards, streets and buildings and in the midst of them there is operated an electric railway with a grounded return. It is obvious that the means for adequately protecting this immensely valuable property must be most complete. This situation was early recognized and steps were taken as follows:

(1) A substation was located in the Terminal. This was done primarily to reduce the transmission losses, but it also made possible the maintenance of the structural steel at a low potential—a most important circumstances, as will appear later.

(2) This substation was connected to the return rails by seven 2,000,000 c.m. cables, which in consequence of their short length provided a return circuit of very low resistance.

(3) Independent negative cables were connected to the terminal steel and the Post Office Building, the first of the group of buildings which will cover the terminal.

(4) A system of inspection, in the nature of an electrolytic survey, was established with regular dates for inspections and a prescribed form of report.

Such precautions were adequate during the early stages of construction, but as additional steel was erected, the ratio of the resistance of the copper to the steel was steadily falling and the protection correspondingly became less effective.

Voltmeter Method.—The early electrolysis survey consisted of taking readings of the potential between the steel structure and the adjacent tracks, pipes, etc., and noting the direction of the flow. It was realized, however, that the difference of potential method was not satisfactory. For should a potential of four volts exist between a column and an adjacent pipe, it might be assumed that the situation required immediate attention, whereas if only one-tenth of a volt existed, the condition would be regarded as entirely satisfactory. As a matter of fact, if the four volts were due to there being good insulation between the columns and the pipe with no flow of current there would be no electrolytic action, while, on the other hand, if the one-tenth volt was due to a low resistance path over which a large volume of current was flowing, electrolysis would surely be taking place. In other words, the readings indicated only the potential difference between two points of a circuit and the important factor, the amount of current flow, was unknown. Appreciation of the incompleteness of this system of readings, which, however, is the one in common use, lead to the development of a new method, briefly described as follows:

Galvanometer Method.—The problem in the Grand Central Terminal is to protect the column bases. It is accepted that when current flows upwards from a column foundation that this column is free from any possible electrolytic damage. If, however, it flows downward to the foundation, then electrolysis is possible and it becomes important to know the volume of the current. There is one other condition, when the current reverses, sometimes flowing upward and sometimes downward. With equal reversals of current electrolysis is only one-thirtieth as destructive as when persisting in one direction. Because of the large sections of the Grand Central Terminal steel and the small current flowing, it was impossible with the instruments in common use to determine either the direction of flow or the volume of current. After investigation and experimental work a special portable galvanometer was constructed that would read to three-millionth (.000003) of a volt, per division. Reading points were established five ft. apart on the columns to be surveyed, the concrete protection being pierced and the steel columns drilled, a ¼-in. pipe inserted and the terminals of the instrument attached. By this method it has been possible to obtain readings on columns having a resistance as low as two hundred and thirty-five millionths (.00000235) of an ohm between terminals and current flows as low as one ampere in such a column can be read and its direction determined. The instrument has not proven too delicate for practical use.

A complete electrolytic survey of the terminal has been made and the current flow in each column measured, its direction ascertained and the data plotted. In general, the steel was found to be in a state of balance; current flowing up some columns, down others, and reversing in many of them. Such being the case, it appears that without much change the balance can be deflected to the safe side by making the current flow up all the columns, all the time, and that condition made permanent.

Upward Drainage System.—To effectually drain the steel structure and cause all current to flow up the columns, it is first necessary to directly connect the steel deck and the upper tracks with the substation negative bus by short cables of large cross-section, and second, to remove all metallic connections between the tracks and the steel structure. In view of the enormous section of this steel and the small current it carries, the steel work may be at a slightly higher potential than the substation negative bus and all escaping current will tend to flow towards it, which is in the harmless direction. However, to make sure and to accentuate this action, especially at the column bases, it is proposed by an arrangement of circuits to raise the potential of the lower level track rails so that at all times they and the surrounding earth will be strongly positive to the columns, thus preventing any flow of current from the columns into the earth without which there can be no electrolysis.

The above described plans of reducing the potential of the structure and draining it upward to the substation is now in course of execution. The water pipes and gas pipes crossing the Grand Central Terminal are carried on wooden supports and insulated from the steel structure, and when the work is completed all such pipes and their connections will be insulated from the steel structure and the negative conductors.

Recently the bases of some of the columns were exposed for examination and although some rusting was found, there was no distinct evidence of electrolysis. These columns have been in place carrying electrified track for six years.

An experimental electrolysis investigation has been started to determine the best means of protecting future structures by various compounds and processes and to determine the amount of electrolysis per square foot of steel per year under a given flow of current when the steel is painted and enclosed in concrete in accordance with standard practice.

Pennsylvania Terminal—New York City.

This system is operated with a grounded return and no attempt has been made to insulate the negative conductors from the ground. In the return circuits both track rails are used except at interlockings. All lead-covered cables in each manhole are covered with asbestos and steel tape and the lead sheaths bonded together. The sheaths of all cables are bonded to the negative wires at each substation, in order to take the current flowing in the sheaths back over a cable and thus prevent damage by electrolysis. The sheaths almost without exception are negative to tracks and tunnel linings. There are 25 cables, including high and low tension, control and telephone cables leaving the power house, and two 5,000,000 c.m. bare negative cables connecting the negative bus in the substation with the rails at the nearest point to the power house. The lead sheaths of the above cables are equivalent to about 2,400,000 c.m. of copper. There have been only two cases of trouble caused by electrolysis of lead sheaths and they have been remedied by locally bonding them at points of outflow of current.

A number of examinations of the rails, tie-plates and screw spikes have been made at various points on the system, but no serious trouble has been found. The rails and tie-plates are found to be in good condition at all points.

There has been no trouble with water pipes, which run parallel with the tracks. The signal air pipes are carrying considerable current at times, due to insufficient cross-bond-

ing between the tracks in one of the yards. This trouble is being remedied by bonding at local points and by installing additional cross-bonding between tracks. Regular investigations are made to determine the amount of current on the steel columns and girders in the station area and almost no current has been found. No trouble has developed and there are no indications to lead one to expect any trouble.

The track bonds are tested every year and the cross-bonding is frequently inspected. Very few bad bonds are found. Provision is made at each station to find the amount of current carried on the cable sheaths. Readings of these amounts are taken frequently and when any material increase or decrease in these amounts is found the matter is looked into. By keeping the cable sheaths bonded together and negative to tracks and iron, no trouble is anticipated from electrolysis.

Baltimore & Ohio Railroad—Baltimore, Md.

Electric propulsion is in use on the Baltimore & Ohio from the vicinity of its power house just west of Camden station, Baltimore to Waverly, 3.73 miles east; 1.11 miles of this line is four-tracked, the rest being double-tracked. Within the electric territory there is a total of 1.79 miles of tunnel, the longest of which is Howard Street Tunnel, 7,340 ft. in length. The grade varies from 1 per cent. to 1½ per cent. towards the east. Two motors drawing 5,000 amperes under maximum tonnage of 2,250 tons are used on the trains up the hill, eastbound. Westbound trains drift through the tunnel, the motors returning light. The track is well constructed of 100-lb. rail on good ties and clean stone ballast. The subsoil consists of heavy clay and is in places wet. Drainage conditions are good. The track is high and dry and conditions are such as to discourage the escaping of currents as much as are usual in track circuits. In Howard Street Tunnel drainage is effected by a conduit between the tracks, the track being carried on stone ballast; this in turn on one-man stone, the latter resting on the inverted arch of the tunnel. Conditions here are generally wet. There is a heavy seepage of water through the walls of the tunnel, which in places saturates the ballast and ties, the water escaping through the ballast to the conduits between tracks.

The electric system is direct current, 750 volts, third rail contact, and return through running rails. The power is supplied at two points; the Company's power house at Camden and the substation at Mt. Royal, at which purchased power is furnished. The positive conductor consists of 100-lb. R. B. aection rail placed in 1912 in Howard Street Tunnel, and 80-lb. Mexican Central rail placed in 1901 over other parts of the line. Previous to the renewal of third rail in the tunnel in 1912, 1901 Mexican Central 80-lb. rail had been in use. The renewal was made necessary by the corroded and eaten condition of the rail, especially at wet points, where one-third of the rail section had disappeared. Previous to the renewal, the insulation and bonding had not been of the best, having greatly deteriorated since installation. The eastbound third rail is reinforced by two 1,000,000 c.m. copper cables from the power house to Huntington avenue, laying in close contact with its base. The westbound rail is not reinforced. The east and westbound third rail are cross-bound every 300 ft. in the tunnel and every 1,000 ft. over the rest of the territory. The third rail is bonded at the joints with the two 500,000 c.m. copper bonds. The negative conductor consists of the running rail, 100-lb. titanium in Howard Street tunnel and 100-lb. A. S. C. E. Bessemer on the other parts of the line. The rails are reinforced through the four-track territory and through Howard Street tunnel by a 1,000,000 c.m. copper cable. This cable is uninsulated and is covered with stone ballast laying between tracks throughout the four-track territory and on the footing course of the tunnel throughout Howard Street tunnel. It was installed in 1901, and has been much patched on account of deterioration. The running rails and negative cable are cross-bonded every 1,000 ft. The rail joints are bonded with one 500,000 c.m. copper bond. The negative bus bars at Camden power house and Mt. Royal substation are connected with the negative conductor and neither is grounded at the respective points in question.

The evidence of electrolysis observed has been the corroding and eating away of negative conductors. The running rail now in Howard Street tunnel, laid in 1910, already shows pitting at points where the ties are saturated and is eaten away slightly at the spikes. The rail removed from the tunnel in 1910 had been in the track for three years only and was so far corroded and eaten at the base that its removal was necessary. Just how much the gases of the tunnel assisted in the deterioration of the rail, we are unable to say. Outside the tunnel where the gas factor does not exist and where the drainage is good, there is still unmistakable evidence of electrolysis. The rail here was laid in 1906 and 1908. Its base is pitted and eaten away, especially in the vicinity of the spikes, where a semi-circle of metal has disappeared about each spike. The spikes themselves deteriorate rapidly, requiring renewal about once in two years, in some cases the head entirely disappearing in this time. The 1906 rail is intended for renewal next year. It appears that we are getting about twice the life out of the rail in the electric zone outside the tunnel that we are getting in the tunnel, and that the renewal in both cases is due to the action of electric currents rather than mechanical wear. Data on electrolytic action on neighboring water and gas pipes caused by escaping currents from the Baltimore & Ohio Railroad System are meager, no survey having been made. The city water works several years ago made connection between their pipes and the negative conductors at the power house in order to concentrate the discharge from their pipes, but how serious the difficulty was they were trying to remedy or the result of the connection is unknown. Two years ago, so much difficulty had been experienced in maintaining the Company's water pipes at Mt. Royal that these also were connected electrically to the negative conductor. Time enough has not yet elapsed to note the effect. A neighboring railroad has several times complained of injury to its water pipes at North avenue and various arrangements for improving the negative conductors have been resorted to, but the trouble has not yet been eliminated. A test shows Baltimore & Ohio rail four volts negative to pipes at this point, except when motors are passing, when Baltimore & Ohio rail is five volts positive to pipes. Connection will probably be made between the pipes and negative return of Baltimore & Ohio circuit. Nothing definite can be shown regarding stray currents from the Baltimore & Ohio rails until survey has been made.

RECOMMENDATIONS FOR NEXT YEAR'S WORK.

The Rules and Regulations of the National Fire Protection Association are frequently used by the National Board of Fire-Underwriters in formulating rules and instructions for the guidance of their inspectors, and since the wiring and other electrical work of the railroad companies must conform to the rules and requirements of the Underwriters' Association, it is the recommendation of this committee that a representative of the Association be delegated to serve with the National Fire Protection Association.

This committee respectfully recommends the continuation of work already outlined, particularly consideration of "Clearance for overhead third rail working conductors and automatic safety stops," "Electrolysis" and "Insulation" and the consideration of any new information that may develop in reference to "Maintenance Organization" and "Relation to track structures."

George W. Kittredge (N. Y. C. & H. R.), chairman; J. B. Austin, Jr. (L. I.), vice-chairman; D. J. Brumley (I. C.), R. D. Coombs (Cons. Engr.), A. O. Cunningham (Wabash), L. C. Fritch (C. G. W.), Geo. Gibbs (P. R. R.), G. A. Harwood (N. Y. C. & H. R.), E. B. Katte (N. Y. C. & H. R.), C. E. Lindsay (N. Y. C. & H. R.), W. S. Murray (N. Y., N. H. & H.), Frank Rhea (Cons. Engr.), J. W. Reid (C. & A.), A. F. Robinson (A. T. & S. F.), J. R. Savage (L. I.), Martin Schreiber (Public Service Rys.), W. I. Trench (B. & O.), H. U. Wallace (Cons. Engr.), committee.

Discussion on Electricity.

Mr. Kittredge: The report is one of progress and information. Under the heading "Transmission lines and crossings," we desire to have the last sentence of that section read: "Your committee, however, is not prepared at this time to make any further recommendations for the reason that more time is required to study the development of the art in respect to voltages over 70,000, and further, because of the fact that all of the various similar associations have not yet modified theirs or formally adopted ours so as to make a uniform specification. We know of no reason, however, why those that have not should not do so as opportunity for revision comes up. In other words, our specifications are not objectionable."

Under "Electrolysis," we want to substitute for the members of the joint committee appointed by the American Electric Railway Association Messrs. Townley, Richey and Palmer.

The President: If there is no objection the changes desired by the committee will be made and the report of the committee accepted. Are there any remarks? If not, the committee is relieved with the thanks of the association.

CONSERVATION OF NATURAL RESOURCES.

The Committee has under consideration the fostering of closer relations between it and the officers of the National Commission, as well as with the National Association of State Conservation Commissioners and the Western Forestry and Conservation Association, believing as it does that more officially recognized co-operation with these Asso-

ciations would be conducive to the attaining of the general objects for which Conservation Commissions were established, and more particularly those features in which the railways are vitally interested.

DOMINION OF CANADA.

Tree Planting and Reforestation.

The Forestry Branch, Department of the Interior, has taken the lead in connection with forest planting in Canada. The forest nursery at Indian Head, Sask., has been furnishing a constantly increasing amount of plant material for free distribution among the farmers of the prairie provinces. The number of trees and cuttings sent out has increased steadily from 48,000 in 1901 to 2,729,135 in 1912, with a total all told, of approximately 23,000,000. These trees are scattered in small plantations throughout the settled portions of Alberta, Saskatchewan and Manitoba, so the actual showing is much greater than the number alone would indicate.

In addition to supplying trees for distribution to farmers, the Forestry Branch is inaugurating a policy of reforestation on the Dominion Forest Reserves in the prairie provinces. Some of these reserves, entirely surrounded by large farming sections, formerly supported a good forest growth, but are now largely denuded as a result of forest fires.

WILLIAM McNAB,
Chairman Committee on Conservation of Natural Resources.

The Department of Agriculture of the Province of Ontario has, since 1904, encouraged the development of farmers' woodlots, through the distribution of trees and cuttings. The principal tree-planting activity in the Province of Quebec has been in connection with the fixation of certain areas of shifting sands in the eastern portion of the Province. About 300 acres of shifting sands at Lachute have been purchased at $1 an acre from farmers who have the privilege of buying it back within the first 15 years at a price covering the original cost, the cost of reforestation and interest at 4 per cent. The Province, however, guarantees that the cost of such repurchased lands shall not exceed $10 an acre. On the area purchased, 40,000 white pine, white spruce, elm and green ash seedlings were planted in 1912. At Berthierville there is a government forest nursery where forestry students are trained each Spring in reforestation.

The Canadian Pacific has done considerable planting along its line in the prairie sections in places where there has been trouble with drifting snow. The intention is to secure a growth of trees which shall replace the numerous snow fences along portions of the line. This company is also encouraging the planting of trees and shrubs for shelter-belt purposes by farmers who have purchased land from the company in specified sections of Southern Alberta. One-half the trees required are furnished free, and prizes are offered for the best plantations.

Prevention of Fires from Railways.

On May 22, 1912, the Board of Railway Commissioners for Canada issued an order requiring railways subject to its jurisdiction to take certain measures for the prevention of forest and grass fires along their lines. This order included in a slightly modified form provisions contained in former orders for the use and inspection of fire-protective appliances on locomotives, the construction of fireguards in the prairie provinces and the non-use of lignite coal. In addition, provision was made for the appointment of a chief fire inspector, who is given authority to prescribe special patrols to be maintained by the railway companies where such action is considered necessary. The regulation of the burning of inflammable material along the rights-of-way during the fire season is also provided for. Railway employes are required to report and extinguish railway fires, and any fires starting or burning within 300 feet of the track are presumed to have started from the railway, unless proof to the contrary is furnished.

Regulations of a similar nature have been issued by the Public Utilities Commission of the Province of Quebec, applicable to provincially chartered railways. The prevention of railway fires along provincially chartered lines in British Columbia, through the adoption of similar measures, is provided for by the new Forest Act, which became law early in 1912.

Order of the Board of Railway Commissioners for Canada, Describing Regulations to be Adopted by Railway Companies for the Prevention of Fires.

2. Until further order, every railway subject to the legislative authority of the Parliament of Canada, under construction, or being operated by steam, shall, unless exempted by a special order of the board, cause every locomotive engine used on the said railway, or portion of railway, being constructed or operated by it, to be fitted and kept fitted with netting mesh as hereinafter set forth, namely:

(a) On every engine equipped with an extension smoke-box, the mesh shall be not larger than 2½x2½ per inch of No. 10 Birmingham wire gauge, and shall be placed in the smoke-box so as to extend completely over the aperture through which the smoke ascends, the openings of the said mesh not to exceed 17-64 inch to the square.

(b) On every engine equipped with a diamond stack, the mesh shall be not more than 3x3 per inch of No. 10 Birmingham wire gauge, and shall be placed at the flare of the diamond of the stack, so as to cover the same completely, the openings of the said mesh not to exceed 13-64 inch to the square.

3. Every such railway company shall cause—

(a) The openings of the ashpans on every locomotive engine used on the railway, or portion of railway, operated or being constructed by it, to be covered, when practicable, with heavy sheet-iron dampers; and, if not practicable, with screen netting dampers 2½x2½ per inch of No. 10 Birmingham wire gauge, such dampers to be fastened either by a heavy spring or by a split cotter and pins, or by such other method as may be approved by the board.

(b) Overflow pipes from lifting injectors, or from water pipes, from injecter-delivery pipe, or from boiler, to be put into the front and back part of the ash pans and used from the first day of April to the first day of November, or during such portion of this period as the board may prescribe for wetting ashpans.

4. Every such railway company shall provide inspectors at terminal or division points where its locomotive engines are housed and repaired, and cause them, in addition to the duties to which they may be assigned by the officials of the railway companies in charge of such terminal or division points—

(a) To examine, at least once a week—
- (1) The nettings;
- (2) Dead plates;
- (3) Ash pans;
- (4) Dampers;
- (5) Slides; and
- (6) Any other fire-protective appliance or appliances used on any and all engines running into the said terminal or divisional points.

(b) To keep a record of every inspection in a book to be furnished by the railway company for the purpose, showing—
- (1) The numbers of the engines inspected;
- (2) The date and hour of day of such inspection;
- (3) The condition of the said fire-protective appliances and arrangements; and
- (4) A record of repairs made in any of the above-mentioned fire-protective appliances.

The said book to be open for inspection by the chief fire inspector or other authorized officer of the board.

(c) In case any of the said fire-protective appliances in any locomotive are found to be defective, said locomotive shall be removed from service and shall not (during said prescribed period) be returned to service, unless and until such defects are remedied.

(d) Every such railway company shall also appoint one or more special inspectors, as may be needed, whose duties shall be to make an independent examination of the fire-protective appliances on all the locomotives of such company, at least once each month, and report the condition of such fire-protective appliances direct to the chief mechanical officer of the railway company, or other chief officer held responsible for the condition of the motive power of said company.

5. Any authorized officer of the board shall have power to inspect at any time any and all locomotives, and may remove from service any locomotive which is found to be defective in the said fire-protective appliances; and any such locomotive so removed from service, shall not (during the said prescribed period) be returned to service unless and until such defects are remedied.

6. No employe of any railway company shall—

(a) Do, or in any way cause, damage to the netting on the engine smokestack or to the netting in the front end of such engine;

(b) Open the back dampers of such engine while running ahead, or the front dampers while running tender first;

(c) Or otherwise do or cause damage or injury to any of the fire-protective appliances on the said engine.

7. No such railway company shall permit fire, live coals, or ashes, to be deposited upon its tracks or right-of-way outside of the yard limits, unless they are extinguished immediately thereafter.

8. No such railway company shall burn lignite coal on its locomotive engines as fuel for transportation purposes, unless otherwise ordered by the board—lignite, coal consisting of and including all varieties of coal between peat and bituminous, with a carbon-hydrogen ratio of 11.2 or less, such ratio being based an analysis of air-dried coal.

9. Every such railway company shall establish and maintain fire-guards along the route of its railway as the chief fire inspector may prescribe. The nature, extent, establishment and maintenance of such fire-guards shall be determined as follows:

(a) The chief fire inspector shall each year prepare and submit to every such railway company a statement of the measures necessary for establishing and maintaining the routes of such railways in a condition safe from fire, so far as may be practicable.

(b) Said measures may provide for the cutting and disposal by fire, or otherwise, of all or any growth of an inflammable character, and the burning or other disposal of debris and litter on a strip of sufficient width on one or both sides of the track; the plowing or digging of land in strips of sufficient width on one or both sides of the track; and such other work as may, under the existing local conditions and at reasonable expense, tend to reduce to a minimum the occurrence and spread of fire.

(c) Said statements of the chief fire inspector shall be so arranged as to deal with and prescribe measures for each separate portion of such railway upon and adjacent to which the fire risk calls for specific treatment. The intention shall be to adjust the protective measures to the local conditions and to make the expense proportionate to the fire risk and the possible damage.

(d) Said statements of the chief fire inspector shall prescribe dates on or within which the foregoing protective measures shall be commenced and completed, and the fire-guards maintained in a clean and safe condition.

(e) No such railway company shall permit its employes, agents, or contractors to enter upon land under cultivation, to construct fire-guards, without the consent of the owner or occupant of such land.

(f) Wherever the owner or occupant of such land objects to the construction of fire-guards, on the ground that the said construction would involve unreasonable loss or damage to property, the company shall at once refer the matter to the board, giving full particulars thereof, and shall in the meantime refrain from proceeding with the work.

(g) No agent, employe, or contractor of any such railway company, shall permit gates to be left open or to cut or leave fences down whereby stock or crops may be injured, or do any other unnecessary damage to property, in the construction of fire-guards.

10. In carrying out the provisions of Section 297 of the Railway Act, which enacts that "the company shall at all times maintain and keep its right-of-way free from dead or dry grass, weeds, and other unnecessary combustible matter," no such railway company or its agents, employes, or contractors, shall, between the first day of April and the first day of November, burn or cause to be burned any ties, cuttings, debris or litter upon or near its right-of-way, except under such supervision as will prevent such fires from spreading beyond the strip being cleared. The chief fire inspector or other authorized officer of the board may require that no such burning be done along specified portions of the line of any such railway, except with the written permission or under the direction of the chief fire inspector or other authorized officer of the board.

11. The railway company shall provide and maintain a force of fire-rangers fit and sufficient for efficient patrol and fire-fighting duty during the period from the first day of April to the first day of November of each year; and the methods of such force shall be subject to the supervision and direction of the chief fire inspector or other authorized officer of the board.

12. The chief fire inspector shall, each year, prepare and submit to each and every railway company a statement of the measures such railway companies shall take for the establishment and maintenance of said specially or ganized force. Said statements, among other matters, may provide for—

(a) The number of men to be employed and the said force, their location and general duties, and the methods and frequency of the patrol;

(b) The acquisition and location of necessary equipment for transporting the said force from place to place and the acquisition and distribution of suitable fire-fighting tools; and

(c) Any other measures which are considered by him to be essential for the immediate control of fire and may be adopted at reasonable expense.

13. Whenever and while all the locomotive engines used upon any such railway, or any portion of it, burn nothing but oil as fuel, during the aforesaid prescribed period, under said conditions as the board may approve, the board will relieve the said railway of such portions of these regulations as may seem to it safe and expedient.

14. The sectionmen and other employes, agents, and contractors of every such railway company shall take measures to report and extinguish fires on or near the right-of-way, as follows:

(a) Conductors, engineers, or trainmen who discover or receive notice of the existence and location of a fire burning upon or near the right-of-way, or of a fire which threatens land adjacent to the right-of-way, shall report the same to the agent or persons in charge at the next point at which there shall be communication by telegraph or telephone, and to the first section employes passed. Notice of such fire shall also be given immediately by a system of warning whistles.

(b) It shall be the duty of the agent or person so informed to notify immediately the nearest forest officer and the nearest section employes of the railway, of the existence and location of such fire.

(c) When fire is discovered, presumably started by the railway, such sectionmen or other employes of the railway as are available shall, either independent or at the request of any authorized forest officer, proceed to the fire immediately and take action to extinguish it; provided such sectionmen or other employes are not at the time engaged in labors immediately necessary to the safety of trains.

(d) In case the sectionmen or other employes available are not a sufficient force to extinguish the fire promptly, the railway company, shall, either independently or at the request of any authorized forest officer, employ such other laborers as may be necessary to extinguish the fire; and as soon as a sufficient number of men, other than the sectionmen and regular employes are obtained, the sectionmen and other regular employes shall be allowed to resume their regular duties.

Note.—Any fire starting or burning within 300 feet of the railway track, shall be presumed to have started from the railway, unless proof to the contrary is furnished.

15. Every such railway company shall give particular instructions to its employes in relation to the foregoing regulations, and shall cause appropriate notices to be posted at all stations along its lines of railway.

16. Every such railway company allowing or permitting the violation of, or in any respect, contravening or failing to obey any of the foregoing regulations, shall, in addi-

tion to any other liability which the said company may have incurred, be subject to a penalty of one hundred dollars for every such offense.

17. If any employe or other person included in the said regulations, fails or neglects to obey the same, or any of them, he shall, in addition to any other liability which he may have incurred, be subject to a penalty of twenty-five dollars for every such offense.

Coal Resources.

As a result of an investigation by the Commission of Conservation it was found that there was in Saskatchewan, Alberta and British Columbia, a considerable waste of slack coal which had been mined and brought to the surface. This waste of unmarketable slack coal varies from 10 to 35 per cent of the output. In Saskatchewan, 10 to 25 per cent of the output from the mines is slack coal, which is dumped on the ground and wasted. In the vicinity of Estevan, 10 to 12 per cent of the output from some of the larger mines is dumped on the prairie and burned. It is necessary to remove this coal (lignite) from the mine plant, as it readily ignites by spontaneous combustion.

The waste of slack coal varies from 10 to 12 per cent in the Lethbridge district, and from 20 to 35 per cent in the Edmonton district. In the Crowsnest Pass district, in Alberta and British Columbia, the coal is of better grade and some of the slack is marketable; the remainder is made into coke in beehive coke ovens. At Bankhead, briquettes are made from the slack coal. On Vancouver Island, some of the large producing mines waste from 10 to 15 per cent of their output as slack coal, and, unfortunately, it is generally dumped into the sea. The high freight rates make it impossible to market this slack at a profit.

In order to save the community what amounts to more than 15 per cent of the total output of coal, besides the low-grade coal which is often left in the mine, it was suggested that the following studies be made:

(1) To ascertain the price of coal in different parts of the West, and which portions of the country are supplied with coal from the different mining centers, also the prices of coal in Canada and the freight rates on the same from the mines to the market.

(2) Owing to the necessity of obtaining a suitable domestic fuel and cheap power for the prairie provinces, it is desirable that investigations be carried on with a view to utilizing the lignites which underlie the greater portion of these provinces. In this connection, it is of interest to know that the United States Bureau of Mines has demonstrated that suitable briquettes can be made from low-grade lignites. The bureau has also shown that many fuels of such low-grade as to be practically valueless for steaming purposes, including slack coal, bone coal, and lignite, may be economically converted into producer gas and may thus generate sufficient power to render them of high commercial value.

Petroleum Resources.

While the actual petroleum resources of Canada are comparatively small, nevertheless, the potential resources are considerable. In New Brunswick and Nova Scotia there are enormous deposits of oil shales which are valuable as a source of oil. On an average these shales will give a higher yield of crude oil per ton than the oil shales worked so extensively in Scotland. In the vicinity of Fort McMurray and Fort McKay, on the Athabaska River, Alberta, there are enormous deposits of tar sands. The bitumen in the tar sands is the residue from evaporated petroleum. It has been estimated that there is 6½ cubic miles of solid bitumen in the tar sands exposed on this river. Although enormous quantities of oil have evaporated from this district, nevertheless it seems probable that accumulations of petroleum may exist in places where the geological structure was such as to prevent its escape. This is also exemplified by the fact that natural gas occurs in quantity in districts where the tar sands are capped by overlying measures. If large quantities of petroleum were discovered in Alberta it would be a factor of great importance to the railway interests which operate in the Rocky Mountains and Jasper Parks and the forest areas in British Columbia and Alberta.

The Canadian Pacific is now using oil-burning engines on its main line between Kamloops and Field, in British Columbia. The Grand Trunk Pacific and some of the Canadian Pacific coast steamships also burn oil, and other boats are being changed from coal-burners to oil-burners. The oil is at present obtained from the California oil fields. If supplies can be obtained at the prices now prevailing, its use will be very largely extended. Its cleanliness, the greatly decreased smoke, the decrease in the number of firemen required, the economy, particularly in intermittent service, the increased efficiency—two boilers with oil, in steamship service, giving the same steam as three with coal—and other considerations, make it an almost ideal fuel.

William McNab (G. T.), Chairman; R. H. Aishton (C. & N. W.), Moses Burpee (B. & A.), F. F. Busteed (C. P. R.), A. W. Carpenter (N. Y. C. & H. R.), C. H. Fisk (Chat. Sou.), W. A. McGonagle (D. M. & N.), G. A. Mountain (Can. Ry. Com.), W. L. Park (I. C.), G. H. Webb (M. C.), R. C. Young (L. S. & I.), committee.

Discussion on Conservation of Natural Resources.

Mr. McNab: This report on conservation may be accepted as one of progress.

L. A. Downs (I. C.): I have not been clear in my mind as to why this association fosters this committee on conservation of natural resources. We are an association of builders. Unfortunately, in this country, at the present time, conservation is getting mixed up with the differences between the "interests" and the common people. I was in Alaska this past summer, and Alaska is dead. It is dead because of the conservation policy in this country.

The Copper River and Northwestern Railroad operates 194 miles of road in Alaska. They had been burning coal in their locomotives until about a year ago, importing the coal from Canada and paying a duty on it, while the hills of Alaska are full of coal, but the laws of the United States preventing them from getting the coal out of the hills. This road is now burning oil in its locomotives because oil is cheaper than coal which they buy in Canada and pay a duty on it.

I think that God, in His Almighty wisdom, never intended, when he placed us on this continent, that we would run out of anything. While some things have become somewhat scarcer, I question whether you can recall anything which we have run out of entirely.

It seems to me if we could have a committee to prevent waste, a committee to prevent forest fires and other things, rather than a committee of conservation as holding the opinions of those great conservators in this country who seem to array the "interests" against the common people, then it would be all right.

Prof. S. N. Williams (Cornell College): Unfortunately in this country we have suffered during the past four or five years to the extent of millions of dollars by forest fires which have been caused by the railways. I know that in some cases the railways have not taken the precautions to prevent forest fires, and have not provided the means for the extinguishment of forest fires, after they have started along the lines of the railways, which they should have done. I think if you have paid any attention to the situation in this country for the last five years you will be convinced that this is one of the most important subjects which can be presented to us in the association, and still further that the matter of reforestation, which has been considered to be so important in Europe and which has been developed to a limited extent in our own country, is one of the most practical matters which can be considered.

George W. Andrews (B. & O.): The gross waste of timber in this country has been outrageous. There are probably no corporations in the world to-day that are suffering more on account of the gross waste of timber than the railroads, and many important railroad systems in this country have realized that fact, and they have gone into the planting of trees on an extensive scale, and many others are contemplating doing it.

Mr. McNab: Now, gentlemen, this question of conservation is one concerning which we must divorce from our minds the idea that it has anything to do with any one country. Whatever interests Canada in the way of conservation interests the United States. We are all really working for the conservation of the resources of the one continent.

J. L. Campbell (E. P. S. W.): I understand that primarily conservation is intended to provide for the efficient and economical use of our resources, saving those parts of our resources which we do not need for the present for future generations, and I believe we can all agree on that feature of conservation. As engineers, I believe it is our special duty to see that the resources of the country which we handle are efficiently and economically used.

R. C. Young (L. S. & I.): The railroads are interested in conservation in many ways. In the first place, a great many of our railroads are dependent more or less for their business on the products of the forest and the products of

the mines. I do not think it is our province to conserve these products to such an extent that they cannot be used, but to see to it that they are conserved to such an extent that they can be used at the right time, and the portions not used now will be conserved for use by future generations.

Prof. Williams: One of our governmental departments has recently made the statement that the annual waste of resinous products in the United States is estimated at 15,000,000 cords, and if made up into paper-making products in the shape of wood pulp would be worth $300,000,000. I think that is a sufficient commentary on the waste which is being practiced at the present time. The Chicago & North-Western, and I believe also the Pere Marquette, some time since issued a circular letter to all the agents of these railways advising them that they must be careful in the use of the stub ends of pencils, and also in the use of pens, and all the other office stationery, and giving an estimate as to the waste which was being incurred in the use of these articles.

(The report was received and the committee relieved.)

BALLAST.

The work assigned to the Ballast committee was divided between three sub-committees, as follows:

PROPER DEPTH OF BALLAST OF VARIOUS KINDS TO INSURE UNIFORM DISTRIBUTION OF LOADS ON ROADWAY.

In last year's report on this subject the committee had as a basis for its report several reliable and thorough tests,

H. E. HALE,
Chairman Committee on Ballast.

such as the tests made by the Pennsylvania railroad at Altoona and by Director Schubert, of the German Railways, and on the information obtained for these tests the committee drew its conclusions and made its recommendations to the association, which recommendations covered the subject as far as the information permitted. These recommendations were printed in the report of 1912, and adopted by the association, but the subject in a modified form was again referred to the committee.

The tests on which the committee based its conclusions have been conducted largely under artificial conditions, which were designed to be, as nearly as possible, those which actually existed in the track under regular traffic, but under the circumstances it was impossible to absolutely reproduce conditions existing in track under regular traffic.

Careful search has been made to obtain reports or results of tests on this subject, both in foreign and American engineering papers, and this search has been practically without result. It therefore appears that if further investigation or report is to be made by the committee, it must be based upon new tests, which should be made in track under regular traffic—preferably heavy traffic.

Discussion of this subject by the committee with other members of the association has led the committee to believe that many members of the association feel that a further test in track under regular traffic is desirable, and to place this before the association in tangible form, the committee has worked out the following proposed test:

Proposed Test to Determine Proper Depth of Ballast of Various Kinds to Insure Uniform Distribution of Loads.

(1) Select a stretch of track on clay roadbed, under heavy traffic, where trouble has been experienced with clay working up between the ties.

(2) Excavate the roadbed to a uniform depth of 30 in. below the bottom of the ties, for a space of two rail lengths; prepare the adjacent rail lengths in the same manner, decreasing the depth 3 in. under each successive two rails, until the bed is 12 in. below the bottom of the tie (14 rail lengths).

(3) Place on this bed a thin layer of fibrous material, such as hay, to make a well-defined separation between the roadbed and the ballast.

(4) Place stone ballast on the bed to the above-mentioned depths, tamp well, and put the track in good line and surface.

(5) Make note of tie spacing and width of ties, keep accurate levels and record of amount of time spent on surfacing various parts of track, also keep record of axle loads and amount of traffic. Take photographs at regular intervals to show deformation of roadbed.

(6) Make similar test for gravel and similar for ballast section, having a sub-ballast of gravel equal to one-half the total depth and a top ballast of stone equal to one-half the total depth of ballast.

(7) The estimated cost of this test is as follows:

(a)	Cost of material (stone), 500 yds. at 80 cents...	$ 400
(b)	Labor, preparing track and widening bank, where necessary, at $30 per rail (14 rails per test)..	420
(c)	Labor, inspecting, six inspections at $2 per rail.	170
(d)	Line and surface to be paid for by railway owning track, at regular maintenance charge.....	
	Total for one test.....	$ 990
	Three tests	$3,000

Conclusion.

The committee recommends that the above test be made under the direction and supervision of the Ballast committee, and that it be financed by the association or some railroad or railroads. The location for the test to be arranged for by the committee with a railroad that would be willing to have this test made in their main tracks under heavy, regular traffic.

CONTINUE STUDY OF PHYSICAL TESTS OF STONE FOR BALLAST.

The committee has previously recommended certain physical tests of stone for ballast, with full description of the tests and how to have same made by the United States Government at Washington. Further investigations by the committee this year have resulted in practically no additional information except a paper read at the Sixth Congress in New York of the International Society for Testing Materials by A. T. Goldbeck and F. M. Jackson, which quoted, in part, the table and data given in the American Railway Engineering Association report of 1912 and practically give the same information as given in our reports. The table showing results of physical test of stone for ballast, as presented to the association last year, has been checked, and the various railroads represented have advised that they had nothing further to add to the table. This table is considered by the committee to be a very good guide for comparing stone from various quarries when selecting it for ballast.

The further consideration of the physical tests of stone for ballast by the committee resulted in their recommending the physical tests as a guide only in the specifications for stone ballast, and it is recommended that the following note be added in the manual to the specifications for stone ballast.

Conclusion.

NOTE—"*Attention is called to the physical tests of stone for ballast printed in the manual, page 47, which are recommended as a guide, in connection with the specifications.*"

After further consideration of this subject, the committee feels that the information, as at present printed in the manual in regard to the physical tests of stone for ballast, was not clear to some of those who were not familiar with the subject, and it is recommended that the information given in the manual on this subject on page 47, under the heading of "Physical Tests of Stone for Ballast," be changed to read as follows (portion in italics is additional):

"It is recommended that the following be used for physical

tests of stone ballast. *Other things being equal, the maximum or minimum results as indicated will govern in selecting stone for ballast:*

(a) Weight per cubic foot—*Maximum.*
(b) Water absorption in pounds per cubic foot—*Minimum.*
(c) Per cent. of wear—*Minimum.*
(d) Hardness—*Maximum.*
(e) Toughness—*Maximum.*
(f) Cementing value—*Minimum.*
(g) Compression test—*Maximum.*"

SIZE OF STONE BALLAST.

The committee wishes to present to the association a copy of a report of a test made by the Pennsylvania railroad in regard to the first cost of putting in ballast and maintaining same for various sizes of stone ballast; the report is given below.

Sizes of Ballast.

Investigation conducted by the Pennsylvania company between August, 1899, and October, 1903, inclusive, record of experimental tests of three different sizes of broken stone ballast:

	Size of Stone Ballast.		
	¾ in	1½ in.	2½ in.
Double track ballast, feet.....	5,280	5,211	5,280
Double track ballast, miles.....	1.0	0.987	1.0
Stone ballast used, cars.....	228	171	198
Stone ballast used, tons.....	6,200.5	4,651.8	4,947.9
Cars stone per mile double track.	228	173	198
Tons stone per mile double track.	6,200	4,713	4,948
Linear ft. double track to 1 car..	23.1	30.5	26.7
Linear ft. double track to 1 ton..	.85	1.12	1.07
Average depth ballast under ties.	7.25 in.	6.5 in.	6.75 in.
Total first cost of ballast, freight, unloading, putting in tracks, lining and surfacing, etc.	$7,911.60	$5,633.51	$5,263.92
Average cost per ft. double track.	1.50	1.08	.997
Average cost per mile d'ble track	7,911.60	5,708.10	5,263.92
Cost ballast per ton at quarry...	60-70c	60-68c	58-69c
Average cost of maintenance for period of 51 months, per mile.	94.66	84.94	82.13

Conclusion.

After considering this information, the committee does not wish to make any change in the size of stone for ballast, as now recommended in the manual.

CONTINUE INVESTIGATION ON GRAVEL BALLAST AND RECOMMENDED METHODS OF GRADING DIFFERENT QUALITIES.

The committee has made extensive tests in regard to classification of gravel for ballast in past years. During this year Mr. Meade, chairman of the sub-committee on this subject, had a very thorough test made, which is presented herewith.

Tests made last year of river gravel gave results that indicated that gravel which was much higher in sand than called for in the manual for first-class roadbed gave first-class results, and, therefore, the committee was unwilling to approve the former recommendations, but further investigations this year show that the reason for this discrepancy was largely due to the use of improper screens and different methods of selecting the sample. The committee, therefore, wishes to incorporate in the manual a brief but complete description of the method of making the test of grading gravel for ballast, as follows:

Method of Testing Quality of Gravel for Ballast.

(1) The size of the sample to be tested should be approximately one cubic foot.

(2) Five average samples of about one cubic foot each should be selected from various parts of the pit, which is to be tested. The five samples should then be thoroughly mixed and about one cubic foot of the mixture selected for testing.

(3) To separate the gravel from the sand and dust use a No. ten (10) screen (ten meshes to the inch), made of No. 24 wire (B. & S. gage); to separate the sand from the dust use a No. fifty (50) screen (fifty meshes to the inch), made of No. 31 wire (B. & S. gage).

(4) Measure the percentage of gravel, sand and dust taken from the sample by volume, giving the percentage of each ingredient, compared to the volume of the sum of the ingredient, as follows:

$$\text{Per cent of sand} = \frac{S}{G + S + D}$$

Where S = Volume of sand.
G = Volume of gravel.
D = Volume of dust.

(5) When sample is shipped for test it should be securely packed and securely marked with name and location of the pit from which it was taken.

The above will necessitate canceling the following paragraph on page 47 in the manual: "The term percentage above is used to indicate the proportion of the original bulk."

CLEANING STONE BALLAST.

Appendix B is a copy of report on cleaning stone ballast made by W. I. Trench, division engineer, to S. A. Jordan, engineer maintenance of way of the Baltimore & Ohio, which report was forwarded to the chairman after the last ballast committee meeting and is included as information. The investigation by Division Engineer Trench and Supervisor Zepp has resulted in a very material saving in this class of work.

RECOMMENDATIONS FOR NEXT YEAR'S WORK.

The committee recommends the following subjects for investigation for the year 1913:

(1) Further investigation of the proper depth of ballast of various kinds to insure uniform distribution of loads on roadway.

(2) Revise the ballast sections, with particular reference to the use of a sub and top ballast.

(3) Investigate methods of cleaning stone ballast and obtain cost of same by various methods.

C.), William McNab (G. T.), T. C. Burpe (Intercolonial), A. S. Moore (C. C. C. & St. L.), O. H. Crittenden (I. & G. N.), J. V. Neubert (N. Y. C. & H. R.), F. T. Darrow (C. B. & Q.), S. B. Rice (R. F. & P.), J. M. Egan (I. C.), E. V. Smith (B. & O.), T. W. Fatherson (C. R. I. & P.), F. J. Stimson (G. R. & I.), H. L. Gordon (B. & O.), S. N. Williams, Cornell Colby, G. H. Harris (M. C.), Committee.

APPENDIX B.

CLEANING STONE BALLAST BY USE OF SCREENS.

By W. I. Trench,
Division Engineer, Baltimore & Ohio.

During the summer of 1912 experiments were made on the Baltimore & Ohio with screens in cleaning stone ballast, as opposed to the method of shaking out with ballast forks now generally in vogue on the railroads of this country. A screen developed by the writer and Supervisor A. G. Zepp of Baltimore is the subject of this discussion. In approaching the problem of cleaning ballast by means of screens it was recognized that the present methods involved one of the most expensive and tedious operations in railway maintenance and that for this reason the periodical cleanings are often deferred much longer than good practice would seem to demand. It was felt that if a screen could be designed which would make a proper separation of stone and dirt and at the same time dispose of these two materials in a way to avoid further handling, with a single cast of the shovel instead of the repeated sifting motion and the further shoveling of the dirt in its disposal as required by the fork, an enormous saving could be made.

It was believed that to be practicable this screen must be as cheap as was commensurate with durability, easily portable, and so related in position to the track when in use as to make its removal unnecessary on the passage of trains. Its operation must be progressive along the track and complete, working toward the dirty ballast and leaving the clean ballast behind it in such shape as to require no further handling. Its capacity must be limited only by the speed with which the laborers can handle the shovel, and it must be susceptible to use by a gang, so arranged that the work of every man is continuous and unchanging and so proportioned that no man's work is dependent on the progress made by another; that is, there should be no halts. It is believed that these results have been secured in the screen to be described and that its use, by a properly organized gang, will result in such a saving as to make the further general use of the fork method improbable.

Experiments on the Baltimore & Ohio were made on a portion of its double track line, and it was found that the most efficient gang for this condition was one of 12 men equipped with three screens. The photograph shows such a gang at work. It will be seen from this photograph that there is a screen for each berm and one for the center ditch. The construction of all three is identical, there being interchangeable legs for use on the berm and in the center ditch. The legs for use on the berm are so designed that the screen rides on the ends of the ties outside the rail at such a distance from the

track as not to interfere with traffic, and at the same time deposits the cleaned stone on the berm in final position. It stands at such an elevation that the dirt is deposited directly into a wheelbarrow standing on subgrade. The legs for use in the center ditch are designed to ride on the cleaned subgrade as the screen is slid along and are of such a height that the dirt is deposited in a handbarrow, which is placed beneath the screen, and the clean stone is left in the center ditch in final position. The upper end of the screen is carried on supports, which are readily adjustable in height to accommodate it for use in the center ditch or on the berm in either cut or fill. When in use in the center ditch the screen is laid flat upon the ground on the passage of trains and lies wholly below the top of rail.

A short description of the structural details will be made so that a better understanding will be had of the method of operation to follow. The screen frame is constructed of standard 2-in. x 3-in. x 1¼-in. angle iron set up so that the short leg turns out, the long leg forming the vertical sides of the screen. The screen proper is formed of ¼-in. rods, crimped together, giving a mesh ¾ in. x 8 in. It was found with this mesh and with the screen inclined at 45 deg. that the separation of stone and dirt was perfect even in damp weather, and this cannot always be said of the results secured from forks. These crimped rods are set in a rectangular steel frame made of 1-in. x ½-in. x ⅛-in. channel iron, and this frame is bolted inside the main frame so that the screen proper can be readily detached, as a whole, and sent to the shop for repairs. The entire screen is backed with a galvanized iron slide, which is so formed that it gathers the dirt which has come through any part of the screen and deposits it in a receptacle set beneath by means of a spout. The spout is really a hinged door suspended at its outer end by a chain and convenient fastening so that its height can be regulated, and when the receptacle is removed for emptying, can be

Ballast Screens on Double Track.

closed. With this door closed the screen will hold about one wheelbarrow load of dirt, so that the operation of the screen is not stopped while dirt is being dumped. At the top of the screen is a hood which is used in the position shown when in the center ditch, forming a deflector for the ballast thrown over the top, the method of operation in this case being to slide the screen backwards from the cleaned ballast towards the uncleaned ballast, the latter being thrown over the top and being left in clean condition at the bottom. When the screen is in use on the berm this hood is thrown back and forms the top against which the ballast is thrown when in this position. The screen constructed as indicated is practically indestructible and will support the weight of a man without impression.

A galvanized iron handbarrow for use with each screen is provided, which is so formed that it fits exactly upon the horizontal legs when in use on the berm, being so placed after a sufficient quantity of cleaned ballast has been allowed to fall outside the rail, the remainder being caught in the handbarrows and drawn across the rail to be deposited in the cribs. When in use in the center ditch the handbarrow is placed beneath to catch the dirt.

The cribs are cleaned to the bottom of the ties, the center ditch 18 in. below the top of rail and the berm 24 in. below top of rail at the end of tie and sloping to 3 ft. below top of rail at back of side ditch. Every 50 ft. one crib is cleaned to the bottom of the center ditch on one end and to the top of subgrade on the other, forming an outlet for water collected in the center ditch. This arrangement gives an absolutely dry and stable roadbed. The dirt from the ballast, or so much of it as is required, is dressed upon the subgrade outside the ballast line, and in addition to giving a neat black appearance and a pleasing contrast to the white stone ballast, serves to keep down weeds very effectually. What is not required for this purpose is used to widen the embankment along the line.

As stated above, for double track work, three screens are used. When tracks are on fills on both sides the dirt from each side screen is disposed of on its own side of the embankment, and the dirt from the center ditch is dumped directly from the handbarrow over the bank on the side most desirable. When one side is on a fill and the other side in a cut wheelbarrow loads of dirt are wheeled or carried bodily from the cut side to the fill side. When it is necessary to carry dirt across tracks care is used to keep the screen on the side from which it is carried in an advanced position, with reference to the other screens, so that the dirt will be carried over the uncleaned roadbed and not over that which has been cleaned. This is clearly illustrated in the photograph, where the side of the track towards the observer is in a cut and the other side on a fill. It will be seen that dirt carried to the fill on the other side of the tracks from the center screen passes over dirty ballast before the arrival of the screen to the right, and likewise, dirt from the screen to the left passes over the tracks before the arrival of either of the other two screens, the screens in this case traveling from right to left. When the tracks are in a cut, on both sides, wheelbarrow loads are wheeled out to the end of the cut at the nearest end, the handbarrow from the screen in the center ditch being dumped into a wheelbarrow or shoveled directly from the pan to the barrow standing across one rail. It is found that dirt can be wheeled out of a cut for a distance of 800 ft. to 1,000 ft. at less expense than would be the case if thrown upon the ground and loaded again upon a work train on a busy railroad.

The following gang organization is adhered to: For the operation of three screens, as indicated under ordinary circumstances, 12 men are sufficient; with long hauls of dirt, more men to be added for wheelbarrow work, so screen gang will be kept going. Of the 12 men two shovel from each side of berm onto their respective screens, two from the center ditch onto the center screen, and one man in the center of each track shoveling from the cribs onto the screen most available. One man with a pick advances ahead of the shovelers to loosen the hardened ballast before their arrival. These are dispensed with if ballast is loosened by means of a plow attached to the work engine. Long stretches of ballast can be loosened in this way in a short time by the work engine sufficient to keep a gang going for several days. The remaining three men are sufficient usually to handle wheelbarrows in disposal of dirt, dress dirt down on berm and fork a uniform ballast line, although if a hand laid ballast line is required, more men would be necessary. By careful handling of this gang ballast and dirt are disposed of at one operation in their final position and no further attention is necessary. In most cases it is found that the cleaning of ballast so reduces its volume that additional stone is necessary. In this case the disposition of the stone from the screens is so handled that the berms and center ditch are filled out completely, and any deficiency occurs between the rails where additional stone can be most conveniently distributed from Rodger ballast cars without further handling. The gang of 12 men cost per day: Foreman, $2.40; 11 laborers at $1.60, $19.60; total, $20.

We find that a gang equipped and organized as above will cover 165 ft. of double track per day of 10 hours, making the cost per mile of double track $640. This, of course, includes cleaning ballast, dressing ballast and disposal of dirt. Single track work would cost considerably less than half this amount, as there would be no center ditch to contend with. The ballast really handled in this test was considerably more than the cross-section would indicate, as before cleaning the ballast was plied above the rail in the center ditch and rounded high on the berm. An average of 227 wheelbarrow loads of dirt were removed per 100 ft. of double track cleaned.

For comparison with the fork method, the identical gang used above was tried with forks and advanced but 72 ft. per day. This also included the dressing complete and disposal of dirt, it being necessary to shovel the latter in wheel and handbarrows. This shows a cost per mile of double track, $1,466.

We see various figures given from time to time on the cost of cleaning ballast per mile. Some of them are very much less than the above, and we can only believe that this is occasioned by omitting to include the disposal of dirt and dressing the road complete, or on account of cleaning to a less depth in track than indicated above, or perhaps a less thorough separation of stone and dirt. In many cases a raise is given the track and the ballast is put under without cleaning. In the above test no raise was made. For the quality of work done we do not believe the figures can be much lessened. This shows a saving of 56 per cent by use of screens over forks.

This screen weighs about 325 lbs., and can be easily propelled along track by the two shovelers at work at the re-

spective screens, and with the material used in them with careful handling and pointing, they should last for years. The trial lot of three made for us with handbarrows complete by a Baltimore firm cost $45 each. We believe, if made in quantity and bid on by competitive firms, the cost would be greatly reduced.

Discussion on Ballast.

The President: This is a progress report, and is offered for information. The recommendation that funds be appropriated is a matter that will be handled by the directors, and we have reason to believe that it can be handled in some way. This report is submitted as a matter of information as to the methods of procedure that this committee proposes to follow.

John R. Leighty (M. P.): I would call attention to the very short distances over which the various depths of ballast proposed is to extend, under the heading of "Proposed Test." We all know that a bad spot in a track will grow like a bad spot anywhere else. It seems to me if you take 2 rail lengths of track under one condition and compare those 2 rail lengths with the adjacent 2 rail lengths, such a comparison will not lead to any definite information. The result of the test you get on one section of 2 rail lengths long will very materially influence the conditions that will be found on the adjacent 2 rail lengths, and it would be my suggestion in carrying out this experiment that the sections of track be made sufficiently long so as to make sure that the conditions existing on one section of track will not influence the conditions existing on an adjacent section of track, so that you will get a comparison which will really amount to something.

Mr. Hale: Concerning the investigation on gravel ballast and recommended methods of grading different qualities. Last year your committee obtained from various railroads report of the percentage of sand and dust in their ballast, and they tabulated this information and presented it to the association, but the results were so erratic that little conclusion could be drawn from it. One of the reasons for this, your committee found, was that the method of testing was not uniform; far from it. Some of the railroads weighed the ballast to determine the percentage of sand and dust, others measured it by volume and others had different methods of calculating the percentage. The committee felt it was of the first importance to have a uniform method of measuring or testing the sand in ballast, and, with that end in view, we have recommended the accompanying method, to be printed in the Manual.

C. C. Cook (B. & O.): That first "S" is confusing.

Mr. Hale: S means volume of sand.

Mr. Cook: In both cases?

Mr. Hale: In both cases.

E. A. Hadley (M. P.): I note that if this formula is adopted, it will change the wording in the Manual. Ballast is generally purchased by the cubic yard and generally the per cent. of sand in the ballast is specified; for instance, 35 per cent., which I understand to mean 35 per cent. of the original volume. It seems that in making the other formula the committee have omitted one of the component parts of the ballast, which is the voids, as without the voids the ballast will not properly serve its purpose, and should they add the voids in their formula they would still come out with 100 per cent. at the end. If the committee's suggestion is adopted it would add to the percentage of sand in the ballast, and as ordinarily accepted, it would amount to from 5 to 8 per cent., depending on the quality of the material. It seems to me in leaving out all consideration of the voids an omission has been made which should be corrected.

Mr. Hale: The committee considered that, but instead of making it 100 per cent. by the old method, or the method now printed in the Manual, by taking into consideration the voids, we simply get a percentage of voids by the old method of possibly 10 or 15 per cent., or maybe more, which is added to the percentage, and the sum therefore becomes 140 or 130 per cent., which is very unsatisfactory in practice. Your committee investigated the methods of washing gravel by several of the gravel companies and selling it by contract, and it found the method being used by the contractors similar to this method recommended by the committee. It was almost impossible to explain to a contractor when complaining to him that he had too much sand, and when the sand was added to the gravel the sum equaled over 100 per cent. The contractor refused to believe the figures. The committee is not altogether satisfied with this formula in one sense, but it is by far the best that has been suggested.

Maurice Coburn (Vandalia): I would like to ask if the committee considered the question of measuring by weight?

Mr. Hale: Your committee did consider that and the variation due to moisture was so great that they abandoned it. The C. B. & Q. and the Santa Fe made quite a number of extensive tests by weight which were not satisfactory.

E. A. Hadley: I cannot agree with the chairman of the committee that the use of the percentage of voids in the ballast would go to make 140 per cent., as the percentage of voids properly used is a minus quantity, as the sand runs into the voids in the gravel, partially filling them, the same as the dust running into the voids in the sand, if properly used, the percentage would still equal 100.

Mr. Hale: Fifth paragraph. Some of these clauses seem rather unnecessary, possibly. The committee has had so much trouble in getting samples properly tested that they found every clause here very important. I would like to make a motion that the above method of testing quality of gravel for ballast be accepted and put in the Manual. (The motion was carried.)

Mr. Hale: The carrying of this motion automatically cancels one paragraph of the Manual, on page 150: "The above will necessitate the cancelling of the following paragraph, on page 49 of the Manual."

The President: If there is no objection, this will be done.

S. B. Rice (R. F. & P.): We have operated a ballast pit on the R. F. & P. branch, known as the Richmond-Washington line. It is immediately in the center of the road; it is 57 miles in either direction. We first started to handle this ballast as pit-run material. We had good results from it. We afterwards considered that we would get better track by having a washer. It was started in November, 1908. Since that time the entire line was reballasted with washed gravel, at a cost, in track finished, of less than 58 cents. The average loading was 8½ cents, washing 11½ cents, hauling 13½ cents, placing in track 24½ cents; total 58 cents. The extreme haul was 57 miles. There were cases where the loading was as low as 6 cents. The pit varied from 6 to 22 ft. in depth. Of course the deeper the cut the slower the loading. Of course the long and short hauls made a difference, the average in 400,000 yards—these were the average figures made up after three years' work. The track that was ballasted in 1908 is in good condition to-day. Of course it shows a little dirt from trains, but we have not had any bad joints. The track is in good condition. In regard to our maintenance, for the month of December, 1912, January and February of the present year, we had an average of $19.00 per mile per month, or an average of 63 cents per day per mile. We have 24 through passenger trains over our line. We are handling the Coast line and Seaboard trains, which are very heavy. We have an average of 22 freight trains. Our tonnage is from 10,000 to 12,000 tons per day. We think we have as good track with that washed ballast as we ever could get with any stone that could be furnished.

Prof. W. K. Hatt: In the formula at the end of the report the ratio is given and not per cent.

Mr. Hale: The committee will accept that suggestion.

BUILDINGS.

The following subjects were assigned to the committee by the Board of Direction:

(1) Present principles covering the design of inbound and outbound freight houses.

(2) Report on recommended methods of heating, lighting and sanitary provisions for medium-sized stations.

(3) Complete report on roof coverings.

(4) Report on the advantages and disadvantages of various types of freight house floor construction.

Progress is reported on subject (1).

Reports on (3) and (4) are presented herewith.

No recommendations are made as to revision of the manual.

ROOFING.

The following report on roofing combines the matter presented in the reports of the two past years, with some corrections and some additions.

The Bituminous Roofing Materials.

The bituminous roofing materials are varied and complex and what accurate knowledge there is about them is largely held by the experienced manufacturers. This is gradually being disseminated and the intelligent purchaser every year is able to buy with more confidence.

The bitumen substances are organic compounds, largely composed of many different hydrocarbons, with different chemical formulæ and widely-varying melting points. They vary so and the knowledge concerning them is so limited and new that considerable confusion exists in regard to nomenclature and classification. They are always accompanied by greater or less amounts of impurities, and are obtained either

naturally or as the heavier distillates or residues of coal, petroleum or other organic substances. Their distinguishing characteristics are their elasticity and binding power or adhesiveness, their considerable immunity from action by water and their solubility in oils and certain other organic compounds.

Asphalt.—The term asphalt is ordinarily considered as referring to bitumens found naturally in the solid state and will be so used in this discussion. These are obtained all over the world with widely-varying qualities. Mention will be made of those most important commercially in this country.

The asphalts are generally stable in the atmosphere. As found naturally, they are not commercially available, even after the impurities are removed, being too hard and brittle for most purposes. This is ordinarily remedied by softening or fluxing with various oils, an operation requiring skill. The character of the fluxes has a most important effect upon the finished product. Petroleum products are ordinarily depended on for this purpose. The fluxes should be sufficiently stable to insure against too rapid hardening of the fluxed asphalt. They should be free from deleterious constituents and should be of such a character that they will combine with the asphalt to be fluxed so as to make a homogenous and perfect solution. Certain fluxes which work well with certain asphalts are not at all suitable for use with other asphalts. Tars are sometimes employed for fluxing purposes, but they do not mix easily with the asphalt. As asphaltic compounds age they

MAURICE COBURN,
Chairman Committee on Buildings.

tend to become brittle and hard, losing their elasticity and binding power. Poor fluxing hastens this process.

Commercial refined asphalts, intelligently and honestly refined, should and do run very uniform. When they are compounded, however, brand names have very little significance and less value, and should not be taken in themselves as indicative of the character or value of the compound. Some types of asphaltic compounds properly prepared and used have qualities which make them almost indispensable for some classes of roofing.

Rock Asphalt or Mastic Rock.—Sandstone saturated with bitumen is found naturally in various places in the country, principally in California. It is sometimes known as mastic rock, and is more valuable for paving and floors than for roofing or waterproofing, where it is rarely used. There is also bitumen saturated limestone, of which that found in Uvalde County, Texas, is an example.

Petroleum Residuals.—The petroleums found in the United States vary in quality according to their location.

The Pennsylvania oils are rich in the paraffines and in the lighter and more valuable illuminating oils and naphthas. Most of the California oils are practically free from paraffines and have comparatively small quantities of the illuminating oils. They are darker in color, have a greater specific gravity and have what is known as an asphaltic base. The oils found in the intermediate fields have qualities varying between the two extremes in the order named.

Eastern oils are largely made up of compounds of the paraffine series, varying in consistency from comparatively thin oil to hard scale paraffine. While most of the paraffine compounds are useless as binding materials, many of the fluid paraffines are excellent solvents for certain asphalts and are in every way suitable for use as a flux.

The heavy residue from the distillation of the California oils is a substance with many of the desirable qualities of the best asphalts. The crude oil is distilled down to the required density and a product obtained with even and valuable qualities. Very large quantities of California oil asphalt have been used throughout the United States for paving and roofing purposes. It is probably true that more asphalt roofing felt has been saturated with California oil asphalt than with any other kind of asphalt. This oil asphalt when heated becomes very liquid at comparatively low temperatures, and, for this reason, is especially suitable for saturating felt.

The heavy residuals of the Gulf, Mid-Continent and Illinois petroleums are used in large quantities as substitutes for asphalts, frequently under that name. They are ordinarily less expensive than the natural asphalts. As compared with the California residuals, they contain more paraffine, are lower in ductility and adhesiveness and, except that some of the residuals of the Texas oils are very stable, are in most ways inferior for roofing. Sometimes they are used as adulterants with better materials.

To make them more stable and less affected by heat and cold, air is blown through them while hot. This reduces their ductility and adhesiveness as well as their susceptibility to temperature changes. Their use has in the past been limited by patents, but the original ones have expired and the validity of others is now before the courts. They are not as good saturants as an untreated residual, but for the protective coating of ready roofings they have considerable value, as they are stable and are not readily affected by the heat of the sun. They are not selected for stone-surfaced roofings because of their lack of adhesiveness.

The Tars.

Coal Tar—Coal tar contains some water, various impurities and free carbon which, after the water has been removed, is ordinarily from five to 35 per cent of the total. This is carbon formed by the cracking of the hydrocarbons and is in a very finely divided condition. The percentage varies with the method of manufacture. The distillates or bitumen are composed mainly of hydrocarbons which have widely varying melting points and degrees of volatility. These may be roughly classified into light oils, creosotes and pitches. The character of the tar varies with the coal used and the manner in which the process is carried on. The tar from each plant has its individual characteristics. The greater the heat, the more the hydrocarbons are cracked into their constituents and the greater the amount of free carbon and of gas found and the less the amount of coal tar.

The question of the relation between the free carbon and coal tar is one of considerable importance. It is generally considered to be a valuable adjunct to roofing tars and pitches. Free carbon makes the material less affected by changes in temperature. Comparing two pitches of similar consistency at normal temperatures, the one having the greater amount of free carbon must have to neutralize it a greater per cent of the lighter, more elastic and to some extent more volatile hydrocarbons and less of the heavy pitches. When it is cold the pitch is less brittle and when it is hot it does not flow so readily because of the carbon present. Thus a tar of given consistency may, notwithstanding the fact that it contains large quantities of an inert material, apparently have more life than another with less of the free carbon. To determine the probable action of any tar or pitch under different temperatures its percentage of free carbon must be known as well as its melting point. The free carbon in moderate amounts does not interfere with the saturating power in felt.

When coal tar pitch is exposed to the weather there is found upon its surface a thin layer, hard and brittle, the residue after the drying out of the volatile oils. This acts as a sort of protective coating to what is underneath. As soon as it is disturbed, exposing fresh pitch, the process is repeated. High carbon tars seem to weather better than low carbon.

Water Gas Tar—In the process which it undergoes the oil residues of water gas tars are so changed by the high heat as to lose many of their characteristics and to acquire some of those of the compounds found in coal tar. Compared with coal tar, its oils have less antiseptic properties.

Water gas tar contains some free carbon, but usually not over two per cent. Its pitch is not acted upon by water. There is a very general opinion among practical roofing men that the water gas tar products are less stable than the coal tar pitches, but we cannot find that there has been any accurate proof of this. Its small percentage of free carbon materially interferes with its value as a roofing pitch. It is said that carbon can be added, but we doubt the commercial practicability of such a scheme.

Oil tar decomposes more easily than coal tar. It often contains some paraffine, though ordinarily not in sufficient quantities to affect the product as compared with coal tar. The crude water gas tar is also much more affected by water and is capable to a considerable extent of forming an emulsion with it. Good coal tar is practically unaffected by water, and it deteriorates from the surface only.

We would sum up the remarks on the bituminous materials as follows:

With skill in compounding, based on a thorough working knowledge of the materials used, asphaltic compounds can be prepared of natural asphalts and oil residuals with valuable qualities for many different roofing needs, whose durability under known conditions can be foretold with considerable accuracy. The same can be said, perhaps with more certainty as to results, of the different tars. Either can suffer from adulteration and poor preparation. Considering first-class materials the coal tar is cheaper, more easily affected by temperature changes and is not acted upon by water nor is it liable to internal changes.

In order to meet the statements concerning the difficulties in getting, at the present time uniform straight run coal tar pitch of good quality, the leading manufacturer of coal tar is making arrangements with the Underwriters' Laboratories to make factory inspection of his labeled products. Preparations for this are being made in a thorough manner and competitors, to put their products in the same class, must also arrange for the same inspection. This, together with the specifications, enlarges considerably the possibility of being sure of getting good materials for a built-up coal tar roof.

Felts.

The felts used with almost all bituminous roofings play a very essential part in the final product. The desirable qualities of the felt vary with the saturating material to be used. With asphalt saturating power is the main desideratum. For coal tar, which under heat is much more liquid, this quality is not so necessary. All must be strong enough to avoid damage in handling before saturation. The strength of the finished product is due to a great extent to the saturation.

The felts are mainly made of rag stock, which is chiefly cotton rags. Notwithstanding the statements of many manufacturers, all-wool felt is never used for roofing, because of its expense and because it would be too soft and tender to work. A certain proportion of wool rags helps to make a felt which is open and spongy with considerable saturating power. Felts for saturation by asphalt rarely contain more than 25 per cent of wool. As ordinarily used the term wool felt applies to a soft open felt with very little wool in it.

Sometimes paper stock, which is ordinarily wood pulp, though it may contain an appreciable percentage of straw, is used in small quantities if the felt is getting too soft. It has practically no saturating power, but it can add to the cheapness of the material. If used in anything over two or three per cent, it is an adulterant to cheapen the product when it is made to sell to roofing manufacturers, or to make it less absorbent, as in the case of slaters' felt or hard felt for making up into two and three ply coal tar felt.

The dry felts are sold by weight. The standard is the amount which would lay 480 sq. ft. If a felt weighs 28 lbs. to 480 sq. ft., it is known as No. 28. For this reason felts sometimes have their weight increased by the addition of a mineral filler. This is nothing more than an adulterant which interferes with the saturating power. Some specifications which require a certain weight of felt get around such adulteration by requiring that the ash in the unsaturated felt must not exceed 5 per cent.

Felts of asbestos are used in one or two roofings. These are poor saturants and are more in the nature of protection to the asphalts. They will not burn or decay. Jute woven in the form of burlap or canvas is used in some roofings to add strength. Its value is debatable. It is not a saturant like the felts and its fibers are not so thoroughly protected, making it liable on exposure to rot. Burlap decays much more readily than the average cotton felt. The main use of tar for roofing has been in the construction of built-up roofs, where layers of felt saturated with tar are nailed down and by the use of a tar pitch protected and cemented together.

The following specification accompanied by the necessary diagrams give what is considered as good practice in the construction of a flat built-up roofing on wooden sheathing.

Specification for Felt, Pitch and Gravel or Slag Roofing Over Boards.

Incline.

This specification should not be used where roof incline exceeds three in. to one ft. For steeper inclines modified specifications are required.

Roofing.

First, lay one thickness of sheathing paper, or [illegible] felt, weighing not less than five lbs. per 100 sq. ft., lapping the sheets at least one in.

Second, lay two plies of tarred felt, weighing 14 to 16 lbs. per 100 sq. ft., lapping each sheet 17 in. over the preceding one, and nail as often as is necessary to hold in place until remaining felt is laid.

Third, coat the entire surface uniformly with straight run coal tar pitch.

Fourth, lay three plies of tarred felt, lapping each sheet 22 in. over the preceding one, mopping with pitch the full 22 in. on each sheet, so that in no place shall felt touch felt. Such nailing as is necessary shall be done so that all nails will be covered by not less than two plies of felt.

Fifth, spread over the entire surface a uniform coating of pitch, into which, while hot, imbed not less than 400 lbs. of gravel, or 300 lbs. of slag, to each 100 sq. ft. The gravel, or slag, shall be from ¼ to ⅝ in. in size, dry and free from dirt.

Flashing.

Flashings shall be constructed as shown in detailed drawings.

Labels.

All felt and pitch shall bear the manufacturer's label.

Inspection.

The roof may be inspected before the gravel or slag is applied by cutting a slit not less than three ft. long at right angles to the way the felt is laid.

N. B.—To comply with the above specifications, the material necessary for each 100 sq. ft. of roof is approximately as follows: 100 sq. ft. sheathing paper, 80 to 90 lbs. tarred felt, 120 to 160 lbs. straight run coal tar pitch, 400 lbs. gravel, or 300 lbs. slag.

In estimating felt, the average weight is practically 15 lbs. per 100 sq. ft., and about ten per cent extra is required for laps.

In estimating pitch, the weather conditions and expertness of the workmen will affect the amount necessary for the moppings, and to properly bed gravel or slag. The sheathing paper or unsaturated felt is placed on the bottom next to the roof boards, mainly to keep any pitch which might penetrate the two-ply felt above it from cementing the roofing to the sheathing. It also is of value in preventing the drying out of the roof through open joints from below.

To combat severe conditions encountered like those at locomotive engine houses, an asphalt or oil-saturated felt is sometimes used instead of the dry sheet. This does not so readily deteriorate. One roofer uses for this purpose asphalt asbestos sheets.

For a concrete roof the practice is similar except that a dry sheet is not necessary, there is no nailing and the concrete is first coated with pitch. Special care should be taken in regard to flashing and to prevent the roofing from being loosened at the edges either by wind or fire. Most leaks occur around flashings and openings.

The two layers of saturated felt first laid are necessary in order to carry and give full value to the amount of pitch which must be handled in one mopping. One of the troubles with built-up roofing as ordinarily laid is the difficulty in getting thorough moppings between the felt layers.

The felts are saturated with tar about as it comes from the gashouse, with the water and other impurities removed. Oil-tar with its liquid qualities is said to be much used for this purpose. This is more permissible than it would be if the felt were to be exposed.

The coating of gravel, crushed stone or slag helps to hold the pitch in place, protects it from wear and from the action of the elements and has considerable fire retardent value. If the material be too fine, its holding power is lessened. If it be too large, the stones are more apt to roll off and to damage the roof when it is walked upon and the pitch is not properly protected. Crushed material with its rough, sharp edges has a much better holding than rounded gravel. It can be used to help get results on a steep roof.

In the final coating of a coal tar roof the effort is to get the maximum amount of pitch coating which can be kept in place. The flatter the roof the greater the amount of pitch that can be used and the better both pitch and gravel will stay where put.

Where thorough inspection is not provided during construction the roof can be inspected by cutting a strip three feet long at right angles with the way the felt is laid before the gravel is applied. This can be readily repaired so that no damage is done to the roof.

When a built-up roof is in need of repair it can frequently be kept tight for a considerable time by patching and recoat-

ing, as may be necessary, with pitch and gravel. When the original roof was well laid it can be repaired by scraping off the coating of gravel and laying a new two or three ply roof on top.

Tile or brick can be substituted for the gravel or slag where the roof is liable to have much wear and when the structure warrants the expense. The tile are sometimes grouted in Portland cement, but a bituminous cement is usually considered better. Properly built, this makes almost an ideal roof.

The built-up coal tar roofs have shown by many years' trial their value for protecting flat roofs. Instances where a life of from 20 to 30 years has been obtained are not at all rare, but poor results due to poor workmanship and poor materials are not new. The claim that at the present time the ordinary purchaser cannot be sure of getting coal tar of the quality of the best of that formerly produced would seem to have justification. At the same time, the oil tar may be no worse than the fluxes and residuals frequently used with competing materials. Pure coal tar and coal tar pitch are still made, and the dealers in roofing materials can, if they desire, furnish materials as good as any which have been sold in the past. Such materials, of course, are not the cheapest and where competition is severe the quality is liable to suffer. About all that can now be done to get the desired results is to be willing to pay the price and trust to the dealers.

The chances for poor workmanship are many and the most thorough inspection is very desirable. The moppings between the felts can be slighted, the flashings and work around gutters and openings neglected, the materials may be adulterated on the work and the quantities of pitch and gravel cut down. The cost of materials and the cost of laying for any job can be estimated within close limits and no contracts should be let which will require a slighting of the work to avoid a loss.

As an indication of what can be done in territory adjacent to Chicago and St. Louis, the following figures may be of interest. They show actual costs on a roundhouse roof of about 500 squares laid according to the specifications given above. The work was 75 miles from the gravel supply and 175 miles from the headquarters of the contractor, who paid all freight and fare. This work was done in 1910 close to a railroad track, so that nothing was necessary for hauling to the work. Nothing is included for overhead or fixed charges or for profit.

Cost per square:	
5 lbs. sheathing paper	$ .12
155 lbs. pitch at 60c per cwt.	.93
85 lbs. felt to square at $1.65 per cwt.	1.40
Nails and caps	.05
Cleats for flashing	.05
Gravel (about one-seventh of a yard)	.23
Labor, including hauling, board, railroad fare.	1.15
	$3.93

Costs have been revised to show 1912 prices for materials.

Where, for temporary buildings or other causes, a cheaper roof than the standard specifications call for is desired, a saving in the quantities of material can be made by reducing the number of piles. From this fair results can be obtained.

Built-up Asphalt Roofing.—Built-up asphalt roofs have been used with considerable success. Asphalt is much less affected by temperature changes. For a roofing cement it must have considerable proportions of flux to make it easy of application. Coal tar felts are used with asphalt roofing cements. With asphalt, the dry sheet can ordinarily be avoided. Where first-class material is used it is ordinarily expensive and it is harder to handle. Except for steeper slopes than are suitable for coal tar, its use is not recommended unless unusual conditions make it more economical.

Asphalt coatings on a concrete deck are liable to lose their adhesion to the concrete. Asphalt used on a built-up roof is liable to have a short life and the builder of built-up roofs avoids it ordinarily. General specifications for an asphalt built-up roof cannot well be prepared because of the differences in materials, and ordinarily must come from the manufacturers of the materials.

Built-up Asbestos Roofing.—There are on the market materials for a built-up asbestos and asphalt roof. The asbestos felt is not as absorbent as are rag felts and acts more as a protection to the bitumens than as a saturant.

It is claimed that asbestos felt, acting as it does more as a protection to the layers of waterproofing material and not merely as a medium for carrying them, does not have any capillary action on the oil fluxes, and that the bitumen is so protected that it retains its elasticity and waterproofing qualities much longer than with the other types of felt. If this can be sustained, asbestos felts have a superiority for asphalt roofing over the ordinary felts which may more than overbalance the increased costs. While the experience obtained from this material is not nearly as extended as that which has been had from rag felts, these roofings have been in use for about eleven years, and we have so far found nothing to disprove this claim.

As compared with a five-ply tar and gravel roof, a four-ply asbestos roof will ordinarily cost at least from one to two dollars more a square. A three-ply roof is supposed to give good results over concrete, but for wood sheathing it would seem to be approaching too closely to the conditions met with in ready roofing, for first-class work.

This roof is ordinarily applied by the manufacturer.

Prepared or Ready Composition Roofings.

To compete with it and to meet some of the conditions where a built-up roof is not satisfactory or too expensive, innumerable prepared or ready roofings have been put on the market. These ordinarily come in rolls accompanied by the nails and cement necessary to apply them. They vary from a very light felt with the cheapest possible saturant and enough sand or soapstone coating to prevent sticking in the rolls, to a sheet so heavy that it cannot be rolled, built up of heavy felts and strengthening materials and saturated and protected by carefully prepared compounds, possibly protected also by a coating of crushed stone. The durability and fire-resisting value vary to as great a degree. Ordinarily the ready roofings are cheaper than any other types, but some brands sell at prices considerably above the cost of a good built-up roof. To a certain extent the weight is designated by the ply, but there is no uniformity of practice among the different manufacturers. A two-ply roofing may mean a heavier weight than a one-ply, or it may mean two separate felts stuck together.

The saturant should be liquid enough at workable temperatures to thoroughly impregnate the felt. The protective coating should be stable and not easily affected by the elements. The saturation of the felt is a very vital feature. This must retain its life and elasticity to keep the roofing efficient. A protective coating of material similar to the saturation is often used with the idea of helping to maintain the life of the saturating material. In any event, the coating must be elastic like the saturated felt.

With a coal-tar roofing made to be rolled, it is impossible to use nearly as much material as is found necessary for a good built-up roofing, and such a roofing, even if made in the very best manner, cannot be expected to have a life comparable with that of a first-class built-up roof. Tar is not considered the best material for a high-grade ready roofing.

Some ready roofings are adjusted by the manufacturer to suit the climate at the point of application. One concern selling all over the world keeps careful records of the temperature at its different markets and makes shipments accordingly.

The prepared roofings may be divided into two general classes—smooth and stone-surfaced. The stone-surfaced roofings are to a certain extent an adaptation of the built-up roofings. They frequently have at least two felts cemented together. The gravel or slag used must be uniform in size and finer than that available for a built-up roof. The steeper the roof the more chance they have to lose their stone coating. The amount of material that can be used in the heavier brands is limited to the amount that can be successfully rolled. If the stone is too large, the stone may damage the felt in rolling; if too small, the amount of pitch is limited.

The smooth-surfaced roofings are usually coated with some finely divided material to prevent sticking in the roll. Tar is not suitable for their protective coating. The protective coating must be stable and not easily affected by changes in temperature. Blown oils are frequently used for this purpose. The smooth-surfaced roofings, as a general proposition, have less insulating and fire-resisting value than the heavier stone-surfaced materials, and with them a regular recoating or painting is frequently necessary in order to get satisfactory results. This point and the chances of getting the necessary regular attention should be considered in making selections.

Tarred felts in which there are two or three plies of felts cemented together with pitch are sold all ready to be laid, at frequent intervals to show any value at all.

They must be covered with a tar coating upon laying and

The asbestos roofings are made to include one or more plies of asbestos felt, sometimes with a jute center. They are cemented together by asphaltic cements. In the heavier brands they are as expensive as a five-ply built-up tar and gravel roof. The asbestos felts are poor saturants. These roofings give promise of good results and are widely used. The asbestos will not burn, but the amount used is so small that its insulating value is not great, and the value of these roofings from the standpoint of fire protection is probably frequently overestimated.

Burlap or jute canvas is used in ready roofings as a strengthening material. It is not a good saturant and must

be kept thoroughly coated, as otherwise it goes to pieces readily. It is employed in conjunction with either felts or asbestos sheets. We question its value, feeling that better results can be obtained from a proper quantity of ordinary felt.

The ready roofing is weak in that with the narrow lap and a large part of the roof covered with but one layer of material a single defect can cause a leak. The fact that on a flat roof water is liable to back up under the upper layer is a chance for trouble.

One of the chances for trouble with many of the ready roofings is their tendency to stretch and wrinkle and the difficulty in laying them absolutely tight and flat. As the roofing grows older and brittle, the wrinkles become danger spots which are liable to crack if walked on. The roofing should be as thoroughly stretched as possible in laying. Knot holes should be covered before applying the roofing. In cold weather it is well to warm the rolls to avoid any chance of cracking.

The ready roofings usually commence to show deterioration after they have been kept in stock for three or four months. In purchasing care should be taken to avoid stock material.

The ready roofings are of value for small and isolated buildings, where the cost of laying a built-up roof would be excessive, and for temporary structures where a roof of long life is not necessary. They can be laid without the special workmen usually considered necessary for built-up roofing, but careful workmanship and skill are necessary to get good results.

Most brands can be used on any slopes, but on a flat roof extra precautions are needed to avoid leaks, and on a steep roof some kinds do not do well. On steep roofs trouble from bagging is avoided by laying the strips vertically instead of horizontally. They can be obtained at almost any desired price, but ordinarily cheaper than a good built-up, coal-tar roof.

So many inferior roofings have been sold, so many have been poorly laid or used in the wrong places, so much has had to be learned by bitter experience, and there is such a chance for fraud, that the ready roofings are shunned altogether by many builders who want good results. But experience is being gained gradually, and they fill many needs so well that their use is bound to increase in their proper field.

Most of the ready roofings are sold under a five or ten years' guarantee, and many contracts for built-up roofs are similarly prepared. To depend upon these guarantees alone does not give satisfactory results, even though the manufacturer be financially responsible. He can expect more immediate profit by preparing a roof which he is sure will last six or seven years and selling it under a ten years' guarantee than by preparing a roof which he is sure will last for ten years.

New and untried brands are constantly being put on the market. In some of the older ones, which have gained a reputation, inferior products are substituted. Many of the best ready roofings are made of compounds whose composition is kept secret. The only way now of being fairly sure of good results is to use a brand which has been shown by long tests to meet the desired conditions and which is made by a concern with a reputation for fair dealing. The same course would seem to be desirable in the awarding of contracts for built-up roofs, though with them track can be kept of the weight of material used and the work on the roof can be inspected.

This is not a satisfactory condition, and, as indicated in the earlier part of the report, it is hoped that before many years specifications can be devised, which, coupled with the necessary tests and with efficient factory inspection, such as that the Underwriters' Laboratories is furnishing for some materials, which is explained below, will do away with the ignorance and fraud now too often met with in the bituminous roofing industry. We should then be able to buy roofing with as much certainty of quality as we can now expect in ordering steel rail. To this end our Association, working in conjunction with other organizations, should do its part.

Tile.

The term tile roofing is ordinarily considered as referring to roofing made of hard burned clay tile made with overlapping or interlocking edges.

Originally the cost of tile was more than slate, but at the present time the price of ordinary patterns is about the same as for a good quality of slate.

Besides the interlocking tile, clay shingles are made which are laid like slate and give about the same results as slate.

With tile it is a little harder to get a tight roof than with slate. Tile should not be used on a roof having a less pitch than one-quarter, and a steeper roof is preferable. With them, as with slate, the less the chance for driving snow the flatter the allowable pitch, and for this reason in the South the use of tile can be more extensive than in the North.

Where there is a chance of driving snow, it is best to make a water-tight roof of prepared roofing, preferably a thirty pound or heavier asphalt felt laid horizontally with well-lapped, cemented and nailed joints, as with slate. Sometimes the tile are imbedded in asphalt or coal tar pitch, but this method does not insure the best results. The waterproofing felt is better and cheaper.

It is usual to apply the tile directly over the asphalt roofing felt with heavy nails. They are sometimes fastened with copper wires from a pierced lug toward the lower end of the tile. The wire is fastened to battens nailed horizontally on top of vertically laid battens or laths and fastened on by wire. Copper wire not less than No. 12 gage should be used for this purpose. Steel wire or bands corrode quickly.

Sometimes the tile are laid directly on steel or wooden purlins, which must be placed to suit the lengths of the tile, with the omission of roofing boards and felt. This construction is objectionable when the building is to be heated, but is suitable where escape of heat through the roof is desired or not objectionable and where an absolutely waterproof roof is not necessary. When so laid, to prevent the entrance of dust or dry snow, the joints may be pointed on the under side after laying with elastic cement.

Some manufacturers of roofing tile make glass tile of the same pattern as the clay tile, so that they may be worked in with them and used in place of skylights. These glass tiles have been used on the roofs of train sheds, shops and factories.

Hips, valleys and combs of tile roof are formed of special designs for that purpose.

Roofing tiles weigh from 750 to 1,200 pounds per square.

It is a little harder to get a tight roof with tile than with slate. If there is any difference, the tile roof is liable to cost a little more. Tile better withstands great heat, contains more material and is so laid as to have more insulating value than slate. Properly made, it does not deteriorate through the action of the elements. It is a poor conductor of heat and cold. It is not so brittle as ordinary slate and is less liable to be damaged by settlement of the roof. Tile, with the possible variations in color and shades, can be better varied to meet the architectural requirements of the building. With the improvements in the manufacture of clay roofing tile, it would seem that its importance will be gradually increased.

Slate.

Slate comes with considerably varying qualities. It should be hard and tough and have a well-defined vein, which must not be too coarse. If too soft it will absorb moisture; if too brittle it cannot be cut and punched without splitting, and it will easily be damaged by walking on the roof. Crystals are sometimes found which disintegrate on exposure to the weather. Acid gases in the air and freezing of absorbed water tend to cause a disintegration of the slate.

The surface when freshly split should have a bright, metallic luster, be free from all loose flakes or dull surfaces, and be straight and true. Most slates contain ribbons or seams which traverse the slate in approximately parallel directions. Slates containing soft ribbons are inferior and should not be used in good work. Hard ribbons do not necessarily indicate inferior wearing quality. A clear, metallic ring when struck is an indication of soundness. A cracked slate gives a different sound, easily distinguishable. A soft slate gives a dull, muffled sound.

The color varies widely, but does not necessarily indicate the quality. Good, unfading black slate can be obtained. Some of the black slates fade rapidly on exposure to the atmosphere, assuming colors considerably varied. Various shades of green, red and gray may be purchased, some of which retain their original color very well. Some slates are marked with bands or patches of a different color, and the dark purple slates often have large spots of light green upon them. These spots do not, as a rule, affect the durability of the slate. Black ribbon slate may be obtained at less cost than strictly all black slate, and is suitable where slight variation in color is not objectionable.

Stock sizes of slate range from 7 in. x 9 in. to 14 in. x 24 in. They vary in thickness from 1/4 to 3/4 in. Three-sixteenths inch is the usual thickness for ordinary sizes. For large plain roofs the larger sizes, such as 12x16, 12x18 or 12x20, are best adapted. They break a little easier, but make fewer joints in the roof, require fewer nails and better avoid small pieces at hips and valleys. For roofs cut into small sections, the smaller sizes, 7x14 or 8x16, look better.

Slate should not be laid on a roof having less than one-quarter pitch. Where the roof is flatter than one-quarter pitch, it is liable to leak from capillary attraction. Finely

powdered snow driven under the slate by a high wind, later on melting and freezing, is liable to cause damage to a roof.

The best practice is to lay slate on wooden sheathing, tongued and grooved to an even thickness, and covered with a waterproof paper or felt to act as a bed and as an insulating medium. Tarred products should not be used, but a felt saturated with asphalt and weighing 30 lbs. or more is preferable.

Each course of slate should lap the slate in the second course below three inches, although this can be slightly cut down on the steeper roofs. In laying care should be taken to avoid cracking the slate by driving nails carelessly or too tightly.

The slates are fastened with two four-penny nails, one near each upper corner. The nails should have large, flat heads, so that they may get a good hold on the surface of the slate, and their length should be twice the thickness of the slate, plus the thickness of the sheathing. Three-penny nails are one and one-eighth and four-penny nails one and three-eighths inches long. Composition nails should ordinarily be used for railroad buildings.

Slate roofs rank well in regard to fire hazard, although they are not as good as tile on exposure to adjacent conflagrations.

Cement Roofings.

Reinforced concrete tile, several square feet in area, have been used to a considerable extent on shop buildings and freight houses with steel roof trusses. They are usually formed with projections, so that they can be placed directly on the purlins and held in place by their own weight, without additional fastenings. Wire glass can be successfully inserted in these tiles, thus avoiding expensive skylight construction. Their cost compares favorably with that of slate. The reports from them are good; but, unless the roof framing is stable and even, there would seem to be danger of leaks from driving rain and snow.

Small cement tile are in use to a limited extent and the criticism given concerning the reinforced tile also applies to them. They are less expensive than clay tile, but are more absorbent and brittle. Improved methods of manufacture and further tests may later develop their merits for some purposes, but no economy has so far been shown by their use.

Asbestos sheets made of Portland cement and asbestos under pressure give promise of good results. They can be made in different colors and have some desirable features. The different manufacturers use different methods and the results obtained must be used with caution, as it is claimed that the methods of manufacture have an important bearing on the results which may be expected.

For small buildings, or where the design is such as to make tile undesirable, they have especial advantages. Their cost is somewhat greater than good slate, but their uniformity is such that they can more successfully be laid French or diagonal method than can slate. A considerable saving can be made by laying them French method, but we do not consider this good practice with large sheets. The material is somewhat brittle, and with this method considerably greater amounts of breakage are to be expected, especially on the points.

The corrugated sheets should have value as a substitute for corrugated iron sheets. They must be laid with good fastenings and sufficient lap to insure against leakage. Some of these materials are strengthened by wire mesh and some with perforated steel sheets, giving a product grading toward the metal protected by asphalt and asbestos.

Shingles.

A wood shingle roof, properly laid and of good material, will last many years. The old clear white pine shingles, formerly obtainable, were superior to anything now on the market, but red cedar shingles of good quality can be obtained from the Pacific Coast. In the South red cypress from the Gulf States is preferable.

The main objection to a shingle roof is its fire hazard. When the roof is old, especially in a dry climate, shingles crack and get out of shape, providing a place for the lodgement of sparks and materially increasing the danger from fire hazard.

There should be two, and only two, nails for each shingle. If more are used the shingles will crack. They should not be laid too close together when dry, or they will tend to buckle when wet.

Metallic Roofings.

Metallic roofing may be laid in large sheets sometimes without any sheathing. These sheets are often strengthened by corrugating them. They are sometimes cut up into small sheets and laid as are shingles. Sometimes they are bent into [illegible] like clay tiles. The first cost of these [illegible] of copper, is much less than that of clay [illegible] and they do not require as heavy roof framing.

They are also soldered together on the roof into a single structure, of which the ordinary tin roof is typical. Copper, lead, Monel metal and tin are used this way. This type is especially valuable for flat roofs.

Iron or Steel.

Iron and steel are largely used as a basis for metallic roofings because of their strength and cheapness. Their corrosion, especially for railroad buildings, is the most important factor in connection with their use as roofing materials.

This question of the corrosion of iron and steel is a live one, but the following conclusions seem to be accepted by the best authorities:

The rate of corrosion depends much less upon the amount of impurities present than upon their distribution in the metal. Segregation, strain, or anything which causes differences in electric potential, hastens corrosion. Mill scale is a very important factor, causing pitting. The better results often obtained from wrought iron as compared with steel are due mainly to the greater homogeneity of the iron. Good wrought iron is not appreciably better than good homogeneous steel.

There are some elements like sulphur which, when present in steel, tend to hasten corrosion and some, like copper, nickel and silicon, tend to retard it. An absolutely pure iron in use on a building would not show results appreciably different from a high-grade steel, and with mill scale or internal strain might do much worse. Accelerated acid tests are not a fair index of the value of metals for roofing purposes. Part of the dissatisfaction with steel in recent years is due to the thin sections used. Cast iron is protected by a silicious skin formed from contact with the mold at the time of casting and it is used in thick sections.

Where two sheets of different manufacture come together on a roof galvanic action and corrosion are liable.

Iron or steel may be used unprotected except by paint. This, of course, requires regular attention and unless access can be had to all the exposed metal satisfactory results cannot be had. Galvanizing, or coating with zinc, if properly done, gives excellent results.

One method employed in the preparation of steel for roofing purposes is to pickle the steel in acid baths to cleanse the sheets of scale and dirt. Unless this process is most carefully followed by thorough cleansing, minute particles of acid remain to form within the plate itself an agent for its final destruction. This may occur either with tin plate or galvanized iron.

Asbestos-protected metal is sheet steel covered with a coating of bitumen and asbestos. It has not been long enough in general use to show just what place it should hold. Commercial tin or terne plate is iron or steel coated with an alloy of lead and tin. About 75 per cent. of lead is a common percentage.

Tin Plate.

When tin is specified, the coating should consist of not less than 30 per cent. pure tin nor more than 70 per cent. pure lead. Not less than 20 lbs. of the coating should be used per box of 112 sheets 14 in. by 20 in. A great deal of very poor coating has been put on the market by the manufacturers of tin roofing material. Good tin plate for roofing can be had, and where it is desired to use this material for roof covering, one of the reliable brands of hand-dipped plate, not less than IX or No. 28 gage, should be selected. Rolled tin plate should not be used for roofing, guttering or valleys.

Tin roofing must be painted with a good paint to preserve it. Tin roofings can be shown which have laster 20 or 30 years on railroad structures, but the danger of securing poor material and the cost of maintenance have made conservative builders very cautious in its use. It has the great advantage of being available for all slopes and it is adaptable to special and difficult conditions.

Gutters.

Gutters for many classes of railway buildings may and should be omitted. This is more particularly true of buildings with steep roofs near tracks, where cinders from passing locomotives roll down the roof into the gutters and in time, unless more care is taken to keep them clean than is usual in railway buildings, the downspouts become choked and fail to carry off the water.

Gutters may be of metal, wood, or be formed in roof of the materials used in the construction of the roof, the latter being ordinarily preferable where the design of the building permits.

Flashing.

A large part of the trouble with roofing comes from leaks due to poor flashing around the edges, at gutters, parapet walls and openings. Provision must be made for expansion

and contraction, due to heat and cold, to loading and settlement and to shrinkage. It must be used far enough back to prevent any possible backing up of water. It is advisable to use as little metal as possible. Special care must be used in working up against parapet walls, as with two kinds of material this is difficult, special terra cotta block to insert in the parapet wall and give a point of application for the roofing material is on the market. It is valuable and would be more used were it not for the trouble in getting this special material on the ground unbroken and in getting it properly set in the wall. On a composition roofing the edges should be cut off to a straight line and project over above the gutter. For a built-up roof a metal gravel stop is desirable. Where no other metal work is used, a wood strip is used. For concrete the edge of the roof should be provided with a wooden nailing strip fastened by a bolt inserted into the concrete.

Conclusions.

The committee recommends the substitution for the last conclusion in the manual under roofing (reading as follows: "Steel or impure iron materials should be avoided, no matter how protected") of the following:

The various metallic roofings have an important place among the roofing materials. Care must be taken to have them properly used and protected.

In using iron or steel for roofing purposes every effort should be made to get a metal of best quality.

The roofings using Portland cement, either with re-enforced concrete or with asbestos, have value under the proper conditions.

FREIGHT HOUSE FLOORS.

Freight house floors should ordinarily be built to carry a uniformly distributed load of at least 250 lbs. per sq. ft. They should be of materials which will not in any way damage any articles placed upon them, which will provide a surface smooth and durable, and be so constructed that they can be easily repaired. Except for small houses, a filled-in floor, considering the cost of maintenance, is ordinarily cheaper than joist construction. It is also advantageous, because it will carry the unusually heavy loads that sometimes occur.

The usual method of construction consists of filling up to the required level with sand or gravel, thoroughly flushed and compacted. To insure a dry floor, a bed of cinders about six inches thick, thoroughly compacted, on this filling is laid. In the cinders are bedded sleepers, preferably about 4 in. x 6 in., laid flat, about two ft. six in. centers. These and the plank above them should be thoroughly treated with creosote or zinc chloride, where there is to be an additional wearing surface applied. With untreated timber renewal is sometimes necessary within four years, though under favorable conditions a life considerably greater is usually obtained. When no cinders are used on top of the sand the decay seems to be hastened.

In place of cinder filling and sleepers a layer of coal tar pitch spread upon a layer of sand over a course of concrete is being quite extensively used. This is durable and is said to give good results. Specifications for this method are obtainable from the coal tar producers. Either on the sleepers, laid in cinders, or on the pitch are laid planks about two inches thick. With the pitch sub-floor the plank should be laid with broken joints, toe nailed, and imbedded in the pitch by hammering until the proper stability is obtained. Care should be taken to see that they are brought to an exact grade. The plank need not necessarily be toe-nailed with the wooden sleepers.

To get a smooth-wearing surface on top of the plank, hard maple is generally preferable. It does not splinter and it wears evenly. It has a short life when exposed to the weather. It is growing scarce and getting expensive. Beech is often sold for maple, they being difficult to distinguish. It is somewhat darker in color and it splinters more. Birch is softer than beech or hard maple, but does not splinter so readily as beech.

Gum, especially tupelo, is recommended as a substitute for maple and it probably will, to some extent, displace it. It is darker in color and somewhat softer, but it wears evenly and it does not splinter much more than maple. Thorough seasoning is particularly essential. There is a large supply of gum in the South and its use for floors should be extensive.

Under most conditions, the best floor can be had by laying the top floor diagonally, putting the plank lengthwise and the sleepers crosswise of the house, without any bearing on the side walls. Inequalities in settlement of the floor are then less liable to make trouble, the plank can be laid with minimum expense, and the top floor gives the best results after considerable wear. This costs for the top slightly more for laying and more for repairs. Where there is a pronounced amount of trucking in one route, it is sometimes thought desirable to put the flooring parallel to this trucking, but where the amount of traffic warrants it would seem best to put a runway of steel plates.

Wood block pavements may be used in place of the board floor. They are best used on top of a concrete sub-floor, with a one-in. sand cushion between. With wood blocks care should be taken to obtain sufficient expansion joints, as many floors have failed from a lack of this precaution. One in. for 50 ft. is about the correct amount. Care should also be taken to avoid the use of creosoted blocks where flour or similar articles which are easily damaged by odors are handled. There is also a chance of such damage from tar used in the expansion joints. Zinc chloride is for this reason recommended as a preservative for wood blocks when used for freight house floors. Zinc chloride is cheaper than creosote, and in a freight house the blocks will not suffer from the leaching which takes place when they are exposed to the weather, the main objection to the use of zinc chloride for treatment of crossties and paving blocks. It is almost impossible to get this kind of floor as smooth as a maple floor, but if properly laid it tends to wear smooth. It is adapted to points where wear is especially severe, such as are due to the handling of castings and heavy machinery. Its main advantages are in the ease with which it can be repaired. The blocks are ordinarily made of pine. It would seem that gum blocks would be better. Maple blocks are also used, but are expensive.

Concrete has been used successfully where the wear is not too severe. There is chance of damage by falling freight, and its use must be restricted to places where there is little chance of castings and similar articles being handled, unless the top surface is carefully made of the best of hard aggregates. Under such conditions excellent results have been obtained.

A concrete sub-floor protected by a layer of asphalt mastic will give excellent results. It will cost more than the concrete floor, but it will not chip and scars made in its surface soon disappear. It is not so cold as the concrete floor and has been used for this purpose with success. Asphalt blocks properly made would seem to have some advantage for this purpose. They should make a smoother floor than the wood blocks and be easier repaired than the mastic floor.

Maurice Coburn, Vandalia, chairman; M. A. Long (B. & O.), vice-chairman; G. W. Andrews (B. & O.), J. B. Canty (B. & M.), O. P. Chamberlain (C. & I. W.), D. R. Collin (N. Y. C. & H. R.), C. G. Delo (C. G. W.), W. T. Dorrance (Me. Cent.), C. H. Fake (M. R. & B. T.), C. F. W. Felt (A. T. & S. F.), W. H. Finley (C. & N. W.), G. H. Gilbert (Q. & C.), A. T. Hawk (C. R. I. & P.), H. A. Lloyd (Erie), L. G. Morphy (B. & A.), C. W. Richey (P. R. R.), W. S. Thompson (P. R. R.), committee.

Discussion on Buildings.

Mr. Coburn: We would like first to consider the report on freight house floors. In going over this report and attempting to make conclusions for the Manual, it was decided that we would ask that this entire report on freight house floors be printed in the Manual.

Mr. Lindsay: I would like to call attention to the first paragraph, and to the new development that has given rise to some question in our minds as to the permissible load per square foot, and that is the use of electric trucks in freight houses, transfer stations and so forth, and the heavy loads that will result therefrom. We have a new freight house that was designed for 250 lbs. loading per square foot, and since then we have adopted the electric truck, with very heavy loads. I do not advocate increasing that at all, but I call your attention to the fact that it is coming and we must prepare for it.

Mr. Coburn: The committee will be pleased to insert in this report a paragraph stating that where there is any possibility of using this, that matter should be considered. It seems to me that should be a part of this report.

(The report on freight house floors was accepted.)

The President: The report on roofing was adopted, with the understanding that the committee will co-operate with the Committee on Publications and the proper material will be put in the Manual. The conclusions were also adopted for publication in the Manual.

WATER SERVICE.

The Board of Directors assigned the following subjects to the committee:

(1) Report on the design and relative economy of track pans from an operating standpoint.

(2) Report on the design of water stations using deep well pumps as source of supply.

(3) Report on recent developments in pumping machinery.

THE DESIGN AND RELATIVE ECONOMY OF TRACK PANS FROM AN OPERATING STANDPOINT.

The committee asks for further time in which to make a final report on this subject.

DESIGN OF WATER STATIONS USING DEEP WELL PUMPS AS SOURCE OF SUPPLY.

The committee felt that a study of deep well pumps would cover the vital subject in the design of deep well pumping stations and submits a report which outlines the various types of deep well pumps and the conditions favorable to their use. The committee believes that most of the members are familiar with the ordinary single-stroke steam deep well pumps, but are not acquainted with other types and with conditions essential to satisfactory operation. It was desired to submit data on efficiency, but this was found lacking. It may be possible that tests and further report can be made later. The report will serve, however, to inform the Association in a general way and probably to insure against improper installations, and it is hereinafter submitted as information.

REPORT ON RECENT DEVELOPMENTS IN PUMPING MACHINERY.

Report progress. The subjects under consideration are: internal combustion engines, centrifugal pumps and turbines

ROBERT FERRIDAY,
Chairman Committee on Water Service.

and the use of electric power for water stations. The latter subject is thought timely in view of the availability of that power which is rapidly spreading through the construction of interurban roads paralleling steam roads.

WATER TREATMENT.

Report progress. A study is being made of water softeners from an operating standpoint.

Deep Well Pumps.

In this report a deep well is assumed to be a well usually of small diameter, in which the water does not stand within economical suction limits of the ordinary surface pump, or one in which the drop or draft with the desired yield brings the surface of the well water beyond an economical reach. This condition makes necessary the separation of the water end and the power end of the ordinary pump, the former being depressed into the well either to a point of submergence or within easy suction reach of the water during all its stages and the latter being placed on the surface of the ground within easy access of the boiler or other source of power. This arrangement has given rise to various devices known as "Deep well pumps."

Deep well pumps are of many varieties, but without attempting to include the many special devices for lifting deep ground water, those generally used with success in railway practice can be classified under the following heads: reciprocating, displacement or plunger pumps; centrifugal pumps, propeller pumps, air lifts and air displacement pumps.

Reciprocating, Displacement or Plunger Pumps.

The old-fashioned domestic, or yard pump, is of the first class. In this type the working barrel or cylinder is depressed in the well, either to a point of submergence, or within easy suction reach of the water, and the piston is connected with a power head located on the surface of the ground by means of a set of jointed rods of convenient length. The source of power may be either steam applied directly to the upper end of the rod as in a direct acting steam head, or a geared or belted power working head may be used.

This type of pump may have either a single-acting working barrel, in which water is discharged on the upstroke only of the piston; or double-acting, in which there are two pistons, one above the other in the same cylinder, operated by separate rods, working in opposite directions. One of the rods is a pipe and the other an inside solid rod. The inside rod is connected to the lower piston and the hollow rod to the upper. There is also on the market a double-acting type of displacement plunger pump having a single rod and a system of valves in the barrel so designed that water is discharged on both the upstroke and the downstroke of the plunger.

Of the double-acting pumps operated by double rods there are two types. In the first, the two plungers come to rest at the same time, one at the upper and the other at the lower end of the stroke, which results in an intermittent flow. The other type, called "constant flow" or "non-pulsating" pumps, are operated on the same principle as the quick-return mechanism used on shop machinery. About 53 per cent of the revolution of each plunger is spent in the upstroke and about 47 per cent on the downstroke. The plungers therefore come up more slowly than they go down, with the result that the first plunger has completed its downstroke and has picked up the load before the other plunger has come to rest at the end of the upstroke. In other words, one plunger is always lifting, and the column of water which does not come to rest as in the ordinary type of plunger has a constant and practically uniform flow.

Centrifugal Pumps.

There has recently come into use a vertical shaft, high speed, centrifugal pump of a diameter small enough to be lowered into a well of small bore to a point of submergence or within suction reach of the water in the well. The pump can be operated by a direct connected electric motor, steam turbine or with a belt drive having a quarter twist. The last arrangement will be found less desirable than the other two, as it is rather cumbersome for a permanent railway installation. Either single stage centrifugals, or multiple stage, where the lift makes it necessary, are suitable for the purpose. They are usually made for pumping water from wells whose diameter to the water level is twelve inches or larger, and a flexible connection between the motor and vertical shaft is generally used.

Propeller Pumps.

In this device, which is a modification of the old screw-pump, the power head is attached directly to the well casing and carries a vertical shaft that extends to a point of submergence in the well, both before and during the pumping. Propellers are placed on the shaft at regular intervals of about five feet. One propeller at least must be always submerged. Each propeller is usually provided with a stationary surrounding shield that protects the well casing against injury from the rapidly revolving propeller and also serves to center the shafting. The shields are usually riveted to several flat vertical spacing bars which form a caging to enclose the shaft and propellers.

Either a direct-connected vertical motor with a flexible coupling is attached to the power head or a yoke is provided to receive a pulley attached directly to the shafting. In the latter case, the pump is operated by a quarter-twist belt from a steam engine or other source of power.

This pump was first designed to discharge the water at the surface of the ground only, but there has recently been developed a combined turbine and propeller pump that will discharge against pressure, or, in other words, lift water above the level of the power head. The turbine is placed in alignment with the power head and propeller sections and the whole forms a concentric unit that will discharge water to the desired height above the pump head.

Air Lifts.

Opinions as to the true theory of the air lift differ widely, but it is generally accepted that its principle is that of a column of intermingled air and water in a vertical discharge pipe being lighter than the outside column of ground water, giving rise to a lack of equilibrium in the well, and resulting in the mixed air and water rising in the discharge pipe

and overflowing at the top. The air lift consists essentially of a discharge pipe, of which the well casing may or may not form a part, and an air pipe which leads the compressed air into the bottom of the discharge pipe. Many forms of nozzles for the end of the air pipe are in use, but experience has shown that an open air pipe pointing downward is fully as efficient as any other form. The air pipe may be inside or outside the discharge pipe and the pressure of the air need only be slightly in excess of the pressure resulting from the static head of the water at the point of air admission. The distance from the water surface in the well to the point in the discharge pipe at which the air is admitted is called the submergence. Experience has shown that for unexplained reasons best results are obtained when the submergence, while pumping, is about 60 per cent. of the total distance between the point of air admission and the point of water discharge at the top. With greater or less submergence the efficiency of the air lift has been shown experimentally to rapidly decrease.

The diameter of the air and discharge pipes must be properly related to the quantity of water to be delivered in order to avoid undue resistance and loss of efficiency. A discharge pipe with a sectional area so large that the velocity of the water exclusive of the entrained air falls below four feet seems to permit the air to escape through the water with great loss of efficiency, while a discharge pipe of so limited area that velocities over six feet are attained also causes decreased efficiency, probably due, at least in part, to friction resistances. Experiments conducted in San Francisco in 1890 indicate that the highest efficiency is obtained when the velocity in the discharge pipe is about 4 to 6 ft. for the net volume of water discharged, not including the mass of intermingled air.

In Turneaure & Russell's "Public Water Supplies," the formula given as "commonly used for determining the relation of the various factors in an air lift problem" is—

$$q = \frac{125\ A}{h}$$

in which q = gallons of water per minute.
A = cu. feet of free air per minute.
h = height of lift in feet from water surface to point of discharge.

Air Displacement Pumps.

In this device for raising ground water, the air acts as a piston upon the upper surface of the water in a discharge chamber, depressing it to a given level and discharging it through an eduction pipe to the desired point. In wells of small bore the discharge chamber consists of a vertical pipe or barrel to which is connected the air pipe at the upper end and the discharge pipe at the lower end. The discharge chamber fills either by gravity or by suction. The air is admitted by a reversing valve that is actuated either by trip valves located in the discharge chamber, which in turn are operated by floats when the water has reached a predetermined level; or by the increase and decrease of pressure in the air line due to the rise and depression of the water surface in the discharge chamber.

In some types the air is exhausted into the atmosphere, while in others it is led back to the suction of the compressor under gradually diminishing pressure. The water flows into the discharge chamber by gravity as the air is displaced, and if the compressor forms a partial vacuum the discharge chamber will be filled by suction to a level above that of the water in the well.

In wells of large bore, two discharge chambers are sometimes placed side by side, from which the discharge takes place alternately with a practically constant flow. The same result is accomplished by connecting two or more wells with the same delivery pipe and the same reversing valve which admits air into the several discharge chambers alternately.

Conditions Governing Selection of Type and Efficiency.

It is beyond question that all the devices for raising deep ground water described have their particular field of usefulness. The intermittent flow plunger pumps undoubtedly have a low efficiency. In both the single and double-acting types the column of water in the vertical discharge pipe comes to rest at the end of each stroke. The shock of overcoming the inertia of the column of water at the beginning of every stroke is necessarily violent and leads to great loss of power. The speed is limited to about 100 ft. of piston travel per minute to prevent undue injury to the mechanism, and this limits the yield of the well to the actual displacement capacity of the pump at this speed. In the "constant flow" or "non-pulsating" type, much higher speeds are practicable and the loss of efficiency due to the violent shock of stopping and starting the column of water is largely overcome.

Where the desired output is small and the lift is relatively low, the reciprocating pump undoubtedly has a wide field of usefulness. The first cost of installation is relatively small and the interest and depreciation charges are therefore correspondingly low. At water stations having a small output the fuel consumption, which is the factor most influenced by low efficiency, is a small part of the total cost of operation; the greater part of the operating cost usually represents the attendance and the interest and depreciation charges. However, this pump is simple and reliable and is giving good results where the yield per well or the desired quantity is small. The output can be increased approximately 100 per cent. by the use of the double-acting type as compared with the single-acting, with some increase in first cost. High efficiencies are shown by the "non-pulsating" type and an increased yield is obtained on account of the higher practicable speeds. A test made by the Engineering Experiment Station at the University of Illinois with a motor-driven pump of the "non-pulsating" type showed an overall efficiency for motor and pump of 47.7 to 49.2 per cent. Subsequent experiments indicated that the efficiency of the motor was about 70 per cent. and the pump efficiency was therefore also about 70 per cent., which is unusually high.

The reciprocating plunger pump does not lend itself well for operating scattered wells unless electric power is available. The maintenance of separate steam plants is impracticable, and where the character of the water-bearing formation requires a wide spacing of wells for good results, the loss in steam transmission is necessarily large. Such wells, however, may be located in a straight line and be operated from a single shaft, or may be located at random and operated by the device familiar in oil-producing territory, a description of such plant for a water station being given in the 1911 proceedings.

Where the yield per well is large and large quantities are desired at a constant rate, pumps of the centrifugal and propeller types offer particular advantages. Units of this type are simple and compact, and their output is perhaps larger than that of any other device for raising deep ground water except the air lift. Relatively high efficiencies result where the type and design selected are made to fit the quantity of discharge, lift and other conditions of service. Where electricity is available scattered pumps of this type can be operated by individual motors at a minimum expense for supervision. This pump also possesses the particular advantage of successfully handling waters that contain considerable sand, which in the reciprocating pump will soon destroy the wearing parts of the working barrel, but its use in wells that are not straight is not successful on account of the necessary bending and distortion of the shaft with every revolution. The maximum practical length of vertical shaft does not usually exceed 200 feet.

Air Lift and Air Displacement Pumps.

The air lift is not an efficient device, but it is capable of raising a larger amount of water from a small hole than any other deep well pumping method. The comparatively poor method of power application and many energy transformations can only result in limited efficiencies. However, it lends itself very well to serve scattered wells from one central power station, provided the spacing of wells is not so large as to result in excessive cost for piping the air supply. Its principal objections are the low efficiency and the disadvantage of providing the necessary submergence for best results, which under certain conditions is impracticable. The efficiency falls off so rapidly with a submergence decreasing below 60 per cent. that any wide departure from this submergence renders the loss of energy practically prohibitive. In the air displacement pump a fixed submergence for good results is not required, as it is only necessary to have the discharge chamber sufficiently submerged to insure its filling by gravity or by suction.

The air lift offers particular advantages in handling wells that contain considerable sand, as there are no valves to be affected, also in operating wells that are so crooked that the ordinary pump rod or vertical shaft cannot be used and in holes of too small bore for other methods, but unless the wells are located in the immediate vicinity of the tank, a second pump is necessary to elevate the water into the tank, as the air lift will not convey water horizontally, which, however, is true only of the air lift and not the air displacement pump.

Robert Ferriday (C. C. C. & St. L.), chairman; J. L. Campbell (E. P. & S. W.), vice-chairman; H. M. Church (B. & O.), C. C. Cook (B. & O.), G. M. Davidson (C. & N. W.), A. F. Dorley (M. P.), E. G. Lane (B. & O.), Curtiss Millard (C. G. W.), A. Mordecai (Cons. Engr.), W. A. Parker (S. J. & G. I.), Chas. E. Thomas (I. C.), committee.

The report was received without discussion and the committee relieved.

GRADING OF LUMBER.

One of the aims of the committee was to secure the actual adoption of the rules drawn up jointly by this committee and the various lumber manufacturers' organizations. The committee can report this year that the standard rules for maintenance of way lumber adopted last year by this association, when submitted back to the lumber organizations interested, were agreed to, with slight modifications, as follows:

For southern yellow pine, by the Yellow Pine Manufacturers' Association.

For hardwoods, by the Hardwood Manufacturers' Association of the United States.

For Douglas fir, by the West Coast Lumber Manufacturers' Association.

The Northern Pine Manufacturers' Association refused to accept the white pine rules. The acceptance of the rules adopted last year by the three associations referred to was made subject to slight modifications in the rules made since the time when these rules were first proposed. These modifications are so slight, however, that the committee believes that they can be readily adjusted in individual cases.

The committee has been engaged in making further studies of rules for classes of lumber not included in the rules already adopted. These considerations are well under way, and it is expected two or three additional sets of rules will be ready for submission next year.

Consideration has also been given to the grading rules for cypress submitted for information last year.

The committee recommends that the lumber grading rules for cypress, as published in Appendix E, Bulletin No. 144

Dr. H. Von Schrenk, Chairman; B. A. Wood, Vice-Chairman; W. McC. Bond, D. Fairchild, R. Koehler, A. J. Neafie, W. H. Norris, J. J. Taylor, F. B Walker, Committee.

The rules submitted last year on cypress were adopted, to be included in the Manual.

DR. H. VON SCHRENK,
Chairman Committee on Grading of Lumber.

ROADWAY.

The committee on roadway has had under consideration during the past year the four subjects assigned by the Board of Direction.

PRESENT FORMULAS OF GENERAL APPLICATION FOR DETERMINING WATERWAY AREAS UNDER VARYING CONDITIONS, INCLUDING CONSIDERATION OF HYDRAULIC FEATURES.

Considerable space has been given to the subject of waterway areas in the Association bulletins and proceedings in recent years, and somewhat favorable action has been taken tending to support the general practice of using formulas as an aid to the judgment in such work. Successive reassignments of this subject for committee work has been made by the board during the past two years and some further progress has been made. It does not appear, however, that data can be had at this time which would justify a further attempt to derive a simple formula having general application.

On the subject of the hydraulic features of culverts considerable information has been collected, but owing to incompleteness of certain features, it is deemed advisable to defer the presentation till a later date in one of the Association bulletins.

REPORT ON AND RECOMMEND UNIT PRESSURES ALLOWABLE ON ROADBEDS OF DIFFERENT MATERIALS, CONFERRING WITH COMMITTEE ON BALLAST.

The chairman of the committee on ballast advises that "the determination of the proper unit pressure with any degree of accuracy and without guesswork necessitates certain tests or experiments, and so far the ballast committee has not been able to find any information on this subject which has not already been given to the Association"; and the committee on roadway has failed to discover anything new on the bearing power of soils or on the magnitude of the unit pressures to be carried by the roadbed.

Under these circumstances the committee can do no more than again direct attention to the following resolution heretofore submitted:

"Resolved, That the Board of Direction be requested to set aside an appropriation and to appoint a special committee, consisting of members of the roadway, ballast and track committees, to make experiments to determine the magnitude and distribution of the load transmitted to the roadbed through ballast of various kinds and also to determine by test the bearing power of various materials under varying conditions ordinarily found in the construction of the roadway."

As the experiments should extend over a considerable period of time to cover seasonal variations and should be conducted under actual traffic conditions, the expense would be quite heavy and probably should be borne jointly by several of the larger railroad systems. The present high percentage of rail failures, together with the undoubted advent of the 100-ton car and the constant increase of locomotive axle loads, make it imperative that some systematic study of the roadbed be made as a foundation for the track.

W. M. DAWLEY,
Chairman Committee on Roadway.

REPORT ON TUNNEL CONSTRUCTION AND VENTILATION. THE VENTILATION OF SUBWAY TUNNELS.

The ways in which subways have been ventilated may conveniently be considered under four separate heads:

(1) By introducing or exhausting air at various points by means of fans.

(2) By forcing a current of air from one end to the other of the whole line by fans.

(3) By so-called natural ventilation.

(4) By the piston action of trains.

Fans are almost invariably employed to exhaust air, not to supply it. They may exhaust through side chambers directly to the outside air, as in older portions of the Boston subway, or by means of air ducts communicating at various points, as in the Severn and Mersey tunnels. In the former case a number of comparatively small ventilating fans are employed at the points where the air is to be extracted; in the latter

large central pumping plants are used. In any case, fresh air is expected to enter at stations or other appropriate points as rapidly as the foul air is exhausted.

In the plenum principle the fresh air is forced in by the fans and the foul air escapes as best it can. This method is more often used to supply air during construction of deep subways than in subways after they are built. Many arguments have been brought forward to show the advantages of renewing the air at stations rather than elsewhere. It has been urged, for example, that the air should be exhausted between stations and allowed to flow in at the stations, since more passengers are congregated at stations than at other points, and in this way they will get the freshest air; the air in the cars is renewed at stations and not between them, so the air should be at its best there, and this method would most rapidly remove smoke and heat in case of fire and give the best opportunity for escape through the stations.

The earliest use of a fan for assisting the ventilation of a railway tunnel is believed to have been in 1870 in connection with the Lime street tunnel of the London & Northwestern Railway at Liverpool. Following the generous proportions of fans which had been employed in ventilating mines, this fan was 29½ ft. in diameter and discharged its air into a conical brick chimney 54 ft. in diameter at the base. The quantity of air thrown was 431,000 cu. ft. per minute. The air was taken from a point midway between the two ends of the tunnel. The tunnel was 6,075 ft. in length.

The Boston subway is about 4 1/3 miles long and is operated by electricity. It is used by trains and single trolley cars, most of whose routes lie in the open air. The speed is so slow that the ventilating currents set up by the moving cars are often scarcely noticeable. The typical section is 332 sq. ft. where the subway is occupied by two tracks and 707 sq. ft. where it is four tracks wide. In the section of the road first built ventilating fans are placed in chambers alongside the subway at points between stations and the air is discharged upwards through grated openings in the sidewalk overhead or through short shafts to the other air. The fans are 7 to 8 ft. in diameter. They were intended to be of such capacity as to enable them to completely renew the air every ten minutes. In the section under the harbor the same general plan is followed of taking air in at the stations and removing it between stations. In this case, however, an exhaust duct has been placed along the top of the tunnel with occasional openings which can be opened or closed at pleasure. The cross-section of the duct is about 48 sq. ft.; the openings are about 4 ft. long and 1 ft. 5 in. wide and they are placed at intervals of about 550 ft. The air is withdrawn at each end of the tunnel and exhausted by means of fans through shafts about one mile apart, on the opposite shores. At the East Boston end the air is exhausted through grated openings in the sidewalk 40 ft. long and 7 ft. 1 in. wide. At the other end the air is discharged about 21 ft. above the surface of the street. The fans consist of two 8-ft. vertical fans at the East Boston end and two 7-ft. horizontal fans at the Atlantic avenue shaft. At 175 to 218 revolutions per minute and about 12 h. p. each, the total rated capacity of the whole ventilating plant is 90,000 cu. ft. per minute. This gives a theoretical velocity for the whole air in the tunnel of about 2½ ft. per second and is equivalent to a renewal of the air every fifteen minutes.

The Severn tunnel of the Great Western Railway was opened in 1886. It is about 4¾ miles long. It is occupied by two tracks for steam railway travel. There is a ventilating shaft located near the center, through which air is exhausted by means of a fan 40 ft. in diameter. It is said that the capacity of the fan is sufficient to renew the air of the tunnel about every ten minutes.

The Mersey tunnel, connecting the cities of Liverpool and Birkenhead, is about 2 miles long and is occupied by a double line of electric railway. Air is exhausted through numerous passages communicating with ventilating galleries which lead to exhaust fans. These fans are from 12 to 40 ft. in diameter and are located at stations above ground. The combined capacity of these fans is estimated to be about 950,000 cu. ft. per minute, or sufficient to renew the air of the tunnel every nine minutes. This tunnel is often referred to as affording an example of the most perfect system of artificial ventilation yet devised. It was certainly the earliest tunnel in which a comprehensive system was adopted.

The general plan of ventilating the new tubes of the Electric Underground Railways Company of London is to take advantage of the piston action of the trains, as do all the London subways, and to supplement this by fans at the stations. The fans exhaust air from beneath the station platforms and carry it through airways averaging 12 to 16 ft. in cross-section to the roofs of the buildings used for subway stations, there to be discharged into the free atmosphere. The fresh air enters through these stations, stairways and lifts. The fans are of a designed capacity sufficient to remove 1,000,000 cu. ft. of air per hour when working at moderate speed. This is sufficient to renew all the air in the average length of subway between two stations in each of the parallel tunnels every 30 minutes. The fans are located at the tops of the buildings. They have been found, upon test, to deliver 18,250 cu. ft. per minute when operated at a velocity of 242 revolutions per minute. Great care was used to avoid vibration and noise from the motors and fans.

A system of forcing air through an electric subway has been installed in connection with the Central London Underground, a good example of the deep London tubes. The ventilating arrangement of the Central London Railway is capable of renewing all the air contained in this subway three times over every night. In order to accomplish this result double doors are arranged at the station entrances and shut at night. The air flows in at the city end of the Bank of England, passes through the two tubes, each over six miles long, and is exhausted by a fan at Shepherd's Bush.

The fan is 20 ft. in diameter and of the Guibal type. It is said to be capable of exhausting 100,000 cu. ft. of air a minute as measured at a point near the far end of the line. During the day it is not possible to run this far with much effect, because, with opening the station doors by passengers, it draws air from the stations, chiefly from the nearest one. But at night after the last train has run out of the subway on the surface at the west end all the doors are closed and the fan is started. It is kept going until the first train is run in the morning. The results are said to be excellent.

Although many subways are now provided with some system of ventilation requiring the use of fans, by far the greatest number still depend for a circulation of air upon currents set up without special mechanical aid. Among the more common ways of securing the so-called natural ventilation, the use of blowholes, or free openings to the outside air, deserves special notice. It is to ventilation accomplished in this way that the frequent renewal of air in the New York subway is due. The draught of air passing through the blowholes is sometimes violent. An average velocity of 16½ miles per hour through the stairways of the New York subway was observed as a result of several hours' observation with anemometers. Had this current taken place through one-half of the openings between Ninety-sixth street and the Brooklyn Bridge, the quantity of air so supplied would have been capable of renewing the entire atmosphere of the subway every few minutes. At first sight it would appear that nothing could be easier than to ventilate a subway by this means. It seems as simple as opening the window of a living room. Yet to get the best effects from blowholes, ventilation means much more than the opening of the roof. To provide for a suitable and reliable movement of air requires careful study. Apparently the very simplicity of the idea of blowhole ventilation has prevented the development of this principle in the best manner. To some subways and tunnels it is peculiarly suited. The term blowhole is here used to include all openings through which the confined air can escape and fresh air enter, whether they be stairways, openings in the roof or openings through side chambers. In shallow subways such openings usually pierce the roof or lead from station platforms with more or less directness to the outside air. They are usually much too small, too indirect and too long to accomplish all the benefit which may be obtained from them.

Inasmuch as the flow of the air is impeded by friction against the walls, blowholes should be as short as practicable. Since the friction increases as the square of the velocity of the current and inversely as the diameter of the passage, they should be large in section and but little obstructed by screen, doorways, nettings and other incumbrances. It is easy to see that blowholes may be more advantageously employed in subways built near the surface of the ground than in railways far beneath the surface. And yet this is the only way in which some of the deep London tubes are ventilated. If, as sometimes happens, the blowholes are open stairways covered by cowl-like kiosks, the direction of the openings with respect to prevailing breezes may materially aid or interfere with the amount of air which passes in or out. Let us briefly examine this effect.

The action of moving trains is more important than any other factor in establishing a circulation of air through blowholes. This so-called piston or plunger action has long been recognized as useful, but it has remained for the New York subway to demonstrate how extremely beneficial it may be. The main principle of the phenomenon of piston action is easily understood. The moving trains force air ahead of them and cause air to rush in after they are passed. The

quantity of air moved depends upon many circumstances. Chief of these are the extent to which the tunnel section is filled by the section of the train; the speed of the train; the opportunity afforded by blowholes for the air to flow in and out; and the shape of the forward end of the train.

In studies made on the Berlin-Zossen railway into the resistance offered by the free outside atmosphere to the movement of trains, it was found that air piled up in front of the first car in the form of a cone of increased pressure and that a cone of reduced pressure followed behind the train. For example, the pressure in front of a car which presented a face perpendicular to the line of the track was 4.09 lbs. per sq. ft. at a speed of 12.4 miles per hour; 6.14 lbs. at 18.6 miles; 8.19 lbs. at 24.8 miles. This pressure was maintained for between 10 and 16 ft. in front of the moving train; beyond this it gradually fell off.

Observations made in the New York subway before any material changes were made in the arrangements for ventilation, with the ordinary train service of early afternoon, have shown that air passed from one station to another sometimes at a rate of over 8 miles per hour and at an average of about 3 miles. The approach of a train toward a station on the four-track road could be felt by the flow of air ahead of it while the train was over 1,000 ft. away.

The exhaling and inhaling action due to the operation of trains is of peculiar value in that it occurs when and where most needed, provided, of course, that the openings to the outside air are properly placed and unencumbered. The greater the number of passengers carried and the greater the number of trains, the greater is the amount of ventilation. And not the least conspicuous of the advantages of so-called natural ventilation is its economy.

No expense is necessary for the operation of mechanical devices in natural ventilation. Experience with the New York subway shows that it is not always necessary or desirable for a train to fit very closely into the tunnel section. In fact it is conceivable that when this fit is close, the cars carry along more of their own air than desirable and the passengers within them enjoy much less interchange than would take place otherwise.

The details of construction and equipment of the New York subway have been made the subject of so many extended and authoritative accounts that it is unnecessary to deal exhaustively with these questions here. The subway structure may briefly be described as virtually a steel cage enclosed and embedded in concrete. The walls and roof were alike in design, consisting of beams weighing from 42 to 70 lbs. per foot, placed about 5 ft. apart. Between these beams square, steel rods 1¼ in. long were placed to the extent of from 4 to 7 per 5-ft. panel. Round rods ⅝ in. diameter connected the columns about 2 ft. below the under face of the roof. The rods were set back from the inner face of the tunnel 2 in., but the beams projected to the surface.

Between the beams of the roof and sides comparatively thin walls of concrete imbedded the steel cage. This concrete has a thickness at the walls of from 14 to 16 in., exclusive of a thin protective wall of waterproofing outside, and of a space of variable thickness occupied by hollow ducts intended to contain electric cables. The roof has a thickness which varies from 18½ to 21½ in. In the four-track section of the subway rows of steel columns extend between each two lines of track at intervals of 5 ft. to support the roof. The floor is of concrete with an enclosed layer of waterproofing.

Nearly all of the studies recorded here, except those of temperature and humidity, refer especially to the representative section between Ninety-sixth street and Brooklyn Bridge. In many cases they have a much wider application. The length of this section was about 6 miles. The cubic air space included was in round figures 26,100,000 cu. ft., including the stations. The section was four tracks wide, excepting a piece of tunnel which ran between Forty-second and Thirty-fourth streets. Here there were two tunnels of two tracks each, running side by side, cut through the rock. The subway was ventilated through the stairways at the stations and through blowholes in the roof. All of the blowholes which were originally built were located in that portion of the road which lay above Sixtieth street. They were rectangular in shape, and opened upon small grass plots which occupied the center of a wide boulevard known as Upper Broadway. Iron railings surrounded the openings. To prevent the entrance of large objects the openings were covered with coarse wire netting.

The blowholes were located above the center of the railway, one being situated a little beyond each end of each station. An additional blowhole was placed midway between stations. The total number of blowholes between Fifty-ninth and Ninety-sixth streets was 18. Each was about 7x14½ ft. in the clear. Wire nettings, beams and other objects took up about one-quarter or more of their space so that the total effective area from these blowholes was about 1,368 sq. ft. Sections of the vault lights were early removed from the stations at Seventy-second and Ninety-sixth streets and left unobstructed by nettings. The area removed at Seventy-second street was about 108 sq. ft. and at Ninety-sixth street about 478 sq. ft. This greatly relieved the unsatisfactory condition of the air at Seventy-second street, where the subentrances had been covered by a building, and at Ninety-sixth street where the roof was very low and the extent of the vault lights extraordinarily great.

The stairways between the streets and the stations varied somewhat as to width and direction. Below Fifty-ninth street they were usually placed at right angles to the line of the road; above Fifty-ninth street they were parallel to the road. There were usually two stairways, each in cross-section about 5½x7½ ft., to each local station above Fifty-ninth street and eight narrower ones to the other local stations.

The subway was about 59 ft. wide and 18 ft. high on the four-track section between Brooklyn Bridge and Ninety-sixth street and the cross-section of a car occupied about 14 per cent. of this section. The trains were from about 150 ft. to 408 ft. long. The local trains usually consisted of five cars and ran at a rate, exclusive of stops, of about 21 miles per hour. The express trains generally consisted of eight cars and ran at a rate, exclusive of stops, of about 26 miles per hour.

As a train moved through the subway air was for ed ahead of it and air followed it. As a rule, a general current flowed along the track on each side of the subway in the direction of the train movement, and these currents continued even when no train was within hearing distance. The important action of a train was to force air along with it, but where stairways or blowholes occurred and offered lines of diminished resistance, the air rushed out through them as a train approached and rushed in as the train went by. The difference in barometric pressure necessary to set up these air currents was exceedingly slight; the effects of friction against the walls and pillars of the subway and the sides of the stairways considerable. A great part of the force with which the air currents were set in motion was generally used up in eddies about the trains.

The movement of the air depended upon the speed of the nearest train, the movement of other trains in the vicinity, the size and location of the neighboring openings to the outside air, the size of the particular cross-section of the subway with reference to the sections of the moving trains, the force and direction of the wind in the streets with reference to the position of the stairways, the difference in temperature inside and outside of the subway and other conditions.

From approximate computations made in a number of ways, it is practically certain that the air was renewed at least as often as once every half hour.

With the object of reducing the heat which had made the air uncomfortably warm during the summer months extensive alterations were made in ventilating arrangements of the New York subway after the above observations were made. The plan embodied several features.

Large sections of the roof were removed at the stations and the openings were covered with gratings. The aggregate area of the opening when allowance was made for the gratings was 2,356 sq. ft. in the section from the Brooklyn Bridge to Columbus Circle, and 1,805 sq. ft. in the section between the latter point and Ninety-sixth street. It was calculated that these openings, together with the openings at the station stairways, etc., would give a ratio of 1 sq. ft. of blowholes for every 3,200 cu. ft. of contents at each station. Blowholes, opening generally from specially constructed chambers, were also provided between stations. These blowholes were fitted with air valves and fans, the object of the arrangement being to induce fresh air to enter at the stations, and pass out through the blowholes between stations.

The air valves, called louvres, were made of galvanized iron and were so fitted into sheet iron boxes that when shut they entirely closed the area of the blowholes in which they were placed. The valves swung automatically upon axles, being so counterweighted as to open and let air out when it was forced ahead by the trains and then close and prevent fresh air from getting in after the trains had passed. The ventilation with the valves was like the natural ventilation which would have taken place without them, in one respect; they were entirely dependent upon the movements of the trains, producing an amount of ventilation which was proportioned to the number of trains passing in a given period.

The fans have been placed at the ventilating openings between stations to accelerate ventilation under special circum-

stances, such, for example, as at night when few trains are running and in order to free the subway of smoke in case of fire. The fans are of the centrifugal type popularly known as blowers. They are from 5 to 7 ft. in diameter. They are operated by electric motors of 15 to 30 horse-power capacity and when run at their normal speed of 235 to 330 revolutions per minute are said to be capable of discharging about 990,000 cu. ft. of air per minute. On the basis that the fans are really capable of operating as effectively as assumed, they should be able to renew the air between Columbus Circle and Brooklyn Bridge in 19 minutes.

A plant for cooling the air at the Brooklyn Bridge station was constructed in 1906. The project required that the heated air of this station should be passed by means of a centrifugal fan over coils of cold water and distributed through ducts opening immediately over the heads of the passengers at the station.

The quantity of air cooled is about 75,000 cu. ft. per minute for each of the two units into which the plant is divided. When first put in operation, it was found that there was a transfer of heat between 9.4 and 11.3 B. T. U. per square foot per degree of difference between the air and the water and that the air which came in contact with the pipes could be cooled about 8 deg. under the conditions of practical operation.

VENTILATION OF THE HUDSON RIVER TUNNELS.

The tunnel system of the Hudson & Manhattan railroad company has been in operation about five years between Hoboken, N. J., and Sixth avenue, New York, and the downtown section between Hoboken and Church street, New York, about four years. Those sections now in operation extend from the Terminal building, at the lower end of New York, under the Hudson River to Jersey City, thence underground to the Erie and Lackawanna railroad stations, whence they pass under the river again back to Manhattan at a point about 1¼ miles above the downtown tubes. Continuing below ground, the tunnels extend to Sixth avenue and thence to Thirty-third street. In Jersey City the line to Newark comes to the surface about 1½ miles west of the Pennsylvania Railroad Station. Extensions now under way will carry the tunnels further up Sixth avenue and eventually to the Grand Central Station at Forty-second street and Fourth avenue.

The total length of the tunnels when completed will be 19 miles.

The Hudson tunnels were designed by Charles M. Jacobs, the chief engineer of the Hudson Companies. They are single track tubes, there being no connection between adjacent tubes except at junctions and at some stations. This plan has been adopted throughout, and it is of great importance in the ventilation, as only by this means can full advantages be taken of the piston action of the trains to maintain efficient circulation of the air. The Fourteenth, Nineteenth and Twenty-third street stations are constructed on the same principle, but structural and operating requirements would not permit the scheme at other stations.

The effective area of the iron-lined tunnel is 160 sq. ft. and of the concrete-lined tunnel 166 sq. ft. This is with ballast and bench wall in place. The cross-section of the standard tunnel car is approximately 90 sq. ft., which leaves a clearance area of 70 sq. ft. and 76 sq. ft., respectively, for the iron and concrete tunnels.

The original layout of the ventilating system was designed to take full advantage of the piston action of the trains and to draw out the foul air with exhaust fans, while using entrances to admit fresh air. But in three cases it was considered necessary to install fresh air blowers to supplement the air delivered through the entrances, which were either too small or too far apart for this purpose, and also to create sufficient circulation should trains become stalled in the tunnels.

The capacity of the fans was designed to give 30 cu. ft. of air per passenger per minute when traffic is at the maximum during morning and evening rush hours, and this capacity would change the air in the tunnels approximately 2½ times every hour. All fans are motor driven, the motors being coupled direct to the fan shaft. The motors are specially built of the inter-pole type, designed to operate under large voltage fluctuations. They are extremely rugged, reliability being of extreme importance in the installation. The speed variations in these motors is 20 per cent. All speed changes are obtained economically by field control. The motors are designed to operate on a 625-volt circuit which has fluctuations between 500 and 750 volts.

In November, 1909, A. W. Hodgson, assistant engineer of the Hudson & Manhattan railroad, made a series of anemometer tests to ascertain the direction and volume of air circulating through the tunnels and station passageways under existing circumstances. All readings were taken with trains running on 2½ minutes headway, except in the tunnels between caissons 1, 2 and 3, where the headway was 5 minutes. The temperature on the street was close to the freezing point or below. The average velocity of the air from the downtown river tunnels was 1,100 ft. per minute with trains on 2½ minutes headway. The highest recorded temperature in the tunnels was 76½ degrees in August, 1909, when the temperature on the street was 88 deg. Many other parts of the tunnel were only 70 deg. on this date. The average temperature of the tunnel is generally 70 deg. The train headway during rush hours is 1½ minutes with four and five car trains. With trains on 2¼-minute headway, the velocity and direction of the air is governed almost entirely by train movements and not by fans. The large exhaust fans at Church Street Terminal, handling 114,000 cu. ft. of air per minute, increase the velocity in the river section of the south or inbound tunnel less than 10 per cent over the velocity in the north or outbound tunnel. The velocity in the river section of the outbound tunnel was influenced largely by the number of doors and ventilators open at Church Street Terminal entrances, being 180,000 cu. ft. on December 13, and falling to 126,000 cu. ft. per minute on December 23, when all doors and ventilation were closed.

It is, therefore, evident that the function of the fans is only to take the air pushed to them by the trains or to deliver fresh air where the trains can push or draw it in through the stations and tunnels, and this fact should mainly govern the location of fans and air ducts.

In the river sections of the iron-lined tunnels, with trains on 2½-minute headway and attaining an average speed of 30 miles per hour, the mean volume of air passing at any point is 180,000 cu. ft. per minute, provided that the air is not restricted by closing all possible inlets. At island platforms, such as Christopher and Erie stations, also crossovers, such as Ninth street and Nineteenth street, about 70 per cent. of the air crosses the platforms or tracks within 50 feet from the end at which it enters and follows the direction of traffic in the adjacent tunnel. The 30 per cent. leaves the station in the same tunnel in which it enters.

The results prove that wherever passages or connections of considerable area are made between two adjacent tunnels, the section of tunnel between any two such connections must be considered independently, and cannot be efficiently ventilated by fans or shafts not within that section.

In the original design it was considered necessary to install all fans in duplicate. This idea has now been abandoned, as it has been found quite possible to shut down any fan for a day or more for repairs without appreciably affecting the air in the tunnels.

In installations of large capacity, such as are required for a system of deep tunnels, where access to the surface is only possible at long intervals, the design of the fans and air ducts requires very careful study. If they are not properly proportioned, the ventilation will become a very expensive proposition, both in first cost and in operation.

The committee presents the foregoing as information, withholding conclusion until experiments now being conducted on single and double track steam railroad tunnel ventilation are completed.

ECONOMICS IN ROADWAY LABOR.

The committee having agreed with the Track, Signals and Interlocking committees on a subdivision of the work, reports progress.

RECOMMENDATIONS FOR 1913.

The committee recommends that subjects 2, 3 and 4 be reassigned, again respectfully calling attention to the resolution above referred to.

W. M. Dawley (Erie), Chairman; J. A. Spielmann (B. & O.), Vice-Chairman; J. R. W. Ambrose (G. T.), John C. Beye (C. R. I. & P.), Ward Crosby (C. C. & O.), W. C. Curd (M. P.), Paul Didier (B. & O.), R. C. Falconer (Erie), S. B. Fisher (M. K. & T.), Frank Merritt (G. C. & S. F.), C. S. Millard (C. C. C. & St. L), W. D. Pence (Univ. of Wis.), A. C. Prime (P. R. R.), H. J. Slifer (Cons. Engr.), John G. Sullivan (C. P. R.), F. L. Wheaton (D. L. & W.), J. E. Willoughby (Carribeau Cons. Co.), W. P. Wiltsee (N. & W.), Committee.

The report was received as information and the committee was relieved.

RECORDS AND ACCOUNTS.

The board of direction assigned the following work to this committee for the current year:

(1) Make a comprehensive study of the forms in the manual, which were adopted a number of years ago, and bring them up to date.

(2) Continue the study of the economical management of store supplies.

(3) Recommend feasible and useful subdivisions of Interstate Commerce Commission Classification, Account No. 6, with a view to securing uniformity of labor costs.

SUBJECT NO. 1.

Some of the forms, particularly those used in connection with the accounts, such as foremen's reports of labor and material consumed, might be changed in some particulars, but it is doubtful if such changes would bring about their more general use by the railroads, as little, if anything, would be gained by suggesting minor changes in these forms. It is the opinion of the committee that no changes be made at the present time in the forms appearing in the manual. It is suggested that since the selection of the proper forms for time books, foremen's material reports, distribution sheets and authorizations of expenditures is a matter in which the Accounting department is as much interested as the Maintenance of Way department, for the reason that these forms and reports are the foundation of the entire maintenance of way accounting structure, it would be advisable for this association to join with the American Railway Accounting Officers' Association in the development of a set of forms, to be recommended by each association, which would be generally adopted by railways.

SUBJECT NO. 2.

The committee carefully discussed the report made last year with Mr. McVeigh, a representative of the Storekeepers'

H. J. PFEIFER,
Chairman Committee on Records and Accounts.

Association, and we believe that the conclusions which we have reached will meet with the approval of Mr. McVeigh, and that there is a strong probability that they will be approved by the Storekeepers' Association. Discussions were confined to the conclusions approved by the association at the annual meeting in 1912, which were under the following headings:

Standardization.
Classification of Material.
Stock Account.
Distribution.
Organization.

Standardization.—No change is recommended for this heading.

Classification of Material.—The committee recommends that the details of classifications should conform to those adopted by the Railway Storekeepers' Association.

Stock Account.—The conclusion reached last year is fundamental. The detailed methods of keeping the accounts may be varied to fit the individual condition. Stock accounts can be kept, first, by ledger account; second, by card system, and third, by personal inspection and estimation.

Distribution.—No change is recommended for this heading.

Organization.—The essential elements are as follows:

Location.—The store should be located as closely as possible to the point of greatest consumption so that the minimum force will be required, and that the delay to material between the store and its destination may be reduced to a minimum. Usually this is at a point where equipment is maintained.

Force.—The force required is dependent almost entirely on the character and volume of material issued and on local conditions. As the prompt and efficient handling of material and tools has a vital effect on the economical operation and maintenance of the railway, the force in the storeroom should be large enough to bring about this result.

Position in Organization.—The consumption of supplies being greatest in the maintenance of way and equipment, the storekeeper should be closely associated with the heads of these departments. It is the opinion of the committee that this can best be accomplished by having the storekeeper, engineer maintenance of way and the master mechanic report to the same officer. In a divisional organization this would place the division storekeeper under the superintendent and the general storekeeper under the general manager or vice-president in charge of operation.

Mechanical Equipment.—Cost of unloading, storing and loading material depends solely upon the volume of business done by each store, and such appliances as will reduce this cost to a minimum are recommended.

Plan.—A typical layout of a store is presented, which can be expanded or reduced as the situation demands.

SUBJECT NO. 3.

The Interstate Commerce Commission, in their Classification of Operating Expenses, which became effective July 1, 1907, included in the maintenance of way accounts primary Account No. 6—Roadway and Track. This account includes about one-third of the total charges for material and labor in the maintenance of way and structures accounts. This account includes practically all of the labor performed by section and extra gangs chargeable to the maintenance of way and structures operating expenses, and it seems desirable to provide subdivisions of this primary account in order to analyze operating expenses and assist in securing uniformity of labor costs.

A brief outline of the reasons for recommending the proposed sub-accounts is as follows:

Sub-Account A—Track Maintenance:

Under this caption is included all labor necessary to maintain good line and surface of track, except for the application of material. In other words, if the material and drainage conditions are good, but the track is in poor line and surface, the labor necessary to place the track in good condition will be charged to this sub-account. Also, if it is necessary to temporarily reduce expenses, the available force should be used on line and surface work so far as possible.

Sub-Account B—Applying Track Materials:

Applying track materials is subdivided into
(B-1) Applying Ballast;
(B-2) Applying Ties;
(B-3) Applying Rails;
(B-4) Applying Other Track Material.

These sub-accounts will furnish as much detail as is practicable for convenience in comparing labor costs.

Sub-Account C—Cutting Weeds and General Cleaning:

This sub-account includes work which is less important than some of the other items, and the amount expended is largely dependent upon keeping the property in presentable condition rather than for reasons affecting safety or economy.

Sub-Account D—Ditching and Bank Widening:

This sub-account includes the most important element in providing good track. Frequently the material removed from cuts is used in widening embankments and, therefore, ditching and bank widening are logically included in the same sub-account.

Sub-Account E—Changing Alignment and Grades:

Under this caption is included the operating expenses resulting from abandoning the present alignment on account of reduction of grades or curvature, and it is necessary to separate this from the other expenses which more directly affect the economical maintenance of the property.

Sub-Account F—Flood Damage:

This sub-account includes the cost of repairing damage to the roadbed and track caused by unusual conditions, such as cloudbursts, floods, etc. It is necessary to separate this class of expenditures from the ordinary maintenance work in order that the latter may truly reflect the average expenses in maintaining the property. This sub-account also furnishes the basis for investigations to determine the amount which may be profitably expended to eliminate future damage.

Sub-Account G—Bank Protection:

Under this caption is included expenses necessary to protect the roadbed and track from slides, washouts and other unusual damage to the property.

Sub-Account H—Filling:

This sub-account provides for the expense of filling bridges.

Sub-Account I—Other Care of Roadway and Track:

This sub-account is intended to include the cost of trackwalkers, watchmen and other expenses not specifically provided for in the other sub-accounts.

It is the opinion of the committee that the subdivisions of the Interstate Commerce Commission Classification, Account No. 6, of Operating Expenses, will be of assistance in securing uniformity of labor costs, but in order to obtain the greatest efficiency and most economical results additional information must be obtained and action taken.

Some of the most important elements in securing uniformity of labor costs and efficiency in handling work are as follows:

(1) Adoption of proper method for doing the various kinds of work under usual conditions. Efficiency in the various kinds of work performed in the Maintenance of Way department has received very little study up to the present time, and it is safe to say that practically the same methods are being followed to-day that have been in use for a great many years. As an illustration, there are probably as many methods employed by section foremen in putting in ties under the same conditions as there are foremen doing this work, and by making a careful study of the elements entering into each operation the best method employed by each foreman may be combined to produce an approved practice for the various items of work under the most usual conditions.

(2) Economical distribution of material so as to reduce the amount of labor necessary in applying.

(3) The selection of proper tools and their maintenance in good condition.

(4) Organization and supervision.

(5) The selection of the proper season of the year for performing the various kinds of work.

H. J. Pfeifer, chairman; M. C. Byers, vice-chairman; J. M. Brown, Edward Gray, E. E. Hanna, Henry Lehn, J. H. Milburn, C. W. Pifer, Guy Scott, W. A. Christian, G. J. Graves, Orlando K. Morgan, Walt. Dennis, G. D. Hill, Frank Ringer, Committee.

The report was received as information.

OTHER BUSINESS.

Mr. Kittredge: I desire to offer the following resolution:

Resolved, by the members of the American Railway Engineering Association in convention assembled, That we desire to, and hereby do, give an expression of appreciation of the able manner in which the retiring president, Charles S. Churchill, has discharged the duties of president during the past year and presided over the meetings of this convention; that this resolution be spread upon the minutes and a copy be furnished to Mr. Churchill.

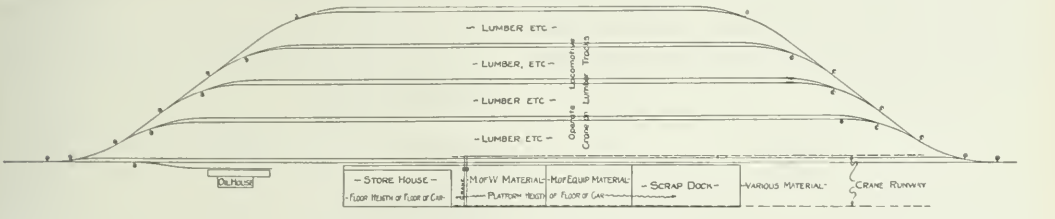
L. C. Fritch: I move that this resolution be adopted, that it be made unanimous, and that the vote be a rising vote.

(The motion seconded and the resolution was unanimously adopted amid applause.)

The President: I thank you very much, gentlemen, for your kind expressions. As one of the ancient members of this association, I enjoy appreciation of this kind. I consider it an honor to have had this position. I wish success to my successor. I know he will have it, because in this association every officer has the hearty support of all the members. That is one peculiarity of this association above all others with which I am acquainted. This is a working organization; it has the respect and esteem of the whole of the United States. It is growing in power and in the results accomplished by it daily, and it is all by the co-operation, by the frank discussion, by turning down mistakes that are made that are clearly mistakes, and by making corrections promptly—in that way we will keep up with the times, and that is what we are trying to do as railroad people. We have got to be alive, up-to-date, and take up the new questions that have been suggested and follow them out to the limit. I thank you, gentlemen.

Address of President-Elect Edwin F. Wendt.

I deeply appreciate the honor which you have conferred upon me. It will be my purpose to so work as to merit your confidence. With your help the work of this association during the coming year will be carried to a successful conclusion. This success will depend on the co-operation of many elements. During next year we expect to have Secretary E. H. Fritch with us, as in the past, however at an increased salary. The Entertainment Committee has been so successful as to have earned what will probably be a life tenure of office. Furthermore, as a business organization we feel justified in congratulating ourselves on having with us year after year two such skillful and faithful stenographers as have served us for so many years. Then, again, I feel that we are justified in saying even another word respecting the value of the exhibition which is given by the National Railway Appliances Association. I had the pleasure yesterday of going through that exhibition and ascertained that the direct expense of that exhibition amounts to as much as $27,000 per year. The attendance at the exhibition is fully up to 50,000 people, and many of whom are employes of railroads for a distance of 1,000 miles from Chicago. That exhibition also represents a capital of not less than $495,000,000.



Typical Layout for Maintenance Department Stores.

Furthermore, we are especially fortunate in having as an aid to the work of our association the technical press, and however excellent their publications have been in the past with respect to our association, we confidently expect that their work will be carried on year by year, even to the greater benefit of our membership. The committees of this association are responsible for the direct, tangible results which find their expression finally in the Manual. Without the help of these 20 standing committees we would accomplish very little, and I say that the thorough work which is done in committee is that which receives the greatest approbation of the membership in general.

If we accomplish in the future that which we wish to accomplish, it is essential that we get more members. At the first of January our membership was 1066. Today we are pleased to say that the membership is about 1115. There are, however, in this country, at least 1500, and no doubt 2,000 persons who ought to be members of our association. They ought to be members because they can do this association much good and because they can derive from the association an equal benefit.

The object of our association is the advancement of the scientific study of those problems that pertain to the construction and maintenance of railways. We believe that the results of this scientific study will be of very great benefit to ourselves and to the railways of America. If we pursue the object of this association and bring about the scientific study of those problems which confront us and temper theory with experience we will have accomplished that which was the intention of the framers of the constitution. Our association was born in the tranquil days which characterized the opening of the 20th century, but since that time there has been a development on the part of the public, so that in 1906 Congress passed the Hepburn Act, which has brought about a great deal of discussion and much disturbance of financial conditions in connection with our business. We must meet these new conditions which have arisen since 1906 under the policy of government regulation, and I for one have no doubt that when we direct our intelligence to the determination of

the scientific principles which underlie the success of the railway business we will be satisfied that a conservative policy of regulation will meet our approval.

A great work before the country during the next few years will be that of the valuation of railways. The Board of Direction has discussed this question for several years and has now under consideration the question as to what action, or what attitude our association should take with reference to this great problem. It is a tremendous problem, one which is being undertaken, we fear, without proper preliminary study, and it behooves every member of our organization to intelligently direct his energies toward the proper solution of this great question. We have in our midst those persons who are able to do this work and we should emphasize the point that was raised by several of the speakers last evening, that our membership should speak freely its mind with respect to the underlying principles which should govern the determination of this great question and I for one will venture a prediction that when the railways of America are intelligently valued the public will discover, contrary to its present idea, that the railway companies and properties are worth a great deal more in money than their present capital.

If there is no other business to come before this convention the Fourteenth Annual Convention will now stand adjourned.

REGISTRATION—AMERICAN RAILWAY ENGINEERING ASSOCIATION.

SPECIAL CAR FOR BOSTON.

The Lake Shore & Michigan Southern, for the convenience of persons attending the convention, will operate a special car for Boston on its train leaving Chicago at 10:30 this morning

MEETING OF TELEGRAPH SUPERINTENDENTS ASSOCIATION.

The Association of Railway Telegraph Superintendents held a quarterly meeting in the assembly room at the North Western office building, Wednesday, March 19. After the meeting a joint meeting of the committees on arrangements of this Association and of the Telephone and Telegraph Appliance Association was held to make preliminary arrangements for the annual convention to be held in St. Louis during the week commencing Monday, May 19. There will be no organized exhibit in connection with this meeting.

J. J. Ghegan, J. H. Bunnell & Co., New York, is chairman of the Telephone and Telegraph Appliances Association; E. E. Hudson, Thomas A. Edison Company, Inc., is vice-chairman, and W. E. Harkness, United States Electric Company is secretary and treasurer. E. A. Chenery, superintendent of telegraph of the Missouri Pacific, is chairman of the arrangements committee of the Telegraph Superintendents Association.

THE THANKS OF THE ASSOCIATION.

The following resolutions were adopted yesterday by the American Railway Engineering Association on motion of L. C. Fritch; seconded by G. W. Kittredge:

"Resolved, by the members of the American Railway Engineering Association, that we desire to place on record our appreciation and extend our hearty thanks to the following: To Mr. B. A. Worthington, Rev. R. W. Dickie, Mr. Geo. A. Post and Mr. R. G. Rennick for their admirable and instructive addresses at our annual dinner; to the National Railway Appliances Association for courtesies extended to the members of the Association, and for the valuable and interesting exhibit of railway devices used in the construction, operation and maintenance of railways; to the technical press for their daily reports of the convention and useful information made available to the members; to the official reporters, Messrs. T. E. Crossman and G. W. Burgoyne for their accurate and painstaking reports and the proceedings of this and previous conventions; to the tellers for their arduous labors in counting and tabulating the ballots for officers for the current year; to committee No. 23 on arrangements, for the highly successful arrangements made for the comfort and entertainment of the members and guests attending the convention. And it is recommended to the Board to increase the committee's salary for the coming year."

THE NATIONAL MENACE OF RAILWAY STRIKES.

The directors of the Railway Business Association, who met here on Wednesday, as announced in yesterday's Daily, have given out the following interesting statement:

The country's bare escape during recent months from railway strikes tying up traffic throughout territory containing in some instances nearly half the whole population makes it imperative to remove at once the possibility of such a situation in future.

What will occur if any one of the classes of labor in the operation of railway trains over such an area shall quit work is beyond anything in American experience. It would paralyze society and bring hunger, misery and even death to rich and poor, but especially to the poor.

There is no reason to doubt that demands for increase of wages or more favorable working conditions will frequently take the form of concerted action by employees on many lines at once. The allegation as to cost of living upon which railway employees have relied for public sympathy in their demand for enlarged compensation has been made simultaneously all over the country. The consequent concurrent demand which has developed the large-scale disputes gives every appearance of having become a permanent feature in such negotiations. The Eastern conductors and trainmen have announced a purpose to press demaads after the firemen's case is concluded.

The urgency of the situation leads the Railway Business Association to go outside its main function of conciliation between railways and the public and seek to arouse the public, the railway employees and the railway managers to co-operation and the President and Congress to action at the extra session. The federal Erdman act, through which until recently strikes causing interruption to train service have been almost wholly prevented, has all but broken down at the point where, mediation failing, arbitration was attempted in the large-scale dispute involving many roads at once. The Eastern engineers' case was arbitrated outside the act. In the Eastern firemen's case the roads agreed to arbitration under the act only after earnest protest and because they believed this to be the only means of averting a strike. The firemen through their officials went on record as favoring amendments which would render the act more applicable to present conditions.

The Erdman act should be amended forthwith or legislation substituted for it providing a form of voluntary arbitration so little open to valid objection as to deprive disputants of all reasonable excuse for declining arbitration under the law. To postpone remedial legislation is to invite widespread and perhaps national disaster at any moment.

While effective in averting strikes through mediation in controversies of whatever extent, the Erdman act is unsatisfactory in large-scale disputes if they reach the arbitration stage.

Arbitration outside the act, on the other hand, as tried in the engineers' case, was declined by the firemen on the ground that they desired the decision to be an award, without recommendation of new legislation, and believed the act would so restrict the findings; and also on the ground that the testimony should be taken under oath as provided by the act.

What are the defects of the Erdman act?

The act provides for a board of but three arbitrators, two of whom represent the respective parties. All concerned urge that a decision involving many roads over a wide area, many thousands of employees and many million dollars annually, should be rendered by a board having more neutrals than one. Provision should be made in the act for fixing upon a larger number when desired. An increase in the proportion of the number of neutral arbitrators to partisans will bring more minds to bear upon the many questions arising in large areas and tend to promote equity in the decisions.

The act limits the time for the investigation to 30 days. It is said that in so short a time the investigation is likely to result in little more than a splitting of differences. The time for the investigation should be made elastic.

If statistics and other data now available are unfitted for this purpose, machinery should be established for standardizing, collecting, keeping and furnishing information which will meet the need.

The statute now affects only employees engaged in train service—engineers, firemen, conductors, trainmen, yard and switch men and telegraphers. Other classes frequently appeal to the government mediators, and their organizations have asked that the law be extended to include them. Some of the most serious strikes affecting large territories have been those of shopmen, signalmen and others not engaged in train service. The act should be made applicable to clerks, trackmen, freight handlers, machinists, boiler-makers, blacksmiths, car repairers and so forth, as well as to the train service groups.

It is urged that the burden of mediation, already heavy, will increase as time goes on, especially if the act is extended to include classes of railway employees other than those in train service. It is also pointed out that only a few federal officers are ex-officio eligible to appointment as mediators. The mediator has the function, when the repre-

sentatives of the parties fail to agree, of appointing neutral arbitrators. There would always be the temptation, in one quarter or another, when a vacancy arose in a position the occupant of which is eligible as mediator, to urge candidates primarily because of their supposed predisposition in labor disputes. Nor is there any assurance that future incumbents, however competent in the offices designated in the statute, will by temperament and training be efficient for the extremely difficult work of mediation. The machinery of mediation should be made adequate to the enlarging demands upon it and eligibility to appointment as a mediator having the function of appointing neutral arbitrators should be made to depend as completely as possible upon personality and experience for the specific function of mediation.

Railway managers, railway employees and the public should co-operate to obtain legislation which will place them squarely on the side of industrial peace and the public convenience and accomplish some progress in the direction of equity for all concerned in the settlement of wage disputes.

Avoidance of the possible horrors of strikes is so imperative that it would seem that the President and the leaders in Congress might well include in their legislative programme for the forthcoming extra session consideration of appropriate measures for the strengthening and improvement of the machinery for arbitration in railway labor controversies.

ASSOCIATION OF PENNSYLVANIA LINES DIVISION ENGINEERS.

The Association of Division Engineers on the Pennsylvania lines west held its spring meeting this week in the assembly hall of the Permanent Manufacturers' Exhibit of Railway Appliances, in the Karpen building, Chicago. The association includes about 40 members and delegates, of which at least 35 were present. All division engineers on the western lines are members of the association, and the officers are elected from among these members. An advisory committee, consisting of the officers and chairmen of committees, selects a number of delegates to the meetings of the association, including a man from the office of the purchasing agent, the assistant engineers of motive power and any other officers that the general manager may suggest. These appointments are approved by the general manager.

This association was organized in 1886, and at present holds two meetings each year; the spring meeting in Chicago during the convention of the American Railway Engineering Association, and the fall meeting in Pittsburgh. George Le Boutillier is president of the association and presided at the meetings. There are seven committees, covering practically all work handled under the direction of division engineers. The most important of these committees are those on Track and Tools, Roadway and Ballast, Bridges and Buildings, Wages and Accounts, and Maintenance. All of the committees presented reports at this meeting.

ELBERT HUBBARD ON "GIVING THE RAILWAYS A SHOW."

"Fra Elbertus,' the sage of East Aurora, and the man who made Emerson famous, visited the Coliseum yesterday afternoon. He had just come from Madison, Wis., where day before yesterday, he delivered before the legislature of that state a lecture on "Giving the Railways a Show." When he got through someone tipped him off to the fact that they already had one this week in Chicago, and he came right down to see about it.

His entrance into the Coliseum was unannounced, and for about thirty feet after he passed the door he was unrecognized. But after his "incog" had been penetrated he submitted to an interview. He said that while this show wasn't the kind he meant to talk about before the solons at Madison, still it was pretty good in its way and was in a class by itself, inasmuch as it was about the only show that railways had been given for some time.

He said he believed, in fact, that if the people of the various states through their representatives in legislature and on commissions would give the railway as good a show in its way as the National Railway Appliances Association is giving them in its own peculiar manner, the railways in turn would be able to show the public, tinged as it is with the "Missouri" spirit, that railway conditions are not so bad after all.

The Fra said he felt quite at home in the various exhibits which he visited. He thought he knew as much about railways as the average citizen. At any rate he has ridden on trains several times in his life. He seemed particularly interested in the signaling exhibits and listened attentively while the various aspects of the subject were explained to him. And from all the indications he understood it perfectly.

He authorized the statement that he believes in advertising.

BRIDGE AND BUILDING ASSOCIATION.

About twenty officers and committee chairmen of the American Railway Bridge and Building Association met at the Congress Hotel late Wednesday afternoon to discuss matters of interest to the association and make preliminary arrangements for the convention at Montreal next fall.

TO-DAY'S PROGRAMME.

The American Railway Engineering Association has this year provided, for the first time, for a fourth day. The day will be spent by the members in visiting the Exhibition of the National Railway Appliances Association in the Coliseum and Armory.

PENNSYLVANIA PUBLIC UTILITIES BILL.

At the public hearing at Harrisburg before the legislative committee having in charge the public utilities bill now pending in the Pennsylvania legislature, George Stuart Patterson, general solicitor of the Pennsylvania Railroad, appeared on behalf of the steam railroads. The following is an abstract of his argument:

The position of the railroads is that:

1. The bill should endow the commission with power to secure reasonable rates and facilities. Nothing in the law, however, should contravene the well-known statement of the United States Supreme Court that "the public is in no sense a general manager."

The function of management should be left to the railroads themselves. To illustrate: The commission should have power to insist that equipment be safe and to pass, if necessary, upon the adequacy of the provision made for safety. It should not, however, be empowered to specify the means by which such safety should be secured.

2. The bill should be clear in its meaning, and its language should in general be the same as that of other similar measures which have already received judicial inter-

pretation. In such manner will the railroads understand the precise purport of their obligations.

3. Above all, the bill must be fair to invested capital. It is comparatively easy to force prosperous companies to submit to any burdens which may be imposed up to the point of actual confiscation.

No way has yet been devised, however, by which a man, or set of men, can be forced to embark upon a new enterprise involving the investment of their money unless there is a reasonable probability of profit from the transaction. Capital is volatile. Create unfavorable atmospheric conditions and it vanishes. It knows no national boundary lines. It seeks unceasingly to find a habitat where it will be welcomed and encouraged.

Now, through the development of its resources by private capital, the commonwealth of Pennsylvania has become the premier industrial state in the Union. Railroads and manufacturers have here prospered. But it is perfectly obvious that if we impose undue burdens, if we restrict the prerogatives of management, if we penalize efficiency, and make it evident that this state will not allow those who risk their capital here to enjoy the fruits of initiative, enterprise and industry—no new railroads will be built, and those which exist will make no improvements involving the slightest risk.

In other words, an impasse will develop through the refusal of private capital further to engage in developing our resources, and the public itself through the government will be forced to embark upon the perilous course of building and managing public utilities.

If government ownership is our goal, we must consider carefully the experience the world has had with government management. In general, it may be said that no country has as yet undertaken government railway ownership as a policy deliberately chosen upon economic grounds. Special and local considerations have determined the choice in practically every case.

The most recent instance of this character is that of the Western Railway in France, acquired by the nation in 1909. In 1909 that company's deficit was $7,750,000; in 1910, $11,700,000; in 1911, $14,000,000; in 1912, $16,000,000; and for 1913, the budget estimates that the people must be taxed $18,000,000 to provide the deficit in railway operation.

NEW ROCKFORD MOTOR CAR.

The Chicago Pneumatic Tool Co., Chicago, has developed a motor car which can be started with a crank and is equipped with clutches, enabling the operator to stop the car without having to stop the motor and to start it without having to push the car and the load.

The car frame is built of 3-in. channels, which is the usual standard for the Rockford cars. All joints are oxy-acetylene welded, and the frame is mounted on 1½-in., semi-elliptical springs to eliminate excessive vibration. The wheels are pressed steel, 16 in. in diameter, with standard M. C. B. tread and flange. One of the wheels on the front axle is given a running fit to compensate on curves and to facilitate the handling of the car when taking it from the track or turning it around on a crossing or in the section house.

The car is driven by bevel gear to the rear axle, allowing two speeds in each direction. The brake is attached to the drive axle, and is of the enclosed expanding type which is used on high-grade automobiles.

The motor is a single cylinder, air-cooled, 4-cycle engine of 3½-in. bore and 4½-in. stroke. It is rated at four h. p. Three systems of ignition are provided. In addition to the combined battery and low tension magneto ignition, which is usually called dual ignition, this car has another complete system with its own spark coil, circuit breaker and spark plug. The motor is equipped with a force feed oiler and automatic carburetor.

STEEL TANKS IN CANADA.

The accompanying cut shows the type of tank being used on the new Grand Trunk Pacific and National Transcontinental railways in Canada. In this region the weather is extremely cold during several winter months, and in portions of the country there are tracts of timber subject to forest fires.

This tank was designed to meet these conditions. In order to make it fireproof, no wood is used in any part of the structure, and so far as possible the location is chosen so that forest fires will not be likely to affect the structure by warping its supports. The usual heating arrangement consisting of steam coil or hot water pipe was not considered equal to direct radiation on this work, as small pipes, if frozen, may burst and cause damage and serious inconvenience. It is also found preferable to have as small and simple a heating plant as possible. For these reasons and others, such as cost and ease of installation in these regions, the usual large steel riser has a diaphram or special flanged head about eight feet from the ground, below which no water is stored. The room formed below this diaphram is lined with fire brick, having an air space between brick and steel, or is built of concrete. A door of convenient dimensions is provided into this room and a coal or oil stove placed therein. The stovepipes pass directly up through the tank

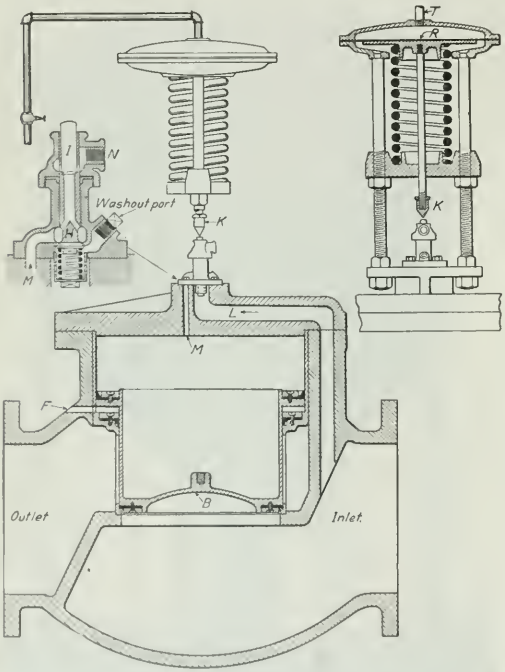
Steel Water Tanks Used on Grand Trunk Pacific.

and roof and water is kept from freezing by direct radiation from stovepipes and heating room. The supply and discharge pipes, also blow-off connection, pass down through the heating room to the ground.

A recent order placed with the Des Moines Bridge & Iron Co., Pittsburgh, Pa., calls for 29 of these structures, most of them to be erected during the present year.

AUTOMATIC CONTROLLING ALTITUDE VALVE

Several changes have been made in the Golden-Anderson automatic cushioned controlling altitude valve, which was described in the *Railway Age Gazette* of February 14, 1908, page 228. The most important of these is in the pilot valve, an enlarged section of which is shown on the drawing. When water is drawn from the tank or standpipe the pressure is



Improved Controlling Valve.

relieved from the top of the diaphragm *R*, causing the valve spindle *K* to raise, thus permitting the high pressure auxiliary valve *H* to close, and the exhaust valve *I* to open, allowing the water above the piston or valve *B* to escape through *M* and *N*. The water above the valve *B* acts as a cushion and when the valve begins to travel upward, air is drawn in through the port *F* and acts as a cushion when the valve closes.

When the water in the tank reaches the required height, the pressure in the pipe *T* and on top of the diaphragm *R* causes the valve spindle *K* to close the auxiliary exhaust valve *I* and open the high-pressure valve *H*, allowing the pressure to come on top of the valve B, which is forced to its seat, thus shutting off the water in its flow to the tank. The upper part of the body is lined with bronze, and the valve *B* is of solid bronze fitted with rubber cups and disc. These altitude valves are so constructed that electrical apparatus may easily be applied and they may be controlled from a distance, in addition to the automatic feature above described. The valve is made by the Golden-Anderson Valve Specialty Co., Pittsburgh, Pa.

SCIENTIFIC SHOVELING.

The application of system to the use of shovels in construction and track work opens many possibilities for economy. The elaborate experiments made by Frederick W. Taylor in his analysis of the hand-shovel service at the Bethlehem Steel Co.'s plant, covering the handling of many kinds of material from iron ore to pea coal, showed that the most economic shovel load to be lifted and thrown a standard distance and height is 21 lbs.

To a degree the problem is one of education of men, but success seems to depend quite as much on the selection of the proper tool as on the development of the men. As the plan contemplates adapting the capacity of the shovel to the weight and character of the material it would seem to require a large stock of shovels. This is the only objection, and it sinks into insignificance when measured with the advantages gained by a standard and uniform load for each movement which becomes impressed on the mind of the workman by the fact that he has changed tools to secure a standard of efficiency.

In the moving of iron ore it was found that the average number of tons handled per man per day was increased from 16 to 59. The average earnings per day per man were increased from $1.15 to $1.88 and the cost of handling was reduced from $0.072 to $0.033 per ton. This system so improved the service that in the second year, when all the work in the yard was task work, it was estimated from the results of the first six months that the saving on the year would be from $75,000 to $80,000.

The application of a standard shovel in railroad track service is now almost an accomplished fact, a large number of roads having adopted a No. 2 for ballast work and tamping. A No. 3 would probably be better as a standard for this work under all conditions. The shovels used in Mr. Taylor's investigation were made by the Wyoming Shovel Works, Wyoming, Pa. Since the great saving made by adapting the shovel to the material has become known, this company is making shovels designed to handle 21 lbs. of any specified material. It has issued a booklet on scientific shoveling, which will be sent on request, in which many of the ways of effecting economy in earth handling by shovels are explained.

UNION SWITCH & SIGNAL COMPANY'S NEW APPARATUS.

The new signal apparatus recently brought out by the Union Switch & Signal Company includes the Type "F" interlocking machine, which is similar in design and principle to the electro-pneumatic type but has a number of improved features which give it a timely interest.

The type "P-3" electro-mechanical machine has also been improved since the exhibit last year. The combination board is made of moulded insulated compound and is built up of units of convenient size. The rollers are so arranged that either top or bottom half can be operated independently or both halves may be rigidly connected together. If one roller does not provide for sufficient contacts and one on either side has more than sufficient space, the bottom half of the second roller may be connected to the first and be made to operate with it. This is done by providing a crank at the bottom of each lever and connecting two adjacent cranks with a link.

Indication lamps are provided below levers for showing condition of track circuits and there is now a mechanical push button for the control of a calling-on-arm from the

same lever as a high arm without the necessity for a stick relay. The arrangement is such that with the lever normal the push button is locked normal and can be operated only when the lever is reversed. With the lever reversed if the button is pushed in it will be locked in until the lever is put normal when it will be automatically restored. There is also a time release.

Another new device is the electric light signal designed for daylight as well as night indications by light only. These light signals have been considerably improved within the last few months as the result of extensive installations particularly on electric railways. The new type consists of a wide sheetiron background in the center of which is mounted the lamp case containing two lenses. These lenses are shielded by a sheetiron hood so as to intensify the daylight indication. The whole device is suspended from the mast by a castiron bracket having a knuckle joint so that the signal may be adjusted to focus toward any desired point.

The new Model 12 polyphase relay consists of an induction motor movement similar to that of the radial type, but instead of having the contacts and fingers mounted radially they are arranged in a manner very similar to those of a direct current relay. The contacts are carried on a slate top. This can be furnished as a two or three position relay, 25 or 60 cycles, and for any voltage.

There are also two new transformers among the new apparatus. One is a standard track transformer and the other is a combined track transformer and reactance. Thus in this instrument two devices are combined, saving space and making for convenience in construction, maintenance, and operation.

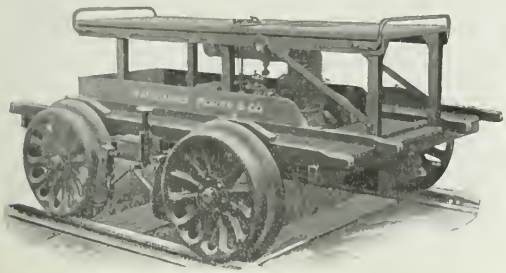
The new stationary automatic reactance is designed to secure a quadrature phase relation between the current in the track coil and that in the local coil of a polyphase track relay. The reactance is connected between the track and the track transformer and is so designed that with the block occupied, the power consumption and flow of current to the track are less than that with the block unoccupied.

The advantages are that it has no moving parts and cannot close up its magnetic circuit during wet weather and thus cause the track relay to open; and it gives ideal quadrature relation between the currents in the two elements of a polyphase track relay.

These and other recent developments are shown at the Union Exhibit at the Coliseum.

NEW FAIRBANKS-MORSE MOTOR CAR.

The Fairbanks-Morse Co., Chicago, has on exhibition at the Coliseum, a new motor car, the No. 29. It has a capacity

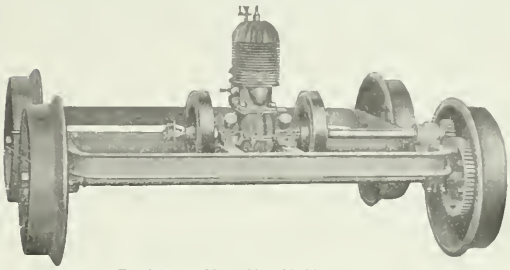


Fairbanks-Morse New No. 29 Section Motor Car.

of six to eight men, seated; weighs 800 lbs., and has a single cylinder, air-cooled, two-cycle, valveless engine, driving the car through a pinion on an extended shaft which meshes with a large gear located within one of the car wheels. The speed of the car is 6 to 18 miles per hour in either direction.

There are also on exhibit light inspection cars, Nos. 28 and 30, and larger cars Nos. 26, 32 and 33 for section, bridge and construction gangs.

The two-cycle engine, air-cooled, is applied to all the cars shown. As these cars go into the hands of many men inexperienced in handling machinery of any kind, the two-cycle engine has advantages for such service on account of its simplicity, having no valves, cams, pawls, gears, etc. Being air-cooled, any trouble from water freezing, etc., is obviated and this also helps to keep down the weight.



Engine on New No. 29 Motor Car.

Lubrication is a distinctive feature on these two-cycle engine cars, the oil and gasoline being mixed, one-half pint of oil to one gallon of gasoline, making it unnecessary for the operator to worry about the engine geting proper lubrication as the system is automatic.

AN IMPROVED DEVICE FOR MEASURING RAIL DEFLECTION.

The customary method of measuring the deflection of a rail under the drop test is to lay a steel straight edge of a given length, or frequently a wooden straight edge with steel corners, on the head of the rail and measure the deflection from the edge of this straight edge to the head of the rail with a rule. This has been found to give rise to considerable inaccuracy. In the first place the straight edges commonly used may themselves become inaccurate, because

A Device for Accurately Measuring Deflection of Rails.

of wear or other reasons. Again, in falling upon the head of the rail the tup makes an indentation in the head. Also, quite frequently the web of the rail buckles more or less, especially under a second or third blow. When measuring from the head of the rail, this buckling and indentation are included in the deflection, and this may explain why there seems at times to be no relation between the deflection and the elongation.

To provide for a more accurate means of measuring this deflection, the device shown in the accompanying photograph has been made to measure the deflection on the base of the rail rather than on the head. This device consists of a steel

bar 3 ft. long, rigidly mounted on two standards, the bases of which are at right angles to the bar. These standards are made of hard steel with a high resistance to wear. In the center a graduated scale passes through a slot provided with springs to retard free movement. This scale is graduated to read to the nearest .05 in., the zero being even with the top of the scale when the lower end is in the plane with the bases of the standards. By simply placing this device on the rail, the scale is pushed up to show the proper deflection and the springs hold it there. It weighs 6.5 lb. This device was developed under the direction of C. W. Gennet, of R. W. Hunt & Co., and has been used by the inspectors of this company for six months at the south works and Gary mills of the Illinois Steel Co. It has given such satisfaction at these points that it is planned to install it in all of the mills in the near future.

D. & A. CONCRETE FENCE POSTS.

The Chicago & North Western established a small plant at Dunlap, Ia., in 1907 for the manufacture of concrete fence posts. This plant was of the open-air character, all work being done when possible in the open air. A small temporary building was erected for a cement storage house. The equipment used was purchased from the D. & A. Post

Concrete Posts on C. & N. W. at Evanston, Ill.

Mold Co., Three Rivers, Mich., and consisted of 265 molds for the 7 ft. line posts and 25 molds for the 8 ft. end and brace posts; also one mold shaker, with a capacity of 12 molds. Three men were employed in this plant, who were paid from 16.5 to 17.5 ct. per hour, and were able to make an average of 60 posts a day. The 7 ft. line posts cost 18.3 ct. each and the 8 ft. end or anchor posts cost 53 ct. each. The posts were reinforced with steel strips ⅛ in. by ⅝ in. and 6 ft. 10 in. long, the concrete mixture being one part cement to six parts gravel.

About 5,000 posts have been manufactured at this plant, most of which have been used in the territory between Dunlap and the Missouri river. The Boyer river for many years was a source of trouble to this portion of the line on account of floods at certain seasons of the year, one result of which was to lift up wooden fence posts and destroy long sections of the right of way fences. The company decided to replace the wooden posts in these fences with concrete, which has been done with satisfactory results. The posts, which were placed in 1907-8, are giving good satisfaction, but it is recommended that future posts be made 8 ft. long and that they have some additional reinforcement in order to further reduce the likelihood of breakage in handling. Some of the posts manufactured at the Dunlap plant have also been used in Evanston, Ill., between the rights of way of the Chicago & North Western and the Northwestern Elevated, as shown in the accompanying photograph.

NEW STEEL DERAIL CONSTRUCTION.

The derailing block of the Hobart-Allfree derailers is now made of cast steel, which is an improvement over previous forms. In addition to this the new design of the base pre-

The No. 5 Hand-Throw Derailer.

sents a smooth outline, and protects yardmen in making it impossible for them to get their feet caught in the device. Another feature of interest is the lip, which brings the lateral thrust incident to derailment directly against the rail rather than against the supporting base. Then, too, the derail is clamped directly to the rail, a feature designed to eliminate trouble caused by partial displacement or by damage during either a derailment or an accidental trailing through.

No. 7 Mechanical-Throw Derailer.

The No. 7 derail for mechanical throw is made longer so as to insure positive action at unexpected higher speeds as well as at low speeds. The No. 5 hand throw is also made of cast steel. This and the No. 7 are both on exhibition at space 107 in the Coliseum, by the Hobart-Allfree Co., Chicago.

Railway Age Gazette

Including the Railroad Gazette and the Railway Age

PUBLISHED EVERY FRIDAY AND DAILY EIGHT TIMES IN JUNE, BY THE
SIMMONS-BOARDMAN PUBLISHING COMPANY,
83 FULTON STREET, NEW YORK.

CHICAGO: Transportation Bldg. CLEVELAND: Citizens' Bldg.
LONDON: Queen Anne's Chambers, Westminster.

Subscriptions, including 52 regular weekly issues and special daily editions published from time to time in New York, or in places other than New York, payable in advance and postage free:

United States and Mexico.....$5.00
Canada.....6.00
Foreign Countries (excepting daily editions).....8.00
Single Copies.....15 cents each

Engineering and Maintenance of Way Edition and four Maintenance of Way Convention Daily issues, North America, $1.00; foreign, $2.00.

Entered at the Post Office at New York, N. Y., as mail matter of the second class.

WE GUARANTEE, that of this issue 8,250 copies were printed; that of those 8,250 copies, 6,796 were mailed to regular paid subscribers and 140 were provided for counter and news companies' sales; that the total copies printed this year to date were 113,309 copies—an average of 8,716 copies a week.

VOLUME 54. MARCH 28, 1913 NUMBER 13.

CONTENTS

*Illustrated.

A STATION agent should be paid what he is worth. Everybody will agree to this. But how to decide the rate of pay is not easy. The significance of the letter on this subject, printed in another column, is in the suggestion which it gives that a straight-edge is not a suitable instrument for regulating agents' pay. To the superintendent this suggestion is a reminder that labor-union principles, forever seeking "standardization," do *not* apply. But the absence of the stimulus of the labor-union grievance committee throws on the superintendent all the greater responsibility for seeing that no grievance arises. "Each case should be considered on its own merits." This means that the superintendent must know *very much* more about the work, at some of his stations, than superintendents usually know. In the absence of well-defined rules for grading the salaries of agents and fixing the number of helpers that they should have, a constant effort to increase the quality of the service will, in the long run, indicate quite well what ought to be done; for if agents are made more efficient, and if this policy is pursued vigorously, the men, when not adequately paid, will resign and go into other business. At any rate the younger men will do this; and these men's status should be reasonably well defined before they become old. An efficient agent, popular in his own town, should have his pay slightly increased every few years. In sticking to the policy of advancing agents only by transferring them to another station, a railroad often goes against its own interest. The worth of a station agent, like that of a physician, or a lawyer, is in large degree measured by his popularity, which in the majority of cases is a plant of slow growth. At least, it is one that cannot be forced.

FOR a number of years the electrical night of the New York Railroad Club has been one of the features of the year's program. Heretofore the discussion has been marked by the crispness of the ideas advanced and the, sometimes, sharp controversy between advocates of rival systems, coupled with some more or less poignant prognostications of what the future was to bring forth. But this atmosphere of the meeting was dissipated on Friday last, and the entire tone was changed from that of a few years ago. The discussion opened with the somewhat startling statement that no new electrification work of steam railroads had been undertaken during the past year. There had been some extensions, but no new work, and the reason given was the frank one that nothing had come up that warranted electrification. It was stated as a matter of course. The flamboyant attitude of the electrical engineer of a dozen years ago, which has been gradually disappearing, showed no signs of even a past existence. The atmosphere was one indicating a settled state of affairs. Electricity no longer needs an advocate. Its capabilities and limitations are known, and it is accepted by all at its face value, and, so, it has dropped out of sight as a question to be discussed as to its availability and possibility of application. It can be made to do its work and its adoption has become merely a matter of local conditions, operating facilities and cost.

ONE of the fundamental contentions of the firemen in presenting their demands for higher wages to the board of arbitration is that labor and, in this specific instance, firemen should share in the increase in revenue of railroads due to increased efficiency of the plant and to the greater volume of business. In presenting their case and in examining both their own witnesses and cross examining the railroads' witnesses they have at times confused with this contention certain socialistic doctrines which may be inadequately summarized by saying that they demand that while labor be protected from any of the risks of a business enterprise, it shall, on the other hand, share proportionately with those who take the risks in profits, if the business turns out to be profitable. On Tuesday issue was squarely joined on the underlying contention of the firemen, in the testimony of D. F. Crawford, general superintendent of motive power of the Pennsylvania Lines West. Carefully prepared figures had been submitted showing that from actual observation it was clear that there was no relationship between the weight of a locomotive and the work of a fireman. Mr. Crawford gave it as his unhesitating opinion that larger locomotives now in service were not worked in general as close to capacity as were the smaller locomotives in service some years ago, and that if the work of the fireman varied in any fixed ratio, it was

more nearly in proportion to the percentage of work that was being gotten out of a locomotive, compared to its total capacity, than on any other basis. Mr. Crawford was asked whether in his opinion the heavier trainloads and greater traffic density were due to any added effort or any increased efficiency on the part of the man firing the locomotive. His answer was an unqualified "no." Cross examining Mr. Crawford, Mr. Carter asked him whether this was not from the point of view of the employer, implying, as we understand it, that the employer's point of view is that labor should not be allowed to share in the profits, in the gaining of which they took no risk; but Mr. Crawford and probably Mr. Carter himself were not confused by this secondary issue. Mr. Crawford made it unmistakably plain that, regardless of any theory supposed to be held by employers at variance with the theories of organized labor, in his opinion the fireman had contributed nothing whatsoever as a factor in the development of heavier trainload and greater traffic density. If we understood Mr. Crawford correctly, the fireman has no more claim to a share in the increase in earnings on freight due to larger locomotives than has the mechanical draftsman who copies from an engineer's instructions the drawings of this locomotive.

THE address by Halford Erickson, member of the Wisconsin Railroad Commission, an abstract of which is published elsewhere in this issue, is of especial interest at this time for several reasons. The general subject of regulation of public utilities by commissions is prominently before the public; and Mr. Erickson's address is a broad statement and discussion of the policy of regulation followed by a commission that has large powers and has for some years been recognized, regardless of changes in its personnel, as one of the ablest and fairest regulating bodies in the country. The specific subject of valuation of railways also is prominently before the public, Congress having just passed a law providing for a valuation of all the railways in the United States; and Mr. Erickson tells in detail how valuations of all kinds of public utilities, including railways, are made, and the factors that are included, by a state commission that has studied this subject thoroughly from the standpoints of law, economics and public policy, and that has had a long and varied experience in making public utility valuations. Finally, the address gains interest from the experience and personality of its author. Mr. Erickson, prior to his appointment to the Wisconsin commission, was active in the politics of his state, was a supporter of the LaFollette wing of the republican party, and was one of Governor LaFollette's original appointees to the commission in 1905, when it was reorganized with largely increased powers. The other members appointed at that time were John Barnes and Prof. B. H. Meyer, both of whom long since retired from the commission. Mr. Erickson is, therefore, the oldest member of the Wisconsin commission in point of service. In view of all these facts, the moderate tone of Mr. Erickson's address, and his outline of the principles and methods that should be followed in public regulation, have much significance. His utterances are equally different in form and substance from those the public is accustomed to hearing from the radicals among politicians and railroad commissioners, and from the extreme conservatives among public utility managers. Undoubtedly both the tone and substance are partly due to the fact that Mr Erickson has a natural disposition to be moderate; but they must also be very largely due to his thorough study of and great experience with the matters he discusses. The basis of the hope for the success of government regulation in the United States is that the number of moderate men among both those who regulate public utilities and those who manage them, is, as indicated by their public utterances, rapidly increasing and that it will continue to do so; for experience in this country has shown that men of moderate temper and views can usually agree on and carry out harmoniously sane and fair policies.

GRADE AND CURVE REDUCTION.

FEW subjects are of more vital importance in the study of economical railway operation than the extent to which grade and curve reduction should be carried. Several roads are now spending large amounts to secure standards of grade and alinement which would not have been considered practicable a few years ago. Theoretically, the best line between two points is a straight line with a uniform grade. Practically, the topography, possible traffic and ability to secure easier grades may make it advisable to vary considerably from a straight line. A reduction in the ruling grade enables larger train loads to be handled and thereby reduces the cost of operation. On the other hand, an increase in the length of the line increases the cost of construction, the fixed charges and the cost of maintenance. It is important to determine the economical limit to which this increase in length may be carried to secure lower ruling grades. This limit varies on different roads, for the greater the traffic, especially of low grade freight which permits heavy train loading, the greater the amount a road is justified in spending to reduce its grades. Obviously, a road having the traffic density of the Pennsylvania Railroad can afford to spend more to secure low grades than a western line having only a few trains a day.

Other considerations also enter, one being the starting resistance of a train, which is considerably greater than the resistance of the train in motion. Numerous tests have shown this starting resistance to be approximately equivalent to that of a 0.3 or 0.35 per cent. grade. Where possible, therefore, ruling grades are either reduced by this amount near stations, water tanks, signals and other points where trains stop frequently, or these facilities are located on grades lower than the ruling. As trains may occasionally have to stop at any point on the road, many engineers have not considered it advisable to reduce the ruling grade below 0.3 per cent.; but in the last few years lower ruling grades have been adopted on several roads, the first of which was the Spokane, Portland & Seattle, which was built in 1907 with a maximum grade of 0.2 per cent. between Pasco, Wash., and Portland, Ore., a distance of 230 miles. While this line was built along the Columbia river, the low grade adopted materially increased the cost of construction and caused considerable discussion. The Baltimore & Ohio fixed 0.2 per cent. as the maximum grade for a second track across the state of Indiana, which has been built during the past two years. The Erie is building a second track between Meadville, Pa., and Corry, which has the same ruling grade and involves some very heavy work. Measured by the standards of previous years, these grades may not be justified, but their adoption is proof that new standards are being developed.

One argument in favor of such low grades is based on the reasoning followed in adopting momentum grades. Within recent years the momentum or velocity grade has come to be considered approved practice when located between stations where there is no cause for regular stopping of trains. In such cases it is considered advisable to run the risk of a train being stopped by some unexpected cause, which would make it necessary to double to the first siding beyond the top of the grade, or to back down and make another run for the hill. The 0.2 per cent. grade may be operated in the same way if the grades at stations, water tanks and other regular stops are so laid that the virtual grade at these points does not exceed the actual ruling grade.

Even more startling than these standards for grade reduction are those which are being adopted for curves. The Burlington for the past three years has been building a second track along its line extending 300 miles south from St. Paul, Minn., along the east bank of the Mississippi river. The old line was built with a maximum curve of 3 deg. at a moderate cost. In connection with the building of the second track, this standard of curvature is being reduced to 1 deg., which adds considerably to the cost. The Milwaukee has been building a second track between Minneapolis, Minn., and Aberdeen, S. D., the past three years

and is at present double tracking its line across the state of Iowa; and in both cases the maximum curvature is 1 deg. The lines included in this work aggregate over 600 miles and involve some heavy construction. These examples indicate that railways are being built today to standards which were not thought of a few years ago. For this reason the analysis of the various kinds of resistance by Walter Loring Webb in an article elsewhere in this issue is especially valuable. The subject is so important that it deserves serious consideration; and a thorough discussion will help to bring together all the essential facts.

"AMERICAN METHODS" AT HOME AND ABROAD.

THE annual report of the North-Eastern Railway of England for 1912 shows interestingly the results gained on an English railway by what are significantly known as "American methods." Some years ago George Paish, editor of the *Statist* of London, published a series of articles criticising the operation of English railways as unnecessarily costly. These papers were republished in a book entitled "The British Railway Position." The main ground of Mr. Paish's criticism was that the English roads handled their traffic in too small train loads. He sharply contrasted the fact that the train mileage of English railways increased practically as fast in proportion as the amount of traffic they handled with the fact that the railways of the United States, by working steadily to increase their freight train loads, handled a rapidly growing business without a proportionate increase in the number of train miles. The railways of the United States long ago began compiling ton mileage, passenger mileage and train load statistics, and it has been largely by constant study and comparison of these that the railway managers of this county have been able to exercise supervision that has resulted in the development of the very large freight train loads in which business is handled here. Mr. Paish urged the railway managers of England to follow the example of their American brethren. He recognized the fact that owing to differences in conditions, traffic in England could not be handled in as large train loads as in the United States, but he was sure that the train loading of English railways could be increased and that thereby substantial economies could be made.

Mr (now Sir) George Gibb, then general manager of the North-Eastern, soon afterward introduced "American" methods so far as he thought they were applicable to British conditions. The North-Eastern ever since has compiled and used statistics similar to those of the railways of the United States. The results are indicated by its train load, train mileage and financial figures. In 1902, when it began compiling these statistics, its average goods train load was 59.76 tons; in 1912 it was 95.4 tons. In 1902 its mineral tonnage per train was 113.81 tons; in 1912 it was 183.86 tons. In 1902 its total average tonnage per freight train was 84.23 tons; in 1912 it was 133.84 tons. The increase in its average freight train load in 10 years was 66 per cent.

The average freight train load of the North-Eastern does not seem large when compared with that of the railways in this country, which, in 1910, was 380 tons. But when its trainload is compared with that of English railways in general the showing is quite different. While no trainload statistics for all of the railways of the United Kingdom are available, other statistics that are available indicate that their average trainload is only 85 to 90 tons. The main reasons for the small train loads in England are that the average haul per ton is very short—it was only 24 miles on the London & North-Eastern in 1912—that freight is shipped in small consignments, and that the railways handle it in small cars and in trains that are run on regular schedules and at high speeds. The experience of the North-Eastern shows, however, that the British roads by the use of American methods can increase their train loading. The North-Eastern, largely because it has secured better train loading has strengthened its financial position. Its property is well maintained; and it announced a dividend for the last half of 1912 at the rate of 7½ per cent. per annum, which is more than twice the average for British railways.

Not many students of railway economics seem to appreciate that the system of economizing by handling freight traffic in large train loads originated in the United States, or how largely it is still confined to this country. For the development of this system the greatest credit to any individual is due to James J. Hill. The only country whose railways handle their freight in anywhere near as large train loads as those of this country is Canada; and there the methods developed in the United States have been applied by railway managers such as Sir William Van Horne, Sir Thomas Shaughnessy and Charles M. Hays, who were born in the United States and received their early railway training here.

The way that the freight traffic of the Canadian roads is handled contrasts sharply with the way in which that of the railways of Australia—the second greatest of British colonies—is handled. The freight traffic density of the Canadian roads is very much larger than that of the New South Wales roads, the average ton miles per mile in Canada in 1912 being 731,776 and in New South Wales only 226,906. While the volume of freight traffic on the New South Wales roads is comparatively light, a large part of it is well adapted to heavy loading, 63 per cent. of it being minerals. Nevertheless, while the Canadian roads handled an average of 325 tons per train in 1912, the New South Wales roads handled an average of only 90 tons per train. In consequence, in spite of the fact that the freight density of the Canadian roads was over 220 per cent. greater than that of the New South Wales roads, the New South Wales roads actually ran more freight trains per mile to handle their very much smaller traffic, the average freight train miles per mile on the Canadian roads being only 2,252 and on the New South Wales 2,512. It is largely owing to this that the Canadian roads can make an average rate of 7.57 mills per ton per mile, while the New South Wales roads charge 1.78 cents.

It strikes a student of American and Canadian railway affairs as rather curious that in Australia, in spite of the light traffic, the matter of "duplicating"—in other words, double-tracking—the lines is being vigorously agitated. Although the New South Wales lines are handling only a traffic which any single track railway in the United States or Canada would handle with ease, it is, nevertheless, a fact that some of their lines are congested. What they are congested with, however, is not traffic but trains. It would seem from their statistics that by increasing their car loads and train loads the New South Wales lines could handle their freight traffic with one-half as many freight train miles per mile as they now run, and thereby make large savings in operating expenses and postpone the time when a large investment in additional trackage will be necessary. Even if they were doubled their freight train loads would be only a little more than half as large as those of the Canadian roads. The Canadian roads handle 63 per cent. more ton miles and passenger miles per mile than those of New South Wales; yet their train miles per mile are 18 per cent. less and their operating expenses per mile are slightly less.

The difference between the rates and operating results of the Canadian and the New South Wales lines, both of them in new and undeveloped countries, show how much more desirable is the application of American methods than of English methods to transportation in such countries. The fact that the New South Wales railways are operated by the government and most of those of Canada by private companies has no small bearing on the matter.

"KEEPING THE BUNK IN BUNKUM."

IN an article in the *Saturday Evening Post* a few weeks ago, Samuel G. Blythe compared the methods in the English House of Commons and in the American Congress. After many years spent in close contact with the American legislator he went to England to take a close look at the legislator and legislation there. He concluded that while there may be a question historically whether it was the English parliamentarian or the American congressman "who first put the bunk in bunkum," there can be no doubt that at some time or other both put it in and that they are both sedulously keeping it there. Congressmen are being assisted in this country by the state legislatures and many other public officials.

Not long ago the Supreme Court of the United States (212 U. S. 1) criticised the disposition of legislative bodies (Congress, legislatures, and city governments) to dodge their duties and leave it to the courts to decide whether private property is being confiscated. Legislators very often "pass it up to the courts," to employ their own language—that is, enact any measure the notion of the hour or the clamor of the street suggests, notwithstanding they may believe it to be unconstitutional or otherwise invalid. This kind of disloyalty to duty and to country has brought undeserved criticism upon the courts for declaring void laws passed by the representatives of the people.

The crying need of the time in getting actual law to conform to business requirements in some way of taking the "bunk out of bunkum." In the House of Commons they have one advantage over us, viz., that, with few exceptions, no bills can be introduced except by the government; that is by the party in power. In this country every member can introduce "bunk" bills without limit.

* * *

For a number of years men seeking to acquire or desiring to retain office have employed the spectacular means of going after "big business" or "the man higher up." This gives the statesman a position in the limelight, does not detract from the voting power behind him, and consequently has become the most popular course to take.

The spectacular regulation of railways has gone so far as to provoke a protest from the sober people of the country, who see that the present earnings of the companies are inadequate for the good of traffic and the safety of the public. But many a quack statesman went into office and achieved distinction by spectacular assaults upon the carriers. The railway companies were largely defenseless; for, even their employees often voted against their interests down to a year or so ago, when many of them began to see on which side their bread was buttered. So the legislator was free to go through his spectacular performance without suffering a loss of votes. Where his activities would alienate voters, or affect unfavorably the interests of those who control votes, he maintains "a masterly inactivity."

There is no objection to the proper supervision of railways to insure reasonable rates and to prevent discriminations. But regulation of railways illustrates what a thundering emphasis has been put upon what is of comparatively little consequence to the man who pays the monthly bills, while matters of living costs bearing with extreme weight on him and his family have passed and still pass unremedied and, indeed, almost unstudied. So when the cry about the steadily increasing cost of living reached its loudest the legislator was unprepared to discuss or deal with the subject. He was bewildered because his ten-year assault on railway rates had proved the prophecy of railroad managers by producing no effect to the benefit of the man who pays the bills. The statesman was outclassed by the occasion and the opportunity; and nothing definite or practical is being done to correct the wasteful and oppressive methods of business that are a real back-breaking weight on the consumer.

Take, for example, the case of the multitudinous class called "middlemen." Sometime ago a railroad officer bought a pound of California cherries in Chicago for 30 cents. The man who had invested his money in the orchard, taken the risks and performed the labor of production, sold the cherries for four cents. The carrier hauled them 2,500 miles for 1.15 cents. The middle-men got the other 24.85 cents. This is not an extraordinary case. The common carrier's charge which enters into the food and clothing and other necessaries of the average family is trifling. Nevertheless, for about ten years the interest and political activities of a school-bred and college-bred country have been turned toward the hammering down of freight rates. If something had been done about eliminating that 24.85 cents on cherries and a similar part of the cost to the consumer of vegetables, eggs, butter, poultry, meat, fruit, and other necessaries, the cost of living might be quite another matter today.

Recently a case was tried before the Interstate Commerce Commission in which middle-men in Kansas complained of freight rates which were prejudicial to them in "their territory" (as they termed it) in comparison with rates paid by middle-men at St. Louis and at Kansas City. There was the so-called "Topeka territory" the "Wichita territory," the "Salina territory," and the "Hutchinson territory," in which the shippers thought they had a right to interject themselves between the consumer and the seller, and thereby add to the costs of living. The consumer should not be obliged to buy in any of the territories mentioned, or in Kansas City or St. Louis, if the thing he wants is not made at one of those places. The consumer should be helped to buy as far as practicable direct from the manufacturer or the producer. Most of the complaints against the rates of carriers made before the Interstate Commerce Commission and before the state commissions have been made by the middle-men, and most of the decisions of the commissions have tended to strengthen and entrench them. The noise of contention which has all but cracked the firmament during the last ten years has not been, as so many think, the sound of combat between freight-payer and carrier between a people struggling to be free and predatory corporations fighting to maintain a thralldom. The strife has been chiefly of middle-man against middle-man, with the carriers and the real freight-payers bearing the burden.

* * *

The monopoly and the largely needless cold storage of eatables has received no adequate attention while the legislator has been "keeping the bunk in bunkum" by clamoring for the head of the man higher up. A lower cost of food and a minimum amount of it that is tainted would do the average worker much more good than he could derive from the presence of a big man in a penitentiary. The grossly inefficient methods of distribution and delivery in the cities have increased as rapidly as the costs of the middle-men. And these costs, unlike railway freight charges, weigh heavily on the individual.

Closely related to the default mentioned in the preceding paragraph is the general uncleanness of food and water. Recently published statistics show that in 50 of the leading cities of Europe the cases of typhoid fever are only one-fifth as many as they are in the leading cities of the United States. In this country anybody has been pretty free to sell anything to anybody else in the way of dirty foods and dirty drinks. Investigations have shown that in many of the kitchens in the cities where food is prepared in large quantities care and cleanness are uncommon. Bread and other foodstuffs are handled and delivered without being wrapped. Formerly Chicago followed the example of the pious Hindoo, who lives where cholera begins, and drank the water from its wash basin and drainage system. Later it constructed a drainage canal and poured its sewage into it; and the cities along the Mississippi complained that it thus kept up to a degree the Saxon practice described by Macaulay of throwing slops and uncleanness out of the windows and into the streets, perchance upon the heads of passers-by. Meantime our legislators have been thundering about railway over-capitalization that cannot be proved and denouncing the lowest freight rates in the world.

Nor have legislators given relief from the injustice of our so-called "system" of taxation. The burden upon the poor householder and the large corporation is very heavy, while it is relatively light on many that are competent to pay. A good side-stepper need pay nothing. But of course there is nothing political to be lost by "soaking" the small taxpayer; there is spectacularity and popularity to be gained by going after the common carrier; and there is some risk in going after the big local business man.

* * *

The law writers say that as the power to tax is the power to destroy, it should be exercised only to the least degree necessary to support the government. But the question with the modern statesman is not where it *should* be exercised, but where it *can* be; and all the inventive genius of the Yankee has been exercised in devising new ways to lay taxes. In several instances the rivalry of publicans in different states to collect an inheritance tax on the property left by a man has portended that one of these times the corpse will be stripped of its cerement. Everybody is paying more taxes than he ever did before, and yet the Taft administration had to invent the corporation earnings tax to get the country out of the hole into which the Roosevelt reign had put it.

Where does all this money go? There is probably not a city in the country of over 100,000 population with adequate schoolhouse facilities. We do not pay our teachers reasonably, and have often been twitted by foreigners with being the only people in the world that let out the education of their children to the lowest bidders. We don't pay our judges adequately. The management of almost any public institution affords material for a scandal on any dull day that a newspaper wants to look in. We don't enforce our laws against crime. What becomes of all the money raised by taxes? The constant increase of taxes, like the constant hammering of freight rates, does not seem to produce results. Should not actual law be brought up more nearly to such needs of business? There would be no "bunk" in a genuine reform of taxation Doubtless that is why the dull and difficult subject does not recommend itself to most legislators.

* * *

One of the results of our grossly inefficient government is that over 9,000 homicides are committed in this country in a year. Might not conditions be improved by regulating railway rates a little less and murder a little more? Another result of inefficient government—of the failure to pass and enforce good laws—is that almost 5,500 trespassers are killed on our railways annually. Is regulation to save the lives of passengers so much more important than regulation to save the lives of the fifteen times as many trespassers who are killed?

How much longer will it take the good people of this country to awaken to the fact that the need of the time is for putting more stress on the important and less on the relatively unimportant; that "bunkum" is not good government; that "bunk" is not the corner stone of good government; and that therefore "keeping the bunk in bunkum" is not the first duty of a statesman?

NEW BOOKS.

Regulation, Valuation and Depreciation of Public Utilities. By S. S. Wyer, consulting engineer, Columbus, Ohio. Published by the Sears & Simpson Co., 116 West Spring street, Columbus, Ohio. Flexible leather binding; India paper; 313 pages. Price, $5.

This book is a discussion and compilation of the pertinent, economic and legal facts relating to the valuation of public utilities. The book is intended not as an argument for or against valuation, but rather an attempt to establish a code for valuation. No attempt will be made here to discuss the author's theory of valuation, since it is sufficient to say that no two engineers agree exactly as to the details of the basis on which a valuation should be made. The book is well gotten up. It contains, besides 13 chapters on the general subject of valuation, two chapters giving engineering and reference data, and a sixteenth chapter containing a bibliography. The book has 47 illustrations.

Letters to the Editor.

ENTERPRISING STATION AGENTS.

Queenstown, Wis., March 20, 1913

To the Editor of the Railway Age Gazette:

In your issue of February 21, page 334, in an article on "What Many Station Agents Miss," we are told in an interesting way how station agents could use their spare time to assist the company by getting new industries located at their stations; giving some instances of what had been accomplished in that line. The agent's time belongs to the company employing him and it is his duty to do all in his power to use his spare time outside of his regular duties to secure extra business.

There are two sides to this question. I prefer the station I am appointed to rather than the one I have worked up to a good business. It is one thing to get in new industries, but it is a decidedly different matter to take care of them after you get them into your town. I think that the main reason that more agents do not keep awake in that line is that the railway companies do not seem to realize that the increased business means increased work on the part of the agent. If some man before him has managed the station without the increased business, they will work the life out of him; and if he cannot do the work, after having been the means of getting the increased business, they will appreciate his work by removing him and getting someone else to take the position, at the same salary and no more help. My experience and observation have convinced me that this is the way it goes. Such an appreciation doesn't offer much inducement for a man to "let out his belt" and work hard.

I am telling you plain facts. It seems to me that in handling different men, each case should be considered in a class by itself, as much as possible. The straight edge of a rigid rule should not be applied to all cases indiscriminately. I believe that, if each case were considered on its own merits, far greater justice and efficiency would be accomplished. If a station is in real need of additional assistance, and does not get it, the surplus business will many times be lost or driven away through inattention or intentional neglect. It does not take much increase in earnings to pay another clerk's salary. M. L. D.

SUITABLE STUDIES FOR STATION AGENTS.

Three Lakes, Wis., March 17, 1913.

To the Editor of the Railway Age Gazette:

Our modern magazines abound with advertisements of correspondence schools guaranteeing to teach everything from Law to Engineering, and from How to Sell Real Estate to How to Speak French. It has been my observation that railroad men, especially station and office men, are great consumers of these so called courses of instruction; and, while for one already somewhat acquainted with the subject which he essays to study they might be of some assistance, I believe that in the majority of cases they are soon dropped, leaving the purchaser out of pocket the amount he has paid, and his employer out the time and energy he has wasted on it.

It is my belief that most of the railroad employees taking up these courses do so, not because they really want to study law, banking, civil engineering, or the dozen and one things they take up, but simply because they are ambitious to fit themselves for a higher and more remunerative position; and the advertisement, with its alluring literature, is the only way they see open. If the railroads would make it possible for them to get in touch with good railroad literature, and books giving instruction on railroad matters they would not waste their money, nor their employers' time, on instructions pertaining to outside occupations; and both the company and the employee would be ahead.

I believe that if some department of the railway made it a

point to keep in touch with all books published pertaining to the railway business, reporting on each as to its merits; and to assist railway employees to any possible reduction in rates of subscription to the better class of railway magazines, such as the *Railway Age Gazette*, much good could be accomplished, and much assistance given to the rank and file of employees in gaining proficiency in their work.

D. E. Lamon,
Agent, Chicago & North Western Railway.

SLOVENLY WHISTLING.

Bradford, Pa., March 8, 1913.

To the Editor of the Railway Age Gazette:

While much has of late been written upon the very commendable "Safety-First Movement," I do not recall having read anything on one subject which might properly come under this head—that of the proper use of the locomotive whistle in conveying signals.

To illustrate, the book of rules prescribes two long followed by two short blasts of the whistle on approaching a road crossing. Stand for a couple of hours at a road crossing on some busy main line—or, better yet, at a place like Depew, N. Y., where the New York Central, the Lehigh, the Lackawanna and the Erie parallel each other within a comparatively short distance—and listen to all of the various interpretations of that rule. You hear two blasts followed by two shorter ones, all consuming from one to three seconds; and, all being quiet and weather conditions perfect, the whistle is heard; with conditions unfavorable it is not heard. Then there is the whistle blown with such poor spacing of the blasts that at a distance it may sound like one long and two short blasts, or like two long and one short. Next you may hear two reasonably long followed by two short blasts, all full, clear and nicely spaced. And so on; as each train comes along there is a different style to the signal, some good and some not.

This applies to other whistle signals as well. Several years ago while spending the night on a farm midway between Dunkirk and Brocton and about half a mile from the Lake Shore tracks I heard a limited train on that road whistle in a manner that sounded good. The two long blasts were each of about three seconds' duration, and the two short ones of about one and one-half seconds and about a two-second interval between the blasts. Have you heard the station whistle of one short blast of less than one second's duration? A blast of from five to ten seconds would have clearly advised the train crew as well as the agent at the station of the train's approach to the station, while it is extremely doubtful if the "less than a second" blast does.

I believe that more care should be exercised in handling the whistle than is now the general practice. The blasts should be sufficiently long and fully spaced to clearly, distinctly and definitely communicate the signal intended. While it may be technically complying with the law to blow the whistle any old way, yet equitably and ethically it is not a reasonable compliance unless the results for which the law is intended are fulfilled.

W. R. Shaw.

[We print this rather long letter because it brings up a subject to which more attention should be given. The title which we have put on the letter expresses an idea which must arise in the mind of the careful railroad officer very frequently on the great majority of roads. We have touched on this subject editorially now and then. The few superintendents who have responded to what we have said have reported their experiences in such a way as to indicate that most superintendents and trainmasters are too much engrossed, with matters deemed more important, to give more than occasional and superficial attention to this one. Our correspondent commends the artistic performance of the engineman of the Lake Shore Limited who cheered the farmers of the "grape belt" with a signal which awoke the echoes of the night for about 15 seconds. We can readily understand that in a lonely farm house, half way between Dunkirk and Brocton, especially if not situated too near the railway, one might be glad, in the silent watches of the night, to hear this evidence that the world was still alive; but, unfortunately for this innocent theory of life, there are thousands of people, all along the railroads of America, who make a very rational demand for less noise instead of more. It is not always easy to adjust the equities with precision, for where trains are very numerous the briefest whistle blasts become a nuisance by their frequency. The only reasonable rule, therefore, is to make every blast as short as is practicable. Two seconds is long enough for the highway crossing signal; three seconds should be called very long. To require every engineman to rightly proportion the length of all the sounds is the duty of every superintendent. In many situations it is a plain duty to the public not only to shorten blasts, but to use softer whistles.—Editor.]

SECTIONAL CROWN FIREBOX.

New York, March 11, 1913.

To the Editor of the Railway Age Gazette:

The article on "Impressions of Hungarian Railway Practice," by Henry W. Jacobs, in your issue of March 7, illustrates a firebox having a crown built up of channel sections and designated as the Polonco sectional crown firebox. The statement is made in a foot note that: "The first one was built 30 years ago by the late Herr Polonco, an Austrian engineer," from which the natural implication is that the design was originated by the party named.

As a matter of fact, it is that which has been applied to some extent in Europe, under the title of the "Polonceau firebox," having been patented by Monsieur Polonceau, a *French* engineer. (French patent No. 124,069, April 25, 1878.) It will be found illustrated in *Organ fur die Fortschritte des Eisenbahnwesens in Technicher Beziehung*, Band 16, 1879, Taf. III, Figs. 13 and 14, and in *La Chaudiere Locomotive et son Outillage*, by G. Richard, Paris, 1886, Figs. 24 to 27, and the following statement (literal translation) is made regarding it: "The entirely recent invention of M. Polonceau has not yet received the definitive sanction of a prolonged practice, but it seems difficult to foresee, for this logical simplification of the firebox of locomotives, anything other than a full success."

In both these publications, strips of metal are shown interposed between the channel sections. It is clear that Mr. Jacobs' informant has, doubtless inadvertently, misled him, and as to "Herr Polonco, an Austrian engineer," I think that "there never was no sich person."

However, this may be, the credit of originality of this design cannot be awarded to either Monsieur Polonceau or "Herr Polonco," nor was it first *built* by either of them, as will appear by reference to the illustrated article entitled "Locomotive Boiler, Designed by Joseph A. Miller, C. E., Boston, U. S.," in *The Engineer*, London, March 3, 1871, page 142, from which I make the following excerpt: "The boiler, illustrated in the accompanying engraving, unites two of Mr. Miller's patents, each of which has been tested by practice. Fig. 1 is a longitudinal section of a locomotive boiler, 15 ft. long with 4 ft. 6 in. barrel. . . . The crown chest (sic) is made up of flanged sections 6 in. wide and 6 in. deep. They are arched, and besides having great strength, Mr. Miller claims that they conduct heat into the water." See also *Eisenbahnwesen*, Band 8, 1871, Taf. K, Fig. 15.

Another application of the same principle is shown in the U. S. patent of H. S. Bryan, No. 198,342, dated December 18, 1877, the channel sections being, in this case, disposed longitudinally, instead of transversely, as in the Miller and Polonceau designs, and it has been carried to its logical development in the Jacobs-Shupert firebox, in which the roof or wrapper is similarly built up of channels, connected to those of the crown by interposing stay sheets.

J. Snowden Bell.

BALDWIN LOCOMOTIVES BUILT DURING 1912.*

Tendencies In Design and Construction of Freight and Passenger Power as Shown by a Survey of Last Year's Output.

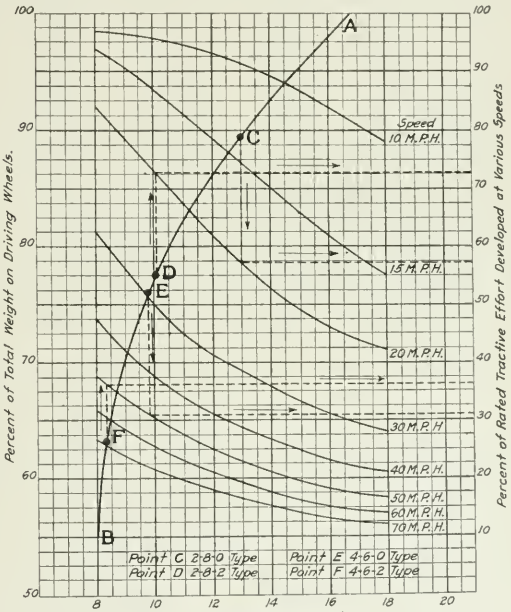
Locomotive development is influenced principally by traffic requirements, and the locomotives built during 1912 clearly illustrate the fact. Increasing train weights, the need for higher operating efficiency, and more stringent regulations with a view to promoting safety in travel, all combined to influence the types of locomotives placed in service. To meet these conditions has required locomotives of increased average weight and a more general adoption of such fuel saving devices as superheaters and brick arches. As a result, the increase in weight and nominal capacity has been accompanied by an increase in efficiency, rendering the locomotives more reliable in service and reducing the amount of double heading formerly required in order to maintain difficult schedules. The observance of stringent speed regulations at curves, junctions and other points where accidents are specially liable to occur, has contributed to the necessity for using locomotives of improved efficiency, capable of maintaining schedules without running at excessive maximum speeds.

FREIGHT LOCOMOTIVES.

In studying the product of The Baldwin Locomotive Works for the year, the most conspicuous feature, as far as freight locomotives are concerned, is the development of the non-articulated locomotive. Comparatively few heavy consolidation locomotives were built, practically all the eight-coupled engines for through traffic on trunk line railways being of the Mikado type. The principal superiority of the latter over the consolidation type lies in its increased relative steaming capacity, as illustrated in the accompanying diagram. The line *AB* shows the average relation between the percentage of total weight on driving-wheels and the ratio of rated tractive effort to heating surface for a large number of locomotives of different types. It is evident that the lower the value of this ratio, the greater will be the steaming capacity in proportion to the tractive effort developed. The point *C* indicates an average value for locomotives of the consolidation type, and the point *D* for locomotives of the Mikado type. The transverse lines indicate the percentage of the rated tractive effort developed at various speeds by locomotives having different relative steaming capacities. These percentages are read on the right hand side of the diagram. At a speed of 20 miles an hour, for example, the consolidation locomotive develops 57 per cent. of its rated tractive effort, while the Mikado develops 72 per cent. This illustrates a fundamental difference between the two types. The Mikado is further favored because of its larger firebox volume, which is a feature of special value when burning high volatile coal. Locomotives of this type are making excellent records in heavy, slow-speed service and also in fast freight service where high horse-powers must be developed. Under favorable conditions, such locomotives, equipped with superheaters, are hauling 30 per cent. more tonnage than the saturated steam consolidation type engines formerly used in the same service, with no increase in actual coal consumption.

The following table contains the leading dimensions of nine heavy Mikado type locomotives built during the year.

Two designs of the Santa Fe, or 2-10-2 type, locomotives were built during 1912, one for the Chicago, Burlington & Quincy and the other for Atchison, Topeka & Santa Fe. The Burlington locomotives, as far as tractive capacity is concerned, are the most powerful non-articulated locomotives thus far produced. The tractive effort developed is 71,500 lbs., and the average weight per pair of driving-wheels is slightly in excess of 60,000 lbs. This design is a logical development of the Mikado, in that the firebox is placed back of the driving-wheels. The necessary con-



Relation Between Percentage of Total Weight on Drivers, Relative Steaming Capacity, and Tractive Effort at Various Speeds.

sequence is a long boiler barrel; but a combustion chamber is used, and the length of the tubes is 22 ft. 7½ ins., which is not abnormal. These locomotives are equipped with automatic

*The following locomotives built by the Baldwin Locomotive Works were described and illustrated in the *Railway Age Gazette* during 1912: January-June—Erie, 2-8-2 type, Page 241; Chicago, Burlington & Quincy, 2-10-2 type, Page 1006. July-December—Virginian, 2-8-2 type, Page 20; Chicago, Rock Island & Pacific, 2-8-2 type, Page 352; Great Northern, Mallet type, Page 572; Chicago, Burlington & Quincy, 2-8-2 type, Page 1045.

stokers and Emerson superheaters. With driving-wheels 60 in. in diameter, it is impossible to put the necessary amount of counterbalance in the main wheel centers, and two cast steel counterweights are accordingly mounted on the main axle between the frames. In this way a satisfactory arrangement of counterbalance is secured. Five of these locomotives were built for handling heavy coal traffic in Illinois. In many respects the Mikado type locomotives previously referred to, are similar to them; and interchangeable details have been used where practicable.

The locomotives for the Atchison, Topeka & Santa Fe, of which 20 were built, are lighter than the Burlington engines, and are a development of the 2-10-2 type locomotives built for this road during the years 1903-1907. These engines used saturated steam in tandem compound cylinders, whereas the new ones use superheated steam in single expansion cylinders. The superheaters are of the Schmidt type, and the locomotives use oil for fuel. In this design the firebox is placed above the rear pair of driving wheels, and the rear truck is of more value as a means of guiding the locomotive when running backwards, than for providing increased boiler capacity. The principal dimensions of the Santa Fe and Burlington locomotives are given in the following table:

MALLET LOCOMOTIVES.

Road.	Cylinders, In.	Drivers, In.	Steam Pressure, Lbs.	Grate Area, Sq. Ft.	Water Evaporating Surface, Sq. Ft.	Superheating Surface, Sq. Ft.	Total Weight, Engine, Lbs.	Weight on Drivers, Lbs.	Tractive Effort, Lbs.	Wheel Arrangement.
Missouri, Oklahoma & Gulf	21 & 32 x 30	55	210	53.4	3,407	685	315,800	277,100	60,800	2-6-6-2
Pennsylvania	25 & 39 x 30	56	205	78	4,936	1,020	408,700	408,700	82,000	0-8-8-0

Southern Pacific	26 & 40 x 30	57	200	68.4	5,626	900	436,200	400,900	85,500	2-8-8-2
Great Northern	28 & 42 x 32	63	210	78.4	6,446	1,368	450,000	420,000	100,000	2-8-8-0

A notable order for Mallet locomotives was filled for the Great Northern, which received 25 engines of the 2-8-8-0 type. These exert a tractive effort of 100,000 lbs. working compound, and are fitted with Emerson superheaters. A device is used, controlled by a hand-wheel and screw, for changing the cut-off in the low pressure cylinders independently of the high pressure. With this arrangement the power developed in the front and back engines may be equalized when running at various speeds. Seventeen of these locomotives are coal burners, while the remaining 8 use oil for fuel. All have boilers of the Belpaire type, with tubes 24 ft. long and combustion chambers 58 ins. long.

The Southern Pacific received 15 Mallets of the 2-8-8-2 type. These are oil burners, and in their general features follow the well-known design first introduced in 1909 on the Central Pacific. The separable boiler with feed-water heater is retained in the new locomotives, but the smokebox reheater is omitted and a Schmidt superheater applied. The superheater is placed in the chamber between the feed-water heater and the boiler proper. This places the header close to the high-pressure cylinders, and the superheater steam pipes are so short that there is but little opportunity for the steam to lose its heat. These locomotives are arranged to run with the cab end leading.

A Mallet locomotive of the 0-8-8-0 type, specially adapted to pushing service, was built for the Pennsylvania. It has a boiler of the Belpaire type, with tubes 23 ft. long, and is fitted with a Schmidt superheater. Another locomotive for special service, with the 2-8-8-2 wheel arrangement, was built for the St. Louis, Iron Mountain & Southern. It is intended for the heaviest class of hump-yard service and is fitted with a separable boiler, feed-water heater and Schmidt superheater. The starting-valve is of the type used on Baldwin two-cylinder compound locomotives, and allows steam to pass direct to the high pressure cylinders at starting, and subsequently changes the engine to work compound entirely.

Five Mallet locomotives for heavy, slow-speed road service were built for the Missouri, Oklahoma & Gulf. These operate on 70-lb. rails, and have a hauling capacity of 3,000 tons on a grade of 0.6 per cent. They are fitted with Schmidt superheaters, and illustrate the suitability of the Mallet type for heavy service on comparatively light tracks.

In all these locomotives special attention has been given to simplifying the arrangement of the steam piping as far as possible, and to providing ample strength in the structural parts. Cast steel has been used to excellent advantage. The high-pressure cylinder saddle is formed with a suitable cavity in which the ball-joint of the receiver pipe is seated. The center line of the ball-joint coincides with that of the articulated frame connection. With this arrangement there are no variations in the length of the pipe when the locomotive is traversing curves. The table above shows the principal dimensions of the Mallet locomotives referred to.

PASSENGER LOCOMOTIVES.

All the locomotives for through passenger service built during the year were six-coupled, the Pacific type predominating. No engines of the Atlantic type were constructed. Traffic requirements today frequently necessitate hauling passenger trains weighing from 600 to 800 tons, and wheel load limitations are such that if double-heading is to be avoided, six-coupled locomotives must be used. With large driving-wheels and high steaming capacity Pacific type locomotives are suitable for high speed service; and some very fine work has been placed to their credit. Superheaters have been applied to the majority of locomotives of this type built during 1912.

SANTA FE TYPE LOCOMOTIVE.

Road.	Cylinders, In.	Drivers, In.	Steam Pressure. Lbs.	Grate Area, Sq. Ft.	Water Evaporating Surface, Sq. Ft.	Superheating Surface, Sq. Ft.	Weight, Total Engine, Lbs.	Weight on Drivers, Lbs.	Tractive Effort, Lbs.
Atchison, Topeka & Santa Fe	28 x 32	57	170	58.5	4,367	910	295,900	248,900	63,800
Chicago, Burlington & Quincy	30 x 32	60	175	88	5,161	970	378,700	301,800	71,500

Referring again to the diagram, the point *E* has been plotted on the line *AB* for the ten-wheel type, and the point *F* for the Pacific type. It is seen that at a speed of 50 miles an hour, the ten-wheel type develops 31 per cent. of its rated tractive effort, and the Pacific type 36 per cent. This represents an advantage for the latter type, of nearly 12 per cent. Individual cases may be found in which the advantage is materially greater than this, because there are many locomotives in successful service whose proportions differ materially from those indicated by the line *AB*.

The table on the following page contains the principal data of nine recent Pacific type locomotives. The locomotive for the Seaboard Air Line, with 63-in. wheels, is specially designed for freight service; and engines of this type, with wheels of moderate diameter, may often be used with equally satisfactory results in either fast freight or heavy passenger service.

The locomotives for the Santa Fe are of the balanced compound type. All the main-rods are connected to the second pair of driving-wheels, and the inside (high-pressure) cylinders are inclined, so that their rods pass above the first driving axle. These locomotives are fitted with Schmidt superheaters, and represent the highest development of the balanced compound as-

used on the Santa Fe. With extensive experience acquired in the operation of balanced compound locomotives of the Atlantic, Pacific and Prairie types, the builders and the railway company, acting conjointly, were in a position to design a particularly satisfactory locomotive, eliminating such features as had proved unsuitable in previous engines.

The locomotives for the Central of Georgia are notable in that they are fitted with the Gaines firebox. In this design a furnace of exceptional length is employed, and the front part is utilized as a combustion chamber. A thorough mixing of the gases is effected by a baffle wall, which separates the combustion chamber from the firebox proper. Provision is made for admitting a supply of pre-heated air in a rearward direction, at the top of the wall. In the new Pacific type locomotives, this furnace is used in combination with a Schmidt superheater. Service tests with the Gaines firebox have shown not only material economy in fuel consumption, but also exceptional freedom from leaky tubes and steam failures.

PACIFIC TYPE LOCOMOTIVE.

Road.	Cylinders, In.	Drivers, In.	Steam Pressure, Lbs.	Grate Area, Sq. Ft.	Water Evaporating Surface, Sq. Ft.	Superheating Surface, Sq. Ft.	Weight, Total Engine, Lbs.	Weight on Drivers, Lbs.	Tractive Effort, Lbs.

A novelty in the product of the Baldwin Works for 1912 is a geared locomotive for logging service. The first locomotive of this type was placed in heavy switching service at the Eddystone plant, where its performance has been most satisfactory. This engine is carried on two four-wheel trucks, with all the wheels connected as drivers. It is symmetrical in construction, with a central drive to all the axles. The gears run in cast-steel housings, which are kept filled with lubricant so that they require a minimum amount of attention. As far as possible, this engine follows existing locomotive practice in its design; while at the same time, its flexibility permits it to operate over tracks so rough as to be unsuitable for direct connected locomotives.

The locomotives built during 1912 have been notable because of the special attention given to details of design, with a view to improving efficiency and eliminating engine failures as far as possible. This is most noticeable in such parts as the valve motion, frames and frame braces; and in the application, to large locomotives of special equipment such as power operated grate shakers, fire door openers and reverse gears. The Ragonnet reverse gear is now being applied, not only to Mallet locomotives, but to a large number of engines of other types. Not the least important feature of this gear is that the mechanism in the cab takes up very little room—a special advantage on large locomotives where the space available is often so limited that it is difficult to arrange the cab fittings in a convenient manner.

Pressed steel domes, made from a single plate, have been used on a large number of locomotives recently built, and are proving highly satisfactory. These domes can be made in diameters up to 33 in. and in heights up to 26 in. They are simple in construction, have ample strength, and the sizes are so standardized as to require a minimum number of dies for their production. In many boilers the auxiliary dome is now located in front of the firebox, and is placed over an opening in the shell of sufficient size to enable a man to enter. The interior of the boiler can thus be inspected without dismantling the fittings in the main dome.

Interchangeability of locomotive details has been carefully studied during the past year, and several examples of locomotives having a large percentage of interchangeable parts have been built. The Mikado and Pacific types offer exceptionally good opportunities in this respect. Under favorable conditions, they may be designed with interchangeable cylinders and boilers; and such features as driving and truck boxes, staybolts, axles, and a large number of fittings, can be made alike in the two classes. This was conspicuously carried out in the case of four Pacific and eight Mikado type locomotives which were built for the New Orleans, Mobile & Chicago. Practically all the parts of these locomotives subject to wear, except the driving tires and a few smaller details, are interchangeable. The engines weigh less than 200,000 lbs. each, and are not included in the tables.

From present indications, a further increase in the capacity of existing types of locomotives may be effected only by increasing wheel-loads beyond the maximum limits now permitted. The application of fuel-saving devices, more careful attention to the design of details, and the building of locomotives specially suited to meet definite operating conditions, have all combined to materially improve efficiency. The result of this policy has been most gratifying, and its continuance may be expected; but time alone can tell what new locomotive types will be evolved, when traffic requirements necessitate motive power units of materially greater capacity than the largest now in service.

REPORT ON GLEN LOCH DERAILMENT.

The derailment of passenger train No. 19, at Glen Loch, Pa., on the Pennsylvania Railroad, November 27 last, was reported in the *Railway Age Gazette* December 6 and 13, pages 1086 and 1137. The train was derailed by the failure of a bridge, and 4 persons were killed. The report of the Interstate Commerce Commission, just issued, gives the causes of the bridge failure as embraced in the conclusions of H. W. Belnap, chief inspector, and James E. Howard, engineer. From this report we quote:

Examination of the bridge after the derailment showed that the cover plate of the most northerly column had broken parallel with the south edge of the column, allowing the box girder to settle 16 or 18 inches upon the column. This in turn allowed the rails of track No. 4, on which train No. 19 was running, to settle under the train, causing the derailment. This break probably occurred under the engines of train No. 19. In the middle of the bridge there were flange marks on the south side of both rails. One rail very much bent, was nearly opposite column No. 8, where the depression in the track was the greatest at the time of the derailment. The depression of the box girder measured about 18 in. over this column, while over column No. 7 it was much less, being only a few inches. The greatest lateral displacement of the bridge also occurred in the vicinity of column No. 8 and the bent rail. It is believed that when the engines were suddenly raised out of the depression into which they had dropped, the flanges of the derailed wheels cleared the top of the south rail.

Mr. Howard in his report states that the initial line of rupture appears to have been the completion of a fracture which existed prior to the accident. The cover plate had previously been ruptured through the greater part of its thickness, which was ¾ in. The initial crack extended from the outer surface downward to a depth of about ⅝ in., leaving about ⅛ in. sound metal. The completion of this line of rupture was the immediate cause of the accident.

It would seem that the cover plate of column No. 8 had been repeatedly subjected to bending stresses both from the downward weight of the trains and from their outward centrifugal

thrust, and that some looseness had permitted of a hammering action of the south web of the box girder upon the cover plate, all of which had resulted in the development of a progressive or detailed fracture. With such a fracture started it was only a question of time when rupture of the plate would be completed and the failure of the bridge consummated.

The formation of a progressive fracture is the result of occasional overloads repeated a greater or less number of times according to their magnitude. If the overload reached a maximum at each application rupture would soon take place, but such is not usually the case under service conditions. Doubtless it was an exceptional incident in the history of this bridge when all the conditions of loading conspired toward developing a maximum stress. In the interval of time since the bridge was built there has been a decided increase in the weights of rolling stock and concentrated loads on wheels, and higher stresses no doubt have been received by the bridge in recent years over those of former ones.

The length of time during which this fracture has been in existence cannot be told. As a matter of judgment it may have been in process of development for a number of years. It could hardly have been developed, however, to any great extent four years ago, the last time the bridge was painted, since paint had not run into the crack. It is not believed to have had its origin within a period of a few months.

During the formation and development of the rupture it would have been visible so far as being covered by any other part of the structure was concerned, but its accessibility for inspection or detection would have been impaired by the double latticing of the vertical webs of the box girders.

On this division of the Pennsylvania Railroad there are from 500 to 600 bridges to be inspected monthly, and the force doing this work consists of six inspectors. In the testimony taken at the investigation conducted by the railroad it was shown that the master carpenter, who has charge of the inspectors, knew prior to the accident that some of the anchor bolts of the main girders were disturbed, and both he and the track foreman were of the opinion that the bolts at the east end of plate girder B were broken off down in the stonework of the abutment.

The bent anchor bolts at three of the corners of the bridge would suggest the kind of forces which were acting to strain the structure, and that the freedom of the floor beams to be moved laterally on the east abutment by centrifugal force [of trains passing rapidly over the 2° curve] leading to the bending of the cover plate, might reasonably have attracted attention. Again, the signs of hammering of the south web of the box girder on the cover plate would suggest that looseness existed prior to the accident. It is believed that these forces led up to the rupture of the cover plate.

To guard against the recurrence of such accidents as this and that at Manchester, N. Y., in August, 1911, examination should be made of all bridges for the purpose of determining whether or not any of their structural members are exposed to overstraining loads under present increased weights of equipment.

FROM THE ENGINEER'S REPORT.

This bridge, No. 43½, was of iron, built in 1891. It is a skew bridge on an angle of about 15 deg. There are two spans of half-through plate girders. The main plate girders were anchored to the abutments by means of two 1⅛ in. bolts at each corner, eight bolts in all. Expansion was provided for at the west end of the bridge. Each main girder was provided with gusset braces, five each for girders designated by the letters A, B, and D, and six for girder C.

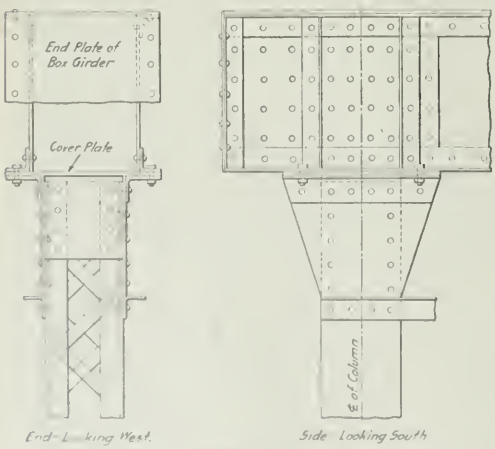
The floor beams, 15 in. I beams, were at their outer ends in part riveted to the webs of the main girders, those, however, which reached to the abutments rested upon the masonry without attachment thereto. Shoes 8 x 10 in. of 2¾ in. plates were riveted to the lower flanges of the I beams and rested directly upon the abutment walls. The inner ends of the floor beams were bolted to the box girder.

Concerning the derailment, the most easterly marks on the ties were found on the bridge about 66 ft. west of the east end of girder B and abreast column No. 8. They were located on the north side of the north rail of track No. 4; that is, the track on which train No. 19 was running. These first marks on the ties were not numerous nor were they very deep. Since the derailed wheels of the two locomotives were found on the opposite side of the rails—that is, on the inside of the curve—it is believed that these most easterly marks represent a secondary occurrence and not a primary one.

Only one rail on the bridge was so bent as to require to be replaced by a new one when the line was reopened for traffic. The steel inner guard rails and the wooden outer ones kept the train in good condition until it cleared the bridge. The bridge ties were bunched but little. They were moved an inch or two.

The shoes of the floor beams had apparently worn smooth seats on the masonry of the east abutment, from which it appears that the frictional resistance of the beams at their ends resting upon the abutment wall was of uncertain value in resisting centrifugal forces during the passage of trains at high rates of speed. The floor beams moved on the east abutment at the time of derailment. Measured after the bridge had been jacked up, the maximum outward movement was about 4¾ in.

There was no evidence that the ends of the main girders were carried northerly on the occasion of this derailment, but three of the corners showed the anchor bolts had been bent in a northerly direction, the result probably of successive impulses



Details of Post No. 8, Bridge No. 43½, Pennsylvania Railroad, Glen Loch, Pa.

received during the period of time in which the bridge had been in service

The bolts of the west girder on the north side were partially withdrawn from the stonework. At the southwest corner of the bridge the bolts of the girder were not disturbed. This corner would not be called upon to resist centrifugal forces of trains rounding the curve at speed, on account of the reaction of the west abutment.

. . . The cover plate prior to the disaster was ruptured through the greater part of its thickness.* There was a bending moment at the top of column No. 8, which put the upper surface of this cover plate into tension. From outside to outside of the gusset plates the column measured 13 in., while the box girder which it supported measured 16¼ in. from inside to inside of its web plates, an overhang of 1⅝ in. on a side. There was evidence of looseness at the joint between the cover plate and the web member of the box girder, at least at the south web, which was the ruptured edge of the cover. Repeated hammering of the web plate had indented and slightly grooved the upper surface of the cover plate.

These conditions are believed to have started a progressive fracture in the cover plate, which was promoted by a deficiency in lateral stability of the bridge along its easterly half. Trains passing over the bridge at high rates of speed would tend to move it outward and exert an overturning tendency on column No. 8, such as it might be, while the floor beams would necessarily deflect under the weight of the train and further intensify the stress transmitted through the south web of the box girder. The load transmitted to column No. 8 by the main girder would still further cause this to be a highly stressed member, and tend to rupture the cover plate. In addition the grain of the iron of the cover plate ran lengthwise the box girder, which caused the bending stress on the plate to be crosswise the grain—that is, it was stressed in its weakest direction.

The tendency of the bridge to shift its position in a northerly direction under the influence of the centrifugal forces of the trains is shown by the bent condition of the anchor bolts at three of its corners. The supporting columns of the box girder could easily be overturned by an outward thrust on the track. These columns were tied together in pairs by braces, but such bracing was not in the direction which would materially increase the stability of the bridge. The easterly end of the bridge was retained on its abutment chiefly by the resistance of the anchor bolts at the ends of the main girders, while they were bent in offering such resistance. Attending these conditions it would seem that the cover plate of column No. 8 had been repeatedly subjected to bending stresses, both from the downward weight of the trains and from their outward centrifugal thrust, and that some looseness had permitted of a hammering action of the south web of the box girder upon the cover plate, all of which had resulted in the development of a progressive or detailed fracture. With such a fracture started it was only a question of time when rupture of the plate would be completed and the failure of the bridge consummated.

It appears that the master carpenter was cognizant of the fact that certain of the anchor bolts of the main girders had been disturbed and that both he and the track foreman were of opinion that the bolts at the east end of plate girder B were broken off down in the stonework of the abutment.

This bridge had evidently been inspected at frequent intervals, none of which had disclosed the presence of a detail or progressive fracture in the fatal cover plate.

The deflection of a girder depends upon the modulus of elasticity of the material which goes to make up the girder. That value appears to remain constant in a given structural member, unless there is a very decided overstrain, one in fact which would occasion such deformation as would throw the structure out of service. Over-straining would need to be quite general to produce an observable effect on the deflection of a girder of this type, by reason of the lowering of the value of the modulus of elasticity of the iron. But the lowering of the modulus of elasticity by overstrain is not a permanent effect. The metal recovers its normal value within a few days or weeks, as shown by laboratory tests, hence such indications would be effaced within a short time, and as applied to the deflection of a girder the test might be considered as lacking in exactness. . . . Bridge No. 43½ was certainly a very much inspected structure, but as the result has shown it was not saved from a disastrous failure. Reliance appears to have been confined to inspection for a period of 21 years to furnish assurance of the safety of this bridge for constantly increasing traffic and heavier rolling stock than in use at the time of its construction. No evidence has been presented to show that any critical examination of the plans of the bridge made during that interim led to the discovery of defects in the structure which the wreck of train No. 19 clearly brought into prominence, details which are recognized as undesirable as they are now seen. In the fatal cover plate an unsatisfactory detail is recognized. The discovery or recognition of such a defective detail might properly have been expected of the custodians of the plans of the bridge. The Pennsylvania Railroad has from time to time had occasion to renew its earlier bridges and replace them with stronger structures. Such renewals may have been in part the result of inspection reports on their condition, but generally from engineering knowledge that the working loads were approaching too high limits.

It is obviously futile to look for reliable indications of impending rupture in the results of tests for deflection under passing trains. A more refined and careful analysis of the condition is needed to be serviceable to judge of the approach of danger. . . . The design of the bridge prevented disclosure of the fracture "under the usual inspection." It was inaccessible but in a comparative sense only, that is, as respecting the usual inspection. The cover plate was a short one and easily reached for painting. The double latticing of the box girder prevented direct visual inspection of the plate along its most strained section, which part otherwise was exposed to full view.

Portable apparatus for the inspection of inaccessible surfaces has been in use for many years in other lines of inspection service, consisting merely of a mirror, with a lamp for illumination. It would doubtless be an innovation to introduce such an apparatus in bridge inspection, but in a case like the present one it is a question whether the most vital part of the structure shall go uninspected because the inspector cannot get his head into position to view the critical part or to employ the necessary means to view the same. Vital parts, demanding careful inspection, should be pointed out to the bridge inspectors by the bridge engineers, since the latter have the plans at hand and opportunity to judge by computation what parts are most strained, according to the design of the structure.

The freedom of the floor beams to move laterally on the east abutment in response to centrifugal forces and leading to the bending of the cover plate of the end column under the box girder might reasonably have attracted attention.

The grain of the cover plate was parallel to the length of the box girder, thus straining the iron crosswise the grain. The tensile tests showed low results, only 29,950 pounds per square inch, in that direction, with the elastic limit and tensile strength nearly coinciding. While iron plates would not be expected to be used in the direction found here, there was no assurance that such would not be the case, and both ruptured covers of columns Nos. 7 and 8 were so oriented so that the bending stresses strained the metal in its weakest direction.

Latticed column No. 8, made of 12-inch channels, 83.7 pounds per yard, should have an ultimate compressive strength of about 500,000 pounds total. The strength of the cover plate, unassisted by the 4 by 6-inch angles, assuming a maximum fiber stress of 30,000 pounds per square inch, would be 83,000 pounds total. The angles no doubt re-enforced the cover plate, still leaving, it is believed, a great disparity in strength of this detail over the strength in the body of the column.

*We reproduce the drawings, showing the behavior of this cover plate, which were given with our report of December 13.—Editor.

ECONOMICAL LIMITS OF GRADE REDUCTION.

Discussion of the Factors Entering into an Analysis of Train Resistances and Their Respective Importance.

By Walter Loring Webb,
Consulting Engineer.

Within the past few years several railroads have adopted ruling grades on certain divisions far lower than would have been dreamed of 50 years ago, at least when the cost of obtaining such low grades is considered. Many thousands of miles of railroads in this country have been located on the basis of maximum grades approximating 60 ft. per mile, with six-deg. curves as the maximum. Recently a realization of the economy of low ruling grades has impelled trunk lines to make large expenditures to reduce these grades, where physically or financially possible, from 1.2 per cent. down to 0.5 per cent., 0.4 per cent., and even 0.3 per cent., and within the past year announcement has been made that the Erie is excavating an average of over 150,000 cu. yds. per mile near Meadville, Pa., in order to establish a 0.2 per cent. grade. About two years ago, President Willard of the Baltimore & Ohio, ordered a maximum grade of 0.2 per cent. established on second track work in Indiana and Ohio.

In constructing a second track along the Mississippi River, between Savanna, Ill., and St. Paul, the Chicago, Burlington & Quincy adopted a 0.2 per cent. grade. Even when these divisions were "river roads," it required a much larger expenditure for grading to obtain these rates of grade than would have been required to make more undulating profiles. The question naturally arises, is there any limitation below which there is no justification for spending any money to reduce the grade, assuming that the traffic is so large that the necessary cost is not in itself a limitation?

It should be clearly understood that this subject is here considered wholly apart from the special question of whether the traffic is or is not sufficient to justify the expenditure, in any particular case, of a certain computed sum. The question is a general one and only refers to whether there is some limitation beyond which the advantage of grade reduction ceases, and therefore does not justify additional expenditure, no matter how small, or how enormous the traffic which may be affected thereby.

The fundamental distinction between ruling and minor grades should be kept in mind. A minor grade adds a small percentage to the consumption of fuel and other engine supplies and an almost inappreciable amount to the expenses of maintenance of way and rolling stock. On the other hand, a ruling grade limits the number of cars which may be hauled by a locomotive. With a reasonably large freight traffic, an increase in the number of cars per train will mean a reduction in the number of trains necessary to handle a certain gross tonnage. Since the revenue received on that gross tonnage is a fixed quantity, a reduction of grade, which will permit that tonnage to be hauled by a less number of trains, will permit a reduction in operating expenses which is largely clear profit. As a general proposition, the very great economy resulting from a reduction of the ruling grade does not need argument. It is only when there is a possibility of reducing a very low ruling grade to a grade still lower, and at a very large expenditure, that the economical justification becomes questionable.

ANALYSIS OF TRAIN RESISTANCES.

The investigation of this subject must evidently include an analysis of all train resistances, the ratio that grade resistance on various grades bears to the total resistance and the economy which would result from reducing the total resistance by a computed proportion. To compare two operating conditions, we may compute the total resistance in pounds per ton under each condition. Any reduction which may be made in the resistance, measured in pounds per ton, and including every form of tax on the power of the locomotive, means a possible increase in the train load which can be hauled by a locomotive of given type, and from this may be computed the possible saving in the number of trains required to handle a given traffic. For the purpose of this discussion the total demand on the locomotive may be divided into four divisions; grade resistance; inertia resistance; the extra tractive resistances which only occur when starting and at very low velocities, and all other resistances.

Grade resistance on a majority of roads is so great that it swallows up and overshadows the others, and yet it is the one form of resistance which may be indefinitely reduced and possibly made zero, provided enough money is spent to accomplish it. It is also exactly computable to the last ounce. It equals 20 lbs. per short ton for each per cent. of grade. For the 1.2 per cent. grade, which was formerly so general as a maximum grade and even now is so common, it is 24 lbs. per ton, while for the 0.2 per cent. limit, referred to above, it is only 4 lbs. per ton.

Inertia resistance is also mathematically computable. The amount of the resistance is controllable and is purely a matter for the operating department. When the elevated roads in New York City were operated by steam locomotives, it was estimated that three-fourths of the fuel consumption was due to this cause. The necessity for a reasonably high average speed between termini, combined with stops every few hundred feet, required abnormal accelerating power. The work of acceleration, using all the power of the locomotive, would be frequently continued to a point at which deceleration would be commenced in order to make a proper service stop at the next station. Of course such a combination of conditions is not applicable to most steam roads, and least of all to through freight traffic. Therefore, this form of resistance is not usually a controlling factor, but it will be shown later that when other forms of resistance have been eliminated as far as possible, operating conditions may require a degree of acceleration which makes its demand on the locomotive a controlling element in the magnitude of the train load. The required accelerative force may be expressed by the formula:

$$P = 70.2\ (V_2^2) - V_1^2 \div s,$$

in which V_2 and V_1 are the higher and lower velocities, respectively in miles per hour, s is the distance in feet and P is the required constant accelerative force in pounds per ton. When the train starts from rest, $V_1 = 0$. A few numerical illustrations will readily show what this force amounts to. If a train must acquire a velocity of 20 miles per hour in a distance of 1,000 ft. and starting from rest,

$$P = 70.2\ (400 - 0) \div 1{,}000 = 28.08 \text{ lbs. per ton.}$$

This is equivalent to the grade resistance on a 1.4 per cent. grade. If the velocity must increase from 20 to 40 miles per hour in the next 1,000 ft., the required force will be

$$P = 70.2\ (1{,}600 - 400) \div 1{,}000 = 84 \text{ lbs. per ton.}$$

This is the equivalent of a 4.2 per cent. grade. Working the problem backward, to find the required distance in which the accelerative force of 28.08 lbs. per ton would increase the speed from 20 to 40 miles per hour, we would have

$$s = 70.2\ (1{,}600 - 400) \div 28.08 = 3{,}000 \text{ ft.}$$

Of course the accelerative force is independent of the other forces, and any change in the other tractive forces due to change in velocity is assumed to be otherwise taken care of.

As before stated, the amount of the inertia resistance or accelerative force is under the control of the operating department. It may be made indefinitely small by adopting a very low rate

of acceleration, but of course this is not economical, since time is wasted on the road. On the other hand, a quick acceleration cannot be accomplished without a very great reduction from the train load, which might be handled with slow acceleration. A uniform accelerative force of 5 lbs. per ton (beside the force required for other resistances) will produce a velocity of 8.4 miles per hour in the first 1,000 ft., 11.9 miles per hour in the second 1,000 ft., 14.6 in the third, and 16.9 in a total of 4,000 ft. For comparative purposes we will use 5 lbs. per ton accelerative force later on.

The extra resistances which only occur when starting or at very low velocities are here given special prominence because, in the minds of some, their unavoidable occurrence constitutes a limitation on the economical reduction of ruling grade. This extra resistance is most readily observed when a number of freight cars are started up after remaining at rest for a long period in freezing weather. On the other hand, such a high resistance is only momentary and is very quickly reduced to a much lower quantity. During some careful tests on the Rock Island system to determine this resistance, a maximum of 30 lbs. per ton was found for a train which had stood over night and was "frozen up." The weighted mean of 35 tests with trains of 34 to 45 cars showed an average resistance of 14.1 lbs. per ton, with a minimum of 6 lbs. per ton when the stop was only instantaneous. Considering that these figures *include* the regular tractive resistances, which must be considered as 5 to 8 lbs. per ton, depending on the condition of the track, proportion of dead load to live load, and many other causes of variation, we must only consider the *excess* over 5 to 8 lbs. as the amount chargeable to starting. When an engineman finds that his locomotive is unable to start his train in the usual way, he frequently backs the engine for a few feet and then, reversing, starts ahead, and frequently succeeds in starting the whole train. By this method he accomplishes three things; the journals are loosened from their rigid condition and the initial high resistance is greatly reduced; the coupler springs are compressed and their expansion during the following forward movement materially assists in starting the train; and the total coupler compression in a long train is so great that the engine moves forward several feet before the last car starts. The cars are started one by one. The last effect will alone reduce the required draw bar pull by nearly 50 per cent.; the first two effects are not so readily computable, but are evidently of considerable influence. By such practical operating methods the extra resistance during starting, apart from inertia, grade, and the ordinary tractive resistance, may be reduced to a relatively small although somewhat indefinite quantity.

The other tractive resistances, which, for the purpose of this discussion, may be lumped together, are dependent on ratio of dead load to live load, on the number of cars, on the condition of track and weight of rail and on velocity. Since the limitations of ruling grade apply first to freight traffic with comparatively slow speed, and since the variations of resistance for variations in velocity between 5 and 35 miles per hour are so small that they may be here ignored, we need not complicate the discussion on account of variations in velocity. Since the tractive resistance per ton is less for fully loaded cars and since train loads of fully loaded cars are the critical loads to be here considered, we may assume that all of these ordinary tractive resistances may be lumped at 5 lbs. per ton.

The resistance due to curvature may be here ignored on the assumption that the grades on all curves are compensated. On the basis of 0.035 per cent. per degree of curve, even a 0.2 per cent. grade is nearly sufficient to compensate a 6 deg. curve. Any road spending large sums to reduce grade to 0.2 per cent. would certainly reduce 6 deg. curves to something easier, and we may therefore consider that curve compensation is always practicable and that it is done. Of course curve compensation does not eliminate curve resistance, but whenever curve compensation has been accomplished, curve resistance has been eliminated as a possible factor in limiting the weight of trains.

If we assume that all of these resistances occur simultaneously and that the rate of acceleration is the same for either grade, we would have, for a 0.4 per cent. grade, a total resistance of 5 + 5 + 8 or 18 lbs. per ton, and for a 0.2 per cent. grade, 5 + 5 + 4 or 14 lbs. per ton, with a small addition in each case for the extra resistances when starting. The inverted ratio of these two figures will be a measure, although not in strict proportion of the relative train loads which can be hauled by a locomotive of a given type on the two ruling grades. For our present purpose it is unnecessary to determine mathematically the relative cost of handling traffic on the two grades. It is unquestionable that the economy of operating the lighter grade is very great, even though the reduction in operating expenses is not measured by the 22 per cent. reduction in resistance per ton. It is likewise true that, no matter what variations may be made in the rate of acceleration demanded, nor in the tractive resistances caused by the particular condition of track and roadbed, the relative value of the two grades will not be radically changed when the resistances other than grade are the same. And there seems to be no escape from the necessity of considering that all of these resistances may happen simultaneously provided that regular stopping places, passing sidings, block signals, or even grade crossings, which may require a stop almost anywhere, are located without regard to the grades of the road. This proviso may be inverted by saying—provided that the grades are designed without regard to the places where regular or occasional stops must be made. The designers of elevated railroads have already utilized the advantages of locating stations on a hump, artificially made so by increasing slightly the height of a few columns near the station. Incoming trains transform their kinetic energy into potential energy and thus save in the use of brakes. Departing trains utilize that potential energy to reduce the demand on the locomotive to provide the accelerative energy when starting. The saving is thus two-fold.

When grades have been so reduced that there is a question whether the ruling grade should be 0.4 per cent. or still further reduced to 0.2 per cent., it requires but little change in the grading to create a hump which will more than make up this difference at some regular stopping place or even at a block signal where a train is liable to be held up. A hump 4 ft. high and running out for 2,000 ft. in either direction will change the grade 0.2 per cent. This four-foot hump will consume the kinetic energy of a train moving at a velocity of 10.7 miles per hour, and therefore a train approaching this hump at a velocity somewhat in excess of this need not be stalled. If the train must stop at the summit of the hump, brake action is saved, with the attendant saving of wear on wheel treads and brake shoes. In addition there is the assistance of a virtual 0.2 per cent. down grade, or 4 lbs. per ton when starting. This gain of 4 lbs. per ton will exist irrespective of the actual grade, for the grade on the farther side of the hump will always is 0.2 per cent. more favorable to traffic than the original grade on which the hump is placed.

If a road could be so constructed that all stopping places were on a level; that the level stretches were long enough so that a train could acquire its normal velocity; and that stops would never be required on the ruling grades: there might be justification for a claim that there would be no advantage in anything less than a 0.4 per cent. ruling grade. Under these conditions the only resistances on the grade would be the ordinary tractive resistances and the grade resistance of 8 lbs. per ton. When starting on the level, there is no grade resistance and the 8 lbs. per ton may be used up in the extra resistances during starting and in acceleration. However, a railway manager would not dare to load up a locomotive to the limit suggested by such figures, for there would be no margin left if an unexpected stop should be necessary on the ruling grade, and if the train

load is cut down to the capacity of the locomotive to start from rest on the ruling grade, then we have the simultaneous combination of all the four classes of resistances, and, as previously pointed out, the reduction of one of these resistances will make a definite and sure reduction in the total resistance and will surely justify a profitable increase in the train load.

Expensive reductions in ruling grade are almost invariably accompanied by a reduction of curvature down to a limit of 3 deg., 2 deg. and even 1 deg. curves. The justification of such reduction is a very different matter from the reduction of the rate of grade. The curvature does not limit the length of trains and cannot therefore have the same importance as ruling grade. It does add something to the resistance, but since this has been determined as the equivalent resistance of 0.035 per cent. grade for each degree of curve, even this is of comparatively slight importance. The real justification for such curve reduction is the safe operation of fast trains. Any railroad having such a traffic that 0.2 per cent. grades can be considered as a maximum, will also wish to operate fast trains, say at 60 miles per hour. The proper super-elevation of the outer rail for even a 2 deg. 30 min. curve, operated at 60 miles per hour, is six inches. Running a train at 60 miles per hour with the track superelevated six inches certainly requires good track construction and good rolling stock and even then its safety is perhaps questionable. A slow order on all curves sharper than 2 deg. 30 min. is therefore imperative for all trains which are to be operated at a speed of 60 miles per hour or faster. Since the engineman's schedule of many of the fast trains of the country include many stretches over which a speed of 60, 65, and even 70 miles per hour must be maintained, it is plain why all projects for grade reduction also include curve reduction, but it should be remembered that the justification has an entirely different basis.

LOCOMOTIVE LABORATORY AT THE UNIVERSITY OF ILLINOIS.*

By Edward C. Schmidt,
Professor of Railway Engineering, University of Illinois.

An accurate knowledge of locomotive performance is as necessary to the railway operating officer and to the locating engineer as to the locomotive designer, and in periods of rapid progress in locomotive development the need of such knowledge becomes the more urgent. In the beginning, such effort had for its chief purpose the improvement of the mechanical features of locomotive design rather than improvement in its economical performance; but in later years, under the demand for decreased operating costs, this effort has been directed chiefly toward developing accurate information about the performance of the locomotive boiler and engines and of the machine as a whole

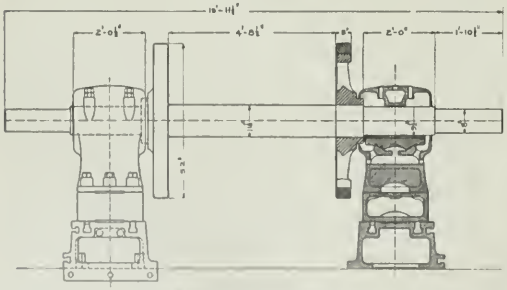


Fig. 1—One Pair of Supporting Wheels, with Axle, Bearings and Bed Plate.

Until about twenty years ago the only other source of accurate and specific information concerning locomotive performance was the data derived from specially arranged road tests. For certain purposes they will never be displaced. The usefulness of road tests is, however, limited by the fact that on the road many of the conditions of operation are entirely beyond control; and consequently even the most skillfully and conscientiously conducted road tests sometimes fail to produce conclusive evidence.

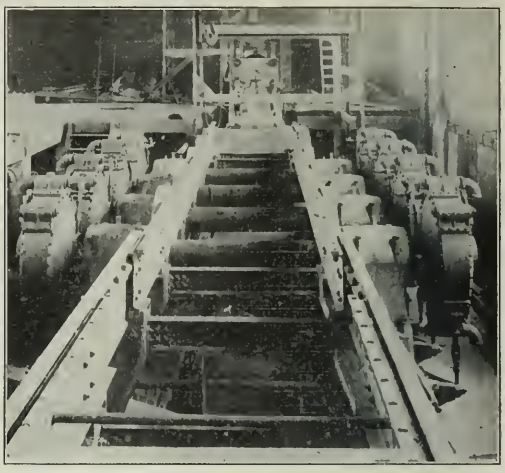

Fig. 2—Rear End of Testing Pit Arranged for a Consolidation Locomotive.

The first locomotive testing plant was built 21 years ago at Purdue University. It was designed by Dr. W. F. M. Goss, who was at that time in charge of the schools of engineering at that institution. At present there are four such testing plants in this country and two in Europe.† The justification for the existence of locomotive testing plants lies in the fact that in them only

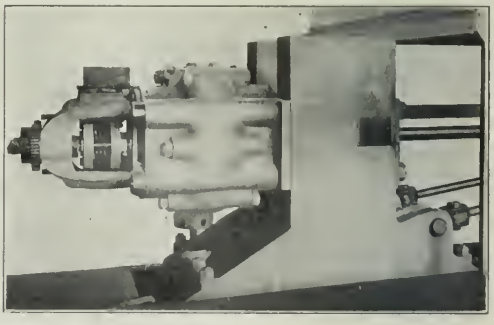

Fig. 3—Weighing Head and Housing of Dynamometer.

*Abstract of a paper presented before the Western Railway Club, March 18, 1913.

†The Purdue plant, erected in 1891, was followed in 1894 by a temporary plant at South Kaukauna, Wisconsin, on the Chicago & North Western, designed under the direction of Robert Quayle. This was succeeded in 1895 by a permanent plant, designed by Mr. Quayle and erected at the C. & N. W. shops in Chicago. In 1899 Columbia University, having been given an Atlantic type locomotive by the Baldwin Locomotive Works, provided a testing plant which is erected in their mechanical engineering laboratory. In 1904 the Pennsylvania Railroad installed at the Louisiana Purchase Exposition at St. Louis, what was at that time the largest and most elaborate plant built. This was removed after the exposition to Altoona, Pa., where it has since been in almost constant operation. In 1904 there was also erected in the Putiloff Works at St. Petersburg, Russia, a similar plant designed by Messrs. M. V. Goloboloff and S. T. Smirnoff. The following year there was erected in England another plant under the direction of G. J. Churchard of the Great Western Railroad, at the Swindon Works of that company.

can the locomotive be run under conditions which may be rigidly controlled and varied at will. It is also true that in the test plant the difficulty and expense of making tests are both greatly reduced; but this in itself is less important than the control of the operating conditions which test plant service puts in the hand of the experimenter. As a consequence of this control practically all questions relating to boiler performance can be better and more easily settled in the testing plant than on the road and the same is equally true of questions touching engine performance. Supplemented occasionally by road tests made by means of a dynamometer car, the locomotive testing plant makes possible a knowledge of locomotive performance as exact as that which is available concerning the stationary steam engine, the turbine, and the gas engine.

At its last session, the legislature of Illinois included among its appropriations for the University of Illinois the sum of $300,000 to be used for new buildings for the College of Engineering. It was decided to use this fund in erecting a transportation building and a locomotive laboratory for the department of railway engineering.

Any locomotive laboratory consists essentially of, first, a means for so supporting the locomotive that its wheels may be rotated and that the power developed may be absorbed and either dissipated or transferred; second, a means for anchoring the locomotive when so mounted and for measuring the tractive effort developed; third, means for supplying and measuring coal and water; and finally, means for disposing of the gases and steam from the front end.

The supporting mechanism consists in this plant, as in all others, of wheels whose position may be varied to conform to the spacing of the locomotive's driving wheels. In this case the supporting wheels are 52 in. in diameter, provided with plain tires and mounted on 11⅛ in. axles. The axles and tires are of the highest grade of heat-treated carbon steel and were furnished by the Midvale Steel Company. The use of 52 in. supporting wheels involves rotating speeds as high as 500 r. p. m. in testing high speed locomotives. Such speeds may give rise to difficulty in the operation of the bearings, although they have been designed with regard thereto. In anticipation of such difficulty, however, provision has been made (in the design of the bearing pedestal) for using 72 in. diameter supporting wheels, if it later proves desirable to do so. The axles are supported at each end, just beyond the wheels, in bearings 9½ in. by 20 in. which are provided on the under side of the journal only. These bearings are carried in self-aligning shells which are supported in pedestals of exceedingly heavy construction. Oil is provided at two points in the bearing cap, where it is supplied under head from an elevated supply tank. The bearing pedestals rest on massive cast iron bed plates which run the entire length of the testing pit, and are secured thereto by the bolts whose heads are held in slots running the length of the bed. The pedestals may thereby be shifted to any desired position on the bed. The general design of the axle, wheels, bearings and bed plate is well represented in Fig. 1. Each of these units, consisting of an axle, two wheels, and two bearings, constitutes the supporting element for one pair of locomotive drivers. So supported, the driving wheels may turn; and there remains to be provided a means for absorbing the power developed at the driving wheel rim.

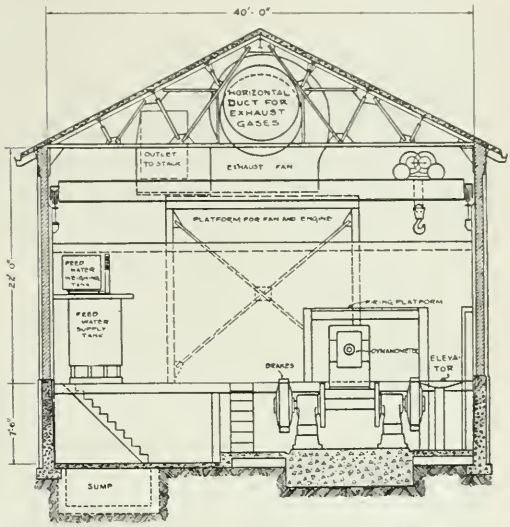

Fig. 5—Cross-Section Through Middle of the Locomotive Testing Plant.

The brakes are of the type used in all other American testing plants, and were designed and furnished by Professor G. I. Alden of Worcester, Mass., under general specifications prepared by the designer of the plant. One of these brakes is mounted on each end of each supporting axle. Each brake consists essentially of three cast iron discs which are keyed to the supporting axle, and which rotate between water cooled copper diaphragms carried in a stationary casing. A cast hub and the three discs form an integral rotating element which is keyed to the axle and turns with it. The casing and its diaphragms are prevented from rotating by means of links attached to the bed plates.

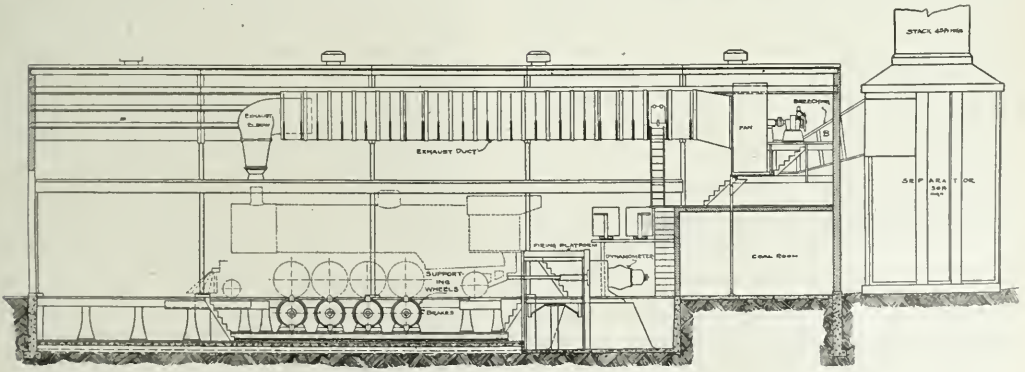

Fig. 4—Longitudinal Section Through the Locomotive Testing Laboratory.

The diaphragms provide within the casing three compartments within which the cast iron discs rotate. The surfaces of the discs and of the diaphragms are lubricated by oil fed in at the periphery of the discs and taken off at the hub. The diaphragms form also within the casing four water compartments which have no communication whatever with the compartments within which the discs rotate. The pressure existing in these water spaces may be varied at will by means of suitable valves in the brake piping. The operation of the brakes is as follows: Power received from the driving wheels of the locomotive is transmitted through the supporting wheels and axle to the cast iron brake discs; these in turn transmit it by friction to the surfaces of the copper diaphragms against which they rub. By varying the water pressure, the friction between the discs and the diaphragms may be varied in accordance with the amount of power to be absorbed. The entire power of the locomotive is thus dissipated at the surface of the diaphragms and carried away as heat in the water which circulates through the brakes. Each brake is designed to develop a resisting torque of 18,000 lbs.-ft., which is more than is likely to be transmitted to it by the most heavily loaded locomotive driver.

The foundation of the plant is a slab of reinforced concrete 93 ft. long and 12 ft. wide, varying in thickness from 3½ ft. at the front to 5 ft. at the rear. It is surmounted at the rear end by a pyramidal base which serves as the anchorage for the dynamometer. The mounting machinery thus far described is shown in Fig. 2 arranged for the reception of a consolidation locomotive. The locomotive to be tested is backed on to the machine; the drivers run on their flanges leaving the treads free to engage the supporting wheels. When the drivers are properly placed and the locomotive is securely anchored to the dynamometer, the track is removed.

The dynamometer, whose chief function is to permit the tractive effort of the locomotive to be measured, is shown in Fig. 3. It is of the well known Emery type, designed and built by the William Sellers Company of Philadelphia. It consists essentially of the "weighing head" shown at the left, carried on the housing, and of a weighing scale not included in the picture. Within this weighing head is an enclosed oil chamber with a flexible wall, which receives and balances any force transmitted from the locomotive. The pressure of the oil in this chamber varies with the load and is transmitted through a copper tube of small bore to a similar smaller oil chamber, the pressure within which moves the beam of a substantial but very sensitive scale. The force transmitted to the dynamometer is thus weighed. Its capacity is 125,000 lbs., which is 15,000 lbs. greater than the tractive effort of any locomotive in existence. One feature of special interest in the design of the scale lies in the fact that the adjustment of the poise weight on the scale beam is accomplished automatically.

Other details include the weighing tanks, hydraulic elevator (for lifting the coal from the floor to the firing platform), scales, coal room, and firing platform. The general water supply of the university is from driven wells, the demand upon which approaches at times their full capacity. No other source of cooling water for the brakes is available. Water from the brakes could not therefore be wasted, and provision has been made for cooling and recirculating it. A supply pump for the brakes draws water from a reinforced concrete reservoir of 100,000 gal., pumps it through control valves to the brakes, whence it returns through another set of control valves to a sump located in the basement of the laboratory. Another pump returns it from here to the reservoir. The feed water is drawn from this reservoir by a separate pump, passed to the weighing tanks and feed tank and thence to the injectors. This feed water, of course, is wasted and must be restored to the reservoir between tests by drawing on the general university supply.

In the design of the means for disposing of the exhaust gases new problems were presented and new solutions have been reached. In view of the importance of determining accurately the total fuel lost in the exhaust gases, it was early decided to try to incorporate in the design of this plant some means for entrapping *all* of the solid matter contained in the gases passing the locomotive front end. The exhaust gases are discharged into a steel exhaust elbow which carries the gases up and over to the center of the building, where they are received in a horizontal duct running through the center of the roof trusses. The gases are drawn through this elbow and duct by an exhaust fan, located near the roof at the rear end of the building. Probably the heaviest cinders will be dropped in this duct, but the velocity within it is such that all but the heaviest particles of solid matter will be carried on through the fan. Whatever does accumulate here may be removed through traps provided in the bottom of the duct, and weighed. From the fan, the gases and the remaining solid matter are passed through a breeching or flue to a separator in which they pass downward around a sleeve, where they are given a whirling motion which causes the cinders to move toward the wall along which they drop to a hopper below, while the gases pass downward and out to the stack through the mouth of the sleeve. The cinders collecting at the bottom of the hopper are drawn off and weighed. This separator is surmounted by a 45 ft. radial brick stack from which the gases are finally discharged 81 ft. from the ground.

The corrosive nature of the mixture of exhaust gas and steam has made it necessary to avoid the use of metal throughout this exhaust system. The exhaust elbow within the building necessarily has been made of steel, and will need occasionally to be renewed. The duct, however, is of asbestos board (Transite) which will resist corrosion. It is 7 ft. in diameter, and made up of separate sections so that its length may be varied. The fan has a runner 6 ft. in diameter, and will pass, at maximum speed, 140,000 cu. ft. of gas per minute. The breeching between fan and separator is built of transite, and has a minimum cross sectional area of about 24 sq. ft. The outer shell of the separator is built of reinforced concrete. To protect the shell from corrosion, it is lined throughout with a hard burnt red brick. Between this lining and the shell is a 2 in. air space to act as an insulator to protect the shell from undue heating. Any leakage of gas through the lining into this space is vented to the outside air through openings which are provided in the shell, and which serve also to circulate cool air through the air space. The inside sleeve and hopper are both built of reinforced concrete. The stack itself is unlined, but is laid up in acid proof cement. It is expected that this whole system will not only permit the collection of all solid matter and thus enable front end losses to be determined in a manner beyond criticism; but that it will also dispose of the smoke so that it will be unobjectionable and at the same time act as a muffler and eliminate objectionable noise from the locomotive stack discharge.

The building which houses this equipment is 40 ft. wide and 115 ft. long, with a height under the roof trusses of 22 ft. A basement with a 6 ft. 9 in. clear depth extends throughout all but 22 ft. of its entire length. The construction is fireproof throughout. The walls are laid up both inside and out with red faced brick, the roof is of reinforced concrete covered with slate, and all floors are of reinforced concrete also. The building is unusually well lighted by windows in the side walls which extend nearly the full height of these walls and occupy almost two-thirds of the wall area. All portions of the building, except the space occupied by the coal room in the west end, are served by a 10 ton traveling crane.

The whole plant has been designed with the intention of making it suitable to test new designs as they appear, in the confidence that the railroads and builders would be willing to keep upon the plant locomotives of recent design, concerning whose performance all railroad officials desire information. The first locomotive to be tested is one of the consolidation type owned by the Illinois Central Railroad.

REGULATION OF UTILITIES BY COMMISSION.*

Principles That Should Be Applied and Methods Used in Dealing with Service, Rates and Financial Return.

By Halford Erickson,
Member of the Wisconsin Railroad Commission.

The earlier systems of regulation were in the latter part of the eighteenth century superseded by the well known *laissez faire* policy under which competition was mainly relied upon for the establishment of fair prices and adequate service. While the policy is well adapted to the subduing of the forest and the prairie, it does not seem to be well fitted for the regulation of public utilities. It has, in fact, been found to be entirely inadequate for the proper regulation of the prices and other conditions of such services. And this fact has in turn led to a well-developed sentiment in favor of abandoning the competitive policy in the public utility field and to substituting therefor government regulation. In fact, in America and England the competitive or let alone policy has never been fully adopted for such facilities as water or canal transportation, toll bridges and turnpikes.

This demand and need for the return to government regulation of industries and services that are fraught with public interest has grown very rapidly during the past fifty years or more and this development has been brought about by the great changes that have taken place in economic and social conditions.

REGULATION OF SERVICE.

As the services rendered by public utilities are necessities, it is of great importance that they should be adequate or up to a reasonable standard. Poor service is uneconomical, irritating and a fruitful source of dissatisfaction and complaint. It is often responsible for the greater part of the ill feeling between the public and the utility, that exists in so many places. Such service, however, can as a rule be furnished at lower cost to the utility than good service, and it is in this fact that the incentive to poor service is found. To furnish inadequate service, especially when the rates charged are high enough to cover the cost of adequate service, is an unjust imposition upon the public. For the consumers are as much entitled to get what they pay for as the utilities are in charging reasonable rates for adequate service.

In the railway field, service questions involve the regularity and speed of trains, connections at junction points, the stoppage of a sufficient number of trains at the smaller stations, the proper care and maintenance of both trains and stations, the prompt and equitable distribution of cars among shippers, the equipment of the line with approved signaling and safety devices, and many other every day matters connected with the operation of trains. Under this head, also, though less directly connected with the comfort and safety of the users of railway service, is the proper protection of highway crossings, and the elimination of grade crossings. Not only are such matters as these investigated when brought to the attention of the commission by complaints and accidents, but the initiative is taken to a considerable extent by the commission itself, by means of frequent inspections by its experts of roadways, bridges, rolling stock, stations and yards, etc. Unless the defects of service are so intolerable as to make an order for their elimination almost a matter of course, the determination of railway service matters involves the consideration of a large number of questions. Where train or station service is being investigated, the population to be served, the amount of business likely to arise from the improved service, the operating difficulties involved, the actual cash outlay required in making the improvement, and many similar facts are to be considered. The maintenance of passenger train schedules which will enable the railway company to meet competition between its terminals may have a bearing on the propriety of requiring the regular stoppage of a train. Another service matter which is the subject of commission supervisions is the construction of spur tracks for the accommodation of industries along railway lines. The Wisconsin law on this subject requires the commission, on application, to order the construction of such spur track not more than three miles in length, when its construction is found to be practically indispensable to the business of the applicant, and is not unreasonably dangerous to the general public.

VALUATION AND REGULATION OF RATES.

With respect to rates our experience varies. In many cases the rates have been found to be unreasonably high as well as unjustly discriminatory. In other instances again, though less frequently, the rates have been found to be unreasonably low. Rates that are thus too high and that under similar conditions are higher for some persons and localities than for others are harmful and against public policy. They result in unequal distribution of wealth. They mean that money is unjustly transferred from one set of pockets to another set of pockets, and that a few are enriched at the expense of the many. They retard industrial development and commercial growth, and, in the same line of business, tend to build up some at the expense of others. They also lead to results that are bad, from a rural and ethical point of view.

Rates that are too low may also be harmful. They usually stand for poor equipment and poor service. When so low as not to provide means for the proper upkeep of the plant they may even lead to the entire ruin or loss of the service. Instances where conditions of this kind prevail are met with from time to time. They are detrimental not only to those who are directly affected, but to the public as a whole. Losses from poor service may be as great as losses from rates that are too high or discriminatory.

The law provides that the rates must be reasonable. The courts have held, in substance, that under normal conditions of a plant when taken as a whole, the rates in order to be reasonable should be high enough so that the revenues therefrom are sufficient to cover reasonable amounts for the operating expenses of a plant, including depreciation thereon and interest and profit on the fair value of the property used and useful for the convenience of the public.

The sum of the operating expenses and fixed charges is thus made the legal basis for rates. The first problem of the rate maker therefore consists of determining what constitutes reasonable amounts for these expenses and charges.

The first step that is necessary in the determination of such rates is to find the fair value of the property upon which the investors are entitled to interest and profit. In this determination one is at the very outset met with conflicting opinions of all kinds, not only as to what should be included in the term "property," but as to what is meant by "fair value." Some insist that the term property includes only the physical property that is used and useful in serving the public. Others again hold that besides the physical property it also includes the cost of developing the business. There are some who argue that the fair value is represented by the original cost, and others again that it is represented by the cost of reproduction at the time of the appraisal. A careful analysis of the facts indicates that the cost of both the physical property and of the business should be

*Abstract of a paper read before the Western Society of Engineers, Chicago, March 24, entitled "The Regulation of Public Utilities in Wisconsin." Mr. Erickson's discussion dealt with regulation of public utilities in general. The abstract here presented is confined chiefly to those parts of the paper dealing with regulation of railroads.

included in the appraisal, and that the original cost as well as the cost of reproduction not only of the physical property, but of the business as well, constitute evidence of value.

The original cost of the physical property includes the cost of all the land, labor, material and equipment of all kinds that are required in order to obtain a complete plant ready for operation. It also covers such overhead charges in connection therewith as organization, legal expenses, engineering and superintendence of construction, insurance and contingencies of all kinds, interest during construction period on the capital used, etc. When a plant is needed and cannot be had on better terms, the original cost may also have to include something for discounts on bonds and for promoters' expenses. In fact, the original cost of the physical property should include all necessary expenditures that were judiciously made in obtaining the plant. Before it can be effectively and economically operated, such a plant must also be provided with a working capital.

The true original cost is difficult to determine. The probable and reasonable cost, however, is not inaccessible, for many items can be closely estimated from the facts obtained from examinations of the present plant, its design, location, growth, character, size, the prices of labor, material and other elements which prevailed when built, and comparisons with similar plants of which the cost is known. Thus in the end a very close approximation of the actual cost of the physical property of the plant can ordinarily be obtained.

The next measure of value is obtained by determining what it would cost to reproduce the plant rather than by what the plant actually cost. In thus determining the cost of reproduction new of the plant, it is necessary to obtain complete inventories of every element that enters into such cost, as well as detailed statements of the prices at which these elements can be had, installed and shaped into an operating plant. The prices so used are the results of most careful and extended studies and compilations of market quotations and of prices at which sales were actually made. In order to avoid the abnormal effects of sudden fluctuations in such prices and to obtain results that are more nearly normal, the prices chosen may be said to represent average conditions for a considerable period, rather than the prices as of any particular date. When the elements which are thus included in the cost cover such overhead expenses as those incurred for organization, for legal and engineering service, for superintendence of construction, for interest and the capital used in construction, for insurance and contingencies, then this cost would seem to fairly represent what the plant would actually have cost. In this case, as in determining the original cost, it may be necessary at times to also consider certain bond discounts and promotion expenses in arriving at the probable total cost of reproducing the plant.

Neither the original nor the reproduction cost new of a plant is a fair measure of its present cost value unless the depreciation that has taken place in the plant has been provided for and goes with the plant. The present values as thus obtained, even when the one is greater than the other, furnish good evidence as to the present fair value of the physical property.

When the value of the physical property of the corporation has finally been determined, there remains still another cost which often is legitimately a part of the investment on which reasonable returns should be permitted. This is the cost of developing a paying business. The most perfectly equipped utility plant in existence is useless if it has no customers. The acquisition of customers is a costly process. It involves not only the expense of advertising, solicitation, free experimental service, and other actual outlays, but it may include the entire amount by which the plant during the first few years of its operation fails to pay operating expenses and a reasonable return on the investment. The latter amount may be to some extent offset by exorbitant profits after the plant reaches a paying basis, or by the fact that failures to earn a return may be in part due to poor management or lack of ordinary business judgment. But when all deductions have been made for such circumstances, there will usually be found, at least for some utilities, a steadily decreasing deficit for the first few years, which is fairly chargeable to the cost of developing a paying business. This deficit, being a large part of the cost of a successful public utility plant, is, as a rule, properly added to the present cost value of the property. It is sometimes termed "going value," but is more properly the cost of building up the business.

Just as in the case of the physical property of the corporation, the cost of the building up of the business may be ascertained by finding what it would cost under present conditions to reproduce the present business. This is done by determining from all the available data as to the amount and density of population, familiarity of the people with the use of the service in question, etc., what time would be required for a new plant to build up a paying business. The operating expenses and revenues during such period being capable of estimation, the total deficit for the period may be taken as the cost of reproduction of the business of the plant. This reproduction cost and the actual original cost of the business can then be compared, and the determination of the going value or cost of the business then depends upon the exercise of a sound judgment, based upon these two costs.

The original cost and the cost of reproduction of the plant and of its business ordinarily constitute the best evidence as to what constitutes the fair value of the property. In some instances these two costs are far apart, but in most cases they seem to approach each other quite closely. When far apart, the difference is mostly due to variations in the general price level of the elements, which enter into the construction of the plant and the development of its business as between the time when the plant was first built and the time of the reproduction, although contingencies, mistakes of judgment and errors of various kinds may play important parts. The tendency today, in appraisals, seems to be to attach greater importance to the cost of reproduction than to the original cost. As to which of these factors is the most important is a matter that is greatly dependent on conditions.

When the fair value of all the property that is used and useful has thus been determined the question arises as to what constitutes reasonable amounts for interest and profit on this value, as well as for depreciation and other operating expenses. These outlays, as stated above, may be said to make up the total cost of the service.

The returns to be allowed to the investor usually consist of two elements: The ordinary rate of interest for the use of his money, and a compensation for the risk he has undergone. Both of these items vary with differences in time and conditions. Bare interest, or compensation for the use of money, is largely a question of market rates, and is determinable by a study of the investment market generally, of local conditions. The second element, or the profit to be returned to the investor as a compensation for his risk, and, to a certain extent, for the business ability and management required to look after the investment, is the resultant of many conditions, such as the location of the plant, the prospects of the municipality or region in which it is situated, the circumstances tending to make operating costs high or low, and numerous other factors. Generally speaking, the risk is greater in a new than in an established enterprise. All of these matters when taken together indicate how far the investor is entitled to a return above ordinary interest for the mere use of his money. The best results are secured by fixing rates of return that will cause an unobstructed flow of capital into the public utility field.

Depreciation also is an element in the cost of the service and must therefore be covered by the rates charged for such services. That this is the case is quite obvious not only from the nature of the depreciation, but from ordinary business conditions. Depreciation is incurred because of the service and must therefore, like the other costs of this service, be borne by the takers. Unless it is so borne it would not be possible to obtain capital at such rates of interest as those which are accepted when it is understood that the property is to be kept up.

The operating expenses of the plants also must be audited, examined and carefully analyzed. The reason for this is that only amounts that are reasonable and necessary under the circumstances should be included in the expenses upon which rates are based. These examinations cannot safely be limited to the expenses alone, but must frequently be so extended as to cover all other records of a plant, its methods of operation, the efficiency of its management and many other factors.

When the total cost of the service has been determined, it is necessary to so classify and apportion the various items therein that proper costs per units can be obtained. Such unit costs are one of the requisites for scientific rate making.

In the railway service, the expenses and fixed charges are first apportioned between passenger and freight traffic. When the total cost of the freight traffic has thus been ascertained, it is further apportioned as between the cost of handling the freight at the stations and the cost of moving it between stations. The latter apportionments are necessary because the terminal cost depends on the number of tons handled, while the movement cost depends on the length of the haul. With these costs, together with other necessary operating and traffic statistics at hand, it is possible to determine, for the average loading per car, the gross and net cost per ton of the terminal expenses and the gross and net cost per ton per mile of haul of the movement expenses. These costs per units under average loading are further modified by the effect upon these costs of the respective loadings per car, by the effect of the weight that is and should be given to the value of the articles in rate making, and by the effect of such differences in the cost as are usually found between local and through transportation; the figures or unit costs so obtained are certain to be of the greatest aid in establishing just and reasonable rates. In fact, these figures are indispensable in rate making, even in cases where they may have to be further modified because of competitive and commercial conditions.

The loading per car greatly affects the cost per unit of transportation. One reason for this is that switching and other terminal expenses per car are about as great for a car that is lightly loaded as for a car that carries a heavy load. Another reason is that in moving the freight between the stations, the cost per ton is as great for the car itself as for the freight in the car, and that in light loading, this cost of moving the car alone must be borne by a smaller quantity of articles or pay freight, while under heavy loading this cost per car alone is distributed over larger quantities of articles. Owing to these facts, the net costs per unit are often several times as great under light as under heavy loading.

Local or way freight trains, owing to the frequent stops that are necessary in handling traffic from station to station, make less mileage than trains which handle through traffic. They also, as a rule, carry lighter loads. The result of this is that the costs per unit of traffic are often somewhat greater for local than for through traffic.

The value of the articles is a recognized element in rate-making. While it costs no more, when other conditions are the same, to transport more costly than cheaper goods, the former involve greater risks, and can bear much higher charges. Rates that cover their proportion of the operating expenses, including interest and profit, at the rate of say 30 per cent., may be less of a burden on high grade traffic than is the case of rates which cover their share of the operating expenses, including interest and profit, at the rate of say only 3 per cent. for low grade traffic. To charge higher rates for more costly than for cheaper commodities is in line with public interest, for it is only at lower than average rates that many low grade materials will move at all.

Competitive and commercial conditions must also be recognized. While, owing to consolidations, active competition is less important than formerly, it is yet a force that must receive consideration in rate-making. To meet conditions of this nature, it is often best for all concerned to accept competitive business at rates which are high enough to cover the additional cost of handling such traffic, plus a small amount [illegible] charges, provided, of course, that such [illegible] effect without unjust discrimination in other respects.

Few subjects are more complex than these which involve rates that are equitable and just to all concerned, and few are also of greater importance to the public. Rate schedules under which each department and each customer are made to bear their just share of the total cost of the services do away with unjust discrimination in rates. They provide like rates for like services under similar conditions. This is of special importance in the transportation field, and in the case of power rates, wherever slight advantages or disadvantages stand for success or failure, not only among industrial enterprises, but among localities as well. The value to the public of the elimination of rates that are too high and of discriminatory practices of this kind and of the establishment of equal conditions in these respects, is many times as great each year as the cost of maintaining the commission.

UNIFORM ACCOUNTS AND REPORTS.

Whether the principles which govern public utility regulation are violated, is largely a question of facts. It is in order to find the facts that the service of such utilities is inspected and other activities investigated. To this end also it is necessary that their accounts and records should be kept on some basis that is uniform, that discloses the integrity of the various items, and under which they are so classified and arranged that they may be subjected to the proper analyses. In fact, effective regulation is largely, if not entirely, dependent upon the degree to which the actual facts involved are known and understood.

The Wisconsin law provides that every public utility shall keep such uniform accounts and records of all the business transacted and make such reports thereon as may be required by the commission. In accordance with this, the commission has prescribed classifications and forms of accounts, records and reports for each class of utilities of the same kind. They have now been in effect for some years and have brought good results.

Accounts so kept and reports so made enable comparisons of like facts for the same utility from time to time as well as between different utilities. They show all changes that take place in the various items and enable one to judge of their integrity. They disclose whether plants are efficiently operated and point out ways of improvements in the operation. They enable the various items to be grouped with reference to the causes from which they emanate as well as in accordance with proper units upon which for one purpose or another they may have to be apportioned. They disclose maximum, minimum, average and normal costs per unit, as well as other elements that are of the greatest importance. In fact no statistical compilations and no unit costs could be secured that would be of real value unless the financial and the operating reports were compiled upon a uniform plan of this kind.

Even when so kept, the accounts and reports often require careful checking and auditing. No important rate case, for instance, is passed upon without the examination of books and records.

CAPITALIZATION.

Another important duty of the commission is to supervise the issuance of securities. Under the Wisconsin law, public utilities cannot issue stocks and bonds without a certificate of authorization from the commission, and they can be issued only for cash, property or services. If the payment is in property or services, an appraisal of their value is made by the commission, so that in no case will the security issues exceed in amount the value paid into the corporation. The commission also takes care that the bonds shall not constitute an unduly large proportion of the security issue. The purpose of all this is to establish as close relations as possible between the investment and the securities issued, and also to keep the management of the property in the hands of those financially interested [illegible]

The evils of overcapitalization of public utilities are many

It makes the securities a speculative instead of an investment proposition. It contributes toward keeping the small local investor out of the public utility field, because the small investor will not risk his capital unless the securities offered to him are not only placed on a safe basis but are fairly demonstrated by some trustworthy authority to be so placed. This exclusion of the local investor from the public utility field is a great loss both to the investor and to the public utility. It deprives the former of a better paying investment than the savings bank, and as to the latter, it prevents that community of interest and harmonious relation between the utility and its customers which is likely to be present if the customers have a financial interest in the utility. This point, though generally overlooked, is exceedingly important, especially under the conditions of public sentiment toward public utilities that are generally prevalent today. A fairly general local holding of public utility securities would go farther in preventing the unpleasant and often expensive controversies that now so frequently arise between utilities and their patrons than almost anything else that can be mentioned.

Furthermore, since overcapitalization increases the risk to investors, it must also tend to increase the rate of return which must be allowed on their investment, for as has already been explained, the element of risk is of much importance in determining the reasonable rate of return. That many utilities, because of their financial methods, find it difficult to obtain needed funds at reasonable rates of interest, is only too well known, and the result is an economic waste that could easily be avoided. Overcapitalization also tends, in the absence of strict regulation of rates, to keep the utilities' rates higher than they would otherwise be, for strong pressure is exerted upon the management to pay dividends on the inflated capitalization, and reductions in rates are vigorously opposed by the security holders. Another result of this pressure is that earnings, which should be used to provide for repairs and depreciation, are often paid out to the security holders in interest and dividends, and the service of the plant naturally deteriorates. Failure to provide needed extensions to the plants is another important result of this policy.

Overcapitalization also has a bad moral effect on officers, employees and the public, because it represents both efforts and training in receiving something for nothing. It is often a means for covering up excessive earnings and an excuse for bad service.

All reasonable expenditures in promoting, financing and constructing the plant and developing its business are proper subjects of capitalization. If such items only are capitalized, then it would also follow that the outstanding securities would agree quite closely with the amounts invested and with the amount upon which investors are entitled to reasonable returns for interest and profit, at least under normal conditions.

As the utilities are managed or operated by the stockholders or their representatives, it is of the utmost importance that there should be a proper relation between the stock and bond issues by which the investment is represented. When, as is often the case, the bonds represent practically the entire cost of the plant and its business, and the stock little or nothing in the way of actual investment, it necessarily follows that the business may be managed and the operations controlled by those who have no actual investments of their own to look after, and who may therefore have more to gain from a reckless than from a proper and honest management.

One of the most effective means, therefore, to bring about honesty and effectiveness in managements is perhaps the one that has been suggested, namely this, that no stock should be issued which does not represent outlays either in cash or property or in performing needed service. Experience teaches that properties and business are, as a rule, much better managed by owners than by those who are not owners. The proportion of the equities in a plant that should thus be represented by stock is a matter that must largely depend on the circumstances in each particular case. Ordinarily, however, it should not be much less than one third.

Applications for security issues must be accompanied by detailed statements showing the purposes for which the issues are desired as well as statements showing the assets and liabilities and the earnings and expenses of the plant. These statements are closely examined by the commission. When the issues are made for other property than cash, such property is also carefully appraised. In addition to this the plants are also required to make subsequent reports upon how the securities issues were exchanged or the proceeds therefrom expended. These reports are also examined and verified by the commission. In this and other ways security issues are closely regulated.

Economic theory and public policy demand that in cases where monopoly conditions prevail there should be close relation between the amounts judiciously invested and the securities by which this investment is represented. Any other course in the public utility field is, in the long run, almost certain to result in poorer service to their customers and in losses to their investors. In other words, the gains which come to the few from improper financial practices are inequitable and in the end are also certain to have to be unjustly borne by the public.

REGULATION OF CAPITAL EXPENSES.

There is one more field in which the commission has an important function in promoting the highest efficiency and lowest cost of public utility service. This is in the prevention of duplication and waste in the establishment and extension of both railway and municipal utility plants. It is recognized by the railroad and public utility laws of Wisconsin that public service corporations are in their nature monopolies, and that the interests of the public are best conserved by protecting monopoly in these industries and at the same time supervising and regulating them in the public interest. To carry out this purpose, competition among public service companies in the establishment of new lines and plants is prohibited except under such conditions as make its existence a benefit to the public.

In the case of railway companies, the Wisconsin law provides that before new lines are built or extensions are made, a certificate must be obtained from the commission stating that public convenience and necessity require the construction of the new line. The problem here is somewhat different than in the case of most municipal utilities, for no two railways serve exactly the same territory, and although the terminals and some of the intermediate stations may be the same, it may well be that the remainder of the territory traversed is so badly in need of railway facilities that the authorization of the entire line may be warranted. In such cases the amount of population, its tendencies as to growth and industry, the availability of existing facilities, and many similar facts are material and require careful consideration. It is also important to determine whether the new line is likely to be capable of profitable operation, for a railway line which cannot make expenses is likely to be more of a burden than a benefit to the community.

By keeping fairly close rein on the investment of capital where another investment has already been made for the same purpose, and at the same time permitting such extensions and even duplication as will result in the greatest development of profitable business and the widest diffusion of needed services among the public, the commission's regulation of capital expenditures is capable of producing very beneficial results to investors and a permanent advantage to the consuming public.

THE WIDE FIELD FOR REGULATION BY COMMISSION.

It appears from what has thus been said that there is a widespread need for effective regulation of the services, rates and financial practices of public utilities, and that such regulation, when fair, is in line with public policy; that such regulation should be largely governed by existing conditions, and that it should be flexible enough to properly adjust its activities to such conditions, that it is more concerned with preventing future wrongs than with redressing past offences; that the wrongs it is designed to prevent are comparatively small when considered individually but large when taken in the aggregate; and that

since many of the individual wrongs are small, it is of the greatest importance that some method should be devised under which they can be adjusted at the lowest possible costs to those who are thus harmed.

We thus find that the work of regulation is of such a character that it does not fit in with the work of the courts. Courts deal with what has happened rather than with what may happen. They redress wrongs already committed and the precedents they establish serve the same purpose. They are not prescribing, establishing and enforcing rates and regulations to be complied with in the future. Not being equipped with trained staffs for this purpose they are not in position to gather the facts that are required for intelligent regulation nor to exercise the necessary supervision in connection therewith. Their methods of procedure are slow, formal, and costly to the litigants. They are adjusted to work of a character different from that which is involved in the regulation of public utilities.

Franchise and other legal provisions fall short of providing such regulation as is needed. Provisions of this sort are seldom based on actual conditions, the data needed for this purpose not being available. Fair rates and adequate services can only be determined by such processes as those outlined above and this work can hardly be continuously carried on except by bodies which are organized for this purpose. Conditions by which such regulation must largely be governed are also constantly changing. Rates, for instance, which are fair when put into effect may be unjust shortly thereafter or long before franchise and other provisions expire. This is also true of service and other regulations. Methods of regulation which are inflexible and which remain the same regardless of conditions are more likely to be harmful than beneficial. In such matters it is seldom safe to rely on guesses as to future conditions. Franchises and other laws of this sort are also as a rule ineffective for lack of proper enforcement.

It is because effective regulation of public utilities cannot be had either from the courts or from franchise and other provisions of this kind and because competition is also ineffective for this purpose, that people in this country are turning to the public utility commissions for relief. From such experiences as we have so far had in this matter, it also seems that such commissions, when provided with such power and such equipment as those conferred by such laws as the public utility law of Wisconsin, are the very tribunals that can best meet this demand.

Public utility commissions of this kind are established and organized for the very purposes of such regulation. They are therefore provided with the employees and other facilities that are needed for the establishing of reasonable rates and standards of service and of seeing to it that these rates and standards are actually complied with. They are also required and equipped to perform much other work in the same line. In addition to that they have all the power that is necessary to carry their work into effect. The inspection and supervisory power which such commissions have are among the most important features of the work. It seems to contribute more towards establishing equitable and fair conditions in the public utility field than almost anything else.

Such commissions being appointed for a long term of years, and charged with important duties of a highly technical character are also likely to be taken almost entirely out of politics. This means that politics alone will not shape their policies; that irrelevant and disturbing influences of all kinds are gradually being eliminated from their work, and that they are able to adopt sound policies and to determine the question before them on their merits. The importance of all this is much greater than is generally realized.

There is perhaps no more important feature of commission regulation than the fact that it affords an inexpensive and, for the most part, prompt remedy for such grievances as are constantly arising between individuals and the public on one hand and utilities on the other. In Wisconsin, for instance, far the greater proportion of the complaints of all kinds are settled either through correspondence or in informal conferences. All the aggrieved party does in most of these cases is to write the facts to the commission. The commission thereupon investigates the matter. In fact it does practically all the work that is necessary for settlement of the same upon the facts.

While state regulation through commissions in the form in which it exists in Wisconsin and a few other states dates back only a few years, it has probably been in existence long enough so that the experience under it will disclose whether it fairly meets the purposes for which it was created and whether it yields results that are in line with public policy. On the one hand it can be said that regulation has resulted in better service at lower rates and that it has done away with most forms of unjust discrimination. The direct benefits thereof to the public have been great. These benefits have also been obtained without injustice to the utilities or their owners. The indirect benefits therefrom, such as accrue from the facts brought to light and published in all work of this kind are also important. Such facts have become the basis for demands for improvements in the conditions as well as the means by which unjust suspicion and unfair agitation have been allayed. Publicity is always an important factor in all matters affecting public interests. This system of regulation has also in a measure taken the utilities out of local politics.

On the other hand, it must be admitted that it has not brought the millennium. Many are much more critical of the service and exacting in their demands in this respect than they were before regulation was ushered in. Others again are much disappointed because the reductions in rates have not been greater and because the values placed on the plants have not been lower than those so far ordered. Some are also more or less disgruntled because the cases they may have started, cannot be decided immediately, or because they cannot always be safely passed upon until the plants have been appraised, their accounts audited, their other records checked, the hearings held and the reports upon the law and the facts prepared. Most of the complaints against regulation of the kind in question here are without foundation. They are much more frequently actuated by personal or political interests than by questions of public policy.

A NOVEL DESIGN FOR A HIGH ABUTMENT.

By E. F. Ackerman,
Assistant Engineer, Lehigh Valley, New York City.

The Lehigh Valley has recently completed the construction of a cut-off 13 miles long between Ashmore and Hays Creek, Pennsylvania. This line extends almost entirely through mountainous country and has a ruling grade of 1 per cent.

The Completed Structure.

compensated for curvature, descending from Ashmore to Hays Creek with a total fall of 437 ft. Among other advantages, the cut-off effects a saving in distance of 10¾ miles in the movement of coal from the Hazleton coal region to points in the west. Work on this line was started about August 15

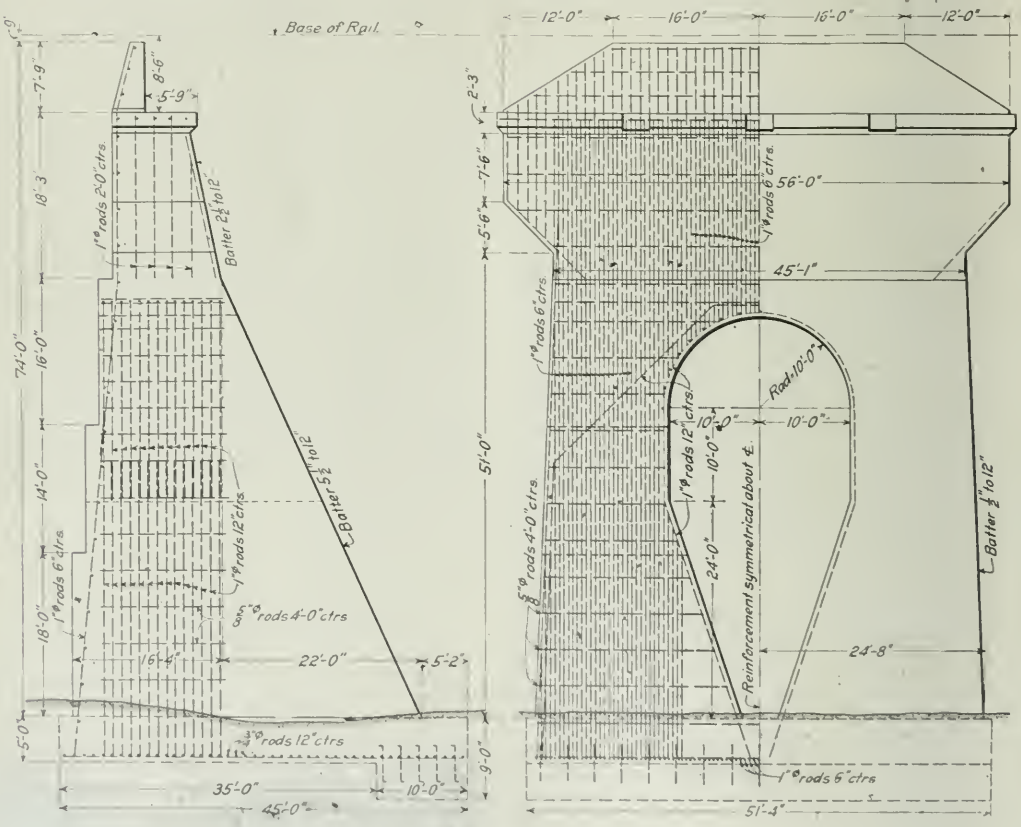
1910, and the line was opened for operation December 26, 1911.

There are three bridges on the line, of which the most important is the one over the main line of the Central Railroad of New Jersey and the Lehigh river. This bridge is 632 ft. long over all, and consists of two deck girder spans over the railway and three riveted deck truss spans over the river, all built for single track. The base of rail is 87 ft above low water. The substructure, which was built for double track, is of concrete and consists of two abutments and four piers, one of which is located in the middle of the river.

One of the abutments was of rather unusual design and was known as the pier abutment, because of the fact that the embankment was allowed to slope about and practically bury it The abutment was located on the river flat which was inacter resting on yielding ground, it was decided to build a structure that would eliminate as far as possible the thrust of the embankment. This was accomplished by filling entirely around the abutment to neutralize to a certain extent the earth pressures, and by placing an arch opening in the structure, thereby reducing the back area by about 18 per cent. The design of the structure is shown by the accompanying plan.

The arch opening was further effective in reducing the foundation pressure by an amount represented approximately by the difference in the relative weight of the concrete replaced by the earth fill. The arch opening represents a volume of 602 cu. yds., or 30 per cent. of the total yardage of concrete above the foundation footing, which amounted in all to 1,995 cu. yds.

The foundation footing containing 640 cu. yds. of concrete



Side and Front Elevations of High Abutment.

[illegible] years ago by a dam then existing about a quarter of a mile down stream. Sawdust from the various saw mills of that period collected and settled over the flat for a depth of about 6 ft. Test pits to a depth of 12 ft disclosed a mixture of silt and sawdust very fine river sand, soft red clay and some boulders and deeper tests with a Calyx drill indicated soft [illegible] numerous boulders. Although ledge rock outcropped along the right shore of the river at a point about 250 ft. up stream from the bridge, it was impossible to test to rock with the [illegible] at hand.

[illegible] originally intended to carry the foundations to rock, but [illegible] was out of the question and as there was to be an embankment 73 ft high built of material of unknown char-

consists of a slab 6 ft. thick and 45 ft. wide by 45 ft. 4 in. long, with a toe in front designed to resist any sliding action, and the base was designed for a uniform pressure of about 2.7 tons per sq. ft. Tests of the bearing value of the foundation material indicated approximately 3.8 tons per sq. ft., at which load practically no settlement was observed in 24 hours. Check levels made during the progress of the work showed very slight settlement, not exceeding 0.02 ft., and after the completion of the structure and embankment around it, there was no settlement whatever, neither was there any evidence of movement due to the action of the embankment In order to economize in the amount of concrete, and at the same time provide against the embankment running around the backwall and covering the

lower chords of the truss, wings or ears were cantilevered out at each end of the bridge seat, thereby lowering the slope line in front of the abutment.

The abutment was constructed during the winter with excellent results. Although freezing weather prevailed, the temperature sometimes falling to zero and below, the work was carried on by placing a steam jet in the mixer and by heating the sand, gravel and stone piles with a system of steam pipes placed underneath. Although the concrete was mixed about 1,500 ft. from the bridge, its temperature when placed in the form was approximately 75 deg. F., and when quitting work for the day, the temperature of the air in the form was approximately 35 deg. F. in zero weather. At night the top of concrete was protected with a covering of tar paper and tarpaulin, and next morning the protective covering would be white with frost, although the concrete was still warm. Three days after filling, the forms would be moved up for the next lift and the supporting rods removed. These rods, when withdrawn were too hot to handle with bare hands.

The accompanying photographs show the masonry during construction. The six rails placed about 4 ft. below the springing line were put in by the contractor to support the centering for the arch and were not provided for in the plans.

The embankment was dumped from narrow gage cars on

The High Abutment Before Forms for the Last Course Were Removed.

trestle placed back of the abutment, rehandled in wheelbarrows and deposited in front of the abutment for a height of about 20 ft. The balance of the fill was made by dumping from the completed bridge, the material being discharged over timber aprons which prevented the dumped material from striking the steel trusses. A gang of laborers rehandled the material, as dumped, so as to conform with the desired slopes. As a precaution against scour by floods, the toe of the slope was protected by a dry stone wall, or rip rap, about 4 ft. thick and 8 ft. high.

The river pier was started late in December, 1911, the first work consisting of the building of a squared timber coffer dam. This dam was constructed on the ice and then sunk through it. Before the work of driving sheeting around the dam was completed, there was a sudden thaw and a rise of water, causing the total loss of the coffer dam. The contractor abandoned the idea of replacing the timber dam and resorted to a bag dam consisting of about four rows of gunny sacks filled with fine loamy sand and piled about six rows high. Excavated material was banked on the outside of the dam and the water which was about 3 ft. deep was pumped out. The excavation work was done during severe winter weather and it was possible to excavate to a depth of 12 ft. below the bed of the stream without resorting to sheeting as the seeping water froze as fast as it appeared on the interior of the excavation, practically preserving nearly vertical excavation faces.

The Completed Abutment.

A 6 in. centrifugal pump readily unwatered the foundation by working about four hours daily.

As a second track may be built at an early date, the down stream line of trusses of the three spans over the river were designed and built to carry one entire track, so that when the second track is required it will only be necessary to add a third truss on the down stream side without moving or changing in any way, the three trusses already built, which will then be center trusses between the two tracks. The plate girder spans on the south side of the river were built for single track, as their spacing permits of building the separate spans. However, the inside column of the bent carrying the long plate girder span was also built to carry the additional weight of the second track.

The work was done under the direction of E. B. Ashby, chief engineer; F. E. Schall, bridge engineer, designed the masonry and the superstructure, and the writer was in charge of the construction.

Railroad Construction in Paraguay.—The concession for constructing the Northeast Paraguay Railway has been extended one year by the government. Its construction should have been started in 1912, and according to the concession the line is to run from Asuncion to the Guayra Falls, joining up there with the Brazilian line to Sao Paulo. It is estimated that by the end of 1915 the line will be completed both in Paraguay and Brazil, thus giving Asuncion direct communication with the cities of Sao Paulo and Rio de Janeiro. Before the close of 1914 the railway known as the Trans-Paraguay will be open to traffic, thereby connecting the Paraguay Central Railway with the Brazilian line at the Iguazu Falls, thus bringing Rio de Janeiro within 60 hours of Asuncion.

TRAIN ACCIDENTS IN FEBRUARY.[1]

Following is a list of the most notable train accidents that occurred on railways of the United States in the month of February, 1913:

Collisions.

Date.	Road.	Place.	Kind of Accident.	Kind of Train.	Kil'd.	Inj'd.
4.	Grand Trunk	Edwardsburg.	rc.	F. & F.	2	4
*6.	St. Louis, I. M.	Collinston.	xc.	P. & F.	0	3
*16.	N. Y., N. H. & H.	New Haven.	rc.	P. & F.	0	0
20.	Boston & Albany	Bondville.	rc.	P. & F.	0	2
21.	Penn. Lines	New Alexandria.	rc.	F. & F.	1	0

Derailments.

Date.	Road.	Place.	Cause of Derailm't.	Kind of Train.	Kil'd.	Inj'd.
1.	Houston & Tex. Cen.	Benchley.	d. track.	P.	2	9
2.	Illinois Central	Seward.	b. rail.	P.	0	0
4.	L. & J. Bridge	Louisville.	ms.	F.	1	0
26.	Atch., T. & Santa Fe.	Weitzer.	unx.	P.	0	0
27.	Ches. & Ohio	Stepstone, Ky.	unx.	F.	0	1

The trains in collision near Edwardsburg, Mich., on the fourth, were eastbound freights. The caboose and three cars of the leading train were wrecked and the engine of the other was badly damaged. Six trainmen and other employees riding in the caboose of the leading train were injured, two of them fatally. The second train should have been held at Edwardsburg, but it is said that by reason of a snow storm the engineman did not see the flag which had been displayed to stop him.

The collision at New Alexandria, Ohio, on the 21st occurred on a side track. A standing freight was run into by a following freight and the flagman of the standing train, who is believed to have been asleep in the caboose, was killed. Failure to protect the standing train and excessive speed in bad weather by the other train are given as the causes of the collision.

The passenger train derailment which occurred near Benchley, Tex., on the first, occurred about 3 a. m. The train was No. 17, and it was running about 40 miles an hour. The engineman and fireman were killed and six passengers and three trainmen were injured, the passengers not very seriously. The derailment was due to irregular track, caused by continuous heavy rains.

The train derailed on the road of the Louisville & Jeffersonville Bridge Company, at Louisville, Ky., on the morning of the fourth about one o'clock, was a switching freight moving backward. A brakeman jumped off or fell off one of the cars and was run over and killed. The cause of the derailment seems to have been a misplaced switch.

The train derailed near Weitzer, Col., on the 26th was southbound passenger No. 568. The derailment is believed to have been caused by the loosening of a tire of one of the wheels of the locomotive, and the engine was overturned. The trainmen and fifty passengers on the train escaped with slight injuries.

The train derailed at Stepstone, Ky., on the 27th was eastbound freight No. 92; and 14 loaded cars were wrecked. A trespasser riding on one of the cars was injured. The cause of the derailment has not been determined, but seems to have been excessive speed with a top-heavy car—a refrigerator loaded with beer.

Electric Car Accidents.—Of the accidents to electric cars recorded in the newspapers as occurring in the United States in the month of February, only one is reported as having been attended by fatal results, a collision between a passenger car, fully loaded and a freight car, near Cheshire, Conn. About 40 persons, altogether, were injured, but only one fatally.

[1] Abbreviations and marks used in Accident List: rc., Rear collision—bc., Butting collision—xc., Other collisions—b, Broken—d. Defective—unf, Unforeseen obstruction—unx, Unexpected—ms, Open derailing switch—ms, Misplaced switch—acc, Accidental obstruction—malice, Malicious obstruction of track, etc—loco, Explosion of locomotive on road—fire, Cars burned while running—P. or Pass., Passenger train—F. or Ft., Freight train (including engine, work train, etc.)—*, Wreck wholly or partly destroyed by fire—D, Dagger, One or more passengers killed.

ARBITRATION OF THE FIREMEN'S WAGE CONTROVERSY.

W. J. Lauck* was the last witness called by the firemen in the arbitration proceedings. After one day's recess the railroads opened their case on Friday morning last. Before calling the first witness, Elisha Lee, chairman of the conference committee of managers, made a statement from which we quote as follows:

"With the indulgence of this board, I should like to say a few words as to the general theory which will underlie the evidence we shall present and ask you to consider. The railways appear before this tribunal as institutions built up by the investment of private capital and yet unable to control the price at which they may sell their transportation, to produce which is the purpose of their existence. We believe that it is wise and in the public interest that the people should, through properly constituted commissions, protect themselves against unreasonable or discriminatory charges or practices by public utilities. But the railroads constitute institutions which not only cannot control the price of their product, but they have not the privilege of getting, in the cheapest market, the labor with which that product is largely manufactured. They must keep the transportation machine moving. The public has given unmistakable evidence of a disposition highly to disapprove of any interference with railroad operation, no matter by whom caused.

"It was in recognition of our responsibility to this public that we consented to abide the arbitrament of this board. We conceded that the firemen were faithful and hard working. We offered to apply the conclusions of the fair and able board which adjudicated last summer the case of the engineers, but the demands of the men were so far beyond what we felt we could in reason concede, that an impasse was created which, to prevent the public inconvenience of a strike, your honorable board was constituted to dissolve.

"This board represents the public in a peculiar sense. It embodies primarily the widespread and justifiable view that strikes on public utilities should not be permitted to take place. It gives visible evidence of the principle that public convenience is paramount and that to that end all interests must bow. To such sentiment the railway companies feel a keen sense of responsibility. Their corporate character renders them peculiarly subject to a belief on the part of the public that responsibility for any cessation of traffic rests solely upon the railway managers. To our firemen friends, however, this sense of responsibility does not seem to be so acute. They represent no one but themselves, not even their fellow-workmen in other lines of railway employment; they cannot experience the direct results of public displeasure. Railway employees have come to know that a strike which would tie up traffic is well nigh unthinkable. They know that if a strike doesn't take place the railways must give way. The men make large demands upon railway managers, not expecting those demands to be granted but believing that arbitration must take place, and that in the end the splitting of the difference between what they demand and what the railways offer will result in their favor. In thus stating the case we but paraphrase the observations of the representative court which adjudicated the case of our engineers but a few months ago.

"The plan of labor leaders has been to get the roads paying lower wages to raise them, then apply pressure to those paying higher wages to re-establish the previous differential. Step by step, the campaign has proceeded. Thus, today, the railways are face to face with large demands from their trainmen.

"We are likewise confronted with constantly increasing demands through mandatory legislation. The New York Central estimates that the cost to them, and the waste to the public, of the extra crew bill now pending in New York, will be over $700,000 per year. The purpose of these citations is to place before this tribunal something of the state of mind and the feeling of un-

*See *Railway Age Gazette* March 21, 1913, page 667. The arbitration proceedings thus far have been reported in the *Railway Age Gazette*, issues of March 14 and March 21.

certainty of railway managers in their dealings with their labor.

"In the presentation which the railways will make to this court, therefore, we shall ask you to bear in mind these somewhat intangible, but nevertheless essential elements in the situation. All the roads concerned in this movement do not plead poverty or impending bankruptcy as a reason why even the whole of the demands of the firemen should not be granted. The basis of our contention, the theory which has pervaded all our negotiations is this: Appreciating our responsibility to the public to provide an adequate and efficient transportation machine, menaced upon every side with growing burdens making it constantly more difficult for us to obtain adequate capital with which to finance needed improvements, unable to estimate either our revenues or upon what basis of cost we shall be permitted to earn them, we have felt it our duty not only to our shareholders, but to the public whom it is our duty to serve, to resist to the breaking point those demands of labor which we believe are extravagant and entirely out of accord with our obligations as a whole. We now propose to show that these men are today well paid for the services rendered and the rules and working conditions are such that they do not require the radical changes requested."

In reply to a question from Judge Chambers, Mr. Lee said that there may be some roads in the conference whose wages to firemen are too low, but he questioned if this were the best way to raise them. He also objected to the basis of weight on drivers as being unfair, and cited the case of a small freight locomotive and a large passenger locomotive, the former often earning more for a railroad than the latter.

W. H. Holbrook, a road foreman of engines on the Pennsylvania Lines West, was the first witness called. He said that in case of a slacking off in business, the firemen are almost invariably the ones to ask for a reduction in the number of men. There are about 40 mechanical stokers in use on his division which are a great help and lighten a fireman's work very appreciably. One fireman told him of making 50 trips with heavy passenger trains and never having to do any hand firing after leaving the terminal. It is necessary to fire about 500 lbs. of coal by hand in preparing the fire. From his experience, he estimated that a stoker at present will do about 70 per cent. of the firing on any locomotive, and that with a few improvements it will do 100 per cent. all the time. He said the firemen were friendly to the stokers, and were glad to fire locomotives equipped with them. He did not consider the filling of a lubricator dangerous work if the instructions which are issued are carried out.

J. H. de Salis, chief road foreman of engines of the New York Central & Hudson River west of Syracuse, N. Y., was the next witness. He said that, in his opinion, firemen do not have as hard a time now as in 1902, considering all conditions. On the Mallet compounds used on the Pennsylvania division an extra man is provided to help over certain hard pulls in the summer months. He told of what are called split runs on the New York Central, in which one engineer runs a locomotive over the entire division but the fireman goes only half way and is then relieved. Going west this results in the company's paying firemen for 180 miles when only 152 are run, and going east they are paid for 200 miles, or $5.90. Mr. de Salis said that his understanding of the schedule now asked would raise this to $10.05 for two firemen in each case, or four over the whole distance. This refers to article nine of the firemen's request, which states, "Rates of wages that are higher and conditions of employment that are better than specified will remain in effect. . . ." Mr. Carter and Mr. Lee discussed this point for some time, but Mr. Carter claimed that it was not the intention to place four men on this run. Mr. Lee said that there was nothing in the article to indicate that four men would not be required. Mr. Carter suggested that any difference later could be referred back to the commission for adjustment and Judge Chambers asked if he would make that a ten-year proposition and attach a salary. Continuing, Mr. de Salis said he did not consider weight on drivers a fair basis for paying the men, and also that locomotives equipped with superheaters greatly decrease the [illegible] work.

Mr. Merkle, assistant road foreman of engines on the Cumberland division of the Baltimore & Ohio, followed. He said that the Mikados on his division are equipped with Street stokers and that as soon as a fireman becomes accustomed to the use of the apparatus he has no trouble. He previously ran a locomotive equipped with a stoker and said there was no reason why a fireman could not familiarize himself with one, and that the older firemen asked for the locomotives so equipped. He estimated that with the Street stoker not over 5 per cent. of the coal has to be fired by hand and also said that, personally, he would just as soon fire a large locomotive as a small one. He did not know about men being paid $1.00 a day extra to go to the Cumberland division, as a fireman witness had previously stated, but said that they had no more trouble keeping men there than elsewhere.

The next witness was J. S. Cavey, of the Baltimore & Ohio. He gave figures for a number of tests which he conducted on Mikado type locomotives in through freight service between Philadelphia and Baltimore. The conditions were as nearly as possible the same, except that in one series the firemen were instructed in the method of firing and in the corresponding series they were not. An average of six trips, instructing the men, showed 12,700 lbs. of coal burned, while without instruction the average was 16,500 lbs. In another case the average of four trips with instructions was 14,600 lbs., and of eight trips not supervised, 20,400 lbs. Mr. Cavey said that, in his opinion, firemen commonly burn much more coal than is necessary.

S. G. Wise, assistant road foreman of engines on the Middle division of the Pennsylvania Lines East, gave the results of a number of tests made to compare superheated with saturated steam locomotives. For consolidation type freight locomotives, one of these tests gave the following results:

	Weight on Drivers.	No. of Cars.	Tons in Train.	Coal Burned.
Saturated	211,000 lbs.	72	5,106	22,000 lbs.
Superheated	219,900 lbs.	82	5,900	18,800 lbs.

Mr. Wise also gave figures to show that firemen make, as a rule, as great a monthly mileage as engineers. In the cross-examination Mr. Carter did not succeed in shaking the witness in any way. Instead of getting him to admit that firemen are poorly paid, he brought out that Mr. Wise, while a fireman at less wages than are paid now, bought his own house and some others which he rents. Asked how he could live today on $60 per month, the witness said that their firemen now make over $100 per month, and that it does not, in his present position, cost him $100 per month to live and pay the expenses of a son at college.

M. C. M. Hatch, superintendent of fuel service, Delaware, Lackawanna & Western, followed Mr. Wise. He gave the following results of tests made on the Buffalo division with consolidation type locomotives with two firemen and Mikados with one:

	Consolidation.	Mikado.
Coal per locomotive mile, lbs.	187.6	182
Coal per hour, lbs., about	2,400	2,100
Average speed, miles per hour	13	15
Average coal per trip, lbs.	26,450	20,000

He said that the second man had practically nothing to do between shifts but take water.

Two of the same class of consolidations, one with a superheater and brick arch and the other without, under the same conditions showed a saving, per locomtive mile, of 11 lbs. of coal in favor of the superheater and arch. Mr. Hatch stated that by actual count, the number of scoops of coal fired on a Pacific type locomotive between Scranton and Hoboken in 3½ hours was 395. He also gave the following figures for passenger locomotive tests, the train and speed being the same in both cases:

	Ten-wheel type. (Wt. on drivers, 171,000 lbs.)	Pacific type. (Wt. on drivers, 180,000 lbs.)
Coal per trip, lbs.	18,350	12,850
Coal per locomotive mile, lbs.	135	94.5

Mr. Staub, statistician of the Delaware, Lackawanna & Western, gave figures to controvert the testimony of a witness on the firemen's side regarding the use of a second man on locomotives on the Buffalo division.

At the opening of the session on Monday Mr. Carter read a telegram from the chairman of the firemen's committee of the Toledo, St. Louis & Western saying that he had been informed by the superintendent that the conference committee had not been authorized to represent this road in agreeing to arbitrate, and that the road would deal directly with its employees. Judge Chambers remarked that if the road ever had been in, the board would attend to their staying in.

Daniel McBain, superintendent of motive power of the Lake Shore & Michigan Southern, presented figures to show that the work of the firemen had not increased to the extent that the testimony of the firemen's witnesses would lead one to believe. Mr. Carter read from the minutes of the convention of the American Railway Master Mechanics' Association at Atlantic City in June, 1912, a statement by C. H Hogan, assistant superintendent of motive power of the New York Central & Hudson River, that it was "almost beyond human endurance" for a fireman to fire one of the new, big freight locomotives at her maximum capacity and with a maximum tonnage. Mr. Carter presented a statement, which was reported as having been made by Mr. McBain at the master mechanics' convention in 1910, to the effect that in the last few years there had been "a tremendous increase" in tonnage with efforts to make better speed, and that it was difficult to get a man who could put into the fireboxes enough coal, and that he recommended mechanical stokers. Mr. McBain agreed that this was true.

The next witness was A. Seiders, road foreman of engines on the Philadelphia & Reading. He said that firemen on the Philadelphia & Reading made as great or greater mileage than enginemen.

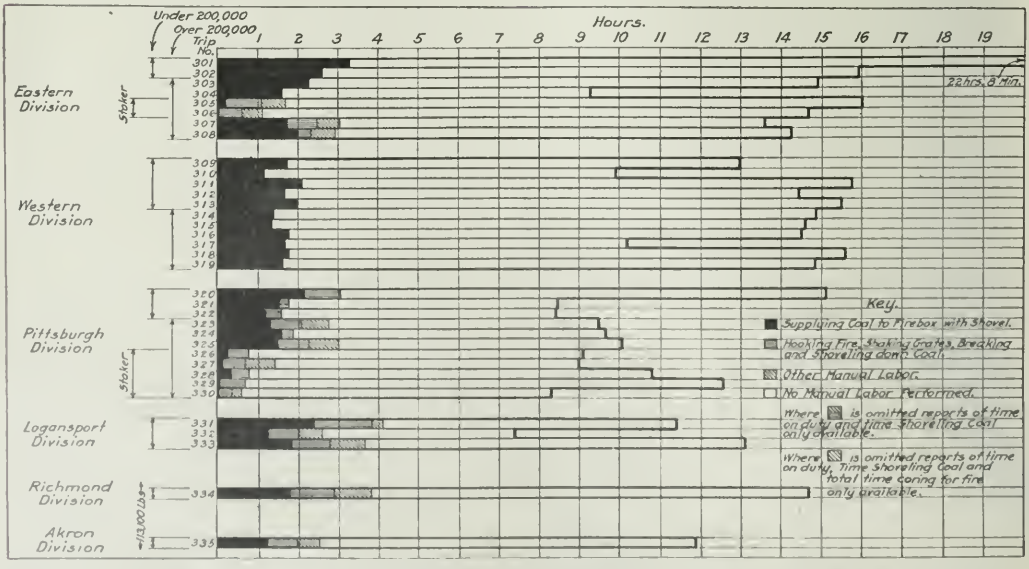
S. A. Bickford, road foreman of engines on the electric division of the New York Central & Hudson River, described the work of a fireman on an electric locomotive as consisting largely in looking out for signals, ringing the bell, and in winter attending to a small boiler which supplies heat for the train.

J. V. B. Duer, foreman of motormen on the New York division of the Pennsylvania Railroad, confirmed Mr. Bickford's statements and said that firemen on the electric locomotives on the Pennsylvania got the same scale of wages as firemen on steam locomotives.

J. F. Carroll, assistant general superintendent of motive power on the Baltimore & Ohio, described the successful use of mechanical stokers on the B. & O.

W. C. Hayes, superintendent of locomotive operation of the Erie, told of his experience with putting two firemen to a locomotive. He said that two men had been put on the Erie's heavy locomotives in response to demands of the firemen, but that the second man had been taken off after it had been discovered that although two men were assigned to a locomotive, only one was in many cases on the locomotive, the men taking turns at laying off and playing pool in the Y. M. C. A. building at the foot of the hill. In cross examination Mr. Carter tried to bring out a statement as to the heat in an attempt to show that the second fireman had remained at the bottom of the hill to get his feet cooled. Mr. Carter himself made the statement that it was 140 deg. 6 in. above the deck of the engine.

On Tuesday morning E. B. Dithridge, chief clerk in the general manager's office of the Pennsylvania Lines West, was the first witness. He said that he worked for nearly 20 years for the Pennsylvania and had been chief clerk in the general manager's office for nearly 11 years. He made a comparison of conditions and rates in 1902 and 1912 on the 100 miles on the Pittsburgh division between Dennison and Columbus. He said that in 1902 there were 24 H-4 engines and 25 H-6 engines in service on this division, and in 1912 13 H-4's and 68 H-6's. He said that just previous to the increase of wages which was made in January, 1902, the trip rate for the H-4's and H-6's was $2.14, with overtime after 11 hours, and that the trip rate today between the same points for the same class of service was $3.05, an increase of 42 per cent. Overtime today is at 30 cents or 30½ cents an hour, as compared with 19 cents in 1902, and overtime now begins after 10 hours. Previously men were allowed 30 minutes preparatory time, and are now allowed an hour. The average earnings for each name on the payroll in January, 1902, was $65.30, and the average for each name on the January, 1912, payroll was $94.26. Mr. Dithridge estimated



Length of Time on Duty and Time Occupied by Firemen in Various Ways on the Pennsylvania Lines West in Freight Service, February and March, 1913.

that firemen as a whole, including yard, freight, passenger and all firemen on the Pennsylvania Lines West, are getting 42.57 per cent. more money for their services now than they would have been paid under the rates and conditions in effect at the end of 1901.

T. F. Crawford, general superintendent of motive power of the Pennsylvania Lines West, was the next witness. He said that he had had no college education, had begun work as an apprentice in the Altoona shops, and had worked his way up through the ranks to his present position. Mr. Crawford presented statistics and diagrams to show that the effect of putting in service larger locomotives was not to increase the manual labor of the fireman. One of the diagrams introduced is shown herewith. Mr. Crawford said that in his opinion the figures which he introduced and those shown on the various diagrams, including the one shown herewith, demonstrate that there is no relation between the manual labor required from the fireman and the size of the locomotive. The following table shows a comparison of the average tractive power per locomotive in pounds; the average weight on drivers per locomotive in pounds; the average pounds of coal per locomotive mile, and the average wages paid firemen per locomotive mile in passenger service on a percentage basis, using 1910 as 100 per cent. and taking the information from 40 roads:

	Tractive power.	Weight on drivers.	Coal.	Wages.
1910.....	100.0	100.0	100.0	100.0
1911.....	103.8	104.0	101.3	104.2
1912.....	106.7	107.2	103.2	106.0

Mr. Crawford's figures showed that while the average tractive power per locomotive in passenger service had increased from 14,890 in 1900 to 22,300 in 1912; the average weight on drivers, from 65,114 in 1900 to 109,400 in 1912, and the average pounds of coal consumed per locomotive mile, from 69.6 in 1900 to 108.3 in 1912, the average wages paid firemen per locomotive mile had increased from 1.82 cents in 1900 to 2.64 cents in 1912. In freight service the average tractive power per locomotive had increased from 22,830 in 1900 to 34,743 in 1912; the average weight on drivers, from 102,630 in 1900 to 150,453 in 1912; the average pounds of coal consumed per locomotive mile, from 133 lbs. in 1900 to 195.2 lbs. in 1912, and wages per locomotive mile from 2.68 cents in 1900 to 4.26 cents in 1912. Mr. Carter asked whether if, instead of taking the average tractive power per locomotive mile they had taken the total tractive power in service, the increase in 1912 over 1900 would not have been a very much larger percentage. Mr. Crawford agreed that this was true. He said that the way his figures had been arrived at were as follows: The total tractive power of all locomotives had been divided by the total number of locomotive miles, and that the same method had been used in 1900 as in 1912. Mr. Carter tried to show that while Mr. Crawford's figures were correct insofar as being a proper exhibition of his method if he had used some other method the results would have been very different; but the witness would not admit that any other correct method could have been used. What Mr. Carter was apparently trying to show was that the percentage of increase of total tractive power was greater than the percentage of increase of total wages paid firemen. As a matter of fact, however, he did not ask the witness this question directly. Mr. Crawford submitted figures showing in detail the way in which the diagrams, similar to the one shown herewith, were compiled.

In redirect examination Mr. Crawford said that in his opinion the firemen had not contributed anything to the greater hauling power of locomotives and to the handling of the heavier tonnage in 1912 as compared with the tonnage handled in 1900. On cross examination he specifically stated that this statement was made not from the point of view of the employers, but actually as a matter of fact and of observation.

On Wednesday morning the cross examination of Mr. Crawford was completed. The questions dealt largely with the use of automatic stokers, and Mr. Crawford said that in his opinion there was no necessity whatever of having two firemen on one engine where a successful stoker was in use, regardless of the size of the engine. Men who have no knowledge of stokers are frequently called upon to fire stoker engines and have been known to make perfect records on their first trips under these conditions. The firemen have a more comfortable time where stokers are used, as the firedoor is closed during the greater part of the time and the coal dust annoyance is practically eliminated.

J. G. Walber, assistant to the third vice-president of the Baltimore & Ohio, presented detailed statistics showing the rates paid firemen for various classes of service by eastern, southeastern and western roads. In general the rates were higher for through freight service than for any other service exclusive of passenger service. The firemen asked for rates on the through freight service basis for these classes of service.

In their second amended proposition the firemen asked that firemen on all freight runs that load or unload freight, and firemen on all freight runs that set out or pick up cars, or do switching at four or more points between their initial and final terminals, be considered as in local freight, way freight, pick-up or set-out service and be paid 25 cents per day in addition to through freight rates. Mr. Lee contended that there should be no uniform rule governing all roads, and that local conditions should continue to determine this practice. Rules of a large number of roads regarding this practice were cited to show that at present they differed widely. Mr. Carter thought that a uniform rule was essential.

In their second amended proposition the firemen also asked that the following rule in regard to terminal delays be adopted: When the actual departure of any train is delayed to exceed one hour after a fireman is required to report for duty, or when a train has reached its final terminal limits and is then delayed from any cause so that the fireman is not relieved from duty within 30 minutes after having reached the final terminal limits, the firemen will be paid an additional compensation for all such delays over one hour at the initial terminal, and for all such delays over 30 minutes at the final terminal. Under this rule the fireman on a train which was due to start on a 100 mile run at 8 o'clock, but which did not start until 10 o'clock, due to unavoidable circumstances, and which arrived at its destination at 2 o'clock, where the fireman was again held 45 minutes, due to unavoidable circumstances, the fireman would be paid for a full day's work or ten hours plus one hour and fifteen minutes terminal delay. In other words he would be paid for eleven hours and fifteen minutes' work when he was only on duty six hours and forty-five minutes. Mr. Carter said that this rule was intended to penalize the roads for keeping the firemen on duty when their services were not wanted. Mr. Lee said that if the roads were to be penalized in this manner the firemen should receive less when their run of 100 miles was compelled in less than ten hours. Mr. Carter said that firemen were kept waiting at terminals when the officials knew that they would not be needed for hours. Mr. Lee said that they received pay for these waits. Mr. Carter replied that the firemen preferred not to work over ten hours a day, regardless of overpay. He said further that yardmasters frequently prevented trains from entering yards, claiming that there were no tracks available, but when those yardmasters found that the ten hour limit of the trip was approaching, they speedily found clear tracks. Mr. Carter thought that this rule would have the effect of allowing trains to enter the yards more promptly. It was shown that the Chesapeake & Ohio had adopted the practice of having the engines made ready by hostlers, so that the firemen were not needed until immediately before the train was due to leave. Mr. Carter advocated the adoption of this practice.

Under the provisions of the Erdman act a decision would be due on April 6. Both sides have, however, agreed to an extension of time and have left it with the board to decide how much more time will be needed. The board will fix a date later on.

General News.

On April 1 the general offices of the Chicago & Alton, now located in the Railway Exchange Building, will be removed to the Transportation Building, 608 South Dearborn street, Chicago.

The United States has begun suit in the federal court at Freeport, Ill., against the Illinois Central to collect penalties amounting to $6,200, for alleged failure to report violations of the hours of service law.

In New York City this week, the New York, New Haven & Hartford was fined $500 for violating the smoke ordinance. The offenses occurred some time ago in the yard at Harlem river, where electric locomotives are now being introduced.

The St. Louis & San Francisco now runs through trains, both passenger and freight, to and from New Orleans over the Yazoo & Mississippi Valley, a contract for the use of these tracks for 99 years having gone into effect on the 16th of this month. The contract covers a distance of 85 miles, the connections being made at Baton Rouge on the north, and Shrewsbury, about 5 miles from New Orleans, on the south. From Shrewsbury to the terminal in the city, the trains of the Frisco will use the tracks of the New Orleans Terminal Company, which is controlled jointly by the St. Louis & San Francisco and the Southern Railway. South of Baton Rouge the Frisco trains have run heretofore over the line of the Louisiana Railway & Navigation Company.

A special committee appointed by the Michigan legislature to investigate the financial history of the Pere Marquette has been holding sessions at Detroit. F. W. Stevens, formerly general counsel of the road, and now connected with J. P. Morgan & Co., produced statements showing that increases in wages, in cost of materials, and in interest and rental charges, had caused a deficit of $1,800,000 in 1911, and a slightly larger deficit in 1912, after the company had earned a surplus of $469,000 in 1910. He said that the wage increase alone in 1911, as compared with 1910, amounted to $1,022,000; that the gross earnings decreased $18,000, and the higher prices of materials cost the company $492,000. He also stated that proposed legislation now pending in the legislature, if enacted, would cost the road $818,000 annually, without giving it anything in return, and that the Michigan legislature had been particularly active in passing laws to increase the road's "cost of living." Even if the Interstate Commerce Commission had allowed the proposed advance in rates in 1910, the Pere Marquette would have received only $500,000 in increased revenue per year.

Large Capacity Wrecking Crane.

In an article describing a wrecking crane used on the Norfolk & Western in our issue of March 14, the weight in working condition was incorrectly stated. It should read 123 tons.

Law Against Stealing from Cars.

One of the measures recently passed by Congress makes it a felony to break the seal of a railroad car containing interstate or foreign shipments of freight, express or baggage, or to enter such a car with intent to steal, or to steal, conceal or by fraud or deception obtain from any railroad car, station-house, depot or platform any goods or chattels which are part of an interstate or foreign shipment of freight, express or baggage. Breaking into or stealing any part of the contents of a piece of baggage also comes under the provisions of the act, which applies with equal force to any person who shall buy, receive or have in his possession any freight, express, baggage or other goods or chattels so stolen, knowing the same to be stolen. The punishment for any of these offenses is a fine up to five thousand dollars or imprisonment up to ten years, or both, and prosecutions may be instituted in any district where the crime shall have been committed.

The carrying or transporting by a person of any such freight, express, baggage or goods or chattels from one state or territory into another, knowing it to have been stolen, constitutes a separate offense for which the same punishment is prescribed. Provisions for such transporting of stolen property may be prosecuted in any district into which the goods or chattels may have been removed or into which they may have been brought.

The making of these acts federal offenses, together with the severity of the punishment provided, is expected to prevent much crime of this character, as all offenders have a wholesome fear of United States courts and the promptness and certainty with which they mete out punishment.

Report on Gothenburg Collision.

The board of inquiry appointed by the Union Pacific to investigate the rear collision at Gothenburg, Nebraska, March 14, between train No. 12, the Denver Special, and train No. 4, the Atlantic Express, which caused the death of four persons, and injury to several others, has submitted a report placing the responsibility for the accident. The board finds that at the time of the accident an extraordinary and unusual blizzard prevailed in the vicinity; that the safety appliances were operating perfectly at the time; and that the cause of the accident was the failure of the engineer, John Weinberger, of train No. 12, to properly observe the signals and place his train under control, when passing the second block signal west of Gothenburg, the distant signal, and the failure to stop at the block signal located 1,100 ft. west of the point of the accident. The report is signed by Charles Ware, general manager, and W. R. Cahill, superintendent of the Union Pacific, and by the general manager of the Gothenburg Telephone Company, and the cashier of the Gothenburg National Bank. Train No. 4 had stopped at the water tank near Gothenburg when it was struck by No. 12, which, according to the testimony of the conductor, was going at the rate of about 10 miles an hour, having slowed down at the caution signal. The coroner's jury which investigated the accident reported that the collision was due to the very unusual severity of the storm, making the observation of signals very difficult.

Proposed New York-New Jersey Bridge.

The Interstate Bridge and Tunnel Commissioners appointed jointly by the authorities of New York and New Jersey have made a report of their doings for the past year; and they propose a bridge across the Hudson River from 58th street, New York City, to Weehawken, N. J., the central span of which is to be 2,880 ft. long. The eastern terminus of the proposed bridge would be near the south end of Central Park. Three miles south of here, at Canal street, there would be the New York terminus of a tunnel, for wagon traffic, beneath the river, which also is proposed by the commission. Preliminary plans and estimates for the bridge have been made by Boller, Hodge & Baird, of New York City, and estimates of the cost of the tunnel have been made by Jacobs & Davies, of New York. The engineers estimate that the bridge would cost twenty-nine millions, to which would be added five millions for land, five millions for interest charges and three millions for engineering and contingencies, a total of $42,000,000.

The length of the bridge entire would be 8,300 ft. It is proposed to carry all of the traffic on one level; two driveways, two tracks for subway railroads, two for elevated railroads, and two for surface street cars. The plan calls for a bridge 170 ft. above the surface of the river, which is 35 ft. higher than any of the bridges across the East river; and the towers supporting the main span would be 545 ft. high.

Railway Legislation.

The Oklahoma legislature has passed a full crew law. It provides that freight trains of thirty cars or more shall have three brakemen.

Fines aggregating $4,300 have been assessed against eight railways in Indiana for violations of the safety appliance act and the ash pan act.

The governor of Missouri has approved the bill passed by the legislature abolishing the railroad and warehouse commission, and creating the office of state warehouse commissioner. It is announced that Commissioner Bradshaw will be appointed to the office of warehouse commissioner, and that Commissioners Knott and Wightman will be made members of the new utilities commission for the period of their unexpired terms on the railway commission.

The Missouri legislature has passed a senate bill providing that no railroad corporation, rail, steam, street, electric, trans-

fer or terminal, except those incorporated and chartered in and under the laws of Missouri, shall be authorized or permitted to carry passengers or freight of any kind between points within the state, under a penalty of from $2,000 to $10,000 for each violation. As mentioned in last week's issue, the house passed a bill for similar purposes, but it has since concurred in the senate bill as noted above.

Disastrous Floods in the Central West.

Abnormal weather conditions throughout the central and western states during the past week have caused hundreds of deaths and destroyed many millions of property. A tornado in Nebraska, which did great damage in the western part of Omaha, wrecked buildings in that city on Sunday by the hundred and resulted in over two hundred deaths and many injuries. This was followed on Monday and Tuesday by heavy rains, causing floods in Illinois, Indiana, Ohio, and western Pennsylvania. The governor of Ohio reported that that state had suffered the worst disaster in its history, and including the floods, fires and deaths in Indiana he believed it would be the greatest tragedy in the history of the republic. From the brief and inconclusive reports published up to the time of going to press, we make the following notes:

Dayton, Ohio, was flooded throughout the business section of the city, and the deaths were estimated all the way from two to five thousand. The flood was followed by great fires.

Columbus, Ohio, suffered enormous damage and railroad traffic was almost completely suspended early on Tuesday. The bridge over the Miami river at Middletown, Ohio, fell. At Louisville, Ky., great damage was done by wind, as well as by rain, the wind blowing at sixty miles an hour.

At Makanda, Ill., a freight train of the Illinois Central was blown off the track. At Delaware, Ohio, twenty or more persons were reported drowned as a result of the flood. Bridges were washed out in hundreds of places throughout the flood district.

A passenger train of the Pennsylvania lines was caught between two floods at West Liberty, Ohio, and one sleeping car fell into the Mad river, but the passengers all escaped with slight injuries, the train having been running at very low speed.

Fort Wayne, Ind., had the highest water in twenty years. Peru, Ind., was submerged throughout the business section of the city, and the number of deaths was estimated at 300.

A passenger train of the Cleveland, Cincinnati, Chicago & St. Louis was derailed at a washout near St. Paul, Ind. A freight train of the Wheeling & Lake Erie was derailed at a trestle bridge near Wellington, Ohio, and the engineman, fireman and one brakeman were killed.

Every creek and river in the state of Indiana was reported as overflowing, and the same was true in Ohio except in the northern part. The property loss in these two states was estimated at scores of millions. The people who were driven out of their homes in the principal cities of Indiana and Ohio were numbered by hundreds of thousands.

The Lake Shore & Michigan Southern was not seriously affected, but no line between this and the Ohio river was open to Chicago. All other lines had to send their passengers and perishable freight over the Lake Shore. The Pennsylvania was open from Pittsburgh to Alliance and from Pittsburgh to Dennison. The Norfolk & Western was reported on Thursday as open from the Ohio river to Columbus. By reason of the almost complete paralysis of telegraph and telephone lines scores of towns had not been heard from, on Thursday morning. Numerous despatches have contained estimates of losses of railway bridges and roadbeds aggregating many millions of dollars, but none of them can be confirmed.

Switchmen's Wage Controversy Under Mediation.

A dispute between the 19 roads serving the Chicago district, and yardmen, members of the Brotherhood of Railway Trainmen, who have made demands for a new scale of wages, and a revision of working conditions, has been submitted to mediation under the Erdman law by Acting Commissioner of Labor G. W. Hanger, and Martin A. Knapp, presiding judge of the Commerce Court. Mr. Hanger arrived in Chicago on Sunday, and at once went into conference with two committees. The demands of the men include time and one-half for overtime, Sundays and holidays, continuous time and one hour penalty for failure to give 30 minutes for meal time, semi-monthly pay, one day's pay if called and not used and pay for time consumed in investigations. The switchmen were represented by a committee headed by Vice-President Whitney of the Brotherhood of Railway Trainmen, and the roads by a committee of managers, of which T. J. Foley, general manager of the Illinois Central, is chairman.

Following the failure of negotiations with the managers a strike vote was announced on March 20, and conferences were resumed. The managers' committee proposed that the men withdraw the items involving payment of time and one-half and that the investigations be continued as to the remaining rules with a view to affecting a settlement by mutual concessions. When this proposal was declined by the brotherhood committee the managers proposed the calling in of mediators, which was accepted. The managers have published as an advertisement in the newspapers, a letter to Vice-President Whitney, which includes the following:

"Your request for time and one-half for overtime and for Sundays and holidays is declined, because it would penalize the roads for conditions they cannot prevent. The principle of time and one-half for overtime for Sundays and holidays for yardmen is wrong, for the reason that it cannot accomplish the purpose for which you intended it, i. e., elimination of overtime. The establishment of such a high rate for overtime would be an incentive for men to work longer hours, and it would result in increasing rather than decreasing the men's day. It cannot be contradicted that a certain amount of yard work must be performed Sundays and holidays, and railroads do not receive any greater compensation for traffic handled on those days than at any other time, and therefore would not be justified in increasing the rates for such days."

Western Railway Club.

A special meeting of the Western Railway Club was held in the Assembly room of the Karpen building, Chicago, on Tuesday evening, March 25, to consider the report of the committee appointed to suggest necessary changes in the rules of interchange. The proposed changes are to be submitted to the arbitration committee of the Master Car Builders' Association.

MEETINGS AND CONVENTIONS.

The following list gives names of secretaries, dates of next or regular meetings, and places of meeting.

Air Brake Association.—F. M. Nellis, 53 State St., Boston, Mass. Convention, May 6-9, St. Louis, Mo.

American Association of Demurrage Officers.—A. G. Thomason, Boston, Mass. Convention, May 20, Chicago.

American Association of General Passenger and Ticket Agents.—W. C. Hope, New York.

American Association of Freight Agents.—R. O. Wells, East St. Louis, Ill. Annual meeting, June 17-20, Buffalo, N. Y.

American Association of Railroad Superintendents.—E. H. Harman, St. Louis, Mo.; 3d Friday of March and September.

American Electric Railway Association.—H. C. Donecker, 29 W. 39th St., New York.

American Electric Railway Manufacturers' Assoc.—George Keegan, 165 Broadway, New York. Meetings with Am. Elec. Ry. Assoc.

American Railway Association.—W. F. Allen, 75 Church St., New York. Next meeting, May 21, New York.

American Railway Bridge and Building Association.—C. A. Lichty, C. & N. W., Chicago. Convention, October 21-23, 1913, Montreal.

American Railway Engineering Association.—E. H. Fritch, 900 S. Michigan Ave., Chicago.

American Railway Master Mechanics' Association.—J. W. Taylor, Old Colony building, Chicago. Convention, June 11-13, Atlantic City, N. J.

American Railway Tool Foremen's Association.—A. R. Davis, Central of Georgia, Macon, Ga.

American Society for Testing Materials.—Prof. E. Marburg, University of Pennsylvania, Philadelphia, Pa.; annual, June, 1913.

American Society of Civil Engineers.—C. W. Hunt, 220 W. 57th St., New York; 1st and 3d Wed., except June and August, New York.

American Society of Engineering Contractors.—J. R. Wemlinger, 11 Broadway, New York; 2d Tuesday of each month, New York.

American Society of Mechanical Engineers.—Calvin W. Rice, 29 W. 39th St., New York.

American Wood Preservers' Association.—F. J. Angier, B. & O., Baltimore, Md. Next convention, January 20-22, 1914, New Orleans, La.

Association of American Railway Accounting Officers.—C. G. Phillips, 143 Dearborn St., Chicago. Annual meeting, May 28, Atlantic City, N. J.

Association of Railway Claim Agents.—J. R. McSherry, C. & E. I., Chicago. Next meeting, May, 1913, Baltimore, Md.

Association of Railway Electrical Engineers.—Jos. A. Andreucetti, C. & N. W. Ry., Chicago. Semi-annual meeting, June, 1913, Atlantic City, N. J.

Association of Railway Telegraph Superintendents.—P. W. Drew, 112 West Adams St., Chicago; annual, May 20, 1913, St. Louis, Mo.

Association of Transportation and Car Accounting Officers.—G. P. Conard, 75 Church St., New York.

Association of Water Line Accounting Officers.—W. R. Evans, Chamber of Commerce, Buffalo, N. Y. Annual meeting, October 8, Philadelphia, Pa.

Bridge and Building Supply Men's Association.—H. A. Neally, Joseph Dixon Crucible Co., Jersey City, N. J. Meeting with American Railway Bridge and Building Association.

Canadian Railway Club.—James Powell, Grand Trunk Ry., Montreal, Que.; 2d Tuesday in month, except June, July and Aug., Montreal.

Canadian Society of Civil Engineers.—Clement H. McLeod, 413 Dorchester St., Montreal, Que.; Thursday, Montreal.

Car Foremen's Association of Chicago.—Aaron Kline, 841 North 50th Court, Chicago; 2d Monday in month, Chicago.

Central Railway Club.—H. D. Vought, 95 Liberty St., New York; 2d Thurs. in Jan. and 2d Fri. in March, May, Sept., Nov., Buffalo, N. Y.

Civil Engineers' Society of St. Paul.—L. S. Pomeroy, Old State Capitol building, St. Paul, Minn.; 2d Monday, except June, July, August and September, St. Paul.

Engineers' Society of Pennsylvania.—E. R. Dasher, Box 704, Harrisburg, Pa.; 1st Monday after 2d Saturday, Harrisburg, Pa.

Engineers' Society of Western Pennsylvania.—E. K. Hiles, Oliver building, Pittsburgh; 1st and 3d Tuesday, Pittsburgh, Pa.

Freight Claim Association.—Warren P. Taylor, Richmond, Va. Next convention, June 18, Bluff Point, N. Y.

General Superintendents' Association of Chicago.—E. S. Koller, 226 W. Adams St., Chicago; Wed. preceding 3d Thurs., Chicago.

International Railway Congress.—Executive Committee, 11, rue de Louvain, Brussels, Belgium. Convention, 1915, Berlin.

International Railway Fuel Association.—C. G. Hall, 922 McCormick building, Chicago. Annual meeting, May 21-24, Chicago.

International Railway General Foremen's Association.—Wm. Hall, 829 West Broadway, Winona, Minn. Next convention, July 22-25, Chicago.

International Railroad Master Blacksmiths' Association.—A. L. Woodworth, Lima, Ohio. Annual meeting, August 18, Richmond, Va.

Maintenance of Way Master Painters' Association of the United States and Canada.—W. G. Wilson, Lehigh Valley, Easton, Pa.

Master Boiler Makers' Association.—Harry D. Vought, 95 Liberty St., New York. Convention, May 26-29, 1913, Chicago.

Master Car Builders' Association.—J. W. Taylor, Old Colony building, Chicago. Convention, June 16-18, Atlantic City, N. J.

Master Car and Locomotive Painters' Assoc. of U. S. and Canada.—A. P. Dane, B. & M., Reading, Mass. Annual meeting, September 9-12, Ottawa, Can.

National Railway Appliance Assoc.—Bruce V. Crandall, 537 So. Dearborn St., Chicago. Meetings with Am. Ry. Eng. Assoc.

New England Railroad Club.—L. E. Cade, Jr., 683 Atlantic Ave., Boston, Mass.; 2d Tuesday in month, except June, July, Aug. and Sept., Boston.

New York Railroad Club.—H. D. Vought, 95 Liberty St., New York; 3d Friday in month, except June, July and August, New York.

Northern Railroad Club.—C. L. Kennedy, C., M. & St. P., Duluth, Minn.; 4th Saturday, Duluth.

Peoria Association of Railroad Officers.—M. W. Rotchford, Union Station, Peoria, Ill.; 2d Thursday.

Railroad Club of Kansas City.—C. Manlove, 1008 Walnut St., Kansas City, Mo.; 3d Friday in month, Kansas City.

Railway Business Association.—Frank W. Noxom, 2 Rector St., New York. Annual dinner, second week in December, 1913, New York.

Railway Club of Pittsburgh.—J. B. Anderson, Penna. R. R., Pittsburgh, Pa.; 4th Friday in month, except June, July and August, Pittsburgh.

Railway Electrical Supply Manufacturers' Assoc.—J. Scribner, 1021 Monadnock Block, Chicago. Meetings with Assoc. Ry. Elec. Engrs.

Railway Gardening Association.—J. S. Butterfield, Lee's Summit, Mo. Next meeting, August 12-15, Nashville, Tenn.

Railway Development Association.—W. Nicholson, Kansas City, Southern, Kansas City, Mo.

Railway Signal Association.—C. C. Rosenberg, Bethlehem, Pa. Meetings, June 10-11, New York; convention, October 14, Nashville, Tenn.

Railway Storekeepers' Association.—J. P. Murphy, Box C, Collinwood, Ohio. Annual convention, May 19-21, Chicago.

Railway Supply Manufacturers' Assoc.—A. D. Conway, 2135 Oliver bldg., Pittsburgh, Pa. Meetings with M. M. and M. C. B. Assocs.

Railway Tel. and Tel. Appliance Assoc.—W. E. Harkness, 284 Pearl St., New York. Meetings with Assoc. of Ry. Teleg. Sups.

Richmond Railroad Club.—F. O. Robinson, Richmond, Va.; 2d Monday except June, July and August.

Roadmasters' and Maintenance of Way Association.—L. C. Ryan, C. & N. W., Sterling, Ill. Convention, September 8-12, 1913, Chicago.

St. Louis Railway Club.—B. W. Frauenthal, Union Station, St. Louis, Mo.; 2d Friday in month, except June, July and Aug., St. Louis.

Signal Appliance Association.—F. W. Edmonds, 3868 Park Ave., New York. Meetings with annual convention Railway Signal Association.

Society of Railway Financial Officers.—C. Nyquist, La Salle St. Station, Chicago.

Southern Association of Car Service Officers.—E. W. Sandwich, A. & W. P. Ry., Montgomery, Ala. Next meeting, April 17, Atlanta, Ga.

Southern & Southwestern Railway Club.—A. J. Merrill, Grant bldg., Atlanta, Ga.; 3d Thurs. Jan., March, May, July, Sept., Nov., Atlanta.

Toledo Transportation Club.—J. G. Macomber, Woolson Spice Co., Toledo, Ohio; 1st Saturday, Toledo.

Track Supply Association.—W. C. Kidd, Rambo Iron Works, Hillsburn, N. Y. Meeting with Roadmasters' and Maintenance of Way Association.

Traffic Club of Chicago.—Guy S. McCabe, La Salle Hotel, Chicago; meetings monthly, Chicago.

Traffic Club of New York.—C. A. Swope, 290 Broadway, New York; last Tuesday in month, except June, July and August, New York.

Traffic Club of Pittsburgh.—D. L. Wells, Erie, Pittsburgh, Pa.; meetings monthly, Pittsburgh.

Traffic Club of St. Louis.—A. F. Versen, Mercantile Library building, St. Louis, Mo. Annual meeting in November. Noonday meetings October to May.

Train Despatchers' Association of America.—J. F. Mackie, 7042 Stewart Ave., Chicago. Annual meeting, June 17, Los Angeles, Cal.

Transportation Club of Buffalo.—J. M. Sells, Buffalo; first Saturday after first Wednesday.

Transportation Club of Detroit.—W. R. Hurley, L. S. & M. S., Detroit, Mich.; meetings monthly.

Traveling Engineers' Association.—W. O. Thompson, N. Y. C. & H. R., East Buffalo, N. Y. Annual meeting, August, 1913, Chicago.

Utah Society of Engineers.—R. B. Ketchum, University of Utah, Salt Lake City, Utah. 3d Friday of each month, except July and August.

Western Canada Railway Club.—W. H. Rosevear, P. O. Box 1707, Winnipeg, Man., 2d Monday, except June, July and August, Winnipeg.

Western Railway Club.—J. W. Taylor, Old Colony building, Chicago; 3d Tuesday of each month, except June, July and August.

Western Society of Engineers.—J. H. Warder, 1735 Monadnock block, Chicago, 1st Monday in month, except July and August, Chicago.

Traffic News.

The spring meeting of the National Industrial Traffic League will be held at the Iroquois hotel, Buffalo, N. Y., on Tuesday, April 15. A number of important subjects will come before the meeting and a large attendance is expected.

The Secretary of Agriculture has declared a quarantine against interstate traffic in Parlatoria scale and Phoenicococcus; but only from certain counties in southern California, in Arizona and in Texas. These things are insects which do damage to date palms. All shipments of date palms from the territory named must be inspected by government inspectors.

Eight wholesale liquor dealers of Winthrop, Mo., across the Missouri river from Atchison, Kan., have been notified by the railroad and express companies that they will accept no shipments of liquor consigned to Kansas points. This action was taken as a result of the enforcement of the new federal liquor traffic law in Kansas. This is expected to put the Winthrop dealers out of business, as they have been selling most of their output in Kansas.

On Sunday, March 23, the Illinois Central and the Nashville, Chattanooga & St. Louis re-established their former fast freight train No. 51 from Chicago to Nashville, Chattanooga, Atlanta and other southeastern points. This train will carry principally perishable freight, through merchandise cars and other high class tonnage. The time will be 50 hours Chicago to Atlanta, which, for the distance, 850 miles, makes it practically the fastest long distance freight service in the world. The route will be via Cairo, Ill., and Martin, Tenn. The schedule provides for leaving Chicago at 11:00 p. m. daily; Martin at 12:30 a. m. second day; Nashville, at 7:45 a. m. second day; Chattanooga, at 5:45 p. m. second day; arriving at Atlanta at 1:30 a. m. third day.

"Salmon Day," March 14, was celebrated this year for the first time. Throughout the northwestern states, and to some extent in other parts of the country, it is declared by its promoters to have been a great success; and they propose to do the same thing again next year. About forty railroads are represented in Seattle, the center of the salmon industry, and all of these lines joined in the movement, and had salmon served on their dining cars. The northern transcontinental lines served portions of the fish to diners free on that day. J. M. Norton, general agent of the Missouri Pacific, at Seattle, was chairman of the committee, and the Seattle Transportation Club, of which he is one of the prominent members, gave a dinner to the salmon packers, at which 300 guests assembled.

The Southern Railway has appointed two assistant live stock agents. They are to assist and instruct the farmers of the southern states in raising beef cattle and other animals, in the most successful way. Dr. Walter Farrell is to be stationed at Greensboro, N. C., and Dr. C. D. Lowe at Chattanooga, Tenn. Both have had years of experience in animal husbandry and have been in the service of the United States government. It looks as though railroad functions and railroad nomenclature were in danger of becoming very much confused. Ordinarily, the live stock agent of a railroad has been supposed to devote his energies mainly to hastening the death of animals, that is, in getting them to the slaughterhouse; but these men, with the self-same title, are going to promote the life and happiness of the animals on the farms which they visit. What conflicting emotions must agitate the breast of a steer, when he sees the "agent" coming!

Traffic Club of Chicago.

At the annual election of the Traffic Club of Chicago, Tuesday evening, March 25, the following were elected as officers for the ensuing year: President, Guy S. McCabe, general western freight agent, Pennsylvania Company; first vice-president, W. M. Hopkins, manager traffic department, Chicago Board of Trade; second vice-president, Frank W. Smith, member, Uniform Classification Committee; third vice-president, L. Richards, traffic manager, Quaker Oats Company; secretary, W. H. Wharton, commercial agent, Nashville, Chattanooga & St. Louis; treasurer, Charles B. Hopper, general freight agent, Goodrich Transit

Company; directors for two years: C. E. Finch, general agent American Express Company; V. D. Fort, assistant freight traffic manager, Illinois Central; H. K. McEvoy, assistant general passenger agent, Chicago & Alton; F. B. Montgomery, traffic manager, International Harvester Company.

Car Surpluses and Shortages.

Arthur Hale, chairman of the committee on relations between railroads of the American Railway Association, in presenting statistical bulletin No. 139-A, giving a summary of car surpluses and shortages by groups from December 6, 1911, to March 15, 1913, says: The total surplus on March 15 was 57,998 cars; on March 1, 1913, 58,529 cars; and on March 13, 1912, 46,028 cars.

Compared with the preceding period; there is a decrease in the total surplus of 531 cars, of which 1,735 is in flat, 172 in coal, 289 in miscellaneous, and an increase of 1,665 [illegible]. The increase in box car surplus is in all groups, except, 4 [illegible] Virginias and Carolinas), 7 (Montana, Wyoming, Nebraska and the Dakotas), 8 (Kansas, Colorado, Oklahoma, Missouri and Arkansas), and 11 (Canadian Lines). The decrease in flat car surplus is general, except in groups 2 (New York, New Jersey, Delaware, Maryland and Eastern Pennsylvania), and 5 Kentucky, Tennessee, Mississippi, Alabama, Georgia and Florida. The decrease in coal car surplus is shown in groups 3 (Ohio, Indiana, Michigan and Western Pennsylvania), 5 (as above), 6 (Iowa, Illinois, Wisconsin and Minnesota), 9 (Texas, Louisiana and New Mexico), and 10 (Washington, Oregon, Idaho, California, Nevada and Arizona). The decrease in miscellaneous car surplus is shown in groups 2, 4, 5, 7, 9, 10 and 11 (as above).

The total shortage on March 15, 1913, was 20,223 cars; on March 1, 1913, 27,148 cars; and on March 13, 1912, 42,985 cars

Compared with the preceding period; there is a decrease in the total shortage of 6,925 cars, of which 4,994 is in box, 1,767 in flat, 585 in miscellaneous, and an increase of 421 coal car shortage. The decrease in box car shortage prevails in all groups, except 4 and 11 (as above). The decrease in flat car shortage is shown in groups 2, 3, 4, 6 and 8 (as above). The increase in coal car shortage is shown in groups 3, 5, 6 and 9 (as above). The decrease in miscellaneous car shortage is shown in groups 1 (New England Lines), 3, 5, 6 and 8 as above.

Compared with the same date of 1912; there is an increase in the total surplus of 11,970 cars, of which 4,722 is in box, 8,023 in coal, 2,311 miscellaneous, and an increase of 3,086 flat car surplus. There is a decrease in the total shortage of 22,762 cars, of which 12,938 is in box, 7,933 in coal, 2,846 in miscellaneous, and an increase of 955 flat cars

The accompanying table gives car surplus and shortage figures

Car Surpluses and Shortages.

Date.	No. of roads.	Surpluses Box.	Flat.	Coal, gondola and hopper.	Other kinds.	Total.	Shortages Box.	Flat.	Coal, gondola and hopper.	Other kinds.	Total.

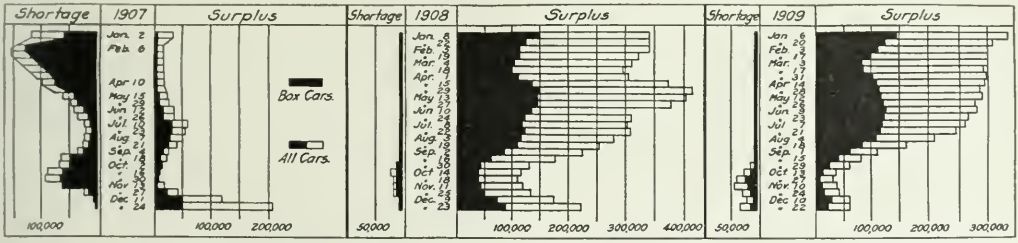
*Group 1 is composed of New England lines; Group 2—New York, New Jersey, Delaware, Maryland and Eastern Pennsylvania lines; Group 3—Ohio, Indiana, Michigan and Western Pennsylvania lines; Group 4—West Virginia, Virginia, North and South Carolina lines; Group 5—Kentucky, Tennessee, Mississippi, Alabama, Georgia and Florida lines; Group 6—Iowa, Illinois, Wisconsin and Minnesota lines; Group 7—Montana, Wyoming, Nebraska, North Dakota and South Dakota lines; Group 8—Kansas, Colorado, Missouri, Arkansas and Oklahoma lines; Group 9—Texas, Louisiana and New Mexico lines; Group 10—Washington, Oregon, Idaho, California, Nevada and Arizona lines; Group 11—Canadian lines.



Car Surpluses and Shortages, 1907 to 1913.

by groups for the last period covered in the report, and the diagram shows total bi-weekly surpluses and shortages from 1907 to 1913.

Car Location.

The accompanying table, which is taken from the car location bulletin No. 4 of the American Railway Association, gives a summary of freight car location by groups on March 1, together with surpluses and shortages on the same date.

Car Location on March 1, 1913.

*Denotes deficiency.

INTERSTATE COMMERCE COMMISSION.

The commission has suspended from March 20 until September 20 certain schedules in Agent F. W. Gomph's tariff, which contain increased rates for the transportation of tin cans and other commodities between points in the State of California and interstate points.

The commission has suspended from March 25 until September 20 the supplement to the tariff of the Union Pacific, which contains increased rates for the transportation of plaster, gypsum rock, stucco and plaster board from Blue Rapids and Irving, Kan., to interstate points.

The commission has suspended until July 8 certain tariffs, which name similar increased rates for the transportation of grain and grain products from points in Illinois to interstate points as are named in other tariffs previously suspended by order issued in same docket.

The commission has suspended from March 19 until July 17 the schedules in certain tariffs which proposed to increase rates for the transportation of cement, in carloads, from Iola, Kan., and other points in what is known as the Gas Belt district to Memphis, Tenn., 6 cents per 100 lbs.

The commission has suspended from March 25 until July 8 the operation of the supplement to the tariff of the Chesapeake & Ohio, which contains advances in rates for the transportation of grain and grain products similar to those suspended by previous orders in the same docket.

The commission has suspended until July 19 the items in certain tariffs, which advance from 7 to 19 cents per 100 lbs. rates for the transportation of fresh meats in carloads, from St. Louis, Omaha and other points to Oklahoma. As an example, the present rate from Omaha to Chickasha is 66 cents and the proposed rate 85 cents per 100 lbs.

The commission has suspended from March 25 until July 23 the schedules contained in a supplement to the tariff of the Chesapeake & Ohio, which cancel through rates on coal, in carloads, from mines in Kentucky and West Virginia to Milwaukee, Wis., via the Grand Trunk and car ferry across Lake Michigan, leaving no through rates in effect via this route.

The commission has suspended until July 12 the schedules in certain tariffs, which proposed to cancel the absorption by certain roads entering Chicago of lighterage and floatage charges of three cents per 100 lbs. on carload and five cents per 100 lbs. on less than carload traffic handled by the Chicago River & Indiana lighterage and float service to and from points on the Chicago river front.

The commission has suspended from March 22 until July 19 the schedules in a supplement to the tariff of the Southern Pacific, which propose to advance rates for the transportation of lumber from points in California to stations in Nevada by the cancellation of established commodity rates and the application of class rates. The proposed rate from New Castle, Cal., to Verdi, Nev., is $5.40 per net ton and the present rate is $2 per net ton, making an increase of $3.40 per net ton. Other points are affected in a like manner.

The commission has suspended from March 25 until September 25 the operation of the schedules contained in a supplement to the tariff of the Kanawha & Michigan, which propose to cancel through rates applying to the transportation of coal in carloads, from mines in Kentucky and West Virginia to Milwaukee, Wis., and other points via Ludington, Mich., and Pere Marquette car ferry.

Complaints concerning westbound rates on freight imported at Boston, New York, Philadelphia and Baltimore are again under investigation by the Interstate Commerce Commission, and a hearing was held at Washington on Tuesday of this week. Mr. Ives, speaking for Boston, claimed that under the present adjustment, Baltimore is getting an increased share of import traffic, while Boston is suffering a decrease.

The commission has suspended from March 25 until July 23 the schedules contained in a supplement to Agent F. A. Leland's tariff, which cancel through rates applicable to the transportation of lumber from points located on the Fourche River Valley & Indian Territory Railroad in Arkansas to points in Oklahoma which were established, effective January 1, 1913, in compliance with an order of the commission in the Tap Line case.

The commission has issued an order, the answers to which are wanted by April 30, calling for information, so far as it can be had from the railroad companies' accounts, showing operating expenses divided as between passenger service and freight service. The totals for the year ending June 30, 1912, are preferred; but any other twelve months will answer, if that year be not available. This part of the commission's work is in the charge of Commissioner Meyer; and it is said that he will be in charge of the work of valuation of railways, under the new law.

Two Thousand Complaints.

Sixty different railroad companies are represented in the reports of violations of the hours of service act which the Interstate Commerce Commission has transmitted to the United States district attorneys since June 30, 1912. Each report is accompanied by a recommendation that the companies be prosecuted for disobedience of the law. In these sixty cases the aggregate number of counts is 2,127.

REVENUES AND EXPENSES OF RAILWAYS.

Secretary McGinty.

The new secretary of the Interstate Commerce Commission, succeeding John H. Marble, who has been promoted to the position of commissioner, is George Banks McGinty. He has been assistant secretary during the past year. Mr. McGinty has had several years' experience in railroad work, having served in clerical departments of the Atlantic Coast Line, the Georgia Railroad and the Southern Railway.

He was born September 8, 1878, in Monroe county, Ga., and was educated at Emory College, Oxford, Ga. After leaving college he commenced the study and practice of law, but he left that to go into the railroad service. On the Atlantic Coast line he was in the soliciting agent's office, at Atlanta. On the Georgia Railroad, he was in a local freight office, and he began on the Southern Railway in the maintenance of way department. During the last two years of his service on this road, he was private secretary to the vice-president and general manager.

George B. McGinty.

In 1906, when the meat inspection bill was passed, he entered the government service, his first position being in the Bureau of Animal Industry, Department of Agriculture. Here he handled correspondence with carriers respecting conformance by meat shippers and carriers with regulations promulgated by the department governing the transportation of meat and meat products. In November, 1908, he entered the service of the Interstate Commerce Commission, in the division of statistics and accounts. Subsequently he served as confidential clerk to Commissioner Clements. When Secretary Moseley died the duties of the secretary's office to a great extent fell to the office of the chairman, which brought much of this work into Mr. McGinty's hands. He was appointed by the commission as special examiner in October, 1911, but was retained in the chairman's office throughout the chairmanship of Commissioner Clements, and likewise served in a similar capacity to Chairman Prouty. When Mr. Marble was appointed secretary on February 10, 1912, Mr. McGinty was made assistant secretary, as before indicated.

Weighing Investigation.

The weighing investigation on which the Interstate Commerce Commission has been at work for over a year, will be assigned for argument at Washington on April 16, at which time all interested parties will be heard upon any subject covered by the investigation. The following matters are particularly suggested by the commission for discussion:

1. Should the federal government assume jurisdiction over the installation and operation of railroad track scales, and if so, to what extent?

2. In what manner should track scales be inspected and tested, and within what limit should variations in weight be permitted before the scale is announced inaccurate?

3. Should cars be weighed in motion? Should they be weighed coupled at either end or at both ends?

4. The tare weight of cars. In what manner should the stenciled weight be ascertained and corrected? In correcting tare weight what tolerance should be allowed?

5. When should the loaded car be first weighed, and to whom should notice of the weight be given?

Under what circumstances should the original weight be changed, and to whom and how should such notice be given?

What tolerance should be permitted before correcting the original weight, and should this be the same as applied to all commodities?

To what extent may platform scale weights or estimated weights be used in correcting track scale weights?

Is there any distinction between those instances where the weight is first ascertained upon the track scales of the carrier and those where that weight is furnished by the shipper under a weighing agreement or otherwise?

The commission will not at this time undertake to formulate rules in detail as to the weighing of carload freight, but will hold that subject over pending present negotiations between carriers and shippers looking to an agreement upon such rules.

Reparation Awarded.

Lindsay Brothers v. Chicago, & North Western. Opinion by the commisison:

In this case the complainant contends that the defendant's rates of 19.5 cents per 100 lbs. in less than carloads and 11.4 cents per 100 lbs. in carloads for the transportation of tank heaters, litter carriers and shoveling boards from Harvard, Ill., to Milwaukee, Wis., are unreasonable to the extent that they exceed 12 cents and 6 cents per 100 lbs. respectively. Reparation was asked. The commission found that the rates now in effect on this traffic are unreasonable to the extent that they exceed 15 cents per 100 lbs. on less than carload shipments and 8 cents per 100 lbs. on carload shipments and prescribed those rates for the future. (26 I. C. C., 329.)

Transit Privilege Denied.

Michigan Cereal Company v. Pere Marquette et al. Opinion by the commission:

The complainant contends that the withdrawal by the defendants of the privilege of splitting peas in transit at Port Huron and Ubly when destined to the Pacific coast is discriminatory and seeks the re-establishment of this transit privilege. It was argued that as grain, including corn, barley, wheat, etc., moving to the Pacific coast was accorded milling-in-transit privileges, those privileges should also be extended to split peas, as that commodity was in fact a grain and was shown as such in certain other tariffs. The commission found that there was not sufficient similarity or competition between peas and grain to warrant an order extending the transit privilege to peas. The defendants stated that they had not been aware of a transit privilege on peas until immediately prior to the date on which that privilege was withdrawn. The commission found that the transit privileges were not extended to split peas in transcontinental territory and decided that there was not sufficient ground for granting the relief sought. The complaint was dismissed. (26 I. C. C., 320.)

Rates on Smokeless Powder Reduced.

United States v. Wharton & Northern et al. Opinion by the commission:

The complainant contends that smokeless powder and nitrocellulose-wet are safe to handle and transport, and that as classified in official classification territory smokeless powder is unjustly and unreasonably assessed double first-class rates for lots under 10,000 lbs., and first-class rates for lots of 10,000 lbs., or over, and nitro-cellulose-wet is unjustly assessed first-class rates, any quantity. The commission found that smokeless powder was not as dangerous as some other explosives, and that it had in a large measure displaced some of the more dangerous varieties and thereby contributed to the increased safety of railroad traffic. The commission decided that smokeless powder should not be classified higher than one and one half times the first-class rates in less than carload lots and second-class rates in carloads with a minimum of 20,000 lbs., per car. As the use of nitro-cellulose-wet is rapidly diminishing, and as it was susceptible to detonation by the explosion of another high explosive nearby, no change was made in the classification of that commodity. (25 I. C. C., 309.)

Equipment of Insufficient Capacity.

Atlas Lumber & Shingle Company v. Northern Pacific et al. Opinion by the commission:

The complainant ordered a 30-ton box car, but the initial carrier was unable to furnish a box car and offered instead a flat car which the complainant was obliged to accept. When loaded

to its full carrying capacity with fir lath the car furnished contained only 44,500 lbs., though the car minimum was 60,000 lbs. A car of the character ordered would have been loaded to or beyond its full minimum weight by this commodity. The complainant was charged 50 cents per 100 lbs., based on a car minimum of 60,000 lbs., for the transportation of this shipment from Tacoma, Wash., to Omaha, Neb. The complainant contends that it was unjust to charge for more than the actual weight of the shipment, and asked for reparation. The tariffs of the defendants provide that when a car of the size ordered by shipper cannot be furnished, and a larger car is furnished, the larger car may be used on the basis of the minimum weight of the car ordered, or on the basis of actual weight of the shipment if greater than such minimum. There was no rule to govern the use of a flat car furnished in lieu of a box car ordered. The defendants were willing to make reparation on the basis claimed, but were not willing to publish a rule to meet similar conditions that might arise in the future. The commission decided that reparation should be awarded, and also that the defendants should be required to amend their tariff to make reasonable and proper provision to meet such conditions in the future, as the fault for not furnishing the desirable equipment lay with the carrier. (26 I. C. C., 313.)

Complaint Dismissed.

Evens & Howard Fire Brick Company v. Wabash. Opinion by the commission:

The alleged excessive charges on a carload shipment of fire brick from St. Louis, Mo., to Detroit, Mich., was found to have been due to the complainant's error in making out the shipping ticket. (26 I. C. C., 152.)

Through Water and Rail Route Restored.

Augusta & Savannah Steamboat Company v. Ocean Steamship Company of Savannah et al. Opinion by Commissioner Prouty:

The complainant operates a line of steamboats between Augusta, Ga., and Savannah. The Ocean Steamship Company and the Merchants & Miners Transportation Company, two of the defendants, operate steamship lines between Savannah and New York, Philadelphia and other north Atlantic points. The remaining defendants are railroad companies leading from these various north Atlantic points to interior destinations. Prior to 1905 joint rates were in force on traffic moving from Augusta to Savannah via the line of the complainant, then to north Atlantic ports by the defendants' steamships and finally to the interior destinations by rail. A joint rate of this character is still in effect between Augusta and North Adams, Mass., upon cotton piece goods. The commission decided that as the defendants had voluntarily subjected themselves to the jurisdiction of the commission with respect to the traffic destined to North Adams, it had the power to compel the filing of similar tariffs with respect to other points similar to North Adams and in competition with it. At present the traffic moves from Augusta to Savannah by rail, thence to the northern Atlantic ports by the steamship lines of the defendant and finally to the interior destinations by rail. The commission found that the complainant had ample facilities for transferring its freight to the steamships of the defendants at Savannah, and ordered that through routes should be established between the same points over which they were in effect previous to their withdrawal by the defendant in 1905. With regard to the rates the commission found that they ought to be slightly less than the present rail-water-and-rail rates, but could not decide as to the precise amount. The case will therefore be held open until satisfactory rates shall have been established. (26 I. C. C., 380.)

Through Routes and Joint Rates Denied.

Blakely Southern v. Atlantic Coast Line et al. Opinion by Commissioner Meyer:

The Blakely Southern is a 22-mile line extending from Blakely, Ga., on the Central of Georgia, to Jakin, Ga., on the Atlantic Coast Line. The complainant asks that the defendants be required to establish through routes and joint rates on interstate traffic to Jakin over the Central of Georgia and the complainant's lines, and to Blakely over the Atlantic Coast Line and the complainant's lines, equal to rates now in effect over the Atlantic Coast Line to Jakin and over the Central of Georgia to Blakely. The Blakely Southern was built as a plant facility by the Flowers Lumber Company, at Jakin, and the Flowers Brothers Lumber Company, at Blakely. This line was subsequently taken over by the Blakely Southern Railroad Company. One of the clauses of the contract provides that if equal rates are offered, all the business of the lumber company is to be delivered to the Blakely Southern. The connecting carriers have voluntarily established joint rates both intrastate and interstate to and from all local points on the Blakely Southern, but have refused to establish joint rates to and from Jakin and Blakely. The Georgia Railroad Commission recently required the defendants to establish joint intrastate rates from Jakin via Blakely and from Blakely via Jakin. The commission found that if the complainant's petition were granted, all of the lumber now moving out by the Atlantic Coast Line would move under the same rate via the Blakely Southern and the Central of Georgia and the Atlantic Coast Line would be compelled, by a competition benefiting only the Blakely Southern, to reduce its reasonably low rate in order to retain traffic to which it was properly entitled. The commission found further that the shippers at Blakely and Jakin now enjoyed adequate transportation service. In nearly every instance class rates to points on the Blakely Southern are higher than the rates from the same points of origin to either Blakely or Jakin. This indicates that if competitive rates at Blakely and Jakin were established, the fourth section of the act would be violated by charging a higher rate for the shorter distance to one of the local stations than for the longer distance to one or another of the termini. The commission decided that the granting of the complainant's petition would not materially benefit the shippers and dismissed the complaint. (26 I. C. C., 344.)

STATE COMMISSIONS.

The Illinois railroad and warehouse commission has issued supplement No. 8 to its official express classification No. 21, effective April 1.

The Indiana railroad commission has entered an order reducing the freight rates in Indiana on crushed lime stone used for agricultural purposes.

The Texas railroad commission has announced a public hearing on April 8, on a plan of revising the demurrage rules. A number of detailed changes in the present rules have been proposed by shippers concerning the notice to be given consignees, and similar matters.

The chairmen of the Michigan railroad commission, the public service commission of Ohio, and the railroad commission of Indiana, will appear before the Interstate Commerce Commission at Washington on April 4 to present oral arguments in support of the petition filed by the three commissions asking for the addition of one or more classes to the Official Classification, and the arrangement of classes so that the rates applicable on commodities named in the lowest class shall not exceed 10 per cent. of the rates on commodities named in the first class.

The Missouri railroad and warehouse commission has served notice on the railways operating in Missouri that the approval of Western Classification No. 51 by the commission is denied, and that on all intrastate traffic Western Classification No. 50 remains in force and effect. This action follows shortly after the decision of the Interstate Commerce Commission allowing Western Classification No. 51 to go into effect with modifications suggested by the commission, after a year of investigation, during which the new classification was suspended.

COURT NEWS.

The Supreme Court of Indiana has rendered a decision affirming the action of the Marion county superior court, denying an injunction asked by the Vandalia to prevent the enforcement of the headlight law of 1909.

Judge Pollock, of the United States district court at Kansas City, Kan., has denied an injunction asked by five railway companies for the purpose of preventing the Kansas oil rate law of 1905 from going into effect. The injunction was denied on the ground that the law has been effectively repealed by the law creating the public utilities commission.

Railway Officers.

Executive, Financial and Legal Officers.

C. S. Snow has been appointed auditor of the St. Louis, San Francisco & Texas, and the Ft. Worth & Rio Grande, with headquarters at Ft. Worth, Tex., succeeding E. B. Pierce, resigned.

J. D. Nettleship, auditor of freight accounts of the St. Louis & San Francisco, has been appointed assistant general auditor, succeeding W. P. Newton, promoted; R. S. Hoxie, first assistant auditor of freight accounts, succeeds Mr. Nettleship; F. C. Freiburg, second assistant auditor of freight accounts, takes the place of Mr. Hoxie, and C. Goehausen succeeds Mr. Freiburg; all with headquarters at St. Louis, Mo.

A. T. Hardin, assistant vice-president of the New York Central & Hudson River, at New York, has been appointed vice-president in charge of operation, maintenance and construction of the New York Central & Hudson River and the Ottawa & New York, with headquarters at Grand Central Terminal, New York. Abraham Tracy Hardin was born in 1868, in South Carolina, and graduated from the University of South Carolina with the degree of civil engineer in 1894. He had been a telegraph operator in 1882 on the Richmond & Danville, and from 1882 to 1890 he was agent and stenographer on the same road. He attended college from 1890 to 1894, and then for four years was in the maintenance of way department of the Southern Railway. From 1898 to September, 1899, he was supervisor and division engineer of the Eastern division of the New York Central & Hudson River, and was then to February, 1903, engineer of track, on the same road. He was promoted in February, 1903, to engineer of maintenance of way, and from July, 1905, to June, 1906, was assistant to the general manager, becoming assistant general manager in June, 1906, which position he held until April, 1912, when he was promoted to assistant vice-president. His appointment as vice-president takes effect April 1.

J. J. Bernet, assistant vice-president of the Lake Shore & Michigan Southern, Lake Erie & Western, Cleveland, Cincinnati, Chicago & St. Louis, Michigan Central, Peoria & Eastern, Cincinnati Northern, Toledo & Ohio Central, Zanesville & Western, Chicago, Indiana & Southern and the Indiana Harbor Belt, has been appointed vice-president of those roads, in charge of operation, maintenance and construction, with headquarters at Chicago, effective April 1. Mr. Bernet was born February 9, 1868, at Brant, Erie county, New York. He was educated in the public schools of Buffalo, and began railway work in 1889 as telegraph operator for the Lake Shore & Michigan Southern. He was advanced to train despatcher in March, 1895, was trainmaster of the Eastern division from April, 1901, to March, 1903, when he became assistant superintendent of that division. On February 1, 1905, he was made superintendent of the same division, and in November of that year he was promoted to assistant general superintendent of that road, which position he retained until October 1, 1906. He was then advanced to the general superintendency, with headquarters at Cleveland, Ohio. Mr. Bernet subsequently, on June 1, 1911, was made assistant to vice-president of the New York Central lines west of Buffalo, and was appointed assistant vice-president of the same lines on April 15, 1912. He now becomes vice-president of those roads, in charge of operation, maintenance and construction, with headquarters at Chicago, as noted above.

J. J. Bernet.

Operating Officers.

W. D. Jenkins, private secretary to President Freeman of the International & Great Northern, has been appointed inspector of transportation and stations of that road and the Texas & Pacific, with headquarters at New Orleans, La.

C. F. Smith, assistant superintendent of the Idaho division of the Oregon Short Line at Nampa, Idaho, has been appointed superintendent of the Montana division, with headquarters at Pocatello, Idaho, succeeding W. R. Armstrong, resigned.

Traffic Officers.

George J. Holder has been appointed traveling freight agent of the Lake Erie & Western, with headquarters at Spokane, Wash.

H. O. Post, city passenger agent of the Chicago Great Western at Des Moines, Ia., has resigned to go with the Star Land Company of Kansas City, Mo.

E. C. Ferguson has been appointed commercial agent of the Toledo, St. Louis & Western, with headquarters at Kansas City, Mo., in place of F. A. Eisminger, resigned.

Daniel J. McCarroll has been promoted to soliciting freight agent, of the Buffalo, Rochester & Pittsburgh, with office at Rochester, N. Y., succeeding W. A. Hammer, resigned to accept service with another company.

G. R. Bierman, traveling passenger agent of the Union Pacific system, with office at Chicago, has been transferred to Pittsburgh, Pa., as traveling passenger agent, in place of W. G. Carmichael, who has been appointed to a similar position at Chicago.

R. H. De Treville, traveling passenger agent of the Louisville & Nashville, at Evansville, Ind., has been appointed city passenger and ticket agent with office at Evansville succeeding L. C. Wolfe, resigned. W. M. Wood, traveling passenger agent at Nashville, Tenn., has been appointed traveling passenger agent succeeding Mr. De Treville, but with headquarters at St. Louis, Mo. W. H. Mustaine, city passenger agent at Nashville succeeds Mr. Wood, and D. R. Murray succeeds Mr. Mustaine.

George B. Haynes, whose appointment as general passenger agent of the Chicago, Milwaukee & St. Paul, with headquarters at Chicago, has already been announced in these columns, was born August 22, 1871, at Ainsworth, Iowa. He was graduated from the Omaha (Neb.) high school in 1890, and began railway work March 16, 1891, with the Union Pacific at Omaha. He entered the employ of the Chicago, Milwaukee & St. Paul, December 28, 1892, as a clerk in the office of the general western agent at Omaha, and was promoted to passenger agent June 1, 1893, being made city passenger agent in 1897. On June 1, 1903, Mr. Haynes was appointed traveling passenger agent, with headquarters at Chicago; from October 1, 1907, to July 15, 1911, he was immigration agent, and on the latter date he became assistant general passenger agent, which position he held at the time of his recent promotion to general passenger agent, as above noted.

Engineering and Rolling Stock Officers.

J. H. Roach has been appointed assistant engineer of construction of the Lake Shore & Michigan Southern, with headquarters at Cleveland, Ohio.

Samuel W. McClure has been appointed resident engineer of the Lake Shore & Michigan Southern at Erie, Pa., in place of H. W. Fenno, transferred.

C. F. W. Felt, chief engineer of the Atchison, Topeka & Santa Fe Railway proper, has been appointed chief engineer of the system, with headquarters at Chicago, succeeding C. A. Morse, effective April first.

Frank Hopper, division master mechanic of the Chicago, Rock Island & Pacific at Estherville, Iowa, has been appointed master mechanic of the Duluth, Winnipeg & Pacific, with headquarters at West Duluth, Minn.

J. E. Saunders, assistant signal engineer of the Atchison, Topeka & Santa Fe, has resigned to become office engineer in the signal department of the Delaware, Lackawanna & Western, with headquarters at Hoboken, N. J.

R. L. Stewart, master mechanic of the Missouri division of the Chicago, Rock Island & Pacific at Trenton, Mo., has been appointed master mechanic of the Chicago Terminal and Illinois divisions, with headquarters at Chicago, in place of L. A. Richardson, promoted. E. J. Harris, master mechanic of the Kansas City Terminal division at Armourdale, Kan., succeeds Mr. Stewart. J. C. Rhodes, road foreman of equipment at Trenton, Mo., has been appointed master mechanic of the Dakota division, with headquarters at Estherville, Ia., succeeding Frank Hopper, resigned.

OBITUARY.

P. J. Tapp, commercial agent of the Southern, at Kansas City, Mo., died suddenly in that city on March 20, aged 50 years.

Howard W. Rogers, traveling freight agent of the Illinois Central, with headquarters at Kansas City, Mo., died in that city on March 14, aged 30 years.

E. A. Peck, superintendent of the St. Louis Southwestern, with headquarters at Pine Bluff, Ark., was found dead near Hot Springs, Ark., on March 20. It is stated that he committed suicide owing to continued ill health. Mr. Peck was 61 years old and had been superintendent at Pine Bluff since June, 1901. From June, 1893, to April, 1901, he was general superintendent of the St. Louis, Iron Mountain & Southern, and previous to December, 1892, he had been with the Cleveland, Cincinnati, Chicago & St. Louis for some years as an assistant general superintendent and general superintendent.

Abraham Fell, formerly general western freight agent of the Delaware, Lackawanna & Western at Buffalo, N. Y., died at his home in that city on January 19. He was born in England in 1832, and at the age of 13 began work on the London & North Western, remaining with that company until 1858, when he came to America and became superintendent of the Buffalo & Lake Huron, of Canada, with headquarters at Buffalo. He was subsequently made general manager. After the road was leased to the Grand Trunk, he became general agent of the Merchants' Despatch Transportation Company at Detroit, and later he went to Buffalo to establish that company's foreign freight business. He then returned to Detroit to go with the Detroit & Milwaukee, now a part of the Grand Trunk. In 1873 he was appointed eastern freight agent for the Michigan Central and the Great Western, with headquarters at Rochester, N. Y. Subsequently he represented the Great Western, at Buffalo, and later the Blue Line, Fast Freight Line, at Philadelphia, Pa., and at Scranton. When the Delaware, Lackawanna & Western completed its road from Binghamton to Buffalo, he was made general western freight agent of that road, with headquarters at Buffalo. He was instrumental in building up the freight business for the Lackawanna, also in establishing a line of steamboats on the lakes in connection with that road, the Lackawanna Transportation Company. After 20 years' service with the Lackawanna, and completing 51 years of railway service, he retired from active work.

Electrification of London's Suburban Railways.—The London, Brighton & South Coast Railway, England, which since 1909 has electrified some 70 miles of its suburban lines, has recently decided upon a further electrification to include, when completed, at least 170 miles of additional trackage. The work will be commenced as soon as the plans are completed and will extend over four years. The lines to be transformed will be divided into sections and the work will be proceeded with accordingly. Under the scheme the whole of the company's suburban system comprised within the area extending from London to Croydon, Purley, and Coulsdon, and from London to Sutton and Cheam, is to be electrified. This action has been decided upon in view of the satisfactory results of the company's electric service now in operation and of the steady growth of competition from other forms of transport, notably the street car and the motor bus.

Equipment and Supplies.

LOCOMOTIVE BUILDING.

The Republic Iron & Steel Company has ordered 1 six-wheel switching locomotive from the Baldwin Locomotive Works.

The Norfolk Southern has ordered 4 consolidation locomotives and 10 ten-wheel locomotives from the Baldwin Locomotive Works.

The Mac a Mac Corporation has ordered 1 mogul locomotive from the American Locomotive Company. The dimensions of the cylinders will be 19 in. x 26 in.; the diameter of the driving wheels will be 56 in., and the total weight in working order will be 133,000 lbs.

The Buffalo, Rochester & Pittsburgh, mentioned in an unconfirmed item in the *Railway Age Gazette* of March 14, as having ordered 15 locomotives from the American Locomotive Company, has ordered 12 mikado locomotives and 3 Pacific type locomotives from that company.

The Intercolonial has ordered 5 consolidation locomotives and 4 Pacific type locomotives from the Montreal Locomotive Company. The dimensions of the cylinders of the consolidation locomotives will be 24 in. x 32 in.; the diameter of the driving wheels will be 63 in., and the total weight in working order will be 236,000 lbs. The dimensions of the cylinders of the Pacific type locomotives will be 23½ in. x 28 in.; the diameter of the driving wheels will be 73 in., and the total weight in working order will be 245,000 lbs. All of these locomotives will be equipped with superheaters.

CAR BUILDING.

The Hocking Valley is in the market for 1,000 freight cars.

The New Jersey Zinc Company is in the market for 12 dump cars.

The Illinois Central has ordered 1,000 fruit cars from the American Car & Foundry Company.

The Havana Central is closing contracts as follows: American Car & Foundry Company, 450 flat cars; Standard Steel Car Company, 250 box cars; Wason Manufacturing Company, 12 passenger cars. This company is still in the market for 50 coal cars.

The Buffalo, Rochester & Pittsburgh has ordered 27 all-steel passenger cars from the Pullman Company. This order will comprise 2 café observation cars, 3 combination passenger and mail cars, 3 baggage cars, 2 combination baggage and mail cars, 10 coaches and 7 combination baggage and passenger cars.

IRON AND STEEL.

The Chicago & Alton has ordered 7,000 tons of rails from the Illinois Steel Company.

SIGNALING.

The Southern Railway is to install automatic block signals on the line between Alexandria, Va., and Orange, Va., 78 miles. With the automatic block system of the Washington Terminal Company, the entire line from Washington, D. C., to Orange, Va., on the completion of this work, will be operated under automatic signals.

Railroad to Connect Spain and France.—Construction work is under way on the Trans-Pyrenean Railway, which will connect Ax, in the southeastern corner of France, with Puigcerda and Ripoll, in the province of Gerona, in the northeastern portion of Spain. The distance from Ripoll to Puigcerda is about 22 miles, and the distance from Puigcera to Ax is about 25 miles. Work on the Tosas tunnel, about half way between Ripoll and Puigcerda, which will be 3.1 miles long, has been commenced. This tunnel is being driven from both sides and on the southern side about 200 yds. have already been completed.

Supply Trade News.

F. A. Mazzur & Co., 141 Milk street, Boston, Mass., have been appointed New England representatives for the Kerr Turbine Company, Wellsville, N. Y.

The Beaver Dam Malleable Iron Company, Beaver Dam, Wis., has moved its New York office from 30 Church street, to the Grand Central Terminal building.

The Galena Signal Oil Company, Franklin, Pa., has declared a common stock dividend of 50 per cent. This distribution will increase the company's common stock from $8,000,000 to $12,000,000, as has been authorized by the stockholders.

The Railway Steel-Spring Company, New York, has declared a dividend of 2 per cent. on its common stock. This is the first dividend on the common stock paid by this company since 1908. Last year the company earned nearly 6 per cent. on the common stock, compared with about one-quarter of 1 per cent. in 1911.

Chrome-vanadium steel, made by the American Vanadium Company, Pittsburgh, Pa., has been specified for the main axles and main crank pins of the 60 mikado locomotives and 30 Pacific type locomotives recently ordered by the Baltimore & Ohio. The tires of the 10 Mallet locomotives recently ordered by that road will be made of the same material.

The Universal Portland Cement Company has started work on the construction of a new plant at Duluth, Minn. This plant will cost about $1,700,000, and will have an output of 1,400,000 bbls. of Universal Portland cement a year. The plant will be electrically operated throughout, requiring about 5,000 h. p. Work will be pushed as rapidly as possible, and it is expected that the plant will be in operation in 1914. With its present plants at Chicago and Pittsburgh this will give the company a total output of 45,000 bbls. a day, or 13,500,000 bbls. a year. During the year 1912, the banner year of the company, the shipments of Universal Portland cement amounted to 10,047,499 bbls.

W. H. Foster has resigned as master mechanic of the Hudson division of the New York Central & Hudson River, to accept a position with the Ashton Valve Company, as representative in the railroad department, with headquarters in New York. Mr. Foster was born June 29, 1873, and entered railway service in June, 1889. After considerable experience in shop work, and as fireman and locomotive engineer, he became air brake instructor for the American Magazine Company, and later became connected in the same capacity with the International Correspondence Schools. In February, 1902, he was appointed supervisor of air brakes for the New York Central, and in 1907 his jurisdiction was extended over the Boston & Albany, which placed him in charge of air brake instruction on all divisions of the New York Central lines east of Buffalo. On January 1, 1908, he was promoted to master mechanic.

Announcement has been made of a plan for the reorganization of the Allis-Chalmers Company, following the sale of the properties of the old company in Wisconsin to the reorganization committee, pursuant to the order of the United States district court of Milwaukee. The new company has been organized under the name of the Allis-Chalmers Manufacturing Company. It is expected that the remaining properties in Illinois, Pennsylvania and California also will shortly be acquired on behalf of the reorganization committee. The properties will be taken over by the new company and operations conducted under the new management at an early date. The board of directors of the new company has been elected as follows: Otto H. Falk, president, Milwaukee; Oliver C. Fuller, president Wisconsin Trust Company, Milwaukee; J. D. Mortimer, president Milwaukee Light, Heat and Traction Company, Milwaukee; Gustave Pabst, president Pabst Brewing Company, Milwaukee; Fred Vogel, Jr., president First National Bank of Milwaukee; Max Pam, Chicago; F. O. Wetmore, vice-president First National Bank, Chicago; John H. McClement, chairman of the board, New York; Arthur W. Butler, of Butler, Herrick & Kip, New York; Charles W. Cox, of Robert Winthrop & Co., New York; Oscar L. Gubelman, of Knauth, Nachod & Kuhne, New York; R. G. Hutchins, Jr., vice-president National Bank of Commerce, New York; Arthur Coppell, of Maitland, Coppell & Company, New York; William C. Potter, vice-president Guaranty Trust Company of New York; and James P. Winchester, president Wilmington Trust Company, Wilmington, Del. The board of directors has appointed an executive committee consisting of Mr. Vogel, chairman, and Messrs. Falk, Fuller, Mortimer and Pabst.

Samuel T. Fulton, general sales agent of the Railway Steel Spring Company, New York, with office in that city, has been made a vice-president of that company, with office in New York.

S. T. Fulton.

Mr. Fulton was born at Topeka, Kan., January 11, 1856, and after receiving a public school education entered railway service as messenger in the telegraph office of the Kansas Pacific at Topeka on July 1, 1879. During the next four years he was telegraph operator and agent at various stations on the Kansas Pacific and Union Pacific and for the following two years telegraph operator for the Western Union Telegraph Company at Topeka. He went to the Atchison, Topeka & Santa Fe as secretary to the superintendent of machinery in 1885; and in 1888 was made secretary to the general superintendent at Chicago. In 1889 he went to the Chesapeake & Ohio as train despatcher, and in 1890 he was made secretary to the freight traffic manager of the Cleveland, Cincinnati, Chicago & St. Louis. He became a stenographer to the chairman of the Central Traffic Association of Chicago in 1891 and in the following year was made secretary to the freight traffic manager of the Kansas City & Memphis. In 1893 he became chief clerk to the general superintendent of the same road; in 1895, chief clerk to the president and general manager, and in 1899, assistant to the president of that road. He was made chief clerk to the vice-president and general manager of the St. Louis & San Francisco at St. Louis in August, 1901, and from January, 1902 to February, 1903, he was general manager of the Crowe Coal & Mining Company, of Kansas City. On resigning that position he returned to railway service as assistant to the vice-president of the St. Louis & San Francisco, and in April, 1904, he went to the Chicago, Rock Island & Pacific as assistant to the president, which position he held until December 1, 1909. After the segregation of the Rock Island and the Frisco, Mr. Fulton entered the railway supply business as western manager of the Railway Steel Spring Company, with office at Chicago. On March 1, 1912, he was made general sales agent of that company, which position he held until his appointment to the vice-presidency, as mentioned above.

TRADE PUBLICATIONS.

Chicago & North Western.—The passenger department has issued an interesting illustrated pamphlet on "How to Grow Sugar Beets."

Blacksmithing.—Tate, Jones & Company, Inc., Pittsburgh, Pa., has published a small instructive folder on Blacksmithing and drop forging.

Battery Charging.—The General Electric Company has devoted bulletin No. 4085 to its battery charging motor generator sets for railway signaling.

Motor Cars.—The Buda Company has issued a folder devoted to its various types of section motor cars, inspection motor cars and track velocipede cars.

Denver & Rio Grande.—The passenger department has issued an interesting folder describing the attractions of its route to the Pacific coast in connection with the Twenty-sixth annual convention of the United Society of Christian Endeavor, to be held in Los Angeles, July 9 to 14.

Railway Construction.

Artesian Belt.—This company has given a contract for building an extension, it is said, from Christine, Tex., southwest to Crowther, and work will be started at once.

Big Blackfoot.—See Chicago, Milwaukee & St. Paul.

Big Sandy & Kentucky.—An officer is quoted as saying that a contract has been given to John O'Kelley, Ashland, Ky., to build a section of 10 miles from Stafford station south. This company was incorporated last year to build from a point on the Chesapeake & Ohio in Johnson county, Ky., south to coal and timber lands, in all about 31 miles. W. H. Dawkins, president, T. N. Fannin, vice-president, Ashland, Ky., and L. N. Davis, treasurer. (September 27, p. 598.)

Birmingham & Tuscaloosa Railway & Utilities Company.—Incorporated in Alabama, it is said, to build from Gadsden southwest via Attalla, Ashville, Birmingham and Bessemer to Tuscaloosa, about 130 miles, and to operate a belt line in Tuscaloosa county. The incorporators include C. R. Carter and C. A. Gannon of Birmingham.

Bryan & College Interurban.—This company will extend its line, it is said, from Bryan, Tex., to Stone City, 6 miles.

Buffalo, Rochester & Pittsburgh.—This company will let contracts at an early date, it is said, for laying second track between Rochester, N. Y., and Scottsville, 12 miles. Contracts will also be let for the construction of a classification yard on the south side of the barge canal, two miles outside the city of Rochester. Ten miles of track will be laid in the yard.

Cambridge & Chesapeake.—This company will build a 25-mile line, it is said, from Cambridge, Md., southwest via Church Creek and Taylors Island, to Fox Creek. V. C. Carroll, Cambridge, may be addressed.

Canadian Pacific.—Contracts for building the final section of the Kootenay Central through the Windermere valley in British Columbia are reported let as follows: To Burns & Jordan, Spokane, Wash., for work on 60 miles. Another contract for work on 20 miles has been let to Boomer & Hughes, also of Spokane.

Chicago, Milwaukee & St. Paul.—According to press report the Big Blackfoot Railway, a subsidiary of the Chicago, Milwaukee & St. Paul, has asked permission to change its articles of incorporation in Montana, to allow it to extend from the south line of section 20, township 14 north, range 11 west, in Powell county, Mont., near Ovando, northeast through Lewis and Clark county, to a point on or near Sun river in township 21 north, range 1 west, near Fort Shaw, in Cascade county, about 110 miles. John R. Toole, president.

Gainesville & Northwestern.—This road is now in operation from Gainesville, Ga., north to North Helen 37 miles.

Independence, Neodesha & Topeka Traction.—Surveys have been made for a line, it is said, from Neodesha, Kan., south to Independence, about 20 miles. Dr. T. Blakesley, president, Neodesha.

International & Great Northern.—President T. J. Freeman is quoted as saying that the International & Great Northern and the Texas & Pacific will carry out a large amount of improvement work during the present year. The entire eastern division of the T. & P. will be re-ballasted from Texarkana, Ark., to Fort Worth, Tex. New rails are also to be laid on sections of the T. & P. and the I. & G. N.

Interstate Development Company's Lines.—An officer writes that the company was organized, to promote and construct about 982 miles of main and branch lines. A point on the Gulf of Mexico in Texas will be one of the terminals. All preliminary reports, estimates of cost of construction and equipment have been approved and accepted by the financial backers. The company expects to develop a traffic in lumber, cotton, live stock, agricultural products and mineral products. Dr. R. B. Bledsoe, president, and Colonel C. A. McCarthy, secretary and chief engineer, both of Lufkin, Tex. (See Texas Roads, March 14, p. 530.)

Interstate Railroad & Traction.—Incorporated in Kansas with $500,000 capital, and headquarters at Blackwell, Okla., to build from Arkansas City, Kan., south via Chilocco, Okla., Blackwell and Tonkawa to Ponca City, about 50 miles. O. L. Brown, president, Arkansas City, Kan., J. M. Van Winkle and C. B. Harold of Ponca City, Okla., and W. L. Cunningham, Arkansas City, Kan., are incorporators.

Iowa Northern.—Incorporated in Iowa, it is said, to build from Clinton, Iowa, northwest to Turkey river in Clayton county. S. G. Durant, president, Clinton.

Lehigh Valley.—A contract has been given to F. H. Clemmens & Company, for excavation work and putting in an additional track, at the entrance to the Bethlehem Steel Works, South Bethlehem, Pa. The cost of the work is $50,000.

Milwaukee, Peoria & St. Louis.—According to press report financial arrangements have been made and work will probably be started next June on the line projected some time ago from Peoria, Ill., north to Rockford, 120 miles. F. W. Cherry, Princeton, Ill., is back of the project, and B. Schreiner is chief engineer. (January 26, 1912, p. 176.)

Missouri, Kansas & Texas.—President C. E. Schaff is quoted as saying, that the company will not begin work at an early date constructing the extensions that are provided for in the bill authorizing the merger of several of the company's lines in Texas into the M. K. & T. system. Improvements to cost more than $2,000,000 will be made this year on the Texas lines. The construction of the gap between the main line and the Trinity-Colmesneil line will be carried on as rapidly as possible. (March 14, p. 529.)

Pacific & Idaho Northern.—An officer is quoted as saying that the company is planning to build the extension this year from New Meadows, Idaho, north along the Little Salmon river to Riggins, 35 miles. (November 29, p. 1063.)

Richmond, Portland & Fort Wayne (Electric).—Incorporated in Indiana with $100,000 capital, and principal office at Portland, Ind., to build from Fort Wayne, south via Decatur, Berne, Geneva, Portland, Winchester and Lyon to Richmond, about 90 miles. G. S. Straub, C. F. Harbison, R. J. McCarty and C. H. Frank are directors.

San Antonio & Austin Interurban.—Surveys are being made for the line from San Antonio, Tex., northeast to Austin, with a branch to Seguin, and construction will be started within a few weeks. W. B. Tuttle, of San Antonio, is at the head of the project. (January 24, p. 191.)

Savannah & Southern.—An officer of this company, which operates a line from Norden, Ga., southwest to Willie 13 miles, and 4 miles of spur lines, writes that surveys are being made for an extension from Willie southwest to Glenville, about 20 miles. The company plans to eventually build an extension east via Clyde to Savannah.

Seattle, Port Angeles & Lake Crescent.—A contract has been given to the C. J. Erickson Construction Company to build from Oak Bay, Wash., via Sequim and Port Angeles, thence west via Lake Crescent. The work is now under way, and includes a trestle over the Elwah river. There will also be a two-mile sea wall at Port Angeles bay. Michael Earles, president; M. C. Morrow, secretary, and C. J. Erickson, chief engineer, Downs building, Seattle.

Sioux Valley & Northern.—Incorporation will be asked for soon by this company, with a capital of $1,000,000 and headquarters at Watertown, S. Dak. The plans call for building through Codington, Grant and Roberts county to the north line of South Dakota, about 100 miles. The incorporators include F. T. Heathcote, C. T. Jones, T. N. Bergam, J. E. Mitchell and Mark Johnson.

Southern Pacific.—An officer writes that all the contracts are let for building the Willamette-Pacific from Eugene, Ore., west to a point on the Pacific coast near the Suislaw river, thence south to Marshfield, about 123 miles. Twohy Bros., and McArthur, Perks & Company, Ltd., are the contractors.

Southern Traction.—This company is building between Dallas and Waco and between Dallas and Corsicana, a total of 158 miles. The Waco division will eventually be extended south to Austin, about 100 miles. The line is in operation between Dallas and Waxahachie and the section to Waco will be completed

about July 1. The line to Corsicana is under contract to be finished by August. (January 10, p. 88.)

Southwestern Traction.—This company is planning to build an extension, it is said, from Temple, Tex., northeast to Marlin, about 30 miles.

Texas & Pacific.—See International & Great Northern.

Texas Roads (Electric).—The Stone & Webster Engineering Corporation, Boston, Mass., is making plans, it is said, to build an interurban line between Dallas, Tex., and Terrell, about 30 miles, and between Beaumont and Port Arthur, 25 miles. It also owns the Rio Grande Valley Traction, which was organized to build between El Paso and Fabens, about 30 miles.

A syndicate of Houston, Tex., and Beaumont men, represented by John W. Maxey, an engineer of Houston, is said to be promoting the construction of an interurban line between Austin and San Antonio, via Lockhart. The plans also call for extending the line east to Houston.

Joseph A. Davidson, of Indianapolis, Ind., and associates, are reported back of a project to build an interurban line between Austin, Tex., and Smithville via Lockhart, Stowall and Bastrop, about 40 miles.

E. P. Turner, of Dallas, Tex., and associates are promoting the construction of an interurban line, it is said, between Dallas and Wichita Falls via Denton, about 150 miles, and between Dallas and Glenrose, about 60 miles.

Willametta-Pacific.—See Southern Pacific.

RAILWAY STRUCTURES.

Catasauqua, Pa.—The Central of New Jersey has given a contract to the American Bridge Company, New York, for putting up a through riveted truss over the Lehigh canal in Catasauqua.

Fairbury, Neb.—The Chicago, Rock Island & Pacific has announced that appropriations have been made for the enlargement of its shops at this point, the erection of a $30,000 passenger station, and additional freight facilities.

Frankfort, Ind.—The Lake Erie & Western is to begin work shortly on the erection of a new station and freight house.

Miller, Ind.—It is reported that the Baltimore & Ohio will expend $800,000 in leveling the sand dunes, and constructing yards and a terminal at this point.

Muskogee, Okla.—The Missouri, Oklahoma & Gulf has let contracts for the erection of new shops and other improvements at this point, to cost about $250,000.

Newnan, Ga.—The Central of Georgia and the city officers of Newnan will jointly put up a 125 ft. span steel truss over the tracks of the Central of Georgia, with trestle approaches in Newnan. The bridge construction is being carried on by the railway company's forces, and the approaches by the city officers.

South Bend, Ind.—The Grand Trunk has announced that work will be started immediately on the erection of a new $50,000 passenger station.

Syracuse, Ind.—The Baltimore & Ohio has given a contract to the Youngstown Construction Co., New York, to build a passenger station at Syracuse. It will be of pressed brick and red tile construction with tile floors, 60 ft. x 21 ft. The improvements will cost about $13,000.

Walkerton, Ind.—A contract has been given by the Baltimore & Ohio to P. Farrell, Cincinnati, Ohio, to build a passenger station at Walkerton. It will be of pressed brick construction, with red tile roof and tile floors, 55 ft. x 30 ft. The platforms will be of brick with concrete curbs. The cost of the station will be about $10,000.

Specifications for New Line in Ecuador.—Specifications for the construction of the Babahoya-to-Balzaparnba railroad, Ecuador, will be loaned on application to the Bureau of Foreign and Domestic Commerce at Washington. This is to be a 37 [illegible] line from the city of Babahoya, capital of the province of Los Rios to the village of Balzaparnba.

Railway Financial News.

Atlantic & North Carolina.—*The Commercial & Financial Chronicle* says that E. C. Duncan, vice-president of the Raleigh, Charlotte & Southern, has offered to all stockholders of the Atlantic & North Carolina to buy their stock at 75. The state of North Carolina owns $1,266,500 of the total $1,797,200 stock. The state has appointed a special committee to make recommendations to the legislature in regard to this offer.

Canada Southern.—The New York Stock Exchange has listed $22,500,000 consolidated guaranteed 5 per cent. bonds of 1912-1962, guaranteed principal and interest by the Michigan Central.

Chicago & Alton.—The $2,500,000 3-year 5 per cent. notes which matured March 15 were paid in cash at the United States Mortgage & Trust Company, New York.

Mexican Union.—This company, which took over the Torres & Minas-Prietas Railway, has authorized an issue of prior lien debenture bonds to pay for completing the line to Ures. The first mortgage debenture bondholders have voted to accept a reduction in interest on their bonds from 6 per cent. to 3 per cent., making the agreement retroactive and effective August 12.

New York Central & Hudson River.—Stockholders are to vote on April 16 on the question of consolidating with the New York Central, the Rome, Watertown & Ogdensburg and other subsidiary companies. The plan will call for an increase in capital stock outstanding of the N. Y. C. & H. R. of $2,851,700.

Norfolk & Western.—The subscriptions for the new issue of Norfolk & Western convertible 4½ per cent. bonds closed Tuesday. The stockholders very generally took their allotments and of the $18,353,000 offered approximately $17,500,000 or 95 per cent. was subscribed. Of this subscription about $11,000,000 was first instalment paid and $6,500,000 was full paid.

Pennsylvania Railroad.—The directors have approved of the long term lease of the railroad property and franchise of the West Jersey & Seashore on the terms prescribed by the latter company, namely:

1. A guaranteed rental of 6 per cent. per annum on the common stock.
2. The interest on its bonds, taxes and other fixed charges.
3. The lease to become effective July 1, 1913.
4. On July 1, 1913, when the new lease goes into effect a dividend of 1½ per cent. in cash is to be paid to the common stockholders.

The lease will be submitted for approval by the stockholders of the W. J. & S. S., at a special meeting to be called for that purpose on April 30, 1913.

Pere Marquette.—At the sale of the $16,000,000 5 per cent. 50-year improvement and refunding mortgage bonds on Thursday of last week, mentioned in the *Railway Age Gazette* of March 21, the bonds were bid in by the committee representing the $8,000,000 6 per cent. notcholders under which notes these bonds were deposited as collateral. The price bid was $6,400,000.

Toledo & Chicago Interurban.—The superior court of Allen county, Ind., has ordered the sale of this electric road at an upset price of $550,000.

Railway Development in Chile.—The Chilean government's railway extension program very thoroughly covers the country and when completed will be one of the most complete systems in Latin America. At the close of 1912 there were 2,393 miles of government railways in operation, with 1,337 miles under construction, and 3,008 miles of projected railways, making in all 6,738 miles. The government has under consideration the making of a loan sufficient to equip the railways properly with rolling stock and to double track certain portions of the lines where the traffic is exceptionally heavy, as between Valparaiso and Santiago.

Subscriptions, including 52 regular weekly issues and special daily editions published from time to time in New York, or in places other than New York, payable in advance and postage free:

United States and Mexico.....$5.00
Canada..... 6.00
Foreign Countries (excepting daily editions)..... 8.00
Single Copies.....15 cents each

Engineering and Maintenance of Way Edition and four Maintenance of Way Convention Daily issues, North America, $1.00; foreign, $2.00.

Entered at the Post Office at New York, N. Y., as mail matter of the second class.

WE GUARANTEE, that of this issue 8,100 copies were printed; that of those 8,100 copies, 6,646 were mailed to regular paid subscribers and 150 were provided for counter and news companies' sales; that the total copies printed this year to date were 121,409—an average of 8,672 copies a week.

Volume 54. April 4, 1913. Number 14.

CONTENTS

* Illustrated.

JAMES McCREA died at his home in Haverford, Pa., on March 28. His death, following so shortly after his retirement from the presidency of the Pennsylvania Railroad, is a severe loss to the higher councils of the railroads of the country, as well as to his own board of directors. Coming as it does only about four months after his retirement from a position which lays so heavy a burden of daily labor on the man who occupies it, it is rather tragic evidence of the force of will power that kept James McCrea in the harness almost to the very last. Mr. McCrea's railroad work was commented on in the *Railway Age Gazette* at the time of his retirement. A brief account of the events of his life is given in another column in this issue. During his presidency of the Pennsylvania Railroad from 1907 to 1912, he devoted his energies to an intensive development of the greatest railroad property in the world, making it possible to reap the benefits of A. J. Cassatt's policy of farsighted expansion and leaving the property enriched and ready for future development.

MANILA is on the other side of the world, but a letter from there, printed in another column, presents a couple of questions that bear very directly on life—railroad life—right here in New York, Pennsylvania and Illinois; also in Arizona, Maine and elsewhere. Our correspondent rightly emphasizes the need of exposing the officer who winks at bad practice. But, to cover the case, his argument should also deal with the negligent or incompetent officer. Winking is an elusive thing; but the officer who knows of misconduct or neglect and does not correct it; and those who do not know, and so cannot take action, may perhaps be classed as all alike. Mr. Scholes' second suggestion is eminently practical. It ought to be carried out by twenty-five railway presidents at once. But usually it is very difficult to formulate in satisfactory shape a charge against the grievance committee which grieves beyond reason, keeping inefficient men in service; and it must be recognized, also, that there is still greater difficulty in making such matters public in a way to benefit the public. But every president would do well to have some cases of this kind formulated for filing in his own office. Putting such cases in systematic shape, as a district attorney would do if he expected to prosecute them in court, would be a very useful service. It would be a great benefit to the railway world if a hundred examples of bad labor-union influence could be aired, in the way that the railway presidents of New York state have this week aired the bad labor-union influence in the matter of the full-crew bill.

THE full crew bill went through the New York legislature regardless of all protests and by the governor's approval is now a law. Governor Sulzer held a hearing and most of the principal railway presidents appeared and showed him the utterly irrational character of the proposition, but all to no effect. It is proper to remind people outside of New York State that nearly all reasonable measures fare this way in the Albany legislature this year. Tammany Hall controls the legislature and the governor seeks popularity with "the masses." He went through the form of respecting public opinion by filing with his approval of the bill an explanatory memorandum, but in this he only stultified himself by accepting the brotherhoods' claim that the presence of the extra brakeman would add to the safety of employees, a claim for which, under the railway managers' challenge, the labor leaders were unable to bring even a shadow of reasonable foundation. The governor's other reasons were weaker even than this one. The people of the country now have before them three shining examples of the drift of public opinion. In the matter of valuation of railway property the country is willing to approve an expenditure of from two to ten millions for the purpose of proving technically, what is already proved morally, that the railways do not use false figures of capitalization for the purpose of extorting high rates for carrying freight. In the arbitration of firemen's wages the public—as represented by the press—weakly allowed the railways' demand for three or five impartial arbitrators to go unheeded because, forsooth, a matter of a few million dollars' loss from the railways' treasuries was less important than to sustain "labor" in its extraordinary respect for "law" as embodied in the makeshift Erdman act. And now the appeal of the New York railroads to be saved from a useless expenditure of $2,000,000 annually is contemptuously ignored for no other reason, really, than that the politician is in duty bound to favor the side which controls the most votes. This last is the underlying reason in all these examples, of course.

IN compliance with the recommendations of the Interstate Commerce Commission and the Public Utilities Commission of Connecticut, the New York, New Haven & Hartford has ordered the lengthening of 78 crossovers to No. 20 in addition to similar lengthening of 12 important switch leads not included in crossovers on its main line between New York and Boston. Besides the actual track work incident to the replacing of the frogs and the lengthening of the switch leads, this will necessitate the rebuilding of 36 interlocking plants. This work will cost $750,000, with an additional outlay of $350,000 for changes in signals, or $1,100,000 in all, which is at the rate of nearly $5,000 per mile of line. If this large expenditure would really insure safety to trains passing through turnouts at high speeds, it would be justified and would receive the approval of all railway men. But, this is not the case in spite of the popular belief based upon statements of the Connecticut commission that a No. 20 crossover is safe for high speeds. Railway engineers fully realize the fallacy of this idea. It will still be necessary to reduce speed through the No. 20 crossovers, although not to the same extent as through No. 15 crossovers. When enginemen disregard signals and attempt to pass through turnouts at speeds such as resulted in the two recent accidents on the New Haven, accidents are certain to occur as they did on the shorter turnouts, and may be more serious, for with the higher speeds permitted in operation over long crossovers the risks in case of disregard of signals are greater. Contrary to general belief, the benefit derived from these longer crossovers will not be so much an increase in safety as an increase in regularity of operation due to the possibility of maintaining higher normal speeds through the crossovers. Whether this advantage will justify the cost is doubtful.

UNIQUE is the concern or class of concerns that does not today feel the teeth of the muckrake and the lash of the reformer. The chief promoters of the current nation-wide movement for the regeneration of business are the newspapers and magazines. The main objects of their objurgations and condemnations have been the railways and other large corporations. When the corporation managers have been disposed to remind the publishers and editors that reform, like charity, should begin at home, many of our esteemed contemporaries have in effect retorted that their case was different from that of the railways, as they are engaged in a purely private business. The public shows an inclination to take a different view; and at Denver a "Citizens' Protective League" has been formed to suppress "vicious journalism" in Colorado. It includes two ex-mayors, the president of the Rotary Club, the president of the Real Estate Exchange, the president of the Ministerial Alliance, the president of the Denver Bar Association, the president of the Denver Women's Club, and numerous other persons prominent in the business, professional and social life of the city, and it has issued a pamphlet bitterly denouncing the local newspapers and saying that it intends to wage war until they are reformed. One of the planks in its platform sets forth that "fake stories, misrepresentations and exaggerations of all kinds should be eliminated." The *Railway Age Gazette* has no special comment to make on the newspapers of Denver. It would seem, however, that every good citizen not only of Denver, but of the United States, might well subscribe to the plank quoted and join a crusade to make American publishers and editors live up to it. It has come to pass that "fake stories, misrepresentations and exaggerations of all kinds" are served up by many newspapers as the staple of daily "news," and the railways of the United States have been among the greatest sufferers from this practice. Among the very worst sinners against decency and truth are the class of newspapers and magazines that hold up the highest standards for railway officers and other business men, and the very biggest liars of all are the professional muckrakers. The public should apply to the press the same standards of honesty, fairness, good service and good citizenship that the press has successfully insisted on having applied to public service corporations. When rebating prevailed most railway traffic men wanted to obey the law against it, but were driven into breaking it by their unscrupulous competitors. A majority of publishers and editors are in the same relative position now that most railway traffic managers were then. They would prefer not to fill their papers with the sensational and the false, and would welcome a reform; but in the newspaper as in the railway business, the effective pressure for reform must come from the public. As no class of men or concerns has suffered more from yellow journalists and journalism than railways and railway officers, so none will more heartily welcome any movement that may tend to abate them.

J. P. MORGAN.

PROBABLY the three men who have exerted the most influence on the development, operation and financial results of the railways of the United States have been James J. Hill, E. H. Harriman and J. P. Morgan. Each of them has exerted an influence, having various phases. Yet the influence of each has had a distinctive character. Mr. Hill has done the most to teach railway managers how to develop the natural resources of their territories and to operate economically. Mr. Harriman's characteristic work was the taking of physically moribund properties and developing them into highly efficient transportation machines. Mr. Morgan's great work was that of teaching—and sometimes compelling—railway managements to conserve their resources by living in peace with each other instead of mutually destroying one another by wasteful, cut-throat competition.

Mr. Morgan, whether dealing with industries or railways, was first, last and all the time, what he always termed himself, a banker. In that capacity he invested other people's capital. Having invested it, he felt a heavy responsibility for seeing that they profited by their investment. Many millions of early investments in railways were destroyed by competitive construction and rate-cutting. Such competition did few people any good, and many besides investors immense harm. Having, in his capacity of a banker, become interested in the welfare of various railways, Mr. Morgan resented and opposed the destruction of values resulting from excessive competition; and many years ago he was largely, if not chiefly, instrumental in bringing about the early "community of interest" arrangements —arrangements that restrained competition by the device of securing for rival railways ownership of more or less of each other's stock and representation on each other's boards. From then to the time of his death Mr. Morgan's influence in the affairs of the railways of the United States was not only one of the most potent, but one of the most salutary. It was potent, not so much because his own direct financial interest in the railways was large—although it was—not so much because the financial interest in them which he represented was great—although it was very great—but because his direct and indirect financial interests were reinforced by a mighty intellect, a powerful will and a reputation for immovable integrity—an intellect, a will and an integrity which inspired the greatest confidence in investors in all classes, and which thereby became the cause and secret of his enormous power.

His power, like that of all great men, in whatever line, was the power of a personality. It was his personality that commanded men's confidence; and it was men's confidence that enabled him to become the possessor, and far more the representative, of a large capital. He insisted on being paid well for the services he rendered in reorganizing railways and other concerns, and putting them on a stable basis; but his aggregate compensation was a drop in the bucket compared with the enormous amounts that his organizing ability and his conservative, honest influence added to the wealth of the United States.

The power of a responsibility dies with its possessor. There will be no successor to J. P. Morgan. Fortunately, conditions in the railway field are now such that it apparently needs no

successor to him. The day of cut-throat competition and financial legerdemain in railway affairs seems to be past. The work of Mr. Morgan and his associates and public regulation have together made them impossible in future. The very fact, that in the transportation field at least, Mr. Morgan needs no successor is perhaps the highest tribute to his ability, integrity and personality, and the wonderful influence they exerted—an influence for good that will continue to be felt for many, many years.

MORAL CHARACTER IN THE ADMINISTRATION OF DISCIPLINE.

In selecting trainmasters, roundhouse foremen, road foremen of engines, master mechanics and other officers who are to be the superintendents of the future, a railroad manager should put a premium on integrity of personal character. This pregnant truth was forcibly set forth by a Southwestern superintendent of long experience, in our issue of March 7, page 425. In a private letter he stated the case even more strongly; he would sacrifice experience, if need be, to make sure of high moral character. And in the letter published (page 426, near the bottom of the first column) he indicates that this sacrifice may not be a great detriment after all. Men of strong moral character learn the essentials of the railway profession quickly. In the railway world, the worship of experience has become so general that the word is really a dangerous shibboleth. It is high time that the other side of the truth were given more attention.

The New York report, to which our correspondent referred, points out two important features, in some respects the most important, in the "character" which is so vital an element in efficient railway operation; (a) justice, (b) fearlessness. The division officers referred to should be "capable of dealing justly and fearlessly" with their subordinates; and "the authority of these officers should be sustained by the officers above them; they should be secure in their positions." (*Railway Age Gazette*, January 17, p. 105.)

Any one interested in these matters will confirm the view here expressed, from his own observations and experience. The foreman who knows nothing but his machinery has a constant deadening influence, and the officers who have made or approved his appointment, soon regret their choice. His mistakes with the employees may be due either to prejudice and favoritism or to mere weakness as a manager; the result is much the same, either way. The foreman, on the other hand, who is fair minded and courageous, but not good in the technical part of his work will have much to learn, and will make mistakes; but he will correct the mistakes, if he sticks to the job, and the value of his moral qualities will be such a constant satisfaction to the higher officers, in the relief that they will experience in dealing with appealed questions of discipline and efficiency, that they will, if they are wise, give ample opportunity and assistance for the correction of mistakes. In short, if the man who is strong minded and high minded can once get over the period of ridicule, outspoken or covert, which is the lot of all who enter a railway office without the time-honored certificate of "experience," he has the opportunity, in the positions which we are here considering, of a most useful and honorable career.

We have said that justice and courage must be the two chief ingredients in the ideal officer's mind and conduct. For all practical purposes, we may simplify our theme by concentrating attention on courage alone. The elements of justice are so well known and the rules for their application so easily mastered, that no one need have much difficulty with this part of his problem. There is not much trouble in seeing the issue. The courage to do what is clearly seen to be needed is the final desideratum. We are not going into a general dissertation on how to cultivate courage. Every one will agree, however, that our correspondent has pointed out one of the first fundamentals of courage in the administration of discipline when he shows the need of a clean moral life. Another thing in this connection, quite obvious, perhaps, yet needing reiteration, is that the principles of character referred to apply in many small things, as well as great. The operating officer needs these qualities not alone in dealing with gamblers or drunkards, but in countless other situations. Such commonplace faults as laziness, petty dishonesty and concealing bad practices demand of the officer the constant exercise of moral strength, wisdom and all the fundamental virtues—courage in its highest form.

The letter of a New Mexico correspondent in this issue, telling of favoritism and poor judgment, furnishes another "exhibit" which goes well with our present topic. Favoritism is injustice, when it impairs the efficiency of train service so as to make lives and property less secure; and, as everybody knows, there are many obscure and apparently small weaknesses in train-service discipline which directly, if not visibly, affect the safety of trains. Favoritism, of this kind described by "M. M." is not confined to New Mexico. This letter may also appropriately be considered in connection with that of March 7, before referred to, because of the different aspect of the same question here presented. In the earlier letter we are reminded that on occasion it may be well to choose (for example) a trainmaster who cannot be marked 100 per cent. in all the details of railway operation; the candidate may be so desirable on other grounds that this point can be waived or modified. In the letter of "M. M." on the other hand, we are shown cases where men were appointed who seem to have lacked both the experience and the necessary strong moral qualities. A situation like this need not confuse the issue. First-class men are not always easy to find, whether one looks for experience or looks for character. The only sure way to get either, of a satisfactory quality, is to begin early enough to be able to train young men for a period of five years or more in your own service. The ideal officer is the one who stands high in both of the respects here referred to, and the railway that is so fortunate as to have trainmasters and foremen of this kind should see that their younger employees are trained, as effectively as possible, to imitate the ideal.

We have been speaking chiefly to division superintendents. Any individual superintendent can carry out these universally-approved principles. We are not telling him anything new, only calling attention to things which he knows already. His success will be measured by his physical and mental strength and his independence of character. But whether in New Mexico or Missouri, New York or Montana, the cure of the defects which are here discussed will be noticeable and widespread only as some general officer sets things agoing.

NEW BOOKS.

Digest of the Decisions Under the Interstate Commerce Act. Compiled and published by Herbert C. Lust and Ralph Merriam of the Chicago Bar. 1100 pages. 6 in. x 9 in. Buckram. Price, $8.

This volume is a continuation of the Digest compiled and published in 1908 by E. B. Peirce, late general solicitor of the Rock Island Lines, which covered the decisions from 1877 to 1908, and covers every case arising under the Interstate Commerce Act from January 1, 1908, to date. Every point of fact and law arising in these cases since that time has been digested in full, including all decisions of the Interstate Commerce Commission (reported and unreported) and of the various United States and state courts. The need for such a compilation is felt not only by lawyers engaged in traffic cases, but by railroad and industrial traffic men, members of state and interstate commissions, students of and writers on railroad subjects, and all who are interested in traffic matters. The book is arranged alphabetically according to such subjects as are the ordinary and accepted divisions in which the principles governing interstate traffic would naturally classify themselves, as indicated by a Table of Contents, covering about 10,000 points of traffic law, which occupies 31 pages. All the cases on any one point are grouped together and frequent cross references are inserted to points which may not be logically classified under a particular heading, but may nevertheless have some bearing on it. In all

cases where it is possible to do so, a so-called "fact point" has been made. These fact points show tersely, but completely, the evidence on which the Interstate Commerce Commission or the court bases its decision in the particular case. The authors have attempted to summarize in easy, readable style ton-mile revenues, distances, commodities, rate comparisons and other evidence presented in the particular cases. Not only, therefore, have the traffic principles been classified, but also the economic principles and facts governing each particular case.

The decisions are arranged chronologically under each section, the most recent decision being placed first. If the decision of the Interstate Commerce Commission has been modified or reviewed by any court, rehearing denied, or dissenting or concurring opinion filed, such fact is noted. At the back of the book are indexes to the cases, commodities and localities involved. A reader interested in any particular case, by referring to the index, will find references to every page of the book on which that case is mentioned, and also references to the fact points on each case.

Practical Locomotive Operating. By Clarence Roberts, Assistant Road Foreman of Engines, Pennsylvania Railroad, and Russell M. Smith, Air Brake Instructor, Pennsylvania Railroad. Bound in cloth, 292 pages, 6 in. x 8¼ in. 92 illustrations and 5 inserts. Published by J. B. Lippincott Company, Philadelphia, Pa. Price $2.

This book is intended for the use of locomotive engineers and firemen, its specialty being the running, firing and care of locomotives in service. No attempt has been made to go into the questions of design and shop repairs, and where formulas are used they are given as briefly as possible, without any involved mathematics. No attempt has been made to describe the air brake system or its operation, the authors leaving that subject to those books which are devoted entirely to it, and no description of appliances which are in experimental use only is included in the book.

Part one deals with horse power, tractive effort, train resistance and locomotive efficiency. Part two takes up the systems of locomotive classification most in use and gives illustrations of prevailing types, with tables of dimensions and characteristics. Part three is devoted to useful notes and tables, and deals briefly with such subjects as physics, mechanics and chemistry. Part four considers steam and its properties, saturated and superheated. Part five deals with boilers and related devices, while part six covers the subject of lubrication. Part seven takes up cylinders, valves and valve gears. Part eight deals with the running and firing of locomotives, part nine with disorders and breakdowns, and part ten with parts and appliances, such as injectors, lubricators, etc. Part eleven is devoted to qualifications and responsibilities and deals with operating conditions, selection of engineers and firemen, etc., and concludes with a series of questions on the locomotive. Part twelve gives a summary of the federal laws pertaining to locomotives. The book is well printed and the illustrations clear.

The Practical Railway Spiral. By E. C. Jordan, principal of civil engineering department, Heffley Institute, Brooklyn, N. Y. 4 in. x 7 in., 155 pages, illustrated, leather binding. Published by D. Van Nostrand Co., 25 Park Place, New York. Price, $1.50.

The author states in his preface that "The Practical Railway Spiral" is intended to clear up and modify the theory and to eliminate the existing inconsistencies of spiral curves. It has been his aim to secure a curve which approaches as closely as possible the perfect easement, which is complete in theory, simple and practical in construction, elastic in its adjustment to speed and curvature and readily applicable to all classes of location and revision work. There are no approximations in the theory and development of this spiral. The book includes tables showing deflection angles for four different lengths of spirals for all degrees of curvature ordinarily employed. Spirals for other degrees may be worked out from the formulæ included in the development of the spiral.

Letters to the Editor.

PUBLICITY AND DISCIPLINE.

Manila, February 17, 1913.

To the Editor of the Railway Age Gazette:

There is no doubt but what most railway men will endorse what Mr. Kruttschnitt, of the Union Pacific and Southern Pacific, has to say in reference to the value of publicity in increasing safety on railways, as quoted in your issue of December 27; but there lurks in one's mind the feeling that, on one important side of the question, he has not laid much stress. That is, the joint responsibility of the subordinate officer for an accident caused by disobedience of a rule, when, to use your own phrase, he had "for a long time been winking at chronic disobedience of exactly the same kind," and the concurrent responsibility of the executive officer who does not take steps to ascertain whether his subordinates are winking at chronic disobedience of the rules. It is all right to spare "neither talent, time nor money" to place the responsibility on the flagman or brakeman who has been derelict in his duty, but why stop the light of publicity at that point? The public is loath to condemn the employee too severely for a disastrous failure to observe an operating rule when it has a suspicion that his superior officer has made no effort to enforce compliance with that rule and may even have encouraged him in its violation in the past. The officer is paid a higher salary than the flagman, presumably because he is a man of greater intelligence and ability; and in the case of an accident due to the failure of both to do their duty, the public is apt to place the larger share of responsibility on the man who is supposed to have the greater intelligence.

There is another direction in which publicity would tend to increase the safety of transportation on railways. That is, the full and complete publication of *specific instances* where labor unions or other organizations have prevented or attempted to prevent the proper administration of discipline in the case of flagrant violations of the rules, whether accident resulted therefrom or not.

The first duty of the Safety First Committee is to ascertain the state of discipline on each division, as measured in terms of daily obedience to orders and compliance with the rules of operation, *before* the accident, not after.

R. T. Scholes,
Inspecting Engineer of Railways, Department of Commerce and Police, Government of the Philippine Islands.

JACOBS-SHUPERT BOILER TESTS.

Urbana, Ill., March 27, 1913.

To the Editor of the Railway Age Gazette:

My attention is called to an editorial discussion appearing in your issue of February 28, under the title of "The Jacobs-Shupert Boiler Tests." This discussion is based on certain facts presented by me in a formal report rendered the Jacobs-Shupert United States Firebox Company. The article presents diagrams in which the coal burned and the water evaporated are plotted in terms of draft. It appears from these diagrams that for a given draft, both the weight of coal burned and the weight of water evaporated are less for the Jacobs-Shupert boiler than for the radial-stay boiler, and it is concluded that "if this were to hold it might mean that, while boiler efficiencies were the same, there would be a great reduction in engine efficiency [in the case of the Jacobs-Shupert boiler] as a direct result because of the increase of back pressure required to maintain the heavy draft."

In further discussion of the question thus raised, I would say, first of all, that the presentation of data set forth by your editorial is entirely correct, and the spirit with which the author approaches the discussion is a matter which I greatly appreciate. The defect in the presentation arises from the fact that the data do not sustain the conclusion.

Draft values are sensitive to a variety of influences. For example, increasing the thickness of the fire normally increases the draft, all other things, including the energy of the exhaust jet, remaining the same. Differences in damper areas are at once reflected in the draft values. Neither of these is a matter of general application in a study of boiler efficiencies, except as it must be taken into account in analyzing the data.

In preparing the Jacobs-Shupert and radial-stay boilers for the comparative tests referred to, every precaution was taken to have the openings under the grate of equal area for both boilers. In the attempt to maintain equal thicknesses of fire, the same fireman served for both boilers. It was intended to have the diaphragm in the front end of the boilers set to provide an equal area under them; but it happened that in some inexplicable way, the diaphragm in the front end of the Jacobs-Shupert boiler was set lower than that in the radial-stay boiler. Evidences of this will be seen by comparing the draft values in front of the diaphragm with the draft values behind the diaphragm for both boilers. If

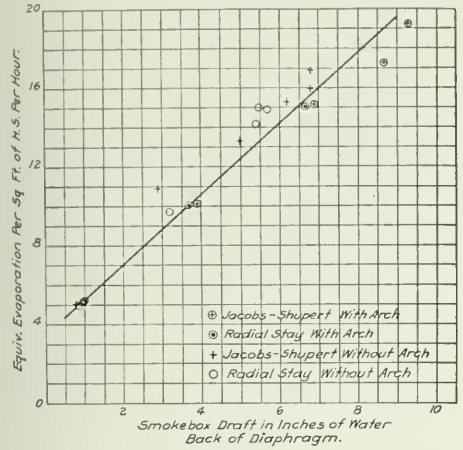

Fig. 1.

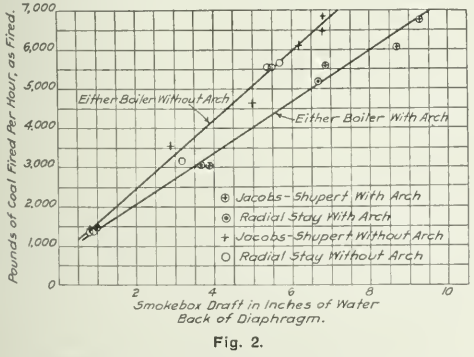

Fig. 2.

in your editorial study, comparisons had been based upon draft value as observed behind the diaphragm instead of those observed in front of it, the performance of the Jacobs-Shupert boiler would not have appeared inferior to that of the radial-stay boiler. Such a comparison is shown by Figs. 1 and 2 accompanying. These figures are similar to those presented in the editorial discussion, except that the draft values are those observed behind the diaphragm. Obviously, the difference in the comparisons made by you and those presented herewith merely discloses the effect of the diaphragm. As it was not the plan of the tests to make the front end arrangement a detail receiving especial attention in the study, all of the comparisons presented in my report are properly based upon draft values as observed behind the diaphragm. The experimental data rightly interpreted contain nothing which suggests the inferiority of the Jacobs-Shupert boiler as compared with the radial-stay boiler.

Dean and Director, College of Engineering and Engineering Experiment Station, University of Illinois.

EVILS OF FAVORITISM.

New Mexico, March 15, 1913.

To the Editor of the Railway Age Gazette:

The article published in the *Railway Age Gazette* of January 17, in regard to the wreck at Corning, N. Y., and especially the statement that there should be greater care exercised in the selection of roundhouse foremen, traveling engineers and trainmasters, must have impressed every well-informed reader.

While we are preaching safety let us remember that though the employees can bring about wonderful improvement by exercising greater care, still the railroads themselves—the officers "higher up"—must put their shoulders to the wheel if they ever expect to accomplish the results desired.

No one disputes that we have in our railroad service a lot of big, brainy, broad minded, capable officers at the helm. But at the same time it is impossible to conceive of any set of men at the head of our large financial and mercantile institutions making selections of heads of departments as these selections are made in railroad work. A bank president would not be selected because he had merely served as paying teller, nor would a man be chosen for the managership of a large wholesale house because he had worked a few years in the shoe department.

In regard to roundhouse foremen: This officer, if, happily, he be a good one, should be highly prized. But, getting right down to brass tacks, how many really good roundhouse foremen are there in the country today? This is one of the most trying positions. Before a man is considered competent to fill it he must have served at least four years as machinist apprentice. The natural inference then is that he worked several years at the bench, as gang foreman and possibly as assistant roundhouse foreman before he finally becomes roundhouse foreman. It is, therefore, safe to say that he has spent at least ten years fitting himself for a roundhouse foremanship; and when the time comes he is "promoted" to such a position at the munificent salary of, say, $115 a month, which is much less than he could earn working at the trade. But, on the other hand, some dude who wears kid gloves, a high collar and a $40 suit of tailor made clothes, and whose entire railroad experience consists of three or four years spent in an office, is promoted to the position of transportation inspector, trainmaster, or something else, at a salary of from $125 to $200 a month. Lots of consolation in this for the poor roundhouse foreman, isn't there?

Now, the traveling engineers. Generally speaking they are men of a high order of intelligence as, in selecting men to fill such positions the brighter men among the runners are chosen. They are at least practical men, and this is more than can be said of a great many who are filling other official positions on our railroads. But, at the same time, it is a well-known fact that many of these traveling engineers were not a brilliant success when they were running engines. How, then, can they be expected to be successful as traveling engineers?

The selection of trainmasters is a most important matter. On a certain road five trainmasters were formerly chief despatchers; two others had been chief clerks to general superintendents and had never put in a day's practical experience at railroading, outside of an office, until they were appointed trainmasters. Another began railroading as stenographer to a division superintendent; was appointed assistant yardmaster, then general yardmaster and finally trainmaster. Still another who is holding down a trainmaster's job was a station agent before his promotion. Now

imagine this galaxy of brainy (?) officials trying to elucidate the rules for the benefit of a company of engineers and conductors who have been up against the grind for twenty years! It is a good deal like having a justice of the peace interpret the law for a supreme court judge.

Not long ago a vacancy occurred in a trainmaster's position and the appointment of a conductor was urged. There was nothing against the man. He had been in the service a good many years and had worked up to a passenger run. That he was qualified to be a trainmaster no one disputed. But the company said they were not making trainmasters out of conductors! No; they will probably give the place to some pencil pusher who is a particular friend of some officer "higher up."

It has often been charged, and not altogether without justification, that too much favoritism is shown in the selection of railroad officers. There is an old saying that "there is plenty of room at the top." That is true in a way, and many men reach the top because they are so energetic and practical that they cannot be kept down. But as a general thing it has been my observation that, in most cases, the top is reached much quicker if you have some fellow up there to give you a helping hand now and then. Promotion in railroad work is not always made on merit. In fact, the opposite is too often true, and it is the fellow who has the most influential friends higher up that gets ahead.

Let us have better roundhouse foremen; but pay them in keeping with the responsibility of their position. Let us have better traveling engineers. Let us have better trainmasters, for God knows we need them; but let us select the right kind of material, conductors or traveling engineers. Make promotions entirely upon merit and fitness for the position. Get away from this favoritism and use some common sense. The railroads, if they ever expect to escape criticism for the annual slaughter of passengers, must wake up to the needs of the hour. If this is not done how can they expect to escape criticism and how will they ever be able to stem the time of anti-railroad legislation?

The foregoing remarks are not intended to reflect on "pen pushers" and clerks. They are an important cog in our great railroad machine, and very few of them are appreciated as they should be. They are generally underpaid and enjoy less privileges than any other class of railroad employees. But you can't take a clerk and make a successful railroad official out of him. That's the point I am trying to make. M. M.

DESIGN OF UNDERFRAME FOR CARS.

Chicago, Ill., March 7, 1913.

To the Editor of the Railway Age Gazette:

Recently in looking over some diagrams of underframing for cars, I was impressed with the fact that the paneling (horizontal plane) was generally quadrangular in form. As the quadrangle will always collapse without altering the length of the members, its strength is limited generally by its corner connections without reference to the individual members. The triangle is the only rigid polygon and a truss is necessarily com-

Fig. 1.

posed of triangles. This fundamental principle has been taken into consideration to good advantage in designing car bolsters and sills to resist vertical forces. We have fish bellied girders and truss rods in endless variety.

The horizontal projection, or plan, is generally somewhat like Fig. 1. There are two center and two side sills with bolsters between them. About the only variation found is in the diagonal strut in the end panel. This is sometimes taken out altogether, and sometimes is placed between the other two corners. The pull and thrust is taken care of by the two center sills, unless the end member is stiff enough to transfer part of the load to the sides.

If, for the purpose of this demonstration, we assume that the two center sills carry all of the load, they will be in tension when the car is pulled, and in compression when the car is pushed with a load ahead, or is bumped in switching. When

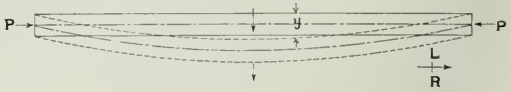

Fig. 2.

the latter happens we have a long column, as shown in Fig. 2. When the car is loaded heavily enough to bend the sill downward, these forces will only add to the deflection in the vertical plane. When the bending takes place in the horizontal plane we will have a bending moment at all points which would be proportioned to the deflection. As this curve would probably be a parabola or a hyperbola it will not be necessary to go into the details at this time. The maximum effect would be pro-

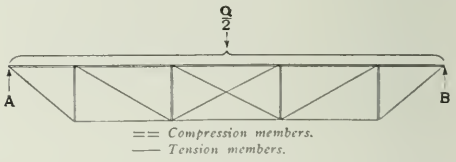

Fig. 3

duced when this force is concentrated at the center of the column. This force would be a load on the center of the top chord of the right hand truss and on the bottom of the left hand one. If now for purposes of illustration we turn this truss through 90 deg., so that it takes a vertical position, we will have the situation shown in Fig. 3. The style of construction required would be a deck Pratt truss supported at *A* and *B*. The number of panels, shown as five, would be increased to seven

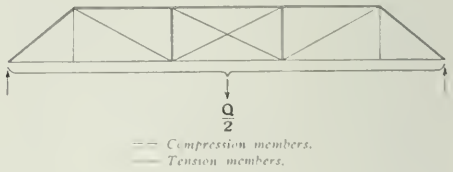

Fig. 4

for a long car. For the left hand side, the style of framing best suited to carry the load would be a through Pratt truss, as shown in Fig. 4. When the bending is in the opposite direction to that shown, we would have similar diagrams with the diagonals in opposite directions.

When the four diagrams are placed so that those for the left

Fig. 5

are over each other, and those for the right are similarly placed, we will have the diagram marked Fig. 5. The compression

members are shown where there are both kinds. This all looks simple enough when based on fundamental principles. The form of truss with vertical struts was selected for the reason that they have to carry vertical loads in any case and sections suitable for bending stresses will be suitable for struts in most cases. If we wish to regard the whole system as a column with the loads uniformly distributed at the ends, we would then have a column with the lattice system now in common use for compression members.

When the train is on a curve, the car ahead and the car behind

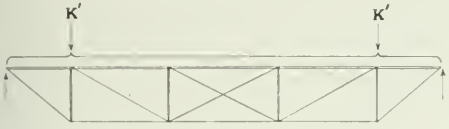

Fig. 6

pull the ends sideways. This brings a lateral thrust on the king bolt of the truck which must be distributed through the floor system. If the speed is greater than that for which the curve is elevated, there will be an outward thrust, which will be applied at the king bolt, but will be in the opposite direction from the preceding. Their algebraic sum will be applied to the floor system, as shown in Figs. 6 and 7. There will be two loads at

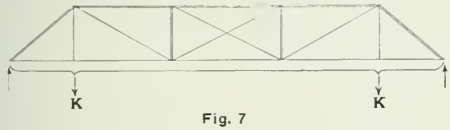

Fig. 7

the panel points, and the same form will be required as in the foregoing. When the speed is less than that for which the curve is elevated, the thrust will add to that of the pull of the train, in front and behind the car in question.

There has been no attempt in the foregoing to take into account the question of elastic distention, etc., but simply to find out if there is any objection to using the truss principle. The truss has been shown to be the most economical for similar forms of construction, and it seems odd that competent designers have not gone into the matter. If they have, I have not been fortunate enough to find their ideas in print, and so cannot tell what have been the objections to the truss in times past. If the material now used is necessary to withstand the lateral stresses, it would appear that a lesser amount can be used to accomplish the same purpose, by making a careful analysis and a scientific design.

Paul M La Bach,
Assistant Engineer, Chicago, Rock Island & Pacific.

THE CONDUCTOR'S AUTHORITY AND RESPONSIBILITY.

San Francisco, Cal., March 25, 1913.

To the Editor of the Railway Age Gazette:

The letter in your issue of March 7, entitled, "The Captain of a Freight Train Crew," is interesting and logical. I do not think, however, the writer gave full expression to the points he had in mind. Particularly, it appears to me the conductor's judgment of and authority over his men is not accorded the rating it deserves, considering his responsibilities, and assuming that he is, fundamentally, a man of good judgment.

He does not have authority to employ or discharge, and when on the road or in a yard with a man who proves indifferent or incompetent the only remedy he may adopt is to relieve the man of responsibility, and reapportion the work; perhaps assume some of the duties himself, and report by wire or in person. Often, however, conditions oblige him to work the man into terminal or to the end of the shift, after which the latter may be superficially questioned by an officer, and, perhaps, with mere reprimand or warning, continued on the run, or assigned to another. Although an inexperienced man may be sent out as a student two or three trips and be approved by the conductor under whom he works, the conductor's judgment of him cannot be other than superficial, as the traits of men cannot be fully studied in so short a time. Aside from this, if the man is accepted after trial he may be assigned to a conductor other than the one with whom he was tried and who, therefore, to some extent is expected to abide by the judgment of others. Brakemen and switchmen are often assigned to work with a conductor with whom they are neither psychologically or mentally fitted to join in responsibilities.

In the army a captain does not recruit his men, ordinarily, but he does have practically unlimited authority over them during engagements on the field; and in times of stress, if he is beyond the range of superior authority, conditions may justify him in exercising the power of life and death; subject to review, of course, by his superiors at any time. From the standpoint of averting disaster the responsibilities of the conductor are as great in their way as are those of the captain. The duties of a train crew are varied and many during the day or trip, while the units of a military organization are, generally, only expected to act in unison in a given action or direction.

Brakemen and switchmen at times are indifferent to duty because of lack of full respect for the orders or judgment of the conductor, knowing the limits of his authority and also knowing that the conductor is invariably involved in the results of failures of his men; and indifference is often the primary cause of accident or disaster. The conductor often handles switches, makes couplings, gages clearances, etc., merely because he realizes his ultimate responsibility, and therefore partially undertakes the duties of his men, fearing to fully trust them under complex or hazardous conditions. Individual instances have occurred where men have damaged equipment or track, or hazarded lives, after the conductor had properly cautioned them to be alert as regards the position of switches, watching clearances, etc. Often, I think, conductors are jointly disciplined with their men when it is not morally just to do so.

Trainmen or switchmen are employed by officers or their office representatives, and the conductors, individually and as a body, can exercise no judgment until on the road or in the yard with the men, and then their estimate, generally practical and fair, can be emphasized by emphatic action if necessary, but only through action by an officer whose judgment, fundamentally, may not be as sound as that of the conductor. Surely, this is no reflection when we recall that many conductors have been appointed to office and have proved themselves efficient.

Would it not be well if conductors were allowed some degree of joint participation in the selection and discipline of men who are to assume responsibilities under their direction? Undoubtedly, it is difficult to determine equitable and practical measures for governing their authority. Nevertheless, this feature is one of the most important and far reaching in the conduct of transportation, and deserves keen study by officers from practical and psychological viewpoints. Generally, the practical phase is given more study than the psychological, although the latter should be regarded equally important with the former.

Edwin Swergal.

EFFICIENCY OF FREIGHT HOUSE FORCES; DAMAGED FREIGHT.

Kansas City, March 10, 1913.

To the Editor of the Railway Age Gazette:

Within the past two or three years practically every railway of importance in this country has inaugurated a campaign to reduce its loss and damage account. While the details may vary somewhat on the different lines, the general principle involved is one of education and instruction among all classes of employees who have to do with the handling of freight, in order that they may better appreciate the causes contributing to loss and damage and thus be in a position to prevent it.

The result, as is frequently the case with reforms of this na-

ture, is for a time extremely gratifying; but after a year or two it is apparent upon analysis that while a substantial improvement has been effected along certain lines, the showing in other directions is very unsatisfactory; and it is felt that the progress made has not been commensurate with the efforts put forth by those who were directing the campaign. Much effective work has been done to better the physical condition of freight cars, to induce shippers to improve the character of their packages and to supervise the handling given freight by train and yard crews; but the most prolific source of loss and damage, in the case of less than carload freight, is the improper handling it receives at freight stations, and the result of the campaign so far as it relates to this feature is in many respects discouraging.

This is due to a variety of causes, but the chief one of them is that we have been unable to develop in certain classes of employees a feeling of personal responsibility for their work. It is only by instilling this into the minds of our employees who handle freight that we can ever hope to bring about the results we are after. This attitude of the employee toward his work may be developed by appealing to his self-interest, or by fear of discipline or loss of position; but, regardless of how it is accomplished, he must have it, if there is to be efficient service obtained from him.

It is apparent to any one who has studied the results of such a campaign as I have mentioned that the employees who have gained the most and whose services have correspondingly improved, have been the ones who had the most to lose and who were therefore the most susceptible to discipline. Unfortunately, however, in the case of station service the handling of the freight is delegated to subordinates, who are hard to reach, and who cause the most trouble.

Our over, short and damage statistics show that from 60 to 70 per cent. of the errors made which result in either loss or damage occur at the transfer stations. I mean by this the district or division terminals where merchandise cars are worked and where platform forces are maintained; and it is at such places that our efforts to improve the service meet with the most discouraging results, because of the changes that are continually taking place among the men and the impossibility of developing and maintaining anything like a satisfactory organization.

These changes are brought about by fluctuations in labor conditions along the line. When farmers or manufacturing industries are in need of men they are in a position to offer better wages than the railroad company, whose scale is far less elastic; and the railroad gets what is left. We are continually breaking in new men in the freight houses whose only idea is to hold the job until something better turns up. In the struggle to keep pace with the demands of a few well organized classes of employees and still operate their roads at a profit, executives have been slow to meet the need for better pay among the great body of unorganized employees, and with the granting of each succeeding demand to the former, the prospects of the latter appear to become more and more remote. The result is that men of fair intelligence and capability who were willing to work formerly for the wages paid station help have forsaken this field for employment that offers better pay and in most cases shorter hours, so that, generally speaking, we are no longer able to secure the same class of help in our freight houses that we did a few years ago.

The wages paid freight-house help at the present time approximate those paid track repairers, and if the railroads of this country are finding it hard to secure good foremen for their gangs it is not surprising that they are experiencing similar difficulty to keep up the standard of their freight-house foremen and check clerks, and when the burden of responsibility for the correct and careful receiving, inspecting, checking, handling and storing of freight together with the interpretation and application of numberless rules and regulations pertaining to these various duties is placed upon these men, it is not difficult to see why we continue to have the same loss and damage troubles year after year. The agent who is face to face with the problem of trying to build up an efficient freight-house organization out of this material is frequently placed in the position of being obliged to retain men whom he knows to be careless and incompetent, through sheer inability to get new men in case he should discharge the present force.

The position of freight-house foreman is one of no little importance. To my mind it demands an equal amount of intelligence and responsibility with that of chief clerk or cashier; and yet we pick up foremen without any regard to their qualifications and pay them lower wages than the average unskilled laborer commands in the same community and then expect them to possess the executive ability necessary to keep things running smoothly on the freight platform. The wonder is that we succeed as well as we do. We pay good salaries to our cashiers and revising clerks so as to secure men who are honest and competent in order that our revenue may be protected, but we turn the job of checking valuable merchandise over to a laborer at a dollar forty a day. Where the incompetent revising clerk may lose a couple of dollars of revenue the incompetent check clerk is more likely to cost us a couple of hundred dollars by delivering a box of household goods with the wrong shipment, or receipting for something he did not get. I believe it is just as vital, if not more so, for us to have honest, competent and reliable freight-house foremen, check clerks and stowmen, as it is to have these same qualities in our chief clerks and cashiers; and the only way I know of to secure and retain such men is to pay them salaries that are somewhere in proportion to the qualifications we expect them to have.

The objection has been raised that to make a general increase in the pay of all station help would mean such an enormous sum in the aggregate that it would be impracticable, and also that in the event that this was done the railroads would still be competing with industries along their lines for the labor of substantially the same individuals at higher wages but with no corresponding improvement in the character of the services obtained. This would doubtless be true if such a horizontal increase were made, but, in my opinion, such a step is by no means necessary to accomplish the desired result. I believe that by judiciously expending a comparatively small percentage of the amount we are now paying out annually in loss and damage claims, we could increase the salaries of foremen, check clerks and stowmen at the more important stations, where most of the errors are now being made, to a point where they would attract into these positions a better class of young men who would not only take an intelligent interest in their work and fill these places efficiently, but would also be capable of being advanced to more responsible posts.

Anyone who has handled o. s. & d. investigations must realize what a tremendous reduction could be made in loss and damage if it were possible to make the man who handles the freight take the same interest in its welfare that he would if the goods belonged to himself; and while perhaps it is not within human nature to attain this degree of perfection, much can be accomplished through appeal to a man's self interest by making his job mean something to him and then holding him strictly responsible for results.

The question of truckers under this scheme becomes a simple one. By taking from them all responsibility except that of pushing a truck we are then getting just what we had a right to expect when we hired them—common unskilled labor—and when we expect anything more from this class of help we are simply deluding ourselves. Truckers can come and go, but if we have competent foremen checkers and stowmen who are interested in their work and who are held strictly to account for all errors that are made, the changes among the truckers will not affect the efficiency of the freight-house force in the least, and we shall then be able to accomplish results through the placing of individual responsibility in connection with an effective system of discipline that will go a long ways toward eliminating what I believe is at present by far the largest contributing cause of our loss and damage payments.

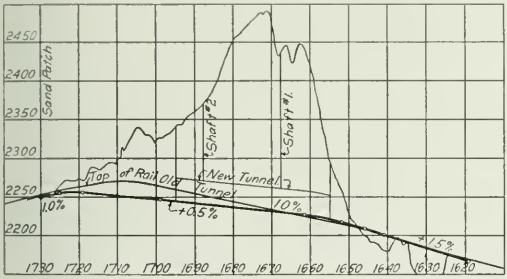
K. J

THE SAND PATCH TUNNEL IMPROVEMENTS.

Additional Facilities Just Completed by the Baltimore & Ohio in Crossing the Summit of the Allegheny Mountains.

The Baltimore & Ohio has just completed the construction of a 4,000 ft. double track tunnel alongside its present single track bore at Sand Patch, Somerset County, Pa., on the Connellsville division. This is an interesting piece of heavy railroad tunnel construction and rock excavation which was complicated by two unusual and disastrous slides, involving 200,000 cu. yds. of solid rock, and the resulting cave-in and tie-up of the existing tunnel, adjacent to the new work.

Sand Patch is located on the main line of the Baltimore & Ohio, from Cumberland, Md., via Pittsburgh to Chicago, at the summit of the Allegheny mountains, at elevation 2,273. It is 23 miles west of Cumberland and 117 miles east of Pittsburgh. The situation at this summit was an especially difficult one from an



Profiles of New and Old Tunnels.

operating standpoint, owing not only to the long and heavy approach grades of 1.5 per cent. from the east and 1 per cent from the west, but more particularly to the old Sand Patch tunnel, located on the steep east approach, which in addition to being on a 1.0 per cent. grade, is only built for single track, restricting the running track facilities of the division from double track.

The old tunnel is 4,777 ft. long, on a tangent, and is located with its west portal 700 ft. east of the actual summit. It was completed in 1871, after an interrupted period of construction of 17 years, during eight years of which work was actually under way. Although constructed for single track, provision was made wherever permanent stone lining was installed, for a future second track, the arch being placed on a bench at the springing line. Dry ashlar masonry was used for lining; this was, however, used only in a relatively few places, where the original builders thought necessary. Owing to the treacherous character of the rock it has since been necessary to timber all the unlined parts, except one section of 100 ft. and to under-timber the stone lined portion as well, thus reducing the overhead clearance to 16 ft. above the rail. Four shafts were built at irregular intervals along the old tunnel; of these one is closed, and the other three provide the only means of artificial ventilation.

The train movements through this tunnel were very numerous, comprising an average of 57 trains per day—16 passenger, 8 fast freight and 35 tonnage freight—as well as numerous switching and pusher movements. This heavy traffic had resulted in considerable congestion, with the incidental delays to trains and train crew over-time. Indeed, so congested had the traffic been that at times for an entire day the tunnel was used to its maximum capacity.

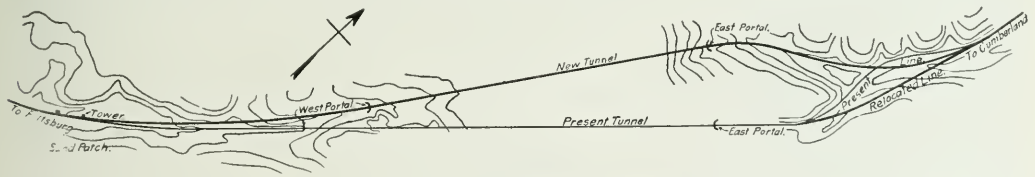
In the face of these conditions—the adverse grades, the single track, poorly lined and poorly ventilated tunnel, and the magnitude and nature of the traffic—the operating difficulties were obvious. They had their most pronounced effect on tonnage freights, which require two pushers both east and west bound. One of the westbound pushers was forced to cut off at the east end on account of the sulphur fumes in tunnel, while the other had to work up the grade through the tunnel using forced draft for the entire length. Both eastbound pushers cut off at the summit at the west end. Aside from the congestion and the resulting costly operation, there was the element of inconvenience in operating through the tunnel due to scant clearance and poor ventilation. Added to this, trainmen have been overcome by the gases, so that, in short, the old tunnel presented a most disagreeable and burdensome feature from every aspect.

PROPOSED LAYOUT.

Studies and investigations to improve these conditions have been carried on for the last ten years, covering a variety of propositions, including a long low-grade cut-off line, and a low-grade line involving a three-mile tunnel. They culminated in the spring of 1911, in the adoption of a plan providing for the construction of a new double-track line 11,000 ft. long, on the north side of the present tracks.

The proposed new line and its relation to the present one is shown in the plan and profile. It will be noted that the new line involves the construction of a 4,000 ft. tunnel just north of, and making an acute angle with, the present line; an east approach cut of 75,000 cu. yds., and a west approach cut of 425,000 cu. yds. The scheme also provides for a revised alinement of the old line east of the tunnel for 2,600 ft., and on the west for a 200-car capacity set-out yard with wye connections for eastbound tonnage trains.

According to the original figures the quantities involved were 130,000 cu. yds. of rock excavation in tunnel; 500,000 cu. yds.



Alinement of New and Old Tunnels.

of rock excavation in cuts, and 27,000 cu. yds. of concrete in tunnel lining and culverts. The item of rock excavation in cuts was, however, increased to 700,000 cu. yds through two successive landslides in the west approach cut, which will be described later.

The maximum grade on the new line is 1.5 per cent. on the east approach to the new tunnel; the same as the existing maximum grade. Through the new tunnel, however, the grade is 0.5 per cent., the ruling road engine grade on the division which will eliminate all pusher service through the tunnel. Because of its short length, the new line will not permit of an increase in the loading of tonnage trains on the division; in fact, the line was not designed, even as a connecting link, to

View of Slide of July 9 from Above West Portal.

View of Slide on August 15, Showing Shaft in Center Above Old Tunnel.

afford permanent relief from the adverse grades in this territory; but, its purpose is primarily to relieve the congested and restricted conditions through the old tunnel.

Outside the limits of the improvement the operating methods on the division will remain practically unchanged, except as to the return trips of the pushers and the loading of eastbound trains. Within the changed district, the contemplated scheme of operation proposes the use of the two new tunnel tracks for westbound traffic only. The old tunnel, after being enlarged and relined, is to be used for all eastbound trains, its grades in this direction being favorable to the traffic.

East and westbound trains will have their tonnage increased somewhat by the use of heavier pushers. Eastbound pushers will cut off at the west end and lighten the trains for safe operation down the long and steep east slope, placing the surplus cars on the eastbound set-out tracks previously mentioned. Westbound pushers will cut off at the east end of the tunnel. When necessary they will bring along extra crews, run light to the west end, pick up the cars on the set out tracks and haul them eastward. Otherwise westbound pushers will back up as heretofore. In this manner the actual pusher mileage will be somewhat reduced, a considerable light return pusher mileage will be eliminated, and above all, a very large amount of overtime of all engine crews will be saved by the facilitated operation.

General View of Concrete Mixing Plant at East Portal.

VERTICAL SHAFTS.

In the spring of 1911 the contract for the work was let, and about May 1 the work was actively begun. One steam shovel outfit with drills, etc., was placed in the east approach cut. While the approach excavation to the tunnel portals was in progress, two vertical shafts, 12 ft. x 22 ft. in size, No. 1, 200 ft. deep and No. 2, 133 ft. deep, were sunk transversely at points 1,300 and 3,300 ft. from the east portal. As little water was encountered, they presented no unusual features. Table 1 shows the rate of progress attained in sinking these shafts.

TABLE 1.

Shaft. Depth.	Yardage.	Period of construction.	Lineal feet of progress per day.	Yardage removed per day.
No. 1, East ...200 ft.	2,904	68 days	2.96	43
No. 2, West ..133 ft.	1,931	52 days	2.56	37

At both shafts a layer of loose earth and soil about 14 ft. in depth was found, from which point to the bottom red sandstone shale prevailed. The loose earth made it necessary to timber the shaft for a depth of 25 ft; below this point timbering was not resorted to, because of the solidity of the rock formation. The timbering consisted of horizontal 10 in. x 10 in. walers placed six ft. center to center; 2 in. x 6 in. lagging, and two intermediate 10 in. x 10 in. struts spaced equally, dividing the shaft into three compartments. While the shafts were provided primarily to expedite the excavation of the tunnel, it is the purpose to use them for ventilation as well. To make them permanently suitable for this, it is proposed to line them throughout with concrete, and carry them above ground level.

HEADINGS.

From the foot of each shaft, headings 9 ft. x 16 ft. in size were immediately started in both directions. The two from the east shaft, driven as top headings, were placed so that their base was at the elevation of the wall plate, the roof being nearly at the elevation of the future roof of the completed tunnel.

From the west shaft the procedure was somewhat different. The west heading was driven as a bottom heading, the floor being on the proposed sub-grade line of the completed tunnel; the east heading from this shaft was started in the same way. This was somewhat in the nature of an experiment for this class of rock, the contractor's idea being that the subsequent excavation work within tunnel sections would be more easily performed by blasting the material from above and dropping it down into the heading and then loading, by which method he was counting on no timber. After the west shaft headings had been driven a distance of 700 ft. it was found that this bottom heading plan was inadvisable, as the rock was not self-supporting and required timbering throughout. The east heading was then continued on an upward grade of 5 per cent. until its base was at the wall plate grade, when it was driven in the same manner as the east shaft headings. The west heading from the west shaft was redriven as a top heading.

By the middle of August, 1911, the excavation of the east approach cut was sufficiently low to permit the driving of a top heading toward the east shaft, which made the fifth heading to be worked, shown in Table 2 as No. 1 heading, east portal.

The excavation of the material in the first headings was carried on by the usual method of column drilling and shooting; the muck was loaded by hand into narrow gage 2-yd. end dump

Oliver cars, hauled to the shafts by mules, elevated to the surface, and wasted on the sides of the mountain. The progress made in this work is briefly given in the following table.

TABLE 2.

Heading from	Length in lin. ft.	Yardage.	Days worked 2 shifts.	Average daily progress. Lin. ft.	Yardage.
No. 1, East portal	700	3,743	75	9.33	49.92
No. 2, Shaft No. 1—East.	594	3,100	81	7.33	38.27
No. 3, Shaft No. 1—West.	979	5,200	113.5	8.63	45.81
No. 4, Shaft No. 2—East.	1,009	5,800	132.5	7.62	43.77
No. 5, Shaft No. 2—West.	694	4,000	106.5	6.52	37.56

The second heading, embracing the enlargement to complete tunnel section of the walls and roof of the first heading, followed closely after the first. The material was handled as that from the first heading.

TIMBER.

The material penetrated by the tunnel is red sand stone shale, the strata of which dips northward rather uniformly at an angle of from 15 deg. to 20 deg. with the horizon and almost directly toward the new tunnel center line. In many places the rock is very solid and stable; in others it is rendered treacherous by transverse and almost vertical seams normal to the dipping plane and approximately parallel with the new tunnel center line.

Under these conditions, and after the change from the bottom to the top heading plan, the contractor decided to timber the tunnel throughout. This proceeded as rapidly as the widening out of the second heading permitted, the average weekly progress being 40 lin. ft. The timberings were spaced on 5-ft. centers and consisted of seven segments of 12 in. x 12 in. timbers sup-

Inside of New Tunnel Showing Brick Facing Over Crown of Arch.

[illegible] 12 in. x 12 in. wall plate. Two inch lagging was [illegible] over the timbers, and the space above this to the limits [illegible] was carefully dry-packed.

BENCH.

[illegible] was broken by simultaneously shooting four vertical [illegible] deep, spaced 10 ft. apart, drilled in transverse rows on 14 [illegible] centers. The outer holes were kept 3 ft. from the wall plate. The [illegible], except in several instances, broke the rock [illegible] complete rock excavation lines without injuring [illegible] plate. From the east portal to shaft No. 2, a distance [illegible] loosened material was loaded from March 1 to June 1, 1912, into narrow gage dump cars by an air-operated Model 40 Marion shovel, which was replaced June 1 by a Model 60 Marion shovel with a special short boom. The cars were hauled to and from the east dump in trains of ten, by 18 ton Porter dinkeys. The dump cars were snatched singly to and from the working face at the shovel by an air hoist and cable. Siding facilities on the dinkey track enabled the switching of these single cars from an empty to a loaded track.

It was originally intended to work a second Model 60 shovel from the west portal eastwardly, but the work in the west approach cut was delayed to such an extent that this proved impracticable. In August, 1912, a Model 40 Marion shovel was brought in dismantled from the west portal through the enlarged

Old Tunnel After Removal of Cave In.

heading, erected at shaft No. 2, and started toward the west portal loading the bench, to expedite this work. The material loaded by this shovel was hauled to shaft No. 2, elevated to the surface and wasted on the mountain side.

The following statement gives the average progress made by each of these shovels, the time worked and the yardage removed.

TABLE 3.

Shovel.	Number of shifts worked (10 hours).	Average progress per shift. Lin. ft.	Yardage.	Maximum progress one shift. Lin. ft.	Yardage.
Model 40.....	107	9.5	109	14	280 cu. yds.
Model 60.....	220	11.0	220	21	420 cu. yds.
*Model 40....	43	14.0	168	20	240 cu. yds.

*Note: Yardage per foot of Model 40 shovel was reduced on account of bottom heading, 40 per cent. of the material being previously removed.

The figures are not comparative, not only because of the different powered shovels, but because of the different methods employed by each in transporting the muck to the dump. Attention is, however, called to the good, general average attained by the Model 60 shovel, which is considerably higher than the usual, and believed to be a record for this class of work.

A trimming gang followed closely after the shovel. It trimmed the falls to proper section where necessary with jap drills, and reinforced the wall plate by plumb posts wherever it was loosened by the shovel operations.

TUNNEL LINING AND PORTALS.

After considering the various advantages and disadvantages of the common types of lining, all brick, all concrete, and con-

crete side-walls with brick arch, a somewhat novel design was adopted. It called for a monolithic concrete structure throughout, with a single row of brick inlaid in the arch between the 25 deg. lines, as shown in an accompanying photograph. Each fourth row of brick are laid as headers, to more thoroughly bind the brick to the concrete.

It is considered that this design provides the economy and other advantages due to a monolithic and completely filled structure of concrete over brick, and at the same time eliminates the objection against the former, in that the row of brick will prevent the otherwise rapid disintegration of the concrete from the locomotive gases and blast. Attention is called to the fact that provision is made for a concrete ditch on one side, for two 4-way

The Completed East Portal.

ducts for electric power and telegraph lines, for cable boxes for electrical apparatus, and for the usual refuge niches. In the design of the portals, a massive structure, and one not lacking in architectural treatment, was sought.

CONCRETE PLANT.

To handle, mix and place the materials embraced by the 27,000 cu. yds. of concrete in the tunnel lining required an extensive concrete plant. This it was decided to concentrate at the east end, because of the advanced stage at which the work at that point was maintained. The plant as built along the standard gage delivery tracks on the north side of the east approach cut is shown in one of the photographs. It embraces essentially a set of sand, stone and gravel storage bins, a hoist and cable with elevating trestle for hauling this material to supply bins over the mixing platform and two steam-driven one yard Smith mixers, with the usual provision for cement storage and water supply.

The three storage bins are located about 700 ft. east of the mixing plant, at the foot of the 1:1 slope from the delivery track. Their floor level is from 12 to 16 ft. below rail. They are of wood, having a capacity of approximately 1,500 cu. yds. each, and are supported by posts over a narrow gage track by which the materials are hauled to the mixer, hopper doors in the floor being provided to load the cars. The material coming in standard gage cars is cast down a slope by hand into the binds or placed by a locomotive crane. This method was made necessary by the lack of vertical headroom at any convenient site.

From these storage bins the material was hauled in single 4-yard ordinary dump cars up an incline to the mixer, by cable and steam hoist, where it was dumped into the supply bins, each of which had a capacity of 110 cu. yds. From the supply bins the aggregates were delivered by gravity chutes to the hoppers above the two mixers. The bins were so arranged—the middle one holding sand—that one mixer furnished gravel concrete and the other stone concrete. The cement was wheeled to the hoppers from the adjacent cement house located along the delivery siding on the same level with the mixing platform, while the water was drawn from a 3,000 gal. tank above the bins, to which it was pumped from a nearby stream.

The concrete specified was gravel or stone to the springing line, and stone in the arch. In either case the mixture required was 1:3:5.

FORMS.

Blaw collapsible steel forms were used, which were mounted on wheels running on a rail laid on top of footings previously constructed. The working platform and dumping aprons were placed at the brick line 16 ft. above sub-grade, which permitted of a rapid and efficient method of handling and placing the concrete. A wooden frame incline approach on a 13 per cent. grade, mounted on narrow gage trucks, provided means of elevating concrete materials to the working platform.

The concrete was hauled from the mixer to the foot of the incline in steel Koppel dump cars by Porter dinkey engines; here the cars were cut loose and were hauled up the incline onto the working platform by an air hoist and cable, where they were dumped. In the side walls up to the end of the steel lagging at the brick line, the concrete was passed down the sloping aprons by hand. Between the limits of the brick lines wooden lagging was used on the forms and placed as the work progressed. The brick and concrete work was carried up simultaneously, the brick being placed in one bay, while concrete was

Big Slide at West Portal.

being placed in another. In this manner, the arch was built up from both sides until a 5 ft. key remained to be put in at the crown. This key was placed longitudinally from one end of the form to the other on transverse lagging cut to fit the 5 ft. opening, the lagging being inserted progressively as the arch was sealed.

Three sets of these forms in units 40 ft. long and one incline were installed in June, 1912, and the concreting was begun by July 1. The program by which it was carried out was as follows: Starting with all three forms in place with the incline at form No. 1, the sidewalls and arch were finished at this form in about 3½ shifts; the incline and hoist were quickly moved to form No. 2; where the concreting was immediately begun and

completed in the same time, No. 1 form being allowed to set; upon finishing at form No. 2 the incline and hoist were moved ahead to form No. 3 and concreting begun there. While this was going on, Form No. 1 was moved ahead and again worked upon the completion of No. 3. In this manner work was carried on continuously, and each arch was given 48 hours in which to set.

On October 1, 1912, a fourth set of forms and two additional inclines were installed to hurry the completion of the work. Up until that time 2,000 ft. of finished lining had been placed with the three forms, an average daily progress with two shifts of 21 ft. having been attained. With the four sets of forms working, this average daily progress was increased to 40 ft.

For the sake of economy in excavation, the north side of the west approach cut was planned on a slope of ⅛:1, this being specially favorable from the fact that the strata dips into the hill on that side. The depth of the cut and the broken nature of the rock made a solid face for this slope very essential. Accordingly, the steam shovel excavation was kept about 8 ft. from the final face of the cut, and this 8 ft. ledge was removed by a Sullivan channeling machine and two sets of quarry bars, holes being driven on 9 in. centers. These were set up along a bench and put to work at the final slope line. As only light charges of dynamite were required to loosen this intervening ledge, the rock wall was disturbed very little.

SLIDES IN WEST APPROACH CUT AND CAVE-IN OF OLD TUNNEL.

For a distance of 800 ft. west of the new west portal the new cut, 90 ft. deep on the center line, is separated from the old tunnel by a ledge of rock tapering in width from 185 ft. at the east end to 75 ft. at the west end. This proximity of the old tunnel, combined with the stratification of the rock in this ledge, which dipped at an angle of from 15 to 20 deg. from the old tunnel directly toward the new cut, produced a situation which was, of course, the subject of much thought and speculation. Accordingly, great precautions were taken in regulating the blasting and other work in this district to avoid any possible interference with traffic through the old tunnel.

It was originally proposed to take out the south side of this cut on a ½:1 slope up to the earth line, then provide a 15 ft. berm and continue on a 1½:1 slope. On this basis the cut had been excavated to within 20 ft. of the proposed sub-grade, when, on March 15, 1912, 80,000 cu. yds. of rock broke away and slid into the cut, burying one steam shovel. The break took place along a seam inclined slightly from the vertical into the hill, and left a projecting face whose maximum depth was 28 ft. The break extends over a distance of about 350 ft., and filled the new cut to a maximum depth of 30 ft. The seam occurred north of the old tunnel, fortunately leaving it intact.

By the end of June, the fall of material had been excavated and the cut practically restored to its former level, the south side having been flattened to a 1¼:1 slope. On July 6 a new movement of the south slope was detected, this time extending east 400 ft. from a point directly over the old portal. New openings continued to appear up into the hill, the extreme breakage being 50 ft. beyond the old tunnel. At the same time some of the arch stones in the old portal showed signs of strain and at noon of July 9, a spall broke off just at the south springing line.

In the face of these conditions, the shovels in the danger zone were pulled back and a very thorough watch was maintained. At 6:05 p. m. of July 9, three days after the first cracks appeared, the hillside gave way, and in sliding cut a void in the old tunnel roof completely filling the old tunnel for a distance of 71 ft. and again partly filling up the west approach cut. The west end of the break within the tunnel occurred about 180 ft. east of the west portal, the intervening portion remaining solid—a very fortunate result, as the breaks indicated trouble would come just where it did not.

Arrangements were immediately made to divert all traffic over the newly completed line of the Western Maryland between Sand Patch, Pa., and Cumberland, Md., a distance of 32 miles. At the same time, it was at once apparent that the only safe and certain method of reopening the old tunnel involved the removal of as much of the overlying hillside as had any effect on the moving portion—a matter of months rather than days.

Accordingly, it was immediately arranged to install all the necessary plant and men. In less than 24 hours, 1,000 men were working continuously, grading and laying a standard gage track up the hill, constructing several narrow gage tracks to nearby dumping grounds, and installing all the available plant. In another day a Model 60 Marion shovel started digging on the side hill, while the following day saw two more Model 60 shovels at work on the overlying material. Thereafter, as rapidly as they could be assembled and shipped, additional steam shovel plants were installed until by July 28 there were three Model 60, one Model 75, one Model 120, one Model 70 and two Model 20 shovels. The five first mentioned were put to work digging away the hillside, the sixth was started casting in the new cut below, because of no available loading track at that point, and the two 20's were held in readiness to enter the tunnel and load the fallen debris.

The plan for reopening the old tunnel that was adopted called for the removal of all material overlying a bench 16 ft. above

View Showing Steel Forms at East Portal and Incline for Bringing in Concrete.

the crown of the old tunnel arch, and the subsequent sinking of a shaft from this bench to the tunnel sub-grade to excavate the fallen material. By August 10, 75,000 cu. yds. of solid rock had been removed and enough of the bench exposed to start the shaft over the cave-in. This shaft was made 110 ft. long and 30 ft. broad. Two stiff-leg derricks with hoists, rigged up 75 ft. apart on the north side, handled the material, loaded by hand into scale boxes, from the pit to dump cars on an adjoining track. In ten days this shaft had been excavated and timbered to the crown of the old tunnel arch, and daylight was let in at both ends of the break. At this juncture the two light model 20 shovels were put in the old tunnel—one at each end—and started loading the fallen debris, hand loading being continued as well where there was no interference.

The ensuing week saw the tunnel cleared of all fallen material, additional timbering put in, and the track relaid and resurfaced, so that at noon, on August 29—after a tie-up of 50 days—the old tunnel was reopened for traffic.

During the construction of the shaft and after its completion, the excavation of the side-hill was continued until the bench

previously mentioned extended from the west portal eastwardly about 300 ft. beyond the east end of the break. It was carried south into the hill for about 50 ft. to prevent any possible future trouble from that slope, which was finished on a 2:1 basis. The limited working area caused considerable interference with the five shovels, but in spite of this, and some extremely poor weather, 120,000 cu. yds. of rock, most of which had to be shot, had been removed by the time the tunnel was opened. As a result of these slides, and to prevent similar trouble in the east end of the west approach cut, the new tunnel has been extended 200 ft. westwardly from the originally planned west portal, building the tunnel arch in the cut and backfilling over it.

CONTRACTOR'S POWER PLANT.

The contractor's power plant, central supply house and main machine shop was located at the west end of the west approach cut, where convenient access through a delivery siding could be had from the adjacent main line of the Baltimore & Ohio. The boiler house embraced four 100 h. p. Ames locomotive type boilers by which steam was supplied to the compressors and electric generator. The compressed air for the drills, hoists and shovels in the tunnel was furnished by two straight line, two stage Ingersoll-Rand compressors, which supplied 1,750 cu. ft. of free air per minute, at a pressure of 120 lbs. per sq. in. at the power house. The air line consisted of two lines of 6 in. wrought iron pipe, and extended over the mountains to the east end, a total distance of 6,000 ft.

The electric generator supplied current to the contractor's line at 550 volts, which was stepped down by a transformer on top of the mountain to 220 volts, in which shape it was used in the tunnel for lighting purposes, clusters of five lights in series being employed.

The work was planned and constructed under the supervision of Francis Lee Stuart, chief engineer of the Baltimore & Ohio, and was in charge of Paul Didier, principal assistant engineer. Its execution was under the direct supervision of A. D. P. Janney, resident engineer on the ground. H. S. Kerbaugh, Inc., of Philadelphia and New York, was the general contractor, with R. C. Hunt and A. H. MacLennan construction superintendents.

A FULL CREW LAW IN NEW YORK.

The legislature of New York passed last week, by large majorities, a bill to require three brakemen on all freight trains of 25 cars or more; and as regards both passenger trains and freight, the bill specifically mentions firemen; so that on the multiple-unit electric trains of the New York Central and the Long Island roads, an extra man will have to be employed as "fireman," although no fireman is needed on such trains. Governor Sulzer gave a hearing on the bill at Albany on Saturday last, and the presidents of the principal roads of the state appeared before him and presented arguments in detail against the passage of the bill; but he signed it nevertheless.

The arguments presented by the presidents had been summarized in a letter to the governor, which they had published as an advertisement in the principal newspapers on Saturday morning. This letter was in substance the same as that which Mr. Rea and other presidents had sent to the governor a week before, and which was reported in the *Railway Age Gazette* of March 21, page 685. The appeal to the public was displayed in the principal newspapers to the extent of a half page in each. Ia was signed by the presidents of the Pennsylvania Railroad, the New York Central, the New York, New Haven & Hartford, the Delaware, Lackawanna & Western, the Lehigh Valley, the Long Island Railroad and the Delaware & Hudson.

On Monday the presidents issued another advertisement, appealing to the public, and reprinting another letter which had been sent to the governor asking him to veto the bill, the fact of his signing it having at that time not been announced. In this second letter the railroads agreed to comply with any orders which the public service commissions might make in respect to the number of men required on trains, and they also offered to co-operate in securing the passage of a law giving the public service commissions full authority if anybody thought that such authority did not already exist.

The advertisement also contained letters from President Willard of the Baltimore & Ohio; President Thomas of the Nashville, Chattanooga & St. Louis; President Miller of the Chicago, Burlington & Quincy, and Vice-president Wood of the Pennsylvania lines west of Pittsburgh, telling of their experience under full crew laws. Both the house and the senate of the legislature of Tennessee have rejected a full crew bill. The statement had been made that full crew laws had been of benefit in the few states where such laws have been in force. Mr. Miller and others denied this.

On Tuesday another half-page advertisement appeared. It was known at that time that Governor Sulzer had signed the law in New York, but in New Jersey it was still unknown what action the governor would take. In this advertisement Mr. Hughart, general manager of the Grand Rapids & Indiana, Mr. Mohler, president of the Union Pacific and Mr. Bush, president of the Missouri Pacific were quoted. Mr. Mohler said that full crew bills had recently been defeated in Kansas, Nebraska, Colorado, Wyoming and Utah, it having been seen that such a law would produce an additional tax on the people, and on the railroads, without one scintilla of benefit. Mr. Bush reported a similar result in Texas.

The railroads also reprinted a letter sent to Governor Sulzer on March 29, by John B. Olmsted, formerly a member of the New York Public Service Commission, telling the governor that the commission had had two applications before it for orders requiring additional brakemen on trains; and that in one case the order had been issued, while in the other the request was denied. If the number of brakemen could be settled by the legislature, why, asked Mr. Olmsted, should not the legislature also with equal reason require a flagman at every grade crossing? Such a measure would greatly promote the safety of the public and of railway employees, but it would entail an enormous expense. Such far reaching questions should be dealt with by the public service commission, which could handle them with due deliberation and intelligence.

The railroads were not the only interests which appeared before the governor to oppose the bill. The State Grange, the State Agricultural Society and other important interests presented arguments. President E. B. Thomas, of the Lehigh Valley, presented at the hearing a petition, signed by fifty conductors of that road, declaring an extra trainman to be unnecessary. President W. C. Brown, of the New York Central, said that enginemen and conductors generally were opposed to the bill. President Peters, of the Long Island, called attention to the fact that the bill would compel his road to employ firemen on electric locomotives.

The governor in giving his approval to the bill sent also a memorandum in which he declared that a similar bill had been adopted with good results in other states.

The law provides that a freight train of more than 25 cars, running outside of yard limits, and on railroads more than fifty miles in length, must be manned with a crew of not less than one engineer, one fireman, one conductor and three brakemen; any train of five cars or more, other than a freight train, must have one engineer, one fireman, one conductor and two brakemen; and, if it is a passenger or baggage train, it must have a baggageman in addition to the crew; any freight train of twenty-five cars or less must have one engineer, one fireman, one conductor and two brakemen; and any light engine must have not less than one engineer, one fireman and one conductor or brakeman.

RAILWAYS AND AGRICULTURE COMPARED.*

Carriers' Outputs Increased Much More in Proportion to Facilities than Farmers', and Farm Prices Rose While Rates Stood.

The present study is a comparison of the increases in the plant and output of agriculture with the increases in the plant and the output of the railways. Bushels and bales are so different from ton-miles and passenger-miles that there cannot be any direct comparison between them, but it is fair to compare in a general way the respective ratios of increase. That is, if during an extended period the ton-miles and the passenger-miles per mile of main track have increased at a substantially greater ratio than have the bushels per acre or the bales per acre of a particular crop, it is fair to say that the railways have made greater progress in efficiency than has agriculture as measured by that particular crop. Then, again, it is perhaps true that an acre of even the most fertile soil does not have an elasticity of production comparable with the range of traffic that can be moved over a mile of railway. The practice of European agriculture, however, demonstrates a vastly greater productivity per acre than has been obtained in the United States. Therefore the present comparison of the increase in productivity is well within the limits of practicable achievement.

In the railway industry so large an initial investment in fixed plant is required in order to operate at all, that for a considerable time after being opened for traffic the plant is likely not to be fully utilized, and hence additional applications of labor and equipment are rewarded by a more than proportionate increase in output. In other words, efficiency tends steadily to increase up to the time that the plant is completely utilized. No such large initial investment is required in agriculture, and the point is more quickly reached where there is even a less than proportionate reward for each new application of capital and labor. That the point of diminishing return has been reached in the case of many railways is undoubtedly true.

It is frequently asserted that the farmer suffers from the disadvantage that the quantity of land is fixed, and that he cannot increase it at will. This impression, only in part true, probably arises from the fact that the governmental policy of free land is practically at an end, and that if the farmer wants more land, he must, as does the railway when it extends its lines, invest more capital. There is still opportunity open to the farmer to extend his productive area.

But efforts to develop efficiency meet hampering restrictions not alone in agriculture. Agriculture is not subject to such public regulation as the railways, and in the railway field much in the way of unproductive or relatively unproductive investment is demanded in the public interest. These investments, being to a considerable degree beyond the control of the railway, may hamper that development of physical plant which is best fitted to handle traffic efficiently. Again the output of the agricultural plant, eliminating natural forces, is within the control of the farmer; within a practicable limit he can produce as much or as little as he chooses, and hence the responsibility for a large or a small product per acre within this limit is his alone. The railway, on the other hand, performs a *service*, is, therefore, dependent upon patronage for its output, and hence its output is not under its sole control. The fact that it is a service which the public are obliged to use modifies the force of this contention, but does not remove the fact that the intensiveness of traffic depends largely upon the volume of traffic offered.

These fundamental differences in the character of the agricultural and railway industries would seem on first thought to destroy the value of any comparison of their efficiency. But it must be remembered, as has been said, that the two industries are not being compared directly with each other; rather the *increase in the efficiency* of each is being compared over a series of years. The record for efficiency of each industry is compared at one period with its record at another. Account is taken of the degree in which the plant of agriculture and the plant of the railways have been extended, of the aggregate increases in output of the increases in output per unit of plant, of increases in value in relation to output, and of the relation that extensions of plant and increases in output bear to the growth of population.

COMPARISON OF PLANTS.

The physical plant of the railways of the United States comprised 206,631 miles of main track in 1900. By 1910 this had grown to 266,185 miles, an increase of 59,554 miles, or 28.8 per cent.

Improved land in the farms of the United States amounted to 414,498,000 acres in 1900 and 478,451,000 acres in 1910, an increase of 63,953,000 acres between 1900 and 1910, or 15.4 per cent.

It is evident that the railway plant has increased at nearly double the rate of the agricultural plant. Additional light is obtained by showing the rates of increase separately for the three principal districts of the United States—Eastern, Southern, and Western.[a]

INCREASE IN RAILWAY TRACK MILEAGE AND IN IMPROVED FARM LAND EASTERN, SOUTHERN, AND WESTERN DISTRICTS.

Item.	1900.	1910.	Increase, 1900-1910. Amount.	Per cent.
Eastern district:				
Railway main track...	64,537	75,129	10,592	16.4
Improved farm land..	90,921,000	89,641,000	*d*1,280,000	*d*1.4
Southern district:				
Railway main track...	33,117	43,694	10,577	31.9
Improved farm land..	82,061,000	88,353,000	6,292,000	7.7
Western district:				
Railway main track...	108,977	147,362	38,385	35.2
Improved farm land..	241,516,000	300,458,000	58,942,000	24.4

d Decrease.

COMPARISON OF AGGREGATE OUTPUT.

Railway output in the United States in 1900 and 1910, expressed in terms of ton-miles and passenger-miles, was as follows:

	Output in— 1900.	1910.	Per cent. of increase 1900-1910.
Ton-miles	141,596,551,000	255,016,910,000	80.1
Passenger-miles	16,038,076,000	32,338,496,000	101.6

The immediate comparison in the case of agriculture will be concerned with the ten principal crops, those which enter into universal use and consumption and constitute over 80 per cent. of the value of all crops—corn, wheat, oats, barley, rye, buckwheat, potatoes, hay and forage, tobacco, and cotton. The area devoted to these ten crops in 1900 aggregated 274,380,000 acres, while in 1910 it was 297,865,000 acres. This area of the ten crops, representing over four-fifths of the total crop area of the United States both in 1900 and 1910, increased 23,485,000 acres during the decade, or 8.6 per cent.

The increases in the respective crops are shown by the following table:

	Production in 1900.	1910.	Per cent. of increase, 1900-1910.
Corn (bushels)	2,666,334,000	2,552,190,000	*d* 4.3
Wheat (bushels)	658,534,000	683,379,000	3.8
Oats (bushels)	943,389,000	1,007,143,000	6.8

a The Eastern district comprises the New England States, New York, New Jersey, Pennsylvania, Delaware, Maryland, the District of Columbia, Ohio, Indiana and Michigan. The Southern district includes all the States south of the Potomac and Ohio and east of the Mississippi rivers. The Western district comprises the States of Illinois and Wisconsin, and all States west of the Mississippi. As regards railway operation, the Eastern district corresponds very closely to combined Groups I, II and III of the territorial classification of the Interstate Commerce Commission; the Southern district to Groups IV and V combined; the Western district to Groups VI, VII, VIII, IX and X combined. The boundaries of the groups that lie along the borders of these districts do not always follow State boundaries; but the districts specified above so closely correspond to the combined groups of the Interstate Commerce Commission that there is no appreciable variation from strict comparability.

* An abstract of Bulletin No. 45, Bureau of Railway Economics, Washington, D. C.

	Production in		Per cent of increase
	1900.	1910.	1900-1910.
Barley (bushels)	119,635,000	173,344,000	44.9
Rye (bushels)	25,569,000	29,520,000	15.5
Buckwheat (bushels)	11,234,000	14,849,000	32.2
Potatoes (bushels)	273,318,000	389,195,000	42.4
Hay and forage (tons)	79,252,000	97,454,000	23.0
Tobacco (pounds)	868,113,000	1,055,765,000	21.6
Cotton (bales)	9,535,000	10,649,000	11.7

d Decrease.

The rate of increase in gross railway output, between 1900 and 1910, is shown to be from 80 to 100 per cent. The increase in the output of the ten crops combined, each crop being assigned a weight proportionate to its acreage, was about nine per cent.

COMPARISON OF OUTPUT PER UNIT OF PLANT.

Agriculture is affected directly and railway operation indirectly by climatic changes, seasonal variations, and calamities of one kind or another—factors that can neither be anticipated nor controlled. The pushing of agriculture into new fields may for a time increase output per unit, while the extension of railway lines into new territory may temporarily decrease output per unit, yet in neither case does this influence play any necessary part in determining for the time being the actual efficiency of operation. With this condition clearly in mind, it will be interesting to compare the output of agriculture and railways per unit of plant.

RAILWAY OUTPUT PER MILE.

	Output per mile of main track in—		Per cent. of increase
	1900.	1910.	1900-1910.
Ton-miles	685,263	958,044	39.8
Passenger-miles	77,617	121,489	56.5

OUTPUT PER ACRE.

	1900.	1910.	Per cent. of increase, 1900-1910.
Corn (bushels)	28.1	25.9	*d* 7.8
Wheat (bushels)	12.5	15.4	23.2
Oats (bushels)	31.9	28.6	*d*10.3
Barley (bushels)	26.8	22.5	*d*16.0
Rye (bushels)	12.4	13.4	8.0
Buckwheat (bushels)	13.9	16.9	21.5
Potatoes (bushels)	93.0	106.1	14.1
Hay and forage (tons)	1.285	1.345	4.7
Tobacco (pounds)	788.1	815.3	3.5
Cotton (bales)	0.393	0.332	*d*15.5

d Decrease.

The rate of increase in railway efficiency from 1900 to 1910, measured by the increase in traffic per mile of main track, is shown to be 39.8 per cent. in respect to ton-miles and 56.5 per cent. in respect to passenger-miles—that is, the increased efficiency of railway operation as a whole was not less than 40 per cent. for the decade. When each crop is given a weight proportionate to its acreage, it will be found that the average of the increases and decreases in the output per acre for the ten crops combined shows a decrease of about one per cent. None of the ten crops shows as great an increase in output per acre as 40 per cent., while the output per acre of four of the ten crops decreased. Without exception the increase in railway efficiency between 1900 and 1910, as measured by increased output per mile, seems to have been greater than the increase in the efficiency in the production of the ten crops. Four of the crops decreased in output per acre, indicating not only that there was no gain in efficiency of production, but probably an actual loss.

COMPARISON BY GEOGRAPHICAL DISTRICTS.

That the same general conclusion is applicable to each of the three great geographical districts of the United States—Eastern, Southern, and Western—is made clear by the comparison given below.

In the Eastern district the gain in railway efficiency ranged above 40 per cent. The efficiency of production of the eight crops, which were raised in sufficient quantities in the Eastern district to warrant comparison with the railways of that district, without exception increased at a lower rate than the 40 per cent. of the railways.

d Decrease.

For the Southern district comparison is made between railways and the three principal crops of that district—cotton, tobacco, and corn. Railway efficiency as a whole increased something more than 50 per cent. The corn and tobacco crops show small increases in efficiency measured by production per acre—less than 10 per cent.—while the cotton crop shows a slight decrease in per-acre production, indicating no gain in efficiency of cultivation and handling.

Comparison is offered for the Western district between the railways and eight crops. Railway efficiency as a whole may conservatively be said to have gained more than 45 per cent. Of the four crops showing increased efficiency, no one has as high a rate of increase as this in output per acre, and four crops show decreases in output per acre.

The general conclusion warranted when the importance of each crop is considered in connection with its relative increase in acreage and output, is that the crop production of the United States increased at no greater rate from 1900 to 1910 than did the crop area. The same fact is presented from a different angle by the Census Bureau in the statement that there was practically no difference in the average quantity of crops produced per acre in 1900 and 1910. In contrast is the record of the railways, in which the increase of 28.8 per cent. in miles of main track was far less than the increases of 80.1 per cent. in ton-miles and 101.6 per cent. in passenger-miles; that is, the average output per mile of main track in 1910 was considerably greater than in 1900.

That the efforts put forth by the farmers of the United States during the past decade have only barely maintained the production of crops at the same level, without leading to any appreciable increase in efficiency of production, is the opinion expressed by John L. Coulter, in the article cited in the introduction. He says:

> It is true that the *hope* has been, and I believe I may say that the *belief* has been, that agriculture was increasing rapidly, if not keeping pace with the increase of population. The people of the United States have been more than willing to supply the Department of Agriculture, state agricultural experiment stations, and a great variety of agricultural schools, colleges, and lecturers with all of the funds necessary, believing that all this pointed towards a larger production of goods as a basis for the food, beverage, and clothing supply of our people. Hundreds of millions of dollars have been expended for this purpose. It may seem that this expenditure has been in vain, since the average production of agriculture has not increased. But without it doubtless there would have been far-reaching decreases due to depreciation of the soil and failure of the farmers to maintain the average production secured when they first took charge. Though hundreds of millions of pages of literature have been distributed among farmers, only a small percentage has actually been read, and only a

small percentage of that read has been put into practice. It has taken almost all, if not all, of the education which has reached the farmers to date to prevent any downward movement in the quantity produced per acre of land actually cultivated.

CROP VALUES AND PURCHASING POWER.

In the light of this agricultural record, which shows an absence of increased efficiency in crop production, it is of interest and significance to note the extraordinary increase in agricultural prices and, in consequence, of the capital value of the agricultural industry.

According to the United States Department of Agriculture the average value of an acre's output of the ten important crops of the United States was $9.13 in 1899 and $15.51 in 1911, an increase of $6.38, or 69.9 per cent.

The details for each individual crop are as follows:

Crop.	Value of an acre's output, 1911.	Per cent. of increase over 1899.
Corn	$14.79	73.8
Wheat	10.96	50.1
Oats	10.98	38.3
Barley	18.38	70.2
Rye	12.96	105.1
Buckwheat	15.29	97.5
Potatoes	64.60	78.1
Hay	11.38	11.8
Tobacco	84.13	61.7
Cotton	20.32	52.3

Compared with the prices of things which farmers buy, the purchasing power of the crop of an average acre was greater in 1911 than in 1899 by 41.6 per cent. In other words, while there has been an increase in the market prices of such commodities as the farmer purchases in considerable quantity, the increase in the prices he receives for his crops has been so much greater that his purchasing power has been increased in considerably greater proportion. Expressing this situation in terms of the several important crops, the purchasing power of an average acre's output of corn in 1911 was 50.7 per cent. greater than in 1899; that of an average acre's output of wheat was 30.2 per cent. greater than in 1899; that of an average acre's output of cotton was 32.3 per cent. greater than in 1899.

This comparison of a farmer's purchasing ability at different periods has been carried a step further by the Department of Agriculture, to apply to specific commodities purchased and used by the farmers of the United States. While many of these commodities vary widely in grade, quality, or size, that grade or quality has in each case been selected which represents what is most generally sold to farmers, and the comparisons from year to year are always of retail prices of the same grades or qualities.

The following table shows the increase in purchasing power in 1911 over that of 1899 of the output of the average acre of corn, wheat, cotton, and of all crops, respectively, in terms of these specific commodities.

PER CENT. OF INCREASE, 1911 OVER 1899, IN THE PURCHASING POWER

Of these Commodities	By an average acre's output of— Corn.	Wheat.	Cotton.	All crops.
Coal Oil	112	83	86	99
Coffee	11	*d* 4	*d* 3	4
Flour	33	20	18	25
Lard	25	8	10	18
Salt	44	23	26	35
Sugar	37	19	20	29
Tea	63	41	43	53
Oatmeal	30	13	14	23
Calico	33	15	16	25
Men's	60	38	40	50
Men's	68	45	47	58
Shoes	57	37	38	48
Stee	70	47	49	60
H	46	26	27	37
Iro	47	28	29	38
Pa	9	*d* 7	*d* 4	4
Twine	71	48	50	61
Sewer	51	30	32	42
Ha	45	20	22	30
Wa	55	34	35	46
Wa	42	23	24	33

The 21 representative commodities entered in this table were taken from a list of 83 commodities in the report of the Department of Agriculture. Between 1899 and 1911 the purchasing power of the output of the average acre of crops increased in the case of 82 of these 83 staple commodities—that is, the price received for an average acre's crop rose at a greater rate than the price paid for these commodities. The only commodity, the price of which rose faster than the prices of agricultural products, was brooms. This increase in the purchasing power of the farmer took place in face of the fact that the prices of 79 of the 83 commodities advanced.

POWER OF AVERAGE ACRE'S CROP TO PURCHASE TRANSPORTATION.

The amount of transportation purchasable by the output of an average acre of these same crops in 1899 and 1911 is shown in the following table:

	Corn.		Wheat.		Cotton.		All crops.	
	1899.	1911.	1899.	1911.	1899.	1911.	1899.	1911.
Ton-miles	1,175	1,954	1,008	1,448	1,843	2,684	1,261	2,049
Passenger-miles	442	749	379	555	693	1,029	474	786

The percentages of increase in the amounts of transportation purchasable with the average output of an acre are as follows:

	Corn.	Wheat.	Cotton.	All crops.
Ton-miles	66.3	43.7	45.6	62.5
Passenger-miles	69.5	46.4	48.5	65.8

PURCHASING POWER OF 1,000 CROP UNITS AND 1,000 TRAFFIC UNITS.

Taking the purchasing power of the farm value in 1900 of 1,000 bushels of the crops indicated, and of 1,000 bales in the case of cotton, as 100, the relative quantities of the commodities named below purchasable at wholesale with 1,000 bushels of the same crops and 1,000 bales of cotton in 1910 are as indicated in the following table:

RELATIVE PURCHASING POWER IN 1910

Of these commodities.	By 1,000 bushels of— Corn.	Wheat.	Seven food crops.	Cotton (bales).
Farm products	120.7	114.0	100.1	129.5
Food	146.9	138.7	121.9	157.5
Cloths and clothing	156.7	147.9	130.0	168.0
Fuel and lighting	175.0	165.2	145.1	187.6
Metals and implements	170.2	160.6	141.2	182.5
Lumber and building materials	137.0	129.4	113.7	147.0
Drugs and chemicals	179.4	169.4	148.9	192.4
House-furnishing goods	172.5	162.9	143.1	185.0
Miscellaneous	149.7	141.3	124.2	160.5
All commodities	152.4	143.8	126.4	163.4
Ton-miles	175.7	165.8	145.7	188.4
Passenger-miles	187.6	177.1	155.6	201.1

Taking the purchasing power of the receipts of the railways from 1,000 ton-miles and 1,000 passenger-miles in 1900 as 100, the relative quantities of the commodities named below purchasable at wholesale with 1,000 ton-miles and 1,000 passenger-miles respectively in 1910 are as indicated in the following table:

RELATIVE PURCHASING POWER IN 1910

Of these commodities.	By the receipts from— 1,000 ton-miles. 1900.	1910.	1,000 passenger-miles. 1900.	1910.
Farm products	100	68.7	100	64.4
Food	100	83.6	100	78.3
Cloths and clothing	100	89.2	100	83.5
Fuel and lighting	100	99.6	100	93.3
Metals and implements	100	96.9	100	90.7
Lumber and building materials	100	78.0	100	73.1
Drugs and chemicals	100	102.1	100	95.7
House-furnishing goods	100	98.2	100	92.0
Miscellaneous	100	85.2	100	79.8
All commodities	100	86.7	100	81.2

The purchasing power of the value of 1,000 bushels of corn has risen from 100 in 1900 to 152.4 in 1910, an increase of 52.4 per cent., similarly the purchasing power of wheat has risen from 100 to 143.8, or 43.8 per cent.; the purchasing power of cotton has risen from 100 to 163.4, or 63.4 per cent.; the purchasing power of the seven principal food crops, covered by earlier tables, has arisen from 100 to 126.4, or 26.4 per cent. The purchasing power of the receipts from 1,000 ton-miles has fallen from 100 in 1900 to 86.7 in 1910, a decrease of 13.3 per cent; the purchasing power of the receipts from 1,000 passenger-miles has fallen from 100 in 1900 to 81.2 in 1910, a decrease of 18.8 per cent. These statistics have reference to purchasing power in general—i. e., power to purchase all commodities. When specific groups of commodities are considered, such as food, clothing, and the like, it is perceived that the purchasing power of the various crops indicated largely increased during the decade, while the power of the receipts from ton-miles and passenger-miles to pur-

chase these same commodities with but one exception decreased.

The increase in the purchasing power by crops of transportation is of course explained by the fact that in contrast to the rapid increase in the average value of farm products during the period, there has been no more than a slight variation in average receipts per ton-mile and in average receipts per passenger-mile

Correlative with the increase in value of farm crops, and in large measure as a direct result of such increase, the value of farm property greatly increased during the decade ending in 1910. This value as a whole, including land, buildings, implements and machinery, and livestock, increased 100.5 per cent., or practically doubled. The value of farm land alone increased 118.1 per cent., an increase in average value per acre of 108.1 per cent. In the same period the cost of road and equipment of the railways increased 40.2 per cent., their gross capitalization increased 60.3 per cent., and their net capitalization increased 63.3 per cent.

OUTPUT OF RAILWAYS AND AGRICULTURE PER 1,000 INHABITANTS.

The next two tables present the increase or decrease in output of agriculture, and the increase in output of the railways, in relation to population, during the decade 1900 to 1910.

OUTPUT OF AGRICULTURE PER 1,000 INHABITANTS.
(Ten Principal Crops.)

	1900.	1910.	Per cent. of increase.
Corn (bushels)	35,085.7	27,749.6	d20.9
Wheat (bushels)	8,665.5	7,430.3	d14.3
Oats (bushels)	12,413.9	10,950.5	d11.8
Barley (bushels)	1,574.3	1,884.7	19.7

OUTPUT OF THE RAILWAYS PER 1,000 INHABITANTS.

	1900.	1910.	Per cent. of increase.
Ton-mile	1,863,256	2,772,759	48.8
Passenger-miles	211,042	351,611	66.6

The output of five of the ten crops increased in relation to population during the ten years ending 1910. The largest increase per thousand inhabitants was that of barley, which was 19.7 per cent. Potato production per thousand inhabitants increased 17.7 per cent., and the production of buckwheat, hay and forage, and tobacco less than ten per cent. The remaining five crops decreased in output as related to population, rye showing a decrease of 4.6 per cent. per thousand inhabitants, cotton of 7.7 per cent., oats of 11.8 per cent., wheat of 14.3 per cent., and corn of 20.9 per cent. The output of the railways for the same period increased per thousand inhabitants, ton miles by 48.8 per cent. and passenger-miles by 66.6 per cent.

The value of the output of these ten crops and of that of the railways in relation to population is shown in the next two tables. Value in the case of agriculture is the farm value, that is, the estimated price at the farm for the crops. In the case of the railways value represents the receipts for handling traffic, and is expressed in terms of freight and passenger revenue.

VALUE OF THE TEN CROPS PER 1,000 INHABITANTS.

	1900.	1910.	Per cent. of increase.
Corn	$10,898	$15,641	43.5
Wheat	4,868	7,151	46.9
Oats	2,857	4,509	57.8
Barley	548	1,005	83.4
Rye	162	222	37.3
Buckwheat	76	101	34.1
Potatoes	1,295	1,810	39.8
Hay and forage	6,372	8,959	40.6
Tobacco	750	1,134	51.2
Cotton	4,260	7,650	79.6

VALUE OF OUTPUT OF THE RAILWAYS PER 1,000 INHABITANTS.

Freight revenue	$13,807	$20,936	51.6
Passenger revenue	4,260	6,839	60.6

The average value of the ten crops per thousand inhabitants increased 50.2 per cent. It should be noted that this relative increase in the farm value of crops has been due entirely to the increased prices received by farmers. The five crops that relatively increased in quantity increased in value at a far greater ratio, and the value of the remaining five crops materially increased, notwithstanding the decrease in quantity. In the case of the railways, however, the increase in revenues per thousand inhabitants is about the same as the increase in ton-miles and passenger-miles, indicating that the increased revenues were due almost entirely to the increase in traffic.

ARBITRATION OF THE FIREMEN'S WAGE CONTROVERSY.

On Thursday, John G. Walber, assistant to the third vice-president of the Baltimore & Ohio, again took the stand as a witness for the railroads. He introduced numerous exhibits to show the pay of firemen and to show the length of time they worked before they got advancement. For the number of roads covered by the exhibit there were in service, in 1908, 26,242 firemen; in 1909, 26,009 firemen; in 1910, 29,399 firemen, and in 1911, 29,161. The number promoted in 1908 was 732, or 2.78 per cent.; in 1909, 1,082, or 4.16 per cent.; in 1910, 2,869, or 9.75 per cent.; in 1911, 1,327, or 4.55 per cent.; in 1912, 2,556, or 8.41 per cent.

It was brought out that by promotion is meant the time of receipt by a fireman of his certificate. Many men, receiving certificates, continue, for some little time, to work as firemen until there is a vacancy for them as enginemen. Mr. Carter called attention to the fact that on the Boston & Maine the average time worked as fireman before promotion, in 1902, was 5.2 years, and in 1912, 8.9 years. In answer to a question from Mr. Carter, Mr. Walber said that the number of promotions in 1912 would depend on the number who had been promoted before. Some of the men who were promoted in 1909 and 1910, during the depression of business may have gone back to firing and worked as firemen for a while and when the increase came in business in 1911, these men were taken off as firemen and put on as enginemen, which made it unnecessary to promote new firemen.

Mr. Walber pointed out that on exactly the same class of engines of the Baltimore & Ohio the number of years served was 5.3 in 1908, 5.4 in 1909, 5.1 in 1910, 5.7 in 1911 and 5.4 in 1912. Mr. Carter tried to show that the Baltimore & Ohio had a particularly difficult time in keeping enginemen, but Mr. Walber would not acknowledge this.

Judge Chambers, in questioning Mr. Walber, in regard to these exhibits, said that he did not find anything in the table, on its face, to controvert the testimony that had been offered by the brotherhood that longer apprenticeship was required now and the goal of quick promotion which had been held out to the firemen is less of a goal now than it was in former times.

Mr. Walber then presented an exhibit showing that during 1910 increases in pay amounting to $2,845,681.29 were granted to firemen; in 1911 additional adjustments involving $189,207.41 and in 1912 adjustments amounting to $5,312, a total of $3,040,-200.70, or 14.15 per cent. on the pay of the firemen of the railroads shown.

Mr. Carter brought out the fact that this was increases in pay which included increases due to changing men to different classes of service. He brought out also that the flat rate for certain classes of passenger engines in 1907 was $2.30, and in 1912, $2.40, and in freight service that the rate on a certain class of engines was $2.80, and that in 1912 the rate on the same engines was $3.00, a single increase of 20 cents, or about 7 per cent. Mr. Walber showed that the increases in the percentage of rates of pay amounted, in passenger service, to 9.18 per cent., and for freight to 9.61 per cent., in local and pick-up to 11.77 per cent., and went on to say that it depends altogether on the proportion of different classes of service as to what the

total increase is going to amount to. He said: "The railroad company pays this money and the firemen get it. The two things are synonymous and the railroad cannot pay unless the men get it, and the dollar paid for the increased size of the locomotive, or the dollar paid for a change for overtime regulations, or a dollar paid in a change for preparatory time buys just as much as any other dollar they get."

In the afternoon further exhibits were submitted showing increases in rates and Mr. Carter objected to these exhibits because they did not show the increases in rates on the same engine over different periods, but showed it only for the same service.

Mr. Atterbury then questioned the witness as follows:

Mr. Walber, I want to find out something here. Are you familiar with Pennsylvania rates?"

Not specifically—generally, Mr. Atterbury.

We have the middle division here.

Mr. Lee: I think, perhaps, I can ask one or two questions on that, sir, I can try to. Now take your Altoona and Harrisburg run, was that $2.05 the rate of the firemen at that time on class E engine?

Mr. Atterbury: Yes, a passenger engine.

Mr. Lee: All engines, yes, sir.

Mr. Atterbury: All right, now is $3.17 your minimum rate today?

Mr. Lee: Yes, sir.

Mr. Atterbury: Then the difference between $3.17 and $2.05, divided by $2.05, would give you the percentage of increase on that road, would it not?

Mr. Walber: 54.6 per cent.

Mr. Lee: For that small engine?

Mr. Atterbury: All right, that is exactly the same engine?

Mr. Lee: Yes, sir.

Mr. Atterbury: So there is no question but that there is a 53 or 54 per cent. increase in the rate for firing the same engine on that particular division, is that right?

Getting down to freight service, Mr. Atterbury showed that a man got $2.55 in 1902 if he ran an H3 engine and in 1912, $3.62, an increase of $1.07 on the same engine and $3.81 for an H6 engine. The chairman asked whether the load had increased with the same engine and the witness stated that it had and that in his opinion this increase was due in part to the change in cars and in part to a change in carloading, due to larger cars.

Mr. Walber's examination continued on Friday morning. Considering 175,746 trains run in slow freight service, the average length of the run was 82.6 miles and the average hours on duty for each fireman was 11 hours 39 minutes. The average earnings of the firemen per train were $3.73, and the average per hour on duty 32 cents. Mr. Walber states that the great number of runs of less than 100 miles for which 100 miles are paid, bring about the high average earnings per day and a rate per mile above the rate per mile shown in the schedule. He said that the Baltimore & Ohio is unfortunately situated with reference to short divisions, practically all the divisions leaving the coal districts in both directions being less than 100 miles. This factor, he claimed, made the comparison of the rate per mile entirely inadequate to convey any idea of what the men are getting for the work performed. The sheet showed that on 175,746 freight train runs the men were paid for 14 miles each, which they did not run on a mileage basis. Mr. Carter said at this point that he judged that the statement showed the total trains run by all the roads and from this it would appear that in slow freight service the freight trains only run at an average speed of 7½ miles an hour. Mr. Walber replied that the average time was 11 hours 39 minutes for 86 miles, and explained that the low average speed, as calculated by Mr. Carter, was brought about largely from the fact that the time began so much earlier than the train actually moved.

There then ensued a discussion between Mr. Carter and Mr. Walber. Mr. Carter finally complained to the board that the witness was attempting to browbeat him and claimed that he should answer the questions by either yes or no. Judge Chambers stated that he thought there were some questions which could be answered by either yes or no, and Mr. Lee agreed that such an answer should be given when it was possible.

Continuing Mr. Walber showed that in passenger service, round trip for turn-around, the statement covered 52,588 trains run, including all passenger trains other than suburban, for which one or more trips or turn-around runs constitute a day's work. The average length of all such runs was 123 miles; the average time on duty was 7 hours 17 minutes; the average time from start to finish was 10 hours 32 minutes; and the average time off duty at terminal or turn-around points was 3 hours 15 minutes. The average earnings per train or per day were $3.24, and per hour on duty 44.4 cents. The next sheet covered suburban passenger service and showed 22,487 trains reported; the average time on duty was 7 hours 58 minutes; from start to finish 11 hours 37 minutes; the average time off duty at terminal or turn-around points, 3 hours 39 minutes; the average earnings per day $3.06, or 38.4 cents per hour.

The next statement showed the number of freight trains run, the number of trains exceeding 16 hours, and the number tied up under the 16-hour law. With a total of 309,622 trains run in the months covered by the reports there were 5,634 trains tied up under the law, or 1.8 per cent. of the trains run. The trains exceeding the 16 consecutive hours were 1,627, or three-quarters of 1 per cent. of the trains run. The average time on duty per train in excess of 16 consecutive hours was 2 hours 17 minutes. In a table which followed it showed that of the trains exceeding 16 hours, 769 were between 16 and 17 hours on the road, 624 between 17 and 18 hours, and 379 between 18 and 19 hours.

In a discussion with Mr. Carter, Mr. Lee showed that of all the cases exceeding 16 hours, 69 per cent. were in December. There was some discussion between Mr. Carter, Mr. Lee and Mr. Walber regarding the accuracy of the latter's figures and the method used in their preparation. It was brought out that a circular had been sent out to each one of the roads concerned and they had sent in the information. During this time Mr. Carter made the statement that one of the firemen's witnesses had, since he had testified, been taken out of service because of the character of his testimony. Mr. Lee stated in reply that perhaps Mr. Carter had special knowledge in this particular case which he had not, but he said that no man who honestly believed that he was testifying to the truth had any reason to fear being so disciplined or discharged, but that if he wilfully testified falsely, no matter what his situation in life, he had something to fear.

Mr. Carter afterwards went into a discussion at some length as to whether the railroads' testimony was or was not correct, and again discussed the matter of their reports to the Interstate Commerce Commission. The point he seemed most anxious to bring out was that while he believed Mr. Walber was testifying to the best of his knowledge, he was in doubt as to what the clerk who prepared the statistics might have done. Mr. Lee replied that while it would be practically impossible to bring all those who worked in the preparation of the reports to testify at the hearing, he was willing to bring as many as the board desired. When asked by the chairman if there was, on the Baltimore & Ohio, any one accountant who could come and swear to the accuracy of the statement furnished by the Baltimore & Ohio, Mr. Walber replied that the chief timekeeper, under whose direction the compilations were made, was competent to do so. Mr. Carter here explained that what he meant was that the clerks in compiling the figures showed that the increased rates would mean an increase in overtime, while the firemen claimed that with the two firemen on the large engines the overtime would be decreased.

Continuing, Mr. Walber showed that the total increase involved by the schedule requested by the firemen would be $10,363,430, or 35.5 per cent. Of this 35.5 per cent., 10.11 per cent

would be for second firemen; 2.52 per cent for keeping coal within reach and 2.54 per cent. for cleaning.

The last statement shown by Mr. Walber on Friday was a comparison of the firemen's daily compensation in the eastern district for 1900 and 1911, which showed an increase of 40.5 per cent., while the increase in the retail price of food was given as 38.8 per cent.

On Saturday Mr. Walber again took the stand and submitted various exhibits, the first one showing wages paid various classes of skilled workmen according to the report of the Bureau of Railway Economics. In these exhibits certain rates of wages for bricklayers and others in building trades were shown. This exhibit agreed with a previous exhibit of the firemen. Mr. Atterbury pointed out that in Mr. Walber's exhibit he did not show blacksmiths, machinists or boilermakers, but in general his exhibit agreed with Mr. Carter and that in Mr. Carter's exhibit it would appear that blacksmiths, machinists and boilermakers are getting from 45 to 50, 55 and 60 cents an hour in the same towns where men in railroad shops are getting from 33 to 39 cents an hour. He asked Mr. Walber how he accounted for this difference. The only explanation Mr. Walber could give was that the employment is steadier in railroad work than in outside shop work. The way the exhibits were prepared was explained at some length.

On Tuesday Judge Chambers announced that a stipulation had been signed, postponing the date of final agreement from April 2 until April 23. Under the Erdman Act arbitration expenses are paid by the government, and this extension of time made it necessary to include in the stipulation an agreement that all expenses incurred after April 2 would be defrayed equally by the railroads and the firemen. It was also agreed that the award should be accepted as binding, both sides waiving the right to appeal.

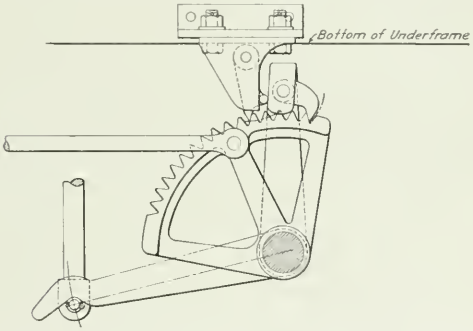
At the hearing on Tuesday a number of witnesses were called by the firemen to refute specific statements previously made by the railroads. One of the witnesses stated that instead of discouraging the use of mechanical stokers, as claimed by the railroads, the firemen had favored them in every way.

On Wednesday more witnesses were called by the firemen. One fireman from the Pennsylvania Lines West stated that in some instances automatic stokers were credited with a higher per cent. of efficiency than they really deserved. He said, further, that these reports were often exaggerated at the request of the engineer. He explained that firemen favored the mechanical stoker in the hope that it would be perfected and so reduce their labors. Other firemen testified that it was more difficult to fire a stoker engine than a stokerless one.

AUTOMATIC BRAKE SLACK ADJUSTER.

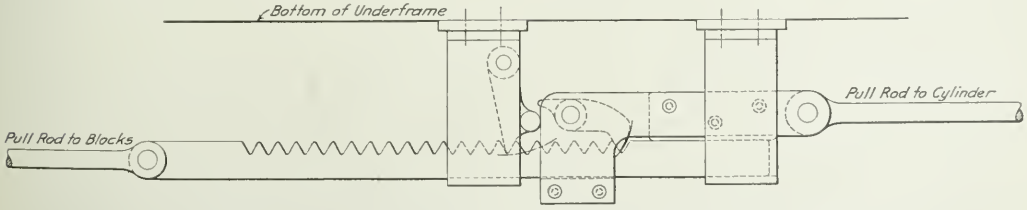
Providing air brakes for freight cars involves a heavy expense, and yet the efficiency of this apparatus is seriously affected by the lack of automatic slack adjusters. These have been perfected for use on passenger cars, but, because of their cost, are not used on freight cars. At a meeting of the New York Railroad Club last year W. H. Sauvage made the statement that from an economical standpoint of labor and time saved in making up long trains, and properly and uniformly adjusting the brakes, the investment required to equip cars with automatic slack adjusters would pay for itself quickly. The discussion at the same meeting indicated that there was no adjuster on the market at that time of simple construction and reasonable cost suitable for general application to freight cars.

It is interesting to note that a brake slack adjuster which is said to meet these requirements is reported to be widely used on many of the leading British railways for freight equipment as well as for that in the passenger service. The same apparatus is also being used on the Indian and South American railways. The illustrations show the application of the Monarch patent automatic block adjuster made by the Monarch Controller Company, Limited, of London, England, and also the arrangement of the device as used in conjunction with the Westinghouse air brake on foreign cars. The adjuster is designed to ensure that the maximum stroke or travel of the piston in the brake cylinder does not exceed a certain distance, and immediately this stroke is completed any slack due to wear on the tire, brake shoes, etc., is taken up, thus giving a constant short travel and a more effective pull on the brake rods. It is a feature of the Monarch system that the brake shoe should be placed above the horizontal center line of the wheel in such a position that the shoe clearance and piston stroke are the same for light and loaded vehicles.



An Ordinary Form of Brake Shaft on an English Car Operated by Either Hand Lever or Vacuum Cylinder, to Which Is Attached the Quadrant Type of Monarch Brake Slack Adjuster.

One of the difficulties to contend with in adjusting brake shoes automatically is that of keeping the clearance between shoe and tire normal, after adjustment has taken place. In the device illustrated the controlling pawl is arranged so that the normal stroke of the piston and the clearance between brake shoe and tire remain constant after the automatic adjustment has taken place. When in the off position the adjuster is locked, thus preventing any movement due to rough switching of the cars, etc. The experience of the English railways is that the device is effective and easy to maintain.



A Horizontal Type of Adjuster for Use on English Cars Fitted with Air Brakes.

REGULATION OF THE STOCK OF MATERIAL.

The Relation of Accounting to this Problem. The Form of Such Accounts and Ends to be Served by Storehouse Accounts.

By George G. Yeomans.

The chief problem confronting the officer who is managing the supply department of a railroad is the regulation of the stock of material in such a way that while the work of all the different departments may proceed without interruption, the unproductive investment in idle material shall be made and kept as small as possible. A stock of material is nothing more or less than a policy of insurance on the continuity of work, and any money expended in excessive premiums on this insurance is money wasted.

The proper regulation of the stock embraces those other problems of procuring the material, of warehousing it when necessary, of distributing it expeditiously and economically, of accounting for it accurately, and of exercising at all times and places a proper police supervision over it.

Procuring material for a railroad means a great deal more than buying what is required. It means, in the first place, the originating of the requisitions on which the purchasing agent acts, the decision as to the quantities to be bought, and the time when it should be delivered; and in the second place, it means the actual control of the product of those sources of supply which the company itself may maintain and operate, so far as that product is intended for distribution and future consumption.

In other words, the operations of the machine shops, planing mills and foundries belonging to the company, with respect to their function of manufacturing any articles for future use, must be governed by the chief supply officer as effectively as he governs the operations of the purchasing department by means of the requisitions which he draws upon the purchasing agent. Where such internal sources of supply have no other function than the production of material for distribution and future use it is better that he should wholly control their operation. This applies to such facilities as the brass and iron foundries and rolling mills, which are frequently maintained by railroads in preference to procuring such supplies from commercial manufacturers, but which, as a matter of fact, produce no finished material and are sources of supply pure and simple. It does not require argument to show that if any individual is held responsible for regulating the amount of material carried in stock, he must effectively control the sources of supply, and this can be accomplished with less friction and better results if he is entrusted with their actual operation.

The manufacturing of material for future use in the regular repair shops is only incidental to their true functions, and here there can be no question of the control of their operations, except in so far as the establishment of an inflexible rule that no articles of any kind should be provided for shipment to any other point, or to be reserved for future use, without the written instructions of the officer who is directly responsible for the quantity of material in stock. In other words, this is one of the means at his command for procuring material, and his orders on the shops should be just as definite and just as binding as his requisitions on the purchasing agent, and the production of material at the shops without his sanction should no more be tolerated than the shipment of supplies by a commercial manufacturer without the written order of the company.

Having thus secured the necessary authority for procuring the requisite supplies, the first step towards a proper regulation of the stock has been taken.

The next, and perhaps even more important, step is the accounting for it in such a manner that the records may form an accurate guide to future performance. Here a distinction should be drawn between bookkeeping and storehouse accounting.

Bookkeeping contents itself with setting forth the final results of operation, eliminating in the process those factors which offset or balance each other. It shows, perhaps correctly enough, the balance on hand at the close of the month's operations, but it does not disclose all of the computations by which that balance was reached. The balance on hand is no more important than the actual consumption; indeed, a comparison of the amount of material on hand with the amount that was in stock at some previous period is a very imperfect guide to the efficiency with which the stock is handled, because the operating conditions may be totally dissimilar; but a comparison of the material available for use with the actual current consumption is a definite and certain measure of results.

Storehouse accounting, on the other hand, must set forth in detail the steps by which those results and monthly balances are reached, so that any mis-step may be immediately detected. In order to accomplish this in the most economical manner, the methods employed must be simple, uniform, concise and accurate; and precisely to the extent which the methods employed approach these four requirements can any exact regulation of the necessary stock of material be reached.

The simplest form of accounting is manifestly a single account. In other words, there should be but one channel through which all material acquired by the company must be accounted for.

No department, save the supply department, should be permitted to carry any material in stock or to have a material account.

The entire connection of the other departments with accounting for material should consist in making the necessary requisitions on the local storekeeper; in stating on the requisitions the account to which it should be charged, or the purpose for which it is to be used; and in returning any released material or unused surplus promptly to the custody of the storekeeper and receiving from him in turn a requisition crediting its value to the account originally charged. The result of this system is a single account to which all material is debited when acquired; in which it is carried when it is not in actual service; and from which it is charged direct to the proper account when it is used, sold or otherwise finally disposed of.

The accounts must be uniform. That is, they must be in precisely the same form at all storehouses, and on all divisions, and they must apply to all material alike. While this would seem to be self-evident, it is amazing how often local irregularities creep into this feature of the work, and what incessant vigilance is required to prevent subordinate local officials from modifying the prescribed methods in a way which will tend to improve their own apparent performance when compared with that of others who are more scrupulous. The best method of insuring uniformity in the accounts is the printing of all the fundamental storehouse records, such as material classifications, stock books, price books and inventory blanks, from a single plate, so that no item will be inadvertently omitted, and so that every record will be precisely like all other records of a similar nature, wherever it is in use.

This has the added advantage of making it a simple matter to transfer a storekeeper or a clerk from one division or office to another, as he can take up the work where his predecessor left it without any hesitation or uncertainty.

While the initial outlay under such a system is comparatively large, the cost of reproduction is so materially reduced that it is cheaper in the end.

The accounts should be concise. It seems almost a misnomer to use that word in connection with any accounting system which embraces such a multiplicity of detail, but it is used in

the sense of avoiding all duplications of work. No word or figure should be written twice where once will suffice, and much can be accomplished in that respect by a carefully systematized use of the carbon sheet, and the preparation of the forms which are used in the daily transaction of the business in such a way that the original entry may be made to serve more than one purpose.

Here again the absolute uniformity of the printed page in the storehouse records comes into play, and with it should be combined a filing system so complete and so uniform, that the original authority for any entry can be produced instantly on demand.

The accounting methods must be accurate. This embraces the correctness of entry and extension, but they must also be accurate in the sense of being comprehensive and definite. It is upon the records of actual consumption and available supply that the chief supply officer must mainly rely in order to base his action in procuring material upon precise knowledge, instead of on estimates and guesswork.

Obviously, the first requisite of such a record is that it must cover all unapplied material of every nature that is in the possession of the company—not merely part of it. It is the uncharted rocks that bring disaster to many a valuable cargo, and this is one of the most prevalent causes of surplus and unproductive investment in material at the present day.

But it is not sufficient that he should have this definite information with respect to material as a whole. The chief supply officer must also have a fairly accurate knowledge of the comparative rate of consumption of different classes of material so that, in procuring it, he may assort his stock intelligently and not have the same quantity of two different kinds, when the consumption of one kind, in a given time, is double that of the other.

It is manifestly impracticable that the chief supply officer should deal, in this way, with each individual item entering into the total stock of materal, but each local storekeeper should have this itemized knowledge and record, for the territory which he serves. This is obtained from his periodical inventories of all unapplied material under his charge, but primarily from his stock books, which, if properly kept, furnish exact information of the actual consumption as well as the available quantity of each particular article.

Further, such records show the fluctuations in the consumption of different materials, and the season of the year in which the use of certain articles reaches its maximum and those in which it becomes a negligible quantity, and enables him to prepare in advance to meet the demands of the service and to curtail his expenditures, also in advance, when necessity ceases to exist.

In order that the chief supply officer may have this information at his command, in sufficiently definite shape upon which to act, the various items should be classified according to character and use and combined into groups or classes of kindred articles, and a monthly classified stock report should be compiled at each storehouse, showing in general outline the exact transactions with reference to each class of material during the month.

In order to aid in securing uniformity among different railroads in this important particular, the Railway Storekeeper's Assocation, after mature deliberation, devised a "Standard Classification" of material which is based upon the Interstate Commerce Commission's classification of operating expenses, and it would be well if this general form could be universally adopted and followed. It contains one serious defect, however, which should be corrected in the interest of accurate stock regulation. This defect is that no distinction is made between those classes of material for which the chief supply officer can be held directly responsible, and those other classes, the quantity of which is determined by the policy of the management, or by other causes which he is powerless to regulate or control. This defect can easily be remedied by a simple rearrangement of the classes, so that the material for which the storekeeper can be held accountable appears in one group, and that which he cannot altogether control in a separate group. In this way the performance of the individual storekeepers may be correctly gaged, and the proper assortment and regulation of the stock may be simplified.

It is evident then that there are four things which are essential to a systematic and precise regulation of the investment in material:

The first is an effective control of the sources of supply.

The second is a concentration of the accounting for all material into one channel, so that the entire situation is disclosed and there is no cross accounting or duplication of work.

The third is a uniform, concise and accurate system of accounting, from which a correct knowledge of the available supply and the actual consumption of all materials can be obtained.

The fourth is a clear and definite division of all material into a sufficient number of classes to form a reliable guide to the relative consumption of the different kinds of material, so that the total stock may be properly assorted.

The extent to which some or all of these essential features are lacking in current railroad practice very largely measures the extent of their unproductive investment in surplus and unnecessary material.

TRANSCONTINENTAL COMMODITY RATES INCREASED.

Interstate Commerce Commissioner Clements has handed down a decision in the case involving the investigation and suspension of advances in rates by carriers for the transportation of various commodities from eastern shipping points to points in California, Oregon, Washington, and British Columbia. The full decision was as follows:

In this proceeding is involved the reasonableness of proposed transcontinental commodity rates, westbound. The rates are contained in three tariffs—Countiss's I. C. C. 952; I. C. C. 953; and I. C. C. 956. The points of origin are the same in the first-named two tariffs and embrace all points between Colorado common points and the Atlantic seaboard north of the Ohio and Potomac rivers. The only substantial difference between them is that I. C. C. 952 names rates to California terminals, such as San Francisco, and I. C. C. 953, rates to north Pacific coast terminals, including Portland and Seattle. These two tariffs contain practically the same items and rates, except that certain rates in the north coast issue are affected by the intermediate adjustment at Spokane, and therefore vary slightly from the California terminal rates. The third tariff, I. C. C. 956, names rates both to California and north coast terminals, but the territory of origin is south of the Ohio and Potomac and east of the Mississippi rivers. All three of these tariffs, which were filed to become effective September 2, 1912, have been, upon numerous protests from shippers, both from the east and on the Pacific coast, postponed in their effective dates by the commission to July 3, 1913, pending inquiry into their reasonableness. Certain other shippers at intermediate points, like Reno and Fresno, petitioned that the advances be permitted to become effective.

The territory of origin in the two tariffs first named is divided into groups from west to east. Formerly group C embraced all points east of Chicago with the exception of certain New York piers owned by the rail lines and with the exception also of New England, which were in groups A and B, respectively. The proposed tariffs make some changes in this grouping, and without reciting these changes in detail, it will suffice for this report to say that, generally speaking, group A will now embrace all points east of the Buffalo-Pittsburgh line; group B all points east of Cincinnati and Detroit to and including Buffalo and Pittsburgh; group C east of Chicago to and including Cincinnati and Detroit; group D the territory east of St. Louis to and including Chicago; and that by similarly marking these group lines farther west, St. Louis will be found to be in group E; Kansas City and Omaha in group F; Nebraska and Kansas in group G; Oklahoma, New Mexico, and parts of Texas in group

H; and Colorado and Wyoming in group J. The territory of origin in I. C. C. 956 is grouped numerically, but apparently without reference to the geographical location of each group.

It has been for many years the practice of the transcontinental rail lines to meet the rates of the steamship lines via Panama and transshipment across the isthmus by rail. Prior to the amendment of the fourth section of the act in 1910, which placed the burden of justifying a higher rate to an intermediate point included within a longer haul upon the carriers, the carriers themselves were the judge in the first instance of whether this competition existed in sufficient degree to warrant a departure from that section of the act. The transcontinental lines, therefore, upon the fact or assumption that this competition affected most commodities in some degree, or in order, perhaps, to meet some commercial or other conditions under this guise on certain of them, added commodities by a gradual process to this competitive list until they had, prior to these suspended tariffs, practically no rates to their terminals which were higher than to Reno and Spokane, and but comparatively few terminal rates as high as to the interior, the latter being cases in which the terminal rates were applied as maxima to the intermediate points.

Recently the Commission passed upon the reasonableness of rates to Reno and Spokane under the amended fourth section, and one of the main purposes of these suspended tariffs is, the carriers state, to realine their intermediate rates in substantial accordance with those findings by increasing their terminal rates to the same or a higher basis than applies to the interior on articles which do not or cannot move by water and as to which there is not therefore any real necessity for the lower rate to the terminal. The result of the carriers' expressed policy in this respect has been to thus increase by the tariffs under suspension their terminal rates principally on nonwater-competitive freight, but in certain cases also on competitive articles, as will more fully appear hereinafter. It is not to be understood, however, that only strictly nonwater-competitive articles are included in these advances, which, it may be explained at this point, can be in a general way summarized under five heads: *First.* Certain increases in minimum weights, the carriers contending that this action is justified on the commodities so affected by the increased carrying capacity of modern equipment. *Second.* Increases due to the cancellation of the commodity rate on certain less-than-carload (and a few carload) articles, the volume of rail movement of which has been in the past so small as to not justify an exception to the classification, to which such articles are accordingly returned. *Third.* Advances on certain articles which have always been and are now subject to acute competition of the steamship lines, but the rates on which, while originally low enough to secure a fair share of the traffic to the rail lines, are not now sufficiently low, in view of the more intense steamship competition in recent years, to secure to them a reasonable proportion of the transcontinental traffic. It is argued that in view of the present low rates via the water lines such articles are doubtless offered to the rail carriers for other reasons than the difference in rate, and would therefore probably be offered in practically the same volume if the rail rates were to be slightly advanced. The rates on these commodities are, however, blanketed east of the Missouri river in accordance with the practice of the carriers with respect to nonwater-competitive freight. *Fourth.* An advance on certain commodities which are not to any appreciable extent, if at all, water competitive, and which accordingly are graded up from the Missouri river east according to the group of origin and graded also from Reno and Spokane to the final or maximum rate at the terminal. The terminal rate on these articles is blanketed also at the western end to include practically the whole state of California in the California tariff and all points west of the Columbia river in the north coast tariff.

It may be explained in this connection that prior to these suspended tariffs transcontinental commodity rates were blanketed in points of origin east of the Missouri river under the water-competitive basis which obtained, as explained, on practically all commodities, but that now, as will appear from the foregoing, while water-competitive freight is still so blanketed, the rate on noncompetitive traffic varies with the eastern group in which the point of origin is located.

It thus appears from the foregoing that the carriers will in future recognize the force of water competition only when it is actually present or reasonably to be apprehended on a given commodity and will then recognize it only in proportion to its degree. The carriers frankly admit, however, that the exact effect of this actual or potential competition is not now definitely ascertainable, and that many of the proposed rates are, therefore, experimental and will be canceled if it is found that mistakes of judgment have been made in this respect, as reflected in the future volume of the individual articles offered to them. The carriers, in fact, recognized during the progress of the hearings that such mistakes had been made on certain commodities and gave assurance that those items would be given further consideration. In this connection they also suggested that the shippers, not only of such commodities, but those interested in any of the suspended items, meet them in conference in further consideration of the entire schedules in the hope that by mutual concessions a satisfactory and equitable readjustment in the nature of a compromise could be agreed upon as to many, if not all, of the advances and such items be eliminated from controversy. Such a conference was accordingly held, and the rates on the commodities so represented at the conference were further discussed informally. Certain modifications were there agreed to by the carriers and the protests as to them accordingly withdrawn by the shippers. There still remained, however, a few commodities as to which no agreement had been reached, and these were the subject of a second informal conference between the parties before the commission at Washington. Certain of these latter items were at that conference also adjusted satisfactorily to the shippers, who accordingly withdrew their protests as to them. The result is that by this commendable co-operation on the part of both shippers and carriers there now remain but a few items as to which the parties have not agreed and the protests been eliminated. And as to these, the carriers have submitted their final suggestions, but have agreed to abide by the decision of the commission without the necessity of its making a formal order.

We shall not discuss the various rates involved in this proceeding in detail. That the changes in these tariffs are numerous follows from the mere statement that the proceeding involves a comprehensive general revision of all the transcontinental commodity rates westbound. To discuss the individual items would, therefore, but unduly lengthen the report. It may be said, however, that all parties have been given an opportunity to present evidence in support of their protests at hearings held in Washington, Portland (Ore.), and San Francisco; that opportunity has been given to present written argument on the voluminous record that has accumulated; and that oral argument has been waived by both parties.

Of the articles finally left to the commission for determination after these informal conferences referred to, furniture, tin cans, and lard pails constitute the chief items. All of these items come within the class alleged by the carriers to be nonwater-competitive, referred to under one of the previous headings, and are graded up in rate according to the proximity of the group of origin to the eastern seaboard in accordance with the practice of the carriers with respect to nonwater-competitive freight.

Most of the items of furniture have been adjusted satisfactorily to the shippers and the protests as to them withdrawn. There is one item, however, which was discussed at the hearings and in the subsequent informal conferences referred to, which, in view of the inability of the parties to agree, is now referred to the commission for determination. This item is the general furniture mixture. Taking Grand Rapids as a representative point of origin, the proposed increase is from $2.20 to $2.52, the

latter being in fact the third-class rate, except that it is subject to a flat minimum instead of a changeable minimum under rule 6-b of the classification. This mixture is of furniture of the better class, many of the articles being of the highest grade and price in the trade. Upon careful consideration of the evidence on this item we are not convinced that the proposed rates are unreasonable. It is therefore our opinion that they should be permitted to go into effect.

The proposed advance on tin cans is from 85 cents to $1.15 under the suspended tariffs, but the carriers as the result of these informal conferences now voluntarily suggest, finally, a rate of $1, minimum 22,000 pounds. The principal protestant against this advance concedes that $1 is a low rate, but contends that on account of the low margin of profit on the commodity his sales on the coast, which now amount only to about 5 per cent. of the gross sales, will be practically eliminated. It is contended that under a rate of 95 cents some of this coast trade could be retained. The principal basis of this specific protest is the fact that the 85-cent rate has been in effect for many years and business built thereon. While we recognize some merit in the latter contention from a commercial standpoint, we do not feel justified in finding that a rate of $1 is excessive on this traffic. It is true as pointed out by this protestant, that the proposed advance on tin plate is only from 66⅔ cents to 70 cents. It appears, however, that the average carload of tin plate weighs at least 60,000 pounds, many cars weighing 100,000 pounds, and that the per-car earnings are much in excess of the earnings on cans, even under the proposed rates. It also appears that tin plate is not only water competitive from the eastern seaboard, but that there is substantial commercial competition from Wales.

The situation as to lard pails is closely analogous to that on cans. The principal protestant is located in Pittsburgh territory, from which the proposed advance is from 85 cents to $1.25. The carriers now finally suggest as a compromise a rate of 95 cents, minimum 24,000 pounds. Our general remarks in reference to tin cans apply equally to lard pails.

In addition to the foregoing there are certain items on which testimony has been presented and written arguments had but which have not been represented at any of the informal conferences referred to and upon which no compromise agreement has been reached by the parties; also a few which were protested against by letter without representation at any of the proceedings before the commission. The advance proposed on some of these items has not in our opinion been justified. These items are as follows:

Fruit jars have been carried at a rate of 85 cents from Pittsburgh and 75 cents from the Missouri river both to California and north coast terminals. It is proposed to advance the rate to 85 cents from the Missouri river to the north coast, but not to advance the rate to California from the same points. There has been shown no difference in conditions at the respective terminals to warrant this discrimination.

Rope is advanced from 95 cents to $1.10 from St. Louis to Portland and Seattle. The rate in the reverse direction is 60 cents, minimum 30,000 pounds, as carried in item 565 to Countiss's I. C. C. 958. The rate is the same in either direction between St. Louis and California terminals. We find that this advance is not warranted.

Brass rods to California terminals are reduced from $1.25 to $1, with an added requirement that they shall be crated, which, protestants state, increases the rate 33⅓ per cent because of the additional weight of the crate. Brass beds made from these rods are reduced from $1.50 to $1.25, with no requirement as to crating. The practical result is a higher rate on the beds than on the rods from which made. The carriers concede that brass beds are nonseagoing freight and that brass rods do move via the steamship lines and that the former rate was reduced in order to permit the eastern manufacturers to compete with manufacturers on the coast. This is a discrimination which is unwarranted by the facts of record, and which we shall leave to the carriers to correct in a suitable manner.

The minimum weight on roofing paper and felt is increased from 30,000 to 40,000 pounds in the north coast tariff, while the former minimum is retained to California. This is also a discrimination which should be removed.

Wooden washboards are advanced from $1, minimum 24,000 pounds, to the woodenware mixture at $1.50, minimum 16,000 pounds, from Saginaw, Mich., and Memphis, while metal washboards are retained at the former rate. We find that this advance constitutes an undue discrimination against wooden washboards.

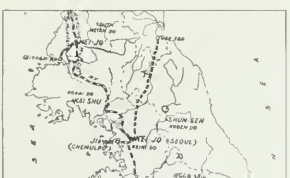
The carriers also propose an advance of 10 cents per 100 pounds on steel products from Denver and on cement-coated nails from Chicago to north coast terminals. They state that this action was taken against their best judgment, but was necessary in order to secure a better relative adjustment at Spokane. It is stated that this advance will be voluntarily canceled if the Supreme Court decides in the cases involving the proper interpretation of the amended fourth section now before it that terminal rates lower than to the interior are lawful. It is our opinion and recommendation that this proposed rate should be suspended until the status of the Spokane and terminal rates is definitely defined by the Supreme Court.

With the exceptions noted above and of those rates voluntarily modified by the carriers following the informal conferences referred to, it is our opinion that the proposed rates are not shown to be unreasonable and that they should be permitted to become effective. It is manifest, however, from what we have said that we are not justified upon this record in expressing a final affirmative approval of every rate involved in this proceeding. But we feel, in view of what has been voluntarily done by the carriers in the way of concessions and compromise, and in view of the further modifications herein, that the proposed rates as now modified are not shown to be unreasonable as a whole.

In conclusion, we deem it appropriate to say that the action of the shippers and carriers alike in freely meeting each other in the discussion of the questions involved, with a view to a fair adjustment of differences within the requirements and provisions of the law, is gratifying.

Upon the filing of tariffs, which may be made effective upon one day's notice, containing both the modifications of these tariffs which have been voluntarily proposed by the carriers and those specifically directed herein, the order of suspension will be vacated. (26 I. C. C. 456.)

Railroad Construction in Korea.—The construction of two railroads in southern Korea has recently been authorized. One will run from Taiden southwest to the port of Mokpo, with a branch to the port of Kunsan. The other will run from Keijo northeast to the port of Genzan. The former line will be 175 miles long, and it is estimated that it will cost $6,421,000, excluding rolling stock, which will cost about $2,090,000. The other line will connect the port of Genzan with the line from Fusan to Keijo at Ryusan, a suburb of Keijo, via Giseifu, Tetsugen and Heiko. The total length of this line will be about 136 miles, and the cost is estimated at $7,165,000, in addition to $1,022,000 for rolling stock. It was at first intended that these lines should be completed by 1921, but it was later decided to complete them by 1916.



DAMAGE BY FLOODS TO RAILROADS.

The railways operating through the flooded districts of Ohio and Indiana experienced during last week the greatest disaster in their history. Bridges and tracks were washed out, yards and stations partially submerged, and the lines so cut up by the floods that train service was entirely abandoned in many districts for several days, being resumed after the floods had subsided only by detouring. Although the conditions had begun to improve on Thursday and Friday of last week, and through passenger trains are now being operated on something like regular schedules, it is even yet impossible to obtain any comprehensive statement as to the extent of the damage suffered by the roads. It is conceded that it will reach into many millions of dollars, but during the early part of the week, on account of the impairment of telegraph and telephone service, and the widespread character of the devastation, it was difficult to obtain accurate information as to the situation.

Underwood & Underwood.

Track Undermined by Flood at East Akron, Ohio; Baltimore & Ohio.

The northern lines, including the Lake Shore, Michigan Central, Grand Trunk and the Wabash line to Detroit, suffered

Derailment at Yosts, N. Y., on the New York Central.

comparatively little damage and were used to detour trains of the other roads. On account of the extent of their trackage in southern Ohio and Indiana, the Pennsylvania lines and the Baltimore & Ohio-Cincinnati, Hamilton & Dayton system sustained the greatest damage, and the Big Four and Monon were almost completely tied up for several days, while parts of the Erie line from Hammond, Ind., to Meadville, Pa., were out of commission.

PENNSYLVANIA LINES.

On Tuesday and Wednesday of last week nearly all trains through Indiana and Ohio were annulled, except on the northern lines. On the Baltimore & Ohio the trouble extended from Chicago Junction, O., to Wheeling, W. Va., and both the northwest and southwest systems of the Pennsylvania lines were affected, the worst damage being at Piqua, Dayton, Columbus, Indianapolis and Logansport, and on lines approaching those cities. On the northwest system two through passenger trains were operated each day by detouring, although the 20-hour train westbound, due to arrive in Chicago on Tuesday, was nearly 26 hours late. This train had gone as far as Columbus when it was necessary to take it back to Pittsburgh, and it finally arrived in Chicago via the Lake Shore tracks from Toledo. Since Thursday, March 27, all through passenger trains on the northwest system have been operated, except the Broadway Limited, although several trains have been consolidated. For several days the Lake Shore tracks were used from Clark Junction, Ind., to Cleveland, but by Thursday the line from Chicago to Mansfield, O., was opened, and the Erie tracks were used to Akron. For three days there was no service on the Panhandle out of Chicago, but by Monday service had been resumed to Indianapolis, Piqua, Dayton, Columbus and Louisville. A train for Columbus via the Lake Shore to Crestline was operated on March 27.

BALTIMORE & OHIO.

The Baltimore & Ohio succeeded in operating one through train between Chicago and the east every day, detouring over the Nickel Plate, and part of the time via the Erie, Cleveland, Akron & Columbus, and Pennsylvania lines to Ravenna, Ohio. On Monday of this week all through trains out of Chicago were resumed via Pittsburgh, and the company's own rails were used for service to Washington and New York. No. 8 out of Chicago, which had been running via Newark and Wheeling, left on Monday on its regular time for New York via Pittsburgh. Except for No. 6 between Chicago and New York through service had been practically abandoned for several days. The Cincinnati, Hamilton & Dayton has probably been the most seriously affected of all lines, although [illegible] reports have been few, because of lack of telegraph service.

ERIE.

The main line of the Erie Railroad between New York and Chicago was closed from March 19 to March 21 inclusive. On the morning of March 22 this line was opened to traffic. Not a bridge was lost on the entire system and the only serious damage to any bridge was the weakening of the abutments of the bridge at Akron, Ohio. The most severe washouts on the main line were between Corry, Pa., and Marion, Ohio. From Marion to Chicago there were about 15 washouts of minor importance. While the main line was closed, traffic from Jersey City moved to Buffalo over the regular route and thence to Chicago over the Lake Shore & Michigan Southern, which was not affected.

The line to Cleveland was closed by a 1,200 ft. washout at Aurora, Ohio. A trestle over this washout was expected to be completed on April 1. While this line was being repaired, and after the main line was opened, Cleveland was reached from Akron via the Baltimore & Ohio. The line from Marion to Dayton suffered heavily and is not expected to be open to traffic until today or tomorrow. From Urbana, Ohio, to Dayton the tracks were entirely under water. About 2,500 carloads of filling will be required to repair this section. Since this line was closed this road has had no access to Dayton.

Underwood & Underwood.

Flood Scene at Dayton; National Cash Register Company's Cars Used as a Bridge for Escape from the Waters.

The Erie Railroad was particularly fortunate in having a force of about 6,000 men at work on the double tracking of the main line in the immediate vicinity of the flooded district. This accounts for the promptness with which the repairs were made. On April 1 it was said at the offices of the company that as far as was known not a single car or locomotive had left the tracks. Passengers on this company's trains did not suffer very serious inconveniences, as all the longer stops were made at large towns.

NEW YORK CENTRAL LINES.

The line to Chicago via the Lake Shore & Michigan Southern was never closed and a large amount of traffic from foreign roads moved over it. The main line of the Cleveland, Cincinnati, Chicago & St. Louis was closed by the destruction of bridges and by serious washouts. Traffic will not be moved over it for several days, as heavy repairs are necessary. A break at Covington, Ind., was repaired on March 31, and since then traffic has moved from St. Louis via Paris, Ind., Danville, Ill., Indianapolis, Bellefontaine, Ohio, and Cleveland. Beginning March 30 a route to St. Louis was available via the C. C. C. &

St. L. to Louisville, Ky., and thence over the tracks of the Louisville & Nashville. The most serious break in the main line was the destruction of a big bridge over the Wabash at Terre Haute, Ind. This bridge was expected to be repaired by April 3. The line from Indianapolis to Chicago via Lafayette and Kankakee was closed for only a short time, and during the interval trains moved via Anderson and Elkhart to Chicago. Dayton was cut off by the destruction of two spans of the bridge over the Miami river at that point. When this bridge collapsed several freight cars fell into the river. Cincinnati was cut off by its destruction and by the fall of another bridge at Shelbyville, Ind. On April 1 connection was established to Springfield via Columbus. Cairo is cut off by heavy floods south of Lawrenceville. On April 1 access was had to all other main points on the C. C. C. & St. L., except Dayton, Cincinnati and Shelbyville. A considerable number of cars and locomotives were overturned on the tracks of this company between Springfield and Cincinnati.

By Monday the situation on the Big Four had been greatly improved and passenger service was being operated between Chicago and Indianapolis, Indianapolis and Cleveland, Cleveland and Columbus, Toledo and Springfield, Mount Carmel, Ill., and North Cairo, Ill., and on several other lines on which service had been suspended last week.

Connection was established on April 1, between Lima and Dayton via the Cincinnati, Hamilton & Dayton. The Lake Erie & Western suffered only slightly, and on April 1, was open at all points except at Cicero, Ind. This break cut off the road's approach to Indianapolis over its own tracks, but it was expected that it would be repaired by April 2.

The damage done in New York state was not so serious. A bad washout at Castleton, about three miles south of Albany, made it necessary to run from New York to Albany over the Harlem division and the Boston & Albany. This break was repaired on March 30. High water in the Mohawk valley caused delays and obliged the traffic to move over circuitous routes. Since March 30 all trains between New York and Chicago have followed their regular schedules and have been subjected to only minor delays.

The eastbound Buffalo express of the New York Central, running at about 30 miles an hour, was derailed at Yosts, N. Y., on the morning of March 30, at 2:40 o'clock, and eight sleeping cars fell down the bank at the right of the roadway, two of them lodging partly in the swollen waters of the Mohawk river. The engine and first three cars passed over in safety. Only six persons were injured, and these were not very seriously. The track had been weakened by the high water, though another train had passed over it in safety only fifteen minutes prior to the accident. The cars were of steel and their bodies were little damaged.

OTHER LINES.

The Chicago, Indianapolis & Louisville was blocked by a washout on the Wabash river north of Lafayette, Ind., and by the loss of bridges at this point and at Indianapolis, and all trains, except for short distances out of Chicago, were annulled until Saturday. The Chicago & Eastern Illinois suffered most from the floods in the vicinity of Terre Haute. Service from Chicago to the south via Terre Haute and Evansville, was discontinued for several days, but trains were being operated on Monday into Terre Haute via Momence and Brazil, Ind., and service was offered to Clinton, Ind., on partial schedules. A [illegible] the Wabash near Vincennes was washed out.

The Wabash line from Chicago east was free from interruptions, but on the through line from St. Louis to the east the floods in the Wabash valley resulted in tracks being washed [illegible] Fort Wayne.

[illegible] that have been opened since the flood began [illegible] pressure has been exerted by the railways to hasten the [illegible] supplies to the people driven from their [illegible] have been asked, both by the railways and by the express companies, announcing that such supplies will be carried free when directed to properly constituted relief authorities.

The floods in the lower Ohio and the Mississippi rivers now threaten great damage. At Cairo railway traffic is already completely blocked, with a prospect of a long suspension. The height of the river on Wednesday was 54.4 ft., the highest on record, and two-thirds of the population had left the city. The Illinois Central arranged to take passengers from Chicago to Memphis by way of Thebes and the Frisco road.

PRINCIPLES OF ELECTRIC RAILROADING.*

By C. L. de Muralt,
Professor of Electrical Engineering, University of Michigan.

I.

If we go over the list of American railroads that have thus far installed electricity as motive power on any part of their lines, we find that in almost every case the installation was planned and carried through by one of the large electric manufacturing companies. Very few individual engineers seem to possess today sufficient knowledge to design and execute work of this kind. Yet, the intricacies of the problem are after all not any greater than those connected with many another railroad question. It is my firm belief that the average man, who applies himself to the solution of these difficulties, will readily be able to get a thorough understanding of all the factors that enter into the problem. The same man, who now has to decide whether the traffic capacity of a certain division had better be increased by grade reduction or by the purchase of heavier locomotives, must be able to say whether or not electricity is advantageous for the operation of any of his lines.

To show how simple the matter really is, will be the object of this series of articles. We will first review some of the fundamental laws that underlie all propulsion of trains on tracks, by steam as well as by electricity. Then we will show how those laws affect the technical as well as the financial side of electrification. In other words we will endeavor to establish under what conditions electricity may be used advantageously as motive power in place of steam, and under what other conditions it will not pay to do so. Finally we will determine what are the advantages and disadvantages of the various types of electric locomotives now on the market and will try to find out what are the specific operating characteristics of each.

INTRODUCTORY.

The movement of all railroad trains is influenced by what might be termed three great natural forces, namely:

(1) Inertia, or the force of the mass, which tends to maintain the status quo and opposes any change in speed. This force tends to prevent the starting of a train from rest, and likewise also the stopping of a train from full speed.

(2) Gravity, or the force which tends to make all bodies get as near the center of the earth as possible. This force opposes the running of a train up a grade or away from the center of the earth, but it helps a train on the down grade or towards the center of the earth.

(3) Friction, or the force which opposes the motion of two bodies in contact with one another. In the case of a train, friction shows itself mainly in three forms, i. e., bearing friction, friction between wheels and rails, and friction between train and surrounding air.

To move any train we must supply an outside force of sufficient magnitude to overcome the combined influence of these three natural forces. To start the train from rest we must use up a certain amount of energy to overcome the inertia and to impart momentum to the train. As the train starts we must supply additional energy to overcome bearing, rail and wind friction. If a grade is to be taken, still more energy must be

furnished to lift the train against the action of gravity. This latter, however, may be liberated again if the train later on runs down the same grade or a grade of similar magnitude. Finally, if we want to stop the train, we generally turn the stored up momentum into heat by the application of the brakes.

All this is perfectly plain, and the difficulty begins only when we try to get at the actual value of the various forces which have to be overcome; in other words, when we try to estimate the power which must be put into a given locomotive so that it will be able to perform a certain specific service. Even this is not so very difficult. At least it is possible to get these values with sufficient accuracy for all practical purposes. With our present knowledge of the art we may even undertake to guarantee that a certain service can be performed by the use of a certain amount of coal or a certain amount of electricity, as the case may be, after having made due allowances of course for variations in the weather and in the human element which enters into this problem due to the presence of the enginemen in the cab. In fact, contracts of this kind have already been made in several instances, and the estimated figures were checked with surprising accuracy by the figures obtained in actual service.

Before taking up a detailed discussion of the effect of each of these three forces upon the movement of the train it may be well to point out that their relative importance varies with the different kinds of railroad service. For instance, in suburban service we find inertia to be by far the most important force to be taken into consideration. It is almost altogether a problem of putting sufficient energy into the train to make a quick start and bring it up to full speed within the shortest possible time. Then, soon after full speed is reached, power is shut off, there is a little period of coasting, and then the brakes are applied and the train brought to a standstill again as quickly as possible. Gravity seldom enters into the calculation to any material extent because there are seldom any serious grades to overcome. And even friction, though present of course, is insignificant in amount as compared with inertia.

In long distance service, on the other hand, we find the influence of inertia of comparatively little importance. It is true that a certain amount of energy has to be spent to get the train under way, but when it is once started, the train is kept going at a steady speed for so long a time that the amount expended to overcome friction gets to be very much greater than that expended to overcome inertia.

In mountain service, or in any other heavy grade proposition, gravity is of course the ruling force, compared with which the other two become insignificant. It is interesting to note in this connection that, whenever means are employed to regain or recuperate the energy which is liberated by the trains on the down grade, the efficiency of this kind of service may be very much improved. This is not feasible with steam operation, but with electricity it may readily be done, and any one interested in this particular aspect of the problem might investigate what has been accomplished by the Italian State Railways on that part of their system known as the Giovi line, near Genoa. By a judicious use of a particular type of electric motor well suited for returning energy to the line on down grades, the coal consumption has been reduced in this instance by from 48 to 62 per cent.

We see therefore that these natural forces are not always to be looked upon as a hindrance to the movement of the trains. Gravity may be a help or a hindrance according to circumstances. Even inertia may be useful under certain conditions. Friction, alone, will always be an opposing force. Before any serious electrification work can be undertaken, it is necessary to calculate as closely as possible the influence of these three forces upon the movement of traffic over the given division or divisions, and in the next few articles we propose going into this matter somewhat in detail in order to show how these influences may be evaluated, and how from their evaluation we may get a very close estimate of the feasibility or non-feasibility of electric traction in any particular instance.

General News.

The government has filed suit against the receivers of the Wabash to recover $3,000 in penalties for alleged violations of the hours of service law.

The Chicago, Burlington & Quincy has announced that the installation of its telephone train despatching system between St. Louis and Burlington will be completed by June 1.

The new member of the Interstate Commerce Commission is named Marble. The railroads, we think, will find that he has his heart in his work.—*Philadelphia North American.*

The Western Maryland has ordered from the Western Electric Company apparatus for a telephone line to be used for train despatching between Hagerstown, Md., and Cumberland, 80 miles.

After several months of negotiations the Queen & Crescent Route has announced an increase in pay of 8 per cent. for its telegraph operators, levermen and station agents. About 400 men will be affected.

The Chicago & Alton has issued an order to all employees, directing them to take places in the smoking car when traveling in the service of the company whenever necessary, in order not to crowd out paying passengers.

The executive committee of the Chicago Association of Commerce has adopted a resolution expressing the opinion that the enactment of the full crew bill now pending in the Illinois legislature would place upon the railways an unfair burden.

The full crew law of New Jersey is noticed below. That of New York is reported on another page. The full crew bill passed by the legislature of Oklahoma, and noticed in last week's issue, was not approved by the governor, and will not become a law.

The Cleveland, Cincinnati, Chicago & St. Louis has increased the length of track-maintenance sections on its lines in central Illinois from seven to ten miles. The forces allotted to each section will be increased, and each gang will have a gasoline motor car.

The Canadian Pacific has increased the pay of locomotive enginemen on the lines east of Cartier, Ont., 10 per cent. On the lines west of Cartier and east of Fort William a small increase has been granted to enginemen on passenger trains and work trains.

Flying from Juterbog to Ploen, Germany, March 31, two officers of the German army remained in the air six hours and nine minutes, flying between these two points, a distance of 372 miles, without a stop. This is the longest distance ever traversed by two persons in an aeroplane.

The Department of Agriculture reports that in the five years preceding March, 1912, the office of public roads of the department built 215 object-lesson roads; in all about 300 miles of road 15 ft. wide, and by expert advice aided in the formulation of more than 650 model county road systems. It has also assisted 26 states in effecting equitable state-aid plans.

Representatives of the legal department of the Chicago, Burlington & Quincy, Missouri, Kansas & Texas, Atchison, Topeka & Santa Fe, and Chicago, Rock Island & Pacific, appeared before the governor of Missouri last week and urged him not to sign the bill just passed by the legislature requiring all foreign railroad corporations either to incorporate under the laws of Missouri, or to cease doing business in the state.

Among the first contributions received for the relief of the sufferers in the storm at Omaha on March 23, were $5,000 checks sent by H. U. Mudge, president of the Chicago, Rock Island & Pacific; W. A. Gardner, president of the Chicago & North Western; A. L. Mohler, president of the Union Pacific, and Darius Miller, president of the Chicago, Burlington & Quincy, on behalf of their respective companies.

New Jersey again takes her place as the banner state in the march of progress; the state in which the legislator and the labor leader most successfully combine to evolve new and valuable schemes for promoting the safety of the public. Assemblyman Arthur F. McGrath, of Jersey City, in bill No. 627, proposes

that the state shall prohibit a railroad from testing the diligence of its enginemen and firemen in the observance of signals. This bill provides that, in cases where tests of apparatus are to be made in the operation of trains, the railroad company shall give previous notice, in writing, to the engineman! In other words, surprise checking will become a crime.

The board of arbitration appointed several months ago to decide on the application of the employees of the Chicago surface street railways for an advance in wages, has rendered a decision allowing an increase in the maximum scale for carmen of two cents an hour under a graduated scale, in accordance with the length of service, ranging from 23 cents an hour for the first three months, to 32 cents for the sixth year. The figures in the scale awarded by the board correspond exactly with the amounts offered by the companies previous to the arbitration, with the exception that 32 cents, instead of 31 cents is allowed for the sixth year.

The Baldwin Locomotive Works, Philadelphia, in carrying freight between its shops in the city and those at Eddystone, 13 miles south of the city, seems to be independent of the locomotive. With ten five-ton Saurer gasolene trucks, a great part of the articles which have to be sent from one shop to the other are taken from the storehouse at the starting point and delivered at the door at the other end, with but one loading, and usually in a good deal less than two hours. All of the ten trucks are used most of the time in making regular trips, two round trips a day. Each truck when in regular use makes about 60 miles a day, and the cost of operation is twelve dollars per twelve-hour day; or, assuming full loads on each trip, four cents per ton per mile.

The legislature of Connecticut passed an act recently requiring all railroad ticket agents to issue free tickets for the members of the legislature at any time when they might wish to attend any meeting of the senate or house of representatives, or of a committee. Governor Baldwin promptly vetoed the bill; and the lower house, in acting on the motion to repass the bill, notwithstanding the objections of the governor, was able to muster only 39 votes in its favor, compared with 154 voting nay. The governor told the legislators that in his judgment they could not require a common carrier to carry them free, any more than they could require an inn-keeper to entertain members of the legislature free. Governor Baldwin reviewed the attempts of the legislators in past years to get around the constitutional provision forbidding anything of this kind, and he showed that definite but unsuccessful action looking to the removal of the constitutional limitation had been taken in 1885, 1889, 1891, 1893, 1895, 1902, 1903, 1905 and 1907. What a persistent idea!

Full Crew Law in New Jersey.

Governor Fielder of New Jersey on April 1 signed the full crew bill of that state; and New York, New Jersey and Pennsylvania now have substantially the same law. The New Jersey law goes into effect in thirty days. The presidents of the principal railroads appeared before the governor of New Jersey, as had been done in New York, and George A. Post, president of the Railway Business Association, also appeared. President Rea of the Pennsylvania told Governor Fielder that unless there was a halt in this kind of legislation, the railroads would be driven to support government ownership of railroads. Full crew bills and grade crossing bills are hurting the credit of the railroads, so that it has become increasingly difficult to raise money for improvements.

Railway Employees to Lose Free Transportation?

A full crew bill is pending in the legislature of Colorado. The general managers of the Colorado lines at a recent conference agreed that if this bill were passed they would issue an order preventing the further issuance of free transportation to the families of railroad employees and to employees themselves except when traveling on the business of the company. The reason taken by the general managers in interviews is that full crew legislation is promoted by the employees, that it tends to increase the operating expenses of the companies, that in order to meet these increased expenses they must make savings in other directions, and that the most feasible way to make them seems to be to curtail free transportation as indicated.

The action of the general managers of the Colorado lines has attracted attention and is the subject of consideration elsewhere. The president of one of the large roads entering Chicago has made the following statement:

"The action of the Colorado lines has, of course, been discussed by railway executive officers in Chicago. The full crew legislation which is being so generally passed is promoted by railway employees. Its effect is to make it necessary to employ more men and thereby to increase operating expenses, and it is deemed by railroad officers to be unnecessary and burdensome. Such laws require that an extra man be provided in the crew of a train for whose employment there is no need either for safety or good service. The net revenues of most railways are not large enough to justify increases in expenses in some directions which are not accompanied by reductions in expenses in other directions. Various means of offsetting the increases in expenses caused by full crew legislation have been considered. The elimination of the issuance of free transportation to employees seems the most feasible and satisfactory method of meeting the situation. There are 1,700,000 railway employees in the United States. There are about five people in the average family, and assuming that each employee represents a family, they represent a total of 8,500,000 people to whom free transportation is now freely given, or about 9 per cent. of the population of the country. It is given to them not only by the lines on which those who request it are employed, but for travel on railway lines throughout the United States. The total cost to the railways of this free transportation is very large and a corresponding saving could be made by withdrawing it. It is issued entirely as a favor to the employees and is seldom or never considered by them in their demands regarding wages and conditions of work. As a class railway employees are very well paid, and therefore do not need free transportation any more than any other class of people. The railway managers would withdraw free transportation from them very reluctantly and would not do so as a matter of retaliation, but merely as a matter of business necessity. However, since the organizations of employees are the principal promoters of full crew legislation it would be simple justice that the necessary economy should be effected by withdrawing free transportation from them rather than by the adoption of some means which would affect other travelers and shippers."

The Ne Plus Ultra of Safety Regulation!

According to press despatches a bill is pending in the Kansas legislature to "regulate the movement" of trains at crossings. "When two trains approach a crossing," says the bill, "both shall stop, and neither shall go ahead until the other has passed by."

An Official Hint.

There are some few agents who still sell tickets to the nearest junction point and instruct passengers to repurchase there. These men are gradually being weeded out. An agent who will not take the trouble to sell a passenger through to destination should get out of the business, as he has no future—*L. & N. Passenger Bulletin.*

Railway Legislation.

The Keckley bill to reduce intrastate freight rates in Nebraska by 20 per cent. has been defeated in the house by a vote of 48 to 46.

The attorney general of Texas has drafted a bill to be introduced in the legislature, providing that when a foreign corporation acquires the ownership of a domestic road, the stock shall be placed in the hands of trustees of the bondholders of the domestic company, and these trustees shall operate the company entirely independent of the foreign corporation that owns it. The railroad commission is authorized to make periodical examinations of the records of the company.

A Government Scale Testing Car.

The Bureau of Standards, Department of Commerce and Labor, utilizing an appropriation of $25,000 which has been made by Congress for use in the next fiscal year, beginning July 1, will extend the scope of its investigation of scales in railroad

yards, grain elevators and other places where interstate traffic is handled, and will have built a test car. This car will not itself be used as a weight, but will carry movable weights, which will be used for testing. It is proposed to have the car carry a number of standard weights of 10,000 lbs. each and a large number of 50-lb. weights. A truck, capable of carrying 50 tons, will be carried on the car to be used for moving the standard weights, in testing scales. The car will be equipped with a crane for lifting the truck and the heavy weights.

S. W. Stratton, director of the bureau, says that officers of railroad terminals and of elevators have shown much interest in the activities of the bureau. Several state commissions of weights and measures are also asking for the car. The bureau will probably co-operate with the Interstate Commerce Commission in the investigation of alleged irregularities in weighing, and the car can be used, of course, to secure information as to the accuracy of shippers' scales, as well as those of railways.

Absurd Valuation Theories.

Estimates of losses to the railroads, caused by the floods, are necessarily only guess-work as yet. The highest figures do not seem unreasonable when one remembers the number of bridges destroyed, the miles of track washed away, the other physical property wiped out, besides the loss caused by demoralization of train service, delays, extraordinary outlay, and the future diminution of transportation business from the ruined districts. Now, we should like to ask the physical-valuation men what place in their calculations they reserve for such unforeseeable and enormous impairments of railway property. Will they undertake the role of an earthly Providence, and tell the managers just what the average loss will be from disasters of this kind, over a period of years? Or, granting that increased capital expenditure warrants higher freight charges, would they say that the thing for the railways to do would be to impose higher rates at the very moment when the people in the afflicted territory are least able to pay them? Such questions go to the heart of the theory that you can exactly and scientifically determine railroad rates by an exact and scientific physical valuation of railway property. For in the latter there are too many variables to make the process at all a safe guide. This is vividly shown just now in the blow which the railways have received through the floods. But the same thing is shown all the time in a thousand ways, less startling, but no less conclusive against the views of the rigidly doctrinaire railway valuers.—*Evening Post,* New York.

Reminiscences of William Mahl.

When the Supreme Court decreed that the Union Pacific should relinquish control of the Southern Pacific, one of the most troublesome problems was the question as to which road should have the men who had occupied positions of joint responsibility. In the realinement there was no doubt as to the disposition of William Mahl, who worked at Harriman's right hand for the ten most active years of the financier's life. The controller of the Union Pacific-Southern Pacific system had handled the accounts of the Huntington road for more than thirty years, and he at once elected to go with Kruttschnitt and his other old associates. Mr. Mahl has been in active railroad service for more than half a century. He is a quiet-spoken, unassuming man.

"I have had great opportunities for learning," he said. "I have worked side by side with some of the greatest railroad builders in history. There was Albert Fink of the Louisville & Nashville; Col. Scott, of the Texas & Pacific; Collis P. Huntington, who I believe built more miles of road than any other American, and Edward H. Harriman. Huntington never built a line that went into a receivership. He bought into roads that had their financial troubles, but I don't believe that any one who shared his faith and stayed with him ever lost money on one of his ventures. Huntington had wonderful patience in waiting for results."

Mr. Mahl began with the Louisville & Nashville in 1860.

"We had way bills for passengers then. When the train was ready to start the conductor was handed a sheet naming the passengers intrusted to him. 'Mrs. Smith and children, Elsie and Frank, from Lexington to Midwood,' etc., and on a separate sheet 'one colored man, from Lexington to Frankfort.' The passenger cars were heated by round stoves, near which was piled cordwood. If the car was not warm enough for a traveler he threw on more wood. When a car was wrecked the fire poured out on the floor and the car went up quickly in flames. I remember the pleasurable excitement that followed the invention of a jacketed stove called Spear's Anti-Fire Heater. This used coal and the fire door locked, so that the stove could be stood on end without setting the car afire. When steam was introduced into the cars we paid $500 for apparatus that we bought after the patents expired, for $90. Most of my mementos were destroyed in the Equitable fire. I had a printed sheet saved from those days with this notice in bold type: 'Any shipment over eight tons will be charged double first-class rates.' You see, 16,000 lbs. was a car's capacity.

"The Louisville & Frankfort was started with a standard gage track. In the war this was changed to 5 ft., then back to 4 ft. 8½ in. To carry out a traffic arrangement the line was afterward changed to 5 ft. again, and then back to standard gage. We got so we could shift almost an entire line of rails simultaneously, dropping the spikes back into their old holes (!) It was comparatively easy to shorten the axles of cars and engines, but it bothered us sometimes to lengthen them.—*New York Times.*

The Pere Marquette Investigation.

Testifying before the legislative committee which is investigating the Pere Marquette at Detroit, F. W. Stevens, formerly general counsel of the road, on March 24, read into the record a statement of his views as to what should be done to improve the situation of the road. He said it will be a good thing for Michigan if the road is able, during the next ten years, to make such additions and improvements as the development of the state makes desirable; that in order for it to issue the necessary securities it is vital that investors should not be deterred by fears of a hostile attitude on the part of public authorities.

He therefore advocated a repeal of the state 2-cent fare law, which he said had cost the road $3,000,000 in five years, and the passage of a new law which will recognize the difference between passenger business in sparsely settled communities and in more populous sections; a radical change in the policy of the state as to railway regulation; and the defeat of bills now pending in the legislature which would increase the expenses of the road by $800,000 per year. He also said that the nature of the report made by the committee at the conclusion of the investigation would have an important effect on the credit of the road.

On March 25, J. L. Cramer, comptroller, was questioned at length regarding various accounts.

S. M. Felton, president of the Pere Marquette and of the Chicago Great Western, testified before the committee on March 26. He said that the combination of the Pere Marquette and the Cincinnati, Hamilton & Dayton in 1904 was unwise, and the acquisition of the Chicago, Cincinnati & Louisville a positive detriment to the Pere Marquette. As to the branches now operated, he had not yet formed a conclusion as to all, but knew that some do not pay. He considered the extension of the line to Chicago a wise move. After having been appointed receiver he had spent a great deal of time familiarizing himself with the condition of the road. At that time the roadway and track were not in good condition, but they have since been improved. The condition of the rolling stock was better, and as soon as the money can be raised additional equipment will be obtained. An effort is now being made to get more work out of the motive power.

Testifying before the committee on the following day, Mr. Felton announced that among the improvements contemplated by the receivers to increase the efficiency of the Pere Marquette are: The laying of 25,000 tons of new rails; the installation of automatic block signals; the building of a new freight terminal at Grand Rapids; grade reductions west of Plymouth; the building of double track Delray to Plymouth; the provision of additional facilities at Grand Rapids and a new freight terminal at Porter, Ind. Mr. Felton would not hazard an estimate as to the cost of putting the road in condition to meet the demands of traffic, nor an opinion as to whether it would ever pay dividends. He said the gross earnings for the fiscal year ending June 30, 1913, were estimated at $18,000,000, compared with $17,160,000 in 1912. He would not make any forecast

of the operating expenses, but said that the state of Michigan had increased taxes more than other states, and that the 2-cent fare law had had a serious effect on the company's earnings. In the period from 1903 to 1907, before the 2-cent law went into effect, the average fare paid per passenger was 75.7 cents. In the period from 1907 to 1912, after the law went into effect, the average fare per passenger was 66.7 cents. Mr. Pelton said that two cents is not enough to pay for the luxuries in travel that the public wants. To illustrate further the situation of the road, he cited figures showing the average freight rate per ton mile, and the freight density for a number of roads, to show that while the average rate is about the same, the traffic density is much greater on the other roads, as follows:

Average freight rate per ton mile.	Road.	Tons moved one mile per mile of road.
6.4 mills	Pere Marquette	757,000
6.1 mills	Illinois Central	1,373,739
6.76 mills	Michigan Central	1,673,590
6.26 mills	New York Central	2,753,318
5.8 mills	Baltimore & Ohio	2,803,648

Report on Collision at Lockport, N. Y.

The Interstate Commerce Commission has issued a report by Inspector Belnap, dated March 14, giving the causes of a rear collision on the International (electric) Railway near Lockport, N. Y., January 25, about 2 a. m. One passenger and one employee were killed, the employee being the motorman of the passenger train, who is held at fault for the collision. The freight had stopped to set out some cars, and, as it was known that the passenger train, an extra, was following, had sent back a flagman. The passenger train came on at full speed, and, disregarding the red light of the flagman, ran into the rear of the standing freight, making a very bad wreck. The passenger train was an extra, which had taken a party of "Eagles" to a "smoker" at Buffalo; and the conductor and motorman being members of, or interested in the "Eagles" attended the smoker and drank some beer; at least two bottles apiece. The motorman had been on duty, off and on, since six o'clock the morning before; and although he had not worked sixteen hours altogether, within the twenty-four hour period, it is believed that he was sleeping in his cab, or at least that the lack of rest, combined with the influence of the beer, had made him oblivious to the red light of the flagman. The motorman having been killed, a chemical analysis was made of his stomach, and this revealed the presence of alcohol. Mr. Belnap says that it is bad practice for any person connected with the operation of a railroad to indulge in intoxicating liquors at any time. He also says that the rules should require the use of torpedoes by flagmen under all conditions. On this road torpedoes are required to be used only in case of fog or storm.

The Pullman-Car Porter.

Lemuel, our porter, is about 50, solid, round, smiling and black, as black can be. It was his proverbial good nature that invited intimacy, and as he blacked away at the shoes I got from him the outlines of the story of the day's work:

"I live on West Twenty-sixth street, New York City. I must be on duty at Hoboken at 6.30 p. m. My train leaves at 9 p. m., but I must have my car all ready, with half the berths made up. My run ends at 9 in the morning. After that I must clean and dust my car, change the linen, and make up about 10 berths so as to be ready at night. It is noon when I am done. Then I get my breakfast, I have the afternoon to myself. I go to bed somewhere. I must be at the car at sunset before 9 in the evening. The train leaves at 9.15. It reaches New York about 8 in the morning. Then I must clean and put up my car, change the linen, cross the river to my home on Twenty-sixth street, shave, wash off this Pullman dirt, get my breakfast and then go to bed. I make eight of these round-trips one night out and the next night back. Then I am supposed to have one-round trip off. I do not get more than one-half these lay-offs, because so often there is no one to take my place. I have been on this run for 13 years. It is 650 miles round trip. I get over four hours' sleep every day, besides the naps I catch on the way."

Of course those of us who travel with Lemuel and know him piece out his stipend by practical appreciation of his kindness and faithfulness. But it is the man and the corporation that loom before us whenever we think of his shiny black face. Why worry about him when he does not seem to worry about himself? But he is a man, a real gentleman. He is industrious, sober, kind. He seems to act so like all true folk that some of us who know a brother human when we meet him cannot be indifferent to his long, long days of unillumined, uninspiring grind. . . . He knows how to get along with nervous women and boorish men. But why in the name of all that is rich and reasonable in our civilization need we overwork and underpay Lemuel? Why should we scrimp his sleep to four hours in 24, with a few cat-naps thrown in?—*The Universalist Leader.*

American Sleeping Cars.

Perhaps if enough respectable English critics will consent to come over here and inspect our sleeping cars and then go back home to write of their discomforts, their shocking lack of privacy, their immodesty, and so on, we shall the sooner see that the critics are perfectly right. No one of intelligence that we have ever heard of defends the American sleeping car. And yet the sleeper trundles stuffily on, mingling the breathings of the inmates, re-echoing the snores of the few who are able to sleep at all, revealing all stages of deshabille that in any other circumstances would be blushed for, and causing unanimous curses. The Pullman people go on doggedly building sleepers that no other country would dream of using, and the railroads go on permitting such cars to be run in their night trains. We know of no other defiance of public sentiment to compare with this. —*Lowell Courier-Citizen.*

MEETINGS AND CONVENTIONS.

The following list gives names of secretaries, dates of next or regular meetings, and places of meeting.

Air Brake Association.—F. M. Nellis, 53 State St., Boston, Mass. Convention, May 6-9, St. Louis, Mo.

American Association of Demurrage Officers.—A. G. Thomason, Boston, Mass. Convention, May 20, Chicago.

American Association of General Passenger and Ticket Agents.—W. C. Hope, New York.

American Association of Freight Agents.—R. O. Wells, East St. Louis, Ill. Annual meeting, June 17-20, Buffalo, N. Y.

American Association of Railroad Superintendents.—E. H. Harman, St. Louis, Mo.; 3d Friday of March and September.

American Electric Railway Association.—H. C. Donecker, 29 W. 39th St., New York.

American Electric Railway Manufacturers' Assoc.—George Keegan, 165 Broadway, New York. Meetings with Am. Elec. Ry. Assoc.

American Railway Association.—W. F. Allen, 75 Church St., New York. Next meeting, May 21, New York.

American Railway Bridge and Building Association.—C. A. Lichty, C. & N. W., Chicago. Convention, October 21-23, 1913, Montreal.

American Railway Engineering Association.—E. H. Fritch, 900 S. Michigan Ave., Chicago.

American Railway Master Mechanics' Association.—J. W. Taylor, Old Colony building, Chicago. Convention, June 11-13, Atlantic City, N. J.

American Railway Tool Foremen's Association.—A. R. Davis, Central of Georgia, Macon, Ga.

American Society for Testing Materials.—Prof. E. Marburg, University of Pennsylvania, Philadelphia, Pa.; annual, June, 1913.

American Society of Civil Engineers.—C. W. Hunt, 220 W. 57th St., New York; 1st and 3d Wed., except June and August, New York.

American Society of Engineering Contractors.—J. R. Wemlinger, 11 Broadway, New York; 2d Tuesday of each month, New York.

American Society of Mechanical Engineers.—Calvin W. Rice, 29 W. 39th St., New York.

American Wood Preservers' Association.—F. J. Angier, B. & O., Baltimore, Md. Next convention, January 20-22, 1914, New Orleans, La.

Association of American Railway Accounting Officers.—C. G. Phillips, 143 Dearborn St., Chicago. Annual meeting, May 28, Atlantic City, N. J.

Association of Railway Claim Agents.—J. R. McSherry, C. & E. I., Chicago. Next meeting, May, 1913, Baltimore, Md.

Association of Railway Electrical Engineers.—Jos. A. Andreucetti, C. & N. W. Ry., Chicago. Semi-annual meeting, June, 1913, Atlantic City, N. J.

Association of Railway Telegraph Superintendents.—P. W. Drew, 112 West Adams St., Chicago; annual, May 20, 1913, St. Louis, Mo.

Association of Transportation and Car Accounting Officers.—G. P. Conard, 75 Church St., New York.

Association of Water Line Accounting Officers.—W. R. Evans, Chamber of Commerce, Buffalo, N. Y. Annual meeting, October 8, Philadelphia, Pa.

Bridge and Building Supply Men's Association.—H. A. Neally, Joseph Dixon Crucible Co., Jersey City, N. J. Meeting with American Railway Bridge and Building Association.

Canadian Railway Club.—James Powell, Grand Trunk Ry., Montreal, Que., 2d Tuesday in month, except June, July and Aug., Montreal.

Canadian Society of Civil Engineers.—Clement H. McLeod, 413 Dorchester St., Montreal, Que.; Thursday, Montreal.

Car Foremen's Association of Chicago.—Aaron Kline, 841 North 50th Court, Chicago; 2d Monday in month, Chicago.

Central Railway Club.—H. D. Vought, 95 Liberty St., New York; 2d Thurs. in Jan. and 2d Fri. in March, May, Sept., Nov., Buffalo, N. Y.

Civil Engineers' Society of St. Paul.—L. S. Pomeroy, Old State Capitol building, St. Paul, Minn.; 2d Monday, except June, July, August and September, St. Paul.

Engineers' Society of Pennsylvania.—E. R. Dasher, Box 704, Harrisburg, Pa.; 1st Monday after 2d Saturday, Harrisburg, Pa.

Engineers' Society of Western Pennsylvania.—E. K. Hiles, Oliver building, Pittsburgh; 1st and 3d Tuesday, Pittsburgh, Pa.

Freight Claim Association.—Warren P. Taylor, Richmond, Va. Next convention, June 18, Bluff Point, N. Y.

General Superintendents' Association of Chicago.—E. S. Koller, 226 W. Adams St., Chicago; Wed. preceding 3d Thurs., Chicago.

International Railway Congress.—Executive Committee, 11, rue de Louvain, Brussels, Belgium. Convention, 1915, Berlin.

International Railway Fuel Association.—C. G. Hall, 922 McCormick building, Chicago. Annual meeting, May 21-24, Chicago.

International Railway General Foremen's Association.—Wm. Hall, 829 West Broadway, Winona, Minn. Next convention, July 22-25, Chicago.

International Railroad Master Blacksmiths' Association.—A. L. Woodworth, Lima, Ohio. Annual meeting, August 18, Richmond, Va.

Maintenance of Way Master Painters' Association of the United States and Canada.—W. G. Wilson, Lehigh Valley, Easton, Pa.

Master Boiler Makers' Association.—Harry D. Vought, 95 Liberty St., New York. Convention, May 26-29, 1913, Chicago.

Master Car Builders' Association.—J. W. Taylor, Old Colony building, Chicago. Convention, June 16-18, Atlantic City, N. J.

Master Car and Locomotive Painters' Assoc. of U. S. and Canada.—A. P. Dane, B. & M., Reading, Mass. Annual meeting, September 9-12, Ottawa, Can.

National Railway Appliance Assoc.—Bruce V. Crandall, 537 So. Dearborn St., Chicago. Meetings with Am. Ry. Eng. Assoc.

New England Railroad Club.—W. E. Cade, Jr., 683 Atlantic Ave., Boston, Mass.; 2d Tuesday in month, except June, July, Aug. and Sept., Boston.

New York Railroad Club.—H. D. Vought, 95 Liberty St., New York; 3d Friday in month, except June, July and August, New York.

Northern Railroad Club.—C. L. Kennedy, C., M. & St. P., Duluth, Minn.; 4th Saturday, Duluth.

Peoria Association of Railroad Officers.—M. W. Rotchford, Union Station, Peoria, Ill.; 2d Thursday.

Railroad Club of Kansas City.—C. Manlove, 1008 Walnut St., Kansas City, Mo.; 3d Friday in month, Kansas City.

Railway Business Association.—Frank W. Noxom, 2 Rector St., New York. Annual dinner, second week in December, 1913, New York.

Railway Club of Pittsburgh.—J. B. Anderson, Penna. R. R., Pittsburgh, Pa.; 4th Friday in month, except June, July and August, Pittsburgh.

Railway Electrical Supply Manufacturers' Assoc.—J. Scribner, 1021 Monadnock Block, Chicago. Meetings with Assoc. Ry. Elec. Engrs.

Railway Gardening Association.—J. S. Butterfield, Lee's Summit, Mo. Next meeting, August 12-15, Nashville, Tenn.

Railway Development Association.—W. Nicholson, Kansas City, Southern, Kansas City, Mo.

Railway Signal Association.—C. C. Rosenberg, Bethlehem, Pa. Meetings, June 10-11, New York; convention, October 14, Nashville, Tenn.

Railway Storekeepers' Association.—J. P. Murphy, Box C, Collinwood, Ohio. Annual convention, May 19-21, Chicago.

Railway Supply Manufacturers' Assoc.—J. D. Conway, 2135 Oliver bldg., Pittsburgh, Pa. Meetings with M. M. and M. C. B. Assoes.

Railway Tel. and Tel. Appliance Assoc.—W. E. Harkness, 284 Pearl St., New York. Meetings with Assoc. of Ry. Teleg. Sups.

Richmond Railroad Club.—F. O. Robinson, Richmond, Va.; 2d Monday except June, July and August.

Roadmasters' and Maintenance of Way Association.—L. C. Ryan, C. & N. W., Sterling, Ill. Convention, September 8-12, 1913, Chicago.

St. Louis Railway Club.—B. W. Frauenthal, Union Station, St. Louis, Mo.; 2d Friday in month, except June, July and Aug., St. Louis.

Signal Appliance Association.—F. W. Edmonds, 3868 Park Ave., New York. Meetings with annual convention Railway Signal Association.

Society of Railway Financial Officers.—C. Nyquist, La Salle St. Station, Chicago.

Southern Association of Car Service Officers.—E. W. Sandwich, A. & W. P. Ry., Montgomery, Ala. Next meeting, April 17, Atlanta, Ga.

Southern & Southwestern Railway Club.—A. J. Merrill, Grant bldg., Atlanta, Ga.; 3d Thurs., Jan., March, May, July, Sept., Nov., Atlanta.

Toledo Transportation Club.—J. G. Macomber, Woolson Spice Co., Toledo, Ohio; 1st Saturday, Toledo.

Track Supply Association.—W. C. Kidd, Ramapo Iron Works, Hillsburn, N. Y. Meeting with Roadmasters' and Maintenance of Way Association.

Traffic Club of Chicago.—Guy S. McCabe, La Salle Hotel, Chicago; meetings monthly, Chicago.

Traffic Club of New York.—C. A. Swope, 290 Broadway, New York; last Tuesday in month, except June, July and August, New York.

Traffic Club of Pittsburgh.—D. L. Wells, Erie, Pittsburgh, Pa.; meetings monthly, Pittsburgh.

Traffic Club of St. Louis.—A. F. Versen, Mercantile Library building, St. Louis, Mo. Annual meeting in November. Noonday meetings October to May.

Train Despatchers' Association of America.—J. F. Mackie, 7042 Stewart Ave., Chicago. Annual meeting, June 17, Los Angeles, Cal.

Transportation Club of Buffalo.—J. M. Sells, Buffalo; first Saturday after first Wednesday.

Transportation Club of Detroit.—W. R. Hurley, L. S. & M. S., Detroit, Mich.; meetings monthly.

Traveling Engineers' Association.—W. O. Thompson, N. Y. C. & H. R., East Buffalo, N. Y. Annual meeting, August, 1913, Chicago.

Utah Society of Engineers.—R. B. Ketchum, University of Utah, Salt Lake City, Utah; 3d Friday of each month, except July and August.

Western Canada Railway Club.—W. H. Rosevear, P. O. Box 1707, Winnipeg, Man.; 2d Monday, except June, July and August, Winnipeg.

Western Railway Club.—J. W. Taylor, Old Colony building, Chicago; 3d Tuesday of each month, except June, July and August.

Western Society of Engineers.—J. H. Warder, 1735 Monadnock block, Chicago; 1st Monday in month, except July and August, Chicago.

Traffic News.

J. D. Brown, assistant general passenger agent of the Erie Railroad, at Cleveland, has counted up the number of students enrolled in four-year courses in the agricultural colleges of Massachusetts, New York, Pennsylvania and ten central states; and he finds that the total number enrolled last year, 6,801, was 22 per cent. greater than the number enrolled in the same colleges in the year preceding.

The number of immigrants (mainly from Europe) arriving in New York harbor during the three months ending March 31, was fifteen per cent. larger than the number arriving during the same quarter of the preceding year, the totals by months being as follows:

	1913.	1912.
January	36 892	30,877
February	50,964	39,890
March (approximate)	89,911	83,608
Total	177,767	154,375

The governor of Maine has appointed two citizens of that state to take part in the "New England railroad conference," the board to represent the six New England states, which was proposed by Governor Foss, of Massachusetts. The appointees are Mr. Emery, formerly chief justice of the state, and Colonel Osgood, of Lewistown.

Governor Felker of New Hampshire, in a special message to the legislature, which body, in connection with the agitation over the proposed Grand Trunk line and proposed measures in relation to the Boston & Maine, has been considering freight rates for a long time past, recommends that the present rates on the roads of that state be legalized for two years, and that, in the meantime, the Public Service Commission, in co-operation with the railroad companies, prepare new tariffs, to be submitted to the legislature in 1915.

The Belt Railway of Chicago announces that arrangements have been perfected for handling less than carload shipments from industries on its rails. Shipments of 10,000 lbs. or more of miscellaneous freight for any number of roads may be loaded into a car at an industry, and will be moved free of charge to a transfer station at Clearing, where they will be transferred into cars for the outbound stations of each of the various roads. Shipments from industries on connecting lines will also be received under the same conditions, and switched free from the junction point of the connecting line to Clearing.

Summary of Revenues and Expenses of Steam Roads in January.

The Bureau of Railway Economics' summary of revenues and expenses and comments thereon for January, 1913, are as follows: The railways whose returns are included in this bulletin operate 220,821 miles of line, or about 90 per cent. of the steam railway mileage of the United States. Total operating revenues for the month of January, 1913, amounted to $241,196,559. Compared with January, 1912, the total operating revenues of these railways show an increase of $37,250,850. These total operating revenues per mile of line amounted to $1,092 in January, 1913, and $933 in January, 1912, an increase of $160, or 17.1 per cent. Freight revenue per mile increased 20.1 per cent., and passenger revenue per mile 10.1 per cent.

Operating expenses amounted in January to $178,405,387. This was $18,883,789 more than for January, 1912. These operating expenses per mile of line amounted to $808 in January, 1913, and $730 in January, 1912, an increase of $78 per mile, or 10.7 per cent. All the five primary operating expense accounts showed increases per mile over 1912.

Net operating revenue amounted in January to $62,791,172. This was $18,367,061 more than for January, 1912. Net operating revenue per mile of line amounted to $284 in January, 1913, and $203 in January, 1912, an increase of $81 per mile.

Taxes for the month of January amounted to $10,116,824, or $46 per mile, an increase of 4.6 per cent. over January, 1912.

Operating income amounted in January to $238 per mile of line, and in January, 1912, to $158. This was an increase of $80, or 50.6 per cent. Operating income for each mile of line for each day in January averaged $8, and for January,

1912, $5. The operating ratio for January was 74.0 per cent., which is comparable with 69.0 per cent. in December, 1912, and 78.2 per cent. in January, 1912.

The railways of the eastern district show an increase in total operating revenues per mile of line as compared with January, 1912, of 17.1 per cent., the railways of the southern district an increase of 16.9 per cent., and the railways of the western district an increase of 17.7 per cent. Operating expenses per mile increased 13.0 per cent. on the eastern railways, 8.4 per cent. on the southern railways, and 9.6 per cent. on the western railways. For the eastern railways net operating revenue per mile increased 32.0 per cent., for the southern railways it increased 47.1 per cent., and for the western railways it increased 46.6 per cent. The increase in taxes per mile was 2.6 per cent. in the eastern district, 7.7 per cent. in the southern district, and 6.2 per cent. in the western district. Operating income per mile increased 40.2 per cent. in the east, 56.1 per cent. in the south, and 60.9 per cent. in the west.

Comparison of the returns for the seven months of the fiscal year with those of the corresponding months of the previous fiscal year reveals an increase in total operating revenues per mile of 10.8 per cent., an increase in operating expenses per mile of 9.5 per cent., and an increase in net operating revenue per mile of 13.6 per cent. This net operating revenue per mile of the eastern railways increased 11.0 per cent as compared with the corresponding period of the previous year, that of the southern railways increased 6.0 per cent., and that of the western railways increased 18.7 per cent.

The diagram shows the variations in operating revenues, operating expenses, and net operating revenue per mile for the separate months of the calendar year 1912 and for January, 1913. The following table shows the per cent. of operating revenues consumed by each class of expenses:

Per Cent of Total Operating Revenues

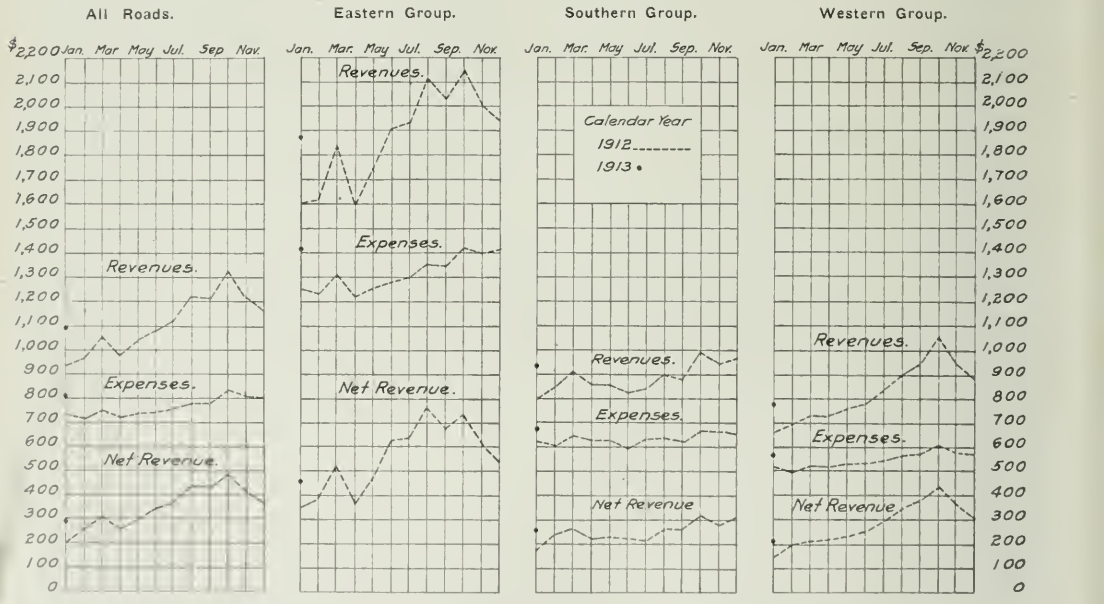
	January		Fiscal year ending		Calendar year ending	
	1913	1912	1912	1911	1911	1911
Maintenance of way and structures	12.3	11.6	12.7	12.9	12.8	12.7
Maintenance of equipment	17.	14.	15.	15.5	16.0	15.7
Traffic expenses	1				2.0	2.1
Transportation expenses	32.	41.0	35.9	35.5	35.8	35.4
General expenses	6	9	5	5	4	5
Total operating expenses	74.0	78.2	69.1	68.6	68.7	68.4

INTERSTATE COMMERCE COMMISSION.

The extensive giving of free passes to shippers, city officers, judges and others by the railroads of Colorado has been investigated by the commission, and Commissioner Harlan, who went to Colorado, says that there was an "orgy of petty graft." He says that the railroads have promised to carry out the wishes of the commission; but it is reported that criminal indictments, against both carriers and shippers have already been returned.

David E. Brown, special examiner, has laid before the Interstate Commerce Commission 147 reports of the work of himself and his assistants in the examination of the accounts of the New York, New Haven & Hartford and its controlled properties. Seventy of these reports deal with the New England Navigation Company and fifteen with Rhode Island Electric lines; eight with the Connecticut Company, and thirteen with the Consolidated Railway Company, which operates electric lines in Connecticut.

The express companies—the Adams, the American, the United States, the Southern and the Wells-Fargo, presented arguments at Washington April 1, against the proposed decreases in rates which have been proposed by the Commission. Walker D. Hines appeared for all five companies. He said that the estimates which had been made by the companies last year, had been wholly upset by the loss of business occasioned by the introduction of the parcel post. During the month of January, the business of the express companies, in packages weighing less than 11 lbs., had fallen off about 18 per cent., and in February about 27 per cent. In February the greatest loss reported was that by the Adams Express, which was 30.5 per cent., and the lowest was that reported by the United States Company, 22.8 per cent. Mr. Hines estimated that if the reduced rates proposed by the commission were applied to all of the present business of the companies, the loss in gross revenue would be $26,000,000 a year. The attorney of the New York Chamber of Commerce attacked Mr. Hines' statement as purely hypothetical, declaring that the present rates are excessive, that the proposed new rates would be reasonable, and that, under the present contracts, the express companies are making excessive allowances to the railroad companies.



Monthly Revenues and Expenses per Mile of Line in 1912 and 1913.

Complaint Dismissed.

Robinson Land & Lumber Company v. Mobile & Ohio. Opinion by the commission.

The commission found that an advance from approximately 4 cents to 5 cents per 100 lbs. in the rate on lumber from Chicora, Miss., to Mobile, Ala., had been justified by the defendants. (26 I. C. C., 427.)

Little Rock Chamber of Commerce v. St. Louis, Iron Mountain & Southern et al. Opinion by the commission:

In this case the complainant contended that the rates on cement from St. Louis, Mo., and from Eagle Ford and Harry's, Tex., to Little Rock, Ark., were unreasonable. From St. Louis, the rate is 17 cents per 100 lbs., and from Eagle Ford and Harry's, 19 cents. The commission found that the evidence was not conclusive. (26 I. C. C., 341.)

St. Louis Blast Furnace Company v. Louisville & Nashville et al.

A. P. DeCamp, as lessee of the St. Louis Blast Company v. Baltimore & Ohio et al. Opinion by Commissioner Meyer:

The complainant contends that the rate of $2.80 per net ton charged for the transportation of coke from points in Virginia, West Virginia and Pennsylvania to Carondelet, Mo., are unreasonable to the extent that they exceed $2.23 per net ton. Reparation is asked. The commission found that the evidence was not conclusive. (26 I. C. C., 355.)

May Brothers et al. v. Yazoo & Mississippi Valley Railroad Company et al. Opinion by Commissioner Clements:

Upon complaint that the provisions in the defendants' tariffs for the application of gross or flat rates on shipments of logs from points on their lines in Mississippi to Memphis, Tenn., and the refund of a portion thereof upon shipment of the products via the lines of either of them, result in unjust and unreasonable charges for the movement of the logs from the forests to Memphis; the commission found that the gross rates were not shown to have been unreasonable. (26 I. C. C., 323.)

Proprietary Association of America v. New York Central & Hudson River et al. Opinion by the commission:

In this complaint the complainant contends that the rates charged for the transportation, between interstate points in official classification territory, of certain printed advertising matter consisting of circulars, pamphlets, almanacs, etc., in less than car load quantities are unreasonable. These articles are rated first-class in less than carloads in official classification, and the complainant asks that they be accorded a fourth class rate. The commission found that the rates complained of were not shown to have been unreasonable. (26 I. C. C., 318.)

American Brake Shoe & Foundry Company v. Alabama Great Southern et al. Opinion by the commission:

Two shipments of brake shoes were transported from Chattanooga, Tenn., to Houston, Tex., on which charges were collected on the joint through carload rate of 30 cents per 100 lbs., minimum weight 40,000 lbs. Under contract between shipper and the Houston & Texas Central, the consignee, the former was to assume the freight charges up to New Orleans, and the benefit is claimed of the less-than-carload rate to that point of 22 cents per 100 lbs. at actual weight. The commission found that the charges had been properly assessed. (26 I. C. C., 446.)

Max O'Buren et al. v. Southern Pacific et al. Opinion by Commissioner McChord:

The complainants contend that certain rates charged by the defendants were invalid because the defendants had not posted them in the stations at the proper time. The commission found that while the posting of tariffs is required by the act and while a failure to post the same may subject the carriers to penalties, the failure to obey the law in this respect does not invalidate the tariff when it has been properly filed with the commission. The commission decided that the rates complained of were legal as the supplements containing them were published and filed with the commission as required by law. (26 I. C. C., 322.)

W. Nelson Edelsten v. Pennsylvania Railroad Company et al. Opinion by the commission:

The complainant purchased a mileage ticket entitling the bearer to 1,000 miles of transportation over the lines of the defendants. This ticket was destroyed by accident after coupons representing 200 miles' travel had been used. The following conditions were printed on the ticket: "If this ticket is lost, mislaid or stolen, it will not be replaced, nor will any refund be made on such account." The defendant refused to refund the value of the unused portion of the mileage book on account of this condition. The commission found that as this ticket was sold at a reduced rate and that the conditions printed on the ticket were not unreasonable the defendant should not be required to make any refund. (26 I. C. C., 359.)

Robertson Paper Company v. Rutland Railroad et al. Opinion by the commission:

Transcontinental rates on plain manila wrapping paper in carloads are 75 cents per 100 lbs.; on the same paper oiled or greased 90 cents; and on waxed paper $1.20. On a petition alleging unreasonableness, and undue prejudice in the rates on oiled, greased, and waxed papers and praying that the 75-cent rate be made applicable on all wrapping papers, the commission found that wrapping paper, as understood in the paper trade, is a generic name covering many grades; that oiled, greased, and waxed papers are separate and distinct commodities not only from the plain paper from which they are made, but also from each other; and that the rates applied on oiled and waxed papers were not shown to have been unreasonable. (26 I. C. C., 430.)

Railroad Commission of Montana v. Northern Pacific et al. Opinion by Commissioner Clements:

In this case the complainant contends that the rates on mining machinery in carload and less-than-carload quantities from Butte, Mont., to points in Idaho and Washington are unreasonable. No one directly connected with the Butte Machinery Company, on whose behalf the complaint was filed, was present at the hearing, and the representative of the Railroad Commission of Montana, the only witness on behalf of the complainant, had no knowledge of the character or the extent of the business of that company. The commission found that if it condemned the present rate it would be acting upon no evidence or information except a comparison of rates pointed out from tariffs on file with the commission by the Railroad Commission of Montana. The complaint was dismissed without prejudice. (21 I. C. C., 407.)

Kalmbach-Ford Company, Ltd., v. Kansas City Southern et al. Opinion by Commissioner Clements:

The complainant seeks the establishment of a differential between the rates on corn and corn products from Kansas City and common points to Shreveport, La. It was not contended that the present rate on corn is unreasonable. The complainant also alleges that it is discriminated against in favor of millers at points in Texas, Arkansas, Missouri and Lake Charles, La., who receive lower rates on corn than on corn products received from Kansas City. The commission found that as a rule a reasonable differential was approved between raw material and manufactured articles, but that wherever the carrier has waived the privilege of a slightly advanced rate for the transportation of the product and where the rate on the raw material was reasonably low, the rate adjustment should not be interfered with. (26 I. C. C., 289.)

American Insulated Wire & Cable Company v. Chicago & North Western et al. Opinion by the commission:

The defendants charge for transportation of copper wire in carloads from Dollar Bay, Mich., to Chicago, a rate of 15 cents per 100 lbs. during the months when navigation on the great lakes is open, and a rate of 22 cents per 100 lbs. during the months when such navigation is closed. The complainant contends that the higher rate is in contravention of the last clause of the fourth section of the act to regulate commerce, and is in itself unreasonable. The commission found that the maintenance of varying rates on copper wire from and to the points in question, depending on whether the great lakes are open or closed to navigation, is not in contravention of the statute, also that 22 cents per 100 lbs. is not shown by the evidence to be an unreasonable rate for the service during the months when that rate is applied. (26 I. C. C., 415.)

News-Times Publishing Company v. the Atchison, Topeka & Santa Fe et al. Opinion by the commission:

The complainant contends that the through first-class rate of $2.34 per 100 lbs. charged for the transportation of supplements to its paper known as the *Sunday Magazine* of the *Rocky Mountain News*, from New York to Denver, Colo., is unreasonable.

In official and western classification magazines are rated first-class. The complainant contends that the publication in question should be grouped with other newspaper supplements, which take the second class rate of $1.91 per 100 lbs. between the points in question. Under western classification newspaper supplements are described as "patent insides and newspaper supplements, folded (not sewed), in bundles." The commission found that the publication in question was sewed, and although it was a supplement it resembled more nearly a magazine than other supplements, such as the comic section. The commission decided, therefore, that the publication does not come within the description of supplements in a classification and is a magazine, and that the rate was properly assessed. (26 I. C. C., 395.)

Reparation Awarded.

McLoughlin Motor Car Company, Ltd., v. Grand Trunk et al. Opinion by the commission:

The commission found that the rate of 51 cents per 100 lbs. charged for the transportation of automobile chassis, k. d. in carloads from Flint, Mich., to Oshawa, Ont., was unreasonable to the extent that it exceeded 37½ cents per 100 lbs., minimum weight 15,000 lbs. As this rate has been in force for over fifteen months, no order regarding a rate for the future was issued. (26 I. C. C., 315.)

Central Commercial Company v. Atchison, Topeka & Santa Fe et al. Opinion by the commission:

The complainant attacks as unreasonable the rate charged by the defendant for the transportation of petroleum residuum, or road oil from Coffeyville, Kansas, to Hastings, Nebraska. Reparation is asked. The commission found that the present rate, which is 33.1 cents per 100 lbs., is unreasonable to the extent that it exceeds 21 cents per 100 lbs. and prescribed that rate for the future. (26 I. C. C., 373.)

Pacific Stationery & Printing Company v. Oregon-Washington Railroad & Navigation Company et al. Opinion by the commission:

The complainant contends that the double first class rate charged for the transportation of less than carload shipments of rotary mimeographs from Chicago to Portland, Ore., is unreasonable and asks for reparation. The commission found that the rate in question was unreasonable to the extent that it exceeded one and one-half times first class rate and prescribed that rate for the future. (26 I. C. C., 370.)

Diamond Crystal Salt Company v. Michigan Central et al. Opinion by the commission:

The complainant ships salt over a through route from St. Clair, Mich., to Savannah, Ga., and Jacksonville, Fla., the traffic moving by rail to Baltimore, Md., and thence via the Merchants & Miners Transportation Company by water to destination, on a through rate of 29½ cents per 100 lbs., of which 15 cents is the separately established rate of the water carrier applied to the through transportation. Upon petitions alleging the unreasonableness of the through rate and charges and asking for reparation the commission found that the through rate on salt over the route in question was unjust and unreasonable to the extent that the separately established rate of the water carrier applied to the through transportation, 15 cents per 100 lbs., exceeds 12 cents per 100 lbs. (26 I. C. C., 434.)

Goodman Manufacturing Company v. Pennsylvania Railroad et al. Opinion by the commission:

The complainant contends that the rate charged by defendant for transportation of machinery from Ridgway, Pa., to Rentchler Ill., was unreasonable. Reparation is asked. In absence of a joint through rate there was charged a rate of 40 cents per 100 lbs., the factors of which were a fifth class rate of 21 cents per 100 lbs. Ex. a commodity rate of 15 cents from Louisville to Belleville, Ill., a sixth class rate of 44 cents, Belleville to Rentchler. The complainant said that there were several other routes over which there were lower combinations than via the route of movement and that the shipment should have been forwarded to Belleville direct via the Louisville & Nashville over which route there was a combination rate of 29.4 cents per 100 lbs. The commission decided that the shipment was misrouted by the initial carrier and that in consequence the complainant was compelled to pay an unreasonable rate. (26 I. C. C., 423.)

Rate on Fertilizer Reduced.

Meridian Fertilizer Factory v. Texas & Pacific et al. Opinion by Commissioner McChord:

The complainant contends that the rates on fertilizer from Shreveport, La., to various destinations in Arkansas are unreasonable and unjustly discriminatory to the extent that they exceed the rates from Memphis and St. Louis to the same destinations. The complainant argued that though there was a good market for commercial fertilizer in Arkansas, the rate adjustment from Shreveport to Arkansas points was so high that the complainant was deprived of its just share of sales in that state, even at points closer to Shreveport than to the competitive market. The commission decided that reduction should be made in most of the rates on fertilizer from Shreveport to Arkansas points and that these reductions would produce a larger volume of traffic to the carriers. Reasonable rates for the future were prescribed. (26 I. C. C., 351.)

Rate on Cottonseed Not Increased.

In re advances in rates on cottonseed from points in Oklahoma to Little Rock, Ark. Opinion by Commissioner Prouty:

The suspended tariffs proposed to cancel joint rates from points on the Missouri, Oklahoma & Gulf in Oklahoma to Little Rock, Ark. The commission found that the advances in the rates which would be effected by the cancellation of these joint rates would seriously affect the shippers, and ordered the defendant to cancel the suspended tariff. (26 I. C. C., 211.)

Hamburg, Mich., Discriminated Against.

Hiram G. Beach v. Ann Arbor Railroad et al. Opinion by the commission:

The complainant alleged that Hamburg, Mich., was discriminated against because the defendant maintained a round trip week-end fare of $1.25 during the summer season from Toledo, Ohio, to Whitmore Lake and Lakeland, Mich., which are summer resorts, while denying this low fare to Hamburg, Mich., a summer resort located between Whitmore Lake and Lakeland. The commission found that this practice constituted a discrimination against Hamburg and ordered that in future the defendant desist from charging lower or more advantageous fares from Toledo to Whitmore Lake and Lakeland than to Hamburg. (26 I. C. C., 410.)

Rates on Phosphate Rock Not Increased.

In re investigation and suspension of advances in rates by carriers for the transportation of phosphate rock in bags from points in Tennessee to Norfolk, Va., and other points. Opinion by the commission:

The proposed advanced rates upon crude ground phosphate rock in carloads transported from points in Tennessee to New England and middle eastern states were found to be unreasonable and the present rates were ordered to be maintained as maxima for two years. The carriers were ordered to cease and desist from discriminating in rates between ground phosphate rock in bulk and ground phosphate rock in bags. (26 I. C. C., 377.)

Shipment Misrouted.

Pole Stock Lumber Company v. Gulf & Ship Island et al. Opinion by the commission:

The complainant forwarded a number of carloads of lumber from points in Mississippi and Louisiana to South Chicago, Ill., and directed routing via Louisville, Ky. A combination rate of 30 cents was applied. At the same time defendants, with the exception of the New Orleans & Northeastern, were parties to a tariff naming a joint rate of 24 cents from points of origin to destination which reserved to the carriers the right to route all shipments of lumber and articles taking the same rates, but the tariff did not specify any particular routes. Adhering to the principle announced in *Kettler Lumber Co. v. G. & S. I. R. R. Co.*, 21 I. C. C., 14, the commission decided that in the absence of routing directions in the tariff the joint rate of 24 cents was applicable to such shipments as moved over the lines of defendants concurring in said joint rate; that as to such shipments participated in by the New Orleans & Northeastern it was the duty of the initial carrier, a party to the joint rate of 24 cents, to

so route the shipments as to secure to them the joint rate, and that not having done so the shipments were misrouted. Reparation was awarded. (26 I. C. C., 451.)

Hard Wood Lumber Rates Reduced.

Blue Grass Lumber Company et al. v. Louisville & Nashville et al.

Robinson Lumber Veneer & Box Company et al. v. Louisville & Nashville et al.

S. C. Major v. Louisville & Nashville et al. Opinion by the commission.

As these three cases involve attacks on the rates on hard wood lumber from points on the Louisville & Nashville in Alabama, south of the Tennessee river, to eastern seaboard territory and interior eastern points, they were consolidated and disposed of in one report. The commission found that the rates in question were unreasonable to the extent that they exceeded the rates on yellow pine between the same points by more than 2 cents per hundred pounds and prescribed those rates for the future. (26. I. C. C., 438.)

Through Rates on Shipments Reconsigned.

New Kentucky Coal Company v. Louisville & Nashville et al. Opinion by the commission:

The complainant shipped coke in carloads via defendants' lines from certain Virginia points to Chicago, and thence, upon reconsignment, to various points beyond. Transportation charges were collected on basis of the rates to and from Chicago. Through rates were in force at the time, which were lower than the combinations on Chicago. The complainant claims that the through rates should have been applied. The commission found that as to the shipments that moved to Chicago via the Louisville & Nashville and Chicago, Indianapolis & Louisville lines the through rates were applicable and should have been charged. Reparation was awarded. Under the tariffs of the Louisville & Nashville and the Cleveland, Cincinnati, Chicago & St. Louis, reconsignment at Chicago on the basis of the through rates was not authorized, and reparation on these shipments was denied. (26 I. C. C., 417.)

STATE COMMISSIONS.

It was announced informally at a meeting of the Louisiana State Railroad Commission, in New Orleans, last week, that the commission would notify all railroads in the state on which more than one train a day is run, to install block signals. The Southern Pacific and the New Orleans & Northeastern already have considerable installations of automatic block signals.

The Iowa board of railroad commissioners will hold a general rate and classification hearing at Des Moines on May 14, and a special hearing on the subject of demurrage rules on May 13. The questions to be considered are, proposed changes in the Iowa rules, to agree with the interstate rules now in effect, and a proposed increase in the demurrage charge from $1 to $3.

The railroad commission of Colorado has handed down a decision ordering reductions ranging as high as 28½ per cent. in the rates on coal from the northern Colorado fields to Denver on the Colorado & Southern, the Chicago, Burlington & Quincy, and the Union Pacific. Commissioner Kendall issued a dissenting opinion in which he says that while he believes the rates are now too high, the reduction ordered is excessive.

COURT NEWS.

The Southern Illinois Coal & Coke Company has filed suit against the Illinois Central for damages amounting to $597,270 because of losses said to have been sustained by the company through failure of the road to provide it with enough cars from August, 1909, to date.

In the Federal court at Minneapolis, April 1, the Minneapolis, St. Paul & Sault Ste. Marie and the Russell-Miller Milling Company pleaded guilty to giving and receiving illegal rebates, and were fined $5,000 each. The offenses were committed in connection with shipments of grain stopped at Minneapolis for milling.

REVENUES AND EXPENSES OF RAILWAYS.

Railway Officers.

Executive, Financial and Legal Officers.

Lewis Lukes has been appointed assistant to the president of the Canadian Northern, with headquarters at Toronto, Ont.

Joseph W. Jamison has been appointed general attorney of the Missouri, Kansas & Texas for the state of Missouri, with headquarters at St. Louis, Mo., succeeding Lee W. Hagerman, resigned.

The jurisdiction of the officials of the Illinois Central has been extended over the Chicago, Memphis & Gulf. M. A. Chambers, auditor of disbursements of the latter road, has been appointed auditor and freight claim agent, with headquarters at Dyersburg, Tenn.

H. A. Scandrett, who has been interstate commerce attorney of the Harriman Lines at Chicago, has been appointed interstate commerce attorney of the Union Pacific, Oregon Short Line and Oregon-Washington Railroad & Navigation Company, with headquarters at Omaha, Neb., effective April 1.

The following appointments have been announced on the Chicago, Milwaukee & St. Paul: W. F. Dudley has been made auditor of traffic; G. J. Bunting and J. Welch are assistant general auditors of material accounts; W. T. Carroll, assistant freight auditor; August Jacobs, assistant ticket auditor; J. A. Mulhall, assistant auditor of expenditures; J. S. Butler, assistant auditor of material accounts, and John Williams, assistant car accountant.

Edward Beecher Pierce, whose appointment as auditor of the Missouri, Kansas & Texas has already been announced in these columns, was born July 3, 1873, at Leavenworth, Kan. He was graduated from the Leavenworth (Kan.) high school and began railway work in February, 1894, in the accounting department of the Kansas City, Fort Scott & Memphis. From July, 1900, to June, 1904, he was in the accounting department of the St. Louis & San Francisco at St. Louis, Mo., and on July 1 of the latter year was made auditor and freight claim agent of the north Texas lines of the Frisco, including the Ft. Worth & Rio Grande and the St. Louis, San Francisco & Texas, with office at Ft. Worth, Tex. He resigned on March 17 to become auditor of the Missouri, Kansas & Texas, with headquarters at St. Louis, as above noted.

Benjamin Akerly Dousman, whose appointment as general auditor of the Chicago, Milwaukee & St. Paul, with headquarters at Chicago, has already been announced, was born March 21, 1859, at Milwaukee, Wis. He was educated in the public and high schools of Milwaukee, and began railway service April 19, 1879, with the Chicago, Milwaukee & St. Paul as junior clerk in the car accountant's office. A year later, in May, 1880, he went to the auditing department in charge of freight accounts, and in November of that year he was transferred to general accounts. On July 6, 1908, Mr. Dousman became assistant general auditor which office he held for two years, when he was made assistant auditor, July 1, 1910. He held the latter position until he was promoted to that of general auditor on March 15 of this year. Mr. Dousman's entire railway service of 31 years has been with the Chicago, Milwaukee & St. Paul. Mr. Dousman has jurisdiction over the Bellingham & Northern, the Tacoma, Puget Sound and the Gallatin Valley.

B. A. Dousman.

Operating Officers.

E. Dowling, trainmaster of the Atchison, Topeka & Santa Fe at Las Vegas, N. M., has been appointed assistant division superintendent at Dodge City, Kan.

J. R. Pickering, acting superintendent of car service of the Rock Island Lines, has been appointed superintendent of car service, with headquarters at Chicago; effective April 1.

William E. Morris, formerly assistant general manager of the Chicago & North Western, has been appointed general manager of the Denver Northwestern & Pacific, with headquarters at Denver, Colo.

W. B. Denham, general manager of the Georgia & Florida, with office at Augusta, Ga., having resigned, all officers heretofore reporting to the general manager will in future report to B. W. Duer, vice-president, in charge of operation, with headquarters at Augusta.

F. R. Blunt, formerly superintendent of the Smithville district of the Missouri, Kansas & Texas, has been appointed general manager of the Palicios, San Antonio & Pecos Valley, which is under construction in southern and western Texas. The headquarters of the company are at Yoakum, Tex.

William Mosby has been appointed superintendent of transportation of the St. Louis Southwestern Railway Lines, with headquarters at Tyler, Tex., succeeding F. J. Hawn, who has been appointed superintendent of the Ft. Worth division of the St. Louis Southwestern of Texas, with office at Mt. Pleasant, Tex., in place of E. Richards, who has been made superintendent of the St. Louis Southwestern, with headquarters at Pine Bluff, Ark., succeeding E. A. Peck, deceased.

Alfred H. Egan, superintendent of the Kentucky division of the Illinois Central, has been appointed general superintendent of the Yazoo & Mississippi Valley, with headquarters at Memphis, Tenn., succeeding George W. Berry, who has been appointed terminal superintendent of the Illinois Central, with headquarters at Chicago, with jurisdiction between South Water street and Matteson and between Twelfth street and Parkway, in place of James H. Brinkerhoff, resigned. Lewis W. Baldwin, engineer of maintenance of way, succeeds Mr. Egan as superintendent of the Kentucky division, with headquarters at Louisville, Ky.

Traffic Officers.

C. A. Rouse has been appointed general agent of the Erie Despatch, with headquarters at Indianapolis, Ind.

W. C. Elmer, chief clerk in the ticket offices of the Canadian Pacific at Chatham, Ont., has been appointed traveling passenger agent, with headquarters at Toronto, succeeding J. J. Brignall, resigned.

C. Hanson, division freight agent of the Texas & Pacific and the International & Great Northern at Ft. Worth, Tex., has been appointed joint live stock agent, with headquarters at Ft. Worth, to succeed D. C. Smith, resigned. George L. Moore, commercial agent at Oklahoma City, Okla., succeeds Mr. Hanson, and M. C. Bailey, traveling freight agent at Dallas, Tex., takes the place of Mr. Moore.

Garnett King, assistant general freight and passenger agent of the El Paso & Southwestern System, and the Morenci Southern, at El Paso, Tex., has been appointed general agent of these companies, with headquarters at St. Louis, Mo., succeeding J. L. Hazzard, resigned to accept service with another company, and the position of assistant general freight and passenger agent at El Paso, has been discontinued.

E. G. Spencer, commercial agent of the Kansas City Southern at Beaumont, Tex., has been appointed general agent of the freight department at Beaumont, Tex., in place of J. L. Boyd, resigned to engage in other business. J. C. Walker, traveling freight agent, with headquarters at Shreveport, La., succeeds Mr. Spencer. S. A. Martin, traveling freight agent of the St. Louis Southwestern at Shreveport, succeeds Mr. Walker.

Engineering and Rolling Stock Officers.

John F. Gardner has been appointed electrical engineer of the Chicago, Burlington & Quincy, with headquarters at Chicago.

D. C. Ross has resigned as master car builder of the Michigan Central, effective April 1, and will reside at his summer home at Algonac, Mich.

W. F. Steffens has been appointed assistant chief engineer of the Chesapeake & Ohio and the Chesapeake & Ohio of Indiana, with office at Richmond, Va.

W. J. McLean, master mechanic of the Duluth, Winnipeg & Pacific at West Duluth, Minn., has been appointed master mechanic of the Kettle Valley Railway, with headquarters at Penticton, B. C.

H. M. Taylor, director of construction of the National Railways of Mexico, with headquarters at Mexico City, Mex., has resigned and his former position has been abolished. All officers and employees who have hitherto reported to Mr. Taylor will in future report to G. P. DeWolf, chief engineer of construction.

Daniel J. Brumley, engineer of construction of the Illinois Central and the Yazoo & Mississippi Valley, has been appointed engineer of maintenance of way of those roads, with headquarters at Chicago, to succeed Lewis W. Baldwin, transferred. Fred L. Thompson, engineer of bridges and buildings, succeeds Mr. Brumley, with headquarters at Chicago, and Maro Johnson, assistant engineer of bridges, takes Mr. Thompson's place, with office at Chicago.

Maro Johnson, who has been appointed engineer of bridges and buildings of the Illinois Central and the Yazoo & Mississippi Valley, with headquarters at Chicago, was born at Iowa City, Iowa, in 1877, and graduated from the engineering department of the University of Iowa in 1898. The same year he entered the service of the Illinois Central as masonry inspector, and subsequently held various positions on that road until 1905, when he went to the Indianapolis Southern, a subsidiary of the Illinois Central, as resident engineer. Two years later he returned to the service of the Illinois Central as resident engineer on the track elevation work at Grand Crossing, Ill. In September, 1912, he was promoted to assistant engineer of bridges, and now becomes engineer of bridges and buildings of the same road as above noted.

M. Johnson.

OBITUARY.

Peter S. Archibald, who was chief engineer of the Intercolonial Railway from March, 1878, to 1898, died on March 16, at his home in Moncton, N. B. He was born on March 18, 1848, at Truro, N. S., and began railway work in July, 1867, in the engineering department of the Intercolonial Railway, and held various positions in that department until his promotion to chief engineer. He resigned from that position in 1898, to become a consulting engineer.

Caspar Buhrer, formerly roadmaster of the Lake Shore & Michigan Southern at Sandusky, Ohio, and later superintendent of the tie and timber-treating plant of that road near Toledo, died at his home in the latter city on March 23, aged 58 years. Mr. Buhrer was connected with the Lake Shore some 35 years and had been roadmaster about 30 years. He retired about two years ago owing to ill health. Mr. Buhrer was the inventor of the Carnegie steel tie and one or two reinforced concrete ties.

J. W. Petheram, formerly from October, 1893, to the latter part of 1909, chief engineer of the Missouri, Kansas & Texas Railway of Texas, died on March 26 at his home in Dallas, Tex., aged 70 years. Mr. Petheram was born in Largo, Scotland, and was educated at Madras College at St. Andrews, Scotland. He entered railway service in June, 1873, as resident engineer of the Credit Valley Railway of Canada, and from February, 1875, to August, 1879, was assistant engineer of the same road. From April, 1881, to January, 1884, he was successively chief engineer of the Georgian Bay & Wellington and assistant engineer of the Chicago & West Michigan, and was then until January, 1888, chief engineer of the latter road. Subsequently to October, 1893, he was general roadmaster of the Missouri, Kansas & Texas of Texas, and was made chief engineer on the latter date, which position he held for about 16 years, when he sustained a stroke of paralysis, from which he never fully recovered.

James McCrea, who, up to the beginning of the present year, was president of the Pennsylvania Railroad, died at his home in Haverford, Pa., near Philadelphia, on the night of March 28, at the age of 65. He had been in failing health for several weeks. An account of Mr. McCrea's life, with a portrait, was given in the *Railway Age Gazette* on November 22 last, when he resigned his position as president. Mr. McCrea was born in Philadelphia, May 1, 1848, and was educated at the Pennsylvania Polytechnic College. He began his railway service as rodman and assistant engineer on one of the minor lines of the Pennsylvania system, and his whole active life was passed in the service of that company. He served on the western lines of the company 25 years. Mr. McCrea leaves a wife, two sons and a daughter. One of the sons, James A. McCrea, is general manager of the Long Island Railroad, at New York City. The funeral was held on Monday of this week at St. Mary's Protestant Episcopal Church, Ardmore, Pa., a large number of railroad officers and financiers from Philadelphia, New York and other cities being present. All traffic on the Philadelphia Division of the road was suspended for three minutes at the time of the burial.

George T. Nicholson, vice-president in charge of traffic of the Atchison, Topeka & Santa Fe System, with headquarters at Chicago, died in Los Angeles, Cal., on March 30, following an operation. Mr. Nicholson was born July 1, 1856, at Belvidere, N. C. He was educated at the Kansas State University and began railway work in 1882 as clerk in the general passenger and ticket office of the Atchison, Topeka & Santa Fe. He was successively rate clerk, chief rate clerk, chief clerk, assistant general passenger and ticket agent and general passenger agent to February 1, 1897, when he left the Santa Fe to become general passenger agent of the St. Louis & San Francisco. He returned to the Santa Fe in May, 1898, as passenger traffic manager of the entire system, and in October, 1905, he was elected vice-president in charge of traffic. Funeral services are to be held at Lawrence, Kan., on Friday. The Santa Fe ran a special train Thursday night to accommodate railway men who wished to attend.

G. T. Nicholson.

PARLOR CAR MAIDS IN PRUSSIA.—The Prussian minister of public works has had occasion to chide the house maids (or car maids) who are expected to keep everything spick and spandy in the cars which correspond to our drawing-room cars. They have not shown proper zeal in attending to their duties, he says. They must maintain extreme cleanliness in all parts of the car; see that fresh drinking and washing water, and clean towels and soap are provided before the supply is exhausted, and not remove them before the car reaches its final destination, as they have done too often. Conductors are made responsible for the proper service of these women, who are especially to see that the car is perfectly neat when transferred from a Prussian to a connecting railway.

Equipment and Supplies.

LOCOMOTIVE BUILDING.

The New York Central Lines are in the market for 180 locomotives.

The Lehigh Valley is considering the purchase of 25 mikado locomotives.

The Atlantic Coast Line has ordered 11 Pacific type locomotives and 9 switching locomotives from the Baldwin Locomotive Works.

The Havana Central has ordered 8 consolidation locomotives from the American Locomotive Company. The dimensions of the cylinders will be 20 in. x 26 in.; the diameter of the driving wheels will be 50 in., and the total weight in working order will be 154,000 lbs.

CAR BUILDING.

The St. Louis & San Francisco is in the market for 1,000 box cars, and 1,000 gondola cars. This company will also soon order some stock cars.

The Baltimore & Ohio has ordered 1,500 all-steel, 50-ton hopper cars. This order was divided equally between the Pressed Steel Car Company, the American Car & Foundry Company and the Standard Steel Car Company. This company has also an option on 1,000 additional hopper cars.

The Atlantic Coast Line has ordered 12 all-steel, passenger coaches, 4 all-steel, combination passenger and baggage cars and 4 all-steel, combination mail and express cars from the Pullman Company, and 2 steel underframe passenger coaches, 2 steel underframe, combination passenger and baggage cars and 3 steel underframe, combination mail and express cars from the American Car & Foundry Company.

IRON AND STEEL.

The Seaboard Air Line is in the market for 10,000 tons of rails.

The Baltimore & Ohio is in the market for 5,000 tons of rails.

General Conditions in Steel.—According to the *Wall Street Journal* the losses sustained by the steel plants in the Sharon, New Castle and Youngstown districts from the recent floods will not be as great as at first estimated. Heads of the different departments are optimistic and say that with a few exceptions the plants will be operated within a few days. In Sharon the North Works of the Carnegie Steel Company will be running the first of next week. The greatest loss sustained by the Carnegie Steel Company was at its coking plant in Farrel. It is feared that the entire plant will have to be rebuilt. Officers of the company estimate that the loss will be close to $200,000. The blast furnaces are in good shape and the other mills were not extensively damaged. The shutting down of a number of plants and the poor transportation service will have its effect on the April shipments of the Steel Corporation, but it is not believed that the resulting decrease will exceed 200,000 tons if adequate freight service is speedily restored. Orders have been small recently, but prices continue to remain firm.

Railways and Collieries in India.—The Bengal Chamber of Commerce has addressed the government of India deprecating the acquisition of colliery land by railway companies. The chamber argues that railways have no right to embark on undertakings which can be more satisfactorily and efficiently managed by private companies. Five years ago the clamour raised this question but the government of India was not impressed by the argument and declared that it was its established policy to permit railways to own and operate collieries. A short time ago the railways had to [illegible] operating their own mines or increasing their freight charges on account of the sharp advance in coal rates.

Supply Trade News.

The Roberts & Schaefer Company, Chicago, has received a contract from the Western Maryland to build a large Holmen coaling station at Williams, W. Va.

Henry Jungerman, formerly in the motive power and inspection department of the Harriman Lines, has been made railway representative of Tate-Jones & Company, Inc., Pittsburgh, Pa.

Charles A. Lindstrom, chief engineer of the Pressed Steel Car Company, Pittsburgh, Pa., has been made assistant to the president, with headquarters in Pittsburgh; B. D. Lockwood, assistant chief engineer of the same company, has been made chief engineer; J. F. Streib, mechanical engineer of the company, has been made assistant chief engineer, and Felix Koch has been made mechanical engineer.

The Duff Manufacturing Company, Pittsburgh, Pa., has moved into its new plant and general office building on Preble avenue, Pittsburgh. The old works on Marion avenue have been dismantled. The new factory building has about 68,000 sq. ft. of floor space, and is located on a tract of ground approximately five acres. It has track connections with the Pennsylvania Railroad and the Baltimore & Ohio. This company is also planning to erect a new plant in the Chicago district, and one at either Windsor or Hamilton, Ont. Both of these plants are expected to be in operation in the fall of 1913.

The Federal Signal Company, New York and Troy, N. Y., last week bought the property of the American Railway Signal Company of Cleveland, Ohio, together with all the company's assets, and stock on hand. It also will carry out the unfinished contracts for construction. The principal contract on which the American company was engaged was for the installation of automatic block signals on 150 miles of single track, of the New York, Chicago & St. Louis in the state of Indiana. There are a number of smaller contracts on other roads. H. M. Abernethy, general manager of the American company will join the Federal company, with office in Cleveland.

H. F. Ball, special consulting engineer, with office in New York, and formerly vice-president of the American Locomotive Company, New York, has been made president of the Economy Devices Corporation, 30 Church street, New York, which has recently been formed. This company has taken over the business of the Radial Buffer Company, which company has been dissolved. Among the devices which will be marketed by the new company is the Radial engine and tender buffer. Mr. Ball entered the service of the Pennsylvania Railroad as an apprentice at Altoona, Pa., in 1884. Four years later he entered the drafting room at Altoona, and in 1890 was appointed chief draftsman of the car department of the Lake Shore & Michigan Southern. Two years later he was made general foreman of the car shops at Cleveland, Ohio, and in 1894 he was appointed general car inspector. In 1899 he was made mechanical engineer of the same road, and was promoted to superintendent of motive power, in February, 1902. In 1906 he left the Lake Shore to become vice-president of the American Locomotive Automobile Company; a few months later his jurisdiction was extended over the American Locomotive Company as vice-president in charge of engineering. In December, 1912, he left the American Locomotive Company to open an office as special consulting engineer. Mr. Ball was

H. F. Ball.

president of the Central Railway Club in 1900, and of the American Railway Master Mechanics' Association in 1905-6.

President R. P. Lamont, of the American Steel Foundries, has submitted the annual report to the stockholders for the tenth fiscal period of the company for the calendar year ended December 31, 1912. The gross sales for the year were $14,319,571.58, and the gross earnings from operations of plants and other income after deducting manufacturing expenses (which includes $1,160,536.32 for repairs and maintenance), also selling, administration, head and district office and other expenses, were $1,588,766.14. The net income of $777,756.17 applicable to surplus shown on the balance sheet is the remainder after deducting all interest and $322,500.90 for depreciation of fixed properties, also $184,173.91 appropriated for the sinking fund. In comparing the earnings for 1912 with the preceding fiscal period, which showed a loss of $259,030.92, it should be borne in mind that such period covered a term of 17 months, only the first few of which showed any profit. If the sales for 1912 be compared with the calendar year 1911, the change is far more pronounced as that 12 months' operations showed a loss of $514,801.82. As shown by the balance sheet $188,249.74 was charged to capital account during the year for new construction, additions, machinery equipment, etc., and in addition a further sum of $135,624.56 was spent for replacements, minor additions, and improvements, and charged to the depreciation reserve. During the year equipment for the production of car couplers has been installed at East St. Louis, and at the Hammond plant a new building for the production of brake beams has been added. President Lamont says that the pronounced business depression of 1911 continued well into the following year, but about midsummer a noticeable improvement in the volume of orders became apparent. The improvement, however, was not reflected in the company's earnings until two or three months later, hence the year's showing is largely the result of the operations for the last six months of the year. At the present time the volume of orders in hand is, with one exception, the largest in the history of the company.

TRADE PUBLICATIONS.

Chicago & North Western.—The passenger department has issued an illustrated booklet describing the special features of its new Overland Limited train that was put in service between Chicago and San Francisco on April 1.

Denver & Rio Grande.—The passenger department has issued a special folder in German describing the city of Denver, and enumerating its principal points of interest in recognition of the Bundesturnfest, to be held in Denver in June.

Bridges.—The Strauss Bascule Bridge Company, Chicago, has issued an interesting booklet devoted to the Strauss direct lift bridge, an application of the counterbalancing mechanism of the Strauss bascule to the vertical lift bridge. The booklet contains a general description of the principles of this type of bridge, and is illustrated with drawings of various types that have been installed.

Paint.—The Sherwin-Williams Company has published an attractive pamphlet containing a story entitled "Making Over Maybridge," which relates the experiences of a young city man who returns to his boyhood town after ten years and over the opposition of some of the more conservative old residents organizes a club to "brighten up" the town, by cleaning up refuse, painting old buildings, and otherwise making the town attractive.

Locomotive Boilers.—The Wm. H. Wood Loco. Fire Box and Tube Plate Company, Media, Pa., has published a folder entitled, Improvements in Locomotive Boilers Versus Regular Standard Boilers with Flexible Stays. In this folder are enumerated a number of results from tests which show the great efficiency of Wood boilers compared with boilers having flexible stays.

Third Class Sleeping Cars in Norway.—Norway follows the example of Sweden in ordering some third-class sleeping cars. They have three berths to a section, each 24 in. wide, and there are 12 sections to a car. These cars will weigh 76,000 lbs., and will cost $8,800 each.

Railway Construction.

Artesian Belt.—An officer of this company, which operates a line from Macdona, Tex., to Christine, 43 miles, writes regarding the report that an extension is to be built from Christine, that contracts were recently let and grading work is now under way on an extension southeast, 17 miles. The work involves handling 15,000 cu. yds. to the mile. Maximum grades will be 1 per cent., and maximum curvature 1 deg. The company expects to develop a traffic in oil, coal, cotton and garden truck. (March 28, p. 779.)

Atchison, Topeka & Santa Fe.—According to press reports plans are being made for double tracking work through a mountainous section from Victorville, Cal., south to Summit, 19 miles.

Boston Elevated.—A contract for the construction of section B, of the Dorchester tunnel, at Boston, Mass., has been given to the Hugh Nawn Contracting Company, Roxbury, at $351,048. The contract covers about 500 lineal feet of a street railway passenger tunnel to be operated by the Boston Elevated.

Buffalo, Rochester & Pittsburgh.—An officer writes that a contract has been given to the Miller Construction Company, Lock Haven, Pa., for grading and masonry work on a five-mile branch at Lucerne, Pa.; and a contract has been given to Lane Brothers Company, Altavista, Va., for grading and masonry work on twelve miles of second track and grade revision between Rochester, N. Y., and Scottsville. (March 28, p. 779.)

Canadian Pacific.—An officer tells us that a contract for grading the Kootenay Central has been let to Foley Bros., Welch & Stewart, on the section from a point 60 miles south of Golden, B. C., to Shookumchuk, about 65 miles. (March 28, p. 779.)

Chambersburg & Shippensburg.—Application has been made for a charter in Pennsylvania, by this company with a capital of $250,000 and headquarters at Chambersburg, Pa. The plans call for building from Red Bridge Park, Chambersburg, north and east through Greene and Southampton townships, Franklin county, following in a general direction the line of the Harrisburg, Carlisle & Chambersburg turnpike to the western line of Shippensburg, nine miles. Thad. M. Mahon, president; W. H. Fisher, W. Alexander, H. B. McNulty, J. G. Schaff and J. F. Shank are directors.

Chicago, Burlington & Quincy.—This company has authorized the construction of second track from McCartney, Wis., to Bagley, 23 miles; Prairie du Chien to Charme, 7 miles; De Soto to Victory, 6 miles, and Fountain City to Alma, 14 miles, at an estimated cost of about $3,800,000. Third track will also be built from Downers Grove, Ill., to Aurora, 11 miles, at an estimated cost of $500,000.

Grading work for second track, parallel with present alinement between Pisgah, Ill., and Virden, 23 miles, is now under way. The grading is being done by J. E. Finncane.

Gulf, Texas & Western.—This company has made two reconnaissance surveys, it is said, for the proposed extension west from Seymour, Tex. One of the surveys extends northwest from Seymour to Floydada, about 150 miles, where connection could be made with the branch of the Santa Fe that runs to Plainview. The other survey was made from Seymour to Crosbyton, about 125 miles. At Crosbyton the line would connect with the Crosbyton-Southplains, which runs to Lubbock. The G., T. & W. recently finished work on the section from Jacksboro south to Salesville, 24 miles. (February 28, p. 411.)

Kootenay Central.—See Canadian Pacific.

Monroe, Louisiana & Gulf.—Incorporated in Louisiana with $1,000,000 capital to construct or purchase a line from Monroe southwest to Winnfield, with New Orleans connection. Financial arrangements have been made. J. M. Parker, New Orleans, is president; T. J. Sheldon, is vice-president, and Percy Sandel, is secretary and treasurer.

Oregon Short Line.—An officer writes that the company expects to begin construction work some time during the next few months on the extension of the Twin Falls branch south from a point in Idaho to a connection with the Central Pacific in Nevada. (March 21, p. 692.)

Plateau Valley.—According to press reports financial arrangements have been made to build a line between Grand Junction, Colo., and Collbran, 48 miles. The company plans to use the tracks of the Denver & Rio Grande from Grand Junction to Palisades, from which place a new line is to be built east through the canyon of Plateau creek via Mesa, Molina and Plateau City to Collbran. Preliminary surveys have been made. It will cost about $1,000,000 to build the line. Jacob Yeckel, president, and A. J. Halter, vice-president, Denver. (January 31, p. 231.)

Suburban Railway.—A bill has been passed by the legislature of New Brunswick authorizing this company to build suburban lines from St. John, N. B., as follows: To Loch Lomond, 10 miles; to Rothesay, 9 miles; to Millidgeville, 3 miles, and to Westfield, 14 miles. The bill provides that the company must spend $50,000 in construction the first year, the same amount the second year, and $100,000 the third year, besides making provision for hydro-electric power.

Texas Roads.—Plans are being made to build from Whiteflat, Tex., south to a connection with the Quanah, Acme & Pacific. This project is being financed by ranchmen and land owners along the route of the proposed line. It will be built and operated as an independent line, and it is planned to ultimately extend it north to Memphis, and south to Spur, in all about 100 miles.

RAILWAY STRUCTURES.

Ashland, Wis.—It is announced that the Chicago & North Western will build another ore dock east of its present docks. The new dock will be of steel and concrete, and will cost about $1,000,000.

Butte, Mont.—Work is to be started soon on the erection of a new passenger station.

Carlton, Minn.—The Northern Pacific has announced its intention of constructing a large terminal at this point, to be used as a storage and makeup yard to relieve the congestion at Duluth. A similar terminal will be constructed at White Bear, Minn., to relieve the pressure of the Twin Cities.

Demopolis, Ala.—The Southern Railway is asking for bids for building a new freight station at Demopolis, to take the place of the old structure recently burned. The new building will be of brick construction with fireproof roof 40 ft. x 153 ft. There will also be an open platform 48 ft. x 60 ft., and the improvements will include loading platforms, paved teamways, and the necessary track changes.

Dickerson Run, Pa.—The Pittsburgh & Lake Erie has given a contract, it is said, for building a roundhouse, a shop structure, a storeroom and a power house at Dickerson Run.

Du Bois, Pa.—The Buffalo, Rochester & Pittsburgh will make improvements to the shops at Du Bois, it is said, to include an extension to the erecting shop, 250 ft. x 137 ft.; an addition to the power house; an extension to the boiler making shop, 150 ft. x 200 ft., a pattern shop will be built 64 ft. x 70 ft., two stories high, and another building 35 ft. x 70 ft. will be put up. The company it is said, has also under consideration plans for the construction of a steel car plant, which calls for a structure 192 ft. x 400 ft., equipped with eight tracks.

Faunsdale, Ala.—Bids are wanted by the Southern Railway for building a combined freight and passenger station at Faunsdale, to take the place of the old station destroyed by fire. The new building will be of frame construction with tile roof.

Pembina, N. D.—The Canadian Northern will enlarge its shops and increase its yard capacity.

Riverside, Pa.—The Buffalo, Rochester & Pittsburgh has given a contract to the American Bridge Company, New York, for a double track bridge, to be built over the Allegheny river at Riverside.

West Toledo, Ohio.—The Lake Shore & Michigan Southern will build two roundhouses and a power plant at its Air Line Junction yard.

White Bear, Minn.—See Carlton, Minn.

Railway Financial News

Atchison, Topeka & Santa Fe.—Under the law which has been passed by the Texas legislature, the Gulf, Colorado & Santa Fe, a subsidiary of the Atchison, Topeka & Santa Fe, is to operate the Gulf & Interstate, the Texas & Gulf, the Concho, San Saba & Llano Valley and the Sweetwater-Coleman division of the Pecos & Northern Texas.

Boston & Albany.—The Massachusetts Railroad Commission has been asked to authorize the issue of $3,627,000 3 per cent. bonds of October 1, 1913-1963. The proceeds of the sale of these bonds is to be used to refund a like amount of 4 per cent. bonds due October 1, 1913.

California, Shasta & Eastern.—The Railway Commission of California has authorized this company to issue $568,000 bonds and $349,500 stock. The securities are to be sold at not less than 80. The original application was for an issue of $797,000 bonds and $1,075,600 stock.

Cornwall & Lebanon.—The Pennsylvania Railroad has bought nearly all of the $800,000 stock of this company, of which previously $542,500 was owned by the Pennsylvania Steel Company, and most of the remainder by the Lackawanna Steel Company.

Galveston, Houston & Henderson.—The issue of $2,000,000 new first mortgage 5 per cent. bonds, which was proposed, and which has been previously mentioned in these columns, has been postponed, owing to the company's inability to adjust the necessary formalities with the Texas railroad commission, holders of the $2,000,000 first mortgage 5 per cent. bonds, which were due April 1, and who were offered the privilege of exchanging their bonds for new bonds, received cash on April 1.

Houston & Brazos Valley.—See Missouri, Kansas & Texas.

Missouri, Kansas & Texas.—This company has bought an interest in the Houston & Brazos Valley. Included in the purchase is trackage rights over the International & Great Northern between Anchor, Tex., and Houston. This gives the M. K. & T. an additional outlet on the Gulf of Mexico at the terminus of the Houston & Brazos Valley at Freeport.

Rutland.—The New York Public Service Commission, Second district, has authorized the company to issue $210,000 equipment trust certificates, to be sold at 94½. The proceeds of the sale is to pay for six freight locomotives, one switching locomotive, one combination mail and baggage car, two baggage cars, three smoking cars, two first class coaches and one kitchen coach.

Railway Construction in Australia.—Good progress is being made with the new railway lines under construction. The line from Bairnsdale to Orbost, 60 miles, will open up a large area of productive country, which hitherto has been handicapped by the absence of transit facilities. About 800 men are employed on the work and bridges, culverts and earthworks have been laid down for a distance of 40 miles from Bairnsdale. The section to Bruthen, 20 miles from the head of the existing line, will be first opened to traffic. A temporary bridge has been constructed over the Mitchel river and another of a more permanent character spans the Nicholson river.

Branch Line for India.—The Iranch line which is under construction from Bhairab-Bazaar to Tangu, which is a continuation of the Akhaura Bhairab branch of the Assam-Bengal Railway, continues to make good progress, and it is expected that the line will be opened to traffic in April, 1914. About 85 per cent. of the earthwork has been completed and about 80 per cent. of the major bridges. The rails are also laid over a part of this branch. There have been labor difficulties on the line owing to the coolies finding work on railway construction nearer home and partly to the heavy rains in the recruiting districts which facilitated cultivation and reduced the annual emigration. It is intended to cross the Magna river by means of a car ferry. This branch line joins the Dacca branch of the Eastern Bengal State Railway at Tong and there will then be through communication between Chittagong and the rich districts of Dacca and Mymensingh.

Railway Age Gazette

Including the Railroad Gazette and the Railway Age

Published Every Friday and Daily Eight Times in June, by the SIMMONS-BOARDMAN PUBLISHING COMPANY, Woolworth Building, New York.

Subscriptions, including 52 regular weekly issues and special daily editions published from time to time in New York, or in places other than New York, payable in advance and postage free:

United States and Mexico.....$5.00
Canada 6.00
Foreign Countries (excepting daily editions)..... 8.00
Single Copies .....15 cents each

Engineering and Maintenance of Way Edition and four Maintenance of Way Convention Daily issues, North America, $1.00; foreign, $2.00.

Entered at the Post Office at New York, N. Y., as mail matter of the second class.

WE GUARANTEE, that of this issue 8,100 copies were printed; that of these 8,100 copies, 6,646 were mailed to regular paid subscribers and 144 were provided for counter and news companies' sales; that the total copies printed this year to date were 129,509—an average of 8,634 copies a week.

Volume 54. April 11, 1913. Number 15.

CONTENTS

* Illustrated.

A UNIQUE meeting took place in New York under the auspices of the American Society of Mechanical Engineers on Tuesday evening. The subject of Steel Passenger Car Design was treated in its most important phases by thirteen engineers, each of whom may be regarded as an expert on the particular part of the subject which he spoke on. The papers were short and, in almost all cases, to the point. It is unfortunate that more time could not have been given to the open discussion, and yet it is doubtful if so much valuable information could have been brought out at one meeting in any other way. The large meeting room was crowded to the very end of the session, which was adjourned at a late hour. The remarkable and widespread interest which has attended the two railway sessions of this society indicates remarkable possibilities for the discussion of mechanical department problems on broad engineering lines, and may well be studied by the managements of our railway clubs and mechanical department associations, several of which are getting anything but efficient results because of a lack of intelligent and active interest on the part of those in charge.

IN Texas the train crew bill was defeated by the opposition of the farmers. In Oklahoma the governor vetoed it, on the ground that it was wrong in principle and would tend to increase railway expenses and rates. We publish elsewhere Governor Cruce's veto message. The Chicago Association of Commerce, perceiving that the tendency of such legislation is to make rates higher, has adopted a resolution opposing it in Illinois. It is very surprising that the commercial travelers and shippers, who in the past have been so active in promoting legislation concerning passenger and freight rates, have been so slow to manifest opposition to measures which without increasing safety increase operating expenses and which thereby tend to keep rates up or to justify advances in them. Every full crew bill passed is an argument for higher passenger and freight rates. Legislatures and commissions in regulating rates can hardly ignore increases in operating expenses forced on the railways by law; and even if they do ignore them, the courts will not. If the traffic representatives of large industrial concerns and commercial organizations were as much alive to the interests they represent, as they have been at some other times, they would be as actively opposing most of the legislation that is being promoted by the lobbyists of the railway brotherhoods, as they were in opposing the general advances in freight rates over two years ago. They would likewise be active in agitating for legislation to so amend the Erdman Act as to secure reasonable settlements of controversies between the railways and their employees regarding wages and conditions of work, for every settlement of one of these controversies that increases wages tends to make more imperative the need for increases in railway rates.

MASTER car builders and mechanical department officers who have been confronted with the problem of efficient maintenance of freight cars have been at their wits' end to devise some unit of comparison which would closely gage the expenditures for maintenance with the duty performed by the cars. The number of these cars is so large that it is impossible to keep a close check on the cost of maintaining individual ones, particularly since a large proportion of them are interchanged generally and may be off the home lines for a considerable part of the time. The cost per car per year is the unit ordinarily used, but, as indicated in the article by Mr. Fritts on another page, it is of little value as a basis for comparison, and the same may be said of the cost per car per mile. Mr. Fritts has given this problem a great deal of attention during the past few years and proposes a unit which takes into consideration the average mileage per car, the average capacity per car, and the average tons per train; a diagram is presented showing the trend of this duty line as compared with that for the cost of repairs per mile run during the last few years on the Lackawanna. The unit proposed seems to be a most reasonable one, and is undoubtedly superior to the basis of comparison which is ordinarily used, particularly if the methods by which these figures are derived in the auditor's office do not vary from time to time.

A TRAIN crew bill is pending in the legislature of Colorado. The general managers of the Colorado lines have announced that if it becomes a law, on the day it goes into effect the issuance of free transportation to the families of railway employees and to railway employees themselves, except when traveling on the business of the companies, will be stopped. Railway managers elsewhere are considering the desirability of following the example of the general managers of the Colorado lines. Such action will be met with the charge that it is "retaliatory." Train crew legislation is being promoted by the brotherhoods of railway employees. While ostensibly in the in-

terest of public safety, it is really intended to increase the number of men that railways must employ. The free transportation issued to employees and their families is sometimes mentioned in the schedules fixing wages and conditions of work. Usually, however, it is not provided for in contracts, and is simply a favor extended by the company to the employee. The activity of certain classes of employees in promoting full crew legislation is a selfish effort to further their own supposed interests at the cost of the companies and the public. Why should the roads and the public be the only ones adversely affected by it? Why should the roads continue to be generous to those who directly or indirectly are responsible for legislation intended and adopted to injure them? If they can save by reducing the free transportation of employees part of the expense caused by train crew and other legislation promoted by employees, why shouldn't they do so? Not all classes of employees are concerned in securing such legislation, however. Clerks, station agents, section foremen, etc., have had little, if anything, to do with it. Furthermore, they are not as well paid in proportion as the members of the various brotherhoods. If action is to be taken reducing free transportation it would seem to be only just that it should be discriminating, and should not affect those who are in no way chargeable with the legislation in question.

WE publish elsewhere an article by H. Bortin, an experienced valuation engineer, advocating early concerted action by the Interstate Commerce Commission, the railways and others interested, for the purpose of laying a broad and deep foundation for the valuation of railways which Congress has required the commission to make. As Mr. Bortin points out, there is no general agreement among even those who have devoted the most study to valuation and had the most experience in making valuations, regarding the exact meaning of some of the most familiar terms used in discussions of the general subject. There is equal lack of harmony of views regarding the methods that should be employed. The usual practice in making valuations has been for the public utility corporations to work up a vast amount of data and furnish it to the commission or other body having the work in charge, and for this body to then check over and revise the data and make such additional investigation as it considered necessary. Doubtless the same course will be followed in making the general valuation of the railways. Certainly, however, the Interstate Commerce Commission should not issue any instructions to the railways regarding their part of the work until an understanding has been reached regarding the interpretation of the various terms that the commission must use in issuing its instructions and the methods to be followed in carrying them out. Preliminary to a conference, or conferences, between the representatives of the railways and the members or representatives of the commission it would seem that the railways themselves should get together through appropriate officers and harmonize their own views and attitude. They have lost much in the past and caused themselves and the commission a great deal of unnecessary trouble by failure to act harmoniously and present a united front. The valuation of railways will be one of the most important pieces of work, if not the most important ever done in connection with the regulation of railways in this country, and the plans for making it cannot be worked out too carefully and thoroughly. The scheme outlined by Mr. Bortin may not be the best that could be suggested, but it has the undoubted merit of being, as far as it goes, the best that has been suggested.

THE tempest in New England has died down, and the railway atmosphere there may almost be said to be natural. The temperature cannot yet be called normal, for the New Haven road, with its enormous outside burden of the Boston & Maine and other non-paying or poor paying properties, still has a hard and complicated problem, straining all its resources. If every city were friendly, Mr. Mellen would still face a thousand perplexities. But the agitators appear to be exhausted, at least temporarily. The directors of the Boston Chamber of Commerce have made a report in which they say that the state of Massachusetts ought not to buy the Boston & Maine, nor require the New Haven to give up its control of it. They see that the weaknesses of the Boston & Maine were not caused by the New Haven management, and in their declaration to that effect, they silence one of the agitators' tom-toms. They call for a "strong" state railroad commission, and would like to have more Massachusetts men on the New Haven's board of directors; and in general present a sane, business-like report. How so conservative a body as the Boston Chamber of Commerce could ever have allowed itself to be used as the tool of irresponsible agitators is something of a mystery. Now, even Mr. Brandeis is quiet. Possibly the reduction in the market price of the railways' stocks, which has now been accomplished, is all that he wants. The New England newspapers also are sane. Those with yellow tendencies have little to say, and the substantial journals, all the time knowing that the proper way to deal with Mr. Mellen, whatever his faults, was through rational discussion, have now found the courage to say so. The city of Boston wants numerous railway improvements and the Chamber of Commerce asks for them, but these are not specified definitely, and the project for aiding new steamship lines, so as to increase the export and import trade of the port, is the principal thing mentioned. The problem of providing railway improvements in a big city, and doing it on a safe basis, financially, is always a difficult one, and the vagueness of the Boston report gives evidence of this fact. The men who framed it realize the magnitude of the task. The city and the railroad are now ready to begin their negotiations where they ought to have begun a year ago.

PROVIDENCE, the other storm center, has had its problem reduced, as compared with Boston's, to the acme of simplicity. The Grand Trunk, after spending two and a half millions on its Providence branch, offers to give away the property outright. If the state of Rhode Island or the city of Providence will take the unfinished railroad and complete the job the Grand Trunk will not only make this big contribution, but will pay 5 per cent. on whatever money the Rhode Islanders may put into the enterprise. In the language of the street, "money talks"; and in this case it talks in very simple terms. Moreover, the answer which it calls for can be (and ought to be) expressed with equal force and simplicity. As an opportunity to translate the talk of stump speeches and irresponsible legislative and newspaper discussions into actual business enterprise, this offer of the Grand Trunk is a notable event. It is claimed that the road is backing out of an agreement dishonorably; that the officers of the company promised to build a railroad to Providence. As to whether this agreement was in writing or what were its precise terms nothing is published. No evidence is produced to show that there was even a moral agreement, nor do we know with whom the agreement was made. That the officers of the Grand Trunk honestly intended to build the road is clear enough from work that has already been done. They would not have spent two and a half millions just to scare the New Haven. Whatever may be the fact as to honor or dishonor, it is difficult to see any better way out than that which is offered. It appears that the Grand Trunk has been forbidden by the Dominion government to involve itself in big investments outside of Canada; and that no money can be raised for the Providence extension without the Grand Trunk's endorsement, because of doubts as to the profitableness of the proposed line. If it be said that the Grand Trunk directors ought to go into their own pockets for the six millions to complete the road, they will reply that Mr. Hays, now dead, went into this enterprise without their authority. We hold no brief for these directors, and know nothing of their thoughts or intentions beyond what is published; but in the present aspect of the case Mr. Chamberlin's offer to operate the road, and pay 5 per cent. on its cost, would seem to be a proposition which the people of Providence ought to regard as

thoroughly business-like. At any rate, as we have said, there will now be a fair opportunity for all citizens to get a very lucid lesson on the general question of the relations of the state to the railroads.

THE SUBSTITUTION OF THE SALE OF LEGISLATION FOR VOTES FOR ITS SALE FOR CASH.

THE enactment of laws in various states, especially to further the supposed interests of railway employees and with the effect of increasing railway operating expenses suggests some not very pleasant reflections on certain contemporary tendencies in politics and government in the United States.

The present is being exalted by many writers and speakers as a period of reform in public affairs. One of the reasons assigned is that the corrupting influence of capital over politics and legislation is being reduced or abolished. There are indications that in the minds of many reform consists in substituting the corrupt and corrupting influence of their own class over government for the corrupt and corrupting influence of other classes. It is true as to railway corporations specifically that in many states and in the nation they formerly used free transportation, and in some cases even cash, to control the action of political conventions, law-makers and even governors. On occasions this was done to secure legislation unduly advantageous to the railways; at other times to prevent legislation unjustly prejudicial to them. The immorality and criminality of these practices have been universally recognized and denounced. In consequence of the aversion to them of honest corporation officials, of the public sentiment that has been manifested, and of legislation which has been passed they have been almost abolished. It is now even against the law for a corporation to contribute to a national campaign fund. Today almost the only means used by railways to influence public regulation of their affairs is the most open presentation of facts and arguments to the public, to regulating commissions, to law-making bodies and to public executive officials.

Capital has much money, but relatively few votes. Labor organizations have relatively little money, but many votes. While the illegitimate use of money to influence legislation has greatly decreased, the illegitimate use of votes to get it is rapidly increasing. Citizens are given the suffrage in order that they may protect and further their legitimate interests; and the *legitimate* interests of every citizen coincide with those of the public. Therefore, no man or class of men has any moral right to use his vote or its votes to promote ends that are contrary to public ends. Men are elected to legislatures and to other public offices solely to serve public purposes. They have a right to solicit and secure votes by promising to carry out, and by carrying out, policies intended and adapted to promote the interests of the public. They have no right to solicit and secure votes by any other means or for any other purpose whatsoever.

Now, the members of the railway labor brotherhoods through their legislative representatives are seeking legislation such as that to increase the size of train crews in the pretended interest of safety, but for the real purpose of increasing the number of men that railways must employ. There is not a single well-authenticated case on record of a fatal accident caused by the want of enough men in a train crew. Governor Sulzer of New York, in a statement defending his action in signing the full crew bill in that state, said "the truth is that nearly all the accidents of recent years might be prevented by the employment of more men." If Governor Sulzer, in making that statement, did not say what he knew to be false, he is the most ignorant man regarding the facts about American railway accidents who ever undertook to discuss them. No assertion on the subject more utterly incorrect and misleading ever emanated from any source; and it is incomprehensible how the governor of a great state, having any sense of his public duty or responsibility, could have given it currency, supported by the weight of his name and official title. The only accident specifically referred to by him —that in which, as he says, 41 persons were killed—was due to neglect of an engineman who had on the engine with him a monitor, presumably competent, in the person of his fireman. How would the third brakeman called for by the new law have tended to prevent the engineman's error? The fact is that the full crew legislation not only does not increase the safety of transportation, but interferes with making it more safe. It has been estimated by the special Committee on the Relations of Railway Operation to Legislation that a federal full crew law would increase railway operating expenses $12,000,000 a year. That amount is 5 per cent. on an investment of $240,000,000. It has been estimated by the same authority that for $200,000,000 all the railways could be equipped with the block system. Now, the universal installation of block systems would materially increase safety, while full crew legislation does not increase it in the slightest degree. In other words, the full crew legislation, by requiring an addition to operating expenses which does not increase safety does tend strongly to interfere with the installation of the block system which would increase safety. The only effect of full crew legislation is needlessly to increase the operating expenses of the railways. This causes economic waste, the ultimate effect of which is to injure the public, because all of the operating expenses of the railways must be paid from revenues derived from freight and passenger rates. Mr. Sulzer's utterance accentuates the change that has taken place in the executive mansion of New York state since Charles E. Hughes was governor; and the fact that the governor of Oklahoma vetoed the full crew bill in that state illustrates one improvement that has taken place in affairs in Oklahoma since Charles N. Haskell was governor.

The means by which the railway employees are securing such legislation is by indicating that the law-makers who vote for their bills and the governors who sign them will benefit by being given their votes, while those who refuse to do so will suffer correspondingly. In other words, they are bribing the law-makers and the governors with votes in the same way, for the same purpose and with the same effect, as corporations have in other years bribed law-makers and governors with cash. The law-makers who are voting for these bills and the governors who are signing them, if they are acting with a scintilla of intelligence, know that they are contrary to the public interest. To all appearances they are being passed and signed because those who pass and sign them believe that while they are designed and adapted to confer special privileges on a class at the expense of the public, they will secure votes for those who pass and sign them. In other words, railway employees are consciously bribing public officials with their votes, and public officials are consciously letting themselves be bribed by them into passing and signing legislation which sacrifices the interests of the many for the supposed benefit of the few.

Neither morally nor in the results to the public does the huckstering of legislation in exchange for votes differ essentially from its purchase and sale for cash. Capital in the one case and labor in the other uses the currency of which it commands the largest supply. That is the only difference. Public men in each case sell the same commodity, namely, the public welfare. The two kinds of transactions equally involve moral turpitude, are equally shameful, equally contrary to the duties of citizens of a democratic state, equally disregard every dictate of honor and duty by which public officials should be governed. That this is not generally recognized simply shows that there is need for a much greater public awakening on moral and political questions than has yet occurred. That the men who in public life are loudest in denouncing improper activities on the part of corporations are also those who are the most forward to rush into the market and to sell the interests of the public for votes for themselves simply shows that the political hypocrite, demagogue and dispenser of buncombe are still with us.

The immorality and wrong to the public of the sale of special privileges to capital for cash has become clearly and generally recognized. When will the immorality and wrong to the public of the sale of special privileges to certain classes for votes become as clearly and generally recognized?

NEW YORK'S FREIGHT TERMINAL PROBLEM.

THERE has never been a far-sighted co-operative plan for handling New York's local freight traffic on Manhattan and for properly developing its harbor. The old hand-to-mouth policy of handling local traffic on the west side waterfront of Manhattan has been pursued until it has reached its limit of development, but the volume of traffic is ever increasing. The serious congestion, delays and excessive terminal expenses entailed by this system make expansion imperative. To continue to develop along the old lines the railroads would require more space on the west side waterfront. This is not available and cannot be created. Moreover, the greater part of the space now occupied by the railroads on the waterfront is urgently needed for the expansion of shipping facilities. This waterfront space is the just inheritance of the steamship companies and the welfare of the city demands that they be permitted to make full use of it. As the railroads can never hope to handle the future growth of traffic with their present facilities, and as expansion on the waterfront is out of the question, only one course is left—to go elsewhere.

Confronted with this situation the roads terminating on the New Jersey shore of the North river have continued to hold back, vainly contending that the steamship companies should be forced away from the waterfront for their benefit. They have made no attempt to solve the problem along new lines and have individually considered and condemned each plan that has been devised for them. Some of the proposed solutions are outlined on another page. Perhaps a successful solution of the problem has not yet been presented, but the thing most to be deplored is that the criticism of the Jersey roads has been solely destructive. The limited amount of desirable space and the enormous expenditures involved make co-operation necessary to secure maximum efficiency and minimum expenses. Obviously a satisfactory solution of this problem can never be reached without the assistance of the railroads, but thus far the Jersey railroads have flatly refused to co-operate because of the rivalry and jealousy which exist between them.

The city stands ready to lend its valuable assistance to the successful completion of any project which shall meet with general approval. Funds for the initial costs of the improvements can be raised at a lower rate of interest by the city than by the railroads, and if these improvements were built and owned by the city the rental charges would only have to meet the interest charges, maintenance and amortization. No profit would be necessary. The city would be willing to do this because the bonds would be self-supporting and therefore excluded from the debt limit, there would be no public burden and the city would reap enormous benefits indirectly.

Apparently the New Jersey roads lose sight of the fact that the New York Central is their common rival, that its position today is decidedly more advantageous than theirs, and that it has plans under way to still further increase this advantage. If the plan, which has been drawn up by the Board of Estimate's committee on terminal improvements, is approved, the New York Central will cover its tracks on the west side of Manhattan above Seventy-second street, will build a subway south from Sixtieth street connecting with all its terminals, and will remove its present surface tracks south of Sixtieth street. The chief advantages of this plan to the city are negative. The city will have a little more park space along the upper west side, a little less smoke and the dangers of the surface tracks will be eliminated. The New York Central will have a much better connection with its terminals, but the great problem of a co-operative terminal policy, the only thing which will materially benefit New York both commercially and industrially, is left entirely to the future. The New York Central is strengthening its position. What are the Jersey roads going to do? Their common rivalry should be a bond between them, for if a co-operative policy were adopted and carried out the New Jersey roads, by reducing their terminal expenses, would be enabled to compete more successfully with the Central, they would secure a larger proportion of New York's traffic and would benefit both individually and collectively.

The undertaking would be momentous and the roads feel that they will not venture on any plan until it can be definitely proved to them that it will reduce costs, facilitate transportation and preserve approximately the same balance of power between them. Until now no committee, properly equipped to draw up a plan to meet all these requirements, has studied the question. A successful plan would involve engineering, operation and the interests of both New Jersey and New York City. Therefore, if a committee were formed, composed of one engineering and one operating officer of each of the roads interested, together with representatives of both New York City and the state of New Jersey, it should not be long before a plan was devised which would be satisfactory to all. Until some such committee is formed there is but little chance of any general policy being agreed upon. In the meantime the situation will become even more aggravated than at present. The present terminal expenses are needlessly high, and therefore involve waste. This waste should be eliminated.

The needed improvements include the evacuation of the west side waterfront by the railroads to permit the expansion of shipping facilities; the establishment of joint terminals and warehouses connected with all railroads and all docks; the diffusion of these terminals to prevent the congestion of drayage; the installation of mechanical devices for handling package freight quickly and cheaply; the partial elimination of railroad traffic from the surface of the harbor to permit more freedom for marine traffic; and above all a reduction in terminal expenses. If it is impossible to devise a plan which will meet all these requirements then the plan which would meet most should be adopted; but until the problem has been properly grappled with there is no means of knowing what can and what cannot be done.

NEW BOOKS.

Locomotive Dictionary. 1912 (Third) Edition. Compiled and edited for the American Railway Master Mechanics' Association by Roy V. Wright, managing editor of the *Railway Age Gazette* and editor of the *American Engineer*, assisted by Porter L. Swift. Illustrated. 901 pages. 9 in. x 12 in. Published by the Simmons-Boardman Publishing Company, New York, and distributed by the McGraw-Hill Book Company, 239 West 39th street, New York. Price, leather bound, $6; cloth bound, $4.

The progress made in the design of locomotives, both steam and electric, during the past three years is well illustrated by the contents of this edition of the Locomotive Dictionary when compared with the 1909 edition. It has been necessary to go beyond a mere revision of the previous edition, and so far as the illustrated section is concerned, it is practically a new book. The definition section also has been thoroughly revised and considerably expanded. While the Mallet, Mikado and Pacific type locomotives have been given special attention, the lighter types are by no means overlooked. This is especially true in connection with the switching and Atlantic type locomotives. In connection with each locomotive elevation a complete list of dimensions, weights and ratios is given, an improvement which, no doubt, will be much appreciated. It is evident that considerable study has been given to the selection of the typical parts and details that are presented and only approved designs that have been successful in service are illustrated. Cross references between the general and detail drawings are included wherever possible. Among the new sections that have been added are one on mechanical stokers and one on locomotive tool equipment; the sections on oil burning locomotives, electric locomotives, air brakes, and frames and frame bracing have been materially enlarged. The illustrations showing the Master Mechanics' Association standards have been entirely redrawn, making them more legible and greatly improving their appearance. The section on machine tools occupies 60 pages and gives photographic reproductions of practically all kinds of metal working machinery used in the repair of locomotives.

Letters to the Editor.

GOOD POINTS IN ENGLISH PASSENGER TRAIN SERVICE.

New York, March 15, 1913

To the Editor of the Railway Age Gazette

During my recent visit to England several practices of the railroads struck me as of possible interest to your readers. The English method of handling commutation is particularly noticeable. They sell what are known as contracts, good for any period desired from one month to a year and for any number of rides. A person simply purchases a contract covering any two stations and rides as often as he pleases. There is no delay to have a piece cut off of the ticket or the necessity of hiring extra men to punch useless holes in tickets, as is done in this country. The contracts are pieces of light cardboard about 3 in. x 4 in., and show the names of the two stations and the date of expiration in large type, so that they may be read at a glance.

The habit of punching holes in tickets in this country is not only to a large extent useless, but is often annoying. The writer vividly recalls missing a train to Philadelphia in order to get a useless hole punched in a ticket. I entered the ferry office in the last few seconds before the boat left, purchased a ticket without delay, waved it at the man with the punch and rushed for the boat, only to be stopped by the man at the gate in response to a yell from the ticket puncher. The man with the punch had seen me purchase my ticket and saw it in my hand as I passed through the chute, but would not permit me to catch my train because he had not succeeded in punching a useless hole. Another incident, amusing instead of annoying, occurred on the New Haven, where a conductor wanted to argue as to my destination because he had punched the ticket so full of holes that the station had disappeared.

So much for the holes. Probably a more important subject is that of train schedules. English trains are on time. As an English railroad is liable for damages in cases of delay, it becomes necessary to have trains on time, and they are. Everyone seems filled with the idea of time and the necessity for keeping trains on time, not only while running but in the departure from stations. It is of this latter feature that particular notice should be taken, as we are entirely too much given to carelessness in this respect, trusting to our giant locomotives to make up the lost time. Our locomotives do make up this loss over and over again, but at a tremendous expense for fuel and repairs.

Only a few days ago I saw one of our fastest trains lose three minutes at a station simply because the passengers were all in a bunch at the far end of the platform from where the train stopped. At another station the ushers had lined the passengers up at the proper places ready to board the train, with the result that not only was no time lost, but one minute of the loss at the other station was made up. Why not extend this idea?

Of course, one could not help noticing the English platforms on a level with the floors of the cars and hoping that the platforms, in at least the more thickly populated sections of this country, would soon be raised.

We are reported to kill on the average fourteen trespassers on the railroads every day throughout the year, and a great hue and cry has recently been made about the matter. Of course, our laws covering trespassing on the railroads are very lax, but the railroads could help by making trespassing difficult. One can hardly manage to walk on an English railroad track without putting himself to great inconvenience.

Those of us who have stood in the vestibule of a dining car waiting what seemed an endless time for a chance to eat, have fervently prayed for a change. The English method is to "book" a passenger for the first or second service, then call him when the meal is ready. This scheme is made easy for the reason that the meals are served in courses to all at the same time just as though it was a large family party. A further advantage is the very considerable reduction in the number of waiters required. Americans would probably not stand for such a procedure at home, but a great improvement over existing conditions could undoubtedly be made. Only last week I found a Michigan Central dining car conductor who made out a regular schedule and notified passengers when they could eat. When I found the diner full and the conductor advised me that he would call me in thirty-five minutes, if I would let him know where I was sitting, I demurred on the ground that someone who stood in the vestibule would get my place. However, he informed me that he ran his car according to schedule and allowed no standing in line. It was certainly far pleasanter to sit down comfortably and read until called, and in my opinion this conductor's method might well be extended.

There are of course many points in which we excel, but my idea in writing this letter is to simply call attention to a few items which may be of interest rather than to make a general comparison.

C. J. Morrison,
Chief Engineer, Froggatt, Morrison & Co.

THE STATION AGENT'S UNIVERSITY.

Texas City, Tex., April 3, 1913.

To the Editor of the Railway Age Gazette:

In your issue of March 28, page 743, there appears an article on "Suitable Studies for Station Agents."

While I have never served a railroad company in this capacity, my railroad experience and an intimate knowledge of the efforts and sacrifices which a small measure of success has cost many of my acquaintances in this line of employment, prompts me to take issue with the writer on some of his views expressed.

While there is but one "royal road to success," there are diversified methods of traveling over that road—depending upon the circumstances of the individual whose ambition spurs him on to something better. Some men who have attained success are really and sincerely of the opinion that experience was their only teacher, yet, if they themselves realized the facts they would be compelled to admit that as a result of one's interest in a particular line one will be impelled to a painstaking study of every article which deals with the subject in which he is interested.

There is no question but that a publication such as the *Railway Age Gazette* is indispensable to a broad view of the various phases of railroading of the present day. The writer is a subscriber for and an ardent advocate of this publication, and acknowledges himself indebted to the publisher and authors of the many valuable articles, which have recently been published, for information which could probably not have been obtained elsewhere. Yet, to the young man who has carefully planned his future course, but who has not been afforded the opportunity of the technical or professional training which he craves through the medium of experience or of a college course, many of the correspondent schools of today afford advantages for advanced study valuable to employee and employer as well.

When one learns to "live on twenty-four hours a day," the time spent in study and mental discipline is an advantage rather than a handicap to his working hours. From practical experience (and for the benefit of others, who, like myself, must acquire their training in the "university of hard knocks") I can state that the subject of law, the various literary branches of a university course, traffic matters, both rail and water borne, and many other important branches, can be successfully taught by correspondence, and that through a study of these courses one can successfully increase his own earning capacity and qualify himself for better service to his employer.

I am submitting this communication solely with the view to offering the encouragement—which I, myself, would have often welcomed—to those who are grasping the only means at hand for attaining to a greater measure of success.

Harvey A. Thomas,
Secretary and Local Attorney, Texas City Terminal Company.

THE DESIGN OF CONCRETE OR REINFORCED CROSS-TIES.

Chicago, March 10, 1913.

To the Editor of the Railway Age Gazette:

I notice in the papers that a representative in Congress introduced a joint resolution on February 4 directing the Interstate Commerce Commission to investigate and report upon the use and necessity of a certain specified combination railroad tie. An appropriation of $25,000 goes with this resolution, to provide for the expense of an investigation of this particular tie and other kinds now in track. The investigators are also to consider the question of accidents due to defective track and roadbed and are to have six months to prepare their report.

The first thing that strikes one on reading this item of news is that the Interstate Commerce Commission is being invited to investigate itself. The commission has recently made a report,

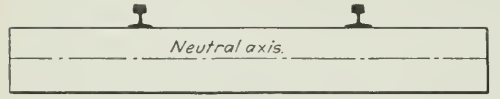

Fig. 1.

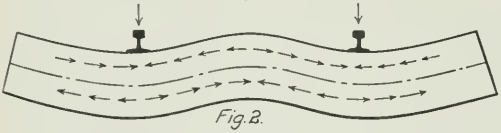

Fig. 2.

Exaggerated elastic line of tie under vertical loads.

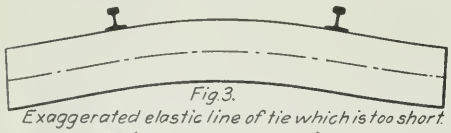

Fig. 3.

Exaggerated elastic line of tie which is too short.

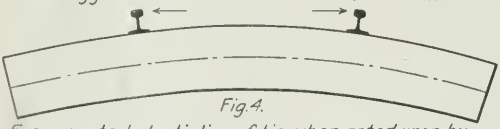

Fig. 4.

Exaggerated elastic line of tie when acted upon by horizontal forces.

after some five years' consideration of these matters, which deals with the subjects mentioned above. (See report of the Block Signal and Train Control Board, *Railway Age Gazette* of February 14, 1913, page 293.) This report covers most of the objections to concrete ties. One point is omitted, however, viz., that the fastenings must provide for different widths of rail bases to allow for relaying.

The joint resolution seems to imply dissatisfaction with this report. Is it because the investigating committee failed to perceive the many exceedingly fine (perhaps invisible) points of some particular make? The *Congressional Record* might consider the propriety of fixing space rates for advertising, and perhaps our bulkiest publication of innocuous fiction might be made to pay. We could then have the pleasure of seeing alongside of speeches that were never delivered, appliances that were never used. Why does our so-called representative feel so much interest in a matter of this sort? Could it possibly be because it is "agin" the railroads?

The impression seems to have gone forth that the railroads are not giving any attention to these matters and know nothing about them. On the contrary, every chief engineer's office in the country is flooded with sundry schemes by which some individual hopes to repeal the laws of mechanics. A little elementary knowledge of mechanics would help most of these inventors. In time, undoubtedly a good compound tie may be invented by some one and its qualifications must be in the line set forth by the board cited above.

I would suggest to those going into the question that they demonstrate what happens when the compound tie is loaded. These demonstrations can be made mathematically. As a starter, the following will indicate the method. Figure 1 shows a homogeneous tie without a load. Figure 2 shows the exaggerated form of the elastic curve assumed by the tie when placed on a uniformly elastic bearing or ballast. This supposes that the tie is of sufficient length. Figure 3 shows the form assumed when the tie is too short. As will be noticed, the tie is subjected to shearing stresses under the base of the rail. In addition to this, the outer fiber of the top of the tie is in tension (Fig. 2) at the middle and in compression under the base of the rail. The bottom of the tie is in tension under the rail and in compression in the middle. This explains why so many ties are faulty; the materials of which they are composed are not calculated to resist certain kinds of stresses. The wooden cross-tie with considerably less powers of resistance still answers the purpose on account of its approximately uniform elasticity. If these manufacturers and inventors of cross-ties will come forward with a rational explanation and demonstration showing why certain materials have been placed at certain points and other kinds at others, they will always receive attention. It may surprise them, no doubt, to find that statute law, even when its constitutionality has been passed upon by the Supreme Court, will not repeal or abrogate the smallest law of mechanics.

Paul M. La Bach.
Assistant Engineer, Chicago, Rock Island & Pacific.

PUNISHMENT FOR INTOXICATION.

Washington, D. C., March 7, 1913.

To the Editor of the Railway Age Gazette:

"Sulzer Signs His First Law."—These were the headlines that attracted my attention in a recent New York paper, and I was further interested in finding that the law which gave the governor so much satisfaction in signing was one for the punishment of drunken chauffeurs. The governor remarked, "I don't think we ought to countenance drunken chauffeurs." He is right; but what about train employees?

Some years ago I suggested to the railroad commissioners in a southern state that they advocate the enactment of a law making intoxication on the part of train employees, or any employee engaged in the operation of trains, a felony; make drinking on duty a crime.

The states and the federal government are forever passing laws and penalizing corporations for violations of law, but such laws seldom provide a penalty or punishment for the real violator. We are trying to safeguard the public by the introduction of mechanical devices; why not also safeguard the people with a few laws applying to the human agency?

Ex-Railroader

[A man in charge of an engine or a train should not be intoxicated or drink on duty; that is generally agreed on; but many railroad officers are now disposed to go further than that; to require total abstinence at all times. It is very difficult, however, to enforce so rigid a rule. Our correspondent is in a sense less radical than railroad managers. He would find it very difficult to enforce his rule; less rigid as a rule, but ostensibly more severe in the proposed punishment. Courts and juries cannot be induced to impose severe punishments except where there is a well defined and serious offense; and cases of drunkenness often are not susceptible of clear definition or satisfactory proof—while yet they are serious enough to afford all necessary moral justification for dismissing and perhaps for punishing the culprit. The brotherhoods, which boast of their influence over legislation, are not very likely to promote a law of the kind proposed; and bills affecting "labor" which are not promoted by the labor unions rarely, if ever, become laws.—Editor.]

STEEL PASSENGER CAR DESIGN.

A Symposium of Papers Prepared by Experts for Presentation Before the New York Meeting of the Am. Soc. Mech. Engrs.

So successful was the railway session of the December meeting of the American Society of Mechanical Engineers that the committee in charge, of which E. B. Katte, of the New York Central, is chairman, immediately took steps, in co-operation with the New York meeting's committee of the society, to plan for another railway meeting to be held in New York. This session, held Tuesday night of this week, was more than ordinarily successful, in spite of the fact that the program was of great length. It consisted of thirteen short papers, each prepared by an expert on the particular phase of the subject assigned to him. Abstracts of these papers follow:

INTRODUCTION TO GENERAL DISCUSSION.

By H. H. Vaughan.

Assistant to the Vice-President, Canadian Pacific.

The advent of the steel passenger car has brought with it many new problems and an opportunity for more diverse opinions than any other change that has taken place in car equipment. The construction of the wooden passenger car developed along fairly uniform lines. The varieties of framing were few and the differences unimportant, while the introduction of steel platforms, wide and narrow vestibules, reinforced end and sill construction and similar improvements occurred gradually, and with practically similar designs on all roads. The change from wood to steel in freight car construction resulted in the abandonment of designs that had almost become standardized and the introduction of many new types, but in this case the principal problem, other than that of obtaining satisfactory designs, has been the extent to which it was advisable to use composite or all-steel construction.

In the case of the passenger car, the types to be employed will probably not be changed by the substitution of steel for wood. The increase in capacity that has taken place in freight equipment cannot be duplicated in passenger cars, and there appears to be no tendency at present toward any increase in length or carrying capacity. The questions that now confront us relate rather to the design and construction of cars of the present type and of the materials that may be advantageously employed in place of the wood which has been used for so long. They are complicated by the necessity of providing for greater safety for the passengers than was secured in the wooden car, with an equal degree of comfort, and the difficulty of anticipating the behavior of this new equipment in the case of accident. Certain difficulties, such as the best systems for heating, lighting and ventilation, are common to both steel and wood construction, and improvements in these matters pertain to general progress rather than the use of steel construction.

The following list, while probably incomplete, outlines in a brief way the important variations that must be considered in deciding on the preferable construction of steel passenger equipment:

Framing	Steel underframe	
	All-steel frame	Center girder
		Side girder
Outside finish	Plated	
	Sheathed	
Roof construction	Clear-story	
	Circular	
Inside finish	Steel	
	Wood	
End construction	Design and strength	
Floor	Design and material	
Insulation	Material	

No doubt questions of equal importance have been omitted, and in many cases those mentioned require careful consideration with regard to degree, as for instance, the strength of the framing or the thickness of the insulation. The list illustrates, however, the diversity of possible solutions of the preferable steel passenger car.

The steel underframe does not appear to be a satisfactory or permanent development. There is but little saving either in weight or cost over the all-steel construction, and it is difficult to see how the same strength in case of accident can be obtained. Experience will show whether the wood superstructure can be secured in such a way as to prevent working as the car gets old, but as it cannot be arranged to carry any weight this appears questionable. It can hardly be regarded except as an intermediate step between all-wood and all-steel construction.

In all-steel construction the side-girder car presents advantages, but, as in freight construction, both types will probably persist. The side-girder construction utilizes the greater strength on the side framing without superfluous weight, and it is possible that greater framing strength may prove necessary. With equal strength of side framing the side-girder car may be made lighter than the center-girder type, and the weight of steel passenger cars is one of the most serious problems to be faced by any railroad not having a level line. American passenger equipment was already excessively heavy per passenger carried with wood construction, and the use of steel has increased this weight from 10 to 20 per cent., which is a most serious matter. Apparently side-girder cars, as so far constructed, have a decided advantage over the center-girder type in their light weight and greater strength in case of accident tending to crush in the side of the car. This will probably lead to the use of this type on roads on which weight is of importance.

In spite of the many advantages of the sheathed car in case of construction and maintenance, it appears that the cost and weight of the additional metal will prevent its extensive use. This question is chiefly one of appearance and convenience, and is of minor importance.

The circular roof has been extensively introduced on steel passenger cars on account of its lightness and simplicity of construction. It has the objection that deck sash ventilation cannot be employed. The Pullman Company while using the clear-story roof have, however, discontinued the use of deck sash ventilation, so that evidently in their opinion this objection is not important. The deck sash is, however, of value in a standing car, and when properly screened is certainly advisable in hot weather, especially when the road is dusty. The Canadian Pacific has compromised on this question and is using a roof of approximately circular form with deck sash. The strength and simplicity of the circular roof are retained with the ventilating qualities of the clear-story type.

The preferable material for inside finish is a matter for future decision. With the ample protection afforded by a steel car against accident, there does not appear to be any objection to wood inside finish on the ground of safety. It is more ornamental than steel and a better insulator. Probably on no question in passenger car design is opinion so divided amongst both railroads and car builders. There is today very little difference in cost, and it certainly appears probable that in the future the tendency will be to adopt steel interior finish, if not entirely, at any rate to a great extent.

The construction of the ends of the cars has received considerable attention, and the strength now usually employed is enormously greater than anything attempted in wood construction.

The floor construction in steel cars is entirely different from that in wooden cars, and is usually of metal covered with a flexible cement. In constructing a sample car for the Canadian

Pacific the writer used in addition an underfloor covered with insulating material, and covered the cement with ½ in. of cork. This car was also exceptionally well insulated at the sides, 2 in. of cork being used next the outside plating. Tests during the past winter have shown that this car is actually warmer than the ordinary wooden car, the same amount of heating surface being used in both types. The floor was tested by taking the temperature of water standing on it in cans, there being no practical difference between the results in the wood and steel cars. The question of insulation is an important one, both in hot and cold weather, and while other insulation might no doubt be equally effective, it is interesting to be able to advise that with proper insulation there is no question of the steel car being satisfactory.

PAINTING OF STEEL PASSENGER CARS.

By C. D. Young.
Engineer of Tests, Pennsylvania Railroad.

A fundamental reason for painting any surface of a passenger car is to protect it from the damaging effects of the air which is more or less loaded with gases and moisture.

The all important point in the painting of iron or steel surfaces is first to have the surfaces thoroughly cleaned and entirely rid of scale and rust, as this is as important as the painting itself. To accomplish this, sand blasting, where possible, was resorted to, supplemented by the use of wire brushes and emery cloth in the more obscure places and the more uneven surfaces. The sand-blasting, however, was confined largely to the outside surfaces and the latter practices to the inside portion of the car.

The schedule for painting steel passenger car trucks, underframes and superstructures is as follows:

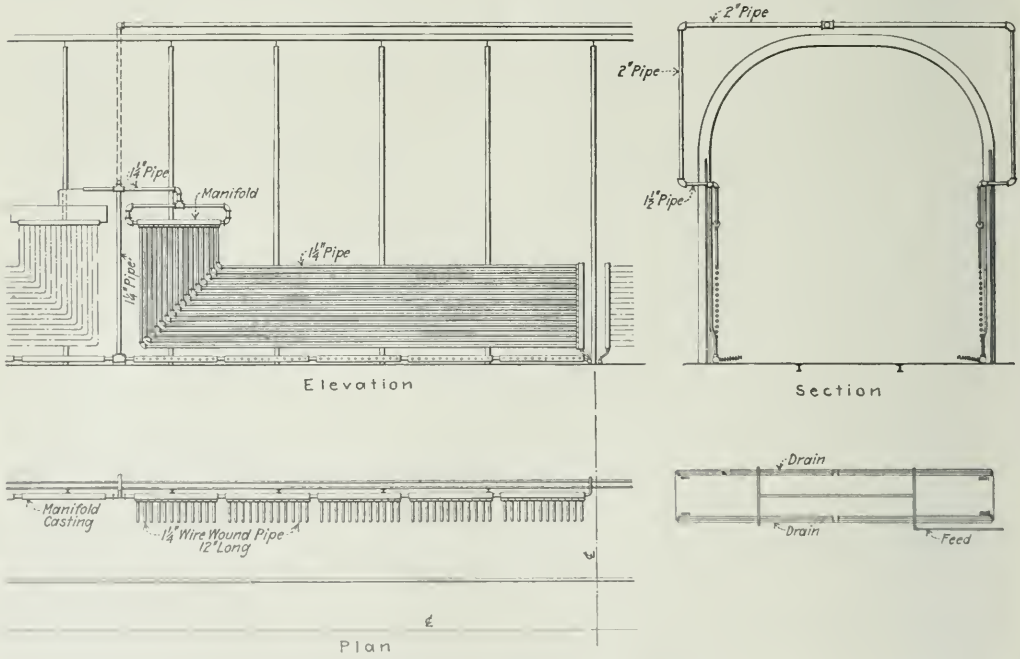
Trucks. Before assembling all surfaces on truck parts (except those which include all concealed surfaces, but not including wheels and axles, must be covered with one coat of suitable primer. After assembling, all surfaces exposed to view after the body of the car has been placed on trucks, except wheels, must be covered with two coats of truck enamel.

Underframes. During the process of construction all parts of the underframe, including concealed surfaces and surfaces where metal bears on metal, must be covered with two coats of good metal preservative of a non-inflammable nature. All accessible surfaces must be covered with a third coat of metal preservative.

Superstructures. Before assembling all parts made of iron or steel, including the roof, must be covered with one coat of primer. A second coat of primer, properly thinned with turpentine or similar material, must be applied to all surfaces, including those which are concealed when the car is completed. Wherever possible, this second coat must be put on after the sheets are in place.

After assembling, the outside of the side and end sheeting, including letter plate and deck plate, must be covered with one coat of surfacer, the rough and uneven places glazed with "surfacer composition," four coats of surfacer being added, rubbed down with linseed oil and emery cloth, two coats of desired color material added, followed by striping and lettering, then finished with three coats of finishing varnish. The outside of the roof must be finished with one coat of heavy protective paint, followed by one coat of a mixture composed by volume of three parts of mixed ground color and one part of the protective coating used. The top surface and edges of the headlining should be painted with two coats of some preservative, or color paint.

The interior of cars should receive very careful attention in order to produce the desired finish. To illustrate fully the various steps and time taken to complete the painting, the following is given as outlining the progress of the work. This is attained with the use of surfacers, colors and varnishes con-



Steam Piping in Oven for Baking Paint on Steel Cars.

taining a relatively large amount of artificial driers and varnish gums, in order to obtain the artistic finish desired for the interior.

Headlining.

1st day.—Apply one coat and stipple after application.
2d day.—Stand for drying.
3d day.—Apply one coat and stipple after application.
4th day.—Stand for drying.
5th day.—Apply one coat and stipple after application.

Sides Above Window Sills and Ends.

1st day.—Apply one coat or primer.
2d day.—Stand for drying.
3d day.—Apply one coat surfacer.
4th day.—Necessary puttying and glazing.
5th day.—Apply as many coats surfacer as are necessary to make a level surface.
6th day.—Same as 5th day.
7th day.—Rub down with emery cloth and linseed oil.
8th day.—Apply one coat of ground color.
9th day.—Apply one coat of ground color.
10th day.—Apply one coat of ground color.
11th day.—Apply one coat and stipple after application.
12th day.—Apply one coat rubbing varnish.
13th day.—Stand for drying.
14th day.—Apply one coat rubbing varnish.
15th day.—Stand for drying.
16th day.—Apply one coat rubbing varnish.
17th day.—Stand for drying.
18th day.—Rub with oil and pulverized pumice stone.

Sides Below Windows.

1st day.—Apply one coat or priming.
2d day.—Stand for drying.
3d day.—Apply one coat surfacer.
4th day.—Necessary puttying and glazing.
5th day.—Same as 6th day.
6th day.—Apply as many coats surfacer as are necessary to make a level surface.
7th day.—Rub down with emery cloth and linseed oil.
8th day.—Stand, awaiting bringing up other work.
9th day.—Stand, awaiting bringing up other work.
10th day.—Apply one coat bronze green.
11th day.—Apply one coat bronze green.
12th day.—Apply one coat of rubbing varnish.
13th day.—Stand for drying.
14th day.—Apply one coat of rubbing varnish.
15th day.—Stand for drying.
16th day.—Apply one coat of rubbing varnish.
17th day.—Stand for drying.
18th day.—Rub with oil and pulverized pumice stone.

Results of Air Drying Paints on Steel.

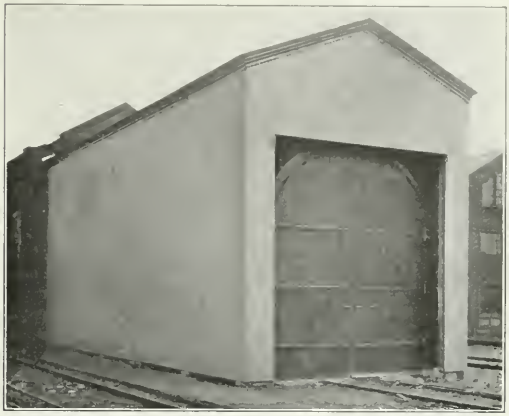
The artificial driers and gums used in hastening the time of drying and hardening of the various coats and permitting the necessary rubbing continue this action so that the paints and varnish increase in hardness and brittleness, rendering them susceptible to cracking and chipping, and the process of disintegration is aggravated by excessive expansion and contraction of the steel surfaces as compared with wood. The linear expansion of steel being more than twice that of wood would seem to indicate the use of more elastic coatings than formerly used for wooden cars.

This fact has been borne out in the service of the paint in a great many cases in an investigation which recently came under my observation. It was noticed that when some of the equipment had been in service about four months, the interiors of the cars showed varnish cracks and checks. As time went on more cars gave evidence of this deterioration, the final outcome being that an investigation was made to see how serious the condition was. Some 400 cars were carefully examined, special attention being paid to choose cars built by various manufacturers, where different makes of surfacers and varnishes were employed. An endeavor was also made to determine whether the cracking of the painted surfaces was confined to the varnish coats or the surfacer coats, or both. In order to classify the various conditions found, four readings of percentages were arbitrarily taken, the condition of a new car being taken at 100 per cent.:

Per cent.	Condition of Varnish and Surface.
90 to 80	Good, no checking
80 to 70	Fair, slight checking
70 to 60	Medium, considerable checking
60 to 50	Poor, checked from outside varnish coat to metal

Sample cars were selected to illustrate these various classes, and photographs were taken of the different defective surfaces so as clearly to indicate to the eye what the different percentages meant.

The result of this examination showed that the exteriors including the sides, ends and vestibules, were in fair condition There were a few exceptions to this, but they amounted to less than 6 per cent. of the total having serious varnish and surface cracks. Interiors were found generally to be in a poor condition. About 80 per cent. of the equipment examined had the



Exterior of Oven Used for Baking Paint on Steel Cars.

varnish checked through to the surfacer. Some of these conditions developed after four to eight months' service, indicating either that an entirely new system of painting would be necessary to overcome these troubles, or that a more elastic paint would have to be used for interior finishing under the present existing practice of painting steel.

To obtain some data indicating what should be done to meet the conditions, preliminary experiments were made by painting a number of panels and baking them in a heated oven. Repeated experiments along this line indicated that artificial driers could almost, if not entirely, be eliminated in the paint formulae

Steel Car in Oven.

and that more elastic materials could be used without the aid of artificial oxidizing agents. It was also observed that the elastic varnish used on the exterior of the cars could, under this system, be used to advantage on the interior, and by the aid of the heat of the oven they could be dried to the desired hardness, permitting the rubbing with oil and pumice to get the "flat finish." The outcome of the experiments indicated that it would be desirable to extend the experimental panels to a full size car and, therefore, a proper baking oven was planned that would accommodate one of the largest existing steel passenger cars for the purpose of baking each coat as applied to the exterior and interior surfaces.

This oven, as designed and built by the Pennsylvania Railroad at its Altoona shops, is 90 ft. 3 in. long, 13 ft. wide and 15 ft. high. The framework of the structure is made up of 3-in. I-beams for the sides, spaced 5 ft. centers. The roof framing is made of the same sections and curved to conform closely to the contour of the car roof. Each end of the oven has two large doors which may be readily opened and closed. The oven is lined on the inside with ⅛-in. steel plate, and on the outside with galvanized iron of 0.022 in. gage. The 3-in. space is filled with magnesia lagging, thus effecting the needed insulation. The doors are insulated in a similar manner. Along the walls of the interior of the oven are placed 16 rows of 1½-in. steam pipes, and along the floor, close to the walls, are arranged manifold castings with small lengths of pipe tapped into them at right angles. By this means over 2,000 sq. ft. of heating surface is provided. A steam pressure of approximately 100 lbs. to the square inch is used, thus making it possible to get an oven temperature of over 250 deg. Fahr. Rectangular openings, made adjustable, are provided on the sides near the floor line, allowing the necessary admission of air for circulation. Four 8-in. Globe ventilators are spaced at equal distances in the roof and are provided with dampers to regulate the size of the opening. By this means of ventilation, fresh air, which is required for the proper drying of paint, is obtained, as well as providing for the egress of the volatile matter present. Automatic ventilation and steam regulation have not, at the present time, been applied, but these have been considered advisable, if the result of the experiment seems to warrant a more extended application of the practice. A track is placed on the floor of the oven and connected at each end of the oven with other tracks leading into the regular paint shop where the different coats of paint are applied to the car before each baking operation.

BAKING PAINT ON STEEL.

The method of painting a car in this oven is briefly as follows: First, a priming coat is given the exterior and interior of car, which is then moved into the oven and baked for three hours. The temperature at the start is about 160 deg., but rapidly rises at about 1 deg. per min. until a temperature of 250 deg. is reached, requiring about 1½ to 2 hours. The oven is held at this temperature until the lapse of 3 hours, when the car is withdrawn and allowed to cool sufficiently to work upon, after which the surfaces are glazed and depressions and uneven places puttied. The car then receives its first coat of surfacer, is returned to the oven for 3 hours, baked and removed for additional coats which vary from two to three in number as the needs of the case require.

Table I.—Time Schedule for Painting Exterior and Interior of Steel Passenger Cars.

	Outside.			Inside.		
Period of Work.	Body.	Roof	Trucks.	Body Above Window Sills.	Head-lining.	Body Below Window Sills.
1	1st prime	1st prime	.....	1st prime	1st prime	1st prime
2	Glaze	.....	.....	Glaze	Glaze	Glaze
3	1st surface	.....	.....	Rub ground	Rub	Rub
4	2d surface	2d prime	.....	.....	.....	.....
5	3d surface	.....	.....	.....	.....	.....
6	Rub	.....	.....	.....	.....	.....
7	1st tuscan	3d prime	.....	3d ground	1st green	1st green
8	2d tuscan	.....	.....	Stipple	.....	.....
9	Stripe and letter	.....	.....	.....	.....	.....
10	1st varnish	.....	Trucks	1st varnish	.....	2d green
11	2d varnish	.....	Oven	2d varnish	.....	.....
12	3d varnish	.....	.....	3d varnish	.....	1st varnish
13	.....	.....	.....	Rub	2d green air dry	.....

After the last coat of surfacer has been applied and baked, the outside surface of the body of the car is rubbed down with emery and oil to produce a flat and smooth surface. The various color coats used, such as tuscan red on the outside, pale green, bronze, and bronze green on the inside, are then put on. Two coats of each color are required to get standard shades. Each coat of color is likewise baked.

The car then receives the required lettering, striping, etc., after which the outside and inside surfaces get three coats of a high grade finishing varnish, especially adapted for the baking process. Each coat of varnish is baked at a temperature from 120 deg. Fahr. at the start to 150 deg. Fahr., which is maintained until the expiration of 3 hours. The interior surfaces of the car are then rubbed with pumice and oil, giving the "flat finish" effect desired, thus completing the painting of the car. To illustrate better the schedule of operation followed, or the timing of the various coats, both for the outside and inside, to secure the most economical conditions, Table 1 is given.

All of the work done by the baking process of painting may be accomplished in six to eight days, thus effecting a saving in time of about ten days as compared with the standard or present air drying system. Further, the paints and varnishes have been worked up so that they are especially adapted for this baking process, having greater elasticity. Exact formulae for the various mixtures are well defined, so that uniformity in material is expected, thus giving greater durability, better appearance and longer life for the paint work.

The checks and cracking previously found will be considerably lessened, if not almost removed. By oven painting the work is done under more uniform conditions, which at the present time are so hard to control. It enables the surfaces of the car to be heated uniformly and dried thoroughly, thus removing any objectionable moisture before the first priming coat is applied, which is a very desirable feature of the new method.

A considerable saving will be effected by the shorter time that cars will be held out of service when undergoing repairs and repainting in the shops. It is expected that dirt, soot, etc., will not adhere or imbed themselves so readily and that the general appearance of the car will be improved.

This oven was placed in service the early part of this year and the results of the complete car at this time seem to justify the experiment. They seem to indicate that the results obtained from a small panel can be duplicated in the full size passenger equipment car and that, if this is the case, this method of painting can be used to advantage not only for the painting of steel passenger equipment cars, but for the painting of any other full size steel structure of a similar character where protection and finish are desired.

Results and indications at this time seem to justify our expectations that the new process of baking will give, over the present air drying system: (*a*) Longer life of material applied. (*b*) A general appearance as good or better. (*c*) Less cost of material at no increase in the labor charge. (*d*) A considerable saving of time for shopping cars, which results in a saving of shop space. (*e*) Complete sanitation for old cars. These advantages are offset by the initial cost of installation and operating cost of the oven.

TRUCKS FOR PASSENGER CARS.

By John A. Pilcher,
Mechanical Engineer, Norfolk & Western.

Six-wheel trucks. The six-wheel, all-metal truck has the following advantages which make for its selection over other types: It is non inflammable. It provides a strong material to resist the heavy loads, and occupies only a limited space. It provides a durable material. It reduces the axle loads, and the unit load on the bearings, lessening the liability to hot boxes, reducing the pressure on the brake shoes, lessening the tendency to heat the wheels and shoes, adding to the life of the brake shoes, and reducing the frequency between renewals and adjustments. It spreads the heavier loads over a greater area of

structure, and brings more points of contact with the rail, reducing the influence of track irregularities on the riding of the car, and in cases of very heavy cars, where the unit pressure between wheel and rail might approximate the elastic limit, reduces the tendency to shell the wheel and roll out the rail, adding to the life of both.

It has been estimated that for a passenger car making 50,000 miles a year, the cost for hauling the car is 5 cents per lb. per year. If the six-wheel trucks weigh 14,000 lbs. per car more than the four-wheel trucks necessary to carry the same car, it means the hauling of 14,000 lbs. additional at a cost of $700 per year, which brings up a question for vital consideration. While the wheels, brasses, and brake shoes, and other such removable parts may individually have a longer life, there are also more of them in service during the period. Careful comparison would have to be made to determine which has the advantage at this point.

Four-wheel trucks. The four-wheel, all metal truck is also available in connection with steel cars, and has the advantage of reduced first cost, reduced weight, smaller number of parts to maintain, and if the car is sufficiently light for the unit stress between the rail and wheel to be kept down to a point well below the elastic limit of the material, they should be given serious consideration. The only drawback under these conditions is the possibility of its reduced riding qualities. Its decided advantage in reducing the weight of the train should help to make it a favorite because of the corresponding reduction in the cost of transportation.

Cast-steel vs. riveted wrought-steel frames. The cast-steel one-piece frame has become a great favorite even in the face of the high unit cost of these castings. The adaptability of the castings to the various changes of form and section necessary on account of the limited available space has no doubt had much influence. The attractiveness of the one-piece structure, eliminating all joints, and furnishing a frame ready set up, is another strong argument in its favor. The manufacturers having control of this cast-steel truck frame have evidently been successful in reducing to a minimum the concealed flaws often met with in steel castings. This, no doubt, has added largely to its popularity.

While the absence of riveted joints and the consequent doubling of material at the joints helps to keep down the weight, the fact that the working fiber stress of cast steel is low, and the sections at many points have to be made larger than is necessary on account of foundry limitations, the weight of the frame as a whole is great. This added to the large unit cost for special steel castings makes the user pay well for the advantages gained.

The riveted wrought-steel frame seems to have been held back in its development by the success of its rival in cast steel. Many users have shown conservatism in making use of the good thing already considered acceptable, hesitating to try out the different construction with the hope of lower first cost, with less weight, and equally good service. Wrought steel at a very moderate unit cost has the advantage of a very reliable material which can be worked to a relatively high fiber stress. The cost of fabrication, when the work is done in any large quantity, when added to the cost of material, will still leave a large margin in its favor. Is it possible that the lack of a specially interested advocate has prevented its virtue from becoming prominent, and delayed the experience needed to prove, in actual service, its worth? We find that practically all of the prominent car builders have already worked up designs for wrought-steel trucks, and are ready to construct them if the purchaser so desires, but they do not seem inclined to push them, as they evidently offer no special inducement to their own advantage.

Experience of several years of careful comparison of the cost of maintenance will be needed to say whether the one-piece cast-steel frame, or the riveted wrought-steel frame truck would be the most advantageous, when both the first cost and weight could be considered along with the cost of maintenance.

Wheels. For passenger service, the wheels have been practically narrowed down to steel tired wheels and wrought-steel wheels. The steel tired wheels have been of many forms of centers and fastenings; the latest recommended practice of the Master Car Builders' Association is that the tire be shrunk on and bolted. The recent development of the solid wrought-steel wheel has made available for passenger car service a wheel equally as safe and durable as the steel tired wheel at a very much reduced cost.

Axles. For passenger service we would recommend the use of from 60 to 75 per cent. of the loads used in freight service on M. C. B. axles, based on the light weight of the car, and limiting the load to about 90 per cent. of that in freight service, considering the weight of both car and lading. The lighter rating is, of course, to be taken for cars such as baggage and express, since the increased weight on account of lading would be heavier, while the higher rating could be taken for coaches and similar cars where the increase of the lading would be light.

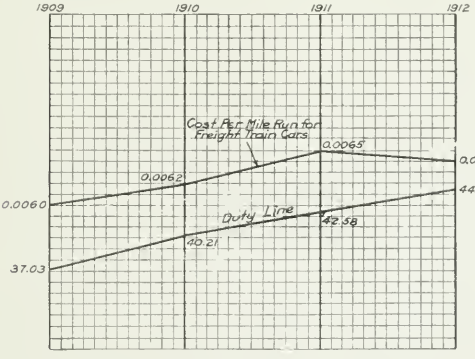
The Postoffice Department has limited the maximum load per wheel for postal cars to 15,000 lbs. when using 5 in. by 9 in. journals, and to 18,000 lbs. when using 5 in. by 10 in. journals, making a further limitation based upon 18,000 lbs. as the maximum brake load for any one cast-iron brake shoe under emergency conditions of brake application. This limitation of wheel loads, after deducting the weights of the wheels and axles, allows a pressure of 304 lbs. per sq. in. projected area on the 5 in. by 9 in. journals, and 300 lbs. per sq. in. projected area on the 5½ in. by 10 in. journals, also a pressure of 1,522 lbs. per lineal in. on the 5 in. by 9 in. journals, and 1,665 lbs. per lineal in. on the 5½ in. by 10 in. journals; from the experience that some roads have had these seem to be just as high as should be allowed.

(To be continued.)

MAINTENANCE COST AND DUTY PERFORMED BY FREIGHT CARS.

By J. C. Fritts,
Master Car Builder, Delaware, Lackawanna & Western.

One of the largest of the many items that enter into the expense incident to railroad operation is repairs to freight train cars; this expense in sum total is increasing from year to year.



Showing Comparative Trend of Maintenance Cost and Duty Performed by Freight Cars on the Delaware, Lackawanna & Western.

It has been claimed that it has increased in a proportion far in excess of the work performed by such cars, the work referred to being considered only from a standpoint of tons carried per car. This, it would seem, is not correct, although it is obviously of interest to know whether the duty performed by freight car

equipment is increasing in the same proportion as the expense incident to the maintenance.

It is the practice of railroad statisticians to prepare figures comparing the cost of maintaining freight car equipment from year to year either on a unit basis or on a per-car-mile basis, and it is questionable in either instance if it can be determined from such figures whether the duty performed warrants the increased cost. The unit basis of comparison is of little value. A railroad may spend an average of $50 per car for maintenance of freight train cars one year, and the following year spend $60 per car; still the equipment may be performing service that would warrant the increased cost. The cost-per-mile basis is misleading, inasmuch as no distinction is made as to the capacity of cars in service or of the main tonnage.

There are many features that influence the expense incident to car maintenance, and when comparative figures are prepared for the information of those interested, it would seem desirable to show more than the mere cost per unit per annum or per car mile, and that in addition to such figures the duty performed should be given, so that reasons for the increased costs would be apparent.

A 25-ton car will be much less expensive to maintain than a 50-ton car, and roads that make a practice of handling short trains should maintain their equipment cheaper than those where long and heavily laden trains are the rule. Therefore, information relating to the duty performed should be as comprehensive as is consistent with existing conditions.

It is realized that if all conditions that enter into the operation of freight train cars were considered in preparing comparative figures, the result would be so complicated that it would be difficult to understand, but it is believed that the three principal items that enter into the matter of duty performed by car equipment should be considered, i. e., car mileage, car capacity, and average tons per train.

The diagram indicates the cost per mile per car for maintenance for the calendar years 1909 to 1912, and also the duty performed by the equipment during the same period, on the Delaware, Lackawanna & Western. The formula used in obtaining the figures shown by the "Duty Line" is as follows: Average mileage per car multiplied by the average capacity per car multiplied by the average train tons divided by 4,000,000. (The figure 4,000,000 has no significance; it is merely used to reduce the result to a figure more easily handled.) The result shows that, while the cost per car mile for repairs has increased 6.6 per cent., the duty performed by the car equipment has increased in the same period 19.9 per cent.

AUTOMATIC STOPS AND AUDIBLE SIGNALS.

The New York, New Haven & Hartford, which a few weeks ago announced that two automatic stops were to be tried on the lines of that company, advises that the two devices referred to are those made by the Union Switch & Signal Company, Swissvale, Pa., and by the International Signal Company, New York. In connection with this announcement it will be of interest to review the general situation, as regards progress in the matter of automatic stops. The following notes summarize the principal news items which have appeared since the issue of the *Railway Age Gazette* of September 20 last, when a list was given of the roads on which experiments were being made. In the present account, we are including the audible distant signal of the Federal Signal Company, as this device is designed to perform substantially the same function as that fulfilled by the automatic train stop.

The account published in September, page 506, contains the names of ten roads on which automatic stops are in regular use. These ten are the Boston Elevated; the Erie; the Great Western of England, the Hudson & Manhattan; the Interborough, of New York; the Long Island; the Pennsylvania; the Philadelphia Elevated; the San Francisco, Oakland & San Jose; and the Washington Water Power Company. The Erie must now be taken out of the list of roads on which automatic stops are in regular operation, as the overhead stops which were in use on that road for several years have been taken out of service. On the portion of line where this apparatus was used, automatic block signals have lately been installed; and it was not deemed advisable, in this location, to rebuild the automatic stop apparatus so as to make it operative in connection with the automatic signals. In connection with the Great Western of England, it should be noted that the number of automatic stops is small; but the number of cab signals in use is considerable.

The Maryland & Pennsylvania is to be added to the list of roads on which automatic train stops are in regular use. The Jones system, made by the Jones Safety Train Control System Company of Baltimore, is now in regular service on that road from Baltimore, through the yards and for several miles northward, and is reported as giving satisfactory service. Nine locomotives are equipped.

The Jones apparatus has been in experimental use for over a year. It is worked by means of an intermittent contact rail. The contact rail is fixed on the sleepers outside of the running rails of the track, and is engaged by shoes depending from the tender truck, one shoe being used for the stopping apparatus, and another for the cab signal. Besides the contact rails fixed at points where the brakes are to be applied, there are separate contact rails for the caution shoe and the stop shoe, the caution rails being placed a sufficient distance in the rear to warn the engineman that he is approaching a stop rail, and giving him an opportunity to apply the brakes before he reaches the stop rail, if the block ahead is occupied. There is also an additional caution rail immediately in the rear of the stop rail, and if the engine is brought to rest with the contact shoe touching this rail, a proceed signal will be given as soon as the track ahead is clear. This prevents the operation of the automatic stop except in cases of emergency.

The cab signal consists of a dial and a miniature semaphore; and there are two electric lights, of different colors, to indicate proceed and stop. The plan provides for a bell to sound whenever a caution rail is passed.

The stop rails and shoes can be so arranged, that if a train is running below a certain speed it can pass the stop rail without operating the automatic valve. This has been installed on this road on only one engine, for demonsfrating purposes.

The electric features of the apparatus are arranged on a "closed circuit" plan, so that any interruption of the electric current will operate to give a stop signal and "stop." The arrangement of the circuits on the engine is such that when the block is clear, a current from the track is picked up, through the contact rail, located at the entrance to a block or elsewhere, and substituted for the battery current in the engine circuits, thus maintaining the cab signal and air-brake valve mechanisms in their normal running positions. If the track current is short circuited, as when the block ahead is occupied, the cab signal or the brake valve, as the case may be, is operated by the lifting of the shoe on the contact rail.

The September list referred to above included nine roads on which experiments had been made or were being made, two of these being roads which also appear in the list given in the preceding paragraph. These nine roads are the Canadian Pacific; the Chicago, Burlington & Quincy; the Chicago & Eastern Illinois; the Detroit River Tunnel; the Interborough Rapid Transit Company; the New York Central & Hudson River; the Pennsylvania; the Pennsylvania Lines west of Pittsburgh; and the Staten Island Rapid Transit Company.

On the Chicago & Eastern Illinois, the Miller automatic stop apparatus is nearly ready for use, and will probably be operated experimentally within two weeks or less. The work has been delayed by the floods.

The experiments on the Niagara Falls branch of the New York Central have been finished.

Of roads on which something new has been done since Sep-

tember there are ten. These are the Chicago Great Western; the Cincinnati, New Orleans & Texas Pacific; the Delaware & Hudson; the Delaware, Lackawanna & Western; the Denver, Northwestern & Pacific; the Erie; the Huntingdon & Broad Top Mountain; the Indianapolis & Cincinnati Traction Company; the Maryland & Pennsylvania (see above); and the New York, New Haven & Hartford. It will be seen that the total number of roads represented in these three lists is 26.

Chicago Great Western.—The experimental use of the Gollos automatic stop on this road was reported in the *Railway Age Gazette*, November 1, page 849.

C. N. O. & T. P.—The Buell automatic stop is in experimental use on this road.

Delaware & Hudson.—An audible signal, made by the Federal Signal Company, is being installed near Troy, N. Y. It is the outcome of the proposal made by Mr. Cade last autumn, and noticed in the *Railway Age Gazette* of September 27, pages 562 and 569. It is an audible distant fixed signal designed to give an alarm loud enough to command the attention not only of the firemen (in case the engineman is incapacitated) but also the conductor and all other persons on the train. In a box located at and connected with the distant semaphore (or, in the case of three-position signals, with the caution indication) there is a magazine of 104 very loud torpedoes. These are fixed within the box in a movable frame in such a way that the frame, when released, as the signal goes to the caution position, will fall by gravity; and in falling it will actuate successively four hammers, at intervals of a half second, each hammer exploding a torpedo. Thus the magazine, it will be seen, contains a supply for twenty-six operations. As the engine enters on the track circuit which begins at this signal it de-energizes a track relay; and the dropping of the relay armature is arranged to so affect the magazine that it will fall. But it is the duty of the engineman to prevent this operation, by another operation, carried out by means of a short electrical conductor and a third rail, fixed at the side of the running rail of the track. The engineman, by depressing a movable member on the engine, and thereby making electrical connection between this short rail and the running rail, prevents the audible signal from going into operation. The lever by which the engineman performs this cutting-out operation is so arranged that he cannot move it until he has first shut off steam (or applied the brakes, or both, as may be deemed desirable). Being alive and attentive to the visual signals, he will habitually cut out the audible signal, and it should never be called into operation. In other words, if the apparatus is maintained properly and the engineman never fails, the signal will never sound. With such an arrangement, regular tests will be made to give assurance that the apparatus is in working order. Additional details of this scheme are described or suggested in the article referred to above, but these have not yet been sufficiently developed to be further described at the present time.

Delaware, Lackawanna & Western.—On this road an experimental installation of the International automatic stop is being made. This was briefly described in the *Railway Age Gazette* of December 27, page 1273. The fixed or stationary ramp used in this system is about 20 ft. long and its upper surface is about 5 in. higher than the top of the track rail; it is placed from 12 in. to 18 in. outside the track. In the case of an engine moving in the direction opposite to the current of traffic, the plunger is not lifted by the ramp. The other roadside member, the one which is controlled by the condition of the track ahead, consists of a horizontal arm, supported on a post about 19 in. above the rail. The post is set 3 ft. 7 in. outside the track. The arm moves around in a horizontal plane. Mr. Webb proposes to arrange the air valve so that, when opened, it cannot be again closed by the engineman until he stops his train and descends to the ground. He also proposes another arrangement in which the engineman may close the valve, provided the speed of his train has been reduced to a pre-determined rate, and, also, a third scheme, so arranged that the engineman may close the valve at once; that is to say, he will be allowed at all times to use his own judgment in the regulation of speed, after the air valve has been opened by the stopping apparatus, the opening having given him an audible warning.

The Federal Signal Company's audible signal will also be tried on the Lackawanna.

An automatic stop recently brought out by the Union Switch & Signal Company is to be tried on this road. It is a mechanical trip apparatus, and will be arranged to operate under limitations regulated by the speed of the train. If, for example, a train passes a distant signal at an excessive speed, it will be stopped at a certain point beyond; while, if the speed at the distant signal is within the prescribed limit, the stopping apparatus will not go into effect. The engineman, therefore, finds the same condition that is found by the motorman on the trains in the Interborough subway, where speed-control apparatus is applied to a succession of signals, with automatic stops, located at very short intervals, approaching the stations on the lines where the express trains have to be run less than two minutes apart, and so must "close up" at the stations. As long as he obeys the speed limit rule, he finds clear signals ahead of him, if the section ahead is clear; but if he exceeds this limit he is stopped, because he reaches the next stopping point before the automatic stop has been made inoperative by the time-limit apparatus.

Denver, Northwestern & Pacific.—An apparatus made by B. F. Wooding has been used on this road for several months. Its peculiar characteristic is the contact rail, lying alongside the running rail. It is a comparatively thin blade, placed vertically. It is covered by another rail lying alongside and pressed against it by springs. This second rail, in section, is in the shape of an inverted L, pivoted at its lower edge so as to turn on an axis parallel to its length. The short member of the L protects the fixed rail from ice and snow. The member carried on the locomotive passes between these two rails, pushing the cover-rail to one side, and thus makes electrical contact with both the fixed rail and the cover, throughout their length. The contact rail is not straight, but for a part of its length bends away from the track; and by means of this change of direction, which gives a slight sidewise movement to the member depending from the engine a mechanical as well as an electrical effect is produced on the engine.

Erie.—Preparations are being made for an experimental installation of the induction apparatus of H. D. Patterson of New York. Mr. Patterson puts the primary of a transformer on the engine and the secondary is fixed on the roadbed. There is nothing movable on the ground.

Huntingdon & Broad Top Mountain.—The experiments of the Safety Block Signal Company on this road were described in the *Railway Age Gazette*, January 31, page 216.

Indianapolis & Cincinnati Traction.—The despatcher's manual block system, with cab signals, made by the Northey-Simmen Company is in use on this road, and in connection with it there is an experimental installation of automatic stops. (Five other electric roads have contracted for the Simmen cab-signal and despatching system.) An account of the Simmen apparatus, with some illustrations, was given in our issue of September 20, last, page 516.

New York, New Haven & Hartford.—The apparatus of the International Signal Company and of the Union Switch & Signal Company, noted above, are both to be tried on this road.

Pennsylvania Lines West of Pittsburgh.—The Gray-Thurber apparatus, installed on this road some time ago, has been changed in some of its details and will be tested within the next few weeks. The automatic stop of the Union Switch & Signal Company is to be tried also on this road.

NATIONAL VALUATION CONVENTION URGED.

Concerted Action Should Be Taken to Make Appraisal of Railways Economical, Intelligent and Just.

By H. Bortin.

On March 1 the United States Senate passed a federal valuation act which had been passed by the House, and which was signed by the President the same day, and thus became a law. Compliance with this act will involve an expenditure of about $5,000,000 by the Interstate Commerce Commission, and at least three times as much, or about $15,000,000, by the railroads of the country, during the next three to five years, depending on the degree of thoroughness and accuracy with which the work of valuation shall be done.

The above estimates, although based on the cost of similar work done by state railway commissions and railways, are, nevertheless, susceptible of considerable increase or decrease, depending on considerations to be treated below. To be more specific, it may be said that instead of this work costing $5,000,000 and $15,000,000, it might be made to cost either $3,000,000 and $9,000,000, or $6,000,000 and $18,000,000, according to the amount of preliminary study and investigation given to the subject, and the efficiency and experience of the organizations formed to do the work, as well as on the adaptability of the organizations to this kind of work.

The ultimate expense to the government will consist largely of the cost of checking the railroads' figures and re-arranging and re-compiling them for statistical and other purposes, while the ultimate expense to the railroads will consist of many different items, chief among them those for doing field work; making up new maps and profiles; making blue prints of maps and profiles, both for use in the valuation and to be returned to the Interstate Commerce Commission; making computations from data taken in the field, and classifying and compiling them; abstracting information from existing records and compiling it uniformly with that obtained from the field notes; and, finally, checking and summarizing all of the details involved in the above.

The ultimate expense of the foregoing, both to the government and to the railroads, will depend in a large measure on the extent to which existing information is utilized; in the case of the railroads, on the extent to which they utilize the information contained in their records, and in the case of the government on the extent to which it utilizes the information furnished by the railroads.

In an undertaking of this magnitude, which is as yet in a developmental stage, there always exist at least three equal possibilities as to ultimate cost, these being as follows:

(1) A fairly low cost which indicates, and is the result of, thorough preliminary study and investigation, and of an efficient and experienced organization.

(2) A rather high cost which produces quite a marked effect upon all those who have to bear the expense, and which is the direct result of insufficient preliminary study and investigation, and of inefficient and inexperienced organization.

(3) A somewhat moderate cost, that is, a cost which would reflect conditions such as mentioned under each of the above categories; such a cost, for example, as mentioned in the first paragraph of these remarks.

Now, it rests entirely with those who are responsible for the authorization of these expenditures as to which of the above marks the ultimate cost will reach.

The valuations that have been made in a few states have cost the railway commissions making them anywhere from $10 to $20 per mile, and the railroads furnishing such valuations to the commissions, two to four times that much, according to the degree of thoroughness with which they have been made, and the amount of field work that has been done. When it is remembered that all these valuations were merely reproduction valuations, and therefore involved only a small portion of the work that will be necessary in order to comply with the provisions of the federal valuation act, it will readily be seen that the cost to the railroads might very easily run up to an average of $75 per mile or more, and the cost to the government to $25 per mile.

Comparatively few railroads in this country have made valuations, and but a very small part of those that have done so, have had any kind of an organization exclusively engaged upon such work. Therefore, there are only a handful of railroad men in this country who have had any experience in this kind of work and who have kept in close touch with the literature of the subject. Furthermore, they have been so widely scattered that there has been no uniformity in their understanding and interpretation of many of the important elements and factors entering into a valuation.

It is, therefore, of great importance to all the railroads of the country that a definite program be planned and laid out before each road starts out an organization upon this work.

At a recent convention of the National Association of Railway Commissioners, a report was read in which the opinions of the engineers and experts of the various commissions who had made valuations regarding the various elements entering into valuation of public utilities were set out in detail, and it was very manifest that there was a wide difference of opinion regarding most of the important elements. The same condition is true as to the engineers of the various railroads. They differ just as widely regarding certain questions of valuation. It is needless to say that such differences exist as between representatives of the railroads and the experts of the railroad commissions. This clearly shows the urgent need for extensive study and investigation of the different phases of this subject by a national, representative and competent organization.

While it is only intended, in this article, to call the attention of the railroads and the Interstate Commerce Commission in a general way, to the urgent need of the creation of a national valuation committee, or commission, or association composed of men experienced in valuation matters as well as in matters involving a knowledge of economics and of transportation, it might nevertheless be well to point out specifically a few of the many important problems that must be solved in making a valuation. And it might be said right here, that unless most of these problems are solved beforehand—and they are easily susceptible of solution by such a national valuation organization as is here to be recommended—they will be solved individually by the hundreds of railroads making valuations and at an enormous expense; and the final results will differ so widely and radically that when they ultimately come up for adjudication by the Interstate Commerce Commission or by the courts, a large number of them will have to be entirely revised and altered, which will add tremendously to the ultimate cost. Nor is this a mere theoretical statement. On the contrary, it is based on experience which is bound to be repeated unless it is properly guarded against.

Among the most important needs is a uniform definition and interpretation of the following terms, together with the specific enumeration of the elements embraced by each:

Cost of reproduction, new.

Cost of reproduction less depreciation.

Present value.

Original cost.

Actual cost.

Original cost plus additions and betterments.
Commercial valuation.
Intangible items.
Non-physical items.
Physical items.
Adaptation, solidification and seasoning.
Going value.
Development cost.
Deficit below a fair return.
Interest during construction.
Engineering.
Contingencies.
Franchise value.
Working capital.
Unearned increment.

In addition to the need for a more or less uniform interpretation of the above terms—where such is possible—it is equally important that questions such as the following be considered and discussed and agreed upon if possible, among these being:

(1) What are to be the basic theories and assumptions that must inevitably be made in undertaking a "reproduction cost" valuation? For example, should it be assumed that in reproducing a road, a partly completed portion will be turned over to operation, or should it be assumed that nothing would be turned over to operation until the entire road is reproduced?

(2) What is to be the dividing line, if there is one, between physical, and intangible or non-physical, items?

(3) How is "depreciation" to be considered in a valuation?

(4) What should be the "program of construction" for "reproduction valuation" purposes, and to what extent is it to be followed in determining sources of material, labor, and freight charges?

(5) How should the construction period during which there will be no revenues from operation be determined for purposes of ascertaining interest and other charges dependent upon the period of construction?

(6) How should apportionment be made of each kind and class of property between the several states and the several sections within the states, as well as between the several accounts embracing such property?

(7) What unit prices should be used? The average for the preceding year or five years or what?

(8) What methods should be used in valuing right-of-way, station and terminal grounds and real estate?

(9) How should government-granted lands and vacated streets and alleys owned or used by the railroads be treated?

There are many more equally important questions which the limitations of this article do not permit mentioning. There is, however, one subject that cannot be properly omitted, and that is the question of forms for field data, for office compilation and for final return to the Interstate Commerce Commission. This matter is of even more urgent and immediate importance.

When it is considered that the above represent only a few of the points that require discussion and interpretation in a "reproduction cost" valuation, and when it is remembered that the "original cost," stock and bond value, and all the other factors called for in the national valuation act will require even more of study, investigation, discussion and interpretation, it will readily be seen how extremely important and urgent is the need for a national valuation organization.

In view of the foregoing the following suggestions concerning an adequate organization, are offered:

First, that each railroad system engaged in working up the information required by the national valuation act appoint two committees, one to be an "advisory committee," and the other a "working committee," the advisory committee to be made up somewhat as follows:

(1) The chief engineer or his principal assistant.
(2) The general counsel or one of his principal associates.
(3) The auditor or one of his principal assistants
(4) The superintendent of motive power and machinery or his principal assistant.
(5) A responsible representative of the executive's or comptroller's office.
(6) The valuation engineer, who should be secretary of the committee.

The working committee to be made up somewhat as follows:
