E. L. Myers, until recently with the Chicago Great Western, has been appointed by the Willard Storage Battery Company, Cleveland, Ohio, to take charge of the company's railway sales in the southwest. Mr. Myers began in 1888 as division lineman and construction foreman for the Western Union and the Santa Fe in California. From 1901 to 1909 he was construction foreman and general foreman on the Mexican Central, and from 1909 to 1913 he was chief electrician in charge of all electrical work on the National Railways of Mexico.

W. L. Clark, formerly vice-president of Niles-Bement-Pond Company, Inc., and for the past few months connected with the purchasing department of J. P. Morgan & Co., has recently left the latter to become connected with the Westinghouse Electric & Manufacturing Company. Mr. Clark is to be manager in charge of operations at the plants of the J. Stevens Arms & Tool Company, Chicopee Falls, Mass., and the Stevens-Duryea Company, Chicopee Falls and East Springfield, which the Westinghouse company has acquired to enable it to fill the large order for rifles which it has recently secured.

William Sterling Hodges, of the Baldwin Locomotive Works, with his wife and two sons, was lost in the sinking of the Lusitania. Mr. Hodges was born in Philadelphia on March 1, 1882, and was a graduate of the Central Manual Training School. He entered the drafting department of the Baldwin Locomotive Works on December 18, 1899. In July, 1912, he went to China as technical representative. He remained there about two years, returning in the summer of 1914. In September, 1914, he went to Russia and remained there until the middle of December. Early in January, 1915, he was assigned to duty as technical representative or agent in Paris. He went there with the intention of returning in April to take his family back with him to France. He returned to this country on the Lusitania when that vessel made her last trip westbound, and a week later, with his family, sailed on the same ship. Mr. Hodges showed great capability as a designer in locomotive construction. He patented a number of devices, the best known of which is the trailing truck bearing his name.

W. S. Hodges

TRADE PUBLICATIONS

Paint.—The Paint Products Company, Chicago, has issued a booklet describing the "Cobar" process of manufacturing paints and paint oils.

Tank Calibration Curves.—The Universal Iron & Supply Company, St. Louis, Mo., manufacturers of tanks, has issued a leaflet containing a calibration curve for horizontal, cylindrical tanks of any dimension. A copy of this curve will be sent to anyone on application.

Arch Tube Cleaners.—The Lagonda Manufacturing Company, Springfield, Ohio, has just issued a 12-page catalog entitled Lagonda Locomotive Arch Tube Cleaners. This catalog deals with the subject of scale removal from arch tubes in locomotive fireboxes and describes cleaners specially designed for this purpose. Copy will be sent on request.

Hydraulic Pumps and Valves.—This is the subject of a mailing folder issued by the Hydraulic Press Manufacturing Company, Mount Gilead, Ohio. This folder contains illustrations and detail dimensions of the various hydraulic equipment manufac-

tured by this company. The folder is designated as bulletin No. 5000, and will be sent free on request.

VACUUM CAR CLEANER.—A four-page leaflet entitled bulletin No. 221A has been issued by the Thurman Vacuum Cleaner Company, St. Louis, Mo., describing the Thurman No. 2 portable electric car cleaning device. This vacuum cleaner is placed at the side of the coach seat to be cleaned and driven through an electric lamp cord from the lighting circuit in the coach or the terminal yard. The system is now in use on over 25 American railways.

LEATHER GOODS.—The Du Pont Fabrikoid Company, Wilmington, Del., has just issued an attractive bulletin on Fabrikoid, which is made with a face of cotton cloth coated with a tough flexible material and embossed by steel plates or rolls to produce the appearance and feeling of any desired natural leather grain. The cover of this booklet is printed in colors and shows five different colors and grains of Fabrikoid. The booklet is well printed and illustrated.

COOLING CONDENSING WATER.—The Spray Enginering Company, Boston, Mass., has issued bulletin No. 101, dated March 1, 1915, illustrating and describing the Spray cooling pond system of cooling condensing water. A number of good illustrations are included, showing various plants equipped with this system, and data is given concerning them. Bulletin No. 151 of the same company is entitled Washing and Cooling Air for Steam Turbine Generators, and contains eight pages dealing with this subject.

HYDRAULIC FORCING PRESSES.—This is the subject of catalog No. 92, issued by the Watson-Stillman Company, New York. This book contains 128 pages, thoroughly illustrated and deals with a large number of force and miscellaneous presses which this company manufactures. The catalog supersedes catalog No. 70 and part of No. 82. It is found convenient to divide the various tools into classes, making each class the subject of a catalog. At the back of this book a list is given of these classified catalogs.

CONCRETE CONVEYOR.—Four pamphlets have recently been issued by the Pneumatic Placing Company, Inc., 45 Broadway, New York City, describing the application of the pneumatic concrete conveyor to the lining of tunnels of small bore, the lining of double track railroad tunnels and the construction of viaduct pipes, retaining walls and abutments. These pamphlets describe the equipment neecssary for each use and contain an estimate of the cost of concrete from the material bins into the forms, which in each case is 30 cents per cubic yard.

IRON AND STEEL.—E. F. Jackman & Company, agents for the Firth-Sterling Steel Company, have issued a folder containing a tribute to the railroads, which reads in part: "A railroad has been likened to an octopus by those who do not know the flesh and blood and personality of railroads. A railroad is a disciplined power; owning rails and cars and locomotives, engaging the highest quality of mechanical skill and expert knowledge, but the glory of a railroad is the united adjustment of its living nerves to patience, courtesy, speed and safety."

WINDOW DEVICES.—The McCord Manufacturing Company, Detroit, Mich., has issued a 56-page catalog dealing with the Universal window devices which this company manufactures. The book is handsomely gotten up and illustrated in color engravings as well as line drawings, the latter giving in detail the arrangement of the different window fixtures. These include weather stripping, locks and racks, sash lifts, anti-rattle bearings, stop casings and parting strips, sash balance brackets, sash balance chain connections, metallic sash, deck sash rachets, etc.

WROUGHT IRON.—The Interstate Iron & Steel Company, Chicago, has prepared for distribution a pamphlet entitled "The Business Message of the Wrought Iron Bar." The first part of this pamphlet contains a copy of the series of advertisements recently published in technical journals on this subject, in which are shown the advantages to be obtained by the use of wrought iron. This is followed by a description of the plant of this company in which various operations in making wrought iron are quite clearly described. Extracts of specifications of the material made are given, and the results of tests of various kinds of wrought iron are also included. The pamphlet is neatly illustrated and it is also written in an interesting manner.

Railway Construction

ATCHISON, TOPEKA & SANTA FE.—This company is constructing about four miles of track, consisting of one main branch and several spurs, to serve the orange and lemon shippers at Corona, Cal. It will require very light work and very little bridging. The grading contract has been awarded to the Sharp & Fellows Contracting Company, Los Angeles, Cal. The track work will be done by the company forces. R. B. Ball, Los Angeles, Cal., is engineer of the Grand division.

CANADIAN NORTHERN, ONTARIO.—An extension of time in which to build the following lines in the province of Ontario has been granted by the Canadian parliament: From Washago to Kincardine; from Arnprior to Gananoque; from Pembroke to Cobourg or Port Hope; from Frenchman's bay to Owen sound; from Niagara river to Goderich; from Hawkesbury to or near Lanark; from Berlin through Guelph, Acton and Brampton to Toronto; from Berlin to St. Marys and Woodstock; from Sarnia to Chatham and from Orillia to Goderich, with a branch to Owen sound.

CANADIAN NORTHERN, QUEBEC.—The Canadian parliament has extended the time in which to build the projected line from Rawdon, Que., northerly to the National Transcontinental, also to build a branch from Jerome to St. Eustache, Que. (February 12, p. 289.)

An extension of time has been granted by the Canadian parliament in which to build the James Bay & Eastern from Lake Abitibi, easterly across the province of Quebec, and along the south end of Lake St. John to the mouth of the Saguenay river. (February 12, p. 289.)

FULTON & EAST RICHMOND (Electric).—Incorporated in Virginia, with $50,000 capital, to build an electric line from Fulton, Va., to Montrose Heights, about 5 miles. E. F. Atwood, president; R. B. Allport, treasurer, Richmond.

GLEN ROSE & WALNUT SPRINGS.—This company has given a contract to the Rail Road Construction Company, New York, for work on a section of the line. Work was started in 1909 from Walnut Springs, Tex., north to Glen Rose, about 14 miles, and extensions are to be built from Glen Rose northeast to Ft. Worth, and from Walnut Springs southwest. About 20 miles has already been graded. J. H. Farr, president, Glen Rose, and D. Morris, chief engineer, Walnut Springs. (December 11, p. 1107.)

INGLESIDE & EAST ARKANSAS.—Plans are being made to build a line, it is said, from Ingleside, in Jackson county, Ark., east via Fisher, to a point in Pointsett county, about 25 miles. C. B. Richmond, St. Louis, Mo., is interested.

JAMES BAY & EASTERN.—See Canadian Northern, Quebec.

LEHIGH VALLEY.—Work is now under way by company forces constructing a new car repair yard at Coxton, Pa.

MCCONNELLSBURG & FT. LOUDON (Electric).—A contract is reported let by this company to Reed & Company, Hazelton, Pa., to build from McConnellsburg east to Ft. Loudon, about 10 miles. E. J. Post, president, Washington, D. C. (March 5, p. 427.)

NEW YORK SUBWAYS.—The New York Public Service Commission, First district, will open bids on May 28, for the completion of certain finish work in the Fourth avenue subway, in the borough of Brooklyn. The line is expected to be open for business in June.

OZARKS RAILWAY.—A contract has been given to the Rail Road Construction Company, New York, to build a section of this line. The plans call for building from Springfield, Mo., through Mountain Home, Ark., thence along Buffalo river, and then south to Little Rock, about 215 miles. T. J. Murray, Mountain Home, Ark., may be addressed. (January 29, p. 211.)

PALM BEACH & EVERGLADES.—The Everglades Construction Company, which has the general contract to build this line from West Palm Beach, Fla., west to Lake Hicpochee, has sublet to E. P. Maule, the work on the first section of 23 miles from West

Palm Beach, along the north bank of the West Palm Beach canal. Charles H. Baker, president, New York. (April 2, p. 767.)

South Dakota Roads.—Financial arrangements have been made, and work may be started soon, it is said, on a line from Waubay, S. Dak., north via Grenville, thence northeast via Effington to Hankinson, N. Dak., about 60 miles. O. M. Henderson is the promoter.

Southern Railway.—In connection with the export coal terminals now being completed at Charleston, S. C., by the Southern Railway, this company will construct a storage yard with a capacity of 400 cars.

Tennessee Roads.—The Whiting Lumber Company, Butler, Tenn., will build a railway, it is said, from Butler to the summit of the Blue Ridge mountains. J. M. Lacy, superintendent of construction, Elizabethtown, Tenn.

RAILWAY STRUCTURES

Ardmore, Okla.—The Oklahoma, New Mexico & Pacific will build a modern brick and concrete passenger and freight station at this place.

Biddle, Ark.—The Chicago, Rock Island & Pacific will build a small repair shop for light repairing at this place.

Chicago, Ill.—The W. C. Newman Company, 19 North Curtis street, Chicago, has been awarded a contract by the Union Station Company, for the construction of trunk sewers in Canal, Monroe and Clinton streets, and also concrete retaining walls. The work is in connection with the new terminal at Chicago.

The Union Station Company is asking for bids for the construction of the substructure and the superstructure of a trunnion bascule bridge to be built over the Chicago river at Monroe street. Thomas Rodd is chief engineer.

Easton, Pa.—The Central of New Jersey has work under way renewing the steel viaduct approach to the bridge over the Lehigh river at Easton. The design consists of eight double track deck plate girder spans varying in length from 53 ft. 5⅜ in. to 62 ft. 4⅞ in., supported on six reinforced concrete piers. The greatest height of the structure from the surface of the ground to the top of the rail is 36 ft. The contract for the steel work, about 550 tons, has been let to the Phoenix Bridge Company. The floor of the bridge will consist of reinforced concrete slabs which are to be molded at a place convenient for handling, to be later put in place by locomotive derricks. No waterproofing is to be used. The contract for the reinforced concrete piers, of which four are required, as two were constructed several years ago, has not yet been let.

Eufaula, Okla.—It is reported that the Missouri, Kansas & Texas will build a 1,000-ft. bridge over the South Canadian river at this point. The new bridge will have 10 steel girders each 100 ft. long and concrete piers set in 10 ft. of solid rock.

Kansas City, Mo.—The Atchison, Topeka & Santa Fe will enlarge its grain elevator at this place. The addition will be of reinforced concrete and will consist of 28 cylindrical bins. Each bin will be 36 ft. in diameter and 90 ft. in height, increasing the capacity of the elevator by 2,062,000 bu. The present elevator contains 72 similar bins. Wells Brothers, 53 West Jackson boulevard, Chicago, have been awarded the contract for the superstructure work.

Lewisburg, Tenn.—A contract is reported let to the E. G. Holladay Co., Nashville, Tenn., to build a new passenger station at Lewisburg, to be used jointly by the Lewisburg & Northern and the Nashville, Chattanooga & St. Louis.

Port Townsend, Wash.—A terminal car barge landing is contemplated at this place by the Milwaukee Terminal Railway in connection with the Seattle, Port Angeles & Western. The work will be done by company forces.

St. Paul, Minn.—The St. Paul Union Depot Company is asking for bids on channel changes, levee walls, sewer extensions and riprapping in connection with the new union station at St. Paul. It was erroneously stated in last week's issue that the Chicago & North Western was asking for these bids.

Railway Financial News

Chicago & Eastern Illinois.—The bondholders' protective committee has added the following to its membership: E. K. Boisot, vice-president, First Trust & Savings Bank, Chicago; Charles R. Butts, assistant treasurer, Norwich Savings Society, Norwich, Conn., and John J. Pulleyn, comptroller, Emigrant Industrial Savings Bank, New York. The committee is requesting the deposit of the general consolidated and first mortgage 5 per cent bonds and underlying bonds with the United States Mortgage & Trust Company, New York, or the First Trust and Savings Bank, Chicago.

Chicago, Rock Island & Pacific.—A petition has been filed in the United States district court at Chicago asking that N. L. Amster, F. W. Bauder, W. C. Crane, E. S. Dickerson, N. French, A. J. Keppelmann, C. Linkroum, G. G. Prentice and G. P. Ten Eyck be allowed to intervene in the suit of the American Steel Foundries against the Chicago, Rock Island & Pacific, which suit was the cause of the appointment of receivers. Among other things the petition says: "The railway company is not insolvent. Your orators, both personally and through their associates, believe it would have been feasible to meet or extend the maturing obligations of the railway company."

New York, New Haven & Hartford.—George B. Holbrook, of Springfield, Mass., has been elected president, succeeding John H. Alvin, of Concord, N. H., of the Connecticut River Railroad, a leased line of the New York, New Haven & Hartford.

Southern Pacific.—General Thomas H. Hubbard has been elected a director of the Southern Pacific, succeeding Hugh Neill, secretary, resigned. [General Hubbard died on Wednesday, as mentioned elsewhere in this issue.]

Third Class Pullmans on the Brighton Railway of England.—The London, Brighton & South Coast has recently entered into a contract with the Pullman Company, Ltd., for supplying a service of third-class Pullman cars on the Brighton main line. The service will be inaugurated soon, beginning with the chief trains from London to Brighton and back, and will be gradually extended. The railway fares will be the same as the present third-class with 18 cents additional. Each Pullman car will have accommodation for 50 passengers, and the seats will be similar to the orchestra stalls of a theatre. Tables will be provided and the third-class passengers will be able to order tea or any other refreshments they require during the journey. The Pullman cars will be well lighted and suitably decorated. They will not be so luxurious as cars on the "Southern Belle," but will be equal in comfort to the usual corridor train, with all the advantages of the Pullman. The cars are now being built by the Pullman Company.

Women as Railway Porters in England.—The announcement that the Great Central Railway is experimentally employing women as platform porters at certain stations shows another development in the policy of setting free more railway men of military age for service with the colors. Women have been successfully employed for some time as carriage cleaners by the Great Central, and it is from these women mainly that the porters have been selected. The experiment is at present being tried at Marylebone, Kilnhurst and Gainsborough, and so far the women porters have not been put into distinctive uniforms, though that matter is under consideration. Their work is confined to platform duties, as obviously women could not be expected to perform the more hazardous duties associated with a railway porter's occupation. Some of the railway companies have already engaged a number of women in the clerical and accountancy departments, and this movement is growing. Women booking clerks have been introduced at Willesden Junction, and there seems no reason why this practice should not be largely extended. At many French stations women were employed to a considerable extent as booking clerks before the war, and at stations on light railways in the south of France we have come across women who were in sole control.—*Railway Gazette.*

Contents

*Illustrated.

The decision of Judge Maxey, holding that a conductor receiving train orders by telephone is not subject to the 13-hour work-day limit prescribed for telephone operators, which was reported May 14, page 1028, will, of course, be appealed to the Supreme Court; and it will afford that body an interesting opportunity to discuss some fine points of strict construction and "human interest." The 13-hour limit applies to "other employees," which term can easily be construed to include conductors. Judges Maxey and Pardee hold that the term only means other employees having primarily the same duties as station operators. It looks as though they would allow a station agent, for example, on duty 14 hours a day, to occasionally or incidentally transmit a train order; but they emphasize the phrase of the law "in towers and offices," etc. What is the rational basis of the 13-hour limit? Partly, perhaps wholly, the need of providing against the ill-effects on the person's bodily or mental health of long confinement in one room. It may reasonably be said that an operator working outdoors, or one so situated that he could take active exercise in fresh air every few hours, could safely be allowed to work longer than one confined continuously to a desk in an office. As every one knows, a freight conductor can often sleep in his caboose. This is one reason why, for him, 16 hours is not an utterly intolerable work day. However, this hairsplitting may as well be left to the august judges of the higher court—or to the brotherhood leaders who will go before the Congressional committees to get the law amended with a view to softening the conductor's hard lot!

Conductors Who Telephone Train Orders

H. U. Mudge, receiver of the Chicago, Rock Island & Pacific, recently gave an interview to the press in which he discussed the reasons for the road's failure financially. Part of what he said was published by the newspapers. The rest was ignored. The result was one of those too numerous cases where a man who is frank with the press and public, was, by a partial quotation, represented as saying practically the opposite of what he did say. Mr. Mudge was credited with giving federal regulation a large share of the blame for the Rock Island's present difficulties. As a matter of fact, few railroad presidents in the country have taken as hopeful a view of the value of federal regulation as has Mr. Mudge. In his remarks after the appointment of receivers for the Rock Island he referred to the 12-year summary given in his last annual report and mentioned government regulation among other contributory causes that had acted to prevent the Rock Island from fulfilling the hopes of its owners in 1912. The Rock Island operates in 14 different states which makes it subject simultaneously to 15 varieties of regulation. Of these 15 varieties Mr. Mudge has often expressed the belief that one—federal regulation—worked in the long run for good rather than evil, and that the other 14 could far better be dispensed with. State reduction of passenger rates and freight rates undoubtedly was a factor in the Rock Island's decrease in earning power in the years 1902-15. Federal regulation pretty surely also nibbled at rates, but to offset this there was positive good aimed at, even if not always achieved. It seems unfair that a misleading emphasis should have been placed on Mr. Mudge's reference to regulation, when he has accepted federal regulation not only without active opposition but actually in a spirit of cheerfulness and co-operation.

The Rock Island and Federal Regulation

Contrary to the practice which has prevailed for some years, a number of state legislatures have met and adjourned without passing any legislation for the regulation of railways and other public utilities. The legislature of Utah did this, and in addition, took a step which is unique. It adopted a set of resolutions for the express purpose of inviting both labor and capital to seek occupation and investment within the state's boundaries and to assure them that they would receive fair treatment if they did so. The resolutions set forth that in all its history, the people of the state have uniformly protected the interests of all classes. The natural resources of the state have been only prospected on the surface and present a most inviting field for investment, profit and return. Therefore, it is resolved, "that the state of Utah by and through its lawmaking body, does hereby invite to its midst the humble and honest laborer from whatsoever clime, who would better his condition, the homeseeker who would set up his household gods in a new country to his better

Utah Invites Both Labor and Capital

advantage, the investor of capital who would seek sound and profitable investment; all under the certain assurance that their rights, liberties and properties will be jealously safeguarded and held in sacred trust by the government of the state." These resolutions are significant not only as indicating the policy of Utah, but also as implying that it is in contrast with the policies being followed by some other states. It certainly is a remarkable commentary on the recent course of legislation that any state should feel called upon formally to announce, and should expect to gain by announcing, that both labor and capital can enter its borders with the "assurance that their rights, liberties and properties will be jealously safeguarded." This was formerly regarded as the chief function of all governments. We commend Utah's resolutions to those numerous states, such as Iowa, Indiana, Oklahoma and Texas, which think that the chief function of government is to pursue and harass capital invested in railways and other public utilities as if it were an enemy of the public welfare.

RAILWAY FUEL ASSOCIATION CONVENTION

THE seventh annual convention of the International Railway Fuel Association was one of the best attended in the history of the association. The Baltimore & Ohio (one of the roads that has eliminated convention expenses this year because of decreased revenue) was represented by 19 men. This certainly is a great tribute to the work of the association and clearly indicates the loyalty of its members and the faith they have in its work.

By far the most important subject presented for discussion was that of Pulverized Fuel. The adaptability of this fuel to locomotive use has been talked of, and more or less experimented with for several years, but during the past year it has received much attention, the experiments made on the New York Central locomotive being especially noteworthy. These were referred to in Mr. Robinson's paper and were also dealt with in an article published in the *Railway Age Gazette*, April 30, 1915, page 941. The Fuel Association has the distinction of being the first association to recognize officially the possibilities of this fuel on locomotives.

This association also went on record as to the permanency of the locomotive stoker. The committee report on this subject is perhaps the best symposium on the value and use of the mechanical stoker yet published. It covers briefly the reasons for the existence of the stoker, its operation and the operating advantages obtained by its use. Both these subjects were actively discussed and a large amount of interesting information was presented. While the more enthusiastic members looked upon the use of pulverized fuel as a panacea for all the locomotive fuel problems, such as smoke, fuel economy, locomotive terminal detention, and, in fact, most of the difficulties now experienced in locomotive operation from a fuel standpoint, it was conceded that there are difficulties yet to be overcome. The advocates of the stoker did not seem to view with very much apprehension the possibility of pulverized fuel cutting into their field.

The committee reports on fuel stations and coal storage also contained much valuable information. It is evident that economies, which are broad in their extent, are made possible by the logical storage of coal. By storing coal, less equipment is required, more equipment is available for revenue tonnage in the busy season, the coal can be purchased at a lower price, the railways are better protected from a shortage of fuel, the mines can be operated to much better advantage from both the operator's and miner's point of view—in fact, the storage of coal by the railways would be of direct economic advantage to the country at large. Several roads have made a careful study and have become convinced of the practicability of thus handling their fuel supply.

Another subject concerning which there is little concrete information, but which presents a lucrative field for improvement, is that of the railway stationary boiler plant. That this subject has received but little or no consideration was evident from the statements of various speakers. It is, however, a subject that requires careful study. A dollar saved from that source is as valuable as a dollar saved from any other. With but little additional work the fuel and mechanical experts on each road should be able to properly supervise these plants, and they would undoubtedly find their time well spent.

Fuel now represents about 25 per cent of the transportation expenses of a railroad. It is, therefore, worthy of the attention of the highest railway officers. Frequently the desired results are not fully realized on account of the lack of proper authoritative support. The opportunities for the economical use of fuel are not restricted to the direct users of the fuel. Much can be done by the transportation men, but without the proper backing, the men held responsible for this item will be severely handicapped.

UNINTELLIGENT AND UNFAIR CRITICISM

IN a statement appearing in the newspapers on May 19, N. L. Amster, chairman of one of the Rock Island protective committees, criticised severely the recent action of the receivers of that road in placing an order for 67 track miles, or approximately 10,000 tons, of new 100-lb. rails to replace the same mileage of "85-lb. rails, most of which have been in place only since 1907-9." Mr. Amster added that "the Great Northern, not in the receivers' hands, which hauls an average train load twice the weight of the Rock Island, has few if any 100-lb. rails on its lines." These statements of Mr. Amster show a lack of knowledge of railway operating conditions, and, coming from the source they do, they may do harm to the railways in general. Such statements as these, coming from persons supposedly familiar with railway operation, complicate the already serious problems confronting the Rock Island and other roads.

The Chicago, Rock Island & Pacific operates over 7,800 miles of line in addition to 475 miles of multiple main tracks. Assuming that 67 track miles of new rails were ordered annually, it would be necessary for the rails to give an average service in main tracks of 124 years before being transferred to the 2,200 miles of side and yard tracks. It is thus evident that even the 67 track miles of rails, the purchase of which is characterized as extravagant, is entirely inadequate for the proper mintenance of the property. This view is supported by a comparison with the rail orders placed this year by several other roads, the Burlington having ordered 36,000 tons, the Santa Fe 66,000 tons and the Illinois Central 35,000 tons, while the Pennsylvania is now inquiring for 138,000 tons.

Regarding the criticism of the 100-lb. rail to replace "85-lb. rail which has been in place only since 1907-9," this latter rail has had from 6 to 8 years' service in the main line. Every railway man knows that as new rail is bought it is advisable to place it in the most important main lines, and the rail released here is not scrapped, as Mr. Amster's criticism would indicate, but is laid again in secondary main and important branch lines where it continues to give further service. It may even again be relaid on less important branch lines or in side or yard tracks, when its condition has become such as to unfit it for further use under heavy traffic. As to the weight of the rail, the use of 100-lb. rail is in accordance with general practice for main lines. The American Railway Engineering Association at its last convention adopted standard sections for rails up to 140-lb., while the Pennsylvania Railroad has been working for two years on a new 125-lb. standard section.

The introduction of a comparison of the train load of the Great Northern with that of the Rock Island is equally out of place and misleading. The primary factors governing the train load are the ruling grades and the size of locomotives, while the weight of rail play a very insignificant part. The relatively

low train load on the Rock Island in comparison with that of the Great Northern is due primarily to the large expenditures made on the latter road to secure low grades, while the Rock Island has been unable to secure the funds to make such expenditures.

THE STATUS OF TRAIN LIMIT LEGISLATION

THE railway labor brotherhoods have succeeded in getting bills to limit the length of freight trains introduced in a large number of legislatures. But they are not having remarkable success in getting them passed. The only state in which such a law has been enacted is Arizona. Such bills were introduced this year in the legislatures of the following states, which have adjourned without passing them:

California	New Jersey
Colorado	New York
Indiana	North Carolina
Iowa	North Dakota
Kansas	South Carolina
Minnesota	South Dakota
Nevada	Utah

Such bills are pending in the legislatures of the following states, which are still in session:

Illinois	Pennsylvania
Michigan	Wisconsin
Ohio	

In other words, the legislation has been defeated in 14 states and is still pending in 5.

The arguments used against these measures in the states where they have been defeated are the same as those being used where they are pending. It has been pointed out that their passage would increase rather than reduce accidents; would cause an entirely unnecessary and very large increase in railway fixed charges and expenses which would have to be borne by the traveling and shipping public, and would tend to cause serious traffic congestions and delays. The fact that only one state has passed a train limit law, and that the lawmakers of 14 states have considered the merits of the proposed legislation and rejected it, ought to carry great weight with the legislatures which are still in session.

There is not a single valid argument in favor of train limit legislation, and there are innumerable overwhelming arguments against it. Nevertheless, it is being vigorously supported not only by the railway labor brotherhoods, but in some states by other labor organizations. In Illinois the railway labor brotherhoods and the state federation of labor are closely and vigorously co-operating in support of it. The Public Utilities Committee of the Illinois house reported unfavorably on it, but the political influence of organized labor was so great as to get it taken up for consideration by the House.

Many lawmakers seem entirely unable to hear the voices of reason and expediency when the paid lobbyists of organized labor are about. It is hardly conceivable, however, that the legislature of any one of the five important states in which train limit legislation is now pending can be induced to pass it.

NEW BOOKS

Engineering Office Systems and Methods. By John P. Davies. Size 6 in. by 9 in., 544 pages, 243 illustrations, bound in cloth. Published by the McGraw-Hill Book Company, Inc., New York City. Price $5.

This book covers a wide range of subjects of more or less direct interest to all office and consulting engineers, a large part of the information being compiled from other sources and put in convenient form for use. The 13 chapter headings include the following: Collection of Preliminary Data for Engineering Projects; Designing and Drafting Systems; Specifications for Engineering Material; Purchasing-Office Methods and Forms; Cost Keeping and Estimating; Sampling, Inspecting and Testing Engineering Material; Domestic and Export Shipping; Progress Charts, Scheduling Systems, etc., and Indexing and Filing Systems for the Engineering Office. The book contains a large number of forms, specifications, rules, reminders, etc., which, if not in themselves applicable, would frequently suggest similar solutions for engineering office problems.

Railway Rate Regulation. By Joseph Henry Beale, professor of law at Harvard University, and Bruce Wyman, of the Massachusetts bar, recently professor of law at Harvard University. Second edition, rewritten by Bruce Wyman. 1,306 pages, 6 in. by 9 in. Bound in law buckram. Published by Baker, Voorhis & Co., 45-47 John street, New York City. Price, $7.50.

This second edition of Beale & Wyman's well known and authoritative work covers the entire law affecting railroad rate regulation, with special reference to the powers of the Interstate Commerce Commission, and on account of the remarkable growth in the law covering the subject treated since the first edition was written in 1906, contains a very large amount of entirely new matter. In this treatise Professor Wyman has cited every opinion of the Interstate Commerce Commission discussing the principles of rate regulation. The work contains also a discussion of every opinion of the federal courts, wherein the powers of the commission under the act to regulate commerce are involved, and many rulings of state commissions on points not fully covered by the Interstate Commerce Commission.

Although the first edition covered nearly 20 years of activity of the Interstate Commerce Commission the commission at that time had just been given power to fix rates for the future; the power to suspend advances in rates was not granted until 1910; likewise its power to order joint rates, granted in 1906, was not perfected until 1910. All of the treatment of the functions of the commission in establishing rates, and the jurisdiction of the commission over joint rates, therefore, which extends over several chapters in the second edition, is new matter written upon the basis of important decisions decided since the first edition. The author remarks that "in writing the first edition we had only the rulings of the original commission to guide us, and the few decisions of the courts, mostly to the effect that the act did not justify what was ordered. In this edition we have the many volumes of the commission making orders as to future conduct, which are supported in most instances by the decisions of the courts." The second edition, therefore, covering the past eight years of the activities of the commission, has several hundred per cent more opinions as the basis for its text than were available for the first 20 years of the commission's existence. The historical development of the general principles of rate regulation receive much attention throughout the work.

The treatise is divided into four books, devoted to "Jurisdiction of the Commission," "Limitation of Charges," "Prevention of Discrimination" and "Powers of the Commission." Fifty pages are devoted to a table of cases cited and 55 to a very comprehensive index. In the appendices are given the complete text of the various statutes, together with the rules of practice and forms of pleading before the commission and the courts.

A most valuable part of the book is made up of long chapters on procedure in which practically every case involving a point of practice of importance has been treated.

The author calls attention in the preface to the way in which the contrast is brought out between opposing theories of rate regulation where the conflict in the law is as yet not determined. The policies of basing schedules as a whole upon the original cost of the plant or upon its present value are elaborately discussed, together with an indication of the collateral effects of a decision one way or the other. Likewise in dealing with particular rates, whether the cost of the service or its value is to be taken as the test, receives treatment to the extent of a chapter on each. The author does not hesitate to let his own preference for cost as the basis of regulation appear, although he appreciates the modifications to

which this theory must be subjected when put into actual practice.

It would seem that this book must be indispensable to all lawyers engaged in practice before the Interstate Commerce Commission or the courts on matters involving rate regulation, and of very great value to all students of the law upon this subject. The headings throughout are made so specific that the reader can easily locate the subject which is of interest to him.

Railroads. Finance and Organization. By William Z. Ripley, Nathaniel Ropes Professor of Economics, Harvard University. Longmans, Green & Co., New York. 638 pages. Price $3.

The first of Professor Ripley's two volumes dealing with railroads was published in 1912, and consisted of a comprehensive study of rates and regulation. The present volume treats of finance and organization. A knowledge of the problems of the financing and organization of American railroads is prerequisite to an intelligent discussion of railroad regulation. Never before, however, has there been made a comprehensive and just study of these problems. The material for such an investigation is scattered through a vast number of documents, and is often in such shape as to require literally months of work to digest it. Professor Ripley has painstakingly and scientifically sifted this great mass of material and made the results of this study available for railroad men and students of the American railroad problem. He has done an immense work and one deserving of the gratitude of any one who aspires to have any real knowledge of the all-important economic questions which are now in process of discussion by the Interstate Commerce Commission, state legislatures and the public press. Public hearings and investigations of railroad questions and of the history of particular railroads have been frequent in the past few years and the amount of testimony elicited has been voluminous. It is in large measure on this material that Professor Ripley has drawn for his facts.

Like the history of a happy country, the history of a successful, well managed railroad company affords little material for interesting and exciting reading. On the other hand, a description of the way spectacular fortunes have been made out of American railroads may be rendered interesting and often quite dramatic. For this reason it sometimes appears that Professor Ripley lays more stress on the destructive criticism of American railroad history than on the record of achievement of which this history is full. Present day problems of regulation, however, are so intimately bound up with past practices in railroad organization and financing that even where these past practices are now considered unfashionable or even unethical a discussion of them is necessary to a thorough understanding of the subject.

Professor Ripley has a New England bluntness in his comments on methods which are now illegal or considered bad practice that makes him a severe but not an unfair critic. He voices in a great number of instances the feelings in regard to certain railroad matters and railroad financing which are harbored by a great majority of straight-thinking, intelligent Americans who are not connected with railroads or with railroad securities. He denounces in an unmistakably forceful way such methods as led to the New Haven and the Rock Island failures and to the predicament in which the Erie found itself in 1907. Since this criticism voices the honest sentiment of so many outsiders, it should be read by railroad men, and especially railroad executives, with interest and with respect. It may be true that the practical railroad man can find inaccuracies in many of the descriptions of misdeeds which Professor Ripley denounces. With some of his conclusions, especially in regard to the benefit to be derived from a physical valuation of railroads, a great many railroad men will entirely disagree. But this detracts in no way from the interest of the book.

Professor Ripley is an ardent advocate of the federal regulation of railroads and sees clearly the needless burdens which state regulation is placing on railroad operation. While recognizing the importance of the "initiative and efficiency which spring from private ownership," he feels strongly that a guarantee for the common weal of a firm, just and steady supervision is necessary. To the railroad man it probably will appear that he underestimates the difficulties of obtaining such a supervision. The genius of a Harriman, with the financial backing of Kuhn, Loeb & Company, made supervision over 30,000 miles of line something more than a name; but there are 250,000 miles of line in the United States subject to the jurisdiction of seven commissioners, none of whom has had experience in the management of railroads.

Professor Ripley's answer to all this is that the best results of regulation can be obtained by co-operation between the federal regulative body and the railroad companies. This view is the one which is being pretty generally adopted by railroad men themselves.

The scope of the book is best indicated by the list of subjects with which it deals. These are Railroad Construction Finance, Capital and Capitalization, Railroad Securities, The Course of Market Prices, Speculation, Stock Watering, State Regulation of Security Issues, The Determination of Reasonable Rates, Physical Valuation, Receivership and Reorganization, Inter-corporate Relations, Combinations, Dissolution Under the Anti-Trust Law, and Pooling and Inter-railway Agreements. Space will permit of only a very brief comment on the book's treatment of most of these subjects.

Construction finance, of course, provides the author with numerous opportunities for denunciation of bad methods. One is inclined to think that if he had ever had any experience in financing a new piece of railroad construction he would be somewhat less ready to severely condemn all promoters' methods. As Frank Trumbull, chairman of the board of the Chesapeake & Ohio, pointed out in his statement before the Hadley Securities Commission, the changing of a $100 bill into 100 one dollar bills is a transaction of unimpeachable honesty, but not particularly profitable. Whether there is or is not going to be an actual profit in a new piece of railroad construction, somebody must be made to believe there is or no capital will be provided for the construction.

In the chapter on capital and capitalization the various definitions of these words are contrasted in such a way as to bring out a point that is very often much obscured by general discussions of "overcapitalization." Professor Ripley's own distinction is that capital is the assets and capitalization the liabilities. It should be borne in mind in any discussion of this kind that the face value of a bond bears a very different relationship to the liability of the company from that borne by the par value of shares of stock. Whatever par value may be given to the shares of stock legally they can represent nothing more than a pro rata equity in the ownership of the property. Bonds, however, are secured by a promise to pay a definite sum which constitutes the face value of the bond. The capital actually invested in a railroad company is the value of its assets. This cannot be shown on its books, but what is shown is the cost of the assets; at least that is what should be shown by the books.

Professor Ripley in discussing state regulation of security issues comes to the conclusion that mere publicity is inadequate. We cannot agree with him if the publicity is immediate and intelligible. Mere publicity has worked remarkably well in regulating security issues by joint stock companies in England. No law that has ever been invented can take the place of intelligence and business acumen in protecting a man against bad investment.

In discussing pooling agreements Professor Ripley is strongly in favor of co-operation between railroads for the elimination of wasteful competition.

The book as a piece of literature is readable. It can be strongly recommended to railroad men and to all other persons who are interested in the matters of which it treats.

Letters to the Editor

WASTE IN PRESENT METHODS OF CAR HANDLING

Chicago, Ill.

To the Editor of the Railway Age Gazette:

For many years car service officers have discussed in their meetings the terrific waste inherent in present methods of car handling. All sorts of remedies have been suggested by practical operating men, both for improved methods under the present ownership basis, and for various degrees of car pooling. Suggestions have been made that the executive and financial officers be informed of the tremendous saving that undoubtedly would accrue from effective co-operation in car distribution, repairs and storage. It is inconceivable that this situation is not fully understood by those responsible for railway operation. It also cannot be admitted that American railroad men are not equal to evolving the details of practicable plans for a drastic readjustment of existing conditions.

Why then, at a time when economy is the supreme desire of every railroad manager, is this problem not given adequate and comprehensive treatment?

Possibly the significance of the issues involved after all are not generally understood, and if so the *Railway Age Gazette* could perform a service of vast importance by analyzing and exposing the wasteful and extravagant features of our present methods.

L. M. Betts,
Car Accountant, Belt Railway of Chicago.

THE GOVERNMENT ACCIDENT RECORDS

New York City.

To the Editor of the Railway Age Gazette:

The Interstate Commerce Commission has issued a second and revised draft of the proposed new blanks for making monthly reports of railway accidents, continuing further the suggestions which were first issued last January. There is no evidence in the pamphlet, or in the accompanying letter, that the commissions of the 45 individual states (which have commissions) have had any voice in the formulation of the proposed rules or in the discussion as to what should or should not be included in them.

As most of the principal railroads have to report both to the federal and to the state authorities, it is much to be desired that the active interest of members of state commissions shall be enlisted in this matter.

This movement for improved records seems liable to failure, or partial failure, by reason of its comparative unimportance. State commissioners will not give it their attention unless they are specially appealed to; and this special appeal ought to be made. In one way of looking at it, the whole thing is only a mass of clerical detail; but it is an important thing for the railroads, nevertheless. A road having to report to six or a dozen states writes, in a year, an innumerable number of pages, in the aggregate, to be included in these records, and the unending diversity which now prevails is entirely unnecessary, if only there could be an agreement. The present lack of agreement exists, not because anybody desires diversity, but simply because there is no one to take the initiative.

No one state will lead off, because there is the feeling that such leadership is not warranted. Committees of the National Association of Railway Commissions accomplish things but slowly.

The railroads, presumably, are using their influence with the Washington authorities, through the committee of which Mr. Kruttschnitt is chairman. Why should not they also use their influence with state commissions? Why should not prominent roads in every state communicate with their commissions and try to get them to put their statistical officers in touch with the commission at Washington, in connection with this matter and thus start some real co-operation?

R. R. N. Y.

MORSE AND CONTINENTAL ALPHABETS

Haileyville, Okla.

To the Editor of the Railway Age Gazette:

Your editorial of May 7, advocating the use of the Continental alphabet on the railroads, in place of the Morse, is too late. So far as "safety first" is concerned there is not much of an argument. There is nothing any plainer than the Morse alphabet when handled correctly. Of course, with the class of operators now being produced the Morse is unmercifully butchered; and there would be little, if any hope for an improvement where any other alphabet is used. As for the wear and tear on the nerves there is no perceptible difference. Inasmuch as the greater percent of telegraph operators coming to the surface now are not capable of handling Morse what would they do with the Continental? The sending machine has, to some extent, in the hands of those who have practiced extensively with it, made their sending better; but in the hands of the beginner the condition is worse than when they use the primitive key.

Would it pay anyone to begin to familiarize himself with a new alphabet? It will be only a short time until the telephone will entirely supplant both the Morse and the Continental, both in despatching and for message work. A large per cent of railroad telegraph operators are using the telegraph now only because the hard times among the railroads prevents them from installing the telephone more extensively. Just as soon as they can see their way clear to appropriate funds for improvements there will be a noticeable extension of the telephone system. The commercial companies as well will fall in line, along with the railroads, by using the telephone to handle their messages. A good typewriter operator at one end of a first class telephone line with a good plain talker at the other will handle an enormous amount of business.

TIPPING ON PULLMAN CARS

New York.

To the Editor of the Railway Age Gazette:

I hold no brief for the Pullman Company, and if its dividend rate were reduced I should survive; but in view of numerous utterances which have recently appeared, it seems to me, and, I believe, to the average railroad man, that attention should be called to the fact that sleeping-car porters are not the only men who live on tips and their employer not the only rich concern to profit by the tipping habit. Hotels and restaurants are far worse. Those extremely philanthropic newspapers which are now denouncing Robert T. Lincoln, seem to forget that he is but one of eleven directors, all of whom might be willing to pay porters $150 a month and who yet would not be likely to be able to improve the service or reduce its cost to the passenger, to any appreciable extent. The critics, however, do not forget that the Pullman Company is a corporation, such as legislators like to "jump on," while hotels may make 50 per cent profits and yet are immune to this sweeping journalistic criticism. And what do these newspapers think of the growing practice of giving tips equal to a third or two-thirds of the legitimate bill, such as prevails in barber shops?

The tipping habit is deeply seated in human nature—or at least in the nature of a good many humans who travel. Protests against it seem to be effective only where there is enough poverty to compel remonstrance, as in Europe. Is not poverty the real reason why a 10 per cent tip goes, over there, when many Americans freely give bonuses of 20 to 50 per cent? Again, is not the objection to tips based largely on dissatisfaction with details rather than on principle? Waiters often fall far short of their duty, notwithstanding the tip, and we blame the "system," when we ought to kick the waiter. Young women who serve

as table waiters at summer hotels and use their tips to get an education are not condemned; they are praised; but where is the difference in principle? There is a large degree of truth in Mr. Lincoln's declaration that the sleeping-car service with its high standards and strict discipline has helped to raise the social and economic position of the American negro. I do not write to defend tips, but merely to call the attention of our impartial press to its careless dissemination of a half truth. E. F. L.

MAKING RATES TO DEVELOP TRAFFIC

Jamestown, Cal.

To the Editor of the Railway Age Gazette:

In one of the papers a few days since I noted an article by Peter Radford, lecturer for the National Farmers' Union, referring to the recent action of the Interstate Commerce Commission granting an increase in freight rates in eastern territory. He writes as follows:

> The freight rates of the nation have been built up along lines of least resistance. The merchant, the manufacturer, the miner, the miller, the lumberman and the cattleman have had their freight bureaus thoroughly organized and in many instances they have pursued the railroad without mercy. . . . The farmer is seldom represented at rate hearings as his organizations have never had the finances to employ counsel and as a result the products of the plow bear an unequal burden of the expense.

It is just this point of view that the railroads are up against at nearly every hearing—this look-out-for-yourself-and-let-every-one-else-fight-his-own-battle idea that every class of shippers takes and which the average commissioner also holds, although he does not permit the railroads to take the same stand.

Now, it is exactly that point of view that the railroad manager must take if he is to work for the best interests of his road—the best interests in the long run. The traffic manager must look at the question from all angles. "Can I afford to grant Mr. Jones' request for a reduced rate on his salt shipments? Can he continue to operate his plant if I do not? If his plant is closed down what effect will it have on the other revenue from his town. Possibly my road may be supplying groceries, etc., to his employees, which he shall lose. Possibly that is the only revenue we obtain from that shipping point and the salt will be shipped in over the road from other places, and if so what motive have we to keep his plant going at our expense?"

Again, reports from agents and others show that if a reduced rate is named on iron ore a large plant will be erected, many thousands of men employed, large quantities of other freight will be handled, etc. Another officer sees vast acres lying idle and finds that very low rates must be made on grain to induce the owners to cultivate the land. He can handle the grain if offered to him at various points along the line at little or no increase in his operating expenses. Now, what shall he do? Self interest answers the question every time—whatever is better for the road.

Therefore, it does not follow that the farmer is discriminated against by one road because grain rates are not relatively as low as on lumber, nor that the manufacturer is discriminated against by another road because his output does not receive the same rate per ton mile as it does in some other localities.

If the railroad commissions would take some such views as these and permit the roads to advance rates with the same willingness that they grant reductions, I feel certain that there would not be one-half the friction that there is today. Restrictions should be maintained, of course. For instance, if a rate is reduced no increase should be permitted for, say, two years. That would prevent any undue preference to shippers or consignees who might be furnished with advance information of an advance. With the publicity given to all rates today, and the manifest intention of all railroads to refrain from rebating and similar actions, the public would get better service, the roads would employ more men, and purchase more supplies. Particular rates, which might need modification, could be investigated much more quickly than at present. Both carriers and shippers would know how to gage affairs ahead, and I believe it would make prosperity in all lines.

S. H. Smith.
Traffic Manager, Sierra Railway of California.

A DISCIPLINE AND WAGES BUREAU

New York City.

To the Editor of the Railway Age Gazette:

The letter of Mr. White in your issue of May 14 proposing that all labor matters should be put into the hands of a single vice-president, he to have no other duties, and comparing the management of labor with the work of the purchasing agent in connection with material, embodies interesting possibilities, but has he not forgotten the vast difference between a man and a piece of timber or a bar of steel? The idea of a central organization surely is good. Several roads already maintain a bureau of this nature, the New York Central, the Delaware & Hudson, the Erie and the Baltimore & Ohio, for instance. These bureaus collect and keep data in connection with wages, discipline and working conditions. The experience of these roads shows that the department is very useful. Each large railroad should have such a central bureau, with records for all classes of employees in each department. This is necessary if for no other reason than to bring about uniformity of wages on the entire system for the same classes of occupation (except when controlled by outside conditions, such as wages paid in other industries). The man in charge of the bureau can be useful in making uniform the interpretation of rules. By thus maintaining uniformity throughout the different parts of a system grievances are minimized.

But you cannot safely relieve heads of departments—the transportation department, the maintenance of way department, the motive power department, etc.—of the responsibility for their expenses; and if responsible for expenses they must have a voice in fixing the agreements with the employees. And probably the head of each department should have not only a voice, but the deciding voice. Moreover, the men desire to deal with their actual boss. It is true that labor leaders like to appeal to the highest boss, but that does not weaken my point. The appeal from general manager to president is normal and natural; but to have to appeal sidewise, instead of upward, would be unnatural. Imagine a road entrusting negotiations with the trainmen to the vice-president in charge of traffic or of the treasury department. How quickly the employees would make a fuss. Mr. White's proposal is hardly less objectionable. He would appoint a vice-president who had had experience with trainmen, very likely; but a very short time would so affect the mental attitude of this vice-president that he would come to be looked on as a non-technical man; as a mere negotiator, like a lawyer. That is what the purchasing agent is—a mere negotiator.

The head of the bureau having charge of these labor matters should be on the staff of the chief operating officer. He should be subordinate to and have the confidence of the heads of each of the departments for which he keeps data. He is the man to make the requisite investigation of all conditions that arise from day to day and always be prepared to advise, through the head of each department, and furnish for that department all necessary information. The superintendent of a division, for example, should be able to go to this bureau and inform himself fully, so as to be able to deal efficiently with each proposition that may come up within his territory, in relation to the pay of the employees or anything affecting the employees which is likely to disturb their feeling or attitude toward the employer.

Labor cannot be bought on the same principle that a railroad buys material. Unless the officers realize the fundamental difference as to this point, they will be very unlikely to make satisfactory progress in their dealings with the labor situation.

A. V. P.

Railway Extension in Manchuria.—The governor of Tsitsihar is said to be interested in a project to construct a railway from Hailunho to Harbin. The governor's office is collecting information regarding the commercial activity of the Hulan district and the industrial contributions of the district to Harbin. It is proposed to run the railway through Tuichingshan to avoid constructing a bridge across the Sungari river.

Preparing for the Federal Valuation of the Railways

Measures Adopted by the Different Roads Now Being or Soon to Be Inventoried by the Government Forces

No problem with which the railways are confronted today is attracting more attention than the federal valuation of their properties. While concerning primarily the engineering, mechanical, legal, real estate and accounting departments, this work is of live interest to all other departments and its progress is being watched closely. The law providing for the physical valuation of the railways has now been in effect over two years, while government parties have been in the field for over a year. The number of important roads on which this work so far has been undertaken is relatively small, and as the valuation work will ultimately extend over all roads, the methods adopted by the lines first selected for examination by the government are of general interest and value to the others, indicating as they do the preparations which all roads must eventually make. For this reason we outline briefly below the manner in which several of the leading roads now being valued are collecting information for the use of the government and themselves.

The extent to which the roads now, or soon to be, under valuation, are preparing for it varies widely. The government requires all roads to provide right of way and station maps, profiles and certain other data for its use. For their own interests all of the roads are also collecting and presenting to the government forces, all the information they can collect concerning hidden quantities and other elements of value not evident from a surface inspection. Beyond this the methods vary, depending on the amount of money the individual roads feel justified in spending to detect errors and omissions in the government inventory. Some roads only furnish a pilot to accompany each government party to give any further information desired and to endeavor to see that no important items are omitted. Other roads are making complete re-surveys independent of and in advance of the government parties with almost as much detail as the federal forces and are comparing their figures with those furnished them by the government to be sure that all property is included. On other roads are to be found all the various degrees between these two methods.

These variations also result largely from the condition of the records of the individual roads. Some of the older lines possess records of little value as indicating the present condition and value of the property. Other lines have been improved and rebuilt without corresponding revision of the records until this data has become obsolete. In such cases the incentive to revise and correct the records or to make new surveys to secure correct information for the use of the road itself as well as for the government is much greater than on lines recently built and possessing fairly accurate original records of construction. Also, a number of the states, particularly in the middle west, have required the roads to make valuations, and where this has been the case the data was in fairly good shape before the government entered the field. Under such conditions the roads naturally have not gone to the expense of making a complete re-valuation. The methods adopted by the roads under inventory so far have also been influenced largely by the time intervening between the receipt of the government notification and the arrival of the parties. In many cases this has been less than three months, and the amount of preparation possible has therefore been very limited.

CHICAGO & EASTERN ILLINOIS

One of the first roads on which the government began work last year was the Chicago & Eastern Illinois. For this reason the road had only a limited time in which to prepare for the federal parties. However, the methods adopted at that time are in general still being followed on this road, on those divisions on which more time was available for preparation.

Some time previous to the arrival of the federal parties on a given section of the line, the chief engineer goes over that portion of the line with his valuation engineer, pilots and those employees and others familiar with the portion of the line under consideration in earlier years. Last summer these trips were made with a motor car, and during the more inclement weather last winter by special train. The line is covered at the rate of about 10 miles per hour and an endeavor is made to gather all the information possible regarding conditions encountered in earlier years and not now so plainly evident. A stenographer accompanies the party, taking elaborate notes which are written up on the return to the office. Each item is entered on a separate loose-leaf sheet. One complete set of these sheets is then turned over to the pilot who goes back over this line, checking each item on the ground. He is given two copies of all notes relative to hidden quantities, one copy of which he gives to the government engineer in charge of the party, each engineer attaching his signature to the sheet retained by the other for identification. The pilots were selected from assistant division engineers and have all had from four to eight years' service on the road. Wherever possible the pilots are retained on those divisions on which they have previously been located in maintenance work.

About 12 men were required in the office last summer searching office records and securing statements of men familiar with the lines regarding hidden quantities, etc. As this road signed the agreement with the government whereby it receives copies of the field notes taken by the federal parties, these men are computing the quantities on the older lines in the office from these notes and checking the figures secured by the government on the newer lines with the construction records. During the winter the office force was considerably increased, as new maps were being made for the entire line in accordance with the requirements of the government.

Four federal parties covered about 560 miles of main line last year, comprising practically all the road in Illinois. One bridge and one signal party were also on the same line. Three roadway parties were returned to these lines on March 20. The government is also now starting to inventory the equipment, the present arrangement being for the government and the road each to assign a man to this who will co-operate, and where possible make a joint report. It is understood that the government will endeavor to examine from 10 to 30 per cent of each type of equipment.

The government has had two real estate men at work on these lines during the past winter, while the railway has also employed two real estate men to do the same work for it, following a short distance behind the government men. As it is the policy of the commission to ascertain information concerning real estate entirely independently of the railways, these two parties are working separately.

ROCK ISLAND

The Chicago, Rock Island & Pacific organization is similar in many ways to that of the Chicago & Eastern Illinois.

Previous to the inauguration of this work, the superintendent of each division soon to be under valuation, called a staff meeting at which were present the division engineer, roadmasters, master carpenters, foremen of water service and section foremen. Using the right of way maps and track profiles each section foreman's territory was gone over in turn and each one present was called on to give any information he could remember regarding work done on that particular section in the past, evidence of which could not now be seen on the ground. Stenographic notes were taken of this meeting, which were written up and furnished to the pilot who was to accompany the valuation party over this territory. About a month before the federal party

arrived, the pilot was given these notes together with maps and profiles. He then spent the intervening time searching through the files and records to substantiate the information brought out at this meeting and to supplement it with any further data. He also made one or two trips over his section to become familiar with it before the arrival of the federal party.

No surveys are being made on those lines on which previous valuations have not been made. This road has agreed with the federal engineering board that the railroad pilot and the man in charge of the government party shall proceed over the line and make the inventory. Having signed the agreement in circular No. 1, this road is receiving copies of all field notes taken and also the areas, quantities and overhaul computed in the calculation of grading quantities. In the states in which valuations have previously been made, comparisons are made between the figures secured by the government and those of the earlier valuation. All data concerning hidden quantities is of course furnished the pilot that he may transmit it to the chief of the government party.

The pilots are selected from the older engineering employees on the system who are familiar with the property and who have more or less recollection of work which has been done, of which no records are available. Men are also selected whose experience and ability are such that when the valuation goes into court, if such should be the outcome, they will be acknowledged the equal or the superiors of the men in charge of the government parties. Eight federal roadway parties started on these lines during the past winter and will continue during the coming summer, moving northward. The first parties began work on the lines in Kansas and Oklahoma, where valuations had previously been made for the state. On April 1, 2,000 miles of line had been covered. In addition 3 signal parties have completed 1,000 miles of line.

CENTRAL OF GEORGIA

The Central of Georgia was another of the roads on which the government placed parties early in its work. Because of the short notice given, the road was unable to collect as much information as desired in advance of the work. Pilots were chosen from the corps of assistant engineers in the office of the chief engineer, and were men who had been with this company for several years, who were familiar with conditions along its line and who had from 6 to 10 years' experience in railway construction and maintenance. Before the arrival of the federal parties the pilots walked over their respective lines accompanied by the supervisors and roadmasters to familiarize themselves with conditions in detail and secure any further information they could from old employees regarding any unusual conditions or construction affecting the cost. At the same time the office records and construction notes were carefully examined for the same purpose. As trains have been running between Savannah, Ga., and Macon since 1843, it was impossible to secure any of the original construction records for this or other old lines. There are very good records of those lines built in recent years.

This road signed the agreement with the government by which the road is furnished copies of all field notes which are checked against any information in the possession of the road. Government calculations of quantities are not being refigured, but are being checked against any original construction records available. A valuation of lines in Alabama was made in 1909 for use in a rate case, and the government quantities on these lines are being checked against the data secured at that time.

For a number of years this company has been perfecting its maps and profiles, and the entire line is mapped on a scale of 100 ft. to the inch, showing topography, right of way and section lines and a complete list of deeds, contracts and leases. These maps practically comply with the requirements of the government.

The first government party started to work on this road on July 9, 1914. Since that time other parties have been added until there are now four roadway field parties and one terminal party. They have completed about 1,700 miles of line. The signal department has completed its inventory of interlocking plants, crossing bells, etc. Three telegraph and telephone parties have completed work on this road. A structural party started work on November 3, and has completed the inventory of bridges and trestles on 1,100 miles. A force of 15 men is at work in the accounting department. An assistant land attorney spent six months of last year identifying all deeds to right of way, securing practically the same information as now called for in order No. 7. The government has started inventory of motive power and equipment, shop machinery, piping, etc. The government has 6 land men at work appraising the land of this company.

THE "SOO"

The lines of the Minneapolis, St. Paul and Sault Ste. Marie may be divided into two classes: First, those built in recent years for which complete records of construction are available and old lines and branches of which the road still has the original records and on which little change has been made since the lines were built; and, second, old lines which have undergone many changes since the original construction and of which there are not complete records. The first class includes about 65 to 70 per cent of the entire mileage.

On those lines on which records are available a pilot engineer is given a complete inventory by I. C. C. accounts of all items to be inventoried, which inventory he checks with records obtained by the government party. This road has signed an agreement with the government whereby it secures copies of all field notes. It is understood that the pilot engineer and the government field engineer will check and agree on all items inventoried from day to day as far as possible. If for any reason differences in quantities cannot be agreed upon, proper record of the differences are made and same are referred to their superiors for adjustment.

On the second class of lines where no accurate construction records are available, the road has placed parties in the field to make complete surveys and to bring the records of inventory up to date. After this data has been collected and compiled the method of procedure will be the same as with the other lines. An office force is also employed in investigating records, completing inventories and in determining in advance as far as possible to what extent field work is necessary to secure the desired information or to check the quantities which the government computes. This force is also employed in gathering and compiling the data and revising the maps and profiles required by the government.

The government placed one party on this line in Dakota on May 1, 1914. Two additional parties were started on this line on October 1. On November 5 these parties were sent south, at which time 400 miles of line had been covered.

GREAT NORTHERN

The Great Northern has organized in somewhat greater detail than the roads referred to previously to secure a complete inventory of its lines. Field parties consisting of an assistant engineer and three men are being sent over the lines in advance of the government parties to obtain the necessary information to correct and bring up to date the existing maps and profiles, and to prepare inventories covering all classes of property. These parties are provided with gasolene motor cars to facilitate their work. Especially designed loose-leaf field books are used and the notes are sent by the assistant engineers to the general valuation division office separately for each consecutive 6 to 10 miles of track covered. A division engineer, selected because of his long and varied experience in railroad construction, is placed in charge of 3 or 4 of these small parties. No recross-sectioning of the roadbed is done by these parties as the grading quantities are being compiled in the office from the records of original construction and of subsequent work. Fairly complete records of this nature are available for about 90 per cent of the mileage of the system. After these grading quantities are tabulated in the general office they are sent to the division engineer to check and compare on the ground to see that all items have been included as far as can be determined from a field inspection.

Seventeen such parties have been employed in this work and

they have covered approximately 4,800 miles of line in Minnesota, North Dakota, South Dakota, Montana, Idaho and Washington, on which the government has expressed a desire to undertake work first. An office force of 40 engineers, draftsmen and clerks is employed in compiling grading quantities from final estimates and other office records, correcting maps and profiles and compiling inventories from the information sent in by the field parties.

Two assistant engineers accompany each government field party as pilots, these men being selected because of their general competency and their general knowledge and experience in connection with the original construction and subsequent improvements on the line being inventoried. Seven government roadway and track field parties were employed on the lines of this company last summer, all being transferred to southern roads late in the fall, after 1,168 miles of line had been covered. Three of these parties were placed in the field by the western district and four by the Pacific district, although a readjustment has now been made whereby all further work on the Great Northern will be handled by the Pacific district alone. All buildings on the 592 miles of line in North Dakota covered by the roadway and track parties last year were inspected by a government structural engineer and an assistant accompanied by a representative of the company. Sketches and general descriptions of all buildings, including furniture and fixtures were prepared by these men.

In the accounting department six clerks were employed in the valuation work by the railroad company last spring. The government placed eight accountants in the offices of the railroad on July 15 The right-of-way department is preparing schedules of right-of-way deeds for the use of the government land men in the field. In addition, the railroad has sent men from the right-of-way department into the field to collect information from the county offices covering all transfers of land from January 1, 1911, to date in each county through which the railway runs. Property owners adjoining the line are being interviewed and their opinions regarding the value of farm lands and town lots obtained, while the latest assessment of these lands is also being obtained and listed. On August 10 two government land attorneys began work on the lines of the Great Northern. After checking over the schedules of deeds in the offices, they secured the same information in the field as secured by the railroad representatives.

KANSAS CITY SOUTHERN

One of the roads which has made a complete survey of its property in advance of the government valuation is the Kansas City Southern. This road decided that the best means of securing to the company a correct valuation of its property was to make independent surveys with its own forces, and to furnish the government with copies of the field notes taken while making these surveys.

These surveys were commenced in November, 1913, and completed in December, 1914. They preceded those of the government, and it was arranged that the pilot who accompanied the government party over any particular portion of road was the same man who had charge of the company's surveys over that particular section. Two pilots were, therefore, alternately in charge of the railroad party and acting as a pilot for the government party.

Individual inspection was made of all company equipment on the line with a view to verifying the existence and determining the condition of the units of equipment. Record was also made at that time of the additions and betterments that have been made on the same. The company representatives have co-operated with the government in making an inventory of the shop machinery and tools. This work has been completed. The inventory of bridges and buildings made by the structural party of the Interstate Commerce Commission, accompanied by representatives of the company, has been completed.

New maps and profiles were made of the entire line and filed with the commission in compliance with the map order. These maps and profiles were made from existing records and notes taken by the company forces in the field. A report has been made on property abandoned by the company during its development and filed with the commission in compliance with valuation order No. 2.

An organization is maintained for the purpose of compiling data in order to comply with the valuation orders issued by the commission at various times, and for developing expenditures which have been made for various items going to make up the cost of the property, such as assessments for public improvements, expenditures account, acquisition of right of way, damages, extraordinary construction, expense, etc.

The government has had five land appraisers in the field determining the market value of lands adjacent and adjoining the right of way, and have completed their work for the entire line with the exception of certain terminals.

BOSTON & MAINE

The Boston & Maine is also making complete surveys of large portions of its lines. After being notified in February, 1914, that the government expected to place parties on its line on May 1, a careful inspection of the maps in the files was made, showing that maps could be completed in accordance with the requirements of the government for about 1,000 miles of line with a small amount of work. Draftsmen at once began making new tracings to the required standards, and four survey parties consisting of two men each went out over these lines collecting missing information and adding further data required by the commission.

For the remaining 1,500 miles it was necessary to make complete surveys. For this purpose nine parties of five men each, one of whom is a draftsman, were placed in the field. These parties prepare maps on a 100-ft. scale showing all buildings and other property on the right-of-way and send them into the general office in approximately 5-mile lengths as fast as they are finished and inked. These maps are then completed in the general office in accordance with the government specifications after the land lines and data regarding deeds and other records have been added. Prints of these plans are then given to the government forces as they start on the various sections.

A pilot and a computer are assigned to accompany each of the government track and roadway parties in the field, the pilot representing the railroad and seeing that all property is included in the inventory while the computer works in the field office with the government employees checking computations. For the assistance of the pilots a "hidden quantity" squad has been organized to investigate all records, books, plans, etc. All the available information regarding the conditions of bridges, buildings and other physical property, such as ties, etc., is also being compiled. The tie records, for instance, show the annual replacement by individual years for the last nine years with the percentage of renewals for each year and the segregated renewals for the entire period. The government forces are accepting these records and prepare their final segregation of ties from them.

The government also has a bridge and building party on these lines with which the railroad has assigned a bridge and building man and a computer. There are also a signal and a telegraph and telephone party on this line. Five roadway and track parties on these lines covered about 650 miles of line to January 1, 1915, in addition to the other parties just enumerated.

The government right-of-way appraisers started work on the Boston & Maine last May. An assistant attorney is engaged in checking the records in the office, while five appraisers are at work in the field securing data regarding the value of adjacent lands, etc. The land department of the railroad is also securing the same information and has examiners going through all the registries securing abstracts of all deeds in the name of the railroad. This has been necessary as in many cases the files of the company were incomplete in this respect. The government land appraisers have completed about 400 miles of line.

STEEL PASSENGER TRAIN EQUIPMENT

To ascertain the progress of the building of steel and steel underframe passenger equipment and to develop the cost of reconstruction in steel of the present wooden passenger equipment in the country, the Special Committee on Relations of Railway Operation to Legislation issued a circular letter to the railways on January 2, 1915. Replies have been received from 284 companies operating 245,721 miles in the United States, and 62,112 passenger equipment vehicles, with 956 under construction on January 1, 1915. The tabulations based on these replies have been published in Bulletin No. 67, showing that of the cars under construction on January 1, 725 were all-steel, 228 steel underframe and 3 wood, and of the 4,495 cars acquired in the calendar year 1914, 3,355 were all-steel, 940 steel underframe and 200 wood, including 56 cars purchased second hand. Of the total number of passenger train cars in service on December 31, 1914, 12,900 were all-steel, 5,700 steel underframe and 43,512 were wood. The character of the various classes of equipment in service on December 31, 1914, is shown in the following table:

	Steel	Steel underframe	Wood
Postal	888	217	461
Mail and baggage	668	404	2,562
Mail, baggage and passenger	31	56	579
Baggage and passenger	528	227	3,519
Baggage or express	1,478	1,315	7,507
Passenger	5,105	1,704	22,266
Parlor, sleeping and dining	3,200	1,526	5,353
Business	32	109	730
Motor	970	142	535
Total United States	12,900	5,700	43,512

A table is also given in the bulletin showing that for the cars acquired during the past six years the percentage of all-steel cars has increased from 26 to 74.6, while the percentage of steel underframe cars has ranged from 14.8 per cent to 30.4 per cent, and was 20.9 per cent in 1914. The percentage of new wooden cars built has decreased steadily from 51.4 per cent in 1909 to 4.5 per cent in 1914.

Another table shows that the number of all steel cars in service has grown from 629 in 1909, an increase of 1,951 per cent, while the number of steel underframe cars has grown from 673, an increase of 747 per cent. A total of 4,614 wooden cars has been retired in three years. Of this number 1,048 were retired during the calendar year 1914. The bulletin also gives the following table showing the approximate cost of replacement of wooden cars:

Approximate Cost of Replacement of Wooden Cars

	Number	Average cost	Amount
Postal	461	$11,000	$5,071,000
Mail and baggage	2,562	10,000	25,620,000
Mail, baggage and passenger	579	10,000	5,790,000
Baggage and passenger	3,519	10,000	35,190,000
Baggage or express	7,507	8,500	63,809,500
Passenger	22,266	12,800	285,004,800
Parlor, sleeping, dining	5,353	22,000	117,766,000
Business	730	15,000	10,950,000
Motor	535	20,000	10,700,000
Total	43,512		$559,901,900
Annual interest charge at 5 per cent			$ 27,995,095

The charge to operating expenses under the classification accounts of the Interstate Commerce Commission, assuming a value of $4,000 per vehicle replaced, would be $174,048,000.

Replies were also received from 10 companies operating 27,628 miles in Canada, showing that of a total of 5,366 passenger train cars in service on December 31, 1914, 79 were all-steel, 187 steel underframe and 5,100 were wood. Of 57 cars under construction on December 31, 38 were all-steel, 16 steel underframe and 3 wood.

Port of London Authority Men and the Colors.—The total number of employees of the Port of London Authority who have been called up or have volunteered for active service is 2,009, including 238 men specially recruited for the army service corps. Up to April 29 the number who had lost their lives while serving with the forces was 53. Of these 24 were in the navy and 29 in the army.

A MODERN CONCRETE AND BRICK ROUNDHOUSE AT DU BOIS, PA.

The Buffalo, Rochester & Pittsburgh has completed a 16-stall roundhouse of reinforced concrete at Du Bois, Pa., directly opposite the old 16-stall brick roundhouse, which is too short for the large locomotives and which will be used for the smaller engines only. Both houses are served by the one turntable. The new house is 105 ft. deep with the inner circle 91 ft. from the center of the turntable.

The foundations for all walls and columns are of concrete carried on piles driven to refusal and cut off 8 ft. below the top of rail in the house, the latter elevation being 2 in. above the top of rail in the adjacent yard. The piles extend 12 in. into the wall foundations, which are reinforced with two rows of 80-lb. rail. The outside walls are of brick 13 in. thick with pilasters 17 in. deep, built separately from the wall. The window panels in the rear wall are built in units so that if struck by a locomotive only the single panel will be damaged and the beams and roof girders will not be injured.

The columns, girders, beams and roof slabs are of concrete reinforced with Kahn shear bars and twisted steel rods. The unit stresses adopted were 16,000 lb. per sq. in. for steel in tension and 500 lb. per sq. in. for concrete in compression.

Interior of B. R. & P. Roundhouse

The roof consists of 5-in. concrete slabs supported on concrete beams 34 in. deep and 14 in. wide over the outer bay, 6-in. concrete slabs on concrete beams 57 in. deep and 18 in wide over the center bay and 5-in. concrete slabs on concrete beams 38 in. deep and 16 in. wide over the inner bay. These slabs are covered with Johns-Manville asphalt roofing, which company also furnished the Transite asbestos smoke jacks.

Each stall is provided with an engine pit 76 ft. long, 4 ft. wide and 2 ft. 6 in. deep, built of concrete with the running rail carried on 8-in. by 12-in. creosoted yellow pine timbers supported on the side walls. The pit slopes 6 in. towards sumps at each end, where the water escapes through 8-in. sewer pipes. The floor of the pit is of concrete 15 in. thick, reinforced transversely by 80-lb. rails 8 ft. long at intervals of 4 ft.

Three stalls are provided with double drop pits 7 ft. 6 in. wide and 6 ft. deep, which are lighted with 60-watt Tungsten lamps recessed in the walls in each side of the pit. Outside of the pits the floor is of concrete 6 in. deep, reinforced in the center with triangular wire mesh and carried on 8 in. of cinders. The windows and doors are of wood construction. The upper and lower sash of the windows are balanced and the center sash fixed. The transom sash in the upper portion of the middle bays are provided with opening devices operated from the crane track.

A 38-ft. 15-ton Shaw electric crane runs through the center

bay of the house on a circular track 27 ft. 5 in. above the main track. This crane is installed for the handling of engine cabs, front ends and other heavy parts.

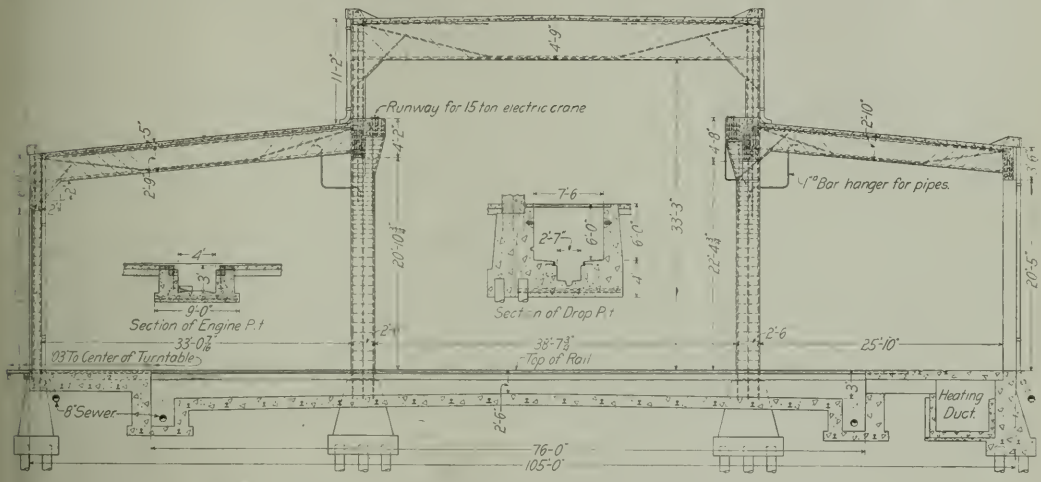
At the outer end of stalls 13 and 14 there is an addition 29 ft. long divided into two portions, one of which is given up to the heating plant and the other to the boiler washing plant. The house is heated with a fan system built and installed by the Buffalo Forge Company, Buffalo, N. Y., the warm air being forced through underground ducts with outlets in the sides of each of the engine pits. A Cowles-MacDowell boiler washout system is also installed with a capacity of 6 engines per 24 hours.

The house is lighted by means of bull's-eye reflectors placed at the ends of each stall, one on each door post and two on each brick pilaster at the back of each stall in such a manner as to avoid shadows. General illumination is provided by clusters in the upper roof. Plugs are also inserted in each column for the use of portable extension lamps. All conduits and boxes are built in the concrete.

Because of unfavorable local drainage conditions a concrete sump was installed with an automatic electric centrifugal deck turntable of the standard American Bridge Company's sump pump to receive and dispose of the roof and pit drainage.

In connection with the construction of this house a 90 ft. design for Cooper's E-60 loading was installed with a concrete pit replacing a 70 ft. deck turnable designed for Cooper's E-40 loading.

This structure was designed under the direction of E. F. Robinson, chief engineer, and W. F. Pond, office engineer, in co-operation with F. J. Harrison, superintendent of motive power, and W. J. Knox, mechanical engineer. It was built by railway company forces under the supervision of G. H. Stewart, master mason.



Cross Section of Reinforced Concrete Roundhouse at Du Bois, Pa.

CORRECTION

In the description of the new line of the Chesapeake & Ohio Northern from Waverly, Ohio, to Edgington, Ky., in the issue of May 14, page 1018, the statement that 40,000,000 lin. ft. of timber piling was required, should have read 40,000 lin. ft. While this error was undoubtedly evident to our readers we make this correction.

New B. R. & P. Reinforced Concrete Roundhouse at Du Bois, Pa.

Cooling Apparatus on Egyptian Railway Cars.—Tanks to hold half a ton of ice and electric fans to circulate the air from them are used to cool the interior of passenger cars of the Egyptian state railways.

THE RAILROAD ACCOUNTING OFFICER

By H. W. Davies
Auditor of the Pacific & Idaho Northern

If the railroad accounting officer is not exercising his full usefulness in the interest of the company he serves it may either be his fault, or it may be due to a condition, or conditions, over which he has no control, and which conditions create his limitations.

It is not an infrequent case, that an accounting officer, unconsciously or otherwise, creates his own limitations; the one cause more common than any other is probably his satisfaction in acceptably fulfilling the rules and requirements prescribed by the Interstate Commerce Commission on the one hand, and the railroad accounting rules and requirements on the other hand; and finally, submitting on time the monthly balance sheet, income statements and other subsidiary reports; which, when accomplished without bringing forth criticisms, is logically accepted as commendation of services well performed. The natural assumption is, and rightly so, that the successful fulfilment of the requirements named carries with it a successfully organized accounting department, which of necessity must exist to meet properly such difficult and varied requirements.

An officer in charge of an accounting department so thoroughly and successfully organized as to fulfil satisfactorily the requirements mentioned, and at the same time to take care of, and keep up to date, his collections, and the many subordinate, though important, branches of his department which contribute to the results as a whole, is indeed to be complimented. He is from a purely accounting standpoint, to be considered an expert and successful accounting officer. And yet, on the face of it, it will be apparent that though the results may embody correctness, completeness and promptness, requiring skill, energy and force of the highest order, it is but fulfilling certain prescribed rules and requirements, which in themselves are but a small part of the economical management of a railroad. Is such a successful and expert accounting officer, in accomplishing such excellent individual results, giving his company the full benefit of his ability? As an accounting officer, very probably, yes; as an officer of the company interested in all its departments and ramifications, no.

Certain department jealousies always have and probably always will exist in all large organizations, whether manufacturing or otherwise, and especially with railroads. The traffic and transportation departments differ over light tonnage cars, the roadway and mechanical departments over derailments, the mechanical and supply departments over supplies. Other natural conditions which affect two departments, whether as to cause or effect, create these little jealousies, and the accounting department gets its share from all other departments. This question of department jealousy may, or may not, properly have any place in connection with the question under discussion. However, if not a direct, it is possibly a contributory cause for the lack of recognition on the part of the management, in many cases, as to the possible usefulness of the accounting officer in the handling of matters not strictly accounting.

The accounting officer is essentially a man of intelligence, at least equal to if not above the average; this coupled with his position as custodian of reports and records from all departments, easily accessible for his examination and comparison, equips him with valuable material not in possession of others, and thus peculiarly fits him for dealing with matters other than those strictly accounting, which could be developed to the interest of the company, and which would otherwise probable be lost sight of. The accounting officer while not necessarily an expert statistician or economist, is by virtue of his constant dealing with figures, earnings and expenses, tonnage and mileage, etc., unconsciously if not consciously, trained to see conditions, conspicuous in detail but not always apparent by mere perusal or study of the condensed reports. Especially is this true with the smaller and middle size railroads which do not employ efficiency men or statisticians, or have in use forms for detailed daily reports to the heads of the different branches of the operating department, by which they can secure the same detailed information which goes to the accounting department.

The monthly report may show engine fuel consumption comparing very favorably for one month as against the previous month, or with the same month in the previous year; and yet, in detail it will very probably be found that two engines of the same class, under similar running conditions, will show a very marked difference, indicating the lack of efficiency in the running of one engine as against another. The monthly report may show the cost of crosstie renewals comparing very favorably with the previous month or with the previous year; yet, an analysis will possibly show a considerably less number of ties laid with a large increase of labor expense not justifiable by conditions.

The matter of station labor, clerical and manual, usually under the jurisdiction and full control of the division superintendent, and frequently left to his sole judgment, is, in many cases, capable of a more equitable and profitable adjustment by the accounting officer, and especially is this true at larger stations.

The president or general manager is invariably forced to delegate the signing of vouchers to some one else, who, while in a position to recognize the validity or lack of authority for the transaction itself, is not in a position to determine of his own knowledge, the reasonableness or excess of the voucher; the auditor, by virtue of his peculiar position of vantage, could be of valuable assistance by bringing to the attention of the proper officer, cases seemingly worthy of investigation, of which there are many.

There is an old saying, "the treasurer is the watchdog of the treasury." This is no doubt still true in a measure; but broadly applied in these days of forced economy, it can be properly said of all other departments, since values are measured not merely by dollars and cents in the treasury, but by material and labor also. Therefore, the accounting officer is as much a watchdog of the treasury as any one, and in many cases similar to those just cited could extend his usefulness to the success of the company beyond that of a "mere" accountant. Opinions will differ very materially as to the proper limitations of the application of mind, force and energy of any one department, especially when that department encroaches upon another. Yet, the general manager, privileged to question acts and to correct irregularities in all departments with his many important duties, finds it a physical impossibility to analyze the results of all departments to the extent of details. However, details are also important in contributing to the success of the road's operation, and the general manager is, therefore, dependent upon voluntary information to a large degree, before he can know of certain irregularities or be able to correct them. These same limitations exist in all departments to a greater or less degree. The very fact that the departments themselves exist, has established certain unwritten laws, recognized by nearly all railroad officers who are invariably governed thereby.

Divisions or departments are essential in all large enterprises, as segregating the several distinct factors or classes of work. Each class of work is distinct and separate as to skill and individual purpose, and carries respective responsibilities, and serves various other purposes not possible but by segregation. And yet, while each department represents separate skill, and turns out distinctly different products, they are but units or parts of the whole, and are each interested in the successful production of the finished article to which they contribute; and to whatever extent one department slights its workmanship, or unreasonably increases its cost, it reflects itself in the finished product, and in turn reflects itself on all departments. Criticisms, therefore, should be unhampered, solicited and freely given, but given and accepted in the fairest of spirit, as assistance rendered by one department to another for its benefit and in the interest of the company and not especially to the individual. The accounting officer can serve as an important factor in accomplishing these results.

International Railway Fuel Association Convention

Mechanical Stokers; Fuel Oil; Storage of Coal; Front Ends, Grates and Ash Pans and the Closing Exercises

A report of the first two days of this convention was published in last week's issue of the *Railway Age Gazette*, page 1054. The following is a report of the remaining sessions of the convention:

MECHANICAL STOKERS

The mechanical stoker today is practical, operating at a mechanical firing efficiency of 90 per cent or more, and effects operating economies that cannot be otherwise obtained—it is no longer in the experimental stage. Improvements in the design and construction of stokers will no doubt be made for many years to come. Locomotive design will undoubtedly be modified until the stoker becomes a part of the original design instead of being merely an attachment to the locomotive, as at present. Notwithstanding the necessity for further improvements, the fact can no longer be questioned that the mechanical stoker today is an important factor in railroad operation and must be recognized as such by all thoughtful railroad officers.

The real economy of the stoker is in the increased tonnage that can be handled by stoker-fired locomotives—not in the saving of fuel, as seems to be the general impression. The large, mechanically-fired locomotives of today are able to handle more tonnage than the same locomotives would be given if hand-fired, and handle this tonnage at a higher speed and with greater certainty than under hand-firing conditions. The development of the stoker has made possible the development of locomotives designed to burn coal continuously at a rate in excess of the capacity of the ordinary fireman to supply it. The real reason, therefore, for the improvement and adoption of the mechanical stoker is found in the economic necessity of reduced operating costs. The capacity of locomotives already in service may be increased and cheaper grades of fuel may be used on such locomotives, with the locomotive stoker.

According to the most reliable figures obtainable at the present time (April 1, 1915) and not including the experimental stokers, there are at the present time approximately 935 locomotives equipped with stokers on about twenty different lines of railroad.

There seems to be no fixed factor which can be used as a sure guide as to what constitutes a stoker job. One report indicates that any locomotive of 200,000 lb. total engine weight, with cylinders of 22 in. or over should be operated with stoker-firing. A second report states that engines having a tractive effort of 50,000 lb. or over should be stoker-fired. It seems to be the consensus of opinion that locomotives should be hand-fired when the coal consumption for extended periods does not exceed 4,000 lb. per hour.

The consensus of opinion is that the stoker will give about 10 per cent increased tonnage capacity, as compared with hand-firing, under the same conditions as to grade and time. Some believe that the tonnage increase will be more than 10 per cent. It should not be expected that stoker-firing will show any advantage in this respect where the job is within the capacity of a competent fireman. Stoker engines will make better time than hand-fired engines and while doing so will haul more tonnage than can be hauled with engines that are hand-fired.

It has not been the intention in the design of the Crawford stoker to use any cheaper grade of fuel than is used on similar engines that are hand-fired, nor does the Crawford stoker require the use of prepared coal. Both the Hanna Locomotive Stoker Company and the Locomotive Stoker Company state that their stoker will handle cheaper grades of fuel than can be successfully hand-fired, and that their stokers will enable locomotives to use some grades of coal that would be impossible with hand-firing. The Erie's experience does not indicate that a cheaper grade of fuel should be used.

The consensus of opinion seems to be that stoker-firing will not show a saving in the gross amount of fuel used, although there is a slight diversity of opinion on this subject. It is believed that there will be a saving on the basis of the amount of coal burned per thousand ton miles. This is due to the fact that additional tonnage is handled by stoker-fired engines with about the same gross amount of coal as with hand-fired engines. A marked saving is also made by the use of less expensive fuel.

While the stoker is a factor in increasing locomotive efficiency—that is, while it increases locomotive tonnage capacity to such an extent as to overbalance considerations as to first cost and maintenance costs—it is not a device for saving fuel. The real economy of the stoker is in the increased tonnage that can be handled. This is the meat of the whole stoker proposi. If increased capacity of locomotives is desired, then stokers are economical. If economical evaporation is what is required on large engines, its attainment may result in a sacrifice of maximum tonnage capacity.

Black smoke can be made with both hand and stoker-firing, or it can be eliminated by careful stoker or hand-firing. Average stoker-firing will probably show less black smoke than average hand-firing, because the coal is delivered to the fire in smaller quantities at a time.

There is less liability of engine failures with stoker-fired engines, owing to the fact that the stoker practically eliminates the necessity of opening the fire-door. Thus a more even temperature is maintained in the firebox, with less liability of leaky flues. In addition to this, if the engine should have leaky flues and bad grates or a bad fire, steam pressure can often be maintained with a stoker, when under hand-firing it would be impossible to keep up steam. Records to date indicate that firebox troubles are less on stoker-fired engines than on hand-fired engines.

The most important phase of the stoker proposition is that the engineer does not have to figure on the stoker tiring out, and is willing to work his engine to its full capacity under all conditions; whereas, under certain conditions with hand-firing, it would not be expected that the fireman could stand up against the largest engines when they were worked to full capacity. It is for this reason that increased tonnage can be handled with a stoker-fired engine, closer meets can be figured on and made, and better general results obtained.

The first cost of stoker installation, giving approximate figures only, is somewhere between $1,500 and $1,700. Maintenance costs, including interest on the original investment, are anywhere from ½ cent to 1 cent per mile. Maintenance cost figures at the present time, however, are not particularly reliable on account of the fact that more or less experimental work is being done with these stokers. It is generally stated that stoker maintenance costs do not nullify the saving in fuel cost possible where the stoker uses a cheaper grade of fuel. The only figures that have been presented on the cost of lubricating the stoker show the cost to be about $1 per 1,000 locomotive miles.

There is no added probability of engine failures which are not stoker failures on stoker-fired engines; and the reverse seems to be the case, on account of reduced liability of boiler failures. The consensus of opinion seems to be that a stoker failure should not imply even a partial engine failure, although the instructions on some roads are that in case of a complete stoker failure, tonnage will be reduced to hand-firing rating. One road reports that a stoker failure means a complete engine failure on account of the fact that such a low grade of fuel is used on

stoker-fired engines that hand-firing cannot be successfully performed with this fuel.

A skilled fireman must be employed on stoker engines, owing to the fact that it is occasionally necessary to resort to hand-firing for short distances, and to the fact that in the case of a partial, or complete stoker failure, hand-firing is necessary. The stoker makes the fireman's job a better one. He makes more money, on account of being able to follow his engine more closely, and a large percentage of the manual labor necessary with hand-firing is eliminated. Any good fireman can easily learn to operate a stoker. A fire which is properly prepared for hand-firing is all right for stoker-firing.

There should be no reason for a failure of the stoker equipment holding an engine beyond the ordinary time required for turning. In fact there are no repair jobs on a stoker that would necessitate delay, providing a proper stock of repair parts is kept on hand and the work handled promptly.

The Pennsylvania record with the Crawford stoker, covering a total of 204,922 trips, including all of the experimental trips during the time the stoker was being developed, shows an efficiency of 83.8 per cent. It can be readily understood that present efficiency is considerably higher than this figure. A six months' record of the use of stokers on the Norfolk & Western shows 97½ per cent efficiency, which makes the statement that the stoker is over 90 per cent efficient at the present time seem conservative. Roads having a considerable number of stokers in service show a performance of over 50,000 miles per engine failure on stoker-fired locomotives.

It seems conservative to state that the stoker will show a very satisfactory fuel economy based on ton-mile performance. That is, while it may not show a reduction in the gross amount of coal consumed per trip, it will show that it can haul more tonnage than a hand-fired engine using about the same gross quantity of the same or a cheaper grade of fuel.

From the coal producers' standpoint, the increased demand for slack coal and screenings for stoker-fired engines will no doubt be of benefit.

The stoker permits general operating efficiencies that would be otherwise impossible. Trainloads can be increased by the application of stokers to locomotives where the cost of grade reduction would be prohibitive or where bridge weights or terminal facilities, or both, might prohibit the introduction of heavier and larger power. On districts where train movement is so frequent as to approach the limit of single or double track capacity the increased speed of trains hauled by stoker-fired locomotives, together with the increased tonnage of such trains, will assist in relieving the congested conditions.

The stoker entirely obviates any question of the necessity for two firemen on large engines.

The stoker lives up to its worth, maintaining maximum steam pressure uniformly when the engine is worked at 100 per cent cut-off or at shorter cut-offs and higher speeds. To sum it all up, the stoker, even in its present state of development, pays and pays well in every case where a real stoker job is indicated.

The development of the stoker makes the design of larger locomotives possible and practicable. In fact, locomotives have been purchased within the last two years and are being built today which would neither have been purchased nor built had it been necessary to have them hand-fired. This refers particularly to the very large Santa Fe type Mallet and Triplex engines.

In closing this report the committee begs leave to call the attention of this association to the fact that the stoker has arrived. It is a success, and, furthermore, it is an absolute necessity from an economical operating standpoint for a great number of the large engines of the present day.

The report is signed by: D. C. Buell (U. P.); W. C. Hayes (Erie); A. N. Willsie (C. B. & Q.); T. R. Cook (Penn.); R. Emerson (S. L. & S. F.); O. L. Lindrew (Ill. Cent.); L. R. Pyle (M. St. P. & S. S. M.); Edw. C. Schmidt (Uni. of Ill.), and C. A. Spaulding (C. & N. W.).

DISCUSSION

It was the general opinion that fuel economy should be considered secondary to the operating advantages the mechanical stoker presents; that is to say, its ability to increase the boiler capacity and thereby permit greater tonnage to be handled at higher speeds warrants a sacrifice in the economical use of fuel. However, tests comparing the stoker with hand firing have in some instances shown an increase of evaporation.

E. A. Averill, of the Standard Stoker Company, called attention to comparative tests made on the Pennsylvania division of the New York Central. Four stoker fired and five hand fired tests were made under as near similar conditions as possible with the same engine, crew, tonnage, etc. However, a poorer grade of fuel was used on the stoker fired engines, this fuel averaging 13,711 B. t. u., as against 14,494 B. t. u. for the hand fired engines. Mr. Averill said: "These tests indicate clearly the following: First, the locomotive when stoker fired evaporated 7.4 per cent more water per unit of heat supplied; second, 18.6 per cent more coal of 5.4 per cent lower heat value was burned per square foot of grate area per hour by the stoker, resulting in the generation of 18.8 per cent more steam; third, while the power in the cylinder was increased 20.2 per cent, if gaged by the amount of steam consumed the amount of dry coal used for the stoker increased but 15.9 per cent and was a 5.4 per cent lower heat value."

Additional tests were made with an increase in tonnage for the stoker, which showed: "First, the locomotive when stoker fired pulled 12.1 per cent greater tonnage at 10.4 per cent greater speed with an increase of but 12.2 per cent in dry coal, which was of 5.3 per cent lower heat value; second, when stoker fired the boiler evaporated 11 per cent more water per unit of heat supplied; third, the power, as judged by the amount of steam consumed by the cylinders per hour, increased 35.5 per cent, while the dry coal per hour increased but 24.2 per cent and was of 5.3 per cent lower in heat value on the stoker fired run; fourth, the cost of coal per million heat units in available steam was decreased 8.5 per cent by the stoker."

A. N. Willsie, Chicago, Burlington & Quincy, stated that from road tests made with stoker and hand-fired Mikado engines of the same class it had been found that 435 tons more could be handled with the stoker than with the hand-fired engine and that 31 minutes were saved on a 156-mile division. The cost of fuel for 10,000 ton miles for the hand-fired locomotive was 45 cents, while that for the stoker fired was 41 cents. On the 2-10-2 type engine, stoker fired, it was found that 1,483 more tons could be handled than with the hand-fired Mikado, at a cost of 34 cents per 10,000 ton miles. F. Kirby, of the Baltimore & Ohio, stated that by use of the stokers the fuel consumption per 10,000 gross ton miles had been reduced 3 lb. and that the tonnage had been increased from 5,450 tons to 6,000 tons.

W. S. Bartholomew, president of the Locomotive Stoker Company, sketched the development of the stoker briefly and stated that this device did not generally find a market until the engines got so large that it was necessary to mechanically fire them in order to obtain their full boiler capacity. The problem for the stoker manufacturers now is to work out a development of the stoker that will provide for the economical use of fuel. Most any kind of coal can be used and from the mechanical standpoint the stoker is a success. Regarding the use of pulverized fuel he believed that there was a distinct field for that as well as the stoker, as the stoker eliminated the necessity of pulverizing the fuel, which must be done at more or less expense, and that many of the advantages to be derived from the use of pulverized fuel will also be obtained in stoker-fired engines. He also strongly favored the use of the brick arch on locomotives with automatic stokers.

FUEL OIL FOR LOCOMOTIVE USE

By G. M. Bean

Pacific Coast Representative, American Arch Company, Los Angeles, Cal.

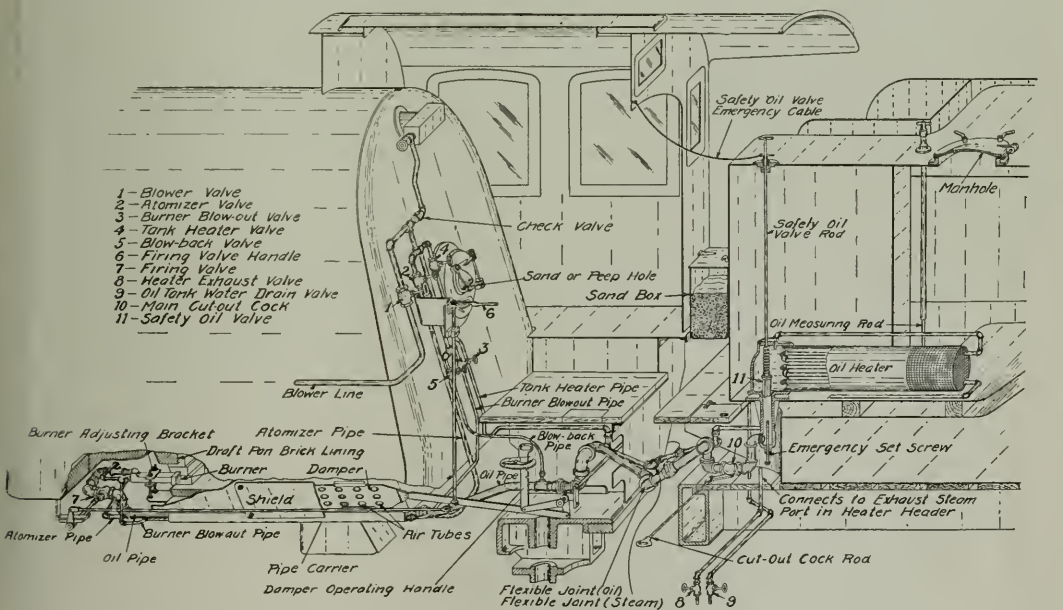
From 1907 to 1914 the use of fuel oil by railroads increased 112 per cent when a total of 31,000 miles, distributed over 50 railways, were operated with this fuel. A study of the use of fuel oil in the locomotive furnace is extremely interesting, because it offers problems that are not met with in other fuels.

With liquid fuel the diffusion must be simultaneous with ignition, with the resultant long flame, and a large furnace volume is essential. While the relative dimensions are of minor import to the volume, it is evident that a flame passage of sufficient length must be provided to prevent unconsumed particles passing to the flues. While it is generally conceded that lack of oxygen is responsible for smoke, the writer believes that restricted furnace volume and the attending lack of time for the proper mixture of the gases in the more highly heated portion of the furnace is the most common cause for black smoke from an oil-burning locomotive. Special attention is directed to this point in connection with locomotive oil-burner furnace design

The proper maintenance of brick work is essential to good results, and the possibility of the brick work falling down in the path of the flame must be avoided, as it usually results in an engine failure.

The oil supply is carried in tanks built to fill the coal space of the tender, and piped from there through suitable connections to the burner. It is generally necessary to provide means for heating the oil so as to insure a proper flow, as gravity is depended on for the necessary pressure. It is probable that the box heater is the most desirable arrangement. It is indirect in its action, only heating a sufficient volume to insure a supply at the burner, and is not liable to cause trouble by allowing water to get into the oil storage.

The illustration shows in detail the general arrangement of oil burner equipment which represents the latest standard practice as applied to locomotives of the Atchison, Topeka & Santa Fe, and is probably as complete and efficient as any so far devised. The indirect heater, together with the large direct oil supply line from oil tank to burner, insures ability to handle the heaviest of oils. The special attention of those interested in the subject of efficiency of oil burner handling and equipment, is



Standard Oil Burner Arrangement; Atchison, Topeka & Santa Fe

because of the general tendency to restrict the furnace volume by carrying the draft pan and brick work too high in the firebox covering up valuable heating surface and bringing about the continual necessity for forcing the fire at the expense of the remaining exposed surfaces.

At the first inception of the idea of using oil in this country the burner was placed under the rear of the firebox and directed forward with an upward incline so that the flame shot under a low, short brick arch, with the result that combustion became so intense in this limited space as to cause the flame to pass from under the arch with such velocity as to impinge on the door sheet, side sheets, and crown sheet, with very detrimental results. The burner is now placed in the front end of the draft pan and directed toward the rear in such a manner that the draft is forced to reverse the direction of the flame before it passes to the flues. The furnace is open, the brick work kept low and the maximum of heating surface is exposed.

called to the necessity for careful supervision of all locomotive equipment and care not to abuse the privilege of having oil burner power to handle your trains by overloading at the ultimate expense of fireboxes and flues. Emphasis should be placed on the fact that the oil fireman is a large factor in the success of the operation of oil burning locomotives. He must intelligently follow every movement of the engineer that demands regulation of the fire.

DISCUSSION

Several members spoke in favor of the use of the brick arch for oil-burning locomotives, as with this device the flame is more equally distributed throughout the firebox and the boiler maintenance is reduced. There is a tendency on account of the ease of operation of the oil-burning engines to neglect their maintenance. This should be carefully watched, as it will not only give a poor performance in oil consumption, but cost more for repairs than if the engines were

properly maintained between the general shoppings. H. T. Bentley, of the Chicago & North Western, stated that the cost of repairs to their oil-burning engines was not more than that to the coal burners. When the oil burners get in bad condition it has been found possible to get more life out of the boiler and out of the engine between shoppings by changing them over to coal burners. The success of the oil burner depends on the fireman and he should be properly educated and supervised.

STORAGE OF COAL

In order that the question might be thoroughly covered and local conditions taken into consideration, the mining districts of the country have been grouped in various sub-divisions, and sub-committees of representatives of railroads and coal operators were appointed for each group.

It has become apparent to all parties interested that there are approximately 50 per cent more coal mining operations in this country than are needed to produce the amount of coal consumed. This surplus of mines represents an investment of approximately $450,000,000. If 25 per cent of this had been invested in storage facilities instead of mines the needs of the country could have been fully and promptly supplied, and the bituminous coal industry of today would be on a solid basis financially instead of the jeopardized state, which, we are told by the operators, actually exists, due to ruinous competition and high cost of production brought about by short running time.

In order to meet the spasmodic strong demands for coal in the fall and winter (further intensified by the biennial mine suspensions) the railroads have been gradually creating a large surplus of coal cars. The average surplus for the period of May 15 to July 15, 1914, was 95,564 cars. This represents an investment of approximately $105,120,400. Fifty per cent of this amount judiciously expended in storage facilities would have accomplished as much in taking care of the coal traffic of the country, and the life of such storage facilities would have been double the life of the cars, with a very much less maintenance cost.

The reports of the sub-committees follow:

EASTERN GROUP

Ohio, Pennsylvania and West Virginia.—If coal is to move from storage near the mines by water, it should be stored during the fall and winter months and moved during the spring and summer. If coal is to be moved by rail, it is the consensus of opinion that it should be stored near the mines during late fall when traffic is heavy and winter when transportation costs are high, and moved to point of consumption during the spring and summer months. The consensus of opinion in regard to the coals named in the region under consideration, which may be screened without excessive breakage, seems to be that the coal best adapted for storage is the ¾ in. to 1¼ in. lump. In the case of very friable coals such a separation of sizes is not practicable, for which reason they should be stored as run-of-mine and the storage piles so made as to minimize the danger attendant upon storing the coal of mixed sizes.

While in the district in question attempts have been made to store coal, there was found to be considerable variation in figures representing cost of storage. It is felt, however, under conditions which are reasonably favorable, the cost of storage should not exceed 35 cents a ton, and under quite favorable conditions, the cost should be less.

This report included reports from the storage of various coals. The report is signed by: W. H. Averill, B. & O., chairman, sub-committee.

SOUTHEASTERN COAST GROUP

The consensus of opinion of both railroad executives and of at least one coal operator in the district, is that it is both desirable and feasible to store coal. From the railroad's standpoint, it is agreed that lump coal of a firm quality, in order to resist powdering, is the best. The Central of Georgia has been very successful in storing slack with a large per cent of nut. From the operators' viewpoint, run-of-mine should be stored, as it leaves nothing on their hands.

All the roads in this district have storage centers and store coal regularly each summer. One coal operator has a storage plant in North Carolina with a capacity of 150,000 tons. The cost of operating this storage plant for two different periods is shown below:

Unloading Cost, June 24 to October 4, 1912:

		No. of tons	Cost per ton
Pay roll	$2,148.74		.0172
Repairs to plant, supplies, etc.	373.14		.0029
Fuel for crane	594.50		.0047
Total	$3,116.38	125,696	.0248
Depreciation at 10 per cent per annum on $71,000 for 6 months	$3,550.00		.0282
Interest at 5 per cent for 6 months	1,775.00		.0141
Total	$5,325.00		.0671
	$8,441.38		

Reloading Cost, October 8 to January 31, 1913:

		No. of tons	Cost per ton
Pay roll	$1,797.62		.0138
Repairs to plant, supplies, etc.	727.44		.0056
Fuel for crane	646.70		.0050
Total	$3,171.76	129,778	.0244
Depreciation at 10 per cent per annum on $71,000 for 6 months	3,550.00		.0274
Interest at 5 per cent per annum on $71,000 for 6 months	1,775.00		.0137
Total	$5,325.00		.0655
	$8,496.76		

Total average cost for dumping and reloading, 13.26 cents per ton.

Unloading Cost, From May 1 to August 31, 1914, Inclusive, 2,703 Cars:

		No. of tons	Cost in cents per ton
Pay rolls	$1,653.74	131,949	.0125
Repairs to plant, supplies, etc.	576.72		.0044
Fuel for crane, estimated at 2½ tons per day	600.00		.0045
Total	$2,830.46		.0214
Depreciation at 10 per cent per annum on $71,000 for 6 months	$3,550.00		.0269
Interest at 5 per cent per annum on $71,000 for 6 months	1,775.00		.0135
Total	$8,155.46	131,949	.0618

One road in this district has a Dodge plant which consists of a 20 ft. by 40 ft. pit, 15 ft. deep, into which the coal is dumped from hopper bottom cars. Encircling this pit is a track for a traveling crane which takes the coal from the pit and stores it in a circular pile around the pit. The same crane is used for coaling engines by placing the coal in an overhead bin from which it is loaded on tenders. This device is both successful and economical.

The report is signed by: A. P. Wells (C. of G.), chairman, sub-committee.

SOUTHWESTERN GROUP

It is the consensus of opinion of executives of railroad and mining companies that Mr. Hall's reasons for, and the desirability and advantages of, storing coal (which were reported at the 1914 convention) are correct. It is generally agreed that lump and nut coal with at least 25 per cent of slack removed is the best kind to store, that is, with the coals which will store without great danger of spontaneous combustion.

All who have tried to store Texas and part of the Arkansas coal have found that it is a failure on account of the liability to spontaneous combustion. All other coals in the second territory—Oklahoma, Kansas, Missouri, and Northern Arkansas—can be stored and the loss in heating value and weight will be from 2 per cent to 8 per cent.

The greatest danger from spontaneous combustion is caused when the coal is stored in the open during the hottest months of the year—July and August. If the coals in this territory were stored in May, June, September, and part of October, the

danger of firing would be greatly reduced, and practically all conditions make this possible. It is the opinion of practically all men in this territory that it is better to store coal at the railroads' larger coaling stations, as the facilities at these coaling stations are sufficient to handle larger amounts of storage coal. Usually there are enough laborers employed around coaling stations who could be used in storing coal part of the time in addition to their other duties.

The cost of handling storage coal varies greatly. The best figures obtainable are as follows:

Tons coal handled, 84,378.

		Average per ton
Cost to unload	$3,576.59	$0.0424
Cost to reload	2,320.15	.0275
Miscellaneous and tracks	2,663.22	.0315
Total cost	$8,559.96	$0.1014

Another system reports that the total cost to unload by—

Clam shell	5 cents per ton
By hand	7½ cents per ton
Reload—Clam shell	5 cents per ton
Reload—By hand	7½ cents per ton

Total average unloading and reloading, including supplies and walls, where necessary, by—

Clam shell	10 cents per ton
By hand	15 cents per ton

Other figures vary from 15 cents to 30 cents per ton for total cost of handling storage coal.

Some roads have mixed fresh coal with coal that has been in storage for several months and have had good results, while some other roads have used a little crude oil with storage coal by throwing several bucketfuls over the coal when it is put on the tender, both methods producing results practically as good as obtained from coal just from the mines.

Some say that their observations have been that the loss in heating value of storage coal (Arkansas and Louisiana) is usually less than 5 per cent. One company's analysis showed a loss in B. t. u. of about 25 per cent on account of so much spontaneous combustion and slacking. This is an exceptional case, but it is likely to be the rule with Texas and some of the Arkansas coal.

The report is signed by: J. B. Hutchinson (Sun. Cent.), chairman, sub-committee.

NORTH CENTRAL GROUP

Indiana, Illinois and Iowa.—The territory supplied by the mines of Illinois, Indiana and Iowa is gradually developing industrial plants which require ever-increasing quantities of screenings for their power plants. The increased production of lump coal in the winter months creates a surplus of screenings, which are sold as low as 10 cents a ton at the mines during the period of demand for domestic coals. In the summer months when the lump coal production has reached its minimum, the same screenings command a price of $1 at the mines. To equalize these two extremes would be a well-nigh ideal condition.

There is no question but that the storage of coal is feasible, when conditions make it desirable. Coal should be stored at ultimate destination during months April to August to be of greatest advantage to producer and carrier. In support of this statement data has been procured showing the relative consumption of the railroads procuring their supply from this district for periods April to July and October to January respectively, and reports from 24 roads (using conservatively 95 per cent of the railroad fuel coal supplied from this district) show:

April-July	8,118,400 tons
October January	15,075,650 tons
Increase in fall and winter months	6,957,250 tons or 85.7 per cent

Lump and egg coal should be stored at destination by railroads, industrial plants and domestic users during months April to August. Screenings should be stored at mines by coal operators during period September to January.

The only storage undertaken by railroads has been previous to strikes or suspension of work at mines. Figures submitted by one railroad covering coal stored in fall and winter 1913-14 and recovered in spring 1914 show:

	Tons	Total cost labor and supplies	Average cost per ton
Unloaded	54,227	$6,507.24	.12
Reloaded	53,763	3,006.36	.055
Loss	464	$9,513.60	.176

Note.—Locomotive crane and grab buckets were used for handling both ways. The higher cost of unloading is due to charging the cost of temporary tracks to unloading expense.

Following are figures submitted by another railroad covering coal stored in year 1910:

Location of pile How stored	C Semi-permanent trestle, drop bottom cars, clam shell used to widen pile	B Drop bottom cars and track jacked up
Tons unloaded	132,314	31,576
Cost of Unloading—Total		
Labor Charges	$19,922.09	$3,946.45
Switching, etc.	2,082.50	673.71
Total	$22,004.59	$4,620.16
Tons reloaded	107,096	31,576
Cost of Reloading—Total	$ 8,818.21	$2,516.95
Cost of Unloading—Per Ton		
Labor charges	$ .150	$ .125
Switching, etc.	.016	.021
Total	$ .166	$ .146
Cost of Reloading—per ton	.082	.080
Cost of Unloading and Reloading	$ .248	$ .226

In storing pile C, tracks were placed at each side of the main pile and a clam shell operating on these tracks took the coal from the main pile after it had been dumped from the cars and transferred it to an auxiliary pile parallel to the main pile and thus leaving the clam shell operating on tracks between the main and auxiliary piles. It is evident that this additional handling ran up the cost considerably, and if interest and depreciation on investment of trestle were included in the table it would seemingly prove to be an uneconomical method.

Pile *B* is just the ordinary storage pile where drop bottom cars are used and track jacked up on the coal.

The following information was furnished by one railroad showing laboratory tests of samples taken in October, 1911, from a storage pile containing 5,651 tons, the most of which was stored in the fall of 1907, the remainder in the previous year. The average results of these analyses are shown in the table in comparison with those of samples taken at the mine in July and August, 1909, and during August, 1911.

	Proximate analysis					B. t. u. determinations and sulphur:	
	Loss of moisture on air drying Per cent	Moisture Per cent	Volatile matter Per cent	Fixed carbon Per cent	Ash Per cent	Sulphur Per cent	B.t.u.
Average of surface samples.	5.9	9.93	34.14	34.75	21.18	4.60	8,953
Average of samples taken 18 in. below surface	6.0	10.93	36.18	34.06	18.83	4.08	9,390
Average of samples taken 4 to 8 ft. below surface	4.3	9.37	40.78	35.10	14.75	4.82	10,296
Average of 6 days' samples of engine lump, July and August, 1909		8.08	37.66	37.01	17.25	....	10,298
Average of 5 days' samples of engine lump, August, 1911		10.15	38.95	35.13	15.77	5.10	10,705

This was Wyoming lump coal prepared over shaker screens and finally over a revolving wire screen having openings which average 17/64 in. square. Therefore this is what would be termed "Lump Coal," though of course it is a very low grade of lump. In the preparation of this lump they make approximately 10 per cent slack. No precautions were taken in storing this coal and it was stored by dumping the cars and then jacking up the track and again dumping the cars. After the pile was completed the track was taken up and the pile was not even peaked on top as it should have been. There was therefore a flat space about 15 ft. wide, and the depth of this pile was about 18 or 20 ft.

The report is signed by Carl Scholz (Rock Island Coal Mining Company), chairman, sub-committee.

NORTHWESTERN TERRITORY GROUP

In Canada, due to the long and severe winters, the open car will never become popular; it is a box car country. Relative to this probability is the reduced usefulness of the locomotive crane and clam shell for purposes of loading and reloading. Again, the same cause puts the ban upon the "submerging method" of storing for this country. These considerations limit and localize the problem for us.

Coal should rest on a dry base, moisture from below being conducive to spontaneous combustion. Provide as much ventilation as possible and distribute the weight of the coal as much as possible. Combustion nearly always takes place within 90 days after storing. The storage plants should be wherever coaling stations are. Extra capacity or storage should have been an accompaniment of every coal-chute built. Even if not financially able at the time, space should be allotted for them, until such time as they could afford to build them. This eliminates the second handling, its enormous expense and blockade of traffic, reducing to a minimum the use of all equipment for our supplies

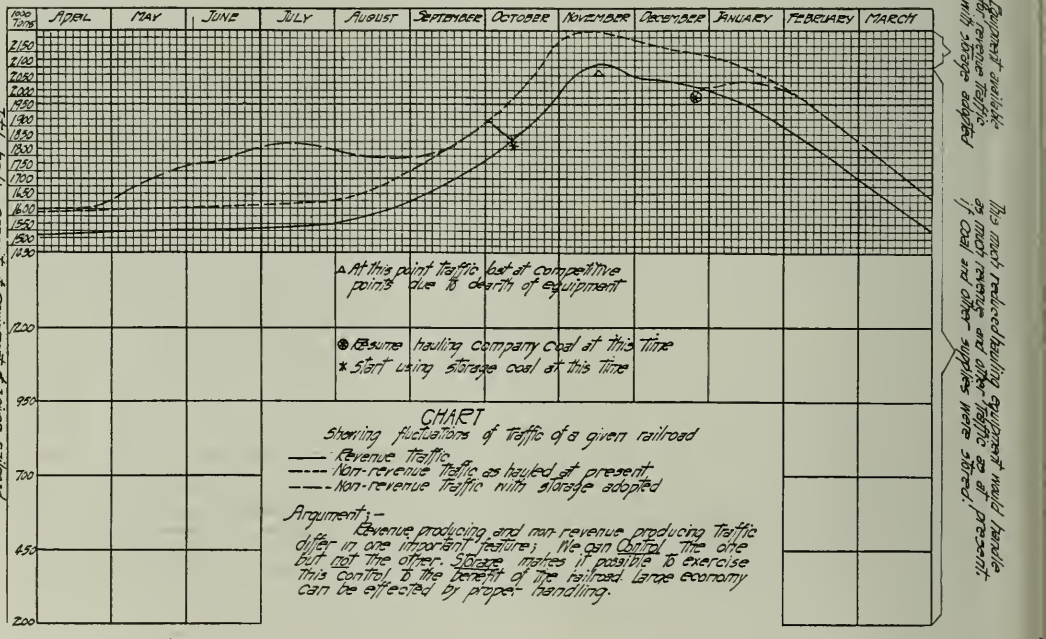
Mr. Hall's paper, that railroads incur higher expenditure in winter, in some cases as high as 31 per cent, implying the fact that the least possible of supplies should be hauled at this season also.

Again a great saving could be effected by eliminating the unnecessary delay to cars under the present system. A considerable number of cars are always held under coal. The storage plants would accommodate this surplus coal, with the result, that very many less cars would be engaged to do the same work. Once more, coal should be stored to protect long stretches of road not served with coal mines, at times of accidents, when supply would be cut off by wrecks, washouts, snow drifts, destruction of bridges or land slides.

The report is signed by: A. H. Davies (G. T. P.), chairman, sub-committee.

DISCUSSION

The storage of coal will not only assist the coal operators, which the railroads should be very willing to do, but also is of advantage to those roads which find it necessary to haul the coal long distances, or find it difficult to procure coal



and thereby provides the maximum of "right of way," in the shape of clear tracks and haulage equipment for revenue producing traffic.

To the railroads the practice of storing offers great benefits, well organized as they are. It opens up possibilities of economy and better organization that are surprising, in face of the apathy, almost antagonism, with which the idea of storing supplies has been received by the people concerned. Assuming for illustration that 15 per cent of our total hauling capacity is being utilized to haul our own supplies, at our busiest season, it is then evident that by hauling and storing at other times we could do without 15 per cent of our present equipment, and still haul the same amount of traffic.

With a view of demonstrating this phase further, through the courtesy of our secretary, the accompanying chart was obtained, that shows those different considerations at a glance. Lines denoting both kinds of traffic are in true proportion. A line is also drawn suggesting how supplies with a system of storage in vogue should be hauled, not forgetting the fact mentioned in

exactly when they want it. By the storage of coal at the proper time the coal carrying equipment will not only be released for carrying revenue coal at the rush periods, but also there will be much less equipment necessary to handle the business. From the fuel department standpoint the storage of coal is desirable, as it protects against strikes at the mines, train wrecks, interruption of traffic, etc. Where possible, the storage piles should be adjacent to the coal chutes in order to prevent rehandling, although in some cases it may be found practicable to store at some central point. Care should be taken to examine the coal piles periodically to prevent spontaneous combustion.

In the storage of coal a concrete floor will be found desirable, and care should be taken that there are no pockets in this floor for the accumulation of moisture. The height of the storage piles will vary according to the characteristics of the coal and the storage ground upon which it is placed. Many instances were mentioned where coal had been stored for 2 to 10 years with no trouble from spontaneous com-

bustion, while new coal would take fire quite readily. When coal is to be stored it should be carefully prepared at the time and not contain an unnecessary amount of impurities.

FRONT ENDS, GRATES AND ASH PANS

The committee on this subject sent out letters of inquiry to various railroads requesting information concerning the front end, grate and ash pan arrangements.

Front Ends.—The drafting of locomotives has always been considered a function of the front end alone, but speaking broadly, this is not correct. Drafting may be defined as the controlling factor in the combustion of the fuel, and rightly starts at the air openings in the ash pan. With these fixed the grate next governs, and then the firebox volume, tube area and length, the brick arch, etc. If these parts are properly adjusted it is not believed that any very delicate adjustment will be needed in the smokebox. There is nothing mysterious about the action of the exhaust jet to induce draft, and if all other factors receive their just due, it is not believed that we would have engines of the same class varying ½ in. in the diameters of their nozzles, with their draphragms clear down or clear up, etc.

Grates.—From a study of the information received regarding the grates it is found that the percentage of air openings of 62 bituminous grates varies between a minimum of 25.8 per cent in one design of interlocking finger grate to a maximum of 49.6 in a design of the herring-bone type, the average of all cases giving a percentage of 37.2 per cent. The degree of coarseness of the grates has been expressed in terms of the maximum dimensions of any air openings. This figure will vary between the limits of ½ in. and 1½ in. The 1 in. dimension of air opening is found to be that most generally used. The nature of the coal and the degree of tendency to form a clinkery ash will naturally govern the design in reference to the width of grate bars or length of the fingers.

Anthracite Grates.—The percentage of air opening for the anthracite grates varies between 32 per cent and 46.9 per cent, the average being 39.4 per cent. The coarseness of the grate in these cases, as represented by a maximum air opening, is ⅜ in. and ½ in.

Ash Pans.—From the information received on ash pans it is evident that there is a very great difference of opinion. The highest percentage of air opening in comparison to grate area for bituminous coal is 15.1 per cent, while the least is 5.78 per cent. With the tube area taken as a basis of comparison the maximum is 127.1 per cent and the minimum 50.8 per cent. The average ash pan air opening for all bituminous burning engines is 11.08 per cent as compared to the grate area and 82.1 per cent as compared to the tube opening. Previous investigations have shown that the air openings should total not less than 14 per cent of the grate area for best all around results. It would seem that the ash pan air opening should be not less than 110 per cent, instead of 75 per cent of the flue openings.

The ash pan volume should be made as large as possible; with modern power it can hardly be made too large. Delays en route might often be obviated if the necessity for dumping the pans could be obviated. On very large power with trailing wheels the use of the six hopper style of pans will often very materially increase the capacity over what might otherwise be obtained. A proper guard against the throwing of fire from the ash pan air openings must be provided. The report is signed by M. C. M. Hatch (D. L. & W.), chairman.

Discussion.—A. G. Kinyon, of the Seaboard Air Line, spoke strongly in favor of the table grate, as it provides a much greater air opening and will better distribute the air through the fire. Some success has been obtained by the use of the double-exhaust, the Delaware, Lackawanna & Western having made it standard on all anthracite burning locomotives and is now trying it out on the bituminous coal engines. The variable nozzle has been tried with but little success.

OTHER BUSINESS

The committees on Fuel Tests and Fuel Accounting submitted reports of progress. Arrangements have been made with the University of Illinois to conduct tests on various classes of fuel, as soon as the necessary contributions can be obtained for conducting the work. The committee on Fuel Accounting reported that it is to seek to reduce the number of forms in order to eliminate the clerical expense of this work. A paper on the Waste of Fuel in Railway Stationary Plants and Locomotives by Jos. W. Hays, of G. L. Simonds & Company, Chicago, was presented by F. A. Moreland, who also showed, by lantern slides, the common defects found in stationary boiler plants. From the statements by the author of the paper and others during the discussion it is apparent that the railways do not give the stationary plants the attention they deserve. Large sums of money can be lost if the plants are not maintained in proper condition.

The following officers were elected for the ensuing year: President, D. C. Buell, Union Pacific; vice-presidents, John G. Crawford, Chicago, Burlington & Quincy; E. W. Pratt, Chicago & North Western; W. H. Averill, Baltimore & Ohio; executive committee, W. C. Hayes, Erie Railroad; H. T. Brown, Illinois Central; M. C. M. Hatch, Delaware, Lackawanna & Western; A. G. Kinyon, Seaboard Air Line, and T. J. Lowe, Canadian Northern. Chicago was chosen as the next place of meeting.

The secretary-treasurer reported a total membership of 680 and a cash balance of $826.62; 316 members registered during the convention.

PROPOSED REVISION OF ACCIDENT RECORDS

William J. Meyers, statistician of the Interstate Commerce Commission, has sent out a series of new blanks for reporting accidents monthly to the commission, together with a further revision of the code of rules governing the preparation of the reports, modifying the proposals submitted by him last January and reported in the *Railway Age Gazette* of January 22, page 164. Since January, conferences have been held with railroad officers, and in particular with the committee of the American Railway Association, Messrs. Julius Kruttschnitt, W. W. Atterbury and W. G. Besler. The number of forms of blanks to be used for the different features is reduced from seven to four, and the principal blank, Form T, conforms pretty nearly to the suggestions made by the Kruttschnitt committee.

The proposed requirement for individual reports of non-train accidents—hitherto called industrial accidents—has been withdrawn, and the commission will require for these only a summary statement, as at present. The requirement of detailed reports of accidents to locomotives is retained, as is the blank calling for reports of the death of persons who have been previously reported as suffering non-fatal injury. A special blank has been added on which to report failures of rails whenever such a failure results in a train accident. The rule requiring reports of injuries to employees which disable them for less than three days is withdrawn. The comparison of accidents with train mileage is not to be asked for, but the blanks retain the forms for comparing the number of injuries to employees in non-train accidents with the number of hours worked by the men of those classes to which the injured men belong, five classes in all, the ratio to be shown for each class separately.

Those injuries, fatal and non-fatal, to persons on or around trains, where there is no train accident, which now are included in class C, are to be called "train-service accidents," and reported according to regulations much like those now in force, but in a great deal more detail. The date when the new regulations are to go into effect is left blank. It is desired that criticisms be received in Washington by June 1.

WOMEN RAILWAY EMPLOYEES IN ENGLAND

The employment of women on railway work in Great Britain is extending apace. The underlying idea is that by getting women to fill the places of men, more and more recruits may enter the army and maintain the requisite supply of soldiers. Even in time of peace the number of female railway employees in Great Britain amounted in the aggregate

Women Ticket Collectors at Paddington, Great Western Railway

to a fairly large figure, although it was mainly in the clerical, accounting and refreshment departments that scope was found for their services. A certain number of women were also employed on Scottish railways as car cleaners before the war. On the European continent the employment of women

Woman Ticket Collector on the London, Brighton & South Coast Railway

on railways has always been much more common than in Great Britain, women frequently acting as booking-clerks at stations and as gate keepers at grade crossings, while female station masters were by no means unknown.

The extension of the employment of women on British railways began with taking over an increasing number of women as clerks and for cleaning purposes.

The London & North Western introduced women clerks at Willesden Junction, about the end of March. At about the same time the Great Central tried the experiment of employing women as platform porters at Marylebone, its London terminal station. These women were selected from the car cleaners whom the company had already been employing with success. Their work is confined to platform duties. Obviously, women could not be expected to perform the more hazardous duties associated with a porter's occupation, such as switching, coupling and uncoupling cars and the like. Women ticket collectors were first introduced on the Great Western. One of the illustrations shows them at work at Paddington station. It will be noticed that the women collectors wear no distinctive uniform beyond a badge on the arm. The London, Brighton & South Coast, on the other hand, is putting its women ticket collectors into smart uniforms, one of which is illustrated herewith. Early in May female ticket collectors began their duties at Euston station

Restaurant Car Waitress, Great Western Railway

on the London & North Western, and that company is also engaging girls in the offices of the locomotive works at Crewe.

Owing to the large number of their employees who have joined the army, the three principal Scottish railway companies (Caledonian, Glasgow & South Western and North British) have also had under consideration the question of increasing the female staffs in their employment. They are already employing a number of women car cleaners. The proposed increase will affect mainly the various clerical departments, but it will also apply to booking clerks, parcel clerks, ticket collectors and telegraph operators.

Turks Building New Railways.—It is reported that the Turks are actively pushing forward the construction of a railway between Zonguldak and Ismidt, an important line, as Ismidt is not far from Skutari, with which it is connected by rail.

How the Operation of One Terminal Was Improved

Continued Serious Congestion Overcome By Change in Organization, Better Methods and Improved Discipline

By G. D. Brooke

Division Superintendent, Baltimore & Ohio, Chillicothe, Ohio

The enormous growth of our cities during the past half century has out-stripped the development of railway facilities within their ever widening limits. Property adjacent to the tracks has been in great demand for industrial sites, and has so increased in value as to render its use for railway purposes generally impracticable under present financial conditions. Moreover, even when suitable property is available, terminal improvements are extremely expensive and it is a difficult matter to justify their cost as an investment. Therefore, for the immediate future at least, the increased demands on terminal facilities will have to be met by more efficient operation of the existing plant.

Fifty years ago a railway extended its line to a certain middle-west city and established a terminal in the center of its commercial district. This terminal consisted of a small yard, a freight house and team tracks and an engine house and machine shop. These facilities, with a passenger station reached by a spur from the main line, were ample for the business then offered and apparently would be for a long time. With the advent of the railway, however, the city began a new industrial development, and the yard and narrow right of way forming the approach to it were walled in by warehouses, factories and industrial plants. To accommodate its facilities to the increasing business, the railway secured a site for another and somewhat larger yard on the outskirts of the city, where the topographic conditions were favorable. This in turn was surrounded by the expanding industrial district and a third yard further out and equal in capacity to the other two, was built on suitable ground and reached by a three-mile spur.

The absorption of another road and the construction of a connecting belt line established a through route, and, incidentally, added two other yards on the opposite side of the city. Five other railways have entered the city, and it is now one of the important gateways. The interchange, both of through business and of local cars for delivery within the switching district, is very heavy.

Meanwhile the industrial development has continued. Along the main tracks, industries have been established and provided with side tracks, many of which are inadequate for the requirements of the plants they serve. On the belt line a blast furnace and two steel mills have been established, also several fertilizer factories, brick yards and a number of smaller industries. In the early days a track was laid along an important street of the wholesale section for a distance of two miles, and a freight house and teaming yard established to serve an important district. A number of spurs lead off this track into warehouses and factories. There are altogether four freight houses and seven teaming yards in the city besides a fruit and produce shed and a team yard recently constructed to develop the wholesale fruit and produce traffic.

Twenty years ago the passenger terminal was rebuilt to accommodate the business of the home road, and to take in that of three foreign lines. It has been crowded for a number of years, and being of the stub-end type, the approach is badly congested during certain periods of the day.

Early in the last decade the main lines were double-tracked and equipped with automatic signals, and the junctions of the branch lines and of several foreign roads interlocked. Three crossings of foreign lines, however, near the throats of yards are operated by crossing watchmen with two-position crossing signals. A number of street crossings at grade have been eliminated, but a great many remain which are protected by watchmen and gates, and speed restrictions are numerous. The heavy increase in business which required these improvements made necessary also the remodeling and enlarging of two of the yards, one on either side of the city, where engine terminals were provided and which constitute the road terminals of the two adjoining divisions.

This terminal presents the most intense problem in operation of the entire system of 5,000 miles. Here is found the combination of a dense road movement, heavy classification work and industrial switching in congested districts. The only successful solution of such a problem is organization.

During the latter part of 1912 the terminal became congested; the heavy business taxed the facilities and the movement of through traffic became very slow; road trains were held out of the yards; there was a serious accumulation of bad order cars; delays to passenger trains and scheduled freights were frequent, and shippers complained bitterly of delays to cars and of poor switching service. These conditions were aggravated by similar congestion in the terminals of other roads entering the city. The situation was serious and the need of a strong directing head was apparent. The position of superintendent of terminals was created and filled by a man from the terminals of a foreign road in a distant city.

The new superintendent of terminals was an organizer. Prior to his appointment the terminal was operated by two general yardmasters reporting to the trainmaster of the division having jurisdiction over the terminal. Two weeks were spent in studying the facilities and the organization, and in becoming familiar with the movements to connections, the requirements of through business, and in a general way of the industries. Then was begun a series of changes in methods—and in a few instances, in men—which finally evolved the form of organization shown on the following page.

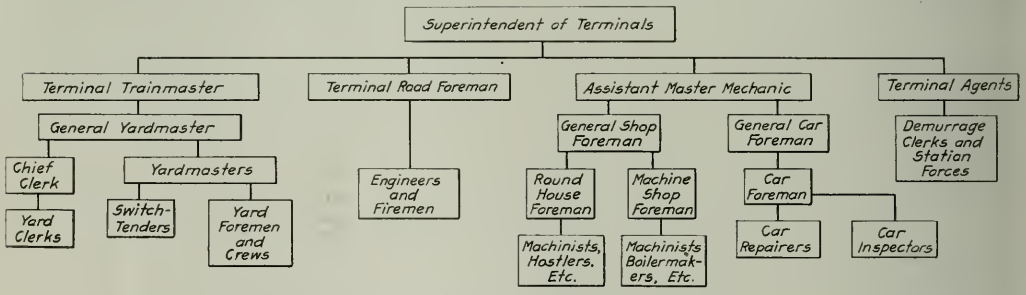
When any stranger enters an organization in a prominent capacity he is met with an instinctive undercurrent of mild antagonism. The organization braces itself to try the mettle of the newcomer. His every move is scrutinized to determine if the "old man" knows the game, and what his policy will be towards the older members of the organization. The new superintendent of terminals realized this, and knowing the value of "esprit de corps," called a staff meeting of the yardmasters, engine and car foremen, agents and clerks. His observation had convinced him that the personnel of the organization was generally good, and that the quickest results could be obtained from the material at hand. He therefore opened the meeting with a statement of reassurance, expressing confidence in the loyalty of each member of the staff and in their ability to contribute towards producing those results which were so obviously desirable. He then outlined his plan of campaign and explained briefly the reasons for each successive step to be undertaken. He emphasized the absolute necessity of each member of the staff supporting this plan in every detail, although he might hold an honest difference of opinion as to the method best suited to the case. In this way all latent prejudice and possible opposition were eliminated and a proper mental attitude towards the work in hand inculcated. Similar meetings were held frequently thereafter and were conducted so as

to elicit free discussion of each subject considered, to reach definite conclusions when there were differences of opinion, and to decide on a plan of action in every case. These plans were later issued in the form of written instructions to all interested parties to avoid all possibility of misunderstandings as to details. Besides accomplishing the immediate purpose in view, these meetings proved of great educational value, particularly to the less experienced yardmasters and clerks, and were very effective in promoting a feeling of joint responsibility and co-operation between the various departments or branches of the service.

The method of procedure consisted in selecting in succession the features of operation in the order of their importance; in studying each one thoroughly and broadly, having in mind its bearing on all the other problems; in determining on a definite course of action and putting it into effect, and in specializing on it until it became self-effective, or, as it were, automatic. Thereafter it required only periodic checking and such variations as might be required to meet changing conditions.

The first active undertaking was to reduce the number of cars in the working yards in the terminal. A comprehensive check indicated that in order to switch economically, a reduction of 40 per cent in the number of cars in the yard was necessary. Authority was obtained to destroy 200 bad order cars of old type and light capacity; a like number of empties were sent to the heavy repair shop at the terminal upon. Some duplicate checking was eliminated by assigning the checking of working yard tracks, interchange tracks and certain industrial tracks in the immediate vicinity of the yards to the yard clerks and the freight house and team tracks and usually the industrial tracks to freight clerks reporting to the several agents. These checks were completed by 7:30 a. m., and each yard and district reported to the car distributer by telephone. By the use of a special form the report for the entire terminal was quickly compiled and contained comprehensive information as to the location and character of movable loads, and the number and class of empty cars available for loading or movement. This report showed the situation in the terminal at a glance, and made it practicable to take steps to relieve promptly any tendencies towards local congestion, and to anticipate the needs of road power for the ensuing 24 hours. It also enabled the car distributer to dispose of the available empty equipment to the best advantage.

The movements between the several yards in the terminals, to foreign line interchange tracks and to certain of the outlying industrial districts required the use of a number of engines in drag or transfer service. These engines were being operated without any definite schedules or predetermined plan. Whenever a cut of cars was ready to move from any yard, the yard master would assign the first transfer engine available to handle it to its destination; if any cars were ready to be returned to the yard from which the engine started it would



Form of Yard Organization at One Important Terminal

of another division; it was arranged to increase the switching at the yards at the ends of the engine districts on each side of the terminal, and to make up the trains so that through business would not be delayed in the terminal yards, back haul would be avoided on business for connections and local delivery, and cars for each district of the terminal moved promptly from the yard where received; and by a campaign with the shippers an accumulation of unconsigned loads was gradually reduced and more prompt loading and unloading secured. Some additional road power was placed in service on the adjacent divisions, and it was arranged to store empty box cars held to protect loading in some unused sidings outside the terminal. These measures produced the anticipated results, and in three weeks the number of cars was materially reduced.

The next step was to establish a central car record office. The car record clerks from the offices of the general yard masters were transferred to the office of the superintendent of terminals and placed under the car distributer. Conductors' wheel reports of trains into and out of the terminals and the switch lists of yard foremen doing transfer, industrial, team track and freight house work reached this office promptly. This enabled the index work to be kept up to date and made an accurate location of all cars entering, leaving or moving within the terminal available at all times within reasonable limits. A daily report of the movable cars within the terminal from actual check of all tracks was determined take them; frequently it returned light and later there would be a light movement in the opposite direction. A meeting of the terminal superintendents of the several lines was called for the purpose of fixing definite hours for receiving and delivering cars at interchange tracks. This being accomplished, a schedule was worked out for the movements of each engine in transfer service, due regard being had for passenger and other scheduled trains. The several yards were required to have the cuts made up for the engines at stated hours and the transfer engines moved promptly on schedule. In working out the schedule it became apparent that more engines were in this service than were necessary, and in a short time three crews were taken off.

This scheduling of the movement of transfer engines brought the organization to a stage where it was practicable to cope successfully with the most important problem of starting passenger and scheduled freight trains on time, and running them on time within the limits of the terminal. The usual staff meeting was held to launch this campaign, the station master and his assistants, as well as representatives of the express companies and the superintendents of terminals of the foreign lines using the passenger station, being in attendance. The importance of starting scheduled trains on time and running them on time was dwelt upon at length, and the value to other movements of accomplishing this duly emphasized. It was pointed out that the conditions were very bad, and that success could be achieved only by

long and continuous effort. Above all things the train must start on time. Then proper respect for passenger trains must be installed into signalmen, switch-tenders, yardmen and men in freight service. Delays from various sources were to be expected, but one by one they would be eliminated and the men educated to the required standard. It was found advisable to appoint a yardmaster in charge of the coachyard and train shed, reporting to the station master and having full authority over all movements of passenger equipment into the station. The handling of express transferred from connections on close time was a serious difficulty, but was finally overcome by increasing the force and quickening the work. A yard foreman had to be dismissed before the practice of yard engines occupying main tracks and stopping passenger trains was broken up. In six weeks a decided improvement could be observed, and after six months of persistent endeavor the trains were moving with marked regularity, and the beneficial effect on the entire terminal was obvious.

The scheduling of the transfer engines and the efforts to run scheduled trains on time developed a weakness in the method of handling train movements within the terminal. Movements of yard engines and extra freights were handled principally by the signalmen and switch-tenders by telephone communication with adjacent offices and the yards. This resulted in frequent interference of movements; often with heavy delays. To systematize the handling of trains a three-trick dispatcher's office was inaugurated at the terminal headquarters. A telephone dispatching circuit was provided with connections at all interchange and heavy industrial points; telephone connection with all the yard and freight offices was also available by commercial service with a private exchange. This central control of all movements proved of great value. Yard engines could be given advantage of delays to passenger trains in making main track movements and still be kept out of the way of these trains; yardmasters could locate quickly any transfer or industrial switch engine with which they desired to communicate; all working at cross-purposes and misunderstandings were avoided and the movements made to the best advantage, having in view the general situation instead of the local one as formerly.

The switching of freight houses and team tracks was done by engines from the yards to which they were most conveniently located, and the general method was good. Definite work had been assigned to each engine to be done on an approximate schedule. The cars for placing were switched in order in one cut by the crews in the working yard; these were moved to the freight house and team yard by the engine assigned to that work and spotted after the outbound cars had been moved. The switching of merchandise and quick-dispatch cars required particular attention.

At a certain freight house the receipt of freight stopped at 5 p. m.; at 5:45 p. m. the cars were sealed and the night engine was standing on the lead ready to move the cars for points beyond the adjoining divisions. These cars were taken rapidly to the working yard and switched into eight classifications, five for the east and three for the west. In the meantime another engine had pulled the team tracks and was soon on the scene with the quick-dispatch loads, which it classified in turn while the first engine returned to the freight house to resume work there, taking with it a cut of cars from industries which had been collected by a day engine. It assisted in completing the classification and in switching the cars into one cut, with which it proceeded in turn to the east and west road terminal yards where the quick-dispatch trains were being made up for movement at 10 p. m.

The reverse of this procedure occurred the following morning, when the Q. D. run from New York arrived in two sections between 5:30 and 6 a. m., in order to have all the cars placed and ready for delivery when the freight house opened.

Success in handling the industrial switching was attained by determining just what service each plant was properly entitled to, and then planning the work of the engines so that this service could be performed with regularity. The smaller industries having a siding capacity of only a few cars presented no difficulties; a switch about the same hour each day was the rule, but it was thoroughly understood that no car should remain in the terminal longer than 36 hours before being placed.

The switching service at some of the larger industries had been the source of much adverse criticism and annoyance for months. The method in such cases was to make a call by appointment, on the manager of the plant and discuss fully the requirements of the industry and the practicability of giving the service desired. In a few instances it was readily shown that the siding capacity was inadequate and steps were taken to remedy this. A frank and thorough discussion of all questions involved always resulted finally in an understanding being reached as to the service to be performed, and in a short time a spirit of co-operation on the part of shippers was apparent. The character of the service having been determined upon in any given case, the work was assigned to a certain engine and followed for a few days by a yardmaster to insure the start being made right. Afterwards the work was checked periodically by observation and by inquiry of the manager of the plant, who was encouraged to report any poor service to the superintendents of terminals, and not to the traffic or general operating officers, as had been done formerly. By this means practically all complaints were remedied or adjusted locally, with much less delay and far greater satisfaction to all interested.

The proper movement and use of cars so as to provide empties for all loading offered required systematic and persistent checking. The agents were impressed with the importance of interesting shippers to load and unload cars promptly, and to place orders only for their actual needs. They were required to keep all demurrage records in such good shape that bills could be substantiated beyond question. Empty cars on industrial tracks not required for immediate use were moved out daily and used at other industries or stored in the working yard. The unloading of material for company use was systematized; a central storage site was selected adjoining a large heavy car repair yard, and a force was organized to unload the material there. The cars were placed regularly by the engine switching the repair yard, and the empties moved as soon as unloaded. The same force was used for transferring loads from bad-order cars for that section of the terminal, and a platform was built to facilitate this work.

While these changes in methods were gradually being evolved, the organization was being built up and strengthened. It was realized from the first that discipline was lax and the entire force disorganized. In going through the terminal, cars were found that had been broken up and others that had been shoved off the ends of stub tracks and not re-railed. Side collisions were not infrequent in the yards, and several accidents causing serious damage had been passed without investigations. These were the unmistakable indications that the men in the ranks did not have the proper respect for authority, and were not obeying the rules, and it was evident that this was applicable to the road crews running into the terminal as well as to the yard men. An undercurrent of dissatisfaction which occasionally amounted to antagonism was apparent, and was traceable to the policy of tardiness and unconcern in the settlement of minor grievances and the tendency to narrowness in considering doubtful wage cases.

A terminal train master was appointed for the distinct pur-

pose of promptly investigating all accidents and infractions of the rules. A man experienced in the administration of discipline was selected, and after he had become somewhat familiar with the physical conditions, he was assigned principally to office duty so as to be ready at all times during office hours to conduct investigations, employ new men and instruct and examine men on the rules. In case of accident he was also ready to proceed at once to the site and make a first-hand investigation on the ground. Notes taken in such instances often proved invaluable in fixing the responsibility ultimately.

In all investigations, and in fact in all dealings with the men, a quiet, dispassionate attitude was assumed, it being the intent to establish the impression that perfect fairness would be shown, and that the development of the real facts in every case was the object sought. At the same time absolute firmness was maintained in requiring obedience to rules and instructions. The system of discipline by record was in effect and it was the purpose to establish the feeling that every infraction of the rules, and every breach of discipline, would result in an entry in the record of the responsible employee. Yardmasters and other officers were encouraged to strengthen their own positions as much as possible by eliminating personal feeling and all display of temper in dealing with the men and by the personal assumption of authority for all instructions; they were afforded thorough support, but cautioned against hasty action which might necessarily mean the reversal of their decision upon appeal to higher authority. All grievances were disposed of promptly and a policy of liberality in disposing of doubtful wage claims adopted; on the other hand it was to be clearly understood that the men were well paid, and that first class service was expected. With the view of reducing accidents, the system of efficiency tests was prosecuted vigorously, and employees failing to comply with the rules in such tests were disciplined promptly. The tests were made as practicable as possible, and it was the aim to have them educational in character, the intended lesson being emphasized when the employee was interviewed in case of failure.

By the discussions at the staff meetings, and by missionary work in the form of conversations with some of the better class of men whenever the opportunity was auspicious, the mental attitude of the entire organization was gradually changed from one of carelessness and indifference to the company's interests to one of co-operation and of personal responsibility on the part of each individual for the success of the organization. The attainment of this "esprit de corps" was probably the most important asset developed in the new organization.

The changes in the methods and the improved discipline were productive of very gratifying results, the most important of which was that the traffic was moved with promptness and regularity. Scarcely less noticeable was the marked increase in efficiency of the switching crews and of the entire working force, which enabled a reduction of 25 per cent in the number of switch engines to be effected, and at the same time eliminated the working driving meal hours by the switching crews, except in the case of two crews which were assigned to switch important passenger trains during meal hours. As the organization became more effective this efficiency was stimulated by the promotion of friendly rivalry between the several yards, by commending crews and individuals for extraordinarily good work, and by establishing high standards and imbuing all with the idea that it was confidently felt that the standards would be maintained.

It was realized that the condition of the yard power had an important bearing on the efficiency of the work, and that there was opportunity for a large saving in the cost of fuel by the application of correct methods of firing and running engines. An assistant master mechanic was appointed to give closer supervision to the repairs to yard engines and a terminal road foreman to supervise the proper care of the locomotives when in service, and the use of fuel and engine supplies. The results obtained soon demonstrated the wisdom of providing this additional supervision and these officers proved of great value during a campaign on the part of the city authorities to abate the smoke nuisance.

The number of cars damaged in switching gradually diminished as the discipline improved, and the cost of repairing tracks damaged by derailed engines and cars showed a similar improvement. This relieved the car repair and track forces to a considerable extent and allowed them to apply their time to legitimate maintenance work. The efficiency of these forces was increased by persistent educational methods similar to those applied to the other terminal forces but adapted to their particular requirements. Car inspection was tightened, bad order cars repaired more promptly and the condition of the air brake equipment of trains leaving the terminal showed much improvement. Track conditions were likewise bettered, scrap of all kinds picked up promptly, material properly cared for and stored in orderly fashion, and yards and their surroundings kept free from accumulations of dirt and rubbish. Neatness seemed to be the order of the day and added materially to the air of businesslike activity which pervaded the entire terminal.

RAILROAD LEGISLATION IN MICHIGAN

The legislature of Michigan, recently adjourned, adopted nine laws affecting railroads. Two of these, house bills 466 and 467 amending the long and short haul law and the section of the railroad commission act relating to interchange of cars at terminals make no material changes, having been adopted to improve the phraseology of the statutes.

Senate bill 70 creates a board of mediation, conciliation and arbitration to deal with differences between employers and employees. So far as railroads are concerned they are allowed the option of taking advantage of the law or not as they may deem best.

Senate bill 234 provides for the inspection of boilers and creation of a board of three with authority to formulate rules for construction and use of steam boilers. Enforcement of the act is vested in the different municipalities. Any ruling of the board requiring changes in construction or in character of material used shall not apply until six months after approval by the governor and attorney general.

Senate bill 241 requires that when a railroad company enters a suit (to restrain the Railroad Commission from enforcing orders, etc.) it must be before the court of Ingham county.

Senate bill 328 provides that in the laying out of new highways the railroad commission shall have power to regulate crossings with railways, with the view of preventing dangerous crossings.

Senate bill 376 amends section 41 of the general railroad law so as to give the railroad commission authority to order connecting tracks laid between one railroad and another wherever practicable. Hitherto the law has required such connections only where the lines of two companies touched each other.

House bill 125 regulates the care and disposition of diseased hogs, and provides for the transportation of such animals to points where they may be disposed of. Under the general laws the railroads, when offered such shipments for transportation, can reject them as unfit freight.

House bill 150 puts on railroad companies the cost of paving streets crossing the railroad, including all necessary improvements and the furnishing of sewers. This, we understand, applies only to new streets.

New Zealand Railway Advertising.—The New Zealand Railway Department has decided that in future it will itself handle the business of advertising on railway stations instead of calling for tenders and letting contracts for that purpose.

Railway Storekeepers' Association Convention

Last Day's Proceedings of Annual Meeting Included Papers on Marking Couplers and Handling Signal Material

A report of the first two days' proceedings of the twelfth annual convention of the Railway Storekeepers' Association, which was held at Hotel Sherman, Chicago, May 17-20, was published in the *Railway Age Gazette*, May 21, 1915, page 1039.

The committee on the Uniform Grading and Inspection of Lumber, of which J. H. Waterman, C. B. & Q., is chairman, presented a brief report outlining the action taken during the year. The chairman stated that very little could be reported owing to a series of disappointments. Various conferences with lumber manufacturers' associations which it was hoped would lead to a better understanding between the railroads and the manufacturers as to specifications, etc., did not take place. These conferences were cancelled or postponed through no fault of the committee.

In a brief address, in which he referred particularly to the paper by W. H. Clifton on Substitutes for Expensive Lumber, A. E. Manchester, superintendent of motive power of the Chicago, Milwaukee & St. Paul, told of cars in service for 35 years on his road equipped with siding and roofing of high grade white pine, the wood still being in perfect condition. He also mentioned a building which has recently been wrecked, the lumber costing at the time the building was erected, 50 years ago, nine dollars per thousand feet. After the building was wrecked this lumber was sold for $27 per thousand feet.

J. H. Waterman, superintendent of timber preservation, Chicago, Burlington & Quincy, condemned the practice of accepting rejected lumber for any use whatever.

G. G. Yeomans told of at one time accepting rejected lumber on the Burlington at lower prices until 50 per cent. of the contents of the yard was culls. Several purchasing agents stated that there was no trouble in getting good lumber if the poor quality lumber is refused and the shipper compelled to pay the freight both ways. About 15 of the railways represented at the convention refuse to accept rejected lumber at any price. A member told of receiving a number of draft timbers, some of which were 10 ft. 3 in. long and some 12 ft. long. The shorter timbers were all satisfactory while about 50 per cent of the 12 ft. timbers were culls, the ends being in such a condition that the timbers had to be cut down to 10 ft. 3 in. The result of this practice was that the storekeeper was overstocked with 10 ft. 3 in. draft timbers while there was a shortage in 12 ft. timbers.

MARKING OF COUPLERS AND PARTS

The committee communicated with all the leading coupler manufacturers of the country and, while their suggestions were of some value, the members came to the conclusion, after tabulating various makes and styles of couplers and repair parts which are manufactured at the present time, that it would be better to number all parts, rather than to number a coupler and use a prefixed letter or letters to designate the parts. The committee therefore recommended the assigning of a series of numbers to each make of coupler and parts; the appointment of a standing committee to take care of assigning additional numbers as required; the publication of a booklet listing the various parts with the assigned numbers; and insistence, on the part of purchasing agents, on having manufacturers show, in raised figures wherever possible, the number applying to any particular part on the body of such part.

The committee submitted a list of such couplers and parts as it has been able to gather and has assigned numbers which it feels will give the desired results.

The report is signed by A. J. Kroha (chairman), C. M. & St. P., and L. H. Tutwiler, B. & O.

Discussion: The chairman of the committee stated that the manufacturers believe that all the information there is room for is now placed on couplers and parts, but he also stated his belief that if the association insists that the recommended numbers be placed on the couplers and parts, the manufacturers will agree to it. The report was adopted and referred to the American Railway Association for its action.

STANDARDIZATION OF TINWARE

W. F. Jones, New York Central, the chairman of the committee on the Standardization of Tinware, stated that the committee had no printed report but that the previous recommendations were still in the hands of a committee of the Master Mechanics' Association and the report was expected at the June convention in Atlantic City. The members of the association were referred to the issues of the *Daily Railway Age Gazette*, published at the Master Mechanics' and Master Car Builders' Association conventions at Atlantic City, for information as to the action of the Master Mechanics' Association.

BOOK OF STANDARD RULES

The report of the committee on the book of standard rules consisted of an index for the book of rules which was adopted at the 1914 convention.

HANDLING SIGNAL MATERIAL

C. R. Ahrens, storekeeper, Delaware, Lackawanna & Western, Hoboken, N. J., presented a paper on the above subject, of which the following is an abstract:

All railroads do not handle signals and repair parts through their stores department. It happens to be the case on the Lackawanna and I believe the practice has been completely successful, both in keeping signal stock down to a minimum and in getting material to the place wanted at the right time, not only for repairs, but on new installations as well. This requires the greatest care and vigilance on the part of the storekeeper in charge of signal material; first, in order to meet the views of the management of the road; second, in regard to the needs of the signal department, in not delaying its work by failing to have material on the ground when wanted.

The storekeeper in charge of signal material should work in accord with the signal engineer or his assistants, not only in regard to any work being done but in changes in types of signals and repair parts.

To keep down the stock to the lowest possible quantity, and yet have material when wanted is no easy task, for where the signal stock is concentrated at one store, the storekeeper cannot borrow or transfer. To keep from getting accumulations of inactive or obsolete material is just as important as it is to have material when wanted, for we must not keep the signals out of operation on account of not having material for repairs. On railroads having large mileage where the signal material is handled by the stores department it is necessary to carry signal material at more than one store unless they have good facilities for quick shipment anywhere on the line where a derailment or breakdown may occur.

Where a freight transfer is located near the storehouse, it may be possible to reduce labor expense in the storehouse and facilitate shipments by having the different division foremen and supervisors have their requisitions for maintenance material forwarded at a certain date, and arrange for material ordered on the purchasing agent's requisitions to arrive about the same date.

In handling the smaller repair parts, bins are used similar to those in any storehouse, while such items as front rods, throw rods, lock rods, etc., I have found are handled more quickly by placing them on a raised floor or platform while

detector bars, ladders, etc., can be placed in the same rack with signal pipe, poles, etc. Foundation legs, piers, etc., are piled on the storehouse platform where they can be conveniently loaded and unloaded.

When a practical man cannot be secured for receiving clerk it will be found helpful on items of signal material, either for stock or direct shipment, to number each item ordered and request the signal companies furnishing them to show on their shipping notices the parts which apply on each item ordered; for instance, if a cylinder complete for a switch movement is shipped to us in three parts each part on the shipping notice is marked "Item 16" or whatever number the cylinder was numbered on our requisition.

We have a signal machine shop in the same building as our storehouse and all relays, mechanisms and such items returned to us for credit or repairs are turned over to this shop and, after they are looked over and repaired, we take them back and allow credit for the value, provided the signal department advises that the repaired material can be used in place of new. All classes of signal scrap are shipped to the division storehouse on each division, except worn out battery elements, for which we have a special place prepared.

Each requisition received from the signal department is numbered. When the material ordered has been shipped we make a shipping notice covering the shipment, sending a copy to the general storekeeper, a copy to the signal engineer and a copy to the supervisor in charge of the division ordering the material. The last named in turn sends the notice with a detachable stub to the maintainer or repairman and, if the material has been received in good condition, the stub is returned to us with the signature of the man who ordered the material. At the end of the month a statement is made up, showing all notices covering signal material, and this is furnished to the signal engineer.

R. D. Long, C. B. & Q., also presented a paper on this subject, in which he stated that the signal supply storekeeper should be a practical signal man. An untrained man in this position can waste much material while a trained man can save much, particularly by reworking and using second hand material. The plan of handling signal material on the Burlington was outlined. A change in signals on this road made obsolete a considerable amount of material such as relays, etc. These were changed so that they could be made use of, and a considerable saving resulted. This could not have been accomplished without a signal man being in charge of the stores for this branch of the work.

ELECTION OF OFFICERS

The nominating committee presented a report recommending that J. G. Stuart, general storekeeper, Chicago, Burlington & Quincy, Chicago, be elected president; W. A. Summerhays, general storekeeper, Illinois Central, Chicago, first vice president; H. S. Burr, general storekeeper of the Erie Railroad at New York, second vice-president, and J. P. Murphy, general storekeeper, New York Central, Collinwood, Ohio, secretary-treasurer. The recommendations of the committee were unanimously adopted by the convention.

Railway Construction in Bolivia.—The government of Bolivia has announced its intention of beginning at once the construction of a railway from Tupiza in southern Bolivia to La Quiaca in the northern part of Argentina. La Quiaca is near the Bolivia-Argentina boundary and is the northern terminus of one of the great Argentine lines. Tupiza is on the Bolivian railway system and is connected with the Pacific coast by three lines touching the coast in southern Peru and northern Chile. The connection of these two lines, now proposed, will mean another trans-continental railway for South America. The Bolivian railway system consists chiefly of a north and south trunk line through the great elevated region in the vicinity of Lake Titicaca which line is connected with the Pacific coast by three distinct lines running respectively to Antofagasta and Arica, Chile, and Mollendo, Peru.

JULIUS KRUTTSCHNITT URGES CHANGES IN MEDIATION AND ARBITRATION LAW

Amendment to the Newlands mediation, arbitration and conciliation act to make the law apply to all railway employees, co-ordination of the Board of Mediation and Conciliation with the Interstate Commerce Commission and compulsory investigation and mediation of labor controversies, are urged in a letter written by Julius Kruttschnitt, chairman of the executive committee of the Southern Pacific, to Frank P. Walsh, chairman of the United States Commission on Industrial Relations. The letter was written for the purpose of amplifying some of the views Mr. Kruttschnitt expressed when testifying before the commission at Chicago on April 10, in reply to questions as to what could be done to settle labor disputes and maintain industrial peace. Mr. Kruttschnitt says in part:

"The act of Congress, approved June 15, 1913, known as the Newlands act, providing for mediation, arbitration and conciliation in controversies between certain employers and employees, is a great improvement on the Erdman act, which it superseded, but it relates to employees engaged in train service or train operation only, of common carriers engaged in interstate commerce. Its usefulness would be greatly increased if it were made to apply to all railway employees engaged in the interstate business of the employer, including those engaged in keeping in repair cars, locomotives, appliances, machinery, track, roadbed, and other instrumentalities of interstate commerce. The Board of Mediation and Conciliation, appointed by the President under the act, has proven useful in maintaining industrial peace; but as it frequently results, as a consequence of invoking the services of this board, that railway expenses are increased, it is very important to the carriers that the board should be closely co-ordinated with, or, better still, subordinated to the Interstate Commerce Commission so that the same authority responsible for increasing expenses of the carriers should at the same time incur a corresponding responsibility for providing revenue to meet the expenditures. The reasonableness of such a provision is apparent when the complete control of revenues, and almost equally complete control of expenditures by the government at the present time, is considered.

"The Newlands act provides that when a controversy arises either party may apply to the Board of Mediation and Conciliation for its adjustment, and the board may offer its services to the parties in controversy where interruption to public service is imminent. There is no obligation, however, other than a sense of obligation to the public, on either employer or employee to submit differences to mediation. Instances have occurred where mediation and arbitration have been stubbornly refused, with utter disregard of the public's interest and rights, and the act offers no remedy. This defect could apparently be remedied, as is done in the Canadian industrial disputes investigation act of 1907, which makes a combination, lockout, or strike illegal until the questions at issue shall have been thoroughly investigated and made public; and there should be a provision that where the board *offers* its services for investigation, mediation, and conciliation, it shall be obligatory on and not optional to the parties, to submit their differences so that the public may judge the dispute intelligently.

"The desirable feature in the Canadian act is that it compels investigation and publicity, and peace pending investigation; and paves the way, as the Newlands act does, to arbitration, which, however, is optional with the parties to the dispute The Canadian Department of Labor, in its bulletin of April, 1914, reviews the proceedings under the industrial disputes investigation act of 1907 for a period of seven years, during which it had been in effect. One hundred and sixty-two applications had been received, as a result of which 141 boards of conciliation and investigation were established. In 19 cases the matters in dispute were adjusted by mutual agreement while steps were

pending for the establishment of boards. Two applications were under consideration at the end of the year. There were altogether only 18 cases in seven years in which strikes were not either averted or ended through the instrumentality of the act. Out of this total, one occurred in the operation of railways, five in railway offices, shops and yards, and one in the operation of a street railway. In a report dated December 9, 1912, on "The Industrial Disputes Investigation Act of Canada, 1907," made by Sir George Askwith, chief industrial commissioner to the British Board of Trade, and presented to both houses of Parliament of Great Britain, the purposes of the act are defined as follows:

> The simple purpose of the act is to insure the recognition of the interests of the public as a third party in trade disputes, and the insistence that that third party, through the government, shall have a voice in regard to a dispute affecting their interests, and, according to the act, before a stoppage of work takes place. In practice, the recognition extends to cases arising before or after a stoppage of work. While this principle of the recognition of the public interest in trade disputes is emphasized in the act, the actual interference with the parties in the settlement of their differences is sought to be reduced to a minimum by the act being confined to industries whose uninterrupted continuance is of high importance to the well-being of the nation (mining, railways, shipping, and other public utilities); and to a brief suspension of the right to stop, as distinct from a complete prohibition of stoppage.

"Reports of the satisfactory operation of the Canadian act, and a conviction that like benefits would accrue through the adoption of some of its provisions in the United States, induced me to send an assistant to Canada in September, 1914, to learn at first hands from the managers of Canadian railways, and from the Canadian Department of labor, their experience with the operations of the act. The opinion alike of railway executives, and of the commissioner of labor, was that their disputes and investigation act was satisfactory and very successful in preventing lockouts and strikes. In discussing the results of our observations with the executive heads of some of our important railway systems the opinion was expressed, without exception, that the provisions of the Canadian act were most helpful in the interests of employers, employees, and the general public, the three parties to every industrial disturbance."

WAGON HAULS FOR FARM PRODUCTS

In a bulletin issued by the Department of Agriculture, Frank Andrews, chief of the division of crop records, describes the results of an inquiry just completed by the bureau of crop estimates, showing that the average distance from market of the farms of the United States is 6½ miles, while those farthest away from market, excluding the rarer instances, average 8.7 miles. The number of round trips per day averages for all farms 2.1, and for the more remote farms 1.6 trips. In other words, it requires about one-half day for the average farmer to make a round trip with a wagon from farm to market and back, and nearly two-thirds of a day for the farmers who are farthest from market. The average wagon load of cotton is three bales, or about 1,500 lb., while the average wagon load of wheat is 53.5 bu., or 3,200 lb., and of corn 40.5 bu. The estimated time spent in hauling from farms in an average year is given as 6,358,200 days for corn, 6,857,400 days for wheat, and 2,532,300 days for cotton.

The article states that while the figures for 1906 are not strictly comparable with those for 1915, it is evident that wagon hauls are shorter than they were nine years ago. In 1906 the average haul from farm to shipping points was, for wheat, 9.4 miles; for corn, 7.4 miles; cotton, 11.8 miles. Railroad building during the past nine years has brought some farms nearer to shipping points and markets and has helped to shorten the average distance hauled and to increase the average number of trips per day. It is also stated that the improvement of wagon roads during the past nine years has probably helped to increase the average quantity of farm products moved by a day's wagon haul.

A. R. A. REPORT ON FREIGHT EFFICIENCY

The report of the Committee on Relations Between Railroads, presented at the semi-annual meeting of the American Railway Association in New York City, May 19, was briefly noticed in our account of the meeting, printed in the issue of May 21, page 1088. The most important feature of this report is the series of resolutions (adopted by the association) which were prepared by the Committee on Packing, Marking and Handling of Freight. These are as follows:

(1) WHEREAS, For the fiscal year 1914 the railways of the United States and Canada have paid out over $36,000,000 for freight loss and damage, a larger amount than ever before; and

WHEREAS, No one department of the railways and no one association is competent to deal exclusively with the prevention of loss and damage and the reduction of these payments, but a combined effort is necessary by practically all railway associations, departments, officers and employees, be it

(*a*) *Resolved*, That, as the extension of interline or through waybilling of freight from point of origin to destination is desirable as an aid in economical and efficient railway transportation, lessens the time required for transporting freight, is helpful in the operation of junction agencies, reduces the number of overcharge claims, and facilitates the investigation of loss and damage as well as overcharge claims, the attention of the traffic associations and the traffic departments of the railways members of The American Railway Association be called to the apparent need for joint through rates and division sheets covering such rates for apportioning among carriers the revenue incident to through waybilling of freight; and be it

Further Resolved, That the utmost co-operation be recommended between the various traffic organizations, the railway traffic departments and the Association of American Railway Accounting Officers in obtaining as promptly as practicable the greatest possible extension of through or interline waybilling of freight.

(*b*) *Resolved*, That the auditing departments be requested to enforce proper rules for the prompt and accurate billing of freight in accordance with the standards of the Association of American Accounting Officers, with special reference to over and astray freight.

(*c*) *Resolved*, That the classification committees be requested to continue their work of adopting uniform and effective rules for the packing and marking of less than carload freight and for the loading of carload freight, and that they be further requested in the formulation of their loading rules to co-operate with the Master Car Builders' Association.

(*d*) *Resolved*, That the traffic associations be requested to eliminate so far as practicable all exceptions to classification rules for the packing, marking and loading of freight.

(*e*) *Resolved*, That the traffic departments be requested to co-operate in the elimination of these exceptions, and that they be further requested to give their hearty co-operation to the other associations and departments in the enforcement of these rules for the packing, marking and loading of freight.

(*f*) *Resolved*, That the operating departments be requested either directly or in co-operation with the inspection bureaus to inspect and enforce the administration of the packing, marking and loading rules in the classifications, the loading rules of the Master Car Builders' Association and the loading and L. C. L. rules of the American Railway Association, and that they be further requested to experiment with and suggest improvements in these rules and standards.

(*g*) *Resolved*, That the inspection bureaus be requested in co-operation with the traffic and operating departments, to inspect and enforce these rules and to suggest improvements therein.

(*h*) *Resolved*, That the Freight Claim Association be requested to so amend its rules that claims involving defective equipment be paid by the road on which the car is loaded, unless that road can clearly show that it has inspected and repaired the car in

accordance with the rules of the Master Car Builders' and American Railway Associations.

(*i*) *Resolved,* That the Master Car Builders' Association be requested to continue its efforts to secure proper inspection and maintenance of equipment and safe loading of freight, and it be requested to co-operate with the classification committees in the question of loading.

(*j*) *Resolved,* That the general managers' associations be requested to continue their co-operation in securing safe carriage of freight.

(*k*) *Resolved,* That the American Association of Freight Agents be requested to continue its efforts in the prevention of loss and damage and that it be asked to recommend to the American Railway Association such changes in the rules as it thinks desirable.

(*l*) *Resolved,* That the operating departments of the railways members of the American Railway Association be further requested to frame and enforce rules for the careful handling of freight during receipt, transfer and delivery by local and through freight trains and in yards, and for the prevention of robbery, and that they be recommended to keep their interested employees, including agents, freight and yard conductors and enginemen, advised as to the extent of loss and damage on their lines, and especially of loss and damage for which they are responsible.

WEIGHING AND PER DIEM

On the recommendation of the committee a resolution was adopted by the association to the effect that over and short reports at all common points be checked at least twice a month.

Three interpretations of the National code of weighing rules, covering L. C. L. freight weighed on track scales and certain phases of the reweighing of cars loaded and light, were presented by the committee and approved by the association. A resolution was also adopted providing that weight agreements at highly competitive points should be issued and checked by weighing and inspection bureaus or other joint agencies.

On the recommendation of the committee a resolution was adopted that when a subscriber to the per diem rules agreement delivers cars subject to the per diem rules to a non-subscriber it should collect not less than the per diem rate.

Per Diem Rule 1 was amended on the recommendation of the committee to read as follows:

1. The rate for the use of freight cars shall be 45 cents per car per day, which shall be paid for every calendar day, and shall be known as the per diem rate; except that where per diem is not reported to car owner within six months from the last day of the month in which it is earned, the rate shall be increased 5 cents per car per day.

An amended form of Per Diem Rule 14, offered by the committee, was ordered referred to letter ballot.

The committee recommended changes in Car Service Rules 3, 14 and 15, which were approved by the association. Rule 3 provides that empty cars may be short-routed, with the consent of the roads over which they are to move and subject to Rules 1, 3 and 4, at a reciprocal rate of 2½ cents per mile, plus bridge and terminal arbitraries, with a minimum of 100 miles for each road handling the car. The road requesting the movement must secure such consent and pay the charges.

Under Rule 14 no mileage will be paid for switching movements at terminals, nor for movement of empty cars for which charges are assessed under freight car tariffs. Rule 15, covering cases where freight is transferred because of a defect in a car that is not safe to run, according to M. C. B. rules, is changed so as not to include cases where the repairs can be made under load as per M. C. B. Rule 2.

An amendment proposed to Car Service Rule 5 was referred to letter ballot. A resolution was adopted requesting the Master Car Builders' Association to enforce its Interchange Rule 30 at all interchange points. The committee reported that the amended demurrage rules providing for an increased rate on refrigerator cars were put into effect generally in New England and Trunk Line territory on February 1, 1915, and in Central, Western and Southern territory on April 1, 1915.

The association approved amendments to Demurrage Rules 6 and 8, making more strict the regulations for collecting demurrage on shipments delayed because the shipper does not furnish billing promptly, and for collecting from consignee on goods so frozen in transit as to delay unloading.

Amendments have been made to Interpretations Nos. 902 and 903 of the Demurrage Rules, and new interpretations have been made of Nos. 364 and 365; and these have been agreed to by the National Industrial Traffic League. On the recommendation of the committee, an amended form of Constructive Placement Notice was adopted, to be put into use October 1, next.

THE REWEIGHING AND RESTENCILING OF CARS

By J. V. James

Chief Clerk, Special Department, Missouri, Kansas & Texas, Parsons, Kan.

One of the greatest leaks in the transportation of freight results from the incorrect weights stenciled on equipment. Recently in relight-weighing and restenciling 500 cars, over 85 per cent showed a decrease of from 200 to 500 lb. in tare weights. These cars were cleaned of all refuse and reweighed in clear weather. Fifteen per cent of the total number showed an increase in the tare weight from 200 to 300 lb. over the old weights, caused by the installation of United States standard appliances and new draft rigging. This discrepancy averaged about 250 lb.

As a rule heavy-repair cars are light-weighed and restenciled at repair points, but there are points where repairs are made where there are no track scales, consequently these cars will probably go several months before being reweighed. On the other hand, wooden and steel underframe cars will run from 8 to 14 months before being reweighed and the new weights will run from 200 to 500 lb. lighter than the old.

M. C. B. Rule No. 30 provides that all wooden cars and steel underframe cars shall be reweighed and restenciled every 12 months during the first two years they are in service, and thereafter every 24 months. All steel cars must be reweighed and restenciled at least once every 36 months. This rule is one of the most important in the M. C. B. code both for the shippers and the transportation companies and yields a good profit for doing the work. Weighing foreign box and other cars, except stock cars, nets an average of about 80 cents each and it saves that much on each system car. On account of the expense of cleaning stock cars, weighing will not net any revenue, but at points where this class of equipment is cleaned and disinfected the light-weighing and restenciling is just as profitable as with any other equipment.

The writer recently started a campaign on the matter of light-weighing and restenciling cars and was surprised to find such a large number of employees whose duties pertained to such work who were absolutely unaware of the fact that any revenue could be derived from such work. It had never occurred to them that in hauling a car weighing 500 to 1,000 lb. less than the stenciled weight, loaded with coal for a distance of 200 miles, at a rate of $1.50 per ton, the company was losing $0.75 to $1.50 and this is the lowest rate applied. After a tentative plan was outlined with all yardmasters, weighmasters, engine foremen and employees of the car department, cars of certain classes which could be held from 5 to 8 hours without unnecessarily delaying them were reweighed. This class of equipment consisted of mine empties coming in during the day that would not be run out until the early morning mine trains. All cars to be reweighed in accordance with M. C. B. rules, system and foreign, were carded by the car department to weigh. As this only requires a few seconds nothing was lost if the yard forces did not get time to switch them out for weighing, but the carding of all cars coming under the rule made it possible to use the yard engines for a valuable service at every possible opportunity. When a car to be weighed was found in making a switch it was placed on the scale track until there was an accumulation of

10 or 15 cars. They were then weighed light, the weighmaster taking the old and new weights and the car men immediately restenciling all cars.

All stock cars brought from the disinfecting plant well cleaned are weighed and restenciled, as it only requires about 30 seconds to weigh each car. Thus the time to weigh a cut of from 15 to 20 cars can be found some time during the day with any kind of business. The scales used are Fairbanks standard beam track scales, 42 ft. long, 100,000 lb. capacity, thus necessitating cutting all cars at one end and at both ends when possible. While it has been claimed that proper weights can be obtained by weighing cars coupled at both ends, our observations are that there is too much of a chance that proper care will not be exercised, and we require that all cars be uncoupled at one end at least when being light-weighed.

After getting all yard employees interested in the matter of reweighing foreign cars to earn a profit and system cars to save the cost of having other lines do it, and at the same time increasing our margin of profit by correct weights, our number of cars reweighed and restenciled per month has increased 300 per cent. A weekly bulletin is issued showing the number of foreign cars light-weighed and the amount earned on same and the number of system cars light-weighed and the amounts saved by doing the work on our own line, also the average discrepancy in weights in favor of the shipper, which, with the correct weights, will reflect a created profit for the company by light-weighing and restenciling. The forces in the different terminals vie with each other to make the best showing which, of course, is based on the number of cars handled at a terminal.

In one weekly review of the light-weighing of cars it was noticed that a foreign car was weighed which had not been light-weighed according to the stenciled weights, for six years. This car's stenciled weight was 36,300 lb., and the new weight was 34,200 lb., a difference of 2,100 lb. To satisfy curiosity the last move of this car under load was traced. It was found that the car had been received loaded with ore. The rate from the point of origin to destination was 11½ cents per 100 lb. The car was not weighed before loading, but was weighed after being loaded and the stenciled light weight on the car was used in determining the weight of the load, which showed the load's net weight was 61,000 lb. The railroad had hauled 2,100 lb. of ore 230 miles for nothing, having practically given the shipper $2.41 in this one trip for the lack of a few minutes work reweighing and restenciling the car to the correct weight at some scaling point.

In this matter, cars of some of the largest and most efficiently operated trunk line railroads in the United States have a tendency to show just as great a neglect as some of the smaller lines. In summing up this matter, it appears to the writer that one of the greatest opportunities for increasing and creating revenue, is to place correct weights on equipment and l. c. l. shipments, which will insure the railroad companies getting paid for what they actually haul.

WITHIN THE MEMORY OF ONE MAN

In a recent address before the Engineers' Society of Western Pennsylvania, A. W. Thompson, vice-president of the Baltimore & Ohio, said that "there is living in Cumberland, Md., the first agent of the Baltimore & Ohio at that point, Judge Oliver Gephart. In company with his father he attended the laying of the corner-stone of the Baltimore & Ohio at Mt. Clare, Baltimore, in 1828, and remarked at the time that it was his desire to reach the age of Charles Carroll, of Carrollton, who was then past 90. Mr. Gephart is now past 96 years of age, is in full possession of all his faculties and his reminiscences are extremely interesting. He worked on the grading of the canal near Cumberland, and associated himself with the Baltimore & Ohio in its early days.

"While serving as ticket agent at Cumberland he studied law, was admitted to the Maryland bar and later became judge of the Orphans' Court. He is a very well-known and influential citizen of Cumberland and takes a keen interest in everything pertaining to his home city. He is a director of the Second National Bank, one of the strongest banks in the state of Maryland, and for 39 years has attended the directors' meetings regularly.

"Thus within the memory of one man, of over a period of 80 years, the American railroad transportation machine has developed from stage coach to steel passenger train. Out of the old stage coach days and the period of early railroading Judge Gephart has passed to our time with its fast engines, dining cars and automobiles to meet them. It is now possible for him to travel in one day, surrounded by comforts undreamed of, a distance which would have required a week in his boyhood."

MASTER BOILER MAKERS' CONVENTION

The annual meeting of the Master Boiler Makers' Association opened at the Hotel Sherman, Chicago, on Tuesday morning, May 25, President James T. Johnston, Atchison, Topeka & Santa Fe, presiding.

An address was made by E. W. Pratt, assistant superintendent motive power and machinery, Chicago & North Western, of which the following is a brief abstract: The work of boiler inspection has been carried on and developed by the government with very little opposition. The government inspectors and the railroad representatives have co-operated for the benefit of both and of the public. There were good reasons for some of the railroad legislation enacted during the past years, but the general opinion seems to be that this has been overdone and that the railroads have been exhausted by the excessive doses of correctives applied. They now need a rest.

Statements made before legislative committees as to the millions of dollars involved by certain enactments do not produce any very great effect. On the other hand, a simple statement made before such a committee in reply to a request for detailed information from the general manager on any topic and showing, for instance, that it is necessary for a railroad to haul 4½ tons of coal one mile to pay for the cost of a postage stamp, has a much better effect on the committee and the galleries than many statements in which millions of dollars figure.

Mr. Pratt also mentioned the tendency of politics to become cleaner and the necessity of men in responsible positions, such as occupied by the master boiler makers, taking an active part in civic affairs. Decreasing the revenue of the railroads, coupled with increases in taxes and wages, makes it dependent upon all interested to see that conditions are improved. To this end every man should go to the primaries and see that the proper men are nominated and elected. Keep in close touch with the employees. Be fair and honest with them, for without the support of rank and file no man can secure permanent advancement. Be courteous and considerate, and be as careful as to how a thing is said as to what is said, and the strength of the individual as well as the Master Boiler Makers' Association will be augmented.

Mr. Pratt recommended the use of oxy-acetylene and electric welding machines and urged the necessity of having as many shops and terminals as possible equipped with them. He also directed attention to the necessity of following closely the minute details of boiler work, such as keeping the flues clean; inspecting the beads on flues; boring out flues; inspecting beading tools to see that they are in proper condition; maintenance of arches, ash pans and front ends; watching the tendency of the sheets to corrode at the grate frame and packing the space between it and the sheets with something to keep the ashes out; last of all the advisability and necessity of being courteous to the men.

The treasurer's report showed a balance on hand of $758.66. The secretary's report was not ready because of illness. This covers the proceedings for Tuesday. The remaining sessions will be covered in our next issue. A list of the exhibitors will be found in the News Section.

General News Department

At the meeting of the American Railway Association held in New York last week, the sum of $7,500 was appropriated to carry on the investigations of rail manufacture conducted by the Rail Committee of the American Railway Engineering Association. This action rescinds that taken last November by which the appropriations which have been made for several years were discontinued.

W. G. Lee, president of the Brotherhood of Railroad Trainmen; A. B. Garretson, president of the Order of Railway Conductors; W. S. Carter, president of the Brotherhood of Locomotive Firemen and Enginemen, and Samuel Gompers, president of the American Federation of Labor, have addressed telegrams to Governor Brumbaugh of Pennsylvania, asking him to veto the bill repealing the Pennsylvania "full-crew" law passed by the legislature.

The "Old Guard" of the Nashville, Chattanooga & St. Louis, recently held, at Nashville, its eighth annual meeting. This organization is composed of men who were working for the road during the civil war, and who have since continued in the service. When the "old guard" was formed in 1907, there were 26 members, but since that time eleven have passed into the great beyond. This year fourteen of the fifteen members were present. Five of the members of the old guard were in the same company of the First Tennessee Regiment, and one of them, J. H. Latimer, was conductor of the train which conveyed Jefferson Davis, president of the Confederate States, and his cabinet, out of Richmond. Major W. L. Danley is the oldest general passenger agent in the United States, in point of service. He began railway service in 1857, and has been general passenger agent since August, 1868.

The "roll of honor" issued by the Pennsylvania Railroad monthly in connection with the doings of its pension department, gives in the last issue a portrait of George W. Barker, who has been track watchman in the tunnel at Baltimore for 34 years. During that time he has walked about ten miles a day, or enough to go nearly five times around the world; and more than three-fifths of this distance was within the tunnel. He has never neglected his duties or received a reprimand. William Furman, who also retires at this time, began his service as second fireman, on a wood burner, of the Camden & Amboy, when all engines on that road had two firemen. George W. Scott, who has just died at Bordentown, N. J., at the age of 93, and who has been on the pension list many years, entered the service of the Camden & Amboy in 1846, was a fireman in 1850 and an engineer in 1852. He was the man who, in 1893, ran the old locomotive "John Bull," from Philadelphia to the World's Fair at Chicago under its own steam.

The United States Civil Service Commission will hold examinations June 23 for the position of junior railway civil engineer for the Interstate Commerce Commission, grade 1 and grade 2; salaries in grade 1 from $1,200 to $1,680, and in grade 2 from $720 to $1,080. Applicants must be between 21 and 36 years old.

The United States Civil Service Commission announces examinations for expert passenger-rate clerk, for men only, on June 23, 1915, to fill a vacancy in this position in the Quartermaster Corps at St. Louis, Mo., at a salary of $1,200. This position is due to the maintenance of troops on the Mexican border, and may not continue permanently. The duties are the revision, preparation and payment of passenger transportation accounts. Applicants must be thoroughly conversant with the intricacies of the various passenger compendiums and tariffs and the rules and customs, both written and unwritten, of carriers in matters of divisions, etc., when used in settlement for service performed for the government over land-grant, bond-aided, free, and indebted carriers. Only those who have had experience in general passenger offices or in ticket-auditing offices of railroads will be considered. Age, 20 years or over on the date of the examination. Applicants must submit to the examiner on the day of the examination their photographs, taken within two years, securely pasted in the space provided on the admission cards sent them after their applications are filed. Tintypes or proofs will not be accepted. Intending applicants should apply for Form 1312, stating the title of the examination for which the form is desired, to the United States Civil Service Commission, Washington, D. C., or to the United States Civil Service Board at any of the numerous cities where such boards are maintained.

Disastrous Collision in Scotland

Press despatches of May 22 report a collision of passenger trains on the Caledonian Railway at Gretna, Scotland, nine miles from Carlisle, England, which, measured by the loss of life, appears to be the worst railroad disaster that ever occurred in the United Kingdom. One of the trains was filled with soldiers, about 500 men, and the total number of persons killed is given as 156, of whom a considerable number were burned to death, the wreck taking fire immediately. Fully as many more were seriously injured. No information is given as to the cause of the collision. It appears that first there was a rear collision on the southbound track and that this wreck was immediately run into by an express train on the northbound track.

Brooklyn Marginal Railroad

The New York legislature, after months of discussion, has passed, and the governor has approved, the Cullen bill, authorizing the city of New York to make a contract for the operation of a freight railroad along the east shore of New York Bay from South Brooklyn northward. Such a line would connect a number of terminal properties where cars are now delivered by boats. To form a satisfactory organization for the operation of a road of this kind, it is necessary to secure the co-operation of the important trunk lines terminating on New York Bay, and the present law removes restrictions, hitherto existing, which forbade the railroads from participating in such an enterprise. Extensive tracts of the property desired are already owned by the city and additional tracts are to be bought.

Illinois Campaign Against Train Limit Bill

In the Illinois legislature the bill limiting the length of freight trains to 50 cars, which was killed in committee, has been placed on the calendar of the house.

In view of this action the railways of Illinois, on May 25, began an advertising campaign in the newspapers of the state to show that the proposed legislation would not only cost the railways large sums of money, but that it would tend to increase rather than reduce the number of accidents. A half-page advertisement was published in the Chicago morning papers of May 25, with the heading in large display type, "A bill to increase accidents on railways." Statistics of accidents and train mileage were given to show that when the number of freight trains run has increased there almost invariably has been an increase in accidents, and when the number of freight trains has decreased there has almost invariably been a decrease in accidents. The advertisement pointed out that the purpose of this proposed legislation is not to promote safety, but to increase the number of men the railways must employ, and that its passage would cause an enormous increase in railway expenses. The advertisement concluded as follows: "Communicate with your representatives and senators at once and tell them that you are opposed to this legislation." This advertisement was followed by another showing the increase in railway expenses, and both advertisements were published in papers throughout the state and posted on bulletin boards at railway stations.

The Lumbermen's Association of Chicago has addressed a circular to its members asking them "to get after the mem-

bers of the legislature immediately" and to oppose the bill. The letter says in part: "As a lumberman you are threatened today with an inexcusable increase in freight rates on account of labor union activity. Your assistance is needed to show the legislators that you do not believe in inefficiency, do not believe in increasing the danger of railroading, do not believe in increasing the cost of operating and do not believe in unnecessarily increasing freight and passenger rates by placing a foolish burden upon the railroads. This bill, if passed, would greatly increase the cost of operating trains of dead freight, such as lumber and coal, but is being strongly urged by the labor unions so as to give more men employment."

A committee of presidents of the railways has sent to the newspapers a statement appealing to the people to cause the defeat of the bill in the legislature. Statistics are given to show that the bill would unnecessarily increase railway expenses in Illinois by $7,350,000 a year, would render valueless investments amounting to over $53,000,000 in Illinois, and would force new and unnecessary investments of over nineteen millions. The interest at 5 per cent on the new investments necessary would be $981,000, and the annual increase in operating expenses would be $6,368,000.

Accidents to Trespassers, Classified

At the annual convention of the Association of Railway Claim Agents, held at Galveston, Tex., May 12, F. V. Whiting, of the New York Central, explained the method by which the committee of the association, in charge of this work, had gathered its statistics concerning the trespassing evil; and in connection with his statement gave, for the fiscal year 1914, the following data covering the statistics of accidents to trespassers on railroads aggregating over 191,000 miles in length. This statement includes nearly 11,000 items, or about 90 per cent of the total for the year reported by the Interstate Commerce Commission. It is as follows:

Classification of Accidents to Trespassers

		Number	Per cent	
4. Extent of accident	Killed	4,746	44	
	Loss of one limb	826	8	
	Loss of two limbs	172	1	
	Other injury	5,041	47	10,785
5. Place	In country district	3,421	32	
	In city	3,482	32	
	In town or village	3,882	36	10,785
6. Residence	Near place of accident	4,994	46	
	Far from place of accident	3,876	36	
	Unknown	1,915	18	10,785
7. Was injured person living at home with family or parents?	Yes	4,914	46	
	No	4,303	40	
	Unknown	1,568	14	10,785
8.	Male	10,224	95	
	Female	561	5	10,785
	Married	2,359	22	
	Single	4,618	43	
	Unknown	3,808	35	10,785
9. Occupation	None	1,846	17	
	Unskilled laborer	3,675	34	
	Skilled laborer	1,160	11	
	Profession	159	1	
	Merchant	99	1	
	Clerical	134	1	
	Housewife	281	3	
	Unknown	3,431	32	10,785
10. Regularly employed at time of accident	Yes	2,391	22	
	No	4,346	40	
	Unknown	4,048	38	10,785
11. Nature of accident	Walking on track	4,712	44	
	Riding on train	3,840	36	
	Other accidents	1,511	14	
	Unknown	722	6	10,785
12. Was injured person known as a tramp or hobo?	Yes	1,313	12	
	No	6,326	59	
	Unknown	3,146	29	10,785
13. Age	5 years or under	145	1	
	Over 5 and under 10	339	3	
	Over 10 and under 15	565	5	
	Over 15 and under 21	1,608	15	
	Over 21 and under 30	3,437	32	
	Over 30 and under 50	3,048	29	
	Over 50 and under 60	627	6	
	Over 60 and under 65	247	2	
	65 and over	316	3	
	Unknown	453	4	10,785
14. Was injured person intoxicated?	Yes	1,789	17	
	No	5,455	50	
	Unknown	3,541	33	10,785
15. Nationality	American	7,282	68	
	Foreign	2,086	19	
	Unknown	1,417	13	10,785

Report of Texas Railroad Commission

The railroad commission of Texas has issued its twenty-third annual report, which is for the year ending June 30, 1914. It shows the length of railroad in the state as 15,569 miles, a net increase of 286 miles in twelve months. The new lines put in operation during the year, with the mileage of track (not road) of each, were the following:

Greenville-Northwestern, 11.48 miles; Riveria Beach & Eastern, 9.70 miles; San Antonio, Fredericksburg & Northern, 25.07 miles; total, 46.25 miles. Old lines increasing mileage were: Galveston, Harrisburg & San Antonio, 9.93 miles; Galveston, Houston & Henderson, 114.61 miles; Gulf, Colorado & Santa Fe, 15.31; Houston & Brazos Valley, 4.36; Houston Belt & Terminal, 6.37; Houtson & Texas Central, 42.38; International & Great Northern, 5.20; Missouri, Kansas & Texas, 18.14; Pecos & Northern Texas, 103.67; Quanah, Acme & Pacific; 40.70; Rio Grande & Eagle Pass, 4.75; Rio Grande, El Paso & Santa Fe, 4.07; San Antonio & Aransas Pass, 11.78; San Antonio, Uvalde & Gulf, 83.30.

The total assessed valuation of railroads in 1914 was $339,410,849; in 1913 it was $433,635,318; average amount per mile in 1914, $21,842, in 1913, $22,598.

Boiler Makers' Association Exhibitors

The following concerns had exhibits at the Master Boiler Makers' Association convention, which met at the Hotel Sherman, Chicago, this week:

American Arch Company, New York—Model of Security arch. Represented by LeGrand Parish, W. L. Allison, John P. Neff, H. D. Savage, J. T. Anthony, George Wagstaff, R. J. Himmelright, G. C. Denney and F. G. Boomer.

American Flexible Bolt Company, Pittsburgh, Pa.—American staybolts. Represented by C. A. Seley, R. W. Benson and Louis Weidmeier.

American Locomotive Company, New York—Photographs of locomotives. Represented by C. A. Delaney.

Baldwin Locomotive Works, Philadelphia, Pa.—Photographs of locomotives. Represented by A. S. Goble.

Bird-Archer Company, New York—Boiler chemicals. Represented by L. F. Wilson, J. M. Robb and C. J. McGurn.

Boiler Maker, The, New York.—Copies of paper. Represented by George Slate.

Brubaker & Bros., W. L., Millersburg, Pa.—Taps, dies and reamers. Represented by W. S. Rose and J. A. W. Brubaker.

Burden Iron Works, Troy, N. Y.—Staybolt iron and rivets. Represented by John C. Kuhns, Fred Gardner, Gilbert H. Pearsall and D. W. Talcott.

Carbon Steel Company, Pittsburgh, Pa. Represented by Fred T. Connor.

Castle, A. M., & Co., Chicago. Represented by George R. Boyce and L. M. Henoch.

Champion Rivet Company, Cleveland. Represented by D. J. Champion.

Chicago Pneumatic Tool Company, Chicago—Pneumatic drills and hammers, Boyer rivet busters and electric drills. Represented by C. E. Walker, J. C. Campbell, J. L. Canby, G. G. Smallwood, W. S. Delaney, Thos. Aldcorn, G. A. Barden, W. P. Pressinger and J. B. Corby.

Cleveland Pneumatic Tool Company, Cleveland—Pneumatic riveters, chippers, air drills and Bowes hose couplings. Represented by H. S. Covey and C. J. Albert.

Cleveland Punch & Shear Works Company, Cleveland. Represented by A. J. Canfield.

Cleveland Steel Tool Company, Cleveland—Pneumatic hammer, rivet sets, chisel blanks, punches and dies. Represented by R. J. Venning and H. W. Leighton, Jr.

Dearborn Chemical Company, Chicago—Descriptive literature of scientific treatment of feed water. Represented by J. D. Purcell, J. F. Roddy and J. H. Cooper.

Ewald Iron Company, Louisville, Ky. Represented by S. F. Sullivan, E. V. Shakleford and R. Kilpatrick.

Faessler Manufacturing Company, J., Moberly, Mo.—Boiler makers' tools, expanders, flue cutters, etc. Represented by J. W. Faessler, C. F. Palmer and G. R. Maupin.

Falls Hollow Staybolt Company, Cuyahoga Falls, Ohio—Samples of iron. Represented by John E. Chisholm.

Flannery Bolt Company, Pittsburgh, Pa. Represented by B. E. D. Stafford.

Garratt-Callahan Company, Chicago. Represented by W. G. Willcoxson.

Globe Seamless Steel Tube Company, Chicago—Boiler flues. Represented by Frank J. O'Brien, H. A. Bowles and T. B. Kirby.

Hilles & Jones Company, Wilmington, Del.—Photographs of punches, shears, bending rolls and boiler shop machinery. Represented by W. H. Connell, Jr.

Imperial Brass Manufacturing Company, Chicago—Oxy-acetylene welding and cutting apparatus. Represented by J. A. Schroeder.

Independent Pneumatic Tool Company, Chicago—Pneumatic and electric tools. Represented by H. H. Henricks, H. F. Finney, F. J. Hurley, R. F. Gummere and W. A. Nugent.

Ingersoll-Rand Company, New York—Pneumatic riveting and chipping hammers and drills. Represented by Geo. A. Gallinger, Walter A. Johnson, R. C. Cole, C. F. Overly and E. J. Welsh.

Interstate Commerce Commission—Boilers in operation demonstrating circulation of water. Represented by E. J. Reardon, district inspector locomotive boilers.

Jacobs-Shupert U. S. Firebox Company, Coatesville, Pa.—Models of Jacobs-Shupert firebox and Lukens iron and steel. Represented by J. H. Smythe and A. W. Whiteford.

Locomotive Superheater Company, New York—Photographs of superheater. Represented by Geo. Bourne, G. E. Ryder and George Spangler.

Lovejoy Tool Works, Chicago—Locomotive jack. Represented by W. H. Dangel.

Mahr Manufacturing Company, Minneapolis, Minn.—No. 15 portable oil burning rivet forge and No. 2 boiler torch. Represented by H. H. Warner and H. B. Hazerodt.

McCabe Manufacturing Company, Lawrence, Mass.—Pneumatic flanging machine. Represented by F. H. McCabe.

Monongahela Tube Company, Pittsburgh, Pa. Represented by W. A. Roome.

Mudge & Company, Chicago—Mudge-Slater spark arrester. Represented by Burton W. Mudge, R. D. Sinclair and G. W. Bender.

Christopher Murphy & Company, Chicago—Tube cutters and square rib chucks. Represented by Christopher Murphy.

National Boiler Washing Company, Chicago—Safety First fire door. Represented by H. A. Varney and E. B. White.

National Railway Devices Company, Chicago—Shoemaker fire door. Represented by V. W. Goodman and J. G. Robinson.

National Tube Company, Pittsburgh, Pa.—Spellerized lapweld locomotive tubes, Shelby seamless locomotive tubes, Kewanee unions and N. T. C. regrinding valves. Represented by P. J. Conrath, G. N. Riley, E. J. Graham, James Goodwin, L. R. Phillips and J. W. Kelly.

Never Slip Safety Clamp Company, New York—Never slip safety clamp for handling boiler plate. Represented by E. R. Adler.

Otis Steel Company, Cleveland. Represented by George E. Sevey.

Oxweld Railroad Service Company, Chicago—Portable and stationary oxy-acetylene apparatus and specimens of cutting and welding. Represented by C. B. Moore, E. V. Lea, F. C. Hasse, E. S. Richardson, M. R. Day, W. L. Bean, G. H. Pearsall and R. W. Alfonte.

Parkesburg Iron Company, Parkesburg, Pa.—Charcoal iron boiler tube. Represented by J. A. Kinkead, W. H. S. Bateman and L. P. Mercer.

Pittsburgh Steel Products Company, Pittsburgh, Pa. Represented by C. R. King.

Q. & C. Company, New York—Ross-Schofield boiler system. Represented by Charles F. Pierce, E. R. Packer and Alfred Robertson.

Rome Merchant Iron Mill, Rome, N. Y.—Rome "Superior" staybolt iron. Represented by C. W. Floyd Coffin and Weston Jenkins.

Ryerson & Son, Jos. T., Chicago—Samples of Ulster special staybolt iron, Ulster engine bolt iron, Nykrome steel tube expanders, high speed drills and small tools. Represented by J. P. Moses, H. S. Smith, H. B. Hench, J. T. Corbett, J. C. Porric and E. T. Hendee.

Scully Steel & Iron Company, Chicago—Staybolt chucks and headers, expanders, bevel and splitting shears, Everlasting blow-off valves and Draper flue welders. Represented by J. W. Patterson, A. Verschuur and C. L. C. Magee.

Superior Oxygen Equipment Company, Pittsburgh, Pa.—Oxy-acetylene welding and cutting apparatus. Represented by J. A. Warfel.

U. S. Graphite Company, Saginaw, Mich.—Mexican boiler graphite. Represented by J. W. Eviston and J. G. Draught.

Worth Bros. Company, Coatesville, Pa. Represented by B. M. Clements.

Railway Signal Association

The second stated meeting of the Railway Signal Association for the year 1915 was held in the Hotel Astor, New York City, May 26 and 27. President T. S. Stevens, signal engineer, Atchison, Topeka & Santa Fe, presided and about 225 members and guests were in attendance.

At the Wednesday session, Committee III on Power Interlocking, presented specifications for electro-pneumatic interlocking containing numerous revisions of the specifications in the Manual. A revised specification for fiber conduit was presented to provide for different sizes of conduit in addition to the 3 in. size to which the present specifications limit this material. The specifications for incandescent electric lamps, which were referred back to the committee at the last annual convention, were presented again in revised form. The discussion brought out the difficulty which is experienced in getting lamps with the dimensions between the base and the point of concentration of the filament accurate and uniform. This is an important point in light signals, although some of the members did not feel that a reasonable variation in this dimension would particularly affect the service of a lamp with a semaphore signal. These specifications will be presented to the annual convention for final action and letter ballot.

Committee V on Manual Block, submitted a paper on the "Care and Maintenance of Dry Batteries" and instructions governing the maintenance of dry cells, gravity cells and caustic soda cells. These instructions are expected to be presented at the annual meeting for submission to letter ballot. Progress was reported on the preparation of instructions governing the maintenance of storage batteries, but these will probably not be ready to preesnt at the next convention.

The special Committee on Electrical Testing presented a progress report outlining methods of testing electrical signal apparatus and circuits, a large part of which was based on the practice of one large road, and specifying suggested ranges and scales for d. c. testing instruments for use in the field. The discussion brought out many points as to the need for better testing methods and further development in testing instruments to cover all conditions.

The members of the association in attendance at the meeting were the guests of the Signal Appliance Association on a trip to West Point Wednesday afternoon. The proceedings of the Thursday meetings will be reported hereafter.

American Railroad Master Tinners', Coppersmiths' and Pipefitters' Association

At the third annual convention of the American Railroad Master Tinners', Coppersmiths' and Pipefitters' Association to be held at the Sherman House, Chicago, from July 13 to 16, papers will be presented as follows: Autogenous Welding, by W. J. Moffett, C. Borcherdt and J. P. Hahn; Tinware, by A. Paulis and J. P. Shoemaker; Crude Oil Burners and Forges, by W. J. Moffett and J. E. Harbough; Locomotive Jackets, by O. E. Schlink, W. W. Nash and T. J. Burke; Lubrication, by C. Borcherdt and A. D. Homer; Smoke Prevention, by J. G. Thompson and J. S. Richards; Metals and their Alloys, by G. B. Hosford; Gaskets and their Application to Locomotives, by F. Bucholtz; Coach Heating, by G. Schwenk and F. B. Gralike, and Piping, by W. E. Jones.

Salt Lake City Transportation Club

R. E. Rowland, secretary of the Salt Lake City Transportation Club, has addressed a letter to the various transportation and traffic clubs of the United States, extending to their members the hospitality of the Salt Lake City Transportation Club during any stopovers that may be made in Salt Lake City during the coming summer. The club has appointed a committee for the purpose of arranging special sight-seeing trips, and is prepared to welcome in every way not only single members of the clubs, but also any organizations passing through the city in a body.

Canadian Railway Club

At the thirteenth annual meeting of the Canadian Railway Club officers were elected as follows: President, L. C. Ord; first vice-president, R. M. Hannaford; second vice-president, George Smart; secretary, James Powell, and treasurer, W. H. Stewart. T. C. Hudson, E. E. Lloyd, J. Hendry, C. Manning, E. B. Tilt and Prof. H. O. Keay were appointed on the executive committee, and W. S. Atwood, W. H. Winterrowd and F. A. Purdy on the audit committee.

Engineers' Society of Western Pennsylvania

At the regular meeting of the mechanical section of the Engineers' Society of Western Pennsylvania, to be held in the society rooms in the Oliver building, Pittsburgh, on June 1, a paper will be presented by R. S. Lord, vice-president of the Hope Engineering & Supply Company, Pittsburgh, entitled, "Pipe Couplings."

MEETINGS AND CONVENTIONS

The following list gives the names of secretaries, dates of next or regular meetings, and places of meeting of those associations which will meet during the next three months. The full list of meetings and conventions is published only in the first issue of the Railway Age Gazette for each month.

American Association of Demurrage Officers.—F. A. Pontious, 455 Grand Central Station, Chicago. Next meeting, July 21, 1915, Milwaukee, Wis.

American Railroad Master Tinners, Coppersmiths and Pipefitters' Association.—W. E. Jones, C. & N. W., 3814 Fulton St., Chicago. Annual meeting, July 13-16, 1915, Hotel Sherman, Chicago.

American Railway Master Mechanics' Association.—J. W. Taylor, 1112 Karpen Bldg., Chicago. Annual meeting, June 9-11, 1915, Atlantic City, N. J.

American Railway Tool Foremen's Association.—Owen D. Kinsey, Illinois Central, Chicago. Annual meeting, July 19-21, 1915, Hotel Sherman, Chicago.

American Society for Testing Materials.—Prof. E. Marburg, University of Pennsylvania, Philadelphia, Pa. Annual meeting, June 22-26, 1915, Hotel Traymore, Atlantic City, N. J.

American Society of Civil Engineers.—Chas. Warren Hunt, 220 W. 57th St., New York. Regular meetings, 1st and 3d Wednesday in month, except July and August, 220 W. 57th St., New York.

American Society of Mechanical Engineers.—Calvin W. Rice, 29 W. 39th St., New York. Next spring meeting, June 22-25, 1915, Buffalo, N. Y. Annual meeting, December 7-10, 1915, New York.

Association of Railway Electrical Engineers.—Jos. A. Andreucetti, C. & N. W., Room 411, C. & N. W. Sta., Chicago. Semi-annual meeting with Master Car Builders' and Master Mechanics' Associations. Annual meeting, October, 1915.

Association of Railway Telegraph Superintendents.—P. W. Drew, Soo Line, 112 West Adams St., Chicago. Annual meeting, June 22-25, 1915, Rochester, N. Y.

Association of Transportation and Car Accounting Officers.—G. P. Conrad, 75 Church St., New York. Next meeting, June 22-23, Niagara Falls, N. Y.

Canadian Railway Club.—James Powell, Grand Trunk, P. O. Box 7, St. Lambert (near Montreal), Que. Regular meetings, 2d Tuesday in month, except June, July and August, Windsor Hotel, Montreal, Que.

Car Foremen's Association of Chicago.—Aaron Kline, 841 North Lawler Ave., Chicago. Regular meetings, 2d Monday in month, except June, July and August, Hotel La Salle, Chicago.

Central Railway Club.—H. D. Vought, 95 Liberty St., New York. Regular meetings, 2d Friday in January, May, September and November. Annual meeting, 2d Thursday in March, Hotel Statler, Buffalo, N. Y.

Engineers' Society of Western Pennsylvania.—Elmer K. Hiles, 2511 Oliver Bldg., Pittsburgh, Pa. Regular meetings, 1st and 3d Tuesday in month, Pittsburgh.

Freight Claim Association.—Warren P. Taylor, R. F. & P., Richmond, Va. Annual meeting, June 16, 1915, Chicago.

General Superintendents' Association of Chicago.—A. M. Hunter, 321 Grand Central Station, Chicago. Regular meetings, Wednesday, preceding 3d Thursday in month, Room 1856, Transportation Bldg., Chicago.

International Railway General Foremen's Association.—Wm. Hall, 1126 W. Broadway, Winona, Minn. Next convention, July 13-16, 1915, Sherman House, Chicago.

Master Boiler Makers' Association.—Harry D. Vought, 95 Liberty St., New York. Annual convention, May 25 to 28, 1915, Chicago, Ill.

Master Car Builders' Association.—J. W. Taylor, 1112 Karpen Bldg., Chicago. Annual meeting, June 14-16, 1915, Atlantic City, N. J.

New England Railroad Club.—W. E. Cade, Jr., 683 Atlantic Ave., Boston, Mass. Regular meetings, 2d Tuesday in month, except June, July, August and September, Boston.

New York Railroad Club.—Harry D. Vought, 95 Liberty St., New York. Regular meetings, 3d Friday in month, except June, July and August, 29 W. 39th St., New York.

Niagara Frontier Car Men's Association.—E. N. Frankenberger, 623 Brisbane Bldg., Buffalo, N. Y. Meetings, 3d Wednesday in month, New York Telephone Bldg., Buffalo, N. Y.

Peoria Association of Railroad Officers.—M. W. Rotchford, 410 Masonic Temple Bldg., Peoria, Ill. Regular meetings, 3d Thursday in month, Jefferson Hotel, Peoria.

Railroad Club of Kansas City.—Claude Manlove, 1008 Walnut St., Kansas City, Mo. Regular meetings, 3d Saturday in month, Kansas City.

Railroad Men's Improvement Society.—J. B. Curran, Erie R. R., 50 Church St., New York. Meetings, alternate Thursdays, October to May, Assembly Rooms of Trunk Line Association, 143 Liberty St., New York.

Railway Club of Pittsburgh.—J. B. Anderson, Room 207, P. R. R. Sta., Pittsburgh, Pa. Regular meetings, 4th Friday in month, except June, July and August, Monongahela House, Pittsburgh.

Railway Electrical Supply Manufacturers' Association.—J. Scribner, 1063 Monadnock Block, Chicago. Meetings with Association of Railway Electrical Engineers.

Railway Signal Association.—C. C. Rosenberg, Myers Bldg., Bethlehem, Pa. Stated meeting, May 26-27, 1915, Hotel Astor, New York. Annual meeting, September 14-17, 1915, Salt Lake City, Utah.

Railway Supply Manufacturers' Association.—J. D. Conway, 2136 Oliver Bldg., Pittsburgh, Pa. Meetings with Master Car Builders and Master Mechanics' Associations.

Railway Telegraph and Telephone Appliance Association.—G. A. Nelson, 50 Church St., New York. Meetings with Association of Railway Telegraph Superintendents.

Richmond Railroad Club.—F. O. Robinson, C. & O., Richmond, Va. Regular meetings, 2d Monday in month, except June, July and August.

St. Louis Railway Club.—B. W. Frauenthal, Union Station, St. Louis, Mo. Regular meetings, 2d Friday in month, except June, July and August, St. Louis.

Salt Lake Transportation Club.—R. E. Rowland, David Keith Bldg., Salt Lake City, Utah. Regular meetings, 1st Saturday of each month, Salt Lake City.

Southern Association of Car Service Officers.—E. W. Sandwich, A. & W. P. R. R., Atlanta, Ga. Next meeting, July 15, 1915, Atlanta. Annual meeting, January, 1916.

Southern & Southwestern Railway Club.—A. J. Merrill, Grant Bldg., Atlanta, Ga. Regular meetings, 3d Thursday, January, March, May, July, September, November, 10 a. m., Piedmont Hotel, Atlanta.

Toledo Transportation Club.—Harry S. Fox, Toledo, Ohio. Regular meetings, 1st Saturday in month, Boody House, Toledo.

Traffic Club of Chicago.—W. H. Wharton, La Salle Hotel, Chicago.

Traffic Club of Jacksonville (Fla.).—R. H. May, Jacksonville, Fla. Meetings, 1st Saturday in month.

Traffic Club of St. Louis.—A. F. Versen, Mercantile Library Bldg., St. Louis, Mo. Annual meeting in November. Noonday meetings, October to May.

Traffic Club of Newark.—John J. Kautzmann, P. O. Box 238, Newark, N. J. Regular meetings, 1st Monday in month, except July and August, The Washington, 559 Broad St., Newark.

Traffic Club of New York.—C. A. Swope, 291 Broadway, New York. Regular meetings last Tuesday in month, except June, July and August, Hotel Astor, New York.

Traffic Club of Pittsburgh.—D. L. Wells, Gen. Agt., Erie R. R., 1924 Oliver Bldg., Pittsburgh, Pa. Meetings bi-monthly, Pittsburgh. Annual meetings, 2d Monday in June.

Train Dispatchers' Association of America.—J. F. Mackie, 7122 Stewart Ave., Chicago. Annual meeting, June 15, 1915, Minneapolis, Minn.

Transportation Club of Detroit.—W. R. Hurley, Superintendent's office, N. Y. C. R. R., Detroit, Mich. Meetings monthly, Normandie Hotel, Detroit.

Utah Society of Engineers.—Frank W. Moore, 1111 Newhouse Bldg., Salt Lake City, Utah. Regular meetings, 3d Friday in month, except July and August, Salt Lake City.

Western Canada Railway Club.—L. Kon, Immigration Agent, Grand Trunk Pacific, Winnipeg, Man. Regular meetings, 2d Monday, except June, July and August, Winnipeg.

Western Railway Club.—J. W. Taylor, 1112 Karpen Bldg., Chicago. Regular meetings, 3d Tuesday afternoon in month, except June, July and August, La Salle Hotel, Chicago.

Western Society of Engineers.—J. H. Warder, 1735 Monadnock Block, Chicago. Regular meetings, 1st Monday in month, except January, July and August, Chicago. Extra meetings, except in July and August, generally on other Monday evenings. Annual meetings, 1st Wednesday after 1st Thursday in January, Chicago.

Traffic News

Both houses of the Ohio legislature have passed a bill repealing the state maximum freight rate law.

The Senate of the Illinois legislature has reported unfavorably the bill authorizing the state public utilities commission to increase passenger fares to 2½ cents a mile.

J. B. Ford, assistant general freight agent of the Queen & Crescent, Cincinnati, Ohio, in his latest bulletin, dated May 11, giving information to shippers and others concerning opportunities for business in foreign countries, fills four pages with statements of dates of sailing of vessels to all parts of the world.

The Western Pacific has announced a partial embargo on traffic destined for the Orient and Australia from San Francisco because of the difficulty in obtaining space on ocean steamers. Agents will be authorized to sign bills of lading on shipments for China, Japan, Australia, New Zealand and the Philippine Islands, provided specific bookings can be made.

The Chicago & North Western has announced an amplification of its present passenger train service between Chicago and Denver, to take effect on May 30, when a new train to be called the Denver Special will be put in service, leaving Chicago at 6:05 p. m., and arriving at Denver at about 9:00 p. m. the next day. Similar service will be established eastbound. This service is in addition to the Colorado Special and the Colorado Express.

A change in passenger train schedules was put in effect on the Baltimore & Ohio on Sunday, May 23, by which the running time of the Interstate Special between Chicago and Washington is reduced by two hours, and train No. 8, from Baltimore to Chicago, is operated by way of Wheeling, W. Va., instead of from Baltimore to Pittsburgh. This train will be known as the West Virginian. Trains No. 9 and 10, which for the past few months have been operated between New York and Pittsburgh, are restored to the old runs between New York and Chicago.

A Novel Railroad Exhibit

The Denver & Rio Grande, the Western Pacific, the Missouri Pacific and the St. Louis, Iron Mountain & Southern have an interesting exhibit at the Panama-Pacific Exposition in San Francisco, consisting of a globe 51 ft. in diameter, on the outside surface of which is shown a relief map of North America with tracks running across it representing the main lines of these roads from St. Louis to San Francisco, on which trains are run back and forth by means of electrical apparatus contained within the globe. The lower part of the globe is cut off so that it stands 44 ft. high. It is supported by a series of arches through which visitors may enter the interior. Between the arches are large sculptured figures about 8 ft. high, representing a brakeman, a farmer, a fisherman, a miner, and representatives of other industries, each standing on a pedestal representing the front part of a locomotive, about 10 ft. high. On the interior of the globe are artistic reproductions of western scenery, such as the Royal Gorge, and model views of Denver, Salt Lake City, Leadville and other cities along the lines. Adjoining the globe is an annex, at the top of which is a replica of Marshall Pass. As the trains cross the continent the names of the principal cities are flashed electrically on the map as the train passes through.

National Industrial Traffic League

At the spring meeting of the National Industrial Traffic League, held at Memphis, Tenn., on April 13 and 14, the Tariff Committee was instructed to formulate a resolution to be sent to the Interstate Commerce Commission, recommending a rule that no other fraction than ½ cent be considered in publishing freight rates. This subject arose from the fact that the recent

decision of the Interstate Commerce Commission allowing a 5 per cent advance in freight rates in Official Classification Territory resulted in a large number of rates containing decimal fractions, which are inconvenient to handle. The plan of requesting the railroads in Central Freight Association and Trunk Line territory to publish association tariffs was also discussed, and the Committee on Simplification of Tariffs was instructed to circularize members of the league and other shippers, asking for suggestions for a basis of simplifying freight tariffs.

The Committee on Transportation Instrumentalities presented a report on the subject of pooling freight cars, including a discussion of the plan adopted by a number of lines in Texas providing for joint use of cars on an equalization basis, and it was recommended that the railroads take steps toward the pooling of cars by adopting some such plan in other territory. It was expressed as the sense of the league, however, that the term "free interchange" is preferable to "pooling." After discussion of a request from a sub-committee of the American Railway Association Committee on Standard Box Cars, asking for suggestions from the shippers, it was decided that while the league was in favor of standardization of cars it should take no position toward determining what the standards should be. There was considerable discussion of the new M. C. B. rules for the protection of car doors, in which the opinion was expressed that while the shippers ought to make carload shipments safe, they should not be required to pay for this additional protection. The Committee on Unit Basis of Classification reported that the Western Classification Committee was using such a basis in some cases, but not using it in others. The committee felt that the system used ought to be revised or else dropped; and the committee was instructed to consider the matter further, reporting at the next meeting whether a feasible and practical unit basis for classification could be adopted.

New Uniform Bill of Lading

C. C. McCain, chairman of the Uniform Bill of Lading Committee for all the roads east of Chicago and north of the Ohio river has issued a circular giving the form of section 3 which hereafter is to be inserted in bills of lading to make them conformable to the Cummins amendment forbidding railroads to limit their liability for loss and damage below the actual value of the goods, which amendment goes into effect June 2. The new section 3 is as follows:

SEC. 3. No carrier is bound to transport said property by any particular train or vessel, or in time for any particular market or otherwise than with reasonable despatch, unless by specific agreement indorsed hereon. Every carrier shall have the right in case of physical necessity to forward said property by any railroad or route between the point of shipment and the point of destination; but if such diversion shall be from a rail to a water route the liability of the carrier shall be the same as though the entire carriage were by rail.

The amount of any loss or damage for which any carrier is liable shall be computed on the basis of the value of the property at the place and time of shipment under this bill of lading.

Except in cases where the loss, damage, or injury complained of is due to delay or damage while being loaded or unloaded, or damaged in transit by carelessness or negligence, claims must be made in writing to the carrier at the point of delivery or at the point of origin within four months after delivery of the property, or, in case of failure to make delivery, then within four months after a reasonable time for delivery has elapsed. Suits for recovery of claims for loss or damage, notice of which is not required, and which are not made in writing to the carrier within four months as above specified, shall be instituted only within two years after delivery of the property, or, in case of failure to make delivery, then within two years after a reasonable time for delivery has elapsed. No claims not in suit will be paid after the lapse of two years as above, unless made in writing to the carrier within four months as above specified.

Any carrier or party liable on account of loss of or damage to any of said property shall have the full benefit of any insurance that may have been effected upon or on account of said property, so far as this shall not void the policies or contracts of insurance.

As the question of just what ought to be done to comply in all respects with the Cummins amendment is still pending before the Interstate Commerce Commission, Mr. McCain suggests that it may not be best to print large numbers of the new form at present and calls attention to the fact that old forms may be made legal by stamping on them a declaration saying that section 3 is subject to the amendment, as above set forth, which amendment is printed in Supplement No. 18, to the Official Classification, which is to take effect June 2.

Commission and Court News

INTERSTATE COMMERCE COMMISSION

A hearing will be held before Examiner Burnside in New York on July 12 relative to the reasonableness of certain tariffs of the Erie proposing increased ferry charges between New York and Jersey City.

Examiner Bell held a hearing at Chicago on May 19 and 20, on tariffs filed by the western railroads which have been suspended by the commission, abolishing the stopping of cars in transit to complete loading or for partial unloading on shipments moving under through rates. Representatives of the packers opposed the change, saying that the present system is no hindrance to the railroads.

The commission has suspended from May 15 and subsequent dates to September 21 tariffs of various carriers in official classification territory proposing to cancel the existing commodity rates on paper and commodities taking the same rates, including wrapping, printing, writing and newsprint paper, boxboard, binder board, strawboard, building and roofing paper and roofing composition in carloads between various points throughout that territory. If such commodity rates are cancelled, as a general rule, class rates will apply.

The Interstate Commerce Commission has set June 1 as the date for a continuation of the hearing begun at Washington on May 17, on advanced ratings carried in Supplement No. 9 of the Official Classification, which have been suspended by the commission, although there is a prospect that the hearing will be adjourned to a still later date. The principal changes involve higher ratings on beer in carloads, tobacco, paper, paper stock and other articles, which are included in the list of commodities named in the first report of the Interstate Commerce Commission in the five per cent rate case, in which the commission suggested that the car mile revenues appeared to be so low as to suggest the advisability of carefully examining them to ascertain whether additions to the revenues might not be made by increasing rates on those commodities rather than by a horizontal advance in all rates. R. N. Collyer, chairman of the Official Classification Committee, was the principal witness for the railroads, and a number of representatives of the shippers testified in opposition to the changes in rating.

Rates on Cotton Piece Goods from North Adams, Mass.

In re rates on cotton piece goods from North Adams, Mass., and other points to New York and other points. Opinion by the commission:

The commission finds that the carriers have justified proposed increased rates on cotton piece goods and woolen piece goods from North Adams, Mass., and other points on the Boston & Maine and Boston & Albany to New York and other points. (34 I. C. C., 41.)

Rates to Freeport and Rockford, Ill.

Chamber of Commerce of Freeport, Ill., v. Chicago, Milwoukee & St. Paul, et al. Opinion by Commisisoncr Meyer:

The commission finds that the present class rates between Freeport and Rockford and points in central freight association trunk line and New England territories are discriminatory, and that the Rockford rates in addition are unreasonable. With the rates in effect at the upper Mississippi river crossings fixed upon approximately a 117 per cent basis, and at Peoria upon 110 per cent basis, the commission believes that the rates at Freeport should be 114 per cent, and at Rockford 112 per cent, an adjustment which will give Freeport an 89.8 cent scale to and from New York and Rockford an 88.3 cent scale. This determination is not an extension of the McGraham scale to Freeport and Rockford, and the bases prescribed are slightly higher than the ratio between the distances Freeport and Rockford to New York and the Chicago-New York distance. (33 I. C. C., 673.)

Rates on Grain and Grain Products

In re rates on grain and grain products from Topeka, Kan., Kansas City, Mo., and other points to Dubuque, Ia., and other points. Opinion by Commissioner Hall:

The commission finds that the carriers have justified proposed increased joint through rates on grain and grain products from stations in Kansas and other states to points in Iowa, published to correct rates published in error. The carriers have also justified a proposed cancellation of joint through rates on grain and grain products from stations in Kansas and other states to points in Wisconsin, leaving in effect combinations of local rates on the Missouri river. (33 I. C. C., 666.)

Rates on Coke from Georgia Points

Durham Coal & Iron Company et al. v Central of Georgia et al. Opinion by Commissioner Hall:

The commission finds that the rate on coke in carloads from Durham and Chickamauga, Ga., to Pacific coast terminals is discriminatory and prejudicial to the extent that it exceeds the rate contemporaneously in effect to the same points from the Birmingham, Ala., district. It is also found that to apply the minimum carload weight is unreasonable when the cars in which the shipments are made are too small to carry that weight. Tariffs should provide that in such cases the marked capacity of the car used will govern. (34 I. C. C., 10.)

Joint Rates With the Kansas City Missouri River Navigation Company

Kansas City Missouri River Navigation Company v. Chesapeake & Ohio et al. Opinion by Commissioner Clark:

The commission finds that the carriers should establish through routes and joint rates on grain and grain products from Kansas City to Norfolk and Newport News, Va., for export, with the complainant, a water line operating on the Missouri and Mississippi rivers between Kansas City and East St. Louis. It is also held that if defendants engage in the practice of exchanging bills of lading they discriminate against complainant in refusing like recognition to its bills of lading. (34 I. C. C., 67.)

Joint Rates With Stone's Express

Stone's Express, Inc. v. Boston & Maine et al. Opinion by Commissioner Clark:

Stone's Express, conducting an express and freight service, the latter under the name of the Lynn & Boston line, by means of a barge and tug service between Lynn and Boston, Mass., is awarded in this case joint rates with a number of other carriers, not including the Boston & Maine, which is the only one of them also serving Lynn. Such joint rates will apply only on freight shipments to and from petitioners' terminal at Lynn, and if the express company continues to perform any team service in connection with such shipments, no part of it may be included in the joint rates. Some 160 rail and water carriers are affected, including the Boston & Albany; the New York, New Haven & Hartford; the Metropolitan Steamship Company and the Merchants & Miners Transportation Company. (33 I. C. C., 638.)

Railway Ownership of Boat Lines

The commission in a number of decisions written by Commissioner McChord has granted the petitions of several carriers to retain their interest in various boat lines. They are as follows: The Pennsylvania Company and the Canadian Pacific are each allowed to retain a one-third interest in the Pennsylvania-Ontario Transportation Company, which owns and operates a car ferry on Lake Erie between Ashtabula, Ohio, and Port Burwell, Canada. (34 I. C. C., 47.)

The Grand Trunk Western may continue its interest in the Grand Trunk Milwaukee Car Ferry operated by the Detroit, Grand Haven & Milwaukee (controlled by the Grand Trunk Railway of Canada), between Grand Haven, Mich., and Milwaukee. (34 I. C. C., 54.)

The Grand Trunk Railway of Canada and the Buffalo, Rochester & Pittsburgh are each allowed to retain their interest in the Ontario Car Ferry Company, Ltd., which operates the Ontario No. 1, a car ferry and passenger vessel plying between Genesee Dock, N. Y., and Cobourg, Ont., connecting the terminus of the Buffalo, Rochester & Pittsburgh at Genesee Dock with the terminus of the Grand Trunk Railway of Canada at Cobourg. A similar boat, the Ontario No. 2, is now under construction. (34 I. C. C., 49 and 52.)

The Ann Arbor may continue to operate its three car-ferry boats from its terminus at Frankfort to the ports of Manistique, where cars are delivered to and received from the Soo line and the Manistique & Superior; Menominee, where deliveries are made to the Chicago, Milwaukee & St. Paul, and the Chicago & North Western; Kewaunee, where connection is made with the Green Bay & Western and, over that line, with the Chicago, Milwaukee & St. Paul; and Manitowoc, where cars are interchanged with the Chicago & North Western and the Soo line roads; all on the west shore of Lake Michigan. (34 I. C. C., 83.)

The Pere Marquette is allowed to continue the operation of its ferries on the Detroit river between Detroit, Mich., and Windsor, Ont., on the St. Clair river between Port Huron, Mich., and Sarnia, Ont., and on Lake Michigan. This road and the Bessemer & Lake Erie are each allowed to continue their interest in the Marquette & Bessemer Dock & Navigation Company, operating a car-ferry on Lake Erie between Conneaut, Ohio and Port Stanley, Ont. (34 I. C. C., 86.)

In each case it is held that the participation of the petitioner (or petitioners) in through all-rail routes between the ports served by the boat line in which it is interested makes it possible for it to compete with such line within the meaning of section 5 of the act as amended by the Panama Canal act. It is also held in each case that the facts support a finding that the existing service by water is being operated in the interest of the public and is of advantage to the convenience and commerce of the people and that an extension of the petitioner's interest is of advantage to the convenience and commerce of the people, and that a continuance will neither exclude, prevent nor reduce competition on the route by water under consideration.

Rates on Vegetables from New Orleans to Chicago

New Orleans Vegetable Growers, Merchants & Shippers' Association v. Illinois Central et al. Opinion by the commission:

The commission finds that the present rates and minimum weights on cucumbers, cabbage, potatoes, beets, beans and vegetables of the lettuce family, moving in carloads from New Orleans, La., to Chicago and other northern markets are not unreasonable. The commission, however, directs complete revision of defendants' schedules of estimated weights applying on such shipments as it appears that the present system is unlawful.

Rates on vegetables from New Orleans to Kansas City and to Buffalo-Pittsburgh territory are found to be discriminatory to the extent that they exceed by more than five cents a 100 lb., the rates contemporaneously maintained from Southport Junction, La. (34 I. C. C., 32.)

STATE COMMISSIONS

The Missouri Public Service Commission has completed the taking of testimony on the application of the railroads of the state for authority to make an increase in passenger fares. R. A. Knapp, president of the United Commercial Travelers of Missouri, protested against any increase in fares and complained of the number of passes issued by the railroads. It turned out, however, that the passes of which he was complaining were those given to railroad employees. S. C. Bates, secretary of the Manufacturers' & Jobbers' Association of Springfield, Mo., told the commission that his organization favors an increase in fares provided the railroads will restore their train service to what it was before the two-cent fare law became effective.

The Pennsylvania Public Service Commission has issued its decision on the long-pending complaint of people in Philadelphia in relation to the increases in suburban passenger fares made by the railroads entering that city several months ago. The principal controversy was concerning one hundred-trip tickets on which the railroads made a large advance in price. The commission recommends that for distances of more than eight miles the present maximum rate, 1½ cents a mile be reduced on a sliding scale, the rate to decrease as the distance increases. It is recommended that these tickets be made good for one year instead of six months. The commission refuses to grant the complainants a further hearing, and they say that they will at once prepare a new case with a view to presenting their grievance even more urgently than before.

PERSONNEL OF COMMISSIONS

The seven men nominated for the Pennsylvania Public Service Commission last week (*Railway Age Gazette*, May 21, p. 1095) were confirmed on May 20 and will organize June 1. Local newspapers speak of "the new commission," but the change is simply one of personnel. The first appointments under the act creating the commission were made in 1913 after the Senate of 1913 had adjourned. The law requires confirmation by the Senate. The next Senate met in January, 1915. When it met there was also a new state administration and the appointments made by Governor Tener in 1913 were not confirmed, this postponement being made out of courtesy to the new governor, Dr. Brumbaugh. Governor Brumbaugh withdrew all of Governor Tener's appointments, saying that he wanted a wholly new commission. But the commissioners named in 1913 held office until their successors were named and confirmed. The governor appointed two of the former commissioners. Next week he will designate a chairman, and officers will be elected. There is pending a bill to allow the commission to have testimony taken by masters anywhere in the state and to simplifying appeals.

COURT NEWS

Arguments in the injunction proceedings instituted by the Ann Arbor to restrain the enforcement of the Michigan two-cents-a-mile passenger rate were heard before the three judges of the United States District Court at Grand Rapids, Mich., on May 19.

The St. Louis & San Francisco and the Kansas City Southern were granted a temporary injunction by the United States District Court at Little Rock, Ark., on May 19, restraining the Arkansas Railroad Commission from enforcing its general freight tariff which was to become effective on May 20. Hearing on the petition for a permanent injunction was set for May 28. The railroads contended the tariff would be confiscatory.

In the federal court at Cleveland, Ohio, May 26, the grand jury returned indictments against the Delaware & Hudson and the Erie railroads and F. D. Underwood, president of the Erie, for making in 1912 illegal reductions in fares of passengers in a private car furnished for W. B. Miller, secretary of the Diamond Rubber Company, of Akron, Ohio, and seven friends, for a trip from Akron to Beverly, Mass. The indictment charges that on July 2, 1912, the trip was made and that instead of charging 25 full fares for the car, as provided in the tariff, Mr. Underwood and the indicted railroads let Mr. Miller and his friends have the private car for eight fares.

Delivered Shipment—Destruction By Fire

The Nebraska Supreme Court holds that when a railroad company has transported freight to destination, has notified the consignee of arrival, and given him permission to unload; and the consignee has broken the seal, locking the door with his own lock, and retained the key, and later a fire occurs in the car, the company is not liable, and it is error for the court to submit to the jury the question of liability, negligence being neither alleged nor shown. McEntire v. Chicago, R. I. & P. (Neb.), 152 N. W., 305.

Lightning Stroke—Workmen's Compensation Acts

A railroad track laborer was killed by a stroke of lightning while he was in a barn in which he had taken refuge from a storm at the direction of his foreman. The Michigan Supreme Court holds that his death did not result from an "injury arising out of and in the course of his employment," since there was nothing in his employment that rendered him particularly liable to lightning strokes. There could, therefore, be no recovery for his death under the Workmen's Compensation Act. This is in line with rulings in similar cases by the English and Wisconsin courts under like statutory provisions. Except in cases where the employment necessarily placed the employee at the time of his injury in a position subjecting him to unusual risk from lightning, compensation has been denied. Klawinski v. Lake Shore & M. S. (Mich.), 152 N. W., 213.

Railway Officers

Executive, Financial, Legal and Accounting

J. L. Lancaster, president of the Memphis Union Station Company, Memphis, Tenn., has been appointed assistant to the vice-president and general manager of the Texas & Pacific, with headquarters at New Orleans, La.

Edward A. Haid, assistant general attorney of the St. Louis Southwestern, has been appointed general attorney, with headquarters at St. Louis, Mo. Samuel H. West has resigned as general solicitor and the office has been abolished.

W. S. Trowbridge, assistant auditor of the Boston & Albany at Boston, Mass., has been appointed auditor, with headquarters at Boston, succeeding W. A. Cormier, who has been assigned to other duties at his own request. W. J. Turck, auditor of freight accounts at Boston, has been appointed assistant auditor, with headquarters at Boston, succeeding Mr. Trowbridge, and Christian Petersen has been appointed auditor of freight accounts, succeeding Mr. Turck, effective June 1.

W. R. Holt, paymaster of the Boston & Albany Railroad at Boston, Mass., has been appointed cashier, succeeding Frank H. Ratcliffe, who has retired as cashier under the pension rules of the New York Central. Mr. Ratcliffe is 70 years old and has been in the continuous service of the Boston & Albany and its predecessors for more than 50 years. He remains as treasurer of the Boston & Albany Railroad Company, with headquarters at Boston, Mass.

C. O. Jenks, general manager of the Spokane, Portland & Seattle at Portland, Ore., has been elected also a member of the board of directors and vice-president and general manager of the Spokane & Inland Empire, succeeding W. D. Scott, deceased. He has been elected also vice-president and general manager of the Pacific & Eastern, with jurisdiction over the operating, mechanical and purchasing departments, succeeding William Gerig, resigned, and vice-president of the Oregon Electric.

Operating

W. R. Armstrong, assistant general manager and chief engineer of the Salt Lake & Utah at Salt Lake City, Utah, has been appointed general manager and chief engineer.

Traffic

Arthur T. Jackson has been appointed district passenger agent of the Union Pacific System, with headquarters at Los Angeles, Cal. Mr. Jackson will take his new position on June 1.

H. H. Taylor, commercial agent of the Texas & Pacific at Kansas City, Mo., has been transferred to Chicago, succeeding James Stuart, transferred to Texas. P. B. Doddridge, commercial agent at Denver, Colo., has been transferred to Kansas City, succeeding Mr. Taylor. A. T. Pratt, commercial agent at Birmingham, Ala., has been transferred to Denver, succeeding Mr. Doddridge. O. E. Duggan, traveling freight agent at Chicago, has been appointed commercial agent at Birmingham, Ala., succeeding Mr. Pratt.

Engineering and Rolling Stock

P. H. McFadden has been appointed roadmaster of the First district, of the Oregon-Washington Railroad & Navigation Company, with headquarters at Spokane, Wash., vice J. Mohr, assigned to other duties.

J. A. Mitchell, locomotive foreman of the Grand Trunk Pacific at Biggar, Sask., has been appointed general foreman at the Transcona, Man., shops, and A. McTavish, locomotive inspector at Transcona, has been appointed locomotive foreman at Biggar.

OBITUARY

John Sullivan, roadmaster of the Chicago, Burlington & Quincy, at Galesburg, Ill., died at Galesburg on May 20, at the age of 73 years. He had been employed by the Burlington for 58 years, starting in 1857 as a section hand, and had been road-

master of a single main line division, the Aurora division, since 1869.

H. E. Howard, formerly and for many years an officer of the Connecticut River and later of its successor, the Boston & Maine, died at his home in Springfield, Mass., May 24, at the age of 77. He was general freight agent of the Connecticut River from 1870 until 1891, when he was promoted to the position of general traffic manager of the company, including its northern connections. In 1893, on the lease of the road to the Boston & Maine, he was made superintendent, and a year later became superintendent of car service for the Boston & Maine System. He held this position until 1908, when he retired from railroad service.

General Thomas H. Hubbard, chairman of the executive committee of the Toledo, St. Louis & Western, whose death on May 19, at his home in New York, was noted in these columns last week, was born at Hallowell, Me., on December 20, 1838. He graduated from Bowdoin College, attended Albany Law School, and was admitted to the bar in 1860. He served with distinction in the civil war, and subsequently became a prominent railroad corporation lawyer in New York. He was vice-president and a director of the Southern Pacific from 1896, to 1900; president of the Mexican International from 1897, to 1901, also of the Houston & Texas Central from 1894, to 1901, and later served as president of the Guatemala Central, director and chairman of the executive committee of the Chicago & Alton, and the Toledo, St. Louis & Western, and also of the American Light & Traction Company. He had been a director and member of the executive committee of the Wabash Railroad, and the Western Union Telegraph Company, also a director of the Philippine Railway Company and of a number of other corporations. A few days before his death he again became a director of the Southern Pacific. He was a trustee of Bowdoin College and made it large gifts.

T. H. Hubbard

Coal in Germany.—Reports from the Rhenish-Westphalian coal-mining district state that it has not been possible to increase the production of coal to any material extent. Extra shifts do not counteract the effect of calling up further instalments of skilled hands. Under these circumstances, it has caused considerable satisfaction that the Department for War, after negotiations with leading coal-mining circles, has decided to allow a fair number of the miners thus called up to return on leave for some fixed time, so as to effect an increase in the production. This step will, it is stated, be taken promptly, and hopes are expressed that the much-longed-for increase in the production will then ensue. In spite of the rise of prices, which came into operation on April 1, there seems to be no falling-off in the demand, rather the contrary. The advent of warmer weather is not expected to make any difference in this respect. The large stocks at the Upper Rhine, and although in South Germany, are almost exhausted, which circumstance, coupled with the uncertainty as to a possible rise in prices from September 1, is likely to produce an active market during the summer. The increased demand for coke, which may now amount to about half the allotment figure, is attributed to the continued increase in the activity of the iron industry. A number of blast-furnaces and other iron industries have recently again been set going, which, of course, means a greater demand for coke. The negotiations about the renewal of the Rhenish-Westphalian Coal Syndicate have led to the acceptance of a draft agreement by the majority of all mines.—*Engineering.*

Equipment and Supplies

LOCOMOTIVE BUILDING

The Havana Central is in the market for 6 Consolidation type locomotives.

The Roby & Northern, Roby, Tex., is inquiring for a number of locomotives.

The Texas & Pacific is in the market for 10 switching and 6 freight locomotives.

The New York, Ontario & Western is in the market for 12 Santa Fe type locomotives.

The Wilmington, Brunswick & Southern is reported to have ordered 1 locomotive from the Georgia Car & Locomotive Company.

Fort Worth & Denver City.—The orders for locomotives and cars reported in the *Railway Age Gazette* of May 14 as having been placed by this company with the Baldwin Locomotive Works and the Haskell & Barker Car Company, respectively, should not have been reported as new orders. These locomotives and cars were but parts of orders placed by the Chicago, Burlington & Quincy, reported in the issues of February 26 and March 12.

CAR BUILDING

Fort Worth & Denver City. See item under Locomotive Building.

The Roby & Northern, Roby, Tex., is inquiring for a number of cars.

The New York, Ontario & Western will build 20 caboose cars in its own shops.

The Norfolk & Western is reported to be contemplating the purchase of 1,000 box cars.

The Detroit, Toledo & Ironton is in the market for 200 40-ft. 40-ton steel underframe box cars.

The Northern Pacific is in the market for 750 center sill structures and 1,500 sets of draft sills.

The Long Island has ordered 100 steel underframe box (X1) cars from the Pressed Steel Car Company.

The Chesapeake & Ohio has ordered 700 steel underframe 30-ton box cars from the Central Locomotive and Car Works.

The Havana Central is inquiring for 500 20-ton and 50 30-ton flat cars, 100 30-ton box cars and 10 30-ton caboose cars.

The Wilmington, Brunswick & Southern is reported to have ordered 5 cars from the Georgia Car & Locomotive Company.

The Western Maryland's inquiry for passenger cars includes 4 baggage cars, 8 coaches, 2 cafe-parlor observation cars and 1 parlor-buffet car.

The Lehigh Valley will repair 2,000 box cars and has divided the work between the American Car & Foundry Company and the Standard Steel Car Company.

The Russian Government is negotiating with the Pullman Company for the purchase of 40,000 freight cars. These cars, if purchased, will be built according to American standards except as to gage, couplings and wheels. The gage will be the broad gage of the Russian railways and the couplings and wheels will also be according to Russian standards. This order may be closed this week.

The Pennsylvania Lines have placed orders for 189 passenger cars as follows: Pressed Steel Car Company, 47, including 10 coaches (P70), 8 combination passenger and baggage cars (PB70) and 5 baggage cars (B74a) for the Lines East, and 14 coaches (P79), 4 combination passenger and baggage cars

(PB70) and 6 dining cars (D78) for the Lines West; Standard Steel Car Company, 39, including 20 coaches (P70) and 12 combination cars (PB70) for the Lines East and 7 baggage cars (B60a) for the Lines West; American Car & Foundry Company, 20 coaches (P70) for the Lines East; J. G. Brill Company, 15 baggage cars (B60) for the Lines East; Pullman Company, 12 baggage and mail cars (BM70e) for the Lines West, and the Altoona shops, 56, including 14 passenger, baggage and mail cars and 42 baggage and mail cars for the Lines East. The order is thus divided 146 cars for the Lines East and 43 for the Lines West. With the completion of these cars the Pennsylvania System will have in the passenger service on its lines 3,823 all-steel cars, 593 of this number being all-steel Pullman cars. The Pennsylvania began substituting steel cars for wooden equipment in 1906, when it was announced that in the future all passenger cars built or ordered would be of all-steel construction. The total number of passenger cars on the system at the present time is 6,869, so that when the cars that have just been ordered have been delivered, more than half of all the passenger equipment used on all of the 11,991 miles of railroad of the system, will be of all-steel construction. This number, 3,283 cars, is almost one-third of all the steel passenger cars in the United States.

IRON AND STEEL

The Baltimore & Ohio has ordered 1,800 tons of rails from the Illinois Steel Company.

The Missouri, Kansas & Texas has ordered 1,200 tons of steel from the Illinois Steel Company.

The Southern Pacific has ordered 25,000 tons of rails from the United States Steel Corporation.

The Chicago & Alton is reported to have ordered 8,000 tons of rails from the Illinois Steel Company.

The Cleveland Railway Company has ordered 1,100 tons of open-hearth steel rails from the Algoma Steel Company.

The Lehigh Valley has ordered 1,500 tons of steel from the Lackawanna Steel Company for the new terminal at Buffalo.

The Boston & Maine has ordered 1,200 tons of steel from the American Bridge Company for a bridge near Greenfield, Mass.

The Russian Government is reported to have ordered 12,000 tons of rails from the United States Steel Corporation, supposedly for use on the Chinese Eastern.

The Pennsylvania Railroad has ordered 1,850 tons of bridge material, 1,100 tons from the McClintic-Marshall Company, and 750 tons from the Fort Pitt Bridge Works.

The Dallas Union Terminal Company has ordered 181 tons of steel for one 152-ft. highway span at Commerce street, Dallas, Tex., from the American Bridge Company.

The New York Central has ordered 15,500 tons of rails from the Illinois Steel Company. Of this order 5,500 tons will be for the Michigan Central, 8,500 tons for the Cleveland, Cincinnati, Chicago & St. Louis and 1,500 tons for the Cincinnati Northern.

The New York Public Service Commission, First district, will receive bids until June 11, for 2,500 tons of rails and corresponding quantities of ties, spikes and other track equipment materials for use on the New Utrecht avenue elevated railroad in Brooklyn, a branch of the Fourth avenue subway.

The Berlin Surface Railways.—The effect of the European war was not felt on the Berlin surface railways until the autumn of 1914, but the annual report of the Grosse Berliner Strassenbahn for last year shows that losses in traffic on account of the war and of additional rapid transit and omnibus competition led to a reduction in dividends from 8 per cent in 1913 to 6 per cent in 1914. During mobilization there was a feverish increase in travel, but in August the loss as compared with 1913 was 13 per cent, and by December it had increased to 15 per cent. The mobilization of 15 per cent of the operating staff made it necessary to reduce service 25 per cent until the 5,000 employees could be replaced. Service on certain parallel lines was reduced or eliminated, while on the active lines trailers were increased, headways were lengthened and schedule speed was raised.

Supply Trade News

M. E. Duncan, vice-president of the Canadian Car & Foundry Company, and formerly of the American Car & Foundry Company, died in Montreal on May 23.

The Laconia Car Company, Laconia, New Hampshire, is working on a contract for shrapnel for the Russian government, sublet to it by the Canadian Car & Foundry Company.

George H. Russel, vice-president and founder of the Russel Wheel & Foundry Company, Detroit, Mich., of which he was president until 1906, died on May 17 at his home in Detroit, Mich.

F. C. Severin, formerly salesman for the Niles-Bement-Pond Company, Inc., at Birmingham, Ala., has been transferred to the New York office, and his territory will cover a portion of New York state.

The Industrial Works, Bay City, Mich., have established as their Pacific coast agents, N. B. Livermore & Co., of San Francisco and Los Angeles, Cal., and the Northwestern Equipment Company of Seattle, Wash., and Portland, Ore.

The United States Cast Iron Pipe & Foundry Company, Burlington, N. J., will open a new office in Kansas City, Mo., at 1404 R. A. Long building, about June 1. The new office will be in charge of R. C. Clifford, formerly of the St. Louis office of the company.

C. B. Yardley, Jr., at present eastern railroad representative of the William C. Robinson & Son Company, Baltimore, Md., with office at New York, will on June 1 become manager of the railway department of the Lubricating Metal Company, 2 Rector street, New York. Mr. Yardley was for a time manager of the railway department of the United States Metal Products Company, and previous to that was for several years railroad representative of Jenkins Brothers, New York. Mr. Yardley is a prominent member of the Railway Supply Manufacturers' Association. In 1912-1913 he served as chairman of the enrollment committee of that organization, and at present is chairman of its badge committee. He has also served as secretary and treasurer of the Railway Materials Association which is associated with the Railway Storekeepers' Association, and in May, 1914, was elected president of that organization.

C. B Yardley, Jr.

The operation of the plant of the Continental Car & Equipment Company at Highland Park, Louisville, Ky., which was shut down when the company went into bankruptcy, will be resumed by the Continental Car Company, which has been incorporated with $40,000 capital stock by A. H. McKinley and others.

The Hyman-Michaels Company has established a well equipped plant in the St. Louis district for the manufacture of scrap iron, having installed a number of shears, an acetylene cutting apparatus and a contrivance for sorting, cutting and testing materials. It has also installed a rail plant for handling new and relaying rails.

Bruce V. Crandall, who has been secretary of the National Railway Appliances Association since July 1, 1911, has resigned, effective on May 31. At a meeting of the board of directors on May 21, C. W. Kelly, of the Kelly-Derby Com-

pany, Chicago, treasurer and director of exhibits of the association, was elected secretary for Mr. Crandall's unexpired term.

The plan of reorganization for the Barney & Smith Car Company, announced May 24, contemplates the organization of a new company under the laws of Ohio with a capitalization as follows: First mortgage five per cent bonds $2,000,000; seven per cent cumulative preferred stock $1,500,000 and common stock $2,000,000; total $5,500,000. The present capitalization has the same amount of bonds and common stock, but also includes $2,500,000 of eight per cent cumulative preferred. The present preferred stock will be exchanged for new common in the ratio of four shares of new common for ten shares of old preferred. The present common stock will be exchanged for new common stock in the ratio of one of new common for ten shares of old common. Of the new preferred, $1,250,000 will be offered to present preferred stockholders at par in proportion to their holdings, one share of new to two shares of old, such preferred to carry with it 40 per cent of new common. The remainder of the new preferred stock will be offered to present common shareholders at par in proportion to their holdings, one share of new preferred to eight shares of old common, such preferred to carry with it 40 per cent of new common. Non-dividend bearing scrip will be issued for fractional shares of preferred and common, exchangeable for shares when presented in amounts of one or more shares of the respective kinds of stock. The committee reserves the right to dispose stock not taken by present stockholders. The committee for the common stockholders will bid for the plant for the sole benefit of stockholders who deposit their stock and assent to this plan. Any money accruing, as the result of a sale to stockholders who enter into this agreement, will not be distributed in cash, but will be applied as a subscription to new preferred stock.

Westinghouse Electric & Manufacturing Company

The Westinghouse Electric & Manufacturing Company and its subsidiary companies in the United States in the fiscal year ended March 31, 1915, had gross earnings of $33,671,485 as compared with $43,733,646 in 1914. Its cost of sales was $31,109,073, so that the net manufacturing profits were $2,562,412. There was also other income of $1,158,527, leaving a gross income from all sources of $3,720,939, as compared with $5,998,078 in 1914. The net income applicable to interest and other charges was $3,278,662. The interest charges totaled $1,268,918, a considerable reduction from the $1,706,005 of 1914, and the net income available for dividends and other purposes was $2,009,744, as against $4,058,809 in the previous year.

The value of unfilled orders on March 31, 1915, was $8,951,410, as compared with $7,951,785 on March 31, 1914. The average number of employees during the year was 15,145, as compared with 18,635 during the previous year.

During the year the company exchanged 85 per cent of the issued capital stock of the Westinghouse Machine Company for the common stock of the Westinghouse Electric & Manufacturing Company on the basis of one share of the latter for three shares of the Machine Company. In the same period the capital stock of the Societe Anonyme Westinghouse (the French company) was sold to the British Westinghouse Electric & Manufacturing Company, Ltd., and payment was received in other securities. The British company now owns the controlling interest in the French company, and through the latter the controlling interest in the Italian company.

On March 31, 1915, the company had total current assets of $18,626,776, of which $8,855,280 was cash and $6,657,731 was accounts receivable. The current liabilities on the same date were $3,704,102, including $2,270,038 accounts payable. The company's liabilities also include $2,720,000 of collateral notes, $4,500,000 of such notes having been retired on maturity in the course of the year. The company's surplus at the close of the fiscal year was $7,473,412.

Canal Extension in Bombay.—The Marquess of Crewe has sanctioned the Gokak canal extension in Bombay as a protective irrigation work.

Railway Rates in Spain.—A syndicate of Spanish railway bondholders and bankers is working to prevent proposed reductions in freight rates.

Railway Construction

Atchison, Topeka & Santa Fe.—This company has purchased the Oil Belt Terminal Railway from Jennings to Oilton, Okla., and the Cushing Traction Company from Cushing to Pemeta. It will build a line connecting Pemeta and Oilton, and also a branch from Pemeta to Drumright. When it is completed it will give the Santa Fe a direct line from Jennings to Cushing. The grading contract has been awarded to Michael Dougherty, Guthrie, Okla. The track will be laid by company forces.

Brooklyn Marginal Railroad.—See an item in General News in regard to this proposed line along the east shore of New York bay in the borough of Brooklyn, New York City.

Chicago, Burlington & Quincy.—Work is now under way on the short section between Wendover, Wyo., and Guernsey, to connect the C. B. & Q. line from the junction with the Northern Pacific near Billings with the company's Nebraska lines. (January 29, p. 211.)

Intercolonial.—Residents of Guysborough and Antigonishe counties, Nova Scotia, are asking for the construction of an extension of the Intercolonial from Sunnybrae east to Eden Lake, thence southeast to Country Harbour and northeast following the valley of the Salmon river to Guysborough, thence around the head of Chedabucto bay and following the shore of the Strait of Canso to Port Mulgrave, where the line will again connect with the Intercolonial.

Musgraves-Merrill Shipment Company.—This company proposes to construct a railroad from Fort Davis, Tex., to Marfa, 18 miles. We are advised that contracts will be awarded as soon as the company obtains the deed to the right of way. B. Q. Musgraves, Fort Davis, Tex., is president, and H. A. Hardaway, Deming, N. M., is chief engineer.

New York Connecting.—Bids are wanted until June 7, by A. C. Shand, chief engineer, Southern division, Broad street station, Philadelphia, Pa., for the construction of the grading and masonry of a portion of Section 2, of the New York Connecting Railroad, extending from a point near Bowery Bay road to the south side of Fremont street, in the borough of Queens, New York, about 4.21 miles.

Nevada Short Line.—This company has just started construction on a 12 to 14 mile extension from Nenzel station on the Southern Pacific to the gold and silver mines at Rochester, Nev. The contract for grading and track laying has been awarded to Ottoman & Duprey, San Francisco, Cal. There will be five timber bridges, about 460 ft. in all, and will be built by the railway company. Depots and sheds will also be built.

New York Subways.—Bids for the construction of Section No. 2, of the Gravesend avenue elevated railroad were opened recently by the New York Public Service Commission, First district, and the contract probably will be awarded soon. This section extends from Bay Parkway to avenue X. The Oscar Daniels Co., was the lowest bidder, and offered to do the work for $863,775.

The commission is having plans made for the construction of the Utica avenue subway, in the borough of Brooklyn. This will be a branch of the Eastern Parkway subway, and is to be constructed from Eastern parkway down Utica avenue to Flatbush avenue.

A new route for an elevated line to be built through Westchester avenue, to connect the Bronx Park branch of the existing subway at Simpson street with the proposed Pelham Bay Park branch of the Lexington avenue subway, in the borough of the Bronx, has been adopted by the commission.

Savannah, Piedmont & Western.—This company, which was incorporated recently in South Carolina has preliminary surveys made and the right of way secured, it is said, for the line to be built from a point on the Savannah river at or near North Augusta in Schultz township, Aiken county, north to a point in Saluda county, thence northwest to Greenwood, about 60 miles.

J. Peyton Clark, New York; S. H. McGhee and K. Baker, Greenwood, S. C., are incorporators. (April 2, p. 768.)

Tucson, Cornelia & Gila Bend.—Bids are being asked for until June 10, to build a railway from Gila Bend, Ariz., south to Ajo, about 42 miles. The company expects to develop a traffic in oil, sulphuric acid, ore, concentrates and copper. L. D. Ricketts, president, Warren, Ariz., and R. H. Jones, chief engineer of construction, Gila Bend.

Wisconsin & Northern.—This company will extend its line from a point just north of Van Ostrand, Wis., north to Crandon, a distance of 29 miles. The contract for grading and timber culverts has been awarded to Peter Nelson & Co., Minneapolis, Minn. The track will be laid by company forces. The Wisconsin Bridge & Iron Company, Milwaukee, Wis., has been awarded the contract for a 307-ft. steel bridge over the Wolf river, just north of Van Ostrand.

RAILWAY STRUCTURES

Algiers, La.—Morgan's Louisiana & Texas Railroad & Steamship Company will construct new shop buildings and probably install some new tools and equipment at this place. The tools and equipment have not yet been definitely determined.

Anderson, S. C.—The Piedmont & Northern has given a contract to the Fiske-Carter Construction Company, Greenville, S. C., to rebuild the freight house at Anderson which was damaged by fire.

Bessemer, Ala.—The Railroad Commission of Alabama has directed the Louisville & Nashville to build a new brick and stone station in Bessemer, it is said, to cost about $30,000, and the Alabama Great Southern to build a station to cost $25,000.

Kinnickinnick, Wis.—The Chicago & North Western contemplates building a 1,000,000-bu., reinforced concrete grain elevator at this point.

Montezuma, Ind.—The Cincinnati, Hamilton & Dayton has asked for bids on a bridge to be built over the Wabash river at this place. It will be a 150-ft. open floor through riveted truss steel span designed for Cooper's E-50 loading. There will be one pier and one masonry abutment.

Sidney, Ohio.—The Cincinnati, Hamilton & Dayton has asked for bids on a bridge to be built over Fair avenue at Sidney. It will be a 79-ft. deck plate girder span designed for Cooper's E-50 loading. It will have two masonry abutments.

Trenton, N. J.—An officer of the Pennsylvania Railroad writes regarding the report that the company will build a new bridge over the Delaware & Raritan canal at Trenton, that the company has submitted a tentative plan to the city for the construction of a structure similar to the bridges already built over the canal. No conclusion has yet been reached as to the location or design of the bridge.

The Pennsylvania Railroad has given a contract to the American Dredging Company for dredging the channel of the Delaware river to a depth of 12 ft. for about three-quarters of a mile, in connection with the new bridge at Trenton. This will involve the dredging of about 92,000 cu. yd. of material.

Troy, Ohio.—The Cincinnati, Hamilton & Dayton has asked for bids on a bridge to be built over a highway, the Miami & Erie canal and the Hydraulic canal, consisting of one 30-foot I-beam span, one through plate girder span 79 ft. long, one deck plate girder span 38 ft. long, two deck plate girder spans 51 ft. long and one deck plate girder span 45 ft. long. It will also have five piers and two masonry abutments.

Van Ostrand, Wis.—See Wisconsin & Northern under Railway Construction.

Walla Walla, Wash.—The Oregon-Washington Railroad & Navigation Company will build a one-story, 10-stall roundhouse at this place. It will have brick walls, mill interior and concrete pits. The approximate cost will be about $25,000. Moore Brothers, Portland, Ore., have been awarded the contract and have just started the work.

Wilkinsburg, Pa.—The Pennsylvania Railroad has given a contract to Irwin & Leighton, Philadelphia, for building a new station at Wilkinsburg.

Railway Financial News

Boston & Maine.—The bill before the Massachusetts legislature providing for the reorganization of this company has been passed in the House by a large majority and is now believed to be in such shape that its final passage by both houses is assured. On the last day of debate the status of the Hampden railroad was discussed at length, but the law was finally so shaped as to allow the absorption of this road by the B. & M. provided the consent of the Public Service Commission shall be secured; which, however, must not be given until after notice and a public hearing; and the commission must find that the proposed acquirement of the Hampden will be in the interest of the public, will be just and equitable as between the two contracting corporations and is to be made for a consideration not exceeding the reasonable and proper cost incurred in the construction of the Hampden Railroad as determined by the Public Service Commission in its report made December 24, 1913.

The law provides that the new company must earn as well as pay 5 per cent dividends before its securities can be accepted as proper investments for savings banks.

Chesapeake & Ohio.—The directors, at their meeting on May 21, took no action in the question of a dividend, the announcement being made at the close of the meeting that a decision would be made at the regular meeting on June 17.

International & Great Northern.—Judge Burns in the United States district court at Houston, Tex., May 17, handed down a decree ordering the sale of this road at Houston on some day subsequent to August 1 next. The Master to conduct the sale is yet to be named.

Missouri Pacific.—The executors of the Gould estate, holding $6,000,000 of the three-year six per cent notes of this company, have agreed to an extension of the notes for one year. It is said that all holders of these notes receive in return for this concession a cash payment of $5 on each one thousand dollar note. It is said that the holders of a large majority of all of the notes—$25,000,000—have agreed to the extension of time.

New York New Haven & Hartford.—Judge William H. Hunt in the United States District Court at New York City has set October 25 as the day for the trial of twelve directors and former directors of the New Haven road in the long pending suit of the government charging conspiracy, in violation of the anti-trust law, in the consolidation and purchase of certain railroads, and other acts done by the board of directors in past years. The defendants are: Lewis Cass Ledyard, Charles F. Brooker, D. Newton Barney, Robert W. Taft, James S. Hemingway, Charles M. Pratt, A. Heaton Robertson, Frederick F. Brewster, Henry K. McHarg, Edward D. Robbins, Alexander Cochrane and John L. Billard. Immunity was granted recently by Judge Hunt to William Skinner and James S. Elton, but the government is appealing from Judge Hunt's decision in this regard. Judge Hunt also granted a separate collective trial to William Rockefeller, George F. Baker, T. De Witt Cuyler, Theodore N. Vail, Edward Milligan and Francis T. Maxwell.

Pere Marquette.—At Detroit, May 24, Judge Tuttle fixed October 1 as the date for the sale of the road, unless some satisfactory reorganization plan is submitted at once. He intimated in reply to the objection of consolidated bondholders that they would have a chance at the hearing on the petition to submit a plan for reorganization as the only alternative. The formal conditions of the sale will be announced June 7 and the receivers will file a petition asking for the disposal of the property for the purpose of paying its debts. Claims against the system which have been recorded in court actions and at various investigations amount to more than $88,000,000. Underlying bondholders, in their petition asking for the sale of the road, guaranteed to bid a sufficient amount of money to clear away the equipment indebtedness as well as their own claims.

The Conference on Valuation

The conference on the valuation of railways, called by Director of Valuation Prouty, and held at Washington last week, was the most important meeting to consider this subject ever held.* It was so important because of the leading character of the questions specifically discussed, because of the large and able representation of the railways and of the states present, and because of the magnitude of the general undertaking to which the conference related. The ultimate success of the valuation work will depend largely on the degree of co-operation obtained between the Interstate Commerce Commission, the railways, the state governments and commercial and banking interests, the latter of which may later awaken to a realization of the extent to which they may be affected. The participation of the railways in the conference was notable not only by reason of the large and able representation of the legal, engineering and accounting departments, but also by reason of the careful preparation of their case, which was evinced, and by the harmony of view manifested in presenting it. It is well known that there are differences of opinion between individual railway men on the subject of valuation, but the railway managers have recognized the expediency of harmonizing their differences and presenting a united front on all the larger issues. The ideal way to carry on the valuation would be to get all the parties concerned to agree on the fundamental principles involved and on the methods that should be used. This is doubtless impracticable, but the course adopted by Director Prouty of bringing representatives together for thorough but somewhat informal conferences of this kind, will tend to reduce the number of points of difference, to simplify and expedite the work and to keep down the expense of doing it.

Accidents to Long and Short Trains

Legislation to limit the length of freight trains is being advocated by the labor brotherhoods as a means of reducing railway accidents. It has been pointed out in reply to this that a reduction in the length of trains would cause an increase in the number of them run, and that the statistics of the Interstate Commerce Commission show that almost invariably an increase in the number of trains run results in increase of accidents, and a decrease in the number of trains run results in a decrease of accidents. This answer to the argument for train limit legislation seems strong enough, but it is interesting to find that statistics show further that on the whole there are more accidents to short freight trains than to long ones. The Illinois railways have compiled statistics which demonstrate that on 23 of the principal steam railroads in that state which operate trains of 50 cars or over, the chance of death or injury to railroad employees was 37 per cent greater in 1913 on trains of 50 cars or less, than on longer trains. These 23 roads in that year operated in Illinois 236,702 trains of over 50 cars, on which 23 employees were killed or injured for every 3,430 trains run. The same roads ran 413,510 trains of 50 cars or less, on which 43 employees were killed and 149 seriously injured, or one to every 2,154 trains run. On the longer trains one man was killed for every 10,291 trains run and one was injured for every 5,145; whereas on the shorter trains one was killed for every 9,616 trains and one injured for every 2,775. Probably the main reason for the greater proportionate number of accidents in connection with the operation of short trains is due to the fact that they ordinarily are run faster. The Kansas railways also have found that there are more accidents to short than to long trains in that state.

The New Haven Bill Vetoed

Governor Walsh of Massachusetts has vetoed the two bills which had been passed by the Massachusetts legislature after conferences with the state public service commission, which it was believed would have made possible a readjustment of the New Haven's financial affairs and the reorganization of the Boston & Maine, at least insofar as Massachusetts is concerned. Some of the comments of Governor Walsh accompanying the veto are published in the financial columns of this issue. The gist of the governor's objections seemed to be that the bill would legalize something which had hitherto been illegal and make it possible for the New Haven at some future date to get out of the clutches of Massachusetts. Regardless of the merits of the charge which the governor makes that the legislature changed in certain very essential ways the two bills at the last moment and without the approval of the railway commission, the whole situation is deplorable. It illustrates in a striking way the evils of state regulation of railroads. Openly and shamelessly the three states principally concerned in the Boston & Maine tangle have

squabbled over local questions. New Hampshire had already passed adversely on a bill similar to the Massachusetts Boston & Maine bill because its interests were not sufficiently "taken care of." On the other hand, both Connecticumt and Rhode Island, which are concerned in the New Haven financial readjustment, have approved bills which would grant the relief aimed at by the Massachusetts-New Haven bill. The Boston Transcript, after the New Haven and Boston & Maine bills had been passed by the two houses of the Massachusetts legislature, and before the governor had acted on them, said:

> With all too little assistance from the governor, who has appeared both confused and vacillating with regard to the whole railroad situation, the legislature has solved its railroad problems in conference and in co-operation with the public service commission. . . . President Elliott of the New Haven and President Hustis and the trustees of the Boston & Maine were freely consulted and showed at all times a realization of their responsibilities to the public as well as to their respective parties.

As has been pointed out before in these columns, the Massachusetts law which did not permit the sale of stock except at the market quotations by making financing through stock issues wholly unattractive, has been as potent as any other one factor in bringing about the present Boston & Maine situation. Now when the whole New England railroad situation is in a most critical state, sectional jealousies, local and selfish interests, and political prejudice are allowed to have a predominating part in the state regulation of the New England railroads.

DEPRECIATION AND RAILROAD CREDIT

THERE is published elsewhere in this issue an article by Morrell W. Gaines, characterizing the commission's rules for charging for depreciation and retirements of equipment as a threatened "billion dollar confiscation." The article brings out in a very interesting way one side of this question of a charge to operating expenses for depreciation concurrently with a charge to operating expenses and to profit and loss for the original cost of the equipment retired. The point is made that this new requirement of the commission, which permits only so much of the original cost of a unit of equipment to be charged against accrued depreciation as has been accrued on that particular unit, and requires that the remainder, less scrap value, be charged in part to expenses and in part to profit and loss, while at the same time a charge must be made to expenses for depreciation of equipment, puts a double burden on the present generation of railroad securityholders that is entirely unwarranted. This fact can hardly be disputed. The commission may argue that if all railroad companies had on July 1, 1907, accepted the theory of depreciation, and thereafter made an adequate charge to expenses for depreciation, there would be now no undue burdening of the expense accounts through charges for retirements, and that the charge to profit and loss was sound accounting, tending in the long run to make the books show accurately the cost of assets and the earning power of the property. The fact remains, however, that the commission's theories of depreciation were a matter on which there could be an honest difference of opinion and that the majority of the roads did not accept these theories on July 1, 1907.

The credit of a railroad company is one of its assets, and if it were a fact that through arbitrary rules enforced by the Interstate Commerce Commission the credit of railroads were seriously detracted from, it would be entirely proper to call this confiscation. On the other hand, if the commission's rules call for a degree of publicity and a form of statement of what is, however stated, an actual fact, it is hardly fair or accurate to call this confiscation, even if it temporarily hurts the credit of some railroads.

The position of each individual railroad is a separate case which presents individual problems. The Interstate Commerce Commission has not as yet fixed a rate of depreciation which is mandatory. It is to be hoped that at least for a number of years the commission will not fix such a rate. The fixing of a rate for depreciation and the charging of depreciation is the distribution of a business risk, but it is also guessing. If the management of a railroad property, familiar with the physical condition of its equipment and its policy in regard to repairs and renewals, guesses at what the rate of depreciation—in practice generally a rate of obsolescence rather than depreciation—will be, the guess may be somewhere near the mark. If the Interstate Commerce Commission were to make a guess for the whole country and then make this guess mandatory, it would in a great number of instances be dangerously wide of the mark and might also work very real and serious harm to some railroad companies.

The situation appears to be this: The commission's theories about depreciation and charges for retirements are in general sound. Any number of individual instances may be cited where the facts would fail entirely to conform to the theory; but this does not vitiate the general soundness of the rules for charging depreciation. If rates are to be fixed with regard to the value of the property, and if the commission is inclined to permit such rates as will yield a fair return on the value of the property, the sooner an accurate method of stating cost of property and an estimate of its yearly depreciation is adopted the better. Co-operation between individual railroad companies and the Interstate Commerce Commission should, if the commission takes a broad point of view and the railroad managements a helpful attitude, minimize the hardship that will be worked on present securityholders. If this attitude of co-operation is adopted and the commission does not arbitrarily fix a rate of depreciation, but continues to make a study of the subject with the aid of the railroad managements, it would seem that the situation ought to work out to the ultimate good of the railroads.

TURN BACK THE CLOCK!

THERE are some people who think that the development of modern transportation has contributed more than anything else to the promotion of the economic welfare of the public. There are others who think that the development of modern transportation has been a crime against the public welfare and ought to be stopped.

The latter class are advocating the passage in Illinois and other states of a law to limit the length of railway freight trains. They could not advocate any measure which would more effectively and completely destroy the principal economies that already have been introduced in railway transportation and prevent the introduction of any more. From the time such a law went into effect all substantial reductions in the cost of railway operation would cease, and, if increases in wages continued, enormous and unprecedented advances in the cost of transportation would begin. For the handling of traffic in larger and larger units has been the most characteristic feature of modern transportation on both water and land; it has been the only thing which has enabled the railway companies to stand the heavy increases in wages and other expenses in recent years without proportionate increases in rates; and if the increase in the size of transportation units is to be stopped there can be no further substantial increases in wages and improvement in working conditions without proportionate increases in transportation costs and transportation rates. The attitude of those advocating this legislation is, "Turn back the clock. Transportation progress must stop. Human welfare demands it. The increase in the size of freight trains saves labor and thereby prevents as many men being employed as otherwise would be employed."

But let us be consistent. If we are to stop progress in railway transportation in the purported interest of labor, let us stop it in all other lines of transportation.

Goods are now being hauled on the highways in five-ton motor trucks. This is all wrong. It causes unemployment of horses and men. A law ought to be passed to prohibit the use of motor trucks. More horses and men would be required to handle the

traffic in four-horse wagons. Better still, let us go back to two-horse wagons. Or, better yet, let us go back to the two-wheel cart drawn by one ox. That was ideal highway transportation. On the precious theory of the "50-car bill" advocates transportation on highways exclusively in one-ox two-wheel carts gave the maximum amount of remunerative employment to labor.

Turn back the clock! In the name of human welfare, restore to us our ox-cart transportation!

So with water transportation. The tendency on the great lakes and the oceans is to handle traffic in larger and larger steamships. The purpose of this is to save labor and other expenses. This is all wrong. A law should be passed to limit and reduce the size of steamships. Better still, let us prohibit steamships entirely. It requires more human labor to carry a given amount of freight in sailing vessels than in steamships. But the ideal toward which we should work is a return to the exclusive use of those ancient vessels known as galleys, which were propelled by slaves chained to the oars. They afforded the maximum employment to human labor in proportion to the amount of traffic handled.

Turn back the clock!

And while we are legislating regarding the length of freight trains, why make their maximum 50 cars? Why not make it 25 cars? That would be twice as beneficent. Why not make it 12 cars? Or, why not provide that a train shall consist of an engine, one freight car and a caboose? Think of the men who would be given employment then!

Why has not one of the innumerable inspired jackasses who busy themselves in framing labor legislation rendered himself immortal by drafting a law to require all water transportation to be conducted in flat-bottomed skiffs and all land transportation to be conducted in wheel-barrows?

RAILROADS IN THE HANDS OF RECEIVERS

THE total mileage of railroads of the United States in the hands of receivers is at present almost exactly the same as the total on June 30, 1896, which was the highest ever recorded in the history of the country. Of course the proportion of mileage in the hands of receivers to total mileage operated is much less than it was in 1896, because of the very much larger mileage now operated.

The comparison is rather startling, however, because on June 30, 1896, the railroad situation was distinctly on the mend. Most of the larger roads then in the hands of receivers were practically already out of the woods. On the other hand, at present not a single one of the important large systems being operated by receivers is out of the woods. It is true that the Wabash has announced a reorganization plan, and although it is drastic and has been underwritten, the company will have to show materially better earnings than it did last year to insure the eventual success of the plan.

At present there is approximately 30,500 miles of railroad in the hands of receivers. The total mileage in the hands of receivers on June 30, 1896, was 30,475. The total par value of securities outstanding of roads being operated by receivers in 1896 was $1,795,900,000. The par value of securities outstanding for the roads now being operated by receivers is approximately $1,815,900,000. The fact that the capitalization of the roads now in the hands of receivers compares so favorably with the capitalization of the roads being operated by receivers in 1896 is apparently a coincidence, although, of course, it might be possible to point out some general truths which this fact probably illustrates. The Philadelphia & Reading, which was in the hands of receivers in 1896, had outstanding securities per mile much in excess of the road's power to earn a return on them. The same is true with the Wabash at present. The larger systems which are now in the hands of receivers are the Chicago, Rock Island & Pacific, with 8,328 miles of road; the St. Louis & San Francisco, with 4,747 miles of road; the Wabash, with 2,514 miles of road; the Pere Marquette, with 2,322 miles of road; the Chicago & Eastern Illinois, with 1,282 miles of road; the International & Great Northern, with 1,106 miles of road, and the Cincinnati, Hamilton & Dayton, with 1,015 miles of road. The principal roads that were in the hands of receivers in 1896 were the Northern Pacific, with 4,533 miles of road; the Union Pacific, with 1,836 miles of road, and its subsidiaries having an additional mileage of approximately 5,900 miles; subsidiaries of the Atchison, Topeka, & Santa Fe, with approximately 2,000 miles; the Baltimore & Ohio, with 2,073 miles; the Norfolk & Western, with 1,571 miles, and the Philadelphia & Reading, with 884 miles.

A study of the table which the *Railway Age Gazette* publishes in its annual review number, giving a record of roads thrown into receiverships since 1876, apparently indicates a very different situation at present than in 1896. The large mileage of roads that were still in the hands of receivers on June 30, 1896, was accounted for principally by the receiverships established in 1892 and 1893, in which two years there was a total of 39,848 miles of road which became insolvent. In 1896 itself only 5,441 miles of road was put into the hands of receivers, and in the previous year but 4,089 miles of road. On the other hand, the present large mileage is accounted for by roads that have gone into receiverships comparatively recently. The Rock Island receivership dates back but a few weeks. The mileage of roads that became bankrupt in 1914 was 4,222; in 1913, however, 9,020. With the exception of 1908, in which year the Seaboard Air Line and the International & Great Northern were turned over to receivers, there was no year in which as much as 4,000 miles of road became insolvent back to 1896. The Seaboard Air Line has been taken out of the hands of receivers since 1908, and the International & Great Northern was taken out, but had to again seek the protection of the courts at the outbreak of the European war.

The ten years following 1896 were years of unparalleled prosperity in the United States. They were, moreover, years in which a very large investment was made in American railroad securities by European investors. By June 30, 1896, the return of prosperity, at least insofar as the bankrupt railroads were concerned, was well in sight. The Atchison, Topeka & Santa Fe had been taken out of receivership in December, 1895, and this might be called the real turning point in the railroad situation. The Northern Pacific was taken out before the end of 1896, as were also the Union Pacific and the Norfolk & Western. The Baltimore & Ohio was reorganized without foreclosure sale in 1899. In 1896 no one of the large roads in the hands of receivers was in what might be called at all a hopeless situation. At present the Pere Marquette, the Western Pacific and the Atlanta, Birmingham & Atlantic have little, if any, immediate prospect of reorganization, and the St. Louis & San Francisco and the Cincinnati, Hamilton & Dayton quite probably cannot be reorganized at least until after the end of the European war. The Chicago, Rock Island & Pacific may have only a very short receivership. The conflicting interests connected with the property apparently hold such divergent views at present that any opinion that might be ventured as to when the property would be reorganized would be the purest guesswork.

One more black touch to the picture and we are done with it. There are two or three large systems which have just scraped off the rocks of receivership through a temporary extension of obligations falling due, and whether or not their mileage shall be added to the 30,500 miles of road now under the protection in the courts will depend largely on the business situation in the next six to nine months.

Of course the railroad situation taken as a whole is by no means as gloomy as one might suppose from looking only at the facts presented above in regard to receiverships. On the other hand, it is only right that railroad men as well as the Interstate Commerce Commission should face squarely the unpleasant facts as well as the hopeful features of the situation.

Letters to the Editor

THE UNIVERSAL HOME ROUTE CARD

Chicago, Ill.

To the Editor of the Railway Age Gazette:

The intelligent use of the universal home route card will pay a big return on the investment—so big, in fact, that if the attention of the chief operating officers can be secured long enough to make the matter clear, they will do the rest. Unfortunately, opposition is developing in unexpected places and differences have already arisen regarding points which must be uniformly understood if the plan is to accomplish its reasonable measure of usefulness.

It is the object of this letter to help to bring about this common understanding.

Our present plan of handling surplus foreign equipment involves a vast amount of telegraphing, much work in divisional and card record offices, switching to and from hold tracks, much unnecessary mileage, unknown amounts exchanged as per diem and more hazard of accident from defective equipment than is generally recognized.

The objective of the universal home route card is to have with the car at all times a complete junction record for use in effecting prompt and economical home routing.

The requisites are a supply of cards, stamps and ink-pads, plus the conscientious stamping of the cards for foreign cars received in interchange and the careful handling of all cards as per instructions. The returns to be secured are:

1. A great reduction in empty car mileage, with a corresponding saving in train miles.
2. Abolition of most of the disposition telegraphing.
3. Elimination of interference with the work of record clerks.
4. A substantial saving in switching.
5. Reduced wear and tear of equipment as per items one and four with proportionate reduction in repair expense.
6. Earlier return of surplus equipment to owners and in better order, making possible earlier restoration to serviceable condition.

That these are not visionary claims will be evident upon analysis. For example, does any one familiar with the matter doubt that if the elimination of that part of the cost of repairing freight cars properly chargeable to empty car movements which can be avoided by the intelligent use of the universal home route card were all there is to gain, it would still be one of the best opportunities yet offered for reducing operating expenses?

It is undoubtedly true that there are many difficulties to be overcome in the practical operation of the plan, but as some of our largest and most important lines are already operating successfully under system cards it is reasonable to conclude that the difficulties are not insurmountable, and surely even a low percentage of the theoretical efficiency would warrant the trouble and expense involved.

In the article on this subject which appears on page 884 of the *Railway Age Gazette* of April 23 occurs the following: "The proposed rule will require that the short route be used where it can be done without creating empty mileage in excess of the original loaded haul."

This statement, based on A. R. A. Circular 1525, I regret to say, is correct.

It may be, and probably is, true that at the present time it is impossible to go further, but it is also true that the entire plan rests on the principle of reciprocity and that much of its possible benefit will be lost unless each road's policy is broad and statesmanlike, including the making of additional empty mileage on its own rails with any car on which a substantial net saving can be made on other lines.

E. H. DeGroot, Jr.,
Superintendent of Transportation, Chicago & Eastern Illinois.

RIPLEY ON RAILROADS: FINANCE AND ORGANIZATION

London, Eng.

To the Editor of the Railway Age Gazette:

In common, I doubt not, with every other student of railroad affairs, I have read Professor Ripley's new book, "Railroads: Finance and Organization,"* with the utmost interest. To praise it is, I feel, almost an impertinence. We are accustomed by now to Professor Ripley's wide knowledge of facts, his capacity of mastering them and his keen-sighted criticism. We take it for granted that these qualities will be displayed in whatever proceeds from his pen. And in this case we are not disappointed.

And yet for my own part I am constrained to wonder whether there is not a good deal of truth in the old proverb that "lookers on often see most of the game." Certainly I cannot myself draw from the facts that Professor Ripley records the conclusion that he does. He, as I understand him, concludes that because there have been failures, mistakes, scandals and frauds in the history of American railways, therefore public authority must interfere with strict and detailed regulations to prevent the possibility of such occurrences in the future. My answer, on the other hand, if I were asked to advise the public authority, would be in the famous words of Lord Melbourne, "Can't you leave it alone?"

If I have a fault to find with Professor Ripley as a historian, it is that he tells us too much about the one sinner and forgets to mention the ninety and nine just persons who need no repentance. We hear much of Jim Fisk and Jay Gould, of the Alton, 'Frisco and New Haven scandals, but not one word of the constructive work of men like Roberts and Cassatt, of the Pennsylvania; of Charles P. Clark, of the New Haven; of Samuel Spencer and William Finlay, of the Southern. Even James J. Hill appears, not as the one man more responsible than any other for the building up of the Northwest, but either as the hero of the Northern Securities fight, or else as the fairy godmother of his fortunate shareholders. With Professor Ripley's summing up of his own conclusions no railway man, jealous of the honor of his profession, could reasonably quarrel. Speaking of construction methods, after a whole chapter of what he himself describes as "rather depressing comment," he writes as follows:

> The magnitude of the achievement, as a whole, must constantly be kept in mind. To have opened up a continent to settlement within the short space of seventy years is an accomplishment unparalleled in history. The creation of the greatest railway net in the world, practically within two generations, in spite of all the obstacles opposed by nature and the limitation of capital resources, should be a matter of national pride.

And again, summing up his chapter on speculation, which he describes as "but a sorry tale at best . . . embracing a range of operations from mystification and petty deceit to utter fraud," he continues:

> But the conclusion must be carefully avoided that, because such offences have at times been committed, American railroad finance on the whole is unsound. Such an opinion would be absolutely unfounded. A large majority of our common carriers are certainly on the whole as honestly administered as are private businesses. Nor has the integrity in the main ever been so high as it is at present.

We may then cite the evidence of Professor Ripley, and there is no more competent witness, as proving that probity and good judgment and honest administration have always been the rule; that the departures from this standard have always been few, and are now fewer than ever. The case for that state interference and minute regulation by public authorities which Professor Ripley pleads for seems hardly made out on his own facts. Indeed to an Englishman it is not clear why, because Jim Fisk robbed the Erie, railroads should be regulated. The essence of that matter is not railroading but robbery. And robbery should be regu-

*Reviewed in these columns in last week's issue.

lated not by commissioners and ministers, but by policemen and jailers. In this oldfashioned country of ours we deal with criminals of the Jim Fisk order by putting them personally in prison, and by making their estates liable in a civil action to the defrauded shareholders.

But one may go further. Before we start regulating railroad directors and officers, we surely ought to satisfy ourselves that the regulators possess the qualities which the regulatees lack. We must postulate that the personnel of legislatures, courts and commissions is superior to railroad personnel not only in intelligence and knowledge, but in honesty and impartiality. This is a subject that Professor Ripley does not discuss. He does mention that as early as 1858 the public authorities of Wisconsin were bribed as follows: Members of the senate, $175,000; members of the assembly, $355,000; clerks, $16,000; governors, $50,000. And, unlike the railroad men whose standard of integrity Professor Ripley tells us has never been so high as at present, legislators do not seem to have improved since, for on page 472 he speaks of "wholesale bribery of members of the legislature, of the press and of influential citizens" as occurring in Massachusetts within the last few years. Dishonesty of a different kind is charged by Professor Ripley against the legislature of Texas: "The conclusion is unavoidable that [owing to the Texas laws] people resident in other states have furnished Texas with transportation for which it does not pay." This dishonesty of course may not be deliberate, it may be merely stupid and untintelligent. Still it is proverbially better to deal with a knave than a fool. But presumably we may take it for granted that sheer dishonesty is infrequent; that even legislatures are imitating the railroad men and getting better. What about fairmindedness and impartiality? Shall we cite the postmaster general of the United States, or the chairman of the Iowa railroad commission as the more ideal type of the impartial regulator? As for intelligence and knowledge the case is even more patent. Nobody would claim that the members of railroad commissions know as much about the railroad business as the railroad men themselves. Would anyone claim that they were their equals in intelligence and general business capacity? If they are, why are they anxious to secure and retain appointments carrying a compensation that not merely presidents and vice-presidents, but even division superintendents and freight agents would decline to accept?

I can imagine Professor Ripley and others who share his views replying to the argument put forward above somewhat as follows: "Let us admit that in integrity and intelligence the personnel of the regulators does not surpass the personnel of the regulatees; and further that in special expert knowledge they are actually inferior. Still the regulators look at matters brought before them from a wider point of view. They take into consideration the interest of the whole community. The railroads naturally regard their own interests only." My answer would be, "Look at the facts." No one will doubt that regulation in the United States is seen at its best in the work of the Interstate Commerce Commission. No one will deny that to the disentangling of tremendously complicated issues, such as, for instance, the inter-mountain rates they have brought much patient toil and hard and clear thinking. No one will dispute that they have redressed very many grievances, not a few quite serious. But, tried by the crucial test of their action on the rates advance case last July, does one business man in a hundred doubt their lamentable failure to face a really big issue in a large way? Can it be doubted that it was the railway men who asked an increase, and not the commission who refused it who more truly represented the public interest? And does anyone doubt that the error of judgment of the Interstate Commerce Commission has cost not the railroads but the American public, millions upon millions of dollars?"

My fundamental difference with Professor Ripley is therefore that he has taken for granted that strict and detailed regulation from outside is in the public interest. He has not proved it. I do not believe that under American conditions it can be proved. Indeed I know no country where it can. Publicity by all means, and the more of it the better; and power to interfere drastically in case of "scandals." But of interference in matters not of morality or of certainty, but of business instinct, the less the better.

I have discussed fundamentals at such length that I have left no room to deal with individual points. But I will just mention two. Is Professor Ripley sure that the decision of the Interstate Commerce Commission, even though upheld by the Supreme Court, requiring the Kansas City Southern to write off out of income the capital cost of road abandonment on re-alinement, is right from a business point of view? Suppose that a railroad makes a tunnel and then, as has often happened in England, finding that the smoke and steam of the tunnel makes operations dangerous, converts it into an open cutting, must it write off out of income so much of the cost of tunnel construction as represents its excess over the cost of the number of cubic yards of open cutting which now replaces it? Or, again, supposing a railroad constructs a long trestle over a valley, and subsequently fills in with a solid embankment, ought the timber and construction cost of the trestle to be written off out of capital? It may be prudent—all writing down of capital is prudent in a sense—but is it not a mere question of business management? Is it essential for honest accounting? And, if not, should it be peremptorily imposed *ab extra?*. Is there in principle any difference between these two cases and the case of the Kansas Southern?

I am disappointed with Professor Ripley's treatment of physical valuation, which seems to me academic rather than practical. I agree that valuation was desirable, were it only to get rid once for all of what Professor Ripley frankly calls the "hoary headed bogey of over capitalization." But he assumes that it can be used as a standard against which to measure reasonable rates. How used, he does not tell us. If all the railroads of the United States were consolidated into one system, I could understand it, though even then outside competition not only of water carriage between United States points, but of Argentina and India and Siberia with the United States in the world's markets would cause some awkward puzzles. But how a reasonable rate, equal by all roads from New York to Chicago is to be connected up with the widely divergent valuations of the dozen different routes that at present compete for the traffic, I am at a loss to conceive. The problem lies so close to the surface that I am quite sure that it cannot have escaped Professor Ripley's attention. I wish he had tackled it.

Another question I think he ought to have tackled. Describing the issue of a stock dividend to the Connecticut River Railroad in 1893, Professor Ripley apparently endorses the description of the transaction by the governor of the state as "unconscionable." He adds in a note: "A lease in 1913 of the Northern Central to the Pennsylvania Railroad with a stock dividend of 40 per cent and a cash dividend of 10 per cent would appear to be a close parallel. This was long contested." It was. It was put forward by the Pennsylvania Railroad, whose financial integrity Professor Ripley does not question. It was contested, if I mistake not, before the commission of the state of Maryland and the courts. And, having run the gauntlet of full publicity and criticism, it was sanctioned. If it was "unconscionable," as Professor Ripley appears to imply, surely he ought to give his reasons, and not condemn it with a mere *ex cathedra* judgment.

Let me conclude by once more heartily thanking Professor Ripley for his book. If some of us cannot agree with him in his fundamental idea, he has at least done us the great service of compelling us to face the facts and search our own minds to see whether we can find there justification for the faith that is in us.

W. M. Acworth.

Douglas Fir Ties in England.—Considerable shipments of Douglas fir railway ties from the Pacific coast have been made to England. It is stated that one English firm placed an order for twenty million feet.

Fundamental Problems Involved in Railway Valuation

A Report of the Conference Held Last Week to Discuss the Important Questions Proposed by Director Prouty

Over 200 representatives of the engineering, legal and accounting departments of the railways and about 30 state railway commissioners met with Director Prouty of the Interstate Commerce Commission Department of Valuation and his staff at Washintgon on Thursday, May 27, for a three-day conference and discussion of some of the important problems now confronting the federal work. To conserve time the views of the carriers were presented by representatives of the President's Conference Committee under the general direction of Thomas W. Hulme, general secretary. The states were represented by a committee of the National Association of Railway Commissioners, M. Maltbie, formerly a member of the New York Public Service Commission, First district, chairman. The conference was limited closely to a discussion of questions presented by the director in a circular issued February 4, 1915. These questions and an abstract of the replies made by the representatives of the carriers and of the states follows:

The form and manner in which the report shall be presented to the commission by the valuation division and by the commission to Congress.

(a) What detail should be furnished Congress for the use of itself and the public?

(b) What detail should be served upon carriers and state commissions and other interested parties by the commission in order that the conclusions of the report may be properly checked up and verified?

(c) How should the report be prepared, to the end that it may be kept up to date by the federal commission and also by state commissions, if desired? Shall the valuation section used in federal and state valuation be the same?

While this question was not included in the revised program for the conference, it was discussed by George F. Patterson, counsel, eastern group, Presidents' Conference Committee, on behalf of the carriers. He quoted those sections of the valuation act outlining the form and manner in which the report is required to be presented by the department of valuation to the Interstate Commerce Commission and through it to Congress. He maintained that if the report to Congress is to be evidentiary to the subsequent proceedings under the Interstate Commerce Act, the detailed records in the commission's office must be so connected by record reference or order that all the information obtained by the commission can be produced in any proceedings. The final report to Congress must contain not only the final value of the property reported on, but all the facts and elements of values upon which the final figures are determined, so that if necessary the court can ascertain for itself the fair final value.

Secretary Hulme discussed the last part of the question, recommending the report on the New Orleans, Texas & Mexico as an example of the detail which should be shown in the final report. In reply to a question by Director Prouty he stated that it was the belief of the carriers that the information required by the commission's valuation order No. 3 with reference to additions, betterments and deletions was all that would be serviceable in keeping the inventories of the quantities up to date. He emphasized the fact that the prices applied to the original valuation would change from time to time so that the value of the property as a whole at any later date must be ascertained in the same manner as the commission is now making its valuation.

In determining "cost of reproduction new," to what extent should reference be had to conditions as they existed at the time of the original construction?

In determining the "cost of reproduction new," E. Holbrook, consulting engineer, Union Pacific, divided the construction of a road into four periods; the promotion, organization, assembling and development, all of which must be considered in reproducing a property. A carefully considered program of construction work must be prepared in the light of the best and most economical methods of the present day. He illustrated this by describing the "reconstruction new" of the Union Pacific today. As over 11,000,000 tons of ballast would be required for this road, all of which would be secured from a point west of Cheyenne, Wyo., it would be advisable to start the reconstruction of this road at the connection with the Colorado & Southern at Cheyenne and build both ways from this point. Work would also be started westward from Omaha and Kansas City. In reply to a question from Director Prouty, Mr. Holbrook stated that while a road could be placed in operation before it was able to operate at a profit, it must receive compensation in some other way if an attempt was made to secure the lowest cost of reproduction. He emphasized the necessity of studying each problem separately, and also urged consideration of the large amount necessarily spent for temporary structures in the building of a new line to hasten the work, citing the building of the timber bridges and the line over the summit of the Cascade mountains on the Puget Sound extension of the St. Paul, all of which have since been replaced.

The answer to this question by the state commissions was made by M. Maltbie, that as a general principle the "cost of reproduction new" should be determined on the basis of present conditions. The discussion of this and the other questions by the state commissioners was in most cases confined to a brief explanation of their answers.

(a) Should an allowance be made for clearing and grubbing, and, if so, shall it be allowed where the road runs through what is now tillage land, but what was at the time of construction a forest?

H. C. Phillips, valuation engineer, Atchison, Topeka & Santa Fe, replied for the carriers that as clearing and grubbing are essentially grading items, if the records of the carriers show that such work was done, it should be allowed the same as other excavation, even though all evidences of the existence have disappeared.

Mr. Maltbie replied to this question for the state commissioners that clearing and grubbing should not be allowed if the adjacent land is now tillage land and is now valued as such, but that allowance should be made for grubbing if the adjacent land is cleared and not grubbed, basing his reply on the fact that he considered the problem to be one of ascertaining the cost of reproduction new and not the original cost or the fair value.

(b) The road runs through an orchard which did not exist at the time of original construction. In determining cost of reproduction new, shall the value of the land be determined with or without the trees?

E. Holbrook replied for the carriers that the value of the trees should be included in the damages paid, while the value of the land should be that of adjacent land used for orchard purposes. The reply of Mr. Maltbie was that the value of the land should be determined without any allowance for trees.

(c) A building was wrecked when the road was constructed Is the expense of wrecking to be included in the reproductive cost?

E. Holbrook replied for the carriers that it should be assumed that at least an equal number of buildings would be c property today, and that therefore the cost of wrecking buildings when the road was constructed should be included. The answer of the state commissioners was "no."

(d) Are present geological and topographical conditions to be taken, or is inquiry to be made as to what these conditions were at the time of original construction?

E. Holbrook stated that the geological conditions existing at the time of construction must still be considered to exist and that a rock cut originally is still a rock cut. In estimating the cost of reproduction, geographical and topographical conditions should be taken as of the time of original construction, except where they have been changed, due to mining or other conditions which create difficulties which would have to be met today.

The reply of the state commissioners was that present conditions should be taken.

(c) Should it be assumed that present transportation facilities are in effect, or must reference be had to such facilities as existed when the road was constructed?

Pierce Butler, counsel for the western group, Presidents' Conference Committee, outlined the position of the carriers that all roads now in existence shall be considered to be in existence other than those of the carrier under consideration. The representatives of the state agreed with this answer. Director Prouty asked Mr. Maltbie if a highway, the moving of which was made necessary by the construction of a railroad at its own expense, should be considered in its original or present location. Mr. Maltbie replied that it was necessary to consider present conditions, but that the valuation department should report such data as an aid in the determination of the fair final value.

Should the road be reproduced in the form and manner in which it was originally built?

(a) For example, gravel was brought from a considerable distance in point of fact, but a gravel bank is today available at much less cost. Shall the road be allowed the haul which was actually made?

(b) The rail originally laid was relay. In determining cost of reproduction new, should we apply the relay price or the price of new rail?

(c) The rail now in branch lines or sidings was originally laid new in the main track and taken from there to the branch or siding. Shall this be treated as new rail and priced and depreciated accordingly, or shall it be treated as relay rail when laid?

W. L. Seddon, assistant to the president, Seaboard Air Line, replied in behalf of the carriers that a road should be reproduced in the form, but not necessarily in the manner originally built, but that it should be built according to the present day modern methods, securing materials at the most economical places. Transportation facilities other than those of the carrier assumed to be under reproduction, should be considered to be in existence to bring construction material onto the property under consideration. Thus, if gravel and other material can be obtained today by more economical sources than originally, it should be so obtained.

Mr. Maltbie replied for the states that the form and manner in which the road was originally built has nothing to do with the cost to reproduce it new unless the original plan and manner were in accordance with present good practice. He agreed with the carriers that gravel should be secured from the nearest available source.

The reply of the carriers to the last two sections of this question was that the price of new rails should be used. Mr. Maltbie answered that relay prices should be used where the present rail is relay rail and the price new where the present rail was new when laid in its present position. His answer to the last section of the question was that the rail should be treated as relay rail at relay prices. The customary practice is to place relay rail on sidings when built and the "cost of reproduction new" should not consider the use of new rail in such track since it is not in accordance with good practice. In reply to a question by Director Prouty, Mr. Maltbie stated that relay rail should be considered as bought in the open market and that freight should be added. He stated that the fair value of such rail would probably be the same when using the relay price or the price of new rail depreciated.

What overhead charges should be allowed and in what amount? By overhead charges are meant items like engineering, contingencies, interest, taxes, etc. How shall the time necessary to reproduce the property be determined?

Pierce Butler outlined the position of the carriers that allowance should be made for all necessary overhead charges, such as organization expenses, financing, administration during construction, legal and engineering expenditures, and interest during construction. There should also be included a proper amount for material on hand and working capital. In considering this problem a property must be considered non-existent and a definite program of construction worked out.

Charles Hansel, consulting valuation engineer, Pennsylvania Railroad, discussed the overhead engineering charges. Previous to 1907 all engineering charges were not allocated so the records of the carriers do not show the complete cost of this item today. A study of the overhead engineering charges on 7,000 miles of line has recently been made. On 4,300 miles in the west the average cost for engineering, excluding charges allocated to land and equipment was 4.1 per cent of the expenditures. Similarly on 800 miles of line constructed in the east this charge was 5.79 per cent, while on 1,700 miles of line constructed in the south this figure was 4.4 per cent, including in this latter case engineering expenditures incurred in the acquisition of land. On the basis of these figures he recommended that in the estimated cost of reproduction the minimum to be allowed for engineering should be five per cent for road accounts, exclusive of land. Since it has been the general practice to add two per cent to equipment cost for engineering, he recommended that this figure be adopted for such accounts until a more accurate figure can be ascertained.

E. Holbrook outlined the position of the carriers regarding contingencies, calling attention to many ways in which an estimate of the cost of reproduction of the property will necessarily fail to include all the proper costs, such as those resulting from storms, personal injuries, delays of transportation, etc. He urged that the percentage for contingencies should be stated for each account rather than being applied to the whole, as this item can be determined closely for some accounts, while not as closely for others. Different percentages should also be applied to the same account on different roads because of the difference of the completeness of the records.

W. E. Bailey, general auditor, Atchison, Topeka & Santa Fe, discussed the subject of interest during construction in which he stated that at the beginning of any year prudent management required that an amount of money equal to the estimated expenditure for construction during that year should be available. While the interest rate would vary in different sections of the country according to local conditions and the hazards of the enterprise, a minimum rate of six per cent should be allowed, while in many cases seven per cent or even more would be necessary.

A. H. Plant, comptroller, Southern, asked that the carriers be given an allowance no greater than the actual expenses necessarily incurred in bringing about arrangements for the leasing of railroads of other companies and for arranging for traffic rights over other lines. He referred to systems made up of lines owned outright, those with trackage rights and those leased, stating that a considerable expenditure was required to join these into one system. Where lines are operated under lease, separate valuations are made for each of the constituent properties and none of these valuations will show this development expense.

Mr. Maltbie outlined the position of the state commissioners on the general subject of overhead charges, by stating that such charges should be allowed on the basis of the present normal cost of such items as determined by actual experience in railroad construction under similar conditions. Overhead charges should include engineering, contingencies, interest and taxes during construction on the above basis, but no separate allowance should be made if such charges were included in the unit prices of material or elsewhere. The normal method of constructing railroads in sections should be adopted as a basis for determining the period of construction. He called attention to the fact that the cost of engineering on equipment items is frequently included in the prices paid for equipment, and should not therefore be al-

lowed again. He opposed considering unusual conditions, such as earthquakes, those leading to the failure of the Quebec bridge, etc., in making allowances for contingencies. He also opposed allowing overhead charges for the consolidation of lines into a system because of the possibility of this leading to absurd results.

Shall allowance be made for appreciation; and if so, as to what parts of the property? Shall account be taken of solidification and adaptation; and, if so, shall this be by addition of a percentage to all grading quantities?

What allowance, if any, shall be made for shrink or swell in determining quantities as shown by actual measurement in present embankment, and shall this allowance be made by reference to local conditions or by some uniform per cent?

W. G. Brantley, counsel, Southern group, Presidents' Conference Committee, opened the discussion of this subject on behalf of the carriers, quoting numerous court decisions showing the necessity for including allowances for appreciation. H. C. Phillips pointed out the improvement in an old well-established line as compared with a new one, showing that the former is a more valuable transportation tool and that therefore an allowance for its appreciation should be made. He defined adaptation as an adjustment of the physical line to its environments and purposes. The value of a property, as outlined in the present valuation act, is not concerned with the source of the money or whether it is secured from capital account or operating revenues. Aside from the roadbed and ballast, appreciation is largely confined to drainage and the adjustment of the line to traffic conditions, all of which are necessary to the development of the property.

In the various valuations which have been made by the state no attempt has been made to deny the existence of this value, although it has not always been allowed because of the difficulty in its determination. He suggested an allowance of two per cent per year for five years on all earth and loose rock quantities, and one per cent per year for five years on solid rock, with an addition of $600 per mile to cover additional maintenance charges. While an allowance should be made for shrinkage, no uniform percentage can apply for materials vary greatly in this regard. Each item must be studied in accordance with its nature and the methods used in construction.

Mr. Maltbie replied for the states that no allowance should be made for solidification and adaptation beyond the charges actually and necessarily made to investment account. In reply to a question of Director Prouty, Mr. Maltbie admitted that the roadbed became better as it seasoned, but stated that as the road was permitted to charge depreciation to operating it was not unjust to refuse to allow appreciation. He opposed allowing it because he stated that it represents no sacrifice on the part of the investor.

How shall depreciation be determined?

(a) By mortality tables? If used, shall these be general or made with reference to the property of each carrier?

(b) By actual observation?

(c) By combination of these two methods? If by combination, what weight shall be attached to age and what to the observed condition?

(d) Should obsolescence and inadequacy be considered?

W. G. Brantley stated on behalf of the carriers that the period of time required for the construction of any large railroad property covered such a period of years that all of the parts could not be new upon the completion of construction, that a condition of absolute newness could never be ascertained and that upon the completion of the property the owners would have made an investment considerably greater than would be found by a detailed examination of the component parts as ascertained by the government engineer. Depreciation cannot be determined by any rule of thumb, but only by the exercise of mature judgment after learning all the facts.

Deterioration is a matter of record, but the question of whether this affects the value of a composite property is a matter of law. If a property is not neglected to a point affecting its operation he maintained that there is no depreciation in its value as a whole, or in the transportation machine, although there will exist deterioration of the individual parts. Depreciation should be determined by a careful study of the records of the particular carrier, followed by an actual inspection of the property, made by a joint inspection party composed of experts representing both the government and the carrier. A standard of operating condition appropriate for the particular portion of the property under valuation should be determined upon by a study of the conditions required to be met by such property. Depreciation should not be determined by general mortality tables, for such tables being tables of averages cannot be closely followed in dealing with a particular property. Neither the age alone, nor the observed condition alone of the particular property, nor both combined, should finally determine the amount of the depreciation. Due weight should be given to each of these factors, but there is also to be considered the conditions required to be met by the particular property and the probable length of useful service life remaining in the property as indicated by the records of the carrier. In ascertaining "cost of reproduction new" and "cost of reproduction less depreciation," under the Act, depreciation due to obsolescence and inadequacy, if any, should not be considered because it is the cost of reproducing that particular piece of property under consideration. In determining the value of the property as a whole, if there exists depreciation due to obsolescence and inadequacy actually affecting such value, the same may be considered.

This question was answered by the state commissioners as follows: Deferred maintenance, if any, should first be determined. The age to date of appraisal and its scrap value shall be ascertained. The expected life shall be determined after inspection, examination of records and consideration of all parts that affect the period of usefulness. The accrued depreciation shall then be ascertained by the ratio which the age to date bears to the total life applied to the cost, less scrap value. Deferred maintenance should be added to this amount.

Mr. Prouty asked Mr. Maltbie when deferred maintenance began, to which he replied that this is a question of maintenance which the engineers must determine from some accepted standards. Mr. Prouty also asked whether if one road had a high standard of maintenance and another a low standard, would the road with the low standard be considered to have deferred maintenance? Mr. Maltbie replied to this that a road with a considerable deferred maintenance may still be able to serve the public satisfactorily. Mr. Maltbie stated that it was the idea of the state commission that depreciation must be shown separately for each unit of property. If this was done, it would then be difficult not to show depreciation on the road as a whole. In the period of years immediately following the construction the depreciation fund is not set aside in a bank by the railroad, but is invested in additional property of the carriers. As an inventory will then include this new property as representing original investment he considered it fair to consider depreciation. He pointed out that expenditures for maintenance alone are not sufficient but that provision must be made for ultimate replacement, illustrating by the fact that it is not only necessary to paint a car but to provide for its ultimate replacement. In reply to a question by Mr. Staples of the valuation board, Mr. Maltbie stated that the same rule cannot be applied to different properties and that conditions vary widely. In considering depreciation due to inadequacy and obsolescence it was not possible to consider that this would be the same in the future as in the past, and that it should only be based on the judgment of present conditions and those now foreseen. Mr. Maltbie expressed the opinion that the deferred maintenance will not be found important on most roads in the final analysis as he believed they are generally well maintained.

How shall unit prices be determined? If for an average period, what shall that period be and shall it be the same for all railroads, no matter as of what date they are valued?

What allowance shall be made for the cost of transportation of men and materials over the line of the carrier itself while under construction?

G. W. Kittredge, chief engineer, New York Central, stated for the carriers that in order that the cost of reproduction new may be estimated by the same measure for all carriers it is necessary that the price bases for determining the costs of materials and labor shall be the same as to time for all carriers. As the date June 30, 1914, is being used for the roads now under valuation, he advocated the continued use of this date. Where prices of this date are normally high or low because of business conditions, average prices for a number of years, not less than five or more than ten, preceding June 30, 1914, should be used. In determining unit prices it must be considered that construction work is carried on throughout the year and climatic conditions therefore must be given due weight. On those portions of the system under which the construction program is assumed to be completed, allowance should be made for the cost of transportation of men and materials at tariff rates. On those portions of the line under construction the actual cost of such transportation should be allowed.

Mr. Maltbie replied for the states that unit prices should be determined by an examination of contracts, records of actual cost and other available information covering a number of roads in that part of the country where the valuation is being made. The average prices for a period of time shall be taken, such periods being so fixed as to secure normal prices. Transportation should be charged at the actual and necessary net cost to the carrier.

How should the "present value" of lands used for transportation purposes be determined?

Should the cost of acquiring the right of way at the present time be determined and stated as a part of the cost of reproduction new?

The act calls for "the present cost of condemnation and damages in excess of present value of lands." What is the meaning of this phrase and how shall the information called for be arrived at?

What is meant by "each piece of property" as used in the paragraph of the Valuation Act designated "First"?

What is meant by "terminals" as used in the paragraph designated "Second"?

In discussing the "present value" of land, Pierce Butler spoke at length of the attitude of the courts on this subject. He stated that the present value of each piece of land used for transportation purposes must be determined upon the same principles which govern in the case of condemnation of private property for public use. In reply to Director Prouty's statement that many roads were built long ago, Mr. Butler stated that no matter how or when the land was acquired, the same principles governed. In the consideration of right of way, station grounds, terminals, etc., the value of the whole is also greater than the sum of the values of the individual parcels comprising the same because the elements of continuity, shape, etc., must be considered.

Mr. Butler called attention to the fact that the Valuation Act was passed March 1, 1913, at a time when the arguments had been made in the Minnesota, Arkansas and Missouri rate cases, but before decisions had been rendered. At this time there was a wide difference of opinion regarding the land question, and Congress therefore required each piece of property to be listed with three values and other elements of value, if any, the purpose of the act being to require the commission to ascertain all the facts so that the data would be on hand to comply with any theory of valuation or rate making. He quoted at length from the decision of the Minnesota rate case and drew the conclusion that this decision did not consider the "fair market value" to be that value for other purpose but what a railroad was required to pay. He cited numerous other decisions showing that an owner is entitled to a "fair market value" of this land, taking into consideration every use for which it may be needed. The value of land is what it costs when purchased prudently.

Secretary Hulme replied, "Yes" to the second subdivision of this question on behalf of the carriers, outlining numerous ways in which the cost of the land is increased above normal acreage prices in large tracts. In reply to the third subdivision of the question he gave numerous figures of the cost of condemnation proceedings on different roads. When acquiring property for extensive second track work on the Norfolk & Western in 1912 and 1913, the average cost of condemnation proceedings was $175 with the awards varying from $25 to $200. In valuing property he called attention to the impossibility of establishing zones in cities and to the necessity of considering conditions as actually found on each piece of property.

The reply of the states as outlined by Mr. Maltbie was that the present value (as used in paragraph "second" of section 19-a of the Valuation Act) of land used for transportation purposes should be determined from the value of similar adjacent land. The answer to subdivision a was, Yes, and to subdivision b, that the phrase means, present, reasonable and necessary cost as shown by existing local conditions. Information should be secured by investigation. The answer to subdivision c, was, that the law contemplates the classification of property and appraisal of each class, due regard being had for large or peculiar units of property.

When are lands "owned or used" for common-carrier purposes? Should lands in any case be classified as held for common-carrier purposes unless they are actually so used?

When are lands "dedicated" to the public use?

Thomas Cooper spoke for the carriers in reply to this question, stating that land actually used for common carrier purposes should be valued as such irrespective of whether owned or not. Land owned and held for future common carrier purposes in anticipation of reasonable need therefor, should be valued as common carrier land, irrespective of whether now actually used or not. Land owned or held for purposes other than those of a common carrier should be valued under paragraph numbered "third." Lands are dedicated to public use within the meaning of this act when originally acquired for the purposes of a common carrier by the present or any predecessor common carrier but where the lands were acquired for other than the purposes of a common carrier the time of dedication to public use shall be taken to be the time when the intention was formed to hold the land for common carrier purposes.

Mr. Maltbie replied to this question that lands to be appraised as "owned or used" for common carrier purposes or dedicated to public use should be only land actually so used, and land needed for such use in the immediate future.

When original cost can not be shown from the books of the carrier, shall an estimate be made?

Secretary Hulme replied to this question that where records of original cost are incomplete, there is no use in making an estimate of the original cost, but that where carriers' records are complete an estimate of the original cost may be of use. A study of the records of the carriers shows that those of many roads have been destroyed by fire or lost.

Mr. Maltbie replied that since the original cost represents the sacrifice of the investors, the determination of this amount was exceedingly important. Director Prouty called his attention to the fact that the original cost and the actual investment may be widely different.

Should the value of equipment be apportioned between different states; and, if so, upon what basis shall the distribution be made?

Shall the value of a great terminal—like, for instance, the Pennsylvania passenger station in New York—be distributed; and, if so, upon what basis?

George F. Patterson replied to this question on behalf of the roads, calling attention to the fact that the Valuation Act provides that the value of the property as a whole and separately as to states and territories must be determined, and that the notes of the tentative valuations shall be given to the governor of any state. It is therefore necessary for the commission to divide the property between states. This is not a serious problem as far as lands and other real property are concerned. The situs of real estate is the state in which it is located. The value of terminal property such as that of the Pennsylvania in New

York should be allocated to the state in which it is situated. The same applies to personal property such as tools. With reference to movable property such as equipment, he outlined four methods for its distribution on the basis (1) equipment days, (2) ton miles, (3) miles of track, (4) car mileage. He recommended that equipment used only in one state or a few states, be assigned to those states, and that the balance be apportioned on the basis of locomotive or car miles. Work equipment could be assigned either on the basis of miles of line maintained or in proportion to the maintenance of way expenses. The car mileage should include both revenue and non-revenue and would also include privately owned equipment.

The committee of the states was in substantial agreement with this reply of the carriers except that they would exclude privately owned equipment. Mr. Patterson contended that in valuing the property the private cars bore the same relation to the road as those owned directly. He would not, however, value foreign cars where found.

Although not included in the revised program, Sanford Robinson, assistant counsel, Eastern group, Presidents' Conference Committee, presented the ideas of the carriers regarding the allowances to be made for going value, location value, earning capacity and other intangible values. He called attention to the Valuation Act requiring the inclusion of all values, and to the discussions on the floor of the Senate where the act was revised to include such values and all reference to the physical valuation alone was eliminated. He quoted from numerous court decisions showing the necessity for the inclusion of such values.

M. Atkinson, chairman, Missouri Public Service Commission, called the attention of Director Prouty to the demands in Missouri for the separation of the properties used for freight and passenger service, and asked that the commission consider the development of a formula to bring out this information. He stated that the valuation now being conducted by the Interstate Commerce Commission is of little value from this standpoint.

Mr. Maltbie asked on behalf of the states that where appraisals have been made by states, the division made in these valuations shall be followed by the Interstate Commerce Commission so that the data so obtained may be of use to the states. Mr. Hulme replied for the carriers that the roads have no objection to this in those states where the sections were determined by the convenience of the work, but that there might be objections where such sections were determined arbitrarily. The determination of valuation sections could be determined after a conference with the carriers.

As both the carriers and the states desire further time to prepare written briefs upon these various questions, Director Prouty gave the carriers to June 15, to file such briefs, and the states one week later to file their briefs and reply to the carriers.

A BILLION DOLLAR CONFISCATION

By Morrell Walker Gaines

In an age of economic vivisection the railroads have been the subjects for the chief experiments and the major operations. Rate theories, valuation processes, new ideas in finance and corrective principles in accounting and operation are being applied to them by powerful federal and state commissions. Their actual administration has been assumed by these bodies in such generous measure that the supremacy of authority over responsibility is now become barren and oppressive. Theory, as ordered and symmetrical as the Garden of Eden in the New England Primer, shoulders to one side experience, rough grown from the soil of struggle. It is a day of counsels of perfection, of control dependent on statute and free of natural law. The investment in railroads meets the common fate of barriers across the flow of governmental regulation. It is tossed about as if it were a toy, to be broken and mended at will.

One of the foremost of the regulatory abstractions, disdainful of evolutionary imperfections and yet itself powerless to produce life and growth, is the project of establishing a valuation of railroad properties. Upon the value when found there is to be decreed a fair and compensating return. It is a valorization downwards. In seeking value the Interstate Commerce Commission turns toward cost, availing itself of fragmentary history and arbitrary estimate. It is, and must be, unbiased by market price, which is the accepted valuation of railroad properties. The re-valuation is thus the application of a brand new acid test to securities. Where hitherto their place in the market has rested on earning power, it must come now to stand on assets, as marshaled and appraised by an extraneous agency, impatient of the existing order.

Valuation of the entire railroad system is still a dim and colossal project of the future. Ten years of field labor and the expenditure of fifty millions of dollars will, perhaps, bring the program to the beginning of the era of court decisions and of working results. But in the meantime the theory of valuation has permeated the Interstate Commerce Commission's accounting orders. The foot of the camel is within the tent of railroad management. The equipment depreciation regulations, as now prescribed, are a form of valuation accounting which strikes at both assets and earnings. They have resurrected from the past a deficiency of a billion dollars of value alleged to be lost, and charged it against the present, and have increased the operating expenses over a period of years, independently, in almost equal amount. These regulations impose a burden which translates itself to stocks and bonds, to construction and improvements, and is conducive to an increasing paralysis of development.

The spontaneity and freedom of railroad growth and adaptation, in other and more flourishing days, was due to a different conception of values, supported by a different method of accounting for equipment. On the whole, the cost of the railroads of the United States has been a speculation in transportation futures. They were financed and built for what they could earn. All value lay in the earning power and the construction and purchase of road and equipment was regarded as an initial outlay, or sunk investment, for the sake of the perpetual annuity from the traffic. Charges to property account showed what had been paid out and not what was coming in. If now a valuation is made that may deduct depreciation, losses and mistakes from the money, or securities, expended, and the income is then limited to a fair return upon this valuation, the case is so altered that there can be no more speculation in railroad construction in the free sense of the past. Few will have the temerity to venture the heavy investment involved in going long of transportation by building railways.

Until 1907 the railroads had, with the sanction and by the express command of the Interstate Commerce Commission, kept up their equipment by charging renewals to expenses, without creating funds or reserves for replacements in advance of the actual destruction. As the roads had been built, so were they operated. The quota of cars and locomotives was treated as incident to the general capital outlay for construction, and the cost was part of the investment sunk against future traffic. The income created by the aggregate expenditure should take care of all regularly recurring repairs, renewals and replacements due to use and age. To add to it by formal reserves would have been either to duplicate invested capital or to cut in two expected income. That this was a sound working theory is proved by the unusual vigor and rapid progress of the American transportation system, which attracted, and sustained, an investment of fifteen billion dollars from the financial markets of the world.

In 1907 the Interstate Commerce Commission issued the Third Revised Classification of Operating Expenses, requiring the railroads to charge to operating expenses each month, for depreciation, "a certain rate per cent" on the cost, or book or estimated value, of locomotives, passenger and freight cars, to be set up as a reserve. No percentage rate was officially prescribed. The depreciation reserve of 1907 could be used for replacements, for purchase of additional cars, or for retirement of car trusts. This was, at the beginning, a mild form of depreciation accounting, aimed at keeping the value of equipment up to the existing

level with greater uniformity than under the superseded renewals charges. It added no burden to expenses.

In 1909 a progressive change began under which it was sought to compel the railroads to maintain equipment at its original, or cost, value, and to throw the difference between that value and the normal, or used, value into the expense and the profit and loss accounts. At first it was ruled that the depreciation reserve could not be used for replacements, but that cars destroyed should be charged to it. In 1910, a year later, more complete regulations were issued providing that the reserves could not be used for any purpose at all, except, mite by mite, as the individual cars against which depreciation was accrued, came in course of time to be destroyed. Thus depreciation was changed from a pooled reserve, available for general equipment needs, to a unit reserve available only for the individual car and locomotive when worn out.

The regulations now finally in effect provide that depreciation must be accrued separately on each car and engine, month by month, and that each unit of equipment sold, destroyed or retired from service shall be credited to capital account, with the appropriate charges to materials account for salvage, to the depreciation reserve for the amount of depreciation already set up against that unit, to profit and loss for the estimated depreciation accrued prior to 1907, and to expenses (retirements) for whatever balance of original cost may remain after deducting the salvage and depreciation. The theory of these highly technical requirements was explained in 1912. "The replacement (depreciation) reserve is not to be closed out, and is not exhausted as long as the road is in operation. At all times it stands as the measure of depreciation."

It is necessary to state the depreciation regulations in order that discussion may not appear a mere vault from premise to conclusion. But it is not necessary to follow out in their entirety the complicated bookkeeping entries. The grounds for objection lie not so much in the narrowness of the concept and the tedious and costly detail of its application, as in the unsound principles upon which the orders are, quite logically, based. The regulations constitute a thrust at values in two different directions, the channels of attack being the profit and loss account and the operating expenses.

With respect to profit and loss the case is simple. Railroad equipment has cost, on a rough estimate deduced from the number of cars and engines owned, upwards of three billion dollars. The age of this equipment averages, probably, eleven to twelve years, or over 40 per cent of a term of natural life that may be taken, for purposes of calculation, as twenty-five years. By simple arithmetic the depreciation already accrued, on the percentage basis, amounts to upwards of one and one-quarter billions of dollars. Depreciation accrued prior to 1907 was one billion dollars, and this amount the regulations formally require the railroads to charge, gradually, to profit and loss surplus. The profit and loss surplus of the railroads of the United States amounted to $750,000,000 in 1907, and to $1,039,000,000 in 1910, when the order was promulgated, according to the report of the Interstate Commerce Commission itself. It is not, today, large enough to carry the burden which the new depreciation accounting has sought to impose on it.

The edge, but not the weight, is taken from the process of subtraction by the fact that it is to be spread out over the term of years during which equipment on hand in 1910 shall come, through age and wreck, to retirement. The commission and the railroads are alike hopeful that a new and larger surplus will have been created in this time to meet the brunt of the depletion with better grace than would be possible now. But, even in this view, a surplus is a commodity of varying distribution. Some roads have an abundance, others little. The difficulty is not only that the general margin of safety and profit built up in three generations of railroad operation is annulled, but that individual roads will be forced into deficits, if they follow the accounting through.

In principle the sums taken from accrued surpluses are profits earned in the years before 1907, profits earned and largely paid out in the form of dividends, ten, thirty or even fifty years ago. These profits and these distributed dividends are required to be paid back through depreciation by the stockholders of the present and the immediate future, although they had been properly made, and properly accounted for during the best part of a generation under rules devised by the Interstate Commerce Commission itself. The accounting for accrued depreciation is retroactive and, clearly, confiscatory.

With respect to expenses the case is more complex. The burden on expense, although a much more serious matter from the practical standpoint, has hardly been generally recognized or understood. Theoretically the current depreciation charged expenses is exactly equal to the annual cost of renewals, on a seasoned road, making good the perennial wastage of cars and locomotives in operation. The increase in expenses arises from the unit system of accruing the depreciation, which makes the roads carry a double burden of renewals and depreciation simultaneously, for an initial period of twenty to twenty-five years.

Each car has its separate reserve. That reserve takes, say twenty-five years, to fill, at the regular percentage rate, to the point where it is adequate to take care of the car against which it stands. It cannot be charged against for another car, or for any other purpose. Cars have a mortality from casualties that is a large share of their total death rate. Furthermore, they may become obsolete from various causes, and are in no sense close observers of the average term of life on which the depreciation is figured. Accordingly a very large number of cars will be retired before their respective depreciation reserves have been built up to the point of providing completely for their cost. The unprovided balance of cost must, under the rules, be charged expenses under the heading of retirements. The company's expenses are therefore increased because the aggregate of the depreciation charges is already, if correctly calculated, equal to the normal annual charge to cover cars destroyed.

Or, to state the case the other way about, a large share of the depreciation charge, for a period of twenty-five years, is an addition to the renewals expense that a railroad would have had to carry if it were maintaining its equipment under the old style of accounting, without depreciation. This increase in expense is not accompanied by any compensating increase in physical maintenance, but is an accounting requirement pure and simple.

Expenses are also increased in three other ways.

Cars of abnormally long life, if owned in 1907, should bring a burden similar to that pertaining to cars of short life. For, the commission has ruled that the charge to expenses for depreciation must be continued until the unit of equipment has been written down to the salvage value, although in the case of old cars much of the depreciation accrued prior to 1907. Thus in the end some considerable part of the heavy toll directed at profit and loss, for past depreciation prior to 1907, will be in fact transferred to the expense account, where it can be borne with greater difficulty.

During the years 1907 to 1914, a large number of roads made only a half-hearted and technical compliance with the depreciation instructions. They used a low percentage rate, insufficient to meet the theoretical requirement based on probable life. The deficiency of the reserves accrued in these seven years must also be made up through expenses, as the cars owned during that period come to be destroyed.

Finally, wherever profit and loss surpluses are exhausted, as a source of depreciation, there will be a tendency to use the expense account to fill the breach. Many conservative railroads are unwilling to draw upon profit and loss for this purpose and are actually charging the entire cost to expenses.

The factors dealt with by the depreciation regulations are of great magnitude. The sum of these four items, even on the assumption that they apply altogether to no more than 40 per cent in value of the aggregate equipment now owned, means an increase of expense that a billion dollars would hardly cover.

It is true that the increase in expenses is spread, in irregular

fashion, over a period of twenty-five years, after which time depreciation imposes no increase in expense. But this period is too short to make the burden equable and too long to allow the investment level of securities to escape its weight. The swelling of the expenses of an arbitrarily selected term of years over and above what is properly the expense of that period is unfortunate for security holders. The revenues applicable to interest and dividends are decreased, the outlook is darkened and the depreciation supercharge comes in the last analysis and to an exaggerated extent out of the present value of stocks and bonds.

As the depreciation reserves are accrued they must be credited to cost of equipment, or stand as an offset against that cost. That is to say, they are in effect deducted from the value of the equipment asset as it stands on the balance sheet, one of the objects of the whole accounting process being the establishment of what is considered by the commission to be a correct valuation for the equipment. When the process is completed, and the reserves are full, the books will, accordingly, indicate some ten per cent of their entire construction investment to have been returned to the railroads in the form of a depreciation reserve. Rates on traffic, if the commission's depreciation theory has the validity as a basis for transportation charges which one section of the railroad valuation law appears to assign to it, must yield a reasonable return upon the remaining 90 per cent only. This is a permanent effect, entirely distinct from the depletion of surplus and increase of expenses, and it is equivalent to another loss to security holders, whenever valuation shall assume effective control over rates, amounting to well over a billion dollars.

Influences of gradual depression act like slow poison. Their direct effect is not conspicuous, even if the general condition is deteriorating. The strong and vigorous throw off the influence, and the first signs of disaster are with the sick and enfeebled. Up to the present time no very great emphasis has been laid by the railroads on the depreciation accounting as one of the larger, among the many, burdens under which they have been approaching a condition of distress. This is especially true, because the wealthier roads do not object to padding their maintenance accounts by means of the depreciation surcharge, while others have hardly begun to make the full percentage compliance with the regulations. Nevertheless, the ultimate goal of the depreciation accounting has already been fully demonstrated, and especially in the case of financially embarrassed railroads.

A large system in the hands of receivers recently defaulted the interest on its underlying bonds, small issues whose protected position had made them absolutely secure in the eyes of investors. Upon the appearance of the annual report it developed that the amount required to pay this interest had been applied by the receivers, under direction of the court, to the depreciation charges. Including a similar accounting requirement in connection with abandoned property, the Interstate Commerce Commission had put two million dollars into expenses, and brought up the operating ratio to 106 per cent, the money so represented being diverted from the physical property instead of put into it, in so far as the unit system of reserves could accomplish this result. This is a somewhat onerous impost for a company in struggle to rehabilitate itself for reorganization. The defaults were of a type previously thought impossible, under any stress of circumstances, and they added a deeper shade to the discredit in which, especially in foreign markets, American railroad securities had come to be held.

Another of the larger systems proposed some time ago to readjust its finances. It had had no mortgage bonds or other salable securities upon which to raise money and, for this reason, its traffic facilities had become inadequate and outgrown and, in the endeavor to keep up its service, it had accumulated a large floating debt. In order to have a sound basis of fact upon which the readjusted corporation could ask of investors the new cash needed in rehabilitation, chartered public accountants were called in to verify, and restate, the books of account. This is the necessary procedure in reorganization. But the accountants insisted that the books of a reorganized company should write off at the outset the past depreciation on equipment which the regulations require living companies to write off gradually. It would not be proper for a new company to enter as an asset the loss of the old. The amount of the accrued depreciation was of sufficient magnitude to convert the corporate surplus into a heavy deficit. As there is no way of issuing securities against a deficit, naturally the financial readjustment became impossible.

Both of these instances are typical of what will happen on a larger and more general scale, if the depreciation regulations are to apply to the numerous companies now in difficulties or insolvent which must, at some time, be reorganized. In the past a bankrupt railroad has paid what it could; fixed interest obligations to the extent of the assured earning power, adjustment bonds and preferred stock to cover probable earnings after convalescence and recovery, and common stock against the hope of the more distant future. This was no more than honest to creditors, and at the same time it provided the only way of attracting liberal supplies of new capital for reconstruction and development. The chance of participating in the revived prosperity after reorganization has, in fact, been the mainstay of strength behind a very large proportion of American railroad securities. But the depreciation accounting cuts off this mainstay. If the theoretical loss on used equipment must be taken into account by corporations formed in reorganization, properties coming out from receivership must cut off their stock and scale down their bonds. Otherwise the liabilities will exceed the assets, and the securities become illegal. Theories of valuation, as applied to equipment depreciation, imply reorganizations of a drastic and circumscribed type, the disastrous effects of which will tend to taint the standing of railroad investments as a class.

The principle followed by the Interstate Commerce Commission in its depreciation regulations is simple, and rests logically upon the idea that railroad assets are subject to valuation as a basis for rates. Cars and locomotives wear out. They are therefore a wasting asset. The waste is continuous, and must be construed as an impairment of capital and of profits, to be balanced by reserves. From a purely abstract point of view this inventory theory of the commission has as much in its favor as the investment theory of the railroad builders, that the equipment in use should stand at cost.

But the results of the commission's idea are destructive. It replaces a vitally constructive principle. Furthermore, it is hardly just to wipe out surplus and overload current expenses for the sake of enforcing a change in methods of accounting. In fairness to railroads and to investors, the commission should offer some reasonable basis of reconciling the old accounts and the new, without burden and without confiscation. In this, as in other matters, it has greatly overestimated the margins of earnings, of solvency and of confidence, to be drawn upon before exhaustion.

The unit system of accruing and segregating the depreciation should be given up, the attempt to create reserves against the past abandoned, and the current reserves made directly available for renewals, replacements and additions. The Interstate Commerce Commission has recently recognized the financial needs of the railroads by granting increases in rates. It cannot consistently impose upon them, at the same time, increase in expenses, depletion of surpluses, and incidental repudiations in reorganization, by a retroactive and confiscatory form of depreciation accounting.

English Passengers Requested to Limit Amount of Baggage.—The Railway Executive Committee has issued an appeal to passengers to refrain from taking an excessive amount of luggage with them. The appeal is based on the grounds that the staff has been considerably depleted.

Norfolk & Western Elkhorn Grade Electrification

Mountain Grades Electrified; Speed of Trains Doubled; Single Phase Transmission and Three Phase Motors

The electrified section of the Norfolk & Western, known as the Elkhorn Grade, is located on the main line in the southern part of West Virginia, about 105 miles west of Roanoke, and extends from Bluefield to Vivian, a distance of about 30 miles. The section is double track throughout, except in the Elkhorn tunnel, which is single track. There are also a large amount of third track, or passing sidings and branches into the coal workings, and yard trackage. A map of the section is shown in Fig. 1. The grades on the line are heavy, varying from 1 per cent at the west end to 1.5 and 2 per cent up the grade, to and through the summit tunnel, a distance of about ten miles. Thence the line descends on a 2.5 per cent grade for about a mile and then

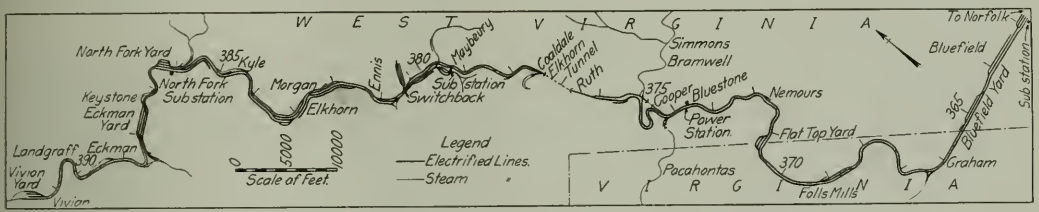

Fig 1—Map of the Elkhorn Grade Electrification of the Norfolk & Western

rises again at the ruling rate of about 0.25 per cent for 10.5 miles, and finally up a 1.22 per cent grade for 3 miles into Bluefield, the easterly end of the division. (See Fig. 2.) Fully 60 per cent of the line is on curves, the maximum being about 12 deg.

The electrification of this section of the railway is primarily for the purpose of collecting from the mine sidings and yards in the coal fields the entire eastbound coal tonnage and transporting it up the grades and over the summit to the classification yard at Bluefield, a division point. From Bluefield, after classification, it is shipped east to the various destination points, chiefly to the

time required to handle trains and to provide a more economical and efficient service over the heavy grades. To this end the heavy freight trains are handled with electric locomotives at a running speed up the grades of 14 m. p. h. as compared with about 7½ m. p. h. under steam operation; and a further saving in time is also effected by the elimination of the delays steam trains have heretofore occasioned by occupying the tracks while the engines take coal and water, one at a time, at the several coal and water stations on the grade. The effect of increased speed is especially marked at the single track Elkhorn tunnel, 3,000 ft. long on a 1.5 per cent grade, where on account of ven-

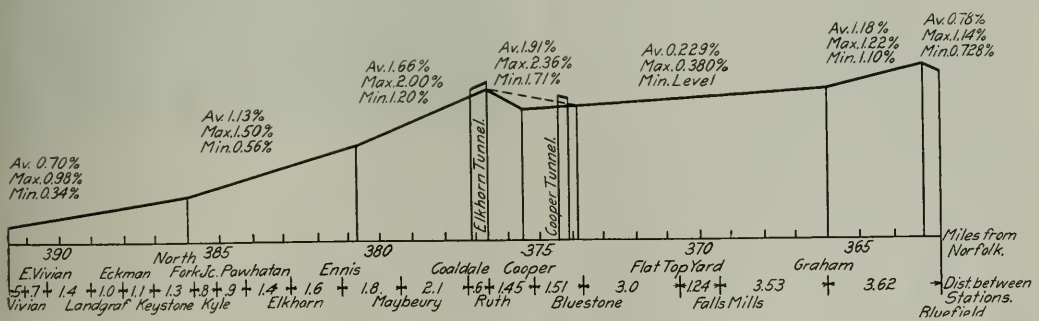

Fig. 2—Profile of the Electrified Section of the Norfolk & Western

Norfolk & Western's marine shipping pier at Lamberts Point, near Norfolk, Va. All coal traffic originates west of Flat Top, about 6 miles east of the summit of the heavy grade, and although much of the coal goes west the easterly shipments are very heavy and this constitutes the chief load handled electrically. Some coal originating east of the summit is shipped to the West, and this is also handled by the electric service to yards near the westerly end of the electrified section.

There are numerous colliery sidings throughout the coal fields, and the electric service includes the collection of loaded cars or

tilation requirements, it has been necessary under steam operation to reduce the speed up grade in the tunnel to about 6 m. p. h. This requires about 7 minutes to clear the block, whereas under electric operation this movement is made in about 3 minutes.

The heavy coal trains, handled in this service, weigh 3,250 tons and have formerly been handled up the grade by three steam locomotives, a road engine and a helper, being used over the entire section, and the third, serving as a pusher up the 1.5 and 2 per cent grades, and being cut off at the summit. These steam engines are of the highly developed heavy Mallet type fitted with

mechanical stokers and superheaters. Under electric operation a single road engine is used over the division and a second electric engine is used as a pusher up the 1.5 and 2 per cent grades. Thus it will be seen that one electric engine takes the place of two Mallets over the division, or two electric engines take the place of three Mallets up the grades and handle the train at approximately double the speed. The speed at which the electric locomotives handle the trains on the 0.4 per cent grade between Cooper and Graham is 28 m. p. h.

Another condition favorable to electric traction is the fact that trains may be despatched at fairly uniform intervals throughout the day, and thus desirable loading conditions on the power system are obtained, and at the same time the full service is handled with a moderate number of locomotives, each making a number of round trips per day.

The electrical installation has been laid out and power plant, locomotives and other equipment provided for handling 20 tonnage trains, or 65,000 tons, a day eastbound over the division and ample provisions have been made for additional traffic and extensions when required. The number of these tonnage trains handled per day at present is about 12, in addition to which pusher and helper service is provided for through freight and passenger trains.

The single-phase system of traction is used, power being generated, transmitted and distributed single phase at 25 cycles and collected from the overhead catenary trolley contact system at 11,000 volts. The locomotives, however, are unique in that they are equipped with phase converters, which, in connection with the main step-down transformers on the locomotive, transform the single-phase power of the trolley to three-phase power for use in the three-phase induction type traction motors. Thus, while retaining all the advantages of high voltage single-phase distribution and collection, the advantages of three-phase induction motors for these heavy traction mountain grade conditions are also secured.

Another characteristic feature of the installation is the fact that as the result of the use of traction motors of the polyphase induction type it is feasible without the use of additional or complicated apparatus and devices to utilize the locomotives for electrically holding or braking the trains at constant speed while descending grades. This utilizes the energy in the moving train descending the grade to drive the motors as generators and thus return energy to the line. On the Elkhorn Grade the conditions are such that the full advantages of this form of braking can be secured in that the trains are very heavy, the grades are severe, and the speeds are relatively high. The performance of this feature of the installation has proven highly satisfactory under operating conditions, the heaviest trains being handled down the mountain grades with a single engine at a uniform speed of about 15 m. p. h. with ease, the air brakes being held in reserve for bringing the train to a standstill when required. This results in a large reduction in the wear on brake shoes and wheel tires and wear and tear on draft gear and on the cars and locomotives generally.

Next to the electric locomotives, the most interesting feature of the electrification is probably the catenary line construction. In designing this feature of the installation, the engineers had uppermost in mind the two important requirements of reliability of service and low cost of maintenance. An effort has been made to secure the maximum degree of flexibility and freedom from hard spots at the contact wire so as to avoid rapid deterioration and frequent breakages and failures, and a special effort has also been made to provide the highest type of insulation so as to avoid interruptions to service due to insulation breakdowns.

In designing the supporting structures an effort has been made to secure a neat and attractive appearing structure which would not interfere with the view of signals and which would present the least surface for corrosion and minimize the cost of painting and repairs as well as the first cost of installation. In working out the design on these lines, the catenary system has taken the form of the single catenary with an auxiliary messenger wire above the trolley, one main hanger being provided for every two intermediate connections between the auxiliary and trolley on tangents. On curves the angularity of the hangers provided the necessary flexibility, the auxiliary messenger and trolley wire being connected to the hanger at the same point.

The principle of providing more than one single insulator between the live parts and ground has been adopted and suspension insulators are used throughout as being the least liable to fail due to transverse stresses. For the main line tracks three suspension insulators are connected in series so that the failure of one or even two at any point will not result in the complete breakdown of the insulation and interrupt the service. For the yard tracks and sidings two such insulators are used. Great care has been taken also to provide ample clearance between every live part and adjacent grounded structures and as a rule this clearance is maintained at not less than 18 in. so as to avoid the

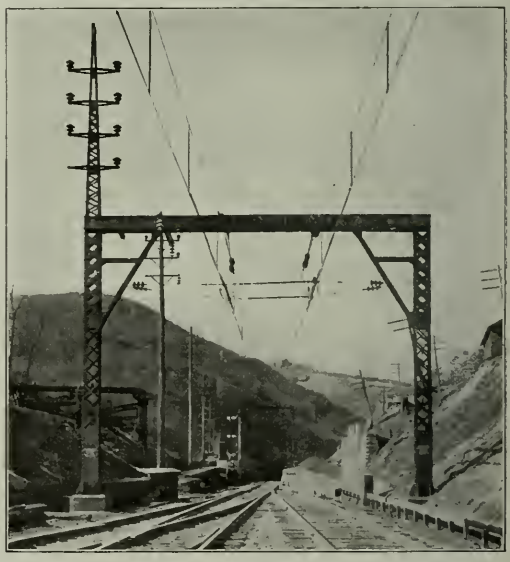

Fig. 3—Self Supporting Bridge at East Portal of Elkhorn Tunnel. Note the Section Break in the Contact Line, the Crossover and Wood Pole Transmission Line Over the Mountains to the Left

danger of birds or foreign materials causing a short circuit. The same principle applies in the tunnels; the insulators are, however, placed off to the side and out of the direct blast from locomotive stacks and here two 44,000 volt transmission line insulators in series are used in all cases between live points and ground.

In laying out the electrical installation a great deal of attention has been given to the provision of adequate and convenient facilities for the inspection and maintenance of all parts of the installation. The center and headquarters of the whole system is at Bluestone, where the power house is necessarily located on account of the water supply. After much study it was decided to locate the inspection building and machine shop for maintenance of electric locomotives here also rather than to try to take care of electric engines at the steam engine shops at Bluefield. The headquarters of the line maintenance force are also located at Bluestone

and are in constant touch, by means of a patrol telephone line and telephone placed at signal bridges, in addition to the usual telephone facilities, with all parts of the electrified section. The company has also provided dwellings for foremen and others on its property near the power house at Bluestone.

In addition to the direct advantages and savings resulting from the electric train service the railway has taken advantage of the presence of an adequate power supply at net cost of generation for the operation of various auxiliary plants. Thus a large steam pumping station at Bluestone for the water supply for steam locomotives has been shut down and the pumping is done at the electric power station located nearby, and the fans for ventilating the Elkhorn Tunnel will now be driven by electric motors. Likewise

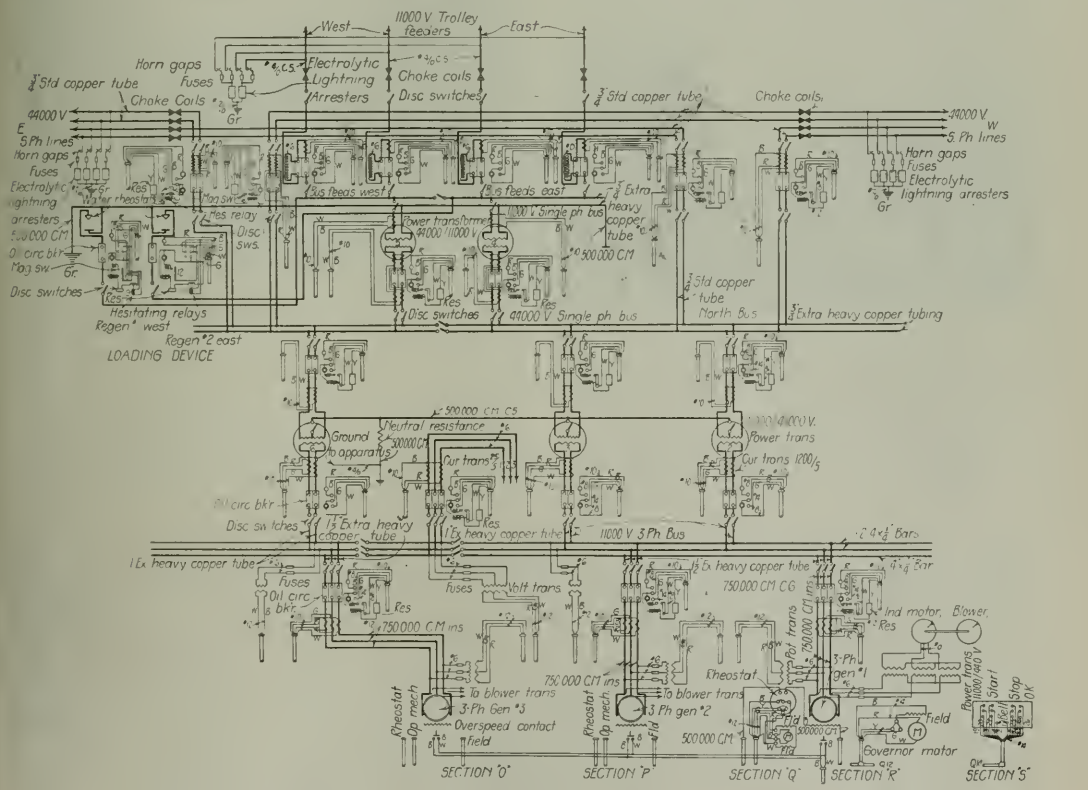

Fig. 4—Diagram of General Connections Between Power House and the Principal Substation Apparatus

electric power will also be ultimately used for operating shops and pumps at Bluefield and several other points on the division.

The electrification of this section had long been under consideration, but the decision to electrify was not reached until about two years ago. The layout and design of the entire installation was worked out in all details by Gibbs & Hill, engineers for the company. All construction, excepting the power house and inspection buildings and some of the power station equipment, was carried out by a specially organized railroad force under the supervision of the engineers.

TRANSMISSION

High tension power is transmitted at 44,000 volts, 25 cycles, single phase. The wires are carried on the catenary supports, except at the tunnels, where the line goes above ground over the summits. The method of support is clearly shown in Fig. 3. There are two single-phase lines between the power house and substations. These consist of four No. 2/0-seven strand hard drawn copper wires. A ⅜ in. steel ground wire is carried on the poles for the length of the line. The high tension insulators are of the four petticoat pin type with a maximum diameter of 12 in. and are tested at 165,000 and 120,000 volts respectively, for dry and wet flashover; their ultimate mechanical strength is about 4,000 lb., applied at right angles to the pin at the wire groove.

The wood poles of the lines over the tunnel summits are of chestnut and vary from 45 ft. to 55 ft. in length. At present they carry three arms each with provision for a fourth. The two upper cross arms carry the 44,000 volt wires and the lower arms the 4,400 volt signal wires. An 11,000 volt trolley feeder is carried over the Elkhorn Tunnel Summit. The cross arms on all poles are connected to the ground wire which is grounded by means of a copper cable which terminates in a copper plate bedded in the earth at the base of every fourth pole. The high tension lines are sectionalized at each substation by means of air break switches on steel structures on the roof.

SUBSTATIONS

All power supplied to the trolley system and trains is obtained from transformers which step down the voltage from 44,000 to 11,000 volts. These are housed in suitable buildings. One of the substations is located in the transformer and switching house at the power station. On ac-

count of objectionable conditions which would result from short circuits it was decided not to feed the nearby sections of trolley lines directly from the power house generator bus. Fig. 4 shows the general connections with the principal substation apparatus. The buildings are all of the same type, similar to the Maybeury station shown in Fig. 5.

The oil circuit breakers in the substations are remote-controlled and will be operated from adjacent signal towers or passenger stations, or at the yard master's offices, thus requiring no attendance. Power at 440 volts for the operation of the oil circuit breakers is obtained from two step-down transformers, one connected to the 11,000 volt bus and one to the 440,000 volt bus.

Fig. 5—Maybeury Substation—Norfolk & Western Electrification

The equipment of substations is as follows:

Bluefield	2—3,000 k. v. a. units	6,000 k. v. a.
Bluestone (power house)	2—2,000 k. v. a. units	4,000 k. v. a.
Maybeury	2—5,000 k. v. a. units	10,000 k. v. a.
North Fork	2—3,000 k. v. a. units	6,000 k. v. a.
Vivian	1—2,000 k. v. a. unit	2,000 k. v. a.
Total capacity		28,000 k. v. a.

The transformers are of the Westinghouse single-phase, oil-insulated, water-cooled type with primaries wound for 44,000 volts and secondaries for 11,000 volts. They are equipped with thermostats which at high temperatures close a bell alarm circuit to the nearest operator's office. Two transformer oil filter outfits have been provided—one for the power house and one for the substations. The latter outfit is transferred from one substation to another as required.

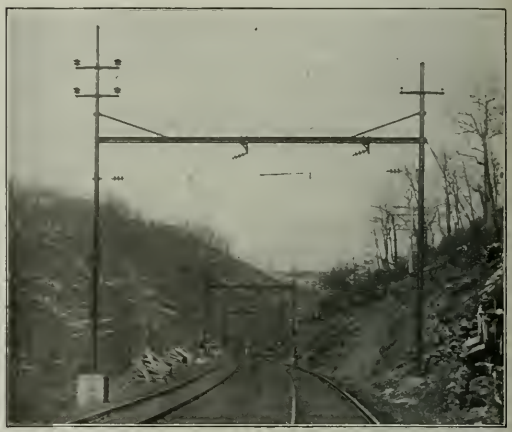

Fig. 6—Tubular Pole Construction at Transition Point, Showing a Typical Curve on the Main Line

Distribution and Catenary Construction

One advantage of using a very high voltage on the contact system is that no supplementary feeders are required, the distribution of power from substations being effected entirely by means of the trolley lines proper.

Supporting Structures.—There are two distinct types of struc-

Fig. 7—Cross Catenary Construction Used in the Yards of the Norfolk & Western at Flat Top—Notice the Small Amount of Obstruction Offered by This Type of Construction

tures used for supporting the system of catenary or trolley lines; one, which is used on the main line, where the wires are suspended from overhead beams or girders and the other, used in yards, where an overhead cross-catenary cable is used to support the longitudinal catenary wires of a large number of tracks. Fig. 6 shows a typical main line structure. It consists of two tubular steel poles set in concrete foundations and carrying between them a structural H-beam. The beam being partially supported by means of sag braces up to the poles. The poles extend above the crossbeam and sag braces and support cross arms which carry the high tension feeders and the signal feeders. The protecting ground wires are clamped to castings

Fig. 8—Norfolk & Western Electric Locomotives Hauling a Tonnage Train

screwed on the top of the poles. The structure as a whole is unguyed if on tangent track, but on curved track is guyed against the curve pull of the catenary system.

The catenary supporting structures are nominally 300 ft. apart on tangent track and somewhat closer together on curves, depending on the degree of curvature and whether or not intermediate pulloff poles are used between adjacent supporting structures. The foundations are of 1:2:5 concrete, reinforced with rods, and cored with a collapsible form. A copper ground plate is set in coke underneath one of the two foundations and a substantial copper cable carried up through the concrete for later attachment to the pole with an expanded pin type bond terminal. The steel poles are built up of various lengths, sizes and weights of steel pipe swedged together.

The guys are of very substantial construction and are relied upon to carry a material portion of the load. The guy anchors are made of concrete slabs containing two or more pieces of old rail. Double guys are used, the two rods making an angle of 20 deg. with the pole. While the above describes the normal main line structure, there are many variations, including bridges having both structural posts and girders which are used where the structures carry signals as well as the catenary system; similar though lighter structural bridges are used on curved track where property for guy anchors is not available.

In the yards the catenary carrying structures consist of two or more high structural steel posts or columns, guyed or self-supporting depending on the location and available property. From the top of one post a cross-catenary cable of extra high tension galvanized steel strand is run across the tracks to the top of the opposite post. In many instances this is 1½ in. cable, having a breaking strength of about 240,000 lb. It is designed to have a large sag which, where the yard is several tracks wide, necessitates high posts. A second strand of steel cable is carried horizontally from post to post, below and suspended from the top cross-catenary cable with ¾ in. rods. Fig. 7, showing a view in the Flat Top yard, is typical of this yard type of construction. The steel structures other than tubular poles were fabricated by the Virginia Bridge Company.

The Catenary System.—The appearance of the catenary system is so simple that one has to actually build it before appreciating the many problems and difficulties that surround its design and construction. The object in the present case is to hold a 3/0 grooved phono-electric contact or trolley wire at a uniform height of 24 ft. above the top of the rails in such a location that it will not vary horizontally more than 12 in. from the center of the rails (allowing for superelevation) and that the bottom of the wire will present an unbroken level surface on which the pantagraph shoe will ride smoothly.

Over tangent tracks the construction is simple. From each of the supporting structures a steel casting attached to the horizontal beam or girder serves as a support for three suspension type insulators. Each of these three insulators is of itself good for a working voltage of 11,000 volts and three are used as a special insurance against line troubles. Since the initial energizing of the line about the middle of December, there has not been a single failure of any of these strings of insulators. To the bottom insulator is attached a malleable iron casting which supports and clamps the messenger wire. This casting has ample bearing for the wire and arcing horns so that should an insulator fail the arc will probably be from the casting instead of the wire.

The messenger wire is ½ in. extra high tension galvanized steel stranded cable having a breaking strength of over 30,000 lb. The nominal sag in the messenger wire is 5 ft. in a 300 ft. span, the actual sag, of course, depending upon the particular span. Spaced 30 ft. apart along the messenger wire are bent strap clips which hold the hanger straps. To the bottom of the hangers is bolted a pair of malleable iron trolley clips which, however, on tangent track do not grip the contact or trolley wire

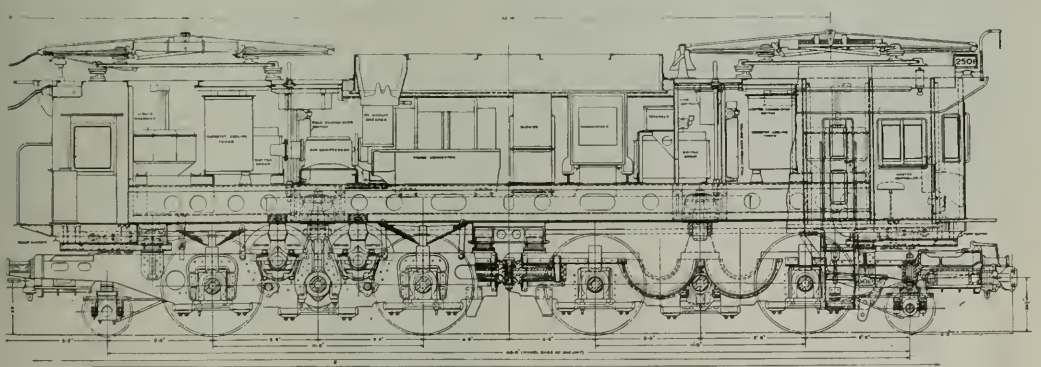

Fig. 9—Section of Norfolk & Western Electric Locomotive

but hold an auxiliary messenger wire. This auxiliary messenger wire is a No. 0 round copper or steel wire depending on whether the load conditions require the added carrying capacity of copper over steel. From the auxiliary messenger wire the 000 grooved contact or trolley wire is supported by a pair of clips bolted together and spaced 15 ft. apart, but so spaced that they are equidistant from the hangers holding up the auxiliary messenger wire. The result is an extremely flexible or "smooth" running trolley. All calculations are made for an average temperature of 60 deg.

Steady strands hold the trolley wires in place crosswise to the tracks where this is found necessary in the longer tangent stretches. All such steady strands are insulated from ground by a string of three suspension type insulators and where one of these cross steady strands from pole to pole of structure attaches to the wires over two or more tracks, it is sectionalized between the tracks by an impregnated wood stick insulator 4 ft. long. The trolley is sectionalized longitudinally where necessary by breaking the messenger wire with two strings in parallel of three insulators each. Directly below this electrical break in the messenger wire the auxiliary messenger and contact wires are attached with turnbuckles to the ends of a heavy impregnated wood stick insulator. Tee iron runners are supported from the trolley wires and from the wood stick insulator, the runners, being supported at opposite ends and sides of the insulators, have ample electrical clearance from each other. At those section breaks which are provided to permit isolation of parts of the line for repairs, but which are normally connected through electrically, specially designed disconnecting knife switches are mounted on top of the wood section break insulators. These can be opened or closed from the ground by means of a long impregnated wooden switch stick.

At certain locations the catenary system is anchored longitudinally or dead ended by being solidly attached to the cross girders of special structural bridges provided for that purpose, the messenger being insulated from the bridge by the double string of three insulators. Such anchors are to limit the zone of trouble should a wreck or other unforeseen accident break a messenger wire. The normal messenger wire support at the bottom of the strings of insulators is so designed that at a certain pull the messenger will slip through. Hence should a messenger break between anchors it is expected it will slip through several supports adjacent to the break and thus distribute the abnormal strain over several bridges instead of the strain coming all on the two structures at each side of the break.

The above while particularly describing main line tangent track construction applies in large measure to all the catenary system. Where the track is curved, as it is in the larger portion of the work, the system has been designed within limits such that the contact wire may be 12 in. off the center line of track in one direction at the bridges or points of support and 6 in. off the center line of track in the other direction at the center of the span. This allows the trolley curvature to be less than the track curvature. In speaking of center of track and departure of trolley wire, therefore, what is really meant is the loci of the middle point on the pantagraph shoe.

The hangers on curves are 15 ft. apart and the clips at the bottom hold both the auxiliary messenger and the contact or trolley wire. This is essential since unless held vertically below the auxiliary messenger by resistance to bending in the clips and the hangers, the curve pull of the contact wire would pull it up to the same level as the auxiliary messenger. This holding of both wires by the same clips at the ends of the hangers does not, however, result in "hard spots" in the trolley. In this district

The extension or wing at the right end of the power house is a substation and the structures for carrying the outgoing feeders are shown.

Fig. 10—General View of Power House from the West, Showing the Inspection Building to the Left, Intake Canal and Cooling Pond to the Right

most of the track is curved and a large portion of it is a relatively high degree of curvature running to a maximum of 12 deg. In order to avoid an uneconomically close spacing of structures on the high track curves one and sometimes two pull-off poles are used between bridges.

In the yards the catenary system is, of course, very similar to that on the main line except that the messenger insulators are

Fig. 11—View of Turbine Room from the West End Showing the Main Generating Units. The Operating Gallery is on a Level with Crane Track

supported from the lower or horizontal wire strand of the cross-catenary bridge. In yards only two of the suspension type insulators are used between live wires and grounded structures and the auxiliary messenger wire is omitted, the clips at the end of the hanger straps holding the contact wire in tangent as well as in curved construction.

In the Elkhorn Tunnel special catenary construction was necessary. This is a single track tunnel, 3,000 ft. long, the walls

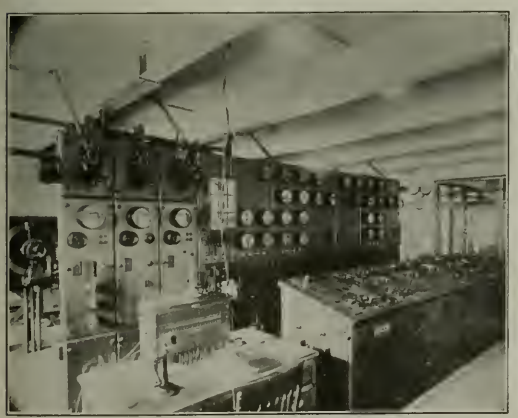

Fig. 12—Control Boards in the Operating Gallery of the Power House

are 14 ft. apart at the spring line and 13 ft. apart at the base, the spring line is 11 ft. 1 in. above the top of the rails, while the top of the arch is 19 ft. 3 in. high. The arrangement adopted was to have a supporting structure every 75 ft. apart. At each side of each structure two cast iron brackets held to the brick lining of the tunnel by large bronze expansion bolts, each carry a 44,000 volt transmission line insulator. A 2 in. brass pipe is carried parallel to the tracks by the pair of insulators on each side. Another line insulator on each side is mounted by bronze castings at the middle of these pipes and a cross pipe bent to follow the arch of the tunnel, forms the support for a bronze messenger wire. The live catenary parts have, therefore, double 44,000 volt insulation to ground. Despite the necessarily very limited clearances, the work in this tunnel stood a test of three times normal trolley voltage and has so far performed very satisfactorily for the several weeks it has been in service. Fig. 3 shows the east portal of this tunnel in which the contact wire is 17 ft. 3 in. above the rails.

On branches and coal mine sidings, the wooden pole bracket type of construction is used. In such places, only two of the suspension type insulators are used. The messenger wire is 3/8 in. steel strand and the contact wire No. 2/0, no auxiliary messenger being used.

Track Bonds.—A special type of track bond has been designed for this installation. By manufacturing the bonds with only one terminal attached and crimping or looping the cable near one end, the bond may be installed by removing only one bolt in the fish plate. In this way these bonds may be installed almost as

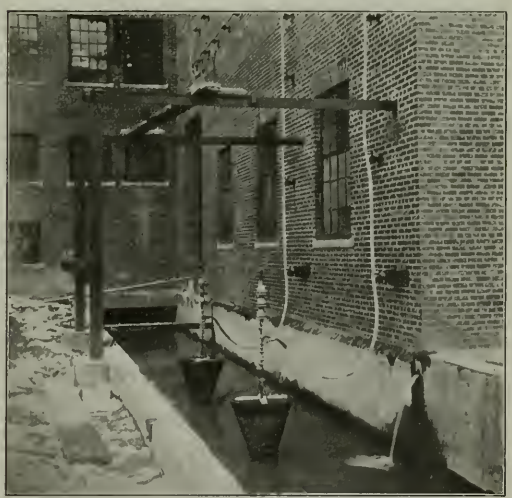

Fig. 13—Water Rheostats for Absorbing Excess Regenerated Power

quickly as the exposed type while retaining all the advantages of the concealed type. The cable consists of 37 strands of 0.0534-0.475-in. copper wire. At signal bridges the rail joints are insulated and it is necessary to install bonds so that the flow of propulsion current shall be continuous. This result is accomplished by the use of impedance bonds which prevent the flow of 60-cycle signal current from getting past the insulated joint, but at the same time do not interfere with the flow of 25-cycle propulsion current.

Protection of Telephone and Telegraph Lines.—In order to protect the telephone and telegraph lines along the railway from danger of interruption of the service due to the electrical installation, it was necessary to make certain provisions, first, against the hazard of physical contact between falling telegraph wires and high tension power wires, and, second, against induction set up in parallel telephone and telegraph lines due to current flowing in the power circuits. It was found preferable to move the telephone and telegraph lines entirely to the north side of the tracks and locate them at the extreme edge of the right-of-way so as to be as far as possible from the power circuits. The nearest 11,000 volt traction power wire to the telephone and

telegraph circuits is the trolley over the northerly or westbound track.

To provide against induction it was decided to place the main transformer substations somewhat closer together than would be required by considerations of voltage regulation and losses and to place the end substations near the ends of the line. This results in feeding each important or long section of trolley from both ends and consequently the induced voltage in parallel telephone and telegraph lines is largely localized and neutralized. In addition to this, however, in order to provide for emergency conditions when one substation may be out of service and for excessively high currents which occur in cases of short circuits and grounds, it was decided to install so-called track transformers or boosters in the trolley and track circuit at intervals of about one mile. The purpose of these transformers is to cause the return current, a considerable amount of which would ordinarily leak to earth, to flow in the track rails and thus keep it at a fixed distance from the trolley wire and the telephone and telegraph wires. There are two sets of coils wound on the core of each transformer, one for the eastbound and the other for the westbound track, hence only one transformer is required at each point. By the use of a combination of all of the above appliances and devices it is found that the telephone and telegraph service is not interfered with by the operation of the electric train service.

LOCOMOTIVES

The traffc on the electrified section is handled by twelve 270-ton Baldwin-Westinghouse locomotives, each consisting of two 135-ton units or halves (see Figs. 8 and 9). It is necessary in handling heavy trains on mountain grades to have a part of the motive power at the rear of the train. In this case the power is divided equally between the two ends of the train and the trains are of such length in this mountainous country that there is difficulty of transmitting the starting and stopping signals from one locomotive to the other and thus the locomotives are subject to treatment which would be considered impossible in ordinary service. This would require very careful handling with the ordinary locomotive, but these locomotives are designed to meet these severe requirements of the service without involving special manipulation. In meeting these conditions the rugged construction of the three-phase induction motor, being free from commutators, and the liquid rheostat are of the greatest importance. The liquid rheostat not only gives the smoothest possible gradations of tractive effort, but the latent heat of steam makes it possible without difficulty to dissipate the large amount of heat generated in the rheostat in meeting this severe requirement. The inherent characteristics of the induction motor which enable the locomotive to automatically hold the train at a constant speed on descending grades by regenerating and returning power to the line, also accentuate the advantages of this type of locomotive.

The locomotive units have a 2-4-4-2 wheel arrangement, the two trucks being connected by a hinge joint. The cab is of the box type and is supported on the main truck entirely by spring cushioned friction plates, there being no weight on the center pins, which serve only to maintain the cab in its proper position on the trucks. An engineer's compartment is provided at one end of each unit, the two units being so coupled as to provide for operation from either end of the locomotive.

Each locomotive is equipped with eight traction motors of the 3-phase induction type, with wound secondaries for 4 pole and 8 pole operation. The motors are forced cooled by air from the main ventilating duct, which also delivers air to the phase converter and to cooling towers for the liquid rheostats. There are two running speeds, 14 and 28 m. p. h. In starting, resistance is inserted in the secondary circuit of the motor by means of a liquid rheostat. For the 14 m. p. h. speed all motors are connected in parallel, having the eight pole motor combination and for the 28 m. p. h. speed they are also connected in parallel, but with the four pole motor combination. The locomotives are equipped with unit switch type of control and arranged for the simultaneous operation of the two units from the control end of either.

The control equipment is built for handling alternating current, which is collected from the 11,000 volt line by the pantagraph trolleys. This current is fed to the main transformers through an oil type circuit breaker. A phase converter is connected to the low tension side of the transformer and operates constantly when the locomotive is in service. To its extended shaft are coupled a blower for cooling the motors, transformers and other parts, and, through a clutch the air compressor. The converter is an induction motor with a short circuited or cage wound secondary having two windings on its stator, one to drive the rotor and the other to furnish current out of phase with the main supply current.

The motor circuit of the primary winding of this converter is connected across the secondary of the locomotive transformer and receives current at 725 volts. The arrangement of windings is such that with the converter running, a current of 90 deg. phase displacement is induced in the second winding on the primary of the converter. By connecting this displacement circuit to the middle tap of the main transformer, a three phase current is produced. It is only necessary to convert a portion of the current used in the main motors as a large portion comes directly from the main transformers. For starting the converter a single-phase series commutator type motor is mounted directly on the shaft of the converter.

Two trolleys are mounted on the roof of each unit; they are of the pantagraph type, but are unique in that they have been arranged so that if necessary they may be fitted with end horns which will automatically fold in when the pantagraph is lowered by the tunnel trolley wire. The trolley is raised and held in contact with the overhead wire by springs and is lowered by compressed air. Double insulation is provided for the pantagraphs, that is, two separate sets of insulators are arranged in series. If one set fails, the other set will be effective in sustaining the service.

On each unit there are four liquid rheostats, one for each motor. The rheostats are operated in pairs, each pair having in common, one storage reservoir and cooling tower, one circulating pump and one operating mechanism. The liquid rheostats provide the motor circuit resistance required in order that the speed of the motors may be slow at starting and may be gradually increased as the resistance is cut out of the circuit.

The essential elements of each rheostat are a cast iron tank in which are mounted electrodes consisting of certain metal plates connected to the motor and another set of such plates adjacent thereto and connected to ground; a hollow plunger, located at the center of the tank for regulating the height of the liquid and which is raised or lowered by an operating mechanism; and a motor-driven centrifugal circulating pump by which the liquid is continuously circulated to prevent excessive heating, the liquid being forced up through the bottom of the tank and over the top of the hollow plunger when the plunger is raised and back through the inside of the plunger to the storage reservoir.

When the liquid is raised so as to submerge the lower ends of the plates, current may flow between the motor-connected plates and the adjacent ground-connected plates, the circuit between the three phases of the motor being thus established. The higher the liquid rises on the plates, the lower the resistance becomes; when the plates are entirely submerged, the liquid going all the way up, the resistance is reduced to the minimum. To keep the temperature of the circulating liquid as low as possible, a portion is by-passed through a cooling tower containing a series of trays so arranged that the liquid will flow over them in a thin sheet and be cooled by air from the main ventilating duct to which the towers are connected.

For the purpose of cooling the various pieces of apparatus, there is a 36-in. Sirocco fan mounted on the shaft of the phase converter, and arranged to deliver the air to a duct built into the cab floor under the deck. The duct runs lengthwise through the cab and is arranged with openings at various points where con-

nections are made to the traction motors, phase converters, cooling towers, etc.

The following table shows the principal dimensions and weight of each complete locomotive:

Length overall	105 ft. 8 in.
Driving wheel base, total	83 ft. 10 in.
Rigid wheel base	11 ft. 0 in.
Truck wheel base	16 ft. 6 in.
Height, rail to pantagraph (locked)	16 ft. 0 in.
Height, rail to top of cab (maximum)	14 ft. 9 in.
Width, overall (maximum)	11 ft. 6¼ in.
Width over cab body	10 ft. 3 in.
Diameter of driving wheels	62 in.
Diameter of pony wheels	30 in.
Weight on drivers	220 tons
Total weight of locomotive	270 tons

The following table shows the performance of these locomotives under varying conditions of load:

	Train on 1.5 and 2 per cent grades	Train on 1 per cent grades	Train on 0.4 per cent grades
Weight of train, tons	3,250	3,250	3,250
Locomotives per train	2	1	1
Approximate speed, miles per hour	14	14	28
Drawbar pull per locomotive, lb.—			
Uniform accelleration	91,800	114,000	79,400
At speed on 2 per cent grade	75,400		
At speed on 1 per cent grade		85,800	
At speed on 0.4 per cent grade			4,600
Maximum guaranteed accelerating tractive effort per locomotive	133,000	133,000	90,000
Approximate maximum guaranteed h. p. developed by motors	5,000	5,000	6,700

On tests and in service the locomotives have developed a drawbar pull considerably in excess of the guaranteed maximum, the highest record with the dynamometer car being 180,000 pounds. This corresponds to an adhesion of about 40 per cent.

POWER STATION

The power station is of the usual type using steam boilers and steam turbines as the prime movers. It is located at Bluestone, on the Bluestone river, about 11 miles west of Bluefield, mainly for the reason that this is almost the only available source of water for boiler feed and condensing purposes in the district. Fig. 10 is a general view of the plant. The building is constructed of hand-burnt brick; the design is plain and substantial in character. The main structure is about 135 ft. by 158 ft., with a 52-ft. by 33-ft. extension at the northeast corner.

The main building contains a boiler room 79 ft 3 in. by 158 ft. 6 in., and a turbine room 56 ft. by 158 ft. 6 in. Across the east end of the turbine room a section 26 ft. wide is assigned for switching equipment, offices and other facilities, and fitted with intermediate floors and galleries. On the second, or mezzanine floor of this section, are located the locker and toilet rooms for the engineers and firemen. Above this, on the main floor, is the low tension switching room, which is separated from the turbine room by heavy wire screens. The next floor is the operating gallery, overlooking the turbine room, and a small office and a lavatory. The top gallery is used for offices. On the ground floor of the extension building or transformer house are the step-up and step-down transformers, and on the second floor is located the high tension switching apparatus.

The boilers, stokers, stoker engines and feed water heaters are located on the main floor of the boiler room, while the pumps, oil filters, air compressor, ash handling equipment, and the forced draft fans are in the basement, the pumps and filters being in a separate room. The main material storeroom also occupies a separate room extending along one side of the basement. The main turbo-generator units, exciters and signal generators, are located on the main floor of the turbine room, the condenser equipment and fans for cooling the generators being in the basement. The turbine room is spanned by a 30-ton traveling crane. The basement floors are at the ground level, while the turbine room floor is 18 ft., and boiler room 13 ft. 6 in. above.

Generators.—The main turbo-generators are of the Westinghouse type having a rating of 10,000 kw. at 80 per cent power factor, 11,000 volts, 25 cycles, single phase. At this rating, the generators are specified to operate for 24 hours with a rise in temperature not exceeding 60 deg. C. above the temperature of the cooling air. They are capable of delivering a single phase output of 12,500 kw. at 80 per cent power factor for 5 minutes without injurious heating. The field coils are of the two pole type wound with copper strap and insulated for a one minute potential of 1,000 v., a. c. Provision has been made for the insertion of plugs for balancing. The armatures are wound for 3-phase power and are insulated for a one minute voltage test of 22,000 volts, and the insulation is capable of withstanding a temperature of 90 deg. C. without injury. Thermo couples imbedded in the armatures furnish a continuous temperature record. A view of the generator room is shown in Fig. 11. Each generator is ventilated by a No. 6 Sirocco blower, having a capacity of 50,000 cu. ft. of air per minute.

There are two turbine-driven and one motor-driven exciter generators. The turbo-driven sets consist of small Westinghouse horizontal turbines rated at 150 kw. The generators are compound wound machines of the rotary armature type with commutating poles and have a rating of 600 amperes at 250 volts when running at 2,200 r. p. m. The motor-driven set consists of a 3-phase induction motor rated at 150 kw. at 440 volts, 25 cycles, running at 720 r. p. m. The generator is a compound wound machine of the 6-pole type with a normal rating of 600 amperes at 250 volts. The motor takes power from a 3-phase self-cooled oil transformer rated at 200 k. v. a. A Tirrill regulator is used to vary the exciter voltage and current over sufficient range to insure practically constant voltage on all three main generators under all operating conditions.

Power for signal service in the electrified zone is supplied by two turbine-driven generators. Each set consists of a horizontal Westinghouse steam turbine direct connected to a 50 kw., 4,400 volt, 60 cycle single phase generator.

Switching Apparatus.—The main 11,000 volt bus is sectionalized and 3-phase power for auxiliary purposes is taken from the island section. No brick or concrete bus compartments are used, the bus being of copper tubing carried on insulators mounted on pipe framework. Copper tubing and bare wire is used wherever possible; insulated wire being used only where conductors are carried in conduits. The power supply to the 11,000 volt side of the three 5,000 k. v. a. step-up transformers is controlled by three 2-pole oil circuit breakers. The high tension leads from the step-up transformers, pass up through openings in the floor above to the oil circuit breakers and 44,000 volt bus. Copper tubing and bare wire are used in the bus work and wiring on this floor. The 44,000 volt bus is sectionalized, two high tension feeders being taken from each side. The high tension feeders and trolley feeders leave the building through openings in the south wall. The lighting arresters are located on the roof of the building.

All oil circuit breakers are electrically controlled from the operating gallery. Knife disconnecting switches are installed between busses and all oil circuit breakers and on the line side of all high tension and trolley feeder circuit breakers. Electrolytic lightning arresters are connected to all feeders.

The electrically operated switching and control equipment receives power from the auxiliary d. c. bus or a storage battery which is located in the northeast corner of the turbine room basement. This set has a capacity of 160 ampere hours at 220 volts, and is charged by a 5 kw. motor generator set located in the operating gallery. All switching apparatus is controlled from the operating gallery. The switchboards consist of a generator bench, main power board, auxiliary power board and a signal power board, as shown in Fig. 13.

Regeneration Loading Rheostats.—Excess regenerated power returned to the power house at no load passes to the 11,000 volt bus and through the various transformers back to the generators if the generators are running under very light load or no load. If no other load were provided, the regenerated power would reverse the generators and operate them as motors. To prevent this a loading device consisting of electrodes immersed in the intake canal and controlled by suitable switches is provided. The operation of the switches is made automatic by means of a group

of relays and magnetic switches, current transformers, etc., so connected as to give the following results.

When the amount of excess regenerated power reaches, say, 300 k. v. a. the closing relays throw in one water rheostat on the 11,000 volt bus. As soon as the regenerated power exceeds the capacity of one water rheostat by 300 k. v. a. another closing relay throws the second water rheostat in on the 11,000 volt bus. The difference between the amount of excess regenerated power and the capacity of the water rheostats in service is made up by the generators.

When the excess regenerated power has become reduced to zero with one rheostat in service all of the rheostat load being supplied by the generators one of the tripping relays trips the circuit breakers which cuts the rheostat off the 11,000 volt bus. With two rheostats in service, when the excess regenerated power drops to 2,000 k. v. a. one of the relays opens the breaker which was closed first and cuts one rheostat out of service. The other rheostat remains in until the excess regenerated power drops to zero when it, too, is cut out of service.

The water rheostats are located outside of the transformer house at the Bluestone power station. (See Fig. 13.) Each rheostat consists of a steel cone carrying a lead from the circuit breakers, and a fixed ingot iron plate located at the bottom of the intake canal, and grounded to a copper plate bedded in the earth outside of the canal. The power dissipating capacity is adjusted by varying the distance between the cone and the iron plate. The cone is raised or lowered in the water of the canal by means of a hand-operated winch and cable carried on a steel bracket across the canal.

Steam Turbines.—The initial equipment consists of three main generating units, with space provided for a fourth. These units are horizontal turbines of the Westinghouse-Parsons impulse reaction double flow type rated at 10,000 kw. with steam at 190 lb., superheated 150 deg. F. and 28½ in. vacuum when running at 1,500 r. p. m. The governor consists of an oil relay mechanism for operating the steam valves. Oil is maintained at a pressure of 45 lb. for the governor mechanism and reduced to about 10 lb. for lubrication. In case of interruption to the oil supply the stop valve automatically and instantly operates and shuts off the steam supply. A simple speed limit governor trips the automatic stop valve whenever the speed of the turbine exceeds a predetermined value. Each turbine is equipped with a separate condenser of the Le Blanc Jet type. The condenser injection water and air pumps are driven by a horizontal turbine. The air pump discharges into the intake canal and the ejection pump discharges into a pipe leading to the spray cooling poud.

Water for all purposes, excepting drinking, is taken from the Bluestone river by way of an intake canal. At the intake are two rows of 5 ft. by 7 ft. screens, having structural steel frames and three kinds of mesh—a fine mesh, 4 in. by 4 in. of No. 12 gage wire, medium mesh, 1 in. square of No. 10, gage wire, and coarse mesh, made up of 2½ in. by ¼ in. flat bars spaced 2½ in. on centers.

The water from the circulating pumps of all condensers is discharged into the cooling pond. If the supply of river water is low or not suitable for boiler use, it being very muddy at certain seasons, the water is sprayed into the pond and thence discharged into the intake canal. If there is sufficient cold river water of suitable quality, the water from the condensers is not sprayed but is discharged into the pond from which it is allowed to flow into the river reservoir several hundred feet below the intake and circulates up stream to the intake, the complete circuit being about 1,400 ft.

The cooling pond is 90 ft. wide, 296 ft. long and 5 ft. deep. Altogether there are 280 nozzles with space provided for addition of 140. The pond is capable of cooling 16,800 gal. per minute.

Boilers and Stokers.—The boiler plant comprises ten Stirling type water tube boilers, arranged in two rows with the firing aisle between, each row consisting of two batteries of two boilers each and one single boiler. Space is provided in the present building for four additional boilers. The boilers are designed for a working pressure of 225 lb. gage, and each has a total effective heating surface of 6,772 sq. ft., comprised in 3 steam drums 42 in. in diameter and 16 ft. 4⅛ in. long, and 487 tubes 3¼ in. in diameter. The boilers are equipped with superheaters capable of superheating the steam 150 deg. F. at normal rating. Each boiler is fitted with an underfeed stoker of sufficient capacity to evaporate 61,000 lb. of water per hour into steam at 200 lb. gage pressure 150 deg. F. superheat when supplied with feed water at 200 deg. F. The stokers are capable of developing 300 per cent of normal boiler rating when burning coal having a heating value of 12,250 B. t. u.'s per pound.

The forced draft installation in the boiler room basement consists of three Sturtevant multivane turbine driven fans, driven by steam turbines through a 4.1 herringbone reduction gearing. These turbines are of the standard Sturtevant E-5 type, and have a normal rating of about 300 hp. each. The stack is of the Custoclis radial brick type 268 ft. in length.

Steam from the exhaust header is discharged into horizontal Cochrane feed water heaters and purifiers located on the boiler room floor. These are of the cylindrical type, and each heater is capable of heating 225,000 lb. of water per hour from 40 deg. to 205 deg. F. The heaters are equipped with oil separators. The feed water is taken from the intake canal and pumped to the heaters by two lowhead pumps of the horizontal volute single stage double suction type, having a capacity of 650 gal. per minute. These pumps are direct connected to 20 hp. steam turbines. There are two suction lines to the lowhead pumps, each containing a Lagonda strainer. The two boiler feed pumps are of the horizontal volume three stage double suction type designed to operate against a working head of 600 ft. These pumps are driven by 175 hp. steam turbines.

The coal is received in hopper bottom cars on a siding along the south side of the power station. The cars discharge into a hopper under the tracks. Below the hopper is a single roll crusher which empties into an inclined conveyor of the continuous bucket type, having a capacity of about 60 tons per hour at a speed of 80 ft. per minute. This conveyor elevates the coal to a hopper at the east end of the boiler room monitor. From this hopper the coal is fed to a horizontal distributing conveyor. Two storage bins are suspended above and between the boilers from the building girders. Their capacity is about 350 tons. The coal handling machinery is driven by A. C. motors.

A narrow gage (24 in.) track is located under each row of boiler ash hoppers in the boiler room basement for steel platform cars, carrying two buckets of one cubic yard capacity each, which are used for removing the ashes. They are run outside the boiler room basement to a loading trolley emptied into the gondolas by means of a traveling electric hoist.

Compressed air is supplied for operating tools in the locomotive repair shop, for cleaning generators and for general use about the plant. The compressor is of the steam-driven type, having a capacity of 412 cu. ft. of free air per minute at 165 r. p. m., maintaining a pressure of about 100 lb. per sq. in. This equipment was supplied by the Chicago Pneumatic Tool Company, of New York City.

A complete signal communicating system has been installed. A monitor board is installed on the south wall of the turbine room. Symbols governing the operation of the main generators, exciters and signal generators are painted on ground glass and are illuminated by the operation of push button switches in the operating gallery. Return signal lamps are also provided on the main power board in the operating gallery. Pneumatic whistles are provided in the boiler room, pump room and turbine room, as well as the indicating signals at each main turbo-unit.

FACILITIES FOR INSPECTION AND MAINTENANCE

The inspection building and repair shop is a 148 ft. by 68 ft. structure of the same type as the power station which is just north of it. There are two main pits running the full length of the building. At the west end of the shop is a short wheel pit which is connected to the two other pits by means of a covered

lateral pit. This pit is equipped with a narrow gage track to handle the pneumatic jack by means of which the wheels are removed from the locomotives and run along to the storage track in front of the heavy wheel lathe. The southern pit is used almost exclusively for inspection. For this purpose a 112-ft. platform has been located 12 ft. 8 in. above the rails. All repair work is done in the northern part of the building, where the machine tools are located. This part of the shop as well as one inspection pit and the short wheel pit are spanned by a 30-ton Whiting crane.

The following machine tools are installed:

Motor Driven Tools—

80-in. heavy wheel lathe.
30-in. by 8-ft. planer.
60-in. by 6-ft. No. 1 horizontal boring and drilling machine.
3-ft. Mueller radial drill.
20-in. Stockbridge crank shaper.
73-in. boring mill.
36-in. double back geared lathe.

Belt Driven Tools

1 Style C Diamond double emery grinder.
1 No. 5 mat Diamond wet tool grinder.
36-in. Aurora vertical drill.
18-in. by 10 ft. single back geared lathe.
14-in. Barr 2 spindle sensitive drill.
50-ton pneumatic press.

The building is well lighted by Tungsten lamps. Rolling steel doors are provided at the entrance to all tracks and the building is steam heated. The locomotives are not handled in the shop by their own power, but are drawn in and out by means of a cable and motor-driven winch, located at the east end of the building between the two main tracks. A blacksmith shop is located in an extension at the northwest corner of the building.

The headquarters for the maintenance of the overhead catenary trolley construction and the transmission lines are at Bluestone. The line repairmen will be available and subject to call at any time during the day or night. On a siding an emergency repair train consisting of a tower car, tool car and flat car is constantly held in readiness for heavy emergency repairs. The ordinary repairs, however, will be taken care of by comparatively small gangs consisting of three to five men, who will be sent out on small gasolene cars. Wherever possible repairs are made from the overhead bridges or from ladders, and in order to avoid interruption to electric service to the greatest extent possible, specially treated and impregnated wooden ladders are provided and can thus be used for light repairs to trolley fingers, clips and other details on the 11,000 volt catenary system while alive. Certain of the line repairmen are regularly stationed at one or two other points on the line from which they can quickly respond to an emergency call by the use of gasolene cars.

In order to expedite the inspection and maintenance of the line, a patrol telephone line is installed over the entire length of the electrified section. This patrol line is connected with the power house, and through the power house telephone operator communication can be had over this line with the train despatcher and other officials.

AUTOMATIC SIGNALING EQUIPMENT

The electrified section of the railway was formerly equipped with automatic signals of the d. c. type requiring primary storage batteries, these signals being usually mounted on posts along the track. Under electric operation, however, it was deemed advisable to make use of these signals, which were only recently installed and practically new, on other parts of the railway, and to provide new a. c. signals in connection with a. c. track circuits, the signals being mounted on the catenary bridges. This part of the work was carried out by the railway company.

Excursion Fares on the Egyptian State Railways Restored.—The Egyptian state railway authorities, who at the beginning of the war increased all first and second-class fares by 10 per cent and suppressed return tickets and week-end tickets at reduced fares, have now re-established the latter, and week-end tickets between Cairo and Port Said, at about a fare and a half are again available. Port said is 210 miles from Cairo.

REPORT OF CHICAGO RAILWAY TERMINAL COMMISSION

The Chicago Railway Terminal Commission, of which John F. Wallace is chairman, has submitted a preliminary report to the Chicago City Council Committee on Railway Terminals, based on its investigation of the Chicago railway terminal situation since its formation on May 25, 1914. In addition to the Chicago situation the commission has made a personal examination on the ground of the terminals at Toronto, Montreal, Boston, New York, Liverpool, Manchester, London, Paris, Brussels and Antwerp. After a general discussion of the development and the present aspect of the Chicago railway terminal situation the commission submits a series of recommendations which it summarizes as follows:

"In the interests of the city, the railroads, the shippers and the general public, the railroad terminals now existing in the congested area bounded by the Lake on the east, Chicago avenue on the north, Desplaines street on the west and Sixteenth street on the south, should be readjusted and simplified by combination and co-operation.

"The through passenger service of all the railroads now using terminals in that portion of the congested area above described, which lies east of the south branch of the Chicago river, should be combined in one, or two, union passenger stations, with the exception of such of these roads as can properly be taken into the new Canal street Union Station west of the river.

"Advantage should be taken of the substantial opportunities which now exist for the practical application of the through routing principle to Chicago suburban service. These opportunities would be increased by certain changes which are easily practicable.

"The present extensive and superficially spread out competitive freight terminals within the congested area should be regrouped and simplified. The commission is gratified to be able to report that it has found, on the part of a number of influential railroad officials, a distinctly favorable disposition toward this suggestion and a willingness to assist in the working out of practicable plans to carry it into effect.

"The south branch of the Chicago river should be straightened so that La Salle street, Fifth avenue and Franklin street can be extended through as continuous north and south thoroughfares, and so that railroad properties now cut off by the river and only superficially used, can be made available for intensive development. Provision for river-straightening was made in the Canal street Union Station ordinance, and the commission has secured assent to substantially similar provisions in the Baltimore & Ohio Chicago Terminal Railroad ordinance, and in the pending ordinance relating to the Chicago & Western Indiana Railroad. Other railroads, whose interests would be affected, have also indicated to the commission their willingness to co-operate in some practicable plan of river straightening. The commission has prepared certain tentative plans showing the river straightened and how the property then thrown east of the south branch of the river can be utilized to the joint advantage of the railroads and the public.

"No carload freight should be handled within the congested area, bounded as above, except that which is intended for consumption or use within the district. All other carload freight should be interchanged, transferred or delivered by co-operative methods, agencies and facilities outside of this district, such as those already adopted at Clearing by 12 of the Chicago railroads, operating 15 trunk lines. Here, or at similar co-operative yards, should be interchanged all carload freight which it is not essentially necessary to handle within the congested area. Less than carload freight should be interchanged or transferred, as far as practicable, on general principles substantially similar to those applied at Clearing to the carload freight. It is apparent that, to the extent that this interchange or transfer can be accomplished at one or more points outside of the congested area

of the city, a distinct public benefit will be conferred, and the railroads themselves will probably be financially benefited.

"Outbound L. C. L. freight should not, as a general rule, be sorted or loaded to destination at the freight terminals within the congested area. No outbound L. C. L. freight which had been loaded into trap cars on private sidings should be brought into this congested area, but should be taken directly from the point of origin to an outlying station or yard where it will be transferred as may be necessary. Outbound L. C. L. freight brought by teams or trucks to freight stations or team tracks within the congested area should be unloaded as directly as practicable from the vehicles into trap cars and should be taken in these cars directly to outlying clearing stations or yards, there to be transferred as may be necessary.

"Outlying L. C. L. clearing stations or yards should be established and operated by roads which do not already have them; and the co-operative or union principle should be applied and extended as rapidly as experience justifies and opportunity permits. This commission is not now prepared to say that the larger railroad systems may not find it advantageous to operate individual clearing station yards of their own or that one joint station or clearing yard may be found as efficient as two or more. It may be that there should be three union co-operative clearing stations or yards located in different sections of the outlying territory of Chicago and devoted to freight destined west and northwest, south and southwest, east and southeast, the sections into which the entire railroad system, when considered in relation to Chicago, naturally subdivides the country.

"Universal freight stations should be established at appropriate points in the central terminal area, in sufficient number to afford convenient opportunity for the shippers in the respective sections of this area to deliver at a single station L. C. L. freight destined to different roads, or at least to any of the roads within one of the above mentioned groups. The freight received at such universal stations should be taken to the outlying clearing station or yard of all the roads, or of the roads of one of these groups, depending on the system, and then this freight should be sorted, transferred and loaded to destination.

"In the event—but only in the event—that this service is found to involve extra expense to the railroads over the cost to them of handling freight teamed to their respective individual receiving stations, the shipper utilizing these universal stations should pay an appropriate charge for the privilege which enables him to reduce the cost and the delays of teaming. It is not suggested at this time that all the railroads should immediately adopt the universal freight station system, or that each railroad should convert all of its existing freight stations into universal stations. But it is believed that a sufficient beginning should be made on the universal freight station plan to give that plan a fair and adequate trial, and under circumstances which will permit of its extension to the extent that this is justified by experience.

"In the plans prepared by the commission, as tentative studies of the terminal situation, locations have been indicated for new universal freight houses by way of suggesting where such houses be located. In actually working out the problems, other locations may be found more suitable or more available. The commission has been gratified to find that the universal freight house principle is being given friendly consideration by Chicago railroad men, and it confidently hopes for the inauguration of this principle in the near future.

"None of the plans submitted is intended to represent the matured judgment of the Chicago Railway Terminal Commission. The sole purpose of all that is here presented is to report progress toward the solution of the railway terminal problem and to indicate some of the practical steps that may lead further in this direction."

The report contains a large number of interesting charts and statistical tables showing the present situation and the proposed development of the Chicago railway terminals, and also a general discussion of the terminal situation in other large cities of the United States and in Europe which the commission visited last summer.

The commission consists of John F. Wallace, chairman, representing the city of Chicago; Walter L. Fisher and Bion J. Arnold, representing the Citizens' Terminal Plan Committee; Edward H. Bennett, representing the Chicago Plan Commission; L. E. McGann, commissioner of public works; John W. Beckwith, corporation counsel; Ellis Geiger, chairman, Council Committee on Railway Terminals.

DEMURRAGE REGULATIONS IN ENGLAND

The Railway Clearing House, London, has announced that on July 1, 1916, the following uniform regulations and scale of charges for demurrage on goods wagons will be put into effect throughout England, Scotland and Wales. The date is set far in the future because in a part of the country (Birmingham, South Staffordshire and South Wales) the new tariff will effect an increase.

FREE PERIOD

Before conveyance—

At stations ..... One day, exclusive of the day upon which the loading is begun.

At private sidings and docks.... Two days, exclusive of the day upon which the loading is begun.

After conveyance—

At stations ..... Two days, exclusive of the day of arrival.

At private sidings and docks.... Three days, exclusive of the day of arrival.

At docks (shipment traffic only).. Four days, exclusive of the day of arrival.

CHARGES

Ordinary wagons.....1s. 6d. (36 cents) per wagon per day.
Sheets.....3d. (6 cents) per sheet per day.

High capacity wagons—	Per wagon per day
Above 16 tons and not exceeding 20 tons carrying capacity	2s. ($0.48)
Above 20 tons and not exceeding 30 tons carrying capacity	3s. (.72)
Above 30 tons	5s. (1.20)
Specially constructed wagons—	
Above 15 tons and under 20 tons carrying capacity	3s. (.72)
20 tons and under 30 tons carrying capacity	6s. (1.44)
30 tons and above	10s. (2.40)
Refrigerator and insulated vans—	
If not unloaded within one day, exclusive of day of arrival	6s. (1.44)

It appears that for many years prior to 1905, owing largely to competition between railway companies, the scheduled charges for demurrage on wagons and sheets were rarely enforced. Thereupon the railway companies' attitude was taken advantage of in several quarters and wagons were detained most unduly awaiting loading or unloading, and sometimes actually used as a trader's storehouse, being moved from place to place as found convenient. Finally, the companies were very seriously affected by shortage of available wagons, congestion in yards where large numbers of wagons were kept under load, and in other ways, and it became imperative to enforce demurrage charges.

Shippers and consignees are much the same, the world over, and we read that for a considerable time there was strong opposition to the new regulations on the part of traders, who withheld payment of the demurrage charges due. At a later date, however, they fell in with the decision given in the Scotch Courts in 1910 in a test case brought by the Glasgow & South-Western against a colliery company, this decision being in favor of the railway.

The rates shown above are already in force, and have been since February 7, last, except in the three districts mentioned.

AUSTRALIA ORDERS LOCOMOTIVES.—The Australian government has recently placed an order with a Queensland company for 20 locomotives for use on the trans-Australian railway, now under construction. Ten are to be delivered at Port Augusta, the eastern terminus, at a price of $37,462, and ten at Kalgoorlie, the western terminus, at a price of $35,355. The locomotives are about equal in weight to the heaviest locomotives now in use in New South Wales.

Convention of Master Boiler Makers' Association

Report of the Proceedings of the Last Three Days of the Ninth Annual Meeting, Held Last Week in Chicago

A report of the first day's proceedings of the ninth annual convention of the Master Boiler Makers' Association was published in the *Railway Age Gazette*, May 28, 1915, page 1129.

Frank McManamy, chief boiler inspector of the Interstate Commerce Commission, presented a paper in which he called attention to a tabulated statement of the work that had been done in the matter of boiler inspection by the commission during the first nine months of each of the fiscal years, 1912 to 1915 inclusive, with the results that had been obtained therefrom.

One of the causes of accidents, in the prevention of which satisfactory progress is not being made, is arch tube failures. Of course, when we take into consideration the increased number of arch tubes in use, some progress towards preventing failures has been made, but inasmuch as the records show that approximately three out of every four of such failures are due to improper application or failure to keep the tubes clean, the progress made is far from satisfactory and the remedy is, to a great extent, in the hands of the master boiler makers.

Accidents due to tube failures also indicate that, in too many instances, quantity rather than quality is the controlling factor, when passing upon the qualifications of the flue welder.

Failure of injector steam pipes is another source of accident in the elimination of which satisfactory progress is not being made.

OXY-ACETYLENE PROCESS FOR BOILER WORK

The report, after citing the necessity of having an oxy-acetylene apparatus in the boiler shop, gave a partial list of the work that can be done with it. This list, with the methods used, is as follows:

Welding in side sheets and patches. When welding in side sheets, some boiler foremen make an allowance for contraction by dropping one end of the sheet, while others get good results by not making any allowance for contraction. The welding in of side sheets, instead of riveting them, has been made a standard practice by some railroads; in fact one railroad is now cutting the side sheets off just above the mud ring and also at the seam at the crown sheet. In this way they save taking out the mud ring rivets and do not disturb the corners. When welding patches in side sheets, good results have been obtained by putting in round or oval shaped patches. Other roads use disk or make box patches for welding. It is necessary to do this to take care of the contraction.

Building up washout plug holes around the firebox or front flue sheet.

Welding cracks in side sheet doors and crown sheets.

Welding up cracked bridges in flue sheets. One method used in welding cracked bridges is to cut out the crack, then hammer the ends of the bridge in and weld. After it is welded and while hot, it should be hammered back straight. This takes care of the contraction. There are some welders who can weld broken bridges without doing this.

Welding seams in door holes instead of riveting or plugging. This is done in two ways; one is to make the lap of the door flange long enough to cover the holes in the back head and weld what would be the calking edge, if rivets were used. The other is to cut the flange in the back head off just back of the rivet holes and butt the door flange to it; then weld it the same as welding in a patch or side sheet.

Welding in tube sheets and door sheets. This is now being done by some railroads; in fact, fireboxes are now being applied in which the only rivets used are those in the mud ring.

Welding cracked and broken mud rings. The general practice in welding cracked or broken mud rings is to cut a piece out of the firebox sheet, then cut a V-shaped piece out of the mud ring and weld the ring from the top side, although some successful welds have been made by cutting out a V-shape and making the weld from the bottom.

Welding tubes in back tube sheet. The welding of tubes in back tube sheets does not seem to be as successful with oxy-acetylene as with the electric process. It is also slower. Some success has been reported where copper ferrules are not used.

Welding up pits in tubes. Large savings are reported by some railroads doing this.

Welding safe ends on superheater flues. In doing this, two methods might be mentioned; one is to butt weld by placing the flue and safe end in an angle iron, spot weld it in four places, then turn the flue while the operator welds it. The other way is to bell the flue if the weld is made on the firebox end and insert the safe end, leaving a lap of ½ in. The weld is then made at the edge of the flue. If the weld is made on the front end of the flue, the safe end should be belled. This is done so the edge will not obstruct the flow of gases or the flames get under the lap. The claim made for welding flues in this manner is that in case the weld should fail, the danger of breaking off is removed by the lap holding the flue.

Welding up staybolt holes in side and crown sheets. This saves bushing holes and sometimes patching.

Some of the uses for the cutting torch are: Cutting out shell sheets; cutting out firebox sheets; scrapping boilers; cutting out superheater flues; cutting out countersunk rivets; cutting off rivets on shells and mud rings; cutting off staybolts and radial stays; and cutting off staybolt ends for driving.

In order to use the oxy-acetylene process to the best advantage, the shop should be equipped with an acetylene generating plant and piped throughout.

Without going into the chemistry of the subject, it is pertinent to point out that purity in oxygen is of first importance, not only because the foreign matter usually enters to some extent into combination with the metal of the weld, but because the flame temperature is reduced and the rate of welding or cutting is also reduced. Oxygen loses rapidly in efficiency with each per cent of impurity much the same as incandescent lamps lose rapidly in candle power for small drops in voltage.

With reference to the manufacture of oxygen, it was stated that at the present stage of the art, it is unwise for any company to generate oxygen by chemical means unless in some small shop exceedingly remote from any source of supply of commercial oxygen.

The largest producer of oxygen in this country employs the liquid air process. That company is admirably equipped for meeting its customers' needs, since it has 10 plants and 16 warehouses at important cities throughout the country. Any user realizes the value of an unfailing oxygen service represented by numerous charging stations and by hundreds of thousands of cylinders. Since freight charges enter into the cost of oxygen, numerous sources of supply and cylinders of minimum weight are both important factors.

Liquid air oxygen has a very small percentage of nitrogen which, being an inert gas, does not make an explosive mixture with the oxygen, and on that account the liquid air product is absolutely safe. Recent competitive tests in cutting operations have shown liquid air oxygen to be high in efficiency; in fact it invariably demonstrated its superiority over oxygen produced by other systems.

Oxygen cylinders can be brought to the work, but in large shops, or in fact in any shop employing two or more welders, it is better to install a pipe and to discharge a battery of 10 to 20

cylinders into it through one reducing valve. This plan has the advantages, first that the gas is available at numerous points in the shop, and second that the operators lose no time through shortage of oxygen, or through carting cylinders from job to job or to and from the storehouse. A continuous supply of oxygen is a valuable asset in doing long jobs.

Acetylene can be used with perfect safety. In selecting a generator, one should only consider those which have been approved by the laboratory of the National Board of Fire Underwriters. None but carbide to water feed should be considered.

In this country there are two principal classes of generators, high pressure, by which is meant pressure over one pound per square inch, and low pressure, or less than one pound per square inch. All things considered, the pressure type is the better for railroad work.

Low and constant pressure is desirable for safe and economical operation. The Underwriters' rules prohibit pressure, on undissolved acetylene, in excess of 15 lb. per sq. in. Most high pressure generators work up to 15 lb., which is taken as the maximum safe pressure because acetylene is unstable under high pressures and one of the essentials, in fact the greatest essential of safe operation, is low pressure.

It is absolutely certain that any shop possessing apparatus generating or storing free acetylene above 15 lb. pressure is courting accident.

It is not wise from the standpoint of safety to truck any form of acetylene generator through a crowded railroad shop. Danger from tipping over, collisions, falling objects, electric wires, portable furnaces, etc., make it much more risky to use a portable generator than to isolate a stationery machine in a small separate building designed for the purpose, and to carry the gas, by approved methods of piping, throughout the shops.

A question might well be asked concerning the attendance expense of the duplex generator. It is very low. In one shop, near Chicago, employing nine welders regularly, one of them tends to the oxygen manifold and acetylene generator. Those duties occupy him, on the average, 1½ hours per working day of nine hours. Therefore the attendance requires 15 per cent of the time of one man out of nine or 1.85 per cent of the total time of all the welders, an almost negligible item of expense.

No operating problems are involved, providing the pipe lines are properly laid out and installed, to give safe and economical service, such as hydraulic flash back traps which absolutely prevent fire from traveling backwards through the hose to the pipe line.

Without going into details here, it is correct to state that any shop regularly employing two or more welders should pipe for both oxygen and low pressure acetylene, rather than to use any form of portable apparatus.

Because of the unstable nature of acetylene under pressure, it cannot be stored in tanks or cylinders like air or oxygen, but must be compressed in receptacles containing fibrous material, usually asbestos and also a liquid known as "acetone."

Acetylene in this form is very useful for lighting purposes and for operating blow pipes at remote points, where pipe lines do not reach and generators would prove too bulky. Emergency work, such as cutting operations at wrecks or occasional jobs at small outlying shops can best be handled in this way, but it is not advisable for many reasons to regularly use the tanks in shops employing two or more operators.

The main repair shops of railroads owning 150 or more locomotives should not entertain compressed acetylene installations, simply because the volume of work warrants a generator plant in order that the highest operating efficiency may prevail.

Compressed acetylene costs the consumer from 2½ cents to 3 cents per cubic foot at the blow pipe, when all items of expense are considered, such as first cost, freight, investment, etc., compared to a cost of less than one cent for acetylene from a generator. The presence of the acetone in the cylinders, mentioned above, has an important bearing on operating expenses. Most acetylene cylinders are made in sizes suitable for lighting purposes, where the demand of the burner is much less in cubic feet of acetylene per hour than when blow pipes are used, especially the larger ones, such as used on locomotive work. Consequently when the blow pipe requires from 40 to 60 cubic feet of gas per hour, as on plates ⅜ in. thick and larger, on mud rings, frames, etc., the cylinder is worked beyond capacity, especially if not freshly charged, and there is difficulty in getting ample acetylene for the burner, without drawing out some of the acetone, which has the bad effect of reducing the temperature of the welding flame, thereby reducing the efficiency and raising the cost of doing work. Also the replacing of acetone at the time of recharging is a factor in the cost of gas.

DISCUSSION

Care must be exercised to see that the proper proportions of oxygen and acetylene are used. If there is too much acetylene there will be a tendency to crystallize the metal, and if the oxygen is in excess the metals will be oxidized. It is also well to have the sheets brought together and heated to a welding temperature so that they are really joined before putting in the welding material.

ELECTRIC WELDING IN BOILER MAINTENANCE

It was the opinion of the committee and a number of boiler makers who were consulted that it is a mistake to weld cracks in fireboxes, more than 8 in. long, as it is only a temporary job and gives much trouble. They have to be rewelded often and this should not be practiced in back shop repairs. A horizontal crack can be more successfully welded than a vertical crack, as the expansion of the firebox is more even vertically than horizontally. This is true in welding cracks in the top flange of tube sheets, as horizontal cracks have been welded and known to give good results for engine house repairs, holding up for six and eight months when cracks from tube holes to rivet holes have to be rewelded often.

In getting sheets, patches and cracks ready for welding, the best results are obtained by beveling both edges of the sheets, or cracks, at 45 deg., and leaving an opening 3/16 in., so as to get the weld through the sheets. In building up thin spots or reducing the size of holes, all scale and grease should be removed, as clean sheets insure good welding. All welds should be built up 1/16 to ⅛ of an inch.

The chairman of this committee has had much success in welding tubes at the firebox end and at the time of this report the Erie division of the Northern Central has tubes welded in passenger service that have been running two years and three months.

The welding of tubes, if properly done, will reduce the tube troubles to a minimum. Where tube welding is a failure it is usually due to the use of improper methods.

The tubes should be applied the same as if no welding was being done, except that no oil should be used on the tools in working the tubes, for electric welding is unsuccessful if oil is on the work. The proper way to prepare tubes for welding is as follows: After ferrules are applied and tubes in place, an oil soft soap should be used as a lubricant instead of oil, on the tube prossers and rollers, after the tubes are beaded; rough the sheet around the head with a roughing tool ¼ in. wide. This will remove all the scale from the sheet and gives good metal for welding; then heat the sheet with a burner, which will burn up the soft soap, and this will leave the sheet free from grease and the tubes are ready for welding. Any time the sheet gets wet, dry it or leaky tubes will result.

Care should be taken that the voltage is not too high. High voltage makes it easier for the operator, but it is not good for the tubes, as the operator with high voltage keeps the metallic pencil ½ to 5/8 in. from the sheet and the metal only sticks and does not weld. A voltage of 64, and 125 amperes makes the operator get within 3/16 in. of the sheet and at this distance a good weld results.

Such good results are not obtainable in welding tubes that have been in service eight or ten months before the welding, as from welding tubes at the time they are applied. Tubes, if properly

welded at the time they are applied, should give three years' service as far as the firebox end is concerned. It pays to weld tubes if only one year of service is obtained as it will eliminate the engine house tube trouble.

The general opinion of the committee is that it is an advantage to use electric welding for side sheets, patches on mud ring corners, small cracks, building up thin spots on sheets and welding tubes, but a disadvantage to weld long vertical cracks in any sheet where there is expansion and contraction.

DISCUSSION

The discussion was almost entirely limited to a consideration of the welding of tubes, as this was the principal use to which the electric welding was applied. It was recommended in connection with this that no oil should be used on the work. The holes should be drilled with soda and a soft soap made of linseed should be used with the expanding and rolling tools.

UNIFORM RULE FOR LOAD ON STAYBOLTS

The maximum allowed load on staybolts and boiler braces has been fixed by the rules of the Interstate Commerce Commission, hence the committee confined itself to a recommendation as to the diameter of staybolts to be used. This recommendation was made because small staybolts are more flexible and give greater life to fireboxes than large bolts; the first firebox will last longer than the second; the second will last longer than the third. The shorter life of the second and third firebox is due to the increase in the size of staybolts made necessary by repeated application of staybolts. It was recommended that ⅞ in. staybolts be applied as a minimum and that 1 in. be the maximum size, and that all bodies of rigid bolts beyond 1 in. be turned down to 25/32 in. between the sheets.

THE STANDARD SLOPE OF CROWNSHEETS

The investigations of the committee showed that there was no standard slope for crownsheets, but the recommendation was made that ½ in. to the foot be used, starting at the tube sheet and going back to the door sheet. The camber should be ¾ in. to the foot each way from the center.

Sheets constructed in this manner are comparatively easy to keep clean and free from scale and sediment, and will give the best results.

The advantages of a sloping crownsheet are:

First: In case of low water the highest point in the crownsheet will become over-heated first, and in all probability will let go quicker and do less damage than if it had no slope.

Second: With this slope the heat strikes the crownsheet more uniformly and is more evenly distributed, thereby causing less strain on the sheet and giving greater life to crownsheets and better results therefrom.

Third: There is more absorption of heat units in the front end than in the rear end of the firebox, and more room is allowed for combustion to take place.

Fourth: A greater amount of heating surface can be used at the front than at the rear end.

Fifth: It gives more room for tube spacing in the back tubesheet.

Sixth: It also gives more room for cab and cab mountings.

The only disadvantage of the sloping crownsheet is that in the construction of the crown and side sheets in one piece there is more waste of material.

TREATING LOCOMOTIVE FEED-WATER

The report gave a general review of the situation as to feed-water treatment and called attention to the fact that an untreated water, although low in incrusting solids, may have a decided tendency to cause foaming, when used in connection with treated water; and at the same time cause incrustations of injectors, line checks, and boiler check valves.

While no recommendation to that effect was made, the tone of the report seemed to favor the treatment of water in the locomotive tanks rather than in roadside treating plants.

DISCUSSION

The treatment of water has effected a very considerable saving on the Missouri Pacific. At Kansas City, where the water is of 36 grains of hardness, the life of tubes when using the raw water was limited to about 10 months, whereas by the use of water treated in a plant, the life has been lengthened to 21 months, while leaks in the firebox and cracks in the sheets have become things of the past. On the Colorado division pitting occurred to such an extent in the tubes that, after cleaning from scale, it was usually necessary to throw at least 65 per cent of the tubes into the scrap. The water also attacked the crownsheet. It has been found that it is not good policy to mix treated and untreated water in the boiler as it is apt to start pitting and other troubles. On the Wichita division, there are no treating plants and the water is treated with soda ash in the tanks, and here, too, the life of the tubes has been increased from 9 to 14 months. However, it is generally recognized that it is not desirable to use the boiler as a treating plant and that the work had best be done before the water is put in the boiler.

This attack on tubes by the water of the Colorado division was not due to the kind of tube used, as experiments have been made with every tube on the market, the results all being the same. In these bad water districts it is necessary to wash the boiler out every 400 miles.

Another speaker stated that the use of soda ash had made it possible to extend the period between washouts by 33 per cent and that there had been no bad effects noticed as the result of the soda ash treatment.

One representative had had an extended experience with the use of polarized mercury and he found that the period between washouts could be extended by about one-third. He found that there is considerable difference in the manner of the circulation of the water when used in boilers having long tubes from what it is in those with short tubes and that this circulation is much freer with the latter. Polarized mercury does not create any tendency to pit, nor does it produce any galvanic action, and when it is used the tubes have a life of about two years and seven months, possibly a little more. Put in figures of miles run this means that the tubes have a life of about 120,000 miles, whereas, before this, they were sometimes limited to 17,000. There were records of a tube life of 147,000 and even 262,000 miles.

In another case it was found that the failures of tubes as indicated by cracking had greatly decreased after the introduction of soda ash treatment, while the number of burst tubes had greatly increased, as the soda treatment seemed to have increased the tendency to pit.

There was a marked difference in the action or apparent action of locomotives fitted with superheaters from those using saturated steam. With the latter, when the tender treatment had charged the water up to the foaming point the foaming was very evident, but in the case of the superheater locomotives, considerable foaming could apparently occur and the water that was carried over into the superheater pipes would be dried out and be delivered to the cylinders in the form of steam.

There was some evidence given to support the idea that the use of soda ash tended to cause pitting, though there were a number of speakers who stated with great positiveness that they could not detect any such tendency.

It was also agreed among those who had had any experience in the use of pure water, such as water that had been treated to a condition of purity, or rain water, that such waters did have a tendency to produce pitting.

CROSS STAYS IN FIREBOXES

In the Belpaire firebox, and some designs of crown bar fireboxes that have flat or nearly flat surfaces where sheets converge from the side to the roof, it is necessary that they be properly braced with cross stays. In this construction, however, there is a considerable distance between the connections of the firebox staybolts to the roof sheet and the necessary slings,

braces or stays in the crownsheet, which permits of a certain flexibility, that will allow some adjustment to take care of the stresses which are the result of the greater expansion of the side sheets of the firebox under the high temperature of direct contact with the fire, as compared with the expansion of the outside side sheets.

The radial stay boiler, however, should have a circular cross section above the crownsheet, and the use of cross stays in this type of boiler restricts the proper equalization of stresses, which result from the unequal expansion of the firebox, as compared with the roof sheet, which, in the case of radial stay boilers, has practically a continuous connection through the staybolts and radial stays. It is believed that a rigid cross stay above the crownsheet in a radial stay boiler increases the bending stress in radial bolts at about the line where cross stays are applied. Breakage of radial staybolts, in the zone indicated, has been experienced, due to the presence of cross stays in this type of boiler, and when their use was discontinued no further trouble from this cause was apparent. The committee does not consider cross stays in the radial stay boiler desirable or necessary, provided the boiler is properly designed with a circular cross section.

REDUCTION OF STRENGTH IN CORRODED OR PITTED BOILER SHELLS

An examination, supplemented by drilling at what appears to be the thinnest part, should be used to determine the thickness of the sheets, and in no case should the boiler be allowed to pass without repairs if the percentage so found has approached closely to that of the joints carrying the same strain.

DISCUSSION

It was suggested, inasmuch as there is no law or generally accepted practice in this matter, that the marine regulations should be adopted, in which the thinnest part of the sheet is the controlling factor. It was also suggested that the age of the boiler should be taken into account in determining the reduced percentage of strength that should be allowed and the practice of the Pennsylvania Railroad was cited as a case in point. On that road the factor of safety is made 4 for the first five years; from 5 to 10 years it is 4½; from 10 to 15 years it is 5; from 15 to 20 years it is 5¾; from 20 to 25 years it is 6½; from 25 to 30 years it is 10 and at the age of 30 years the boiler is scrapped.

DRIVING STAYBOLTS

The objection to driving staybolts with pneumatic hammers and holding-on bar is that the vibration of the holding-on bar, when a pneumatic hammer is used, is such that a number of blows are struck by the hammer while the holding-on bar is rebounding; therefore the bolts are not properly upset in the holes, and naturally the method does not make a good tight job.

To drive staybolts or radial stays successfully with air tools, it is absolutely necessary to hold them on by the same process; the trouble is not in the driving of the bolt any more than it is in the improper methods of holding-on.

In driving these bolts, use a set slightly higher in the center than on the edge, with a small radius on the outer edge, and a staybolt set made especially for this work. This set is used on the inside, as well as the outside end of the bolts; this cuts off all the ragged particles that may be around the edge of the bolts, making a smooth job, which is less liable to gather any accumulations of foreign matter. This work is done with a No. 90 air hammer, and held on with air holding-on tools, made especially for this class of work. In some places a set is used with a center tit to drive the bolt on the outside. This is done where the tell-tale holes are put in staybolts before the bolts are applied. The tit is inserted in the tell-tale hole so as to keep the set centered on the bolt as well as to keep the tell-tale holes in the bolts from being closed up; this is also a very successful method, but some prefer to apply the bolts and have them driven solidly in the center, before the tell-tale hole is drilled. Either one of these methods is good practice.

The trouble with leaky staybolts is not always due to the improper driving, or methods used in driving. There are quite a number of other reasons that contribute directly to these troubles, and if not properly taken care of, the bolts will leak and give trouble, no matter by what method they are driven or held on. It is absolutely necessary to have good threads in all staybolts, as well as radial stayholes, and a full thread on all bolts. It is necessary to have bolts fit the hole properly. If the staybolt and radial stayholes are properly tapped and the bolts have first-class threads, and are properly fitted to the holes, three full threads will be sufficient to make a good serviceable head.

The report closed with a recommendation to use a longstroke air hammer for the work.

REMOVING AND REPLACING FIREBOXES

On the different classes of boilers on the Santa Fe, there is an extra back end suitable for interchange so that when an engine enters the shop, the back end can be cut off and the extra back end complete with new firebox applied, holding the engine not to exceed ten days. This method has a new back end in reserve for interchange, and has proved satisfactory.

It is not necessary to remove the frames or break the connection at the smoke box on engines of the modern type whose firebox is directly over the frames. Experience has also taught that it is a more expensive method to cut the back end and door sheet loose, in order to avoid cutting away at the connection.

In some cases where the O G box passes through the frames, it is customary practice to separate the boiler at the smoke arch and have the work done in the boiler shop, going over the machinery while the boiler is receiving a new firebox. Otherwise it is simply cut off and the back end is replaced in the manner described.

It costs at the Topeka shops from $650 to $900 to put the firebox and back end in first-class shape, depending solely on the size of the boiler. Where the fireboxes are interchangeable, it is not necessary to bring the boiler to the boiler shop, but simply put it in the rear of the file of engines to be turned out of the shop during the month.

The way in which the work is done must be governed largely by the facilities of the shop doing it.

Where there are proper lifting appliances and the erecting shop space, it is more economical to lift the boiler from the frame and send it to the boiler department and the frame to a department for necessary repairs. This will give a track in the erecting department to repair another engine while the boiler and frame are undergoing repairs.

DISCUSSION

The discussion centered around the variations in the methods of removing and replacing the firebox without cutting out the back head, and this was the method in general that was used by the speakers with one or two exceptions. In detail the work was done by cutting off all the staybolts and cutting up the inside sheets with a torch, merely leaving two staybolts in each piece that were cut off, to hold it in place until all of the work was done, and then cutting the pieces loose and allowing them to fall out. The work can be done with the boiler either in the frames or removed. Sometimes the firebox was burned out as a whole and dropped down; sometimes the boiler was turned upside down and the firebox lifted out. In some cases the firebox was put in intact and riveted in place; in others it was put in piecemeal and sometimes each sheet was put in by itself and fitted and riveted. In other words, the new firebox was built in place. It seemed to make no difference whether the firebox were of the wide or narrow type, it is well to cut it out without removing the back head.

OTHER BUSINESS

The report on constructing locomotive tanks consisted of a brief review of the steps to be taken in the construction of a tank of the ordinary type with a mere reference to the circular tank of the Vanderbilt type.

The secretary's report showed that at the beginning of the year there were 419 members in good standing, that there were 77 new members taken in during the year and that there were 125 of these who were dropped, resigned or had died, leaving a present membership of 371.

The following officers were elected for the ensuing year:

President, Andrew Green, general foreman boiler maker, Big Four, Indianapolis, Ind.; first vice-president, D. A. Lucas, general foreman boiler maker, Burlington, Havelock, Neb.; second vice-president, John B. Tate, foreman boiler maker, Pennsylvania Railroad, Altoona, Pa.; third vice-president, Charles P. Patrick, Erie Railroad, Cleveland, Ohio; fourth vice-president, Thomas Lewis, general foreman, Lehigh Valley, Sayre, Pa.; fifth vice-president, Thomas F. Madden, general boiler inspector, Missouri Pacific, St. Louis, Mo.; secretary, Harry D. Vought, 95 Liberty street, New York City; and treasurer, Frank Gray, 705 W. Mulberry street, Bloomington, Ill.

INFORMATION DESIRED BY INTERSTATE COMMERCE COMMISSION FOR PASSENGER RATE CASE

The Interstate Commerce Commission has addressed to the western railroads a list of 18 interrogatories outlining the character of the evidence and data desired by the commission to be presented at the hearings to be held at Chicago beginning on July 6, on the advanced passenger fares filed by the western railroads, which have been suspended. Responses are to be made by the president or chief accounting officer of each road, and filed at the opening of the hearing.

Questions 1 to 5 relate to the separation of operating expenses between passenger service and freight service. Carriers that regularly make such a separation are asked to submit a statement for the years 1913 and 1914, showing for each primary expense account the amount directly allocated to freight service or to passenger service and the amount of expenses regarded as common, giving the division of the common expenses on bases deemed by carrier to be most nearly equitable. Question 1 states that the basis of division should be stated for each account and that the data used in making the apportionment of the common expenses should be given. Question 2 asks for a statement showing the total operating revenues for the years 1913 and 1914 of the freight service and the passenger service. Question 3 asks for a statement showing the operating ratios for both services for 1913 and 1914. Question 4 asks for a statement showing by years for the period 1907 to 1914, the total revenues, expenses and operating ratio for passenger service and freight service, respectively, for each year or for such part of the period as the separation has been made. Question 5 asks carriers that have made any study of the subdivision of the revenues and expenses of passenger service, as between the various classes of service, to describe the methods and results of such study.

Question 6 asks for the information, for the two years ending June 30, 1914, as to passenger miles per passenger traveling, in sleeping and parlor cars; revenues on account of such passengers, essential features, of contract with a sleeping car company, and passenger train car miles classified as between the various kinds of cars. For express cars and cars used for various services the commission desires information as to the car foot miles made in the baggage, mail, express or other service. This question also calls for information as to the average weight and length of standard cars used in the various services and repairs per car mile.

Question 7 asks information regarding the revenues and expenses of dining car service. If dining cars are operated on certain trains or between certain points at a loss, the commission desires to know on what ground the operation of such cars is justified or in what way the just demands of the traveling public could be met without entailing such a loss. Question 8 asks about the profitableness of other branches of the passenger service which can be definitely segregated, with revenues and expenses for a period of two years.

Question 9 asks for a statement as detailed as practicable, showing changes in the character of passenger service during the past 10 years, including specific illustrations as to the speed of trains, kind and weight of passenger train cars and frequency of service, safety and comfort of passengers. Question 10 asks whether the respondent furnishes any passenger train service considered unwarranted or unnecessary to meet the reasonable demands of the traveling public, and if so, a statement of the amount of such service considered unnecessary, with the reasons why it is furnished.

Question 11 asks whether the roads have made any investigation to determine the relative profitableness of passenger trains of different classes, such as suburban passenger business, and if any investigation has been made of the relative profitableness of through passenger trains between important terminals or in highly competitive territory, and trains in districts or communities where competition is not so keen, the commission desires a statement of the results.

Questions 12, 13 and 14 ask for information regarding changes in the labor cost per unit of service rendered, increases or decreases of rates of wages since July 1, 1907, with the effect upon the cost of conducting freight and passenger service, changes in the cost of fuel and in the cost of cross ties since 1907. Specific questions are asked regarding the practice of using treated ties, the proportion of such ties, the estimated average life, etc.

Question 15 asks for information regarding important changes since 1907 in the price of materials and supplies other than equipment, cross ties and fuel. The roads are asked to submit a list of articles on which there have been marked changes in price. Question 16 asks for the purchase price of passenger equipment in 1914 as compared with 1907, with reference to weight and tractive power of locomotives, and weight and seating capacity of passenger cars.

Question 17 asks for a statement of the result of any attempt to separate the cost of road and equipment as between property assignable to passenger and freight service, and property used in common.

Question 18 asks what sums have been expended in raising the standard of the property which have been charged to operating expenses.

Belgian Coal Industry.—The production of coal in Belgium has increased of late, although yet a long way below the normal, and it is still proportionately lower than the reduction in the number of hands. This is due to the less skilled hands, which it has been necessary to employ to a considerable extent, and to the circumstance that, in many places, they do not work every day, only five or four, or even not more than three days, a week. The coal mines belonging to the mixed undertakings—Cockerills, Ougrée-Marihaye, and others—in the first instance satisfy their own requirements. The mines of Louvière and Sars-Longchamps are working, and have even lately added a new pit; also the Houssu concern is working a new pit. The most active working takes place in the Charleroi district, where several concerns have joined in one union so as to be better able to overcome the difficulties of the railway traffic. The improvement in the canal traffic may also help to facilitate the transport of coal, even if only by degrees. The situation at Charleroi has been a little less hopeful of late on account of a reduction in the domestic demand, and stocks are apparently accumulating in the absence of any export, and with reduced requirements on the part of industry and the railways. At the end of December there were about 300,000 tons stock in the Borinage district, but financial difficulties stand in the way of greater activity.—*Engineering.*

MINIATURE RAILWAY AT THE PANAMA-PACIFIC EXPOSITION

By Bradley B. Brown

The large area covered by the Panama Pacific Exposition has created demands for transportation about the grounds which have been met in several ways. The most interesting means employed is the Overfair Railway, a 19-inch gage line operated by steam locomotives.

The road has five locomotives, four of the Pacific type for passenger service and one six-coupled tank engine for switching service. These locomotives are larger and more powerful than

Tank Locomotive for Switching Service

most miniature engines and the design is such that their general lines follow closely those of standard gage steam road locomotives, while the working parts are designed with a view to obtaining the greatest efficiency in the service for which they are intended. As compared with large locomotives the principal dimensions of the miniature engines have been made one-third size but it was necessary to make some parts larger than called for by this scale. For instance the cab had to be made large enough to accommodate two enginemen and as shown in one of the illus-

Pacific Type Passenger Locomotive for the Overfair Railway

trations, it was necessary to use a full size eight-inch air pump.

The principal dimensions of the Pacific type locomotives are:

Gage	19 in.
Fuel	Hard coal
Total weight	24,000 lb.
Weight on drivers	15,000 lb.
Tractive effort	3,765 lb.
Total length	17 ft. 2 in.
Total wheel base	12 ft. 1¾ in.
Height from top of rail to top of stack	5 ft. 6 in.
Diameter of drivers	26 in.
Cylinders, diameter and stroke	8 in. by 9 in.
Valves, type	Piston
Valves, travel	2½ in.
Boiler pressure	200 lb. per sq. in.
Firebox, length and width	36½ in. by 31½ in.
Tubes, number and diameter	162—1¼ in.
Tube heating surface	404 sq. ft.
Firebox heating surface	39 sq. ft.
Total heating surface	443 sq. ft.

The switching engine weighs nine tons, has cylinders 7 in. in diameter by 9 in. stroke and driving wheels 19½ in. in diameter. All five locomotives are equipped with the Walschaert valve gear.

The passenger cars are built of wood and weigh approximately one ton each. They are 20 ft. long, 3 ft. 6 in. wide and 5 ft. 1½ in. high inside. Each one seats 16 people, the seats being so arranged that half the passengers ride forward and half backward. There are 64 of these cars, all of which are equipped with automatic couplers and automatic air brakes.

The line starts at Machinery Hall and follows the bay shore westward for two miles, terminating at the race track. There are five intermediate stations on the line. A branch line continues westward for another half mile, terminating at the aviation field. The engines will start 12 loaded cars on level track and attain a speed of 16 miles an hour in a distance of one-fifth mile. The stations are so near together, however, that full speed is never reached. The time required to make the run between Machinery

Cars Used on the Overfair Railway

Hall and the race track is 15 min. and a fare of 10 cents is charged.

The entire line is double tracked and laid with 20 lb. rails. The track is largely level, there being only a few short grades; the sharpest curves have radii as small as 100 ft. but the trains take these without difficulty. Turntables are provided at the three terminals.

The locomotives and rolling stock were designed and built in the shops of L. M. MacDermot, Oakland, Cal.

English Railways Increase Cartage Charges.—The English railways have recently found it necessary to make increases in their cartage and lighterage charges, the increased rates having gone into effect on May 1. The charge applies particularly to "S. to S." (station to station) traffic, which excludes the service of collection and delivery. The increased rates are due primarily to the increased expenses, particularly the higher cost of horses and feed, resulting from the war. The cartage strength of the railways in addition has been seriously depleted by the shrinkage of horses and men.

General News Department

The Boston & Maine announces that liquors will no longer be sold in the dining cars of the road.

The Brotherhood of Locomotive Engineers, at a convention held in Cleveland last week, adopted a resolution advocating a federal law requiring power headlights on locomotives on all steam railroads in the country.

The Illinois legislature has passed a bill authorizing the construction by the state of a navigable waterway from Lockport to Utica, a distance of 65 miles, connecting the drainage canal with the Illinois river and the Mississippi river.

The Chicago & North Western announces that out of 850 passenger trains operated between Chicago and Milwaukee during the month of April 847 trains arrived at the terminals exactly on time, and in the other three instances there was only a few minutes' delay.

A party of Lehigh Valley Railroad officers, including both operating and traffic men, has just returned from a business trip in the west, where they sought to learn at first hand what their patrons in the middle west had to suggest for the betterment of the service. The party visited all the larger cities, and saw, also, prominent western railroad men.

The Pennsylvania Railroad and the Public

[From statement before the Commission on Industrial Relations.]

The policy of publicity which the Pennsylvania Railroad pursues is framed with a view to keeping the public advised of the company's activities; in short, to take the public into its confidence. The company started its publicity work some nine years ago by first inaugurating a plan of full publicity regarding all accidents on its lines. Since that time the work has been extended to cover the activities of all departments.

The road makes an effort to see to it that what the press publishes about the railroad shall not consist of complimentary notices about the railroad or its officers, but real facts of consequence. If the road is going to be able to work out its problems properly, it has got to be believed in. It must get imbedded in the public mind that it is doing its work as best it can and doing it, in the main, exceedingly well.

The first plan of distribution worked out was to give information in Philadelphia, and then to send copies to the papers throughout the system. But it became obvious that the local representative of the company in each city must of necessity know what was being given to the papers and the plan was developed whereby representatives were appointed to deal with the press in each place, the general superintendent, the superintendent, or the agent.

The road never pays any newspaper anything to print anything as news, or as an editorial, regarding its service. The papers can do as they wish; publish or throw in the waste basket. What they do does not affect in the slightest the attitude of the company toward them.

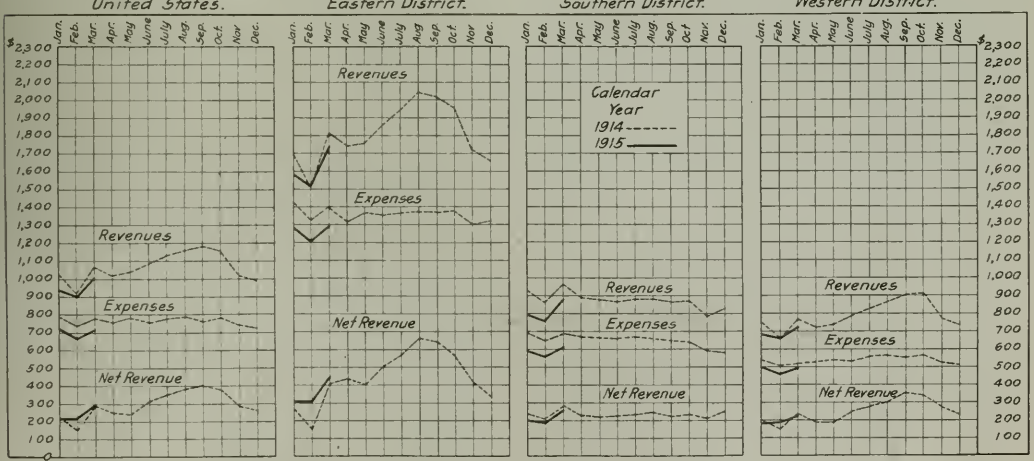
The Pennsylvania Railroad is just beginning its publicity work. It is continually trying to find new angles from which to approach the public with information about the work the railroad is trying to do.

Summary of Revenues and Expenses of Steam Roads

The Bureau of Railway Economics' summary of revenues and expenses and comments thereon for March, 1915, are as follows:

Net operating income of the railways of the United States for March increased $3 per mile, or 1.2 per cent, as compared with March, 1914. This increase was due not to an increase in gross earnings but to reductions in expenses, which have been effected throughout the country, but particularly in the East. In March, 1914, net operating income per mile was 2.9 per cent greater than in March, 1913.

Total operating revenues amounted to $231,499,126, a decrease



Monthly Revenues and Expenses per Mile of Line in 1914 and 1915

from 1914 of $15,923,105. Operating expenses were $164,731,902, a decrease of $16,966,890. Net operating revenue amounted to $66,767,224, an increase of $1,043,785. Taxes amounted to $11,133,218, a decrease of $187,273. This left $55,581,122 for net operating income, available for rentals, interest on bonds, appropriations for improvements and new construction, and dividends. Operating revenues per mile of line averaged $1,012, a decrease of 7.3 per cent; operating expenses per mile averaged $720, a decrease of 10.2 per cent; net operating revenue per mile averaged $292, an increase of 0.7 per cent, while taxes per mile were $49, a decrease of 2.5 per cent. Net operating income per mile

was $243, an increase of 1.2 per cent. Railways operating 228,661 miles of line are covered by this summary, or about 90 per cent of the steam railway mileage in the United States.

Total operating revenues of the eastern railways per mile of line decreased 5.9 per cent as compared with March, 1914, operating expenses decreased 11.0 per cent, net operating revenue increased 12.7 per cent, taxes increased 0.6 per cent, and operating income increased 15.6 per cent.

Total operating revenues of the southern railways per mile decreased 11.9 per cent, operating expenses decreased 12.3 per cent, net operating revenue decreased 10.9 per cent, taxes decreased 4.7 per cent, and operating income decreased 12.0 per cent.

Total operating revenues of the western railways per mile decreased 6.5 per cent, operating expenses decreased 7.8 per cent, net operating revenue decreased 3.8 per cent, taxes decreased 4.5 per cent, and operating income decreased 3.8 per cent.

The nine months of the current fiscal year show a decrease in total operating revenues per mile of line of 7.8 per cent as compared with the corresponding period of the preceding year, a decrease in operating expenses per mile of 9.8 per cent, a decrease in net operating revenue per mile of 2.8 per cent, and a decrease in net operating income of 3.0 per cent.

The net operating income per mile increased 6.0 per cent in the East, decreased 19.5 per cent in the South, and decreased 4.0 per cent in the West.

March net operating income per mile was 1.2 per cent greater in 1915 than in 1914, 3.6 per cent greater than in 1913, 6.7 per cent less than in 1912, and 9.1 per cent less than in 1911.

Railway Signal Association

The May meeting of the Railway Signal Association, held in New York City last week (see page 1132), finished its business on Thursday by discussing the four additional committee reports named in the program.

Committee VI, on standard designs, presented four new and four revised drawings. The revisions include a terminal block, a clamp for the base of ground mast signals, a blade for upper quadrant signals and a binding post. The new plans show tang ends with screw jaws, an adjusting crank and assembly, and switch adjustment brackets, insulated and non-insulated.

Committee VIII, on electric railway and alternating current signaling, presented specifications for reactors. These were discussed at some length and members made numerous suggestions for minor changes.

Committee X, on storage battery and charging equipment, presented, in revised form, a set of specifications for nickel-iron alkaline storage batteries, and gave data showing typical figures for costs of various methods of charging storage batteries for automatic signals.

The special committee on lightning protection presented revised specifications for vacuum-gap and air-gap lightning arresters and for choke coils, to be used with lightning arresters.

The Atlantic City Conventions

J. D. Conway, secretary of the Railway Supply Manufacturers' Association, announces that 67,680 sq. ft. of space on the Pier at Atlantic City has been taken by the exhibitors for the conventions of the Master Mechanics' and Master Car Builders' Associations, and several other firms are negotiating for space. The total space which has been contracted for from the owners of the Pier is 70,000 sq. ft.

All of the entertainment features of the conventions are to be held on the Pier this year. There will be dances on June 9, 10 and 11, the dance on the 11th being a carnival dance, and a vaudeville performance on June 12. The vaudeville performance will be held in the Auditorium, which is directly over the Convention Hall, and which seats 5,000, so that there will be ample room for all members and guests. On Sunday a golf tournament will be held at the Seaview Golf Course.

American Electric Railway Association

After June first the headquarters of the American Electric Railway Association will be located at 8 West Fortieth street, New York. The headquarters were formerly at 29 West Thirty-ninth street.

MEETINGS AND CONVENTIONS

The following list gives names of secretaries, dates of next or regular meetings, and places of meeting.

Air Brake Association.—F. M. Nellis, 53 State St., Boston, Mass. Next convention, May 2-5, 1916, Atlanta, Ga.

American Association of Demurrage Officers.—F. A. Pontious, 455 Grand Central Station, Chicago. Next meeting, July 21, 1915, Milwaukee, Wis.

American Association of Dining Car Superintendents.—H. C. Boardman, D. L. & W., Hoboken, N. J. Next meeting, October 21-23, 1915, Boston, Mass.

American Association of Freight Agents.—R. O. Wells, Illinois Central, East St. Louis, Ill.

American Association of Passenger Traffic Officers.—W. C. Hope, C. R. R. of N. J., 143 Liberty St., New York.

American Association of Railroad Superintendents.—E. H. Harman, Room 101, Union Station, St Louis, Mo. Next meeting, August 19-20, 1915, San Francisco, Cal.

American Electric Railway Association.—E. B. Burritt, 8 W. 40th St., New York. Annual convention, October 4-8, 1915, San Francisco, Cal.

American Electric Railway Manufacturers' Association.—H. G. McConnaughy, 165 Broadway, New York. Meetings with American Electric Railway Association.

American Railroad Master Tinners, Coppersmiths and Pipefitters' Association.—W. E. Jones, C. & N. W., 3814 Fulton St., Chicago. Annual meeting, July 13-16, 1915, Hotel Sherman, Chicago.

American Railway Association.—W. F. Allen, 75 Church St., New York.

American Railway Bridge and Building Association.—C. A. Lichty, C. & N. W., Chicago. Next convention, October 19-21, 1915, Detroit, Mich.

American Railway Engineering Association.—E. H. Fritch, 900 S. Michigan Ave., Chicago. Next convention, March 21-23, 1916, Chicago.

American Railway Master Mechanics' Association.—J. W. Taylor, 1112 Karpen Bldg., Chicago. Annual meeting, June 9-11, 1915, Atlantic City, N. J.

American Railway Tool Foremen's Association.—Owen D. Kinsey, Illinois Central, Chicago. Annual meeting, July 19-21, 1915, Hotel Sherman, Chicago.

American Society for Testing Materials.—Prof. E. Marburg, University of Pennsylvania, Philadelphia, Pa. Annual meeting, June 22-26, 1915, Hotel Traymore, Atlantic City, N. J.

American Society of Civil Engineers.—Chas. Warren Hunt, 220 W. 57th St., New York, Regular meetings, 1st and 3d Wednesday in month, except July and August, 220 W. 57th St., New York.

American Society of Mechanical Engineers.—Calvin W. Rice, 29 W. 39th St., New York. Next spring meeting, June 22-25, 1915, Buffalo, N. Y. Annual meeting, December 7-10, 1915, New York.

American Wood Preservers' Association.—F. J. Angier, Supt. Timber Preservation, B. & O., Mt. Royal Sta., Baltimore, Md. Next convention, January 18-20, 1916, Chicago.

Association of American Railway Accounting Officers.—E. R. Woodson, Rooms 1116-8, Woodward Bldg., Washington, D. C. Annual meeting, June 28, 1916, Detroit, Mich.

Association of Manufacturers of Chilled Car Wheels.—George W. Lyndon, 1214 McCormick Bldg., Chicago. Annual meeting, 2d Tuesday in October, 1915, New York.

Association of Railway Claim Agents.—C. W. Egan, B. & O., Baltimore, Md.

Association of Railway Electrical Engineers.—Jos. A. Andreucetti, C. & N. W., Room 411, C. & N. W. Sta., Chicago. Semi-annual meeting with Master Car Builders' and Master Mechanics' Associations. Annual meeting, October, 1915.

Association of Railway Telegraph Superintendents.—P. W. Drew, Soo Line, 112 West Adams St., Chicago. Annual meeting, June 22-25, 1915, Rochester, N. Y.

Association of Transportation and Car Accounting Officers.—G. P. Conard, 75 Church St., New York. Next meeting, June 22-23, Niagara Falls, N. Y.

Bridge and Building Supply Men's Association.—L. D. Mitchell, Detroit Graphite Co., Chicago, Ill. Meetings with American Railway Bridge and Building Association.

Canadian Railway Club.—James Powell, Grand Trunk, P. O. Box 7, St. Lambert (near Montreal), Que. Regular meetings, 2d Tuesday in month, except June, July and August, Windsor Hotel, Montreal, Que.

Canadian Society of Civil Engineers.—Clement H. McLeod, 176 Mansfield St., Montreal, Que. Regular meetings, 1st Thursday in October, November, December, February, March and April. Annual meeting, January, Montreal.

Car Foremen's Association of Chicago.—Aaron Kline, 841 Lawlor Ave., Chicago. Regular meetings, 2d Monday in month, except June, July and August, Hotel La Salle, Chicago.

Central Railway Club.—H. D. Vought, 95 Liberty St., New York. Regular meetings, 2d Friday in January, May, September and November. Annual meeting, 2d Thursday in March, Hotel Statler, Buffalo, N. Y.

Engineers' Society of Western Pennsylvania.—Elmer K. Hiles, 2511 Oliver Bldg., Pittsburgh, Pa. Regular meetings, 1st and 3d Tuesday, Pittsburgh.

Freight Claim Association.—Warren P. Taylor, Traffic Manager, R. F. & P., Richmond, Va. Annual meeting, June 16, 1915, Chicago.

General Superintendents' Association of Chicago.—A. M. Hunter, 321 Grand Central Station, Chicago. Regular meetings, Wednesday, preceding 3d Thursday in month, Room 1856, Transportation Bldg., Chicago.

International Railway Fuel Association.—C. G. Hall, C. & E. I., 922 McCormick Bldg., Chicago.

International Railway General Foremen's Association.—Wm. Hall, 1126 W. Broadway, Winona, Minn. Next convention, July 13-16, 1915, Sherman House, Chicago.

International Railroad Master Blacksmiths' Association.—A. L. Woodworth, C. H. & D., Lima, Ohio. Annual meeting, August 17, 1915, Philadelphia, Pa.

MAINTENANCE OF WAY AND MASTER PAINTERS' ASSOCIATION OF THE UNITED STATES AND CANADA.—T. I. Goodwin, C. R. I. & P., Eldon, Mo. Next meeting, October 19-21, 1915, St. Louis, Mo.

MASTER BOILER MAKERS' ASSOCIATION.—Harry D. Vought, 95 Liberty St., New York.

MASTER CAR AND LOCOMOTIVE PAINTERS' ASSOCIATION OF THE UNITED STATES AND CANADA.—A. P. Dane, B. & M., Reading, Mass. Next convention, September 14-16, 1915, Detroit, Mich.

MASTER CAR BUILDERS' ASSOCIATION.—J. W. Taylor, 1112 Karpen Bldg., Chicago. Annual meeting, June 14-16, 1915, Atlantic City, N. J.

NATIONAL RAILWAY APPLIANCES ASSOCIATION.—C. W. Kelly, 349 Peoples Gas, Bldg., Chicago. Next convention, March, 1916, Chicago.

NEW ENGLAND RAILROAD CLUB.—W. E. Cade, Jr., 683 Atlantic Ave., Boston, Mass. Regular meetings, 2d Tuesday in month, except June, July, August and September, Boston.

NEW YORK RAILROAD CLUB.—Harry D. Vought, 95 Liberty St., New York. Regular meetings, 3d Friday in month, except June, July and August, 29 W. 39th St., New York.

NIAGARA FRONTIER CAR MEN'S ASSOCIATION.—E. N. Frankenberger, 623 Brisbane Bldg., Buffalo, N. Y. Meetings 3d Wednesday in month, New York Telephone Bldg., Buffalo, N. Y.

PEORIA ASSOCIATION OF RAILROAD OFFICES.—M. W. Rotchford, 410 Masonic Temple Bldg., Peoria, Ill. Regular meetings, 3d Thursday in month, Jefferson Hotel, Peoria.

RAILROAD CLUB OF KANSAS CITY.—Claude Manlove, 1008 Walnut St., Kansas City, Mo. Regular meetings, 3d Saturday in month, Kansas City.

RAILROAD MEN'S IMPROVEMENT SOCIETY.—J. B. Curran, Erie R. R., 50 Church St., New York. Meetings, alternate Thursdays, October to May. Assembly Rooms of Trunk Line Association, 143 Liberty St., New York.

RAILWAY BUSINESS ASSOCIATION.—Frank W. Noxon, 30 Church St., New York. Annual meeting, December, 1915, Waldorf-Astoria Hotel, New York.

RAILWAY CLUB OF PITTSBURGH.—J. B. Anderson, Room 207, P. R. R. Sta., Pittsburgh, Pa. Regular meetings, 4th Friday in month, except June, July and August, Monongahela House, Pittsburgh.

RAILWAY ELECTRICAL SUPPLY MANUFACTURERS' ASSOCIATION.—J. Scribner, 1063 Monadnock Block, Chicago. Meetings with Association of Railway Electrical Engineers.

RAILWAY FIRE PROTECTION ASSOCIATION.—C. B. Edwards, Fire Ins. Agt., Mobile & Ohio, Mobile, Ala. Next meeting, October 5-7, 1915, Chicago.

RAILWAY SIGNAL ASSOCIATION.—C. C. Rosenberg, Myers Bldg., Bethlehem, Pa. Annual meeting, September 14-17, 1915, Salt Lake City, Utah.

RAILWAY STOREKEEPERS' ASSOCIATION.—J. P. Murphy, N. Y. C. R. R., Box C, Collinwood, Ohio.

RAILWAY SUPPLY MANUFACTURERS' ASSOCIATION.—J. D. Conway, 2136 Oliver Bldg., Pittsburgh, Pa. Meetings with Master Car Builders and Master Mechanics' Associations.

RAILWAY TELEGRAPH AND TELEPHONE APPLIANCE ASSOCIATION.—G. A. Nelson, 50 Church St., New York. Meetings with Association of Railway Telegraph Superintendents.

RICHMOND RAILROAD CLUB.—F. O. Robinson, C. & O., Richmond, Va. Regular meetings, 2d Monday in month, except June, July and August.

ROADMASTERS' AND MAINTENANCE OF WAY ASSOCIATION.—L. C. Ryan, C. & N. W., Sterling, Ill. Annual meeting, September 14-16, 1915, Chicago.

ST. LOUIS RAILWAY CLUB.—B. W. Frauenthal, Union Station, St. Louis, Mo. Regular meetings, 2d Friday in month, except June, July and August, St. Louis.

SALT LAKE TRANSPORTATION CLUB.—R. E. Rowland, David Keith Bldg., Salt Lake City, Utah. Regular meetings, 1st Saturday of each montb, Salt Lake City.

SIGNAL APPLIANCE ASSOCIATION.—F. W. Edmunds, 3868 Park Ave., New York. Meeting with annual convention Railway Signal Association.

SOCIETY OF RAILWAY FINANCIAL OFFICERS.—Carl Nyquist, C. R. I. & P., 1134 La Salle St. Sta., Chicago. Annual meeting, September, 1915.

SOUTHEAN ASSOCIATION OF CAR SERVICE OFFICERS.—E. W. Sandwich, A. & W. P. R. R., Atlanta, Ga. Next meeting, July 15, 1915, Atlanta. Annual meeting, January, 1916.

SOUTHERN & SOUTHWESTERN RAILWAY CLUB.—A. J. Merrill, Grant Bldg., Atlanta, Ga. Regular meetings, 3d Thursday, January, March, May, July, September, November, 10 A. M., Piedmont Hotel, Atlanta.

TOLEDO TRANSPORTATION CLUB.—Harry S. Fox, Toledo, Ohio. Regular meetings, 1st Saturday in month, Boody House, Toledo.

TRACK SUPPLY ASSOCIATION.—W. C. Kidd, Ramapo Iron Works, Hillburn, N. Y. Meetings with Roadmasters' and Maintenance of Way Association.

TRAFFIC CLUB OF CHICAGO.—W. H. Wharton, La Salle Hotel, Chicago.

TRAFFIC CLUB OF NEWARK.—John J. Kautzmann, P. O. Box 238, Newark, N. J. Regular meetings, 1st Monday in month, except July and August, The Washington, 559 Broad St., Newark.

TRAFFIC CLUB OF NEW YORK.—C. A. Swope, 291 Broadway, New York. Regular meetings last Tuesday in month, except June, July and August, Hotel Astor, New York.

TRAFFIC CLUB OF PITTSBURGH.—D. L. Wells, Genl. Agt., Erie R. R., 1924 Oliver Bldg., Pittsburgh, Pa. Meetings bi-monthly, Pittsburgh. Annual meeting, 2d Monday in June.

TRAFFIC CLUB OF ST. LOUIS.—A. F. Versen, Mercantile Library Bldgs., St. Louis, Mo. Annual meeting in November. Noonday meetings October to May.

TRAIN DISPATCHERS' ASSOCIATION OF AMERICA.—J. F. Mackie, 7122 Stewart Ave., Chicago. Annual meeting June 15, 1915, Minneapolis, Minn.

TRANSPORTATION CLUB OF DETROIT.—W. R. Hurley, Superintendent's office, N. Y. C. R. R., Detroit, Mich. Meetings monthly, Normandie Hotel, Detroit.

TRAVELING ENGINEERS' ASSOCIATION.—W. O. Thompson, N. Y. C. R. R., East Buffalo, N. Y. Annual meeting, September 7-10, 1915, Chicago.

UTAH SOCIETY OF ENGINEERS.—Frank W. Moore, 1111 Newhouse Bldg., Salt Lake City, Utah. Regular meetings, 3d Friday in month, except July and August, Salt Lake City.

WESTERN CANADA RAILWAY CLUB.—L. Kon, Immigration Agent, Grand Trunk Pacific, Winnipeg, Man. Regular meetings, 2d Monday, except June, July and August, Winnipeg.

WESTERN RAILWAY CLUB.—J. W. Taylor, 1112 Karpen Bldg., Chicago. Regular meetings, 3d Tuesday in month, except June, July and August, Karpen Bldg., Chicago.

WESTERN SOCIETY OF ENGINEERS.—J. H. Warder, 1735 Monadnock Block, Chicago. Regular meetings, 1st Monday in month, except January, July and August, Chicago. Extra meetings, except in July and Wednesday after 1st Thursday in January, Chicago. August, generally on other Monday evenings. Annual meeting, 1st

Traffic News

The Western Maryland has filed tariffs with the Interstate Commerce Commission, making the fare from Baltimore to Chicago $16; and Baltimore now has a differential. The standard rate from Baltimore to Chicago is $18.

The Atchison, Topeka & Santa Fe has put in service seven new package freight cars from Chicago to Arkansas City, Guthrie, Fort Worth, Dallas, Temple and Houston on shortened schedules, giving a third day arrival in Arkansas City, and a four-day schedule to the other points, except Houston, where there is a five-day service.

The Pennsylvania Railroad announces that it will comply with the order of the Public Service Commission of Pennsylvania by making the 100-trip ticket good for a period of one year instead of six months, and all tickets of this character sold since December 14, 1914, will be good for one year, irrespective of the limit of six months, under which they were sold, and this will also apply to tickets for interstate travel.

The Western Classification Committee has filed with the Interstate Commerce Commission supplement No. 6 to classification No. 53, giving the new form of Section 3 of the uniform bill of lading to make it conformable to the Cummins amendment forbidding railroads to limit their liability for loss and damage below the actual value of the goods, which goes into effect on June 2. The new Section 3 in the Western Classification is identical with that published in last week's issue, page 1134, as issued by C. C. McCain, chairman of the Uniform Bill of Lading Committee for the roads east of Chicago and north of the Ohio river. The supplement also contains the new rule 2 of the classification, stating that ratings are conditional upon actual valuations declared by the shippers at time and place of shipment. Where a shipper refuses to declare value at time and place of shipment goods will not be accepted for transportation. The old rule 2 provided that when invoice value is made a condition of the ratings shown in the classification, the shipper must sign a statement declaring that the invoice value of the property does not exceed the value as stated. The supplement also contains amendments to various items in the classification for which ratings are based on value, stating that the actual value of each article is not to exceed certain amounts named, instead of saying that the value of the article is declared by the shipper not to exceed the amount named.

New Transcontinental Rates July 15

Traffic officers of the transcontinental railroads, after a meeting held in Chicago last week, announced their intention of accepting the latest decision of the Interstate Commerce Commission in the transcontinental fourth section cases and putting into effect the rates prescribed on July 15, the date on which the commission made effective its orders in the original fourth section case and the supplemental orders relating to rates to the "back-haul" territory. This puts into effect the system by which rates to western intermediate points are allowed to exceed the rates to coast terminals by fixed percentages from five zones, which was involved in the decision of the Supreme Court sustaining the commission. The order also puts into effect on July 15 the rates covered by the recent application of the railroads for special permission to make low rates to the Pacific coast on articles especially subject to water competition, without correspondingly reducing their rates to intermediate points.

New Passenger Train Service to Pacific Coast

The Chicago, Burlington & Quincy on May 30 put in service seven new passenger trains from Chicago and four from St. Louis to the Pacific coast, including trains leaving Chicago at 10:05 a. m., running west of Denver over the Union Pacific and the San Pedro, Los Angeles & Salt Lake to Los Angeles, and via the Union Pacific and Southern Pacific to San Francisco; a train leaving Chicago at 11 p. m., running over the Union Pacific and the Western Pacific to San Francisco, the Union Pacific and Southern Pacific to San Francisco, and the Union Pacific

and the San Pedro, Los Angeles & Salt Lake to Los Angeles; a train leaving Chicago at 10:10 a. m., in connection with the Northern Pacific west of St. Paul and Minneapolis to Portland, Seattle and Tacoma; a train leaving Chicago at 10:15 p. m., in connection with the Great Northern west of St. Paul and Minneapolis to Portland, Seattle and Tacoma. Two of the trains from St. Louis are for California and two for the North Pacific coast. New service was established also on May 30, by the Wabash, Union Pacific and Southern Pacific, between St. Louis and San Francisco. The Union Pacific has put on three additional trains eastbound and three westbound in connection with the New Burlington and Wabash service, and a new train running between Chicago and Denver via the Chicago & North Western.

Passengers Must Declare Value of Baggage

The various passenger traffic associations are working out the details of the new rules governing the transportation of baggage which will be required under the Cummins amendment. The Interstate Commerce Commission has decided that the law seems clearly to recognize the carrier's right to fix conditions and terms applicable to the transportation of baggage dependent upon the value as declared by the person who offers the baggage for transportation, and the various associations have practically decided to adopt rules, effective on June 15, requiring declaration of value of baggage at the time of checking, with the understanding that where the amount is not known the value is declared to be not in excess of $100. For smaller stations a baggage waybill has been suggested. For large stations large sheets similar to hotel registers on which passengers may declare the valuation and sign their names, has been proposed. The Trunk Line and Southeastern Passenger Associations have already adopted rules and regulations requiring declarations of value by passengers. Most of the trunk lines are expected to apply these rules also to intrastate shipments. The Central, Eastern, Canadian and New England Associations are expected to adopt rules substantially similar to those adopted by the Trunk Line Association. The Western Passenger Association and the Transcontinental Passenger Association still have the rules under consideration, as there are many details to be settled. When the passenger declares a greater value than that which the railroads will carry free under their rules, there will be an additional charge at the rate of 10 cents for each $100 or fraction thereof, above such maximum value.

The Pennsylvania has issued a circular prescribing the new rules necessary to insure compliance with the law and fixing 10 cents as the charge for each $100 value beyond $100 for the baggage of each adult passenger. The circular says:

"Carriers cannot limit their liability for loss or damage which may arise through negligence or carelessness unless the carrier obtains from each owner or shipper of baggage a signature in writing. . . . Baggagemasters [on trains] must not check baggage to interstate points unless they are able to secure a declaration of value, and must not check baggage of excess value beyond the end of their runs, nor to points where there are no agents. All declarations of value will be delivered with baggage to agent at destination, with instructions to collect proper charges for excess value, if any.

"Each declaration of value must be dated by office stamp or in writing, and the same be carefully preserved at the station for ready reference for a period of six years.

"In the many cases of baggage left behind by passengers, any agent asking that same be forwarded must state in his letter or telegram that he has obtained certification of value, and name the amount. Baggage will then be forwarded under C. O. D. charges for excess value, if any. It must be borne in mind that to obtain certification of value of baggage, and issue checks therefor, in some cases and not in others, would be unlawful, and that if, for any reason, this certification cannot be obtained covering any piece of baggage, then in such cases it must not be checked.

"Transfer companies checking baggage will be instructed that they must obtain a declaration of value and attach 'stop check' to baggage check showing such value, for the information of the station agent, who will then compute charges for excess value, if any, and forward C. O. D. the same as in the case of excess weight of baggage.

". . . In the case of baggage checked between intrastate points no declaration of value will be required."

Commission and Court News

INTERSTATE COMMERCE COMMISSION

Rates on Lumber from Norman, N. C.

Snow Lumber Company v. Raleigh, Charlotte & Southern et al. Opinion by the commission:

The commission finds that the rates on lumber from Norman and Ellerbe, N. C., to points in Virginia, West Virginia and various states north thereof are not unreasonable or prejudicial. Complaint dismissed. (33 I. C. C., 587.)

Rates on Salt from Milwaukee

Petit Salt Company v. Chicago, Milwaukee & St. Paul et al. Opinion by the commission:

The rates on salt in carloads from Milwaukee to trans-Mississippi points on the Chicago, Burlington & Quincy are not found to be unreasonable or discriminatory as compared with the rates from Chicago to the same points. (33 I. C. C., 590.)

Minimum Weights on Lumber

Funck Lumber Company v. Baltimore & Ohio Southwestern et al. Opinion by the commission:

The commission finds that the minimum weights on lumber in mixed carloads of 30,000 lb., in cars less than 36 ft. in length and of 34,000 lb. in cars of 36 ft. or more, for shipments from Ohio and Mississippi river crossings to central freight association and trunk line territories are not unreasonable or discriminatory. (33 I. C. C., 511.)

Rates on Lumber from Mackland, La.

Lumbermen's Association of New Orleans v. Morgan's Louisiana & Texas. Opinion by the commission:

An export rate of 8 cents per 100 lb. on lumber and articles taking lumber rates to New Orleans, La., from Mackland, La., and other stations on defendant's Alexandria branch line between Mackland and Opelousas, is found unreasonable to the extent that it exceeds 7 cents. Reparation is denied. (33 I. C. C., 516.)

Automobiles Not Emigrant Movables

L. G. Ochsenreiter v. Atchison, Topeka & Santa Fe et al. Opinion by the commission:

The commission finds that the provisions of defendants' tariffs excluding automobiles from the application of rates provided for emigrant movables is not unreasonable. The evidence is not sufficiently definite to permit a finding with respect to the non-inclusion of gasolene engines with emigrant movables. Complaint dismissed. (33 I. C. C., 518.)

Fourth Section Application Denied

Cullman Commercial Club v. Louisville & Nashville. Opinion by Commissioner Meyer:

The commission finds that the maintenance of higher class and commodity rates from New Orleans, La., to Cullman, Ala., a point intermediate to Decatur, Ala., than are contemporaneously maintained to Decatur, is discriminatory against Cullman. (33 I. C. C., 634.)

Southern Pacific Ownership of Associated Oil Company's Steamers

Opinion by Commissioner Clark:

The Associated Oil Company, a majority of the stock of which is owned by the Southern Pacific, operates seven oil steamers from Monterey, Gaviota and Port Costa, Cal., to San Francisco, Linnton, Ore., Everett and Seattle, Wash., Honolulu, Hawaii, and ports of Alaska. The commission refuses to grant the petition of the carrier to retain its interest in the boats operating to Oregon and Washington, for the reason that although the Southern Pacific does not reach these points over its own rails, it participates in joint rates to them.

On the other hand, it holds that unless the Southern Pacific

participates, by its rail lines, or in connection with other lines, in transportation of oil from California points to a port for transshipment to Alaska, the continued ownership and operation of its oil steamers between the California ports and ports of Alaska, transporting only oil destined to Alaska, will not be in violation of law.

It also grants the petition of the carrier to retain its interest in the oil steamers operating to Hawaii. (34 I. C. C., 77.)

Rates on Roofing Paper to Oklahoma Points

Hooker-Hendrix Hardware Company et al. v. Missouri, Kansas & Texas et al. Opinion by the commission:

The commission finds that the carload rates on prepared roofing paper and building paper from East St. Louis, Ill., St. Louis, Mo., and Kansas City, Mo., to Muskogee, Tulsa and McAlester, Okla., are unreasonable. Rates for the future are prescribed as follows: From St. Louis and East St. Louis, to Muskogee, 37 cents; to Tulsa, 38 cents and to McAlester, 40; Kansas City, to Muskogee, 26 cents; to Tulsa, 27 cents, and to McAlester, 29 cents. Reparation awarded. (34 I. C. C., 3.)

Rates on Coal from the Crooksville District

Son Toy Coal Company v. Akron, Canton & Youngstown, et al. Opinion by Commissioner Harlan:

The commission finds that the rates on bituminous coal in carloads from San Toy, Ohio, and other points in the Crooksville coal district to Chicago and to points in Illinois, Indiana and Michigan discriminate against shipments from the mines of the complainant and others located in the same district in favor of mines located in the middle district of Ohio and defendants are required to remove the discrimination. The rates from San Toy and other points in the Crooksville district to Lake Erie ports for transhipment are not shown to be unreasonable. (34 I. C. C., 93.)

Notice of Arrival of Consignment

Ohio Iron & Metal Company v. Elgin, Joliet & Eastern. Opinion by the commission:

The defendant mailed a notice of the arrival of a car of scrap iron at Chicago Heights, Ill., which was never received by the consignee. As a result the car was held for some time and demurrage charges of $48 imposed. The commission finds that the carrier's duty was performed when it placed the notice in the mail and that the demurrage charges were properly assessed. (34 I. C. C., 75.)

Lumber Rates to Sioux City, Ia.

In re lumber rates from points in Arkansas and other states to Sioux City, Iowa. Opinion by Commissioner Hall:

The commission finds that the carriers have failed to justify a proposed increased rate of 30 cents a 100 lb. on yellow-pine lumber in carloads from the producing territory west of the Mississippi river, generally described as the southwestern blanket, to Sioux City and a rate of 29 cents from the territory lying north of this blanket. The present rate from both territories is 28 cents. (34 I. C. C., 102.)

Complaints Dismissed

Streever Lumber Company v. Chicago, Milwaukee & St. Paul et al. Opinion by the commission:

The reasonableness of a charge of $40 for feeding, watering and resting a carload of horses at Schenectady, N. Y., is found not to be within the jurisdiction of the commission. (34 I. C. C., 1.)

A. P. Brantley Company v. Atlantic Coast Line. Opinion by the commission:

The commission finds that the rates on sea-island seed cotton from points in northern Florida to Blackshear, Ga., are not unreasonable. (34 I. C. C., 21.)

Blackburn-Warden Company et al. v. Illinois Central et al. Opinion by the commission:

The commission finds that the double first-class rating under southern classification for grapes in baskets in less than carloads is justified. (34 I. C. C., 58.)

Parlin & Orendorff Company v. Illinois Central et al. Opinion by the commission:

The commission finds that the discrimination at present existing against Canton, Ill., in favor of Peoria, in the rates on agricultural implements in carloads to local points on the Illinois Central in Kentucky, Tennessee and Mississippi is not undue. The commisison does not decide the question of reasonableness of rates from Canton because of a readjustment which is now under way. (34 I. C. C., 90.)

Otto Jaeger v. Ann Arbor et al. Opinion by the commission:

The complainant purchased a mileage book entitling him to 1,000 miles of transportation over defendants' lines. One of the conditions on which the book was sold provided that if the cover was presented to the proper bureau within 18 months from date of issue a refund of $5 would be made to the purchaser. Complainant lost his book and did not find it in time to present it within the time limit, and when he did finally present it to the defendants in accordance with their tariff regulations, refund was refused. The commission finds that this regulation is not unreasonable. (34 I. C. C., 28.)

Rates on Motorcycles to the Pacific Northwest

Ballou & Wright v. New York, New Haven & Hartford et al. Opinion by the commission:

The commission finds that certain rates charged for the transportation of motorcycles in carloads from Armory, Mass., to Portland, Ore., and Seattle, Wash., were unreasonable to the extent that they exceeded the first-class rates contemporaneously in effect. It also awards reparation, holding that where a shipper has paid an excessive rate he may recover as reparation the difference between the rate paid and what would have been a reasonable rate at the time, even though the freight charges were added to the selling price of the article transported. (34 I. C. C., 120.)

Reconsignment

Reeves Coal Company v. Chicago, Milwaukee & St. Paul. Opinion by the commission:

The complainant ordered a shipment reconsigned, provided the lowest rate between original point of origin and final point of destination would apply. Reconsignment was effected and lawful charges, higher than those which would have accrued at the lowest rate from point of origin to final destination, were collected. The commission finds that this case does not differ materially from one involving merely a misquoted rate and dismisses the complaint. (34 I. C. C., 122.)

Ex-Lake Grain to Middletown, Conn.

Meech & Stoddard, Inc., v. Grand Trunk Railway of Canada et al. Opinion by the commission:

To meet competition from Buffalo defendants maintain joint through rates on ex-lake grain from Georgian Bay ports to numerous points in New England. Middletown, Conn., is a similarly situated point and competes with the other points involved in the purchase and sale of grain and grain products, but defendants refuse to extend these rates to Middletown on the ground that the rates are unremunerative and that they desire not to enhance their losses. The commission finds that by following this policy the defendants discriminate against Middletown and it is ordered that this discrimination be removed. (34 I. C. C., 39.)

Fitting Cars for Grain Shipments

National Council of Farmers' Co-operative Associations v. Chicago, Burlington & Quincy et al. Opinion by Commissioner Clark:

The shippers of grain owning elevators at country stations in Illinois, Iowa, Minnesota, Nebraska, Kansas, North Dakota and South Dakota, allege that the defendants fail to furnish cars in suitable condition for the transportation of grain in bulk, and ask that they be required either to furnish cars suitable in all respects for carrying this traffic or that they make an allowance to shippers for work done and materials furnished to prepare the cars for loading.

The commission holds that it is the duty of the carriers to

furnish cars suitable to transport in safety traffic which they hold themselves out to carry, and that this duty is not fulfilled when a carrier furnishes a car, upon reasonable request of a shipper, which requires repairing to prevent leakage of grain in transit. It is also held, however, that it is not unreasonable to expect shippers to do a limited amount of cleaning or to make minor and inexpensive repairs on such cars and that it would be impracticable to fix by order any allowance that should be paid shippers for labor performed or materials furnished. The suggestion is made that carriers specify in their tariffs what they will furnish in the way of materials, which must be uniform and adequate.

The carriers' practice at terminal points with reference to preparing cars for loading grain in bulk is not found to be discriminatory against complainant's members. Complaint dismissed. (34 I. C. C., 60.)

STATE COMMISSIONS

The State Corporation Commission of Virginia has authorized the New York, Philadelphia & Norfolk to advance its passenger rates on June 10 from two cents a mile to two and one-half cents.

The New York Public Service Commission, Second district, having received inquiries from all quarters of the state, says that the "auto-bus law," which has been in effect for the last two years, has been repealed by the recent enactment of the jitney bus law, and that it is no longer necessary for persons and corporations desiring to operate auto bus lines on state highways to come to the commission for certificates of approval. It will be necessary, however, for all persons and corporations owning or operating state routes, bus lines or motor vehicles carrying passengers for a fare of fifteen cents or less, on any street, in any city, except New York, to procure first the consent of the local authorities and next a certificate of convenience from the Public Service Commission.

COURT NEWS

The United States District Court at St. Paul has issued a temporary injunction restraining the Arkansas Railroad Commission from putting into effect the two-cents-a-mile passenger rate, and the roads are allowed to charge three cents pending the final decision.

The Supreme Court of Appeals of West Virginia has issued a mandamus requiring the Baltimore & Ohio to comply with the order of the State Public Service Commission, forbidding an advance in passenger rates from two cents a mile to two and a half cents, no action to be taken until the Public Service Commission can consider the application presented by the road for authority to make the increase.

Infant Trespassers

A nine-year-old girl and her eleven-year-old brother had been sent by their mother to pick coal on the tracks of the Baltimore & Ohio. They entered the tracks at a crossing where the company's watchman was stationed and were seen by him. They commenced picking coal when about 200 ft. from the crossing, near a standing freight train. On the approach of another train they, not having sufficient time to go around the standing cars, stood with their backs agains them, and while in this position the girl was struck by or drawn under the passing train, receiving injuries for which suit was brought. The Pennsylvania Supreme Court holds that the children were trespassers and no actionable negligence on the part of the company had been shown.—Lumis v. B. & O. (Pa.), 93 Alt., 952.

Delivery of Livestock on Private Tracks

In an action by a Nashville stockyard company it was alleged that the railroads deliver, on the plaintiff's spur track, all kinds of freight, except livestock, which they refused to so deliver, insisting that stock must be first delivered to the Union Stockyards, following which they would deliver cars to the plaintiff's place on receipt of a switching charge of $3. This refusal was alleged to be arbitrary, and illegal, and to be because of a contract with the Union Stockyards by the terms of which the carriers made these yards an exclusive depot in Nashville for livestock. The defendants admitted the existence of the agreement. It was held by the Tennessee Supreme Court that the statute prohibiting the giving of undue preferences, etc., does not require the carrier to make deliveries of livestock shipments in carload lots at private stockyards maintained by the consignee. The company's agreement with the Union Stockyards to make all such deliveries at that company's yards at the carrier's expense was valid, because the nature of the traffic, the necessity for quarantine, and the danger and delay which would be caused by extra switching thereby made necessary was sufficient to justify a different rule from that applied to inanimate freight, which the carrier must deliver on a private track.—Smith v. L. & N. (Tenn.), 175 S. W., 557.

Private Crossings—Duty as to Construction

A Nebraska railroad company, when it obtained its right of way through a farm, constructed an adequate private crossing at grade, under an agreement with the owner of the farm, and maintained it for about 27 years without injury to any person. During that time there was no substantial change of physical conditions. The present owner of the farm now insists that the company construct for him an overhead crossing at a cost of $1,000 and with a heavy maintenance charge. The State Railway Commission made an order requiring the company to construct the overhead crossing desired. The Supreme Court holds the order to be oppressive and unjust. Moreover, to require the company to construct such a crossing would discriminate unjustly in favor of the owner of the farm and against all other persons similarly situated. The commission's order was reversed.—Postle v. C. B. & Q. (Neb.), 152 N. W., 379.

Chicago Switching Rates—Lowery Tariff

The railroads entering Chicago agreed as to through freight rates where one company brought goods to the city and they were there switched by the others. The Illinois Railroad and Warehouse Commission's rates having been suspended, it entered an order continuing such agreed rates until they should be changed by agreement of the parties or by hearing before the commission. The statute authorizes the commission to establish through rates when necessary for the accommodation of the public, provided they do not give one road an undue advantage over another. An appeal from an order requiring the C. M. & St. P. to abide by the agreed rates, the Illinois Supreme Court holds that the order is valid. The establishment of the rates agreed on (known as the Lowery tariff) was not an appropriation of the company's terminal facilities without due process of law, for the entire city could not be regarded as a single terminal point.—C. M. & St. P. v. State Public Utilities Commission (Ill.), 108 N. E., 737.

Roundhouses—Sufficiency of Construction

A hostler, rated as an engineer, in the employ of an interstate railroad company, tried to board an engine as it was passing through the doorway of a roundhouse and was caught between the tender and the doorjamb and killed. In an action for his death the United States Circuit Court of Appeals for the Second Circuit holds that the company was not guilty of negligence in failing to provide a safe place to work, as the doorway, while narrower than those in some of the more recently constructed roundhouses of the road, was sufficient for all ordinary conditions, and the company could not be held responsible because the hostler saw fit to try to mount his engine as it was about to pass through the door. His duties did not make it necessary for him to do so, and no superior officer directed him, either then or at any other time, to do such a foolhardy thing; there was no emergency calling on him to do as he did. The court held the case to be governed by New York Central v. Dailey, 179 Fed., 289, decided in 1910. In that case a dead engine with no air to operate the brakes came in and was handed over to a hostler. A coemployee with another engine kicked it into the roundhouse from the turntable. It was given such speed that the hostler was afraid it would go through the building, and started to jump off to block the wheels, when he struck the post between the stalls and was injured. There was a clearance between the engine and

post of about eleven inches. The court there held that the company was not chargeable with negligence because the space was not greater, the construction being safe under any circumstances to be reasonably anticipated.—Hogan v. New York Central.

Recovery for Mental Suffering

Intending passengers were compelled, because a train properly flagged did not stop, to walk some distance in the rain so as to take another train to their destination. They became ill as a result of the wetting, and were unable to attend the funeral of a relative. In an action for damages the Arkansas Supreme Court holds that damages for mental anguish in not being able to attend the funeral were not recoverable. There was not such causal connection between the physical injury and the mental anguish as to make the railway liable in damages for both. Chicago, R. I. & P. v. Mizell (Ark.), 175 S. W., 396.

Trackage Charges

The Minneapolis & Rainy River operates a number of connecting stub lines, the roadbed and ties of which are owned by a lumber company. It owns the rails and fasteners; it laid the rails, and maintains the tracks and roadbed in condition. It is in exclusive control as a common carrier. It maintains a distance mileage tariff for freight originating on the stub lines and consigned to Deer River, the same as from points on its main line to Deer River. It exacts a trackage charge of one dollar a car, in addition to its published tariff rates, for cars originating on the stub lines, except those of the lumber company, and pays this money to the lumber company. For such charges it renders no service. The Minnesota Supreme Court holds that such charge is invalid, and that shippers, paying involuntarily, are entitled to recover it. McCallum v. Minneapolis & R. R. (Minn.), 151 N. W., 974.

Stipulation As to Manner of Delivery

A bill of lading provided that, when goods were consigned to a station where the carrier had no agent, the carrier might, regardless of the weather, deposit the goods on the platform, whether there was any one there to receive them or not. Goods sent by a freight train which was 50 minutes late in arriving, were deposited in a warehouse, one of the keys to which, for the convenience of consignees, was, by recognized local custom, left with a householder in the vicinity. The Missouri Court of Appeals, in an action for the unexplained loss of the goods, held that the delay in arrival did not entitle the consignee to notice, as it did not appear that the train would have been met if on time, and the placing of the goods in the warehouse was not a conversion rendering the company liable for their loss. Morrison T. & E. Co. v. Illinois Central (Mo.), 175 S. W., 220.

Relief Contracts—Statutory Provisions

A contract between a railroad employee and a relief association, maintained by the railroad company and associated corporations, provided for the payment by the employee of monthly dues to be deducted by the company from his wages, stipulated for benefits in the event of sickness or injury or accidental death, and declared that acceptance of benefits should operate as a release of all claims against the company. The Indiana Appellate Court holds that the contract is void under Burns' Ann. St., 1914, section 5308, declaring that no railroad company may maintain a relief association, the rules of which require any employee becoming a member to surrender any rights or damages against the company for personal injuries or death, and the employee, who had never received any benefits from the association, was entitled to recover the part of the wages retained by the company. Acton v. Baltimore & O., S. W. (Ind.), 108 N. E., 535.

Regular Train

In an action for damages for unreasonable delay in transporting livestock it appeared that the railroad company had operated a stock train, designated as an extra train, on Sundays, Tuesdays and Thursdays of each week for about 10 years. Occasionally the train was not run on Thursdays for want of freight, but that was exceptional. However, evidence that reports were gathered from all the stations as to the amount of freight to be transported showed that the train was not operated unless there appeared to be sufficient freight to warrant making it up. A station agent contracted to furnish the plaintiff a car for the extra train on a Thursday, but the train did not run. The Iowa Supreme Court held that it was a question for the jury whether the extra train was a regular train and held out to shippers, as such, and, their answer being in the affirmative, the contract was not one for special service prohibited by the Interstate Commerce act. J. W. Stewart & Son v. Chicago, R. I. & P. (Iowa), 151 N. W., 485.

Safe Appliances—Couplers—Case for Jury

A brakeman, employed by a railroad company engaged in interstate commerce, inserted his arm between an engine tender and the car next back of it to make an adjustment of the couplers, as they would not work automatically by impact. His arm was crushed, necessitating amputation, for which he sued and recovered damages. The New Jersey Court of Errors and Appeals holds that, under the safety appliances act, the duty of the company to provide couplers which would work automatically by impact was an absolute one; and from the fact that the couplers did not so work on the given occasion, it was inferable that the company had failed to comply with the standard raised by the act. Therefore, under the federal employers' liability act, the employee was to be held not to have been guilty of contributory negligence, nor to have assumed the risks of the employment, and the company was not entitled to a directed verdict, but the case was properly submitted to the jury, which returned a verdict for the plaintiff. Parker v. Atlantic City (N. J.), 83 Atl., 574.

Ambiguous Order As to Rates—Contempt

An order of the Michigan Railroad Commission fixing rates for carriage of logs, put into effect on February 19, 1915, read: "Above rates to apply when the manufactured product is reshipped via the D. & M. And when not to be so reshipped, the railway company will collect in addition to the above rates 50 cents per 1,000 ft. But if later reshipment is made over the D. & M., the company will refund to such shipper the 50 cents per 1,000 ft. collected." In proceedings by the railroad commission against the D. & M. to adjudge that company guilty of contempt for failure to comply with the order of court commanding it to put the rates in effect, the Michigan Supreme Court holds that the commission's order is sufficiently ambiguous to permit the company to exact the extra charge in the first instance and rebate only on proof that the manufactured product of the logs shipped in had been shipped out over its line, without being in contempt of the order of court. Michigan R. R. Commission v. Detroit & M. (Mich.), 152 N. W., 193.

Crossing Other Railroads—Permission of Commission

Illinois Laws, 1889, p. 233, section 1, as amended by laws, 1907, p. 475, provides that any railroad company desiring to cross the track of any other railroad company shall apply to the Railroad and Warehouse Commission for permission, and the commission, after investigation, shall give a decision as to the place where and the manner in which the crossing shall be made, provided that it shall be at such place and made in such manner as will not necessarily impede or endanger the travel on the railroad to be crossed. The Illinois Supreme Court holds that this provision does not repeal Railroad Act 1872, section 19, authorizing a domestic railroad company to cross the tracks of another railroad company. It merely has the effect of withdrawing from the company seeking to make the crossing the arbitrary power of selecting the place and manner and to confer upon the commission the power to prescribe such place and manner. It also withdraws from the companies the power to enter into an agreement as to the place and manner of crossing, and imposes upon the commission the duty, in every instance, of determining at what place and in what manner the crossing shall be made. But the commission cannot withhold its permission to cross at the place and in the manner selected by the company desiring to make the crossing unless it prescribes some other place where or manner in which the crossing may be made. An order of the commission granting the right to cross the tracks of another company will not be disturbed, unless it be shown that the commission abused its discretion in its determination. Railroad & Warehouse Commission v. Peoria & P. U. (Ill.), 108 N. E., 655.

Railway Officers

Executive, Financial, Legal and Accounting

Adam Darling has been appointed claim agent of the Denver & Rio Grande, with headquarters at Denver, Colo., succeeding C. S. Mitchell, resigned.

T. A. Martin, general storekeeper of the Oregon Short Line at Pocatello, Idaho, has been appointed assistant auditor, with headquarters at Salt Lake City, Utah.

W. S. Martin, general manager of the Denver & Rio Grande at Denver, Colo., has been elected president of the Union Railway, with headquarters at Memphis, Tenn., succeeding J. L. Lancaster, resigned.

William S. Trowbridge, whose appointment as auditor of the Boston & Albany, with headquarters at Boston, Mass., has already been announced in these columns, was born on January 11, 1880, at Pawling, N. Y. He attended high school until June, 1895, and the same month entered the service of the New York Central & Hudson River as a clerk in the accounting department, and subsequently held various positions until he became general bookkeeper. He remained in that position for several years, until his appointment on June 5, 1911, as assistant auditor of the Boston & Albany, which position he held at the time of his recent appointment as auditor of the same road, as above noted.

Operating

John C. Maus has been appointed supervisor of demurrage and weighing of the Illinois Central, with office at Chicago, vice Fred W. Souerbry, resigned to engage in other business.

James Russell, assistant to vice-president of the Denver & Rio Grande, at Denver, Colo., has been appointed general manager, with headquarters at Denver, succeeding W. S. Martin, resigned.

J. M. Cameron, assistant general superintendent of the British Columbia division of the Canadian Pacific at Vancouver, B. C., has been appointed general superintendent of the Alberta division, with headquarters at Winnipeg, Man.

M. A. Mulligan, who was recently appointed acting superintendent of the New York division of the Lehigh Valley, has been appointed superintendent of the same division, with headquarters at Jersey City, N. J., succeeding M. C. Roach, deceased.

D. E. Wilcox, assistant superintendent of the second division of the Denver & Rio Grande at Salida, Colo., has been appointed assistant superintendent of the Salt Lake division, with headquarters at Salt Lake City, Utah, succeeding Roscoe Mahon, deceased.

W. H. Hall, superintendent of telegraph of the Missouri, Kansas & Texas at Denison, Tex., has been appointed general superintendent of telegraph, with headquarters at Denison, and J. Hickman has been appointed superintendent of telegraph, with headquarters at Parsons, Kan.

J. W. Wassum, superintendent of the Spartanburg division of the Southern Railway at Columbia, S. C., has been appointed superintendent of the Columbia division, including Columbia terminals, with headquarters at Columbia, vice G. V. Peyton, resigned, and William Maxwell, trainmaster at Columbia, succeeds Mr. Wassum.

M. V. Hynes, superintendent of the Wellston and Delphos divisions of the Cincinnati, Hamilton & Dayton, at Dayton, Ohio, has been appointed superintendent of the Indianapolis division, with headquarters at Indianapolis, Ind., succeeding R. B. White, resigned to go to the Baltimore & Ohio Southwestern. A. A. Iams, trainmaster at Dayton, succeeds Mr. Hynes, and R. W. Brown, road foreman of engines at Lima, succeeds Mr. Iams.

A. E. Stevens, general superintendent of the Alberta division of the Canadian Pacific at Calgary, Alta., has been appointed general superintendent of the Eastern division, with office at Montreal, Que., succeeding George Hodge, who has been appointed assistant to the general manager at Montreal. R. G. Edwards has been appointed assistant superintendent of district No. 2, with office at Montreal, succeeding E. J. Melrose, who has been appointed assistant superintendent of district No. 3, succeeding C. W. Lott, transferred as assistant superintendent to district No. 5, with office at Smith's Falls, Ont.

J. C. Hagerty, superintendent of the Baltimore & Ohio Southwestern at Seymour, Ind., has been promoted to general agent on the staff of the general manager of the Southwestern district, with headquarters at Cincinnati, Ohio. E. W. Scheer, superintendent, at Flora, Ill., succeeds Mr. Hagerty, and R. B. White, superintendent of the Indianapolis division of the Cincinnati, Hamilton & Dayton at Indianapolis, Ind., succeeds Mr. Scheer. G. S. Cameron, assistant superintendent in charge of the Cincinnati terminals of the Baltimore & Ohio Southwestern at Cincinnati, Ohio, has been transferred as assistant superintendent to Chillicothe, succeeding E. N. Brown, deceased, and H. H. Broughton, assistant superintendent at Cleveland, has been transferred to Cincinnati, in charge of the Cincinnati terminals.

Traffic

F. R. Smalley has been appointed district passenger agent of the Minneapolis, St. Paul & Sault Ste. Marie, with headquarters at Duluth, Minn.

C. B. Williamson, superintendent of the Chesapeake Western, has been appointed also traffic manager, with office at Harrisonburg, Va., vice C. A. Jewett, resigned to engage in other business.

Frank D. Powell has been appointed commercial agent of the Canada Southern Line, operating over the Michigan Central via Buffalo, N. Y., and the Pennsylvania Railroad and connections, with office at Chicago, Ill., vice L. S. Livingston, transferred.

E. G. Mustain, division freight and passenger agent of the El Paso & Southwestern, at Tucson, Ariz., having been transferred to another department, the office has been abolished. Territory heretofore under his jurisdiction has been assigned to Richard Warren, general agent at El Paso, Tex.

Engineering and Rolling Stock

R. S. Mounce has been appointed general foreman of car repairs of the Erie, with office at Jersey City, N. J., succeeding P. Fox, deceased.

John Dwyer has been appointed superintendent maintenance of way of the Norfolk Southern, in charge of maintenance of track, bridges and buildings, with headquarters at Norfolk, Va.

M. B. McPartland has been appointed master mechanic of the Colorado and Nebraska divisions of the Chicago, Rock Island & Pacific, with headquarters at Goodland, Kan., succeeding E. F. Tegtmeyer, resigned.

G. E. Sisco, assistant engineer of motive power of the Pennsylvania Lines West, at Columbus, Ohio, has been appointed master mechanic, with headquarters at Toledo, Ohio, succeeding J. W. Hopkins, transferred

E. Keough, roadmaster and assistant trainmaster of the Chicago, Burlington & Quincy, at Aurora, Ill., has been appointed assistant engineer of maintenance of way of the Canadian Pacific Lines East of Winnipeg, with headquarters at Montreal.

O. P. Reese, master mechanic of the Pennsylvania Lines West, with headquarters at Crestline, Ohio, and Pittsburgh, Pa., has been appointed assistant engineer of motive power, in the office of general superintendent of motive power, vice T. R. Cook, resigned.

H. R. Carpenter, engineer of maintenance of way of the Missouri Pacific-Iron Mountain System, has been appointed assistant chief engineer, with headquarters at St. Louis, Mo., succeeding C. E. Smith, resigned. A. F. Dorley, principal assistant engineer, has been appointed engineer maintenance of way, succeeding Mr. Carpenter.

Christopher Thane Sponsel, roadmaster of the Northern Pacific at Mandan, N. D., has been appointed roadmaster at Garrison, Mont., succeeding Frank William Barnes, resigned, and Frank G. Cook, assistant engineer, has been appointed roadmaster, to succeed Mr. Sponsel. John Henry Hayes has been appointed roadmaster at Moscow, Idaho, succeeding Frank Hartman, resigned.

B. Violett, roadmaster of the Chicago, Burlington & Quincy, at Beardstown, Ill., has been transferred to Galesburg, Ill., in the same capacity, succeeding J. A. Sullivan, deceased. J. Emerson, assistant roadmaster at Galesburg, Ill., has been appointed roadmaster at Beardstown, Ill., succeeding Mr. Violett. J. D. Farrington, roadmaster at Council Bluffs, Iowa, has been appointed roadmaster and assistant trainmaster at Aurora, Ill., succeeding E. Keough, resigned. J. S. Miller has been appointed roadmaster at Council Bluffs, Iowa, succeeding Mr. Farrington.

OBITUARY

P. Fox, general foreman of car repairs of the Erie at Jersey City, N. J., died on May 10.

H. W. Cowan, chief engineer of the Colorado & Southern, died at his home in Denver, Colo., on May 29, at the age of 53.

John G. McCullough, vice-president of the Chicago & Erie, died on May 29, at his home in New York. He was born in 1835, at Newark, Del. In December, 1874, he became vice-president of the Panama Railroad, and subsequently became president of the same road. In 1873 and 1874 he served as a director of the Central Vermont. From 1877, to 1883, he was vice-president of the Bennington & Rutland, and later became president of that road. From November, 1884, for several years he served also as president pro tem. of the New York, Lake Erie & Western, and from September, 1890, for over ten years was also president of the Chicago & Erie. From July, 1893, to 1896, he was also receiver of the New York, Lake Erie & Western, and later became vice-president of the Tioga Railroad. At the time of his death he was vice-president of the Chicago & Erie, now a part of the Erie.

RUSSIAN RAILWAYS AND WATERWAYS.—Notwithstanding the war, the Russian government has found it possible to allow a survey for the construction of two large new railways, i. e., for the Achinsk-Minusinsk Railway from the station of Achinsk, on the Siberian Railway to the town of Yeniseisk, from the town of Minusinsk to the village of Grigorievsky, and from Minusinsk to Kuragino, and it is also proposed to build another railway with a total length of 1,150 versts (725 miles) from the station of Krasnoufimsk on the Moscow-Kazan Railway, or one of the near-lying points of this line, to Kostroma, with a branch from Nolinsk to Kotelnich. The Ministry of Ways and Communication has just drafted the grandiose project for a trunk waterway from Ekaterinoslav to Riga. This project embraces almost the entire length of the Black Sea-Baltic waterway, some 1,900 versts (1,200 miles) out of the total length of 2,200 versts (1,375 miles) from Kherson to Riga being included in the new project.

RUSSIA'S IMPORTS OF COAL AND COKE.—The imports into Russia during 1914 of coal across the European frontier amounted to 4,700,000 tons, which compared with the previous year, shows a decrease of 2,820,000 tons, or 37.4 per cent. The deficit falls entirely upon the second half of the year, inasmuch as the first six months of 1914 show an increase compared with the corresponding period of the previous year of 630,000 tons, while the decrease on the second six months amounted to 3,400,000 tons. The imports of coal from different countries were as under:

	1913. Tons	1914. Tons	Decrease. Per cent
England	3,600,000	2,500,000	39.8
Holland	3,250,000	2,000,000	37.5
Austria	89,000	84,000	7.0
Various countries	190,000	200,000	4.0 increase

The imports of coke have decreased still more than those of coal, the imports during 1914 amounting to 530,000 tons, against 960,000 tons in 1913. The decrease consequently amounted to 430,000 tons, or 44.7 per cent, the imports during the second half of last year being quite insignificant.—*Engineering.*

Equipment and Supplies

LOCOMOTIVE BUILDING

THE WESTERN MARYLAND has ordered 15 Mallet type locomotives from the Lima Locomotive Corporation.

THE NEWBURGH & SOUTH SHORE has ordered one superheater Mogul type locomotive from the Baldwin Locomotive Works.

THE YOUNGSTOWN IRON & STEEL COMPANY, Youngstown, Ohio, has ordered 2 standard gage oil-burning locomotives from the H. K. Porter Co.

THE TOLEDO TERMINAL has ordered one superheater Consolidation type locomotive from the American Locomotive Company. This locomotive will have 22 by 28 in. cylinders and 51 in. driving wheels.

THE CHESAPEAKE & OHIO has ordered 24 Mallet type (2-6-6-2) locomotives from the American Locomotive Company. These locomotives will have 22 and 35 by 32 in. cylinders, 56 in. driving wheels and will be provided with superheaters.

CAR BUILDING

THE CHESAPEAKE & OHIO is inquiring for 50 caboose cars.

THE MISSOURI PACIFIC will repair a large number of freight cars.

THE TEXAS & PACIFIC is reported to be inquiring for 500 coal cars.

DARLING & COMPANY, Chicago, are inquiring for prices on 15 tank cars.

THE DELAWARE & HUDSON is in the market for 18 coaches and 6 baggage cars.

THE MISSOURI, KANSAS & TEXAS, reported some time ago as being in the market for 1,200 gondolas, will not purchase any freight equipment this year.

THE UNION TANK LINE has recently exercised an option covering the purchase of 1,000 tank cars from the Standard Steel Car Company. These cars are in addition to the 1,000 cars ordered last December, the option for the additional 1,000 cars having been taken at that time. The specialties for the cars on the new order have already been provided for.

IRON AND STEEL

THE LEHIGH & NEW ENGLAND has ordered 1,700 tons of rails from the Bethlehem Steel Company.

THE CENTRAL RAILROAD OF ARGENTINA has ordered 8,000 tons of rails from the Pennsylvania Steel Company.

THE NEW YORK CENTRAL has ordered 270 tons of bridge material for two bridges to be built at Jersey City from the Fort Pitt Bridge Works.

THE NORFOLK & WESTERN has ordered 5,100 tons of rails from the Carnegie Steel Company, and 3,000 tons from the Pennsylvania Steel Company.

MACHINERY AND TOOLS

THE PENNSYLVANIA RAILROAD is asking bids on four special machines for use in the making of piston valves.

THE SEABOARD AIR LINE is reported to be taking preliminary bids on equipment to replace that damaged recently by fire at its shops.

THE DELAWARE, LACKAWANNA & WESTERN has ordered a steam hammer, a bolt-cutter and one or two other machines, and is taking bids on another bolt-cutter.

Supply Trade News

George C. Wilson, of the Independent Pneumatic Tool Company, Chicago, has been appointed manager of that company's branch at Atlanta, Ga., succeeding F. H. Charbono, who has been transferred to Boston.

J. Drew Allen, northwestern representative of the Taylor-Wharton Steel Company, received a fatal injury while examining the tracks of the Salt Lake City Traction Company, and died on May 16, at the age of 33.

W. D. Waugh, district representative in St. Louis, Mo., of the Kalamazoo Railway Supply Company, Kalamazoo, Mich., has been appointed district representative in charge of the St. Louis office of the Detroit Graphite Company, succeeding Benjamin Randolph, resigned

The directors of the Baldwin Locomotive Works have postponed action on the semi-annual dividend of 1 per cent on the common stock usually paid at this time. They have, however, declared the regular semi-annual dividend of 3½ per cent on the preferred stock payable July 1.

At the annual directors' meeting of Fairbanks, Morse & Company, recently held in Chicago, C. H. Morse, Sr., retired from the office of president of the company, which he has held for 24 years, and C. H. Morse, Jr., was elected to succeed him. Mr. Morse, Jr., has for a number of years been president of the Fairbanks-Morse Manufacturing Company, Beloit, Wis., and will continue to hold that position. Other officers of the company were re-elected.

Merton A. Peacock has been appointed district sales manager of the Terry Steam Turbine Company, Hartford, Conn., for the territory included in Minnesota, North Dakota and South Dakota, with office at 400 Endicott building, St. Paul, Minn. This arrangement supersedes the previous selling agreement with the Robinson, Cary & Sands Company, St. Paul. The company has also appointed the Hawkins-Hamilton Company, Peoples National Bank building, Lynchburg, Va., as its representatives for Virginia.

Benton C. Rowell, an inventor of numerous mechanical devices for use in railroad operation, and one of the most prominent advocates of automatic train control, died suddenly of heart failure on May 29 at Chicago, aged 58 years. He had made practically a life study of automatic train control. In 1891 he demonstrated his safety stop on the Boston, Revere Beach & Lynn, and in 1893 on the Intramural Railway at the Chicago World's Fair. In 1893 and 1894 the device was installed on the Chicago South Side Elevated Railroad, and in 1894 and 1895 on the Metropolitan West Side Elevated Railroad at Chicago. It was also given a service test on the Chicago, Burlington & Quincy in 1908 and 1909. Mr. Rowell also had numerous patents pending on appliances connected with railroad signaling.

Guy E. Tripp, chairman of the Westinghouse Electric & Manufacturing Company, has been quoted as follows: "The Westinghouse Electric & Manufacturing Company has purchased the property and assets of the Stevens Arms & Tool Company and the Stevens-Duryea Automobile Company, and a company has been incorporated under the laws of Massachusetts to own and control these two properties. This company will be known as the New England Westinghouse Company, and all of its $2,000,000 capital stock is owned by the Westinghouse Electric & Manufacturing Company. The company has no bonded debt. These two companies were purchased by the Westinghouse as a result of the order for 1,000,000 rifles which we have taken from the Russian government. This large order will be filled entirely from the two Stevens companies that have been purchased. It is not the intention of the Westinghouse Electric & Manufacturing Company to make any alterations whatever to its present plants in connection with this rifle order. In other words, it is to be filled by companies which are thoroughly experienced in the manufacture of this class of product, so that there are few uncertainties in connection with the transaction."

C. E. Smith, recently assistant chief engineer of the Missouri Pacific-Iron Mountain System, has opened an office as consulting engineer at 2075 Railway Exchange building, St. Louis, Mo. He will engage in general railway and municipal practice, with special attention to valuations, terminal problems, grade crossing eliminations, bridges and miscellaneous structures. Mr. Smith has had a varied experience in all branches of civil engineering of about 17 years. He was graduated from the Massachusetts Institute of Technology in 1900 in civil engineering, and during vacations worked as rodman for the New England Railroad, and also as assistant city engineer of the cities of Putnam and Willimantic, Conn., which position he also held from June, 1900, to November, 1900. In November, 1900, he entered the service of the New York, New Haven & Hartford as bridge engineer at New Haven, which position he held for three years. From November, 1903, to March, 1904, he was with the bureau of yards and docks of the United States Navy Department at Washington, D. C., and in March, 1904, he returned to railroad service as assistant bridge engineer of the Lake Shore & Michigan Southern at Cleveland, Ohio. From March, 1905, to December, 1906, he was text book writer and instructor for the International Correspondence Schools, Scranton, Pa. From December, 1906, to July, 1907, he was with the United States Geological Survey as field assistant at Washington, D. C., San Francisco, Cal., and St. Louis, Mo., engaged in investigating and reporting the effects of the fire and earthquake on San Francisco buildings and reporting the results of work accomplished at testing laboratories at the World's Fair grounds, St. Louis. In August, 1907, he became connected with the Missouri Pacific as bridge engineer, and later was promoted to assistant chief engineer, in which positions he was in charge of all bridge and grade crossing work on the system, and during the last two years had full charge of engineering work of every nature, including tracks, bridges, grade crossings, depots and other buildings.

TRADE PUBLICATIONS

Brick Arches.—The American Arch Company, New York, has issued a booklet entitled "Uncle George's Primer," made up of questions and answers pertaining to the use and construction of the locomotive brick arch.

Air Meters.—A four-page folder has been issued by the New Jersey Meter Company, Plainfield, N. J., dealing with the tool-om-eter, a recently developed form of air-blow meter. This device is adapted to checking the amount of compressed air used with the various types of portable pneumatic tools.

Salt Lake Route.—The passenger department of the San Pedro, Los Angeles & Salt Lake has recently issued a very attractive folder containing views and descriptions of Yellowstone and Glacier National Parks. The booklet gives also detailed information relative to tours through these parks.

Wiring.—The Fargo Manufacturing Company, Inc., Poughkeepsie, N. Y., has recently issued catalog No. 800, relative to its type A and B connecting devices for electric wiring. The catalog is well illustrated with sectional drawings and engravings showing the construction of the various types of connectors.

Wagon and Truck Loaders.—This is the title of book No. 210 of the Link-Belt Company, Chicago, relative to a line of portable loaders for use in handling such material as coal, sand, stone, gravel and other loose material from storage piles into wagons, trucks or cars. The book has 47 pages and is profusely illustrated.

Riveters.—Catalog No. 3 of the Vulcan Engineering Sales Company, Chicago, deals with a line of pneumatic riveters manufactured by the Hanna Engineering Works, Chicago. These machines are of various types and sizes, the special feature of the line being the toggle motion by which the power is transmitted to the ram.

Boiler Water Treatment.—The Bird-Archer Company, New York, has recently issued a 40-page pamphlet dealing with boiler maintenance and discussing its system of polarized metallic boiler chemicals for locomotive use. A portion of the book is devoted to a brief treatise on locomotive boiler maintenance prepared by a general boiler inspector.

Arch Tube Cleaners.—Catalog W-1 of the Lagonda Manufacturing Company, Springfield, Ohio, is devoted to its line of arch tube cleaners. Several types of cutting heads are shown,

and there are listed a number of accessories, including repair parts for the cleaner. In addition to the pneumatic cleaners, water and steam-driven cleaners are shown.

Fabrikoid.—In a publication entitled "The Orange Book" the DuPont Fabrikoid Company, Wilmington, Del., presents a number of exhibits which are extracts from proceedings or articles dealing with upholstery, all of which are given to show the superiority of Fabrikoid over the poorer grades of split leather for use in furniture upholstery, automobiles, etc.

Expanded Metal Lath.—Kno-Burn expanded metal lath is the subject of a 52-page booklet, issued by the North Western Expanded Metal Company, Old Colony building, Chicago. The advantages claimed for this type of lath are shown in detail, stock sizes and weights are given, and a large number of illustrations are included giving details of application.

Expansion and Toggle Bolts.—The 1915 catalog, No. 40, that has been recently issued by the Steward & Romaine Manufacturing Company, Philadelphia, Pa., illustrates and explains the many types of expansion and toggle bolts manufactured by this company. It also shows some tools for use in drilling holes for bolts in brick, concrete, granite and hollow bricks, etc.

Portable Air Compressors.—Form No. 3,015, issued by the Ingersoll-Rand Co., 11 Broadway, New York, contains 32 pages, 6 in. by 9 in., and is a complete treatise on the subject of portable air compressing outfits. A list of bulletins is given describing in detail each particular line of portable compressors, as well as catalogs of the various pneumatic tools and equipment mentioned.

Storage Battery Cars.—Bulletins No. 30, 31, 32 and 34, issued by the Railway Storage Battery Car Company, New York, illustrate and describe a number of city and interurban cars equipped with storage batteries for supplying driving power. One of the bulletins gives some comparative costs between standard overhead construction and the equipment necessary when Edison batteries are used.

Locomotive Cranes.—The Ohio Locomotive Crane Company, Bucyrus, Ohio, has issued a 56-page catalog in which the construction of its line of locomotive cranes is set forth in detail. The catalog contains a large number of illustrations of detail parts, as well as reproductions from a number of photographs, showing the cranes in service. Clearance diagrams of various types of cranes are also given.

Water Meters.—The Harrison Safety Boiler Works, Philadelphia, Pa., has issued engineering leaflet No. 18, dealing with the Cochrane V-notch weir, used in the Cochrane metering heater. This pamphlet is a reprint of two papers on the V-notch weir, showing the refinements essential to accuracy in investigating problems in hydraulics and the constancy of the V-notch weir when used under those conditions.

Pressed Steel Building Construction.—"Kahn Pressed Steel Building Construction," is the title of a booklet which has just been issued by the Trussed Concrete Steel Company, Youngstown, Ohio, describing the use of pressed steel construction for small buildings, and showing how such buildings can be erected by any ordinary mechanic with the use of a hammer as the only tool, and can then be covered with stucco.

Safety Rules.—The Whiting Foundry & Equipment Company, Harvey, Ill., has recently issued a poster containing safety rules for cranemen, crane operators, floormen and repairmen. The poster has the words "Safety First" printed in large red letters at the top and the rules are from a safety bulletin issued by the National Founders' Association. The poster is suitable for placing in shops for the guidance of workmen.

Automatic Highway Crossing Gate.—The Cook; Railway Signal Company, Denver, Colo., has recently issued a booklet entitled "Safety First in Reality," describing in detail the construction and operation of the Cook automatic electric highway crossing gate. This gate operates from track circuits or track instruments like an automatic signal. When lowered by the coming of a train, the gate arm is suspended horizontally about 13 ft. above the track, and from it there hang crucible wire tell-tales usually about 8 ft. long. At the same time a bell is rung and two lights are shown, one, a red light, appearing as a warning to the vehicle on the highway and the other, a white light, lighting up the tell-tales and the crossing.

Railway Construction

Chicago, Milwaukee & St. Paul.—The Seattle, Port Angeles & Western has been opened for traffic from Port Angeles, Wash., west 26 miles. The line is being extended from Port Angeles east to Puget Sound, about 45 miles, and it is expected that this section will be completed in about six months.

Cumberland & Manchester.—Incorporated in Kentucky with $50,000 capital and headquarters at Manchester. The plans call for building from Barbourville, Ky., north to Manchester in Clay county 24 miles. C. F. Heidrick, president; F. N. Heidrick, vice-president, both of Brooksville, Pa., and G. M. Richards, Jr., secretary and treasurer, Clarion, Pa. C. B. Lyttle, is a director, Manchester, Ky. (See Cumberland Northern, May 7, page 993.)

Cumberland Northern.—See Cumberland & Manchester.

Edmonton, Dunvegan & British Columbia.—The Canadian parliament has granted an extension of time to this company in which to build the extension from Spirit river, Alta., to a junction with the Pacific Great Eastern at the Alberta-British Columbia boundary, and has also authorized the building of an additional line through Grand Prairie district to Jasper House, Alta. (April 23, p. 913.)

Jacksonville & Florida (Electric).—Organized in Florida with $500,000 capital to build the electric line from Jacksonville, Fla., southwest to Middleburg, about 25 miles, thence west to Providence in Bradford county, in all about 60 miles. Financial arrangements have been made to build the first section of ten miles, and construction work is now under way. A. W. MacKinlay, president; R. F. Ensey, vice-president. (See Jacksonville-Middleburg, March 5, p. 427.)

Kanawha, Glen Jean & Eastern.—Preliminary arrangements are being made to start work soon on a line to the Laura, Red Star and Harvey coal mines in West Virginia. The company now operates an 8-mile line from Glen Jean, in Fayette county, W. Va., south to Tamroy, also a branch from Glen Jean, west to Pax, 9.5 miles, and has plans already made to build an extension from Tamroy, south to Skelton. (March 14, p. 1033.)

Kansas City Connecting Railroad.—The Missouri Public Service Commission has authorized this company to reconstruct seven miles of tracks and terminals of the stock yards at Kansas City, including the construction of a subway under the Union Pacific tracks near the Kaw river. Four and one-half miles of the tracks will be in Missouri and two and one-half in Kansas.

Midland Railway.—A charter has been granted this company in Georgia, it is said, with a capital of $1,000,000, and construction work is now under way. The plans call for building from Savannah, Ga., northwest, via Pineora, Statesboro, Swainsboro, Wrightsville and Sandersville, to Milledgeville, about 150 miles. A number of branch lines are also to be built. H. O. Buman, Savannah, is an incorporator, and G. M. Brinson, Springfield, is said to be interested (May 7, p. 993).

Naas & Skeena River Railway.—See Pacific, Peace River & Athabaska.

New York Subways.—The New York Public Service Commission, First district, will open bids on June 15 for the construction of Section No. 1, between Eastern Parkway and Church avenue, of Route No. 29, a part of the Nostrand avenue subway in the borough of Brooklyn. This line is a branch of the Eastern Parkway subway.

The commission has awarded the contract for the construction of Section No. 2 of Route No. 49 to the Oscar Daniels Company, the lowest bidder, who offered to do the work for $863,775. (May 28, p. 1139).

Bids for the completion of construction and station finish in the Fourth avenue subway, Brooklyn, from Flatbush avenue extension to forty-third street, have been received by the commission (May 21, p. 1099).

Norwich, Colchester & Hartford Traction.—This company's charter has been amended and the time extended for two years in which to complete an electric line between Norwich, Conn., and Hartford. About seven miles of the line is finished, from Silver Lane to Glastonbury, and there remains about 25 miles yet to be built. New York financiers have become interested in the proposition. W. S. Garde, Hartford; E. Robinson, W. A. Strickland, Glastonbury; S. R. Ketcham, New York; Dr. C. E. Stark, Mayor T. C. Murphy, F. Kromer and C. S. Holbrook, Norwich, are directors. (January 29, page 211.)

Oklahoma & Texas Southern.—According to press reports, grading work has been finished by this company on a line from Montague, Tex., southwest to Bowie. It is understood that an extension is to built from Bowie southeast to Denton, about 40 miles. W. A. Sqiores, Henrietta, Tex., is said to be interested.

Pacific, Peace River & Athabaska.—The Canadian parliament has authorized a change in the location of the Pacific coast terminus, from the mouth of the Naas river to the Kitimat arm, and has also granted an extension of time in which to build the line. The plans call for building from the Pacific coast east to Prince Albert, Sask. The company has also secured the charter of the Naas & Skeena River Railway, which has been granted an extension of time in which to build from Nasoga gulf to the Skeena river. The tramway which this company plans to build at Vermillion Falls on the Peace river under the name of the Peace River Tramway & Navigation Company will be standard gage, and is to be five miles long. It will be operated by steam at first, but later by electricity. The company also plans to build another tramway about 15 miles long between Smith's Landing and Fort Smith.

Peace River Tramway & Navigation Company.—See Pacific, Peace River & Athabaska.

St. John & Quebec.—The New Brunswick government has passed an act providing for the appointment of a commission to complete the St. John Valley Railway in case the contractors fail to meet their obligations within a specified time. The central section from Centreville to Gagetown has been completed, and the Intercolonial is now operating the section from Fredericton to Centreville, 88 miles. The line is being built from Grand Falls, N. B., southeast following the St. John river to St. John, about 210 miles. (March 19, p. 649.)

Seattle, Port Angeles & Western.—See Chicago, Milwaukee & St. Paul.

RAILWAY STRUCTURES

Kansas City, Mo.—The Alton Grain Elevator Company, a subsidiary of the Chicago & Alton, is constructing a reinforced concrete elevator, consisting of a working house and 8 bins. Its capacity will be 275,000 bu., but it is so designed that it can be increased to 1,000,000 bu. It will be operated by electricity. The elevator was designed by E. Lee Heidenreich of Kansas City. The contract has been awarded to Wells Brothers, 53 West Jackson boulevard, Chicago. The construction is in active progress under the supervision of H. T. Douglas, chief engineer of the Chicago & Alton, and it is expected the elevator will be completed by September 15.

Ottawa, Ont.—Bids are wanted until June 8, by J. W. Pugsley, secretary, Department of Railways and Canals, Ottawa, for a number of small bridges on the main line of the Intercolonial Railway.

Sayre, Pa.—The Lehigh Valley will at once build a fireproof roundhouse, with stalls for 50 locomotives at Sayre. Contract for the building, which is to be of hollow tile and cement construction, has been given to Westinghouse, Church, Kerr & Company, New York. The total cost of the improvements will be $400,000, including a new turntable and accessories.

Somerset, Pa.—The Baltimore & Ohio has completed plans for a new passenger station, to be built at Somerset, to replace the present structure. The new station will be 30 ft. by 75 ft. of brick construction with tile roof. The work is to be started at once and will be carried out by the company's forces. The present station will be moved across the tracks and fitted up as a freight station, having separate team and house tracks.

Railway Financial News

Missouri Pacific.—On Wednesday night the directors announced that they had received $21,349,000 of the $25,000,000 notes which were due on June 1, and of which they asked the extension to June 1, 1916. The extension plan has been declared operative.

E. E. Ravellain, holding $72,000 notes, presented the notes for payment on Wednesday, and upon the refusal of the company to make payment he brought suit and obtained an attachment on the property of the company in New York state, which is said to consist of nothing but the office furniture. The company gave out a statement saying that Mr. Ravellain did not appear on the company's books as the owner of any of the notes.

National Railways of Mexico.—A cable despatch from London says that the $27,640,000 2-year 6 per cent notes of the National Railways of Mexico, due June 1, were not paid, but it is not announced as to what provisions have been made for the extension of these notes or for legal action under the terms of the indenture securing them.

New York, New Haven & Hartford.—Governor Walsh of Massachusetts has vetoed the validation bill which provided for the reorganization of the finances of the New York, New Haven & Hartford and the Boston & Maine, both of which bills had been passed by both houses of the Massachusetts legislature. In sending his veto to the legislature Governor Walsh said in part:

"This question is now of national importance. The issue is whether the public shall be called on to pay only a return on honest investment, or shall be charged with all sorts of extortion based on all kinds of artificial capitalization.

"Common honesty as well as the common welfare requires that the issue shall be fought out and decided in favor of what is now the sound and established policy of this commonwealth, even if the controversy should require an amendment to the national constitution."

St. Louis & San Francisco.—Bankers connected with the reorganization committees have been quoted as saying that it is hoped that the receivership may be ended by July 1, and that a tentative plan has been accepted by the committees representing the refunding 4 per cent bonds and the general lien 5 per cent bonds, but that the question of the amount of assessment has not as yet been decided on.

Wabash.—National banks of New York City holding, it is said, about $40,600,000 first refunding and extension 4 per cent bonds of the Wabash, recently asked the Controller of the Currency whether they could assent to the plan of reorganization by which the holders of these bonds underwrite the issue of new preferred stock in exchange for an assessment. (May 7, pages 957 and 978.)

Men of English Railway with the Colors.—In the latest Roll of Honor poster issued by the London & North Western Railway, it is stated that 13,659 members, or 15.8 per cent of the whole of the company's staff, have joined the colors.

Electrification in Silesia.—Just before the war trial runs were about to be made on the Silesian lines of the Prussian State Railways, between Lauban and Königszelt. The work has now been stopped, and it is extremely unlikely that anything further will be done until after the war. Altogether, 310 miles of track are being electrified, the line being 170 miles long. The lines are in a mountainous district, where normally there is a heavy coal and passenger traffic. It is intended to run 500-ton passenger trains and 1,200-ton freight trains. In common with all other recent German electrification schemes, single-phase current is to be used, the trolley voltage being 15,000 at 16⅔ cycles. When the war began there were under construction 14 locomotives for high-speed passenger service, 30 for freight and seven for light passenger service. The average speed of the freight engines is to be 12.4 miles an hour, and the maximum speed 27.9 miles an hour.

Subscriptions, including 52 regular weekly issues and special daily editions published from time to time in New York, or in places other than New York, payable in advance and postage free:

United States and Mexico	$5.00
Canada	6.00
Foreign Countries (excepting daily editions)	8.00
Single Copies	15 cents each

Engineering and Maintenance of Way Edition and four Maintenance of Way Convention Daily issues, North America, $1.00; foreign $2.

Entered at the Post Office at New York, N. Y., as mail matter of the second class.

WE GUARANTEE that of this issue 10,011 copies were printed; that of those 10,011 copies 8,572 were mailed to regular paid subscribers to the Railway Age Gazette and the Railway Age Gazette, Mechanical Edition; 150 were provided for counter and news companies' sales; 189 were mailed to advertisers; 100 were provided for bound volumes, and 1,000 for distribution at Atlantic City.

The RAILWAY AGE GAZETTE and all other Simmons-Boardman publications are members of the Audit Bureau of Circulations.

The New Convention Hall

In one of the Dailies of last year we called attention to the necessity for enlarging Convention Hall and improving its arrangement. The very next day we received a letter from the representative of the Million Dollar Pier authorizing us to state that such changes would be made in time for the 1915 convention. Not only has the hall been considerably enlarged, but the arrangement of the presiding officer's desk is such that members can be seated to better advantage and will undoubtedly be able to follow the proceedings much more closely than was possible in the old hall. With the more commodius quarters and the change in the arrangement the members can move in and out between the discussions of the various reports with less disturbance to their fellows. It only remains for those taking part in the discussions to speak loudly and clearly to make this year's proceedings the very best.

This Year's Exhibit

There seemed to be an impression in some quarters that the exhibit this year would be very much smaller than usual. While it is not as large as last year, it covers over 70,000 sq. ft. of space and is in many respects more instructive and novel than any of the previous exhibits. It is doubtful if there were ever so many new appliances on exhibition in any one year. Moreover, there are more new names on the list of exhibitors than has been true for many years past. The average amount of space per exhibitor is somewhat larger than usual. The machine tool exhibit would undoubtedly have surpassed that of any previous year had it not been that the demand for certain classes of these tools has been so great, because of the manufacture of war munitions, that some of the exhibitors had to cancel arrangements for space because they could not secure a single tool for the exhibition at Atlantic City. In spite of this, however, the machine tool exhibit is every bit as attractive and practically as large as that of last year, which was a record breaker.

THE MAN AND THE JOB

A REPORT of more than ordinary interest and importance is being made by Dean Herman Schneider, of the University of Cincinnati, at the annual meeting of the National Association of Corporation Schools, which is now in session at Worcester, Mass. Probably no problem has given progressive railway officers and foremen more anxiety than that of the selection of men—and this not only for the more important or supervising positions but for each individual job on the railroad. The efficiency of a particular piece of equipment or machinery has in many cases been studied and analyzed to the last detail, but when it comes to the human element which controls the machine, the great variety of factors involved, many of them apparently indeterminate, has baffled the ingenuity of railway officers and industrial managers in trying scientifically to select and train the men to secure maximum individual efficiency.

Many officers have been attracted in the past few years

by the possibility of selecting men on the basis of an examination of their physical and other visible characteristics; others have even gone to the study of phrenology. Then, too, applied experimental psychology has seemed to many to present great possibilities for the final and logical solution of the problem. Dean Schneider, in connection with the development of co-operative engineering courses at Cincinnati, has made it his business to have a critical study made of the progress and development of each individual student, both in the practical work in the shops and in the class rooms and laboratories of the university. There are probably at least 1,000 of these young men whose characteristics are thoroughly well known and whose progress has been followed critically. In studying these men from the standpoint of physical characteristics or phrenology, Dean Schneider has been forced to the conclusion that this method of selecting men is not at all reliable, and he reaches the same conclusion regarding applied experimental psychology, which he says seems now to be where chemistry was when it was alchemy.

The final conclusion reached is that the only way by which men can be properly selected for a given job is to actually test them out on the job. Summing up, Dean Schneider finds, first, that a worker's failure is as significant as his success and should be analyzed to indicate a new and fitting job; second, the characteristics developed by analysis of many successes and failures furnish a basis for placement which works better than any known plan; third, while this method is crude and unscientific and requires a period of time much greater than the other methods proposed, it insures a reliable verdict.

THE READING TYPE LOCOMOTIVE

THE Philadelphia & Reading has on more than one occasion exhibited at the Atlantic City conventions an example of motive power designing which has aroused the keen interest of railway mechanical officers. The locomotive which this road has placed on the track exhibit at the conventions this year is of the 4-4-4 type and has been designated by the builders as the "Reading" type. A description is published in another part of this issue. While the wheel arrangement is unique, the engine has in addition a number of special features which make it by far the most interesting example of motive power designing which has been placed in service in this country for some time. Among these may be mentioned the employment of a four-wheel trailing truck which is interchangeable with the leading truck, a boiler with a firebox unusually large for passenger service, a unique design of ashpan, a cable-operated reversing mechanism, hollow axles of a design which is believed to form a precedent, the use of aluminum to reduce the weight of the reciprocating parts, and a weight on each driving axle of 73,100 lb., a figure which exceeds that of any other locomotive on our records, the nearest being that of the Pennsylvania Pacific and Atlantic type locomotives exhibited at last year's conventions, which have a weight per axle of 66,700 lb. and 66,500 lb. respectively.

A glance at the locomotive is sufficient to show that every effort has been made to keep the weight of the running gear to a minimum in order to provide as large a boiler as possible. Heat-treated steel has been used wherever possible and aluminum is used in the crosshead shoes and the main valves; the appearance of the axles, the crosshead and guides and particularly the valve gear is most striking because of the evidence of the extreme lightness of the parts employed. No figure is available for the dynamic augment, but with a weight per driving axle of 73,100 lb. this would of necessity be kept within very reasonable limits, and the appearance of the reciprocating parts indicates that nothing was left undone to keep the augment as low as possible. The design of axle employed should result, with the heat treatment, in the production of a steel of very high quality and the results obtained in service from this feature of these locomotives should prove of exceptional value to locomotive designers.

With a tractive effort of 36,600 lb., it is plain that advantage has been taken of every bit of the 146,200 lb. weight on the drivers. In fact, it would seem that the designer has gone quite to the limit in this feature when we consider that the factor of adhesion is only 3.99. The maximum tractive effort, 36,600 lb., compares with 29,500 lb. for the Pennsylvania Atlantic type locomotive, class E6s, and 41,800 lb. for the Pennsylvania Pacific type locomotive, class K4s. The driving wheel diameter, 80 in., is the same for all three of these engines and the cylinder dimensions for the Reading engine and the Pennsylvania Atlantic type are the same; but the Reading locomotive has an advantage of 35 lb. per sq. in. in boiler pressure. The maximum tractive effort of the new locomotive is exceptional for an engine having only four drivers and is as high as that of many Pacific type locomotives now in service.

For comparison with its boiler the boilers of the same two Pennsylvania locomotives have been chosen, and some of the principal features of each are shown in the accompanying table.

	Grate Area, Sq. Ft.	Heat. Surf. Sq. Ft. Firebox.	Heat. Surf. Sq. Ft. Tubes.	Heat. Surf. Sq. Ft. Equivalent.
Reading 4-4-4..	108	292	2199	3509
P. R. R. 4-4-2..	55	196	2660	3937
P. R. R. 4-6-2..	70	288	3747	5766

It will be noted that there is but little difference between the firebox heating surface of the Reading type and the Pennsylvania Pacific type, although the Pennsylvania engine has a grate area of 70 sq. ft., as against 108 sq. ft. for the Reading locomotive, the latter, of course, being an anthracite coal burner. This is probably accounted for to a considerable extent by the increase in heating surface due to the square corners of a Belpaire firebox over the curved surfaces of a Wootten firebox. When comparing the Reading locomotive with the Pennsylvania Atlantic type, the latter falls far short in firebox heating surface, but a greater number of tubes, and these 18 in. longer than those of the Reading locomotive, give the Pennsylvania engine an advantage of about 400 sq. ft. in equivalent heating surface, the latter being the total evaporative heating surface plus one and one-half times the superheating surface. Employing the system of boiler proportioning developed by F. J. Cole and now used by the American Locomotive Company, the Reading engine has about an 83 per cent boiler.

Regarding the most unusual feature of the Reading locomotive, which is the 4-4-4 wheel arrangement, little can be said until the locomotives have been tried out pretty thoroughly in service. The designer doubtless had a good reason for employing this wheel arrangement, but a first glance at the engine would lead to the belief that with what is practically equivalent to a four point suspension, it would be likely to roll considerably. This, however, as well as other effects on the riding qualities, can only be determined from service results. The four-wheel trailing truck is probably as light as, if not lighter than, some designs of two-wheel trucks, although no figures are available for this weight, but it does not seem probable that it is lighter than the best designs of two-wheel trailer trucks now employed, and there is added another pair of bearings to maintain. That the officers of the Reading have confidence in the design, however, is evident from the fact that four of these locomotives are being built and the results of their operation will be watched with more than passing interest.

PROGRAM FOR THE WEEK
MASTER MECHANICS' CONVENTION

WEDNESDAY, JUNE 9, 1915
9.30 A. M. to 1.30 P. M.

Prayer	9.30 A. M. to 9.35 A. M.
Address of President	9.35 A. M. to 9.50 A. M.
Intermission	9.50 A. M. to 9.55 A. M.
To allow those who wish to retire to do so, although all are requested to remain.	
Action on minutes of convention of 1914	9.55 A. M. to 10.00 A. M.
Reports of Secretary and Treasurer	10.00 A. M. to 10.15 A. M.
Assessment and announcement of dues; appointment of committees on correspondence, resolutions, nominations, obituaries, etc.	10.15 A. M. to 10.25 A. M.
Election of auditing committee	10.25 A. M. to 10.30 A. M.
Unfinished business	10.30 A. M. to 10.35 A. M.
New business	10.35 A. M. to 10.45 A. M.
Discussion of reports on:	
Mechanical stokers	10.45 A. M. to 11.15 A. M.
Revision of standards	11.15 A. M. to 11.45 A. M.
Safety appliances	11.45 A. M. to 12.00 M.
Topical discussions:	
(1) Advantages, if any, of compounding superheater locomotives	12.00 M. to 12.30 P. M.
(2) Side bearings on tenders	12.30 P. M. to 1.00 P. M.
Discussion of report on:	
Smoke prevention	1.00 P. M. to 1.30 P. M.

ENTERTAINMENT

11.00 A. M.—*Orchestral Band Concert.* Entrance Hall, Million-Dollar Pier.

3.30 P. M.—*Orchestral Band Concert.* Entrance Hall, Million-Dollar Pier.

9.00 P. M.—*Social Gathering and Informal Dance.* Special Feature, Costume Recital, Miss Betty Lee. Ball Room, Million-Dollar Pier. Don Richardson Orchestra.

THURSDAY, JUNE 10, 1915
9.30 A. M. to 1.30 P. M.

Discussion of reports on:	
Locomotive headlights	9.30 A. M. to 10.15 A. M.
Design, construction and inspection of locomotive boilers	10.15 A. M. to 10.30 A. M.
Standardization of tinware	10.30 A. M. to 10.45 A. M.
Superheater locomotives	10.45 A. M. to 11.30 A. M.
Fuel economy	11.30 A. M. to 12.00 M.
Individual paper on:	
Variable Exhausts. By Mr. J. Snowden Bell	12.00 M. to 12.30 P. M.
Topical discussions:	
Tender derailments, causes and remedies. To be opened by Mr. H. T. Bentley	12.30 P. M. to 12.45 P. M.
Road instructions for enginemen and firemen	12.45 P. M. to 1.00 P. M.
Cross-head design. To be opened by Mr. A. R. Ayers	1.00 P. M. to 1.30 P. M.

ENTERTAINMENT

10.30 A. M.—*Orchestral Band Concert.* Entrance Hall, Million-Dollar Pier.

3.30 P. M.—*Orchestral Band Concert.* Entrance Hall, Million-Dollar Pier.

9.30 P. M.—*Informal Dance.* Special Feature, Costume Recital, Miss Betty Lee. Ball Room, Million-Dollar Pier. Don Richardson Orchestra.

FRIDAY, JUNE 11, 1915
9.30 A. M. to 1.30 P. M.

Discussion of reports on:	
Joint meetings with M. C. B. Association	9.30 A. M. to 9.45 A. M.
Standardization of tinware	9.45 A. M. to 10.00 A. M.
Revision of air-brake and train signal instructions	10.00 A. M. to 10.15 A. M.
Train resistance and tonnage rating	10.15 A. M. to 10.30 A. M.
Locomotive counterbalancing	10.30 A. M. to 11.00 A. M.
Maintenance and operation of electrical equipment	11.00 A. M. to 11.15 A. M.
Forging specifications	11.15 A. M. to 11.30 A. M.
Boiler washing	11.30 A. M. to 11.45 A. M.
Dimensions of flange and screw couplings for injectors	11.45 A. M. to 12.00 M.
Subjects	12.00 M. to 12.05 P. M.
Resolutions, correspondence, etc.	12.05 P. M. to 12.15 P. M.
Unfinished business	12.15 P. M. to 12.30 P. M.
Election of officers, closing exercises	12.30 P. M. to 1.30 P. M.
Adjournment.	

ENTERTAINMENT

10.30 A. M.—*Orchestral Band Concert.* Entrance Hall, Million-Dollar Pier.

3.30 P. M.—*Orchestral Band Concert.* Entrance Hall, Million-Dollar Pier.

9.00 P. M.—*Carnival Dance.* Special Feature, "Charlie Chaplin Fox Trot," Miss E. M. Kegel and Mr. Frank Carlin. Ball Room, Million-Dollar Pier. Don Richardson Orchestra.

ENTERTAINMENT FEATURES

Those attending the convention this year will find a number of new features in the entertainment program which will add materially to the pleasure of all. The most radical, and what bids fair to be the most appreciated change is that of holding all social gatherings and dances on the pier. The entertainment committee has arranged for the exclusive use of the entire pier on Wednesday, Thursday, Friday, Monday and Tuesday nights, only those wearing badges to be admitted.

One of the severest criticisms of Atlantic City as a meeting place has always been the fact that great difficulty has been found in keeping the crowd together. The concentrating of all entertainment features will do much toward correcting the trouble. In the past, also, the gatherings at the hotels have been much impaired because of lack of room, and the dancers especially will welcome this innovation.

The Don Richardson Orchestra will play at both the morning and afternoon concerts on the Million-Dollar Pier, as well as at the evening dances. Mr. Richardson, the leader, is a talented violinist. The orchestra, which was formed three years ago in New York City, has made a specialty of playing at private entertainments and club affairs. It has a reputation for spirited playing by its various members in special compositions, of which one or two are usually included in each of the programs. Mr. Richardson is the composer of several popular dance airs, and his orchestra was recently retained to make a number of dance records for the Columbia Graphophone Company.

Miss Betty Lee, who appears in special costume recitals at four of the informal dances, is a Southern girl, and has achieved great popularity in rendering the folklore songs of different nations. Her recitals of Southern and Japanese songs are said to be particularly good. She accompanied

the Boston Grand Opera Company on its Canadian tour last year and gave costume recitals as special numbers.

The Carnival Dance on Friday night will be one of the special attractions, and though we are not permitted to divulge the details, there are surprises in store for all.

A special vaudeville entertainment will be held in the Hippodrome on the end of the pier on Saturday night, this being the first time in five years this has been done.

The Second Annual Golf Tournament, open to members of the A. R. M. M. A., M. C. B. A., R. S. M. A. and official registered guests, will be held on June 13, at the Sea View Golf Club, further details of which will appear in The Daily.

ATTEND THE OPENING EXERCISES

The opening exercises of the Master Mechanics' Association will be held in Convention Hall at 9:30 o'clock this morning and all the convention visitors, and particularly the ladies, are invited to attend them. The enlargement of the hall has given it such an increased seating capacity that a much larger number can be accommodated than has been the case in past years, and it is hoped that the guests and more particularly the ladies will take advantage of the opportunity to be present at least at the opening session.

INFORMATION BUREAU, TICKET OFFICE AND POST OFFICE

An Information Bureau is located on the Pier adjoining the Registration Booth. In conjunction with this bureau, the Pennsylvania Railroad and the Philadelphia & Reading have established a local office where tickets and reservations may be secured.

United States mail addressed in care of the Secretary's Office, Million Dollar Pier, Atlantic City, will be taken care of and distributed direct to the exhibitors' booths.

SPECIAL TRAIN FROM CHICAGO

The Chicago M. M. and M. C. B. Pennsylvania special train, consisting of an observation car, seven sleepers, two dining cars and a combination baggage and club car, arrived at Atlantic City at 4.32 P. M. Tuesday. This train left Chicago at 5.30 P. M. Monday as second section of the Pennsylvania Limited No. 2, instead of at 3 P. M. as in former years. The train was in charge of E. K. Bixby, district passenger agent, Pennsylvania Lines.

REGISTRATION

The work of registering M.M. and M.C.B. members was started on Monday afternoon at two o'clock and since that time the booth has been pretty steadily patronized except when it was closed for short periods at the lunch and dinner hours. For the remainder of the conventions the following schedule will be followed for the registration of members and their guests:

Wednesday	(9th).....	9	to 1.30;	2	to 6	P. M.;	7	to 9 P. M.
Thursday	(10th).....	9	to 1.30;	2	to 6	P. M.;	7	to 9 P. M.
Friday	(11th).....	9	to 1.30;	2	to 6	P. M.;	7	to 9 P. M.
Saturday	(12th).....	9	to 1				5.30	to 9 P. M.
Sunday	(13th).....	10	to 12;	2	to 4	P. M.		
Monday	(14th).....	9	to 1;	2.30	to 6	P. M.		
Tuesday	(15th).....	9.30	to 12;	2	to 4.30	P. M.		
Wednesday	(16th).....	9	to 11 A. M.					

The greater number of the members of the Railway Supply Manufacturers' Association registered on Monday and Tuesday. Newcomers may register at the times shown below during the remaining days of the conventions:

Wednesday	(9th).....	9	to 12 A. M.;	1.30	to 5	P. M.;	7	to 9 P. M.
Thursday	(10th).....	9	to 12 A. M.;	1.30	to 5	P. M.		
Friday	(11th).....	9	to 12 A. M.					
Saturday	(12th).....	9	to 1 P. M.				5.30	to 9 P. M.
Sunday	(13th).....	10	to 12 A. M.					
Monday	(14th).....	9	to 12 A. M.;	2	to 5	P. M.		
Tuesday	(15th).....	9	to 12 A. M.;	2	to 5	P. M.		
Wednesday	(16th).....	9	to 11 A. M.					

The following rules, which are quite similar to those of last year and which are authorized by the M.M. and M.C.B. Associations, will govern the registration of M.M. and M.C.B. members and their guests. These will be strictly enforced:

"Badges for members of the Master Mechanics' Association, Master Car Builders' Association, or special guests, shall not be given to any but the rightful owners. No member of the Railway Supply Manufacturers' Association will be permitted to pay for or take one for delivery except upon the owner's written order, and the receiver must sign for the badge.

"No badges shall be issued to members of the Master Car Builders' Association except on the payment of a fee of $1.00. The Master Mechanics' Association and special guest badges will be issued to those entitled to them free of all charges until noon Saturday, June 12, at which time M.M. badges will be withdrawn and a charge of $1.00 will be made for all special guest badges, except that a member of the Master Mechanics' Association taking out a special guest badge and paying the fee of $1.00 will be given his M.M. badge gratis. Likewise members of the M.M. Association who are also members of the M.C.B. Association can get their M.M. badge by paying for the M.C.B. badge."

THE BADGES

Last year a radical change was made in the design of the badges; while those used this year are somewhat similar in general design they differ greatly in appearance from anything which has heretofore been used. The M.M. and M.C.B. badges have the standard enameled emblems included in the center of the badge, presenting a possibly somewhat more symmetrical appearance than the scheme which was followed last year in which the emblem was placed off center and near the upper part of the badge.

The corrugations on the outer edge of the badge, with the projection on the lower side, which carries the number, resemble somewhat a seashell in appearance, making it specially appropriate for use at Atlantic City. The Railway Supply Manufacturers' Association badge is elongated rather than circular, as it was last year, and is not so conventional. The M.M. and M.C.B. monograms on either end of the badge add to the artistic effect. For the supply men the enamel on the badges is royal blue; for the supply ladies, white; for the railroad ladies, light blue; for the complimentary men's badges, red, and for the complimentary ladies' badges, yellow.

WOMEN EMPLOYEES OF THE RAILWAYS OF RUSSIA.—The steps recently taken to introduce women as railway workers in the United Kingdom make it interesting to note that there are between 20,000 and 30,000 women regularly employed on the Russian State railways as gatekeepers, clerks and telegraph operators.

The Railway Supply Manufacturers' Association.

The Remarkable Exhibit of Railway Appliances at the Conventions is Due to the Efforts of this Organization

The work of the Railway Supply Manufacturers' Association is so well understood by attendants at the convention that it would be superfluous to describe it in detail. When one reviews the wonderful exhibition of railway supplies and machinery and considers the vast amount of detail planning which must have been done in advance to get it all delivered to and properly arranged on the Pier, the task appears to be a stupendous one. While the exhibition is somewhat smaller than usual this year the officers of the Association are to be congratulated on the fact that in spite of the peculiar business conditions it covers about 70,000 sq. ft. of space. That officers and committee members of the Association have done some tall hustling is indicated by the large percentage of exhibitors who are at Atlantic City this year for the first time.

But the gathering together and arrangement of the exhibit is only part of the work of the Association—entertainment features must be looked after; transportation matters both as to railroads and the use of roller chairs must be given much attention; the enrollment committee must painstakingly see that several thousand attendants are properly registered and that classified printed lists of the total enrollment are issued each day; the hotel committee sees to it that arrangements are made for the accommodation of the convention attendants at the hotels; and the badge committee looks after the designing and providing of the badges. Then there is the finance committee, with the responsibilities which always rest upon such a committee, and the committee on by-laws, which studies the needs of the Association and sees that the by-laws are revised from time to time in order that the Association may do its work most effectively.

The Association is headed this year by President J. Will Johnson, general manager of the Pyle-National Electric Headlight Company, with which company he has been associated for almost 13 years, as noted in the sketch of his career which appeared in the *Daily* of June 10, 1914, page 1263. For many years Mr. Johnson has been one of the most energetic and efficient workers in the R. S. M. A. Among other positions he has been chairman of the entertainment committee, chairman of the exhibit committee and vice-president, and in all these offices did work which contributed greatly to the success of the conventions. It should be added that when there was a band he was one of the most tuneful members of it. His advancement to the office of president was an honor well earned and well deserved.

Oscar F. Ostby, vice-president of the Association, is with the Commercial Acetylene Railway Light & Signal Company, and last year was chairman of the exhibit committee of the Association. This year in addition to his duties as vice-president he is chairman of the hotel committee. An outline of his past achievements appeared in the *Daily* of June 10, 1914, page 1265.

The secretary-treasurer, John D. Conway, devotes all of his time to the affairs of the Association and has officiated as its secretary since 1910.

EXECUTIVE COMMITTEE

The executive committee is distributed over seven geographical districts as follows: First district (New England states and Canada), one member—F. M. Nellis, Westinghouse Air Brake Company, Boston, Mass. Second district (New York and New Jersey), three members—J. C. Currie, Nathan Manufacturing Company, New York City; O. F. Ostby, Commercial Acetylene Railway Light & Signal Company, New York City; and C. B. Yardley, Jr., Lubricating Metal Company, New York City. Third district (Pennsylvania), two members—P. J. Mitchell, Philip S. Justice & Co., Philadelphia; and C. E. Postlethwaite, Pressed Steel Car Company, Pittsburgh, Pa. Fourth district (Ohio, Indiana and Michigan), two members—C. F. Elliott, Acme White Lead & Color Works, Detroit, Mich.; and J. C. Whitridge, Buckeye Steel Castings Company, Columbus, Ohio. Fifth district (Illinois, Wisconsin, Iowa and Minnesota), two members—J. H. Kuhns, Republic Rubber Company, Chicago; and George H. Porter, Western Electric Company, Chicago. Sixth district (Delaware, Maryland, District of Columbia, Virginia, West Virginia, North Carolina, South Carolina, Georgia, Florida, Alabama, Mississippi, Kentucky and Tennessee), one member—Frank E. Beal, Magnus Metal Company, Altanta, Ga. Seventh district (states west of the Mississippi river, including Louisiana, but excepting Iowa and Minnesota), one member—S. M. Dolan, Chicago Varnish Company, St. Louis, Mo.

Four of these members will automatically retire at the close of the convention, including F. M. Nellis (first district), Oscar F. Ostby (second district), J. C. Whitridge (fourth district), and S. M. Dolan (seventh district).

The four new members of the executive committee elected last year were F. E. Beal, sixth district; Philip Justice Mitchell, and C. E. Postlethwaite, third district; and George H. Porter, fifth district. Brief sketches of these new members follow:

F. E. Beal is a Wolverine, having been born in Detroit. After finishing a high school and a Detroit Business College course he entered the employ of the Fulton Iron & Engine Works in the early eighties as timekeeper. Later he was promoted to the position of assistant cashier, and then bookkeeper. This company was at that time owned by J. B. Wayne, Senator James McMillan and Congressman John S. Newbury and was engaged in the manufacture of car journal bearings under the original Hopkin's patent for lead lined bearings and saw mill machinery. Mr. Beal succeeded to the position of cashier and bookkeeper and served in that capacity until Mr. Wayne's death, when he was appointed assistant general manager, which position he held until 1902 when the company was sold to the National Fulton Brass Manufacturing Company. He was made vice-president, remaining in that position until 1905, when the business was purchased by the Magnus Metal Company. In 1907 Mr. Beal was transferred to New York City as sales manager for the Magnus Metal Company, and after serving in this position for two years was transferred in 1909 to the position of manager of shop operations and sales department of the Georgia plant of that company.

Philip Justice Mitchell was born in Philadelphia and educated at the Friends' Central High School of that city. For several years he was employed by a large banking and shipping concern, and in 1886 went with the firm of Philip S. Justice & Co., importers and dealers in railway specialties. It is said that this firm imported the first steel rails used in the United States. On the death of Philip S. Justice in 1901 Mr. Mitchell, with his father, J. Howard Mitchell, formed the partnership under the same firm name, Philip S. Justice & Co., which continued until the death of his father in 1912. In addition to conducting the business of Philip S. Justice & Co., Mr. Mitchell is treasurer of Dienelt & Eisenhardt, Inc., engineers and machinists, and treasurer of the Lovekin Pipe Expanding & Flanging Machine Company, both of Philadelphia.

George H. Porter, in charge of the steam railway sales department of the Western Electric Company, Chicago, was

George H. Porter

chairman of the transportation committee at the 1914 convention; a brief sketch of his career was given in the *Daily Railway Age Gazette* of June 10, 1914, page 1265.

C. E. Postlethwaite, manager of sales for the central district for the Pressed Steel Car Company, Pittsburgh, Pa., was born in Mount Union, Huntington county, Pa., and after graduating from the Altoona high school in 1883 entered the service of the Pennsylvania Railroad, where he remained until 1890, acting successively as rodman, telegraph operator and car clerk. For the following nine years he was connected with the Norfolk & Western as chief clerk to the general superintendent and later as assistant to the general agent. He became connected with the Schoen Pressed Steel Car Company in October, 1897, shortly after the first steel freight cars were built, and remained with the company when it was merged into the Pressed Steel Car Company. He entered the sales department in February, 1902.

EXHIBIT COMMITTEE.

Joseph H. Kuhns is chairman of this committee, with J. C. Whitridge and C. E. Postlethwaite, also members of the executive committee, as the other two members.

ENTERTAINMENT COMMITTEE.

George R. Carr, vice-president of the Dearborn Chemical Company, Chicago, is chairman of this committee, which is responsible for providing the entertainment features during the convention. One of the notable features of the program this year will be the golf tournament, which is noticed at length in another part of this issue. The other members of the entertainment committee are M. G. Baker, American Vanadium Company, Pittsburgh, Pa.; E. H. Bankard, Jr., Cambria Steel Company, Chicago; Walter H. Bentley, Curtain Supply Company, Chicago; G. R. Berger, Gould Coupler Company, Chicago; B. A. Clements, Worth Brothers Company, Chicago; C. W. F. Coffin, Franklin Railway Supply Company, Chicago; J. F. A. Comstedt, Atlas Automatic Jack Corporation, New York City; T. K. Dunbar, Acme Supply Company, Chicago; C. D. Eaton, American Car & Foundry Company, St. Louis, Mo.; R. J. Faure, Commercial Acetylene Railway Light & Signal Company, New York City; J. F. Forney, Ralston Steel Car Company, Baltimore, Md.; R. H. Gwaltney, T. H. Symington Company, New York City; H. W. Hegeman, U. S. Metal & Manufacturing Company, New York City; Langley Ingraham, Yarnall Paint Company, Philadelphia, Pa.; C. D. Jenks, Edwin S. Woods Company, Chicago; W. K. Krepps, Crucible Steel Company, New York City; J. B. Landreth, Garlock Packing Company, Chicago; Albert MacRae, MacRae's Blue Book, Chicago; William W. Melcher, Massachusetts Mohair Plush Company, Boston, Mass.; Burton W. Mudge, Burton W. Mudge & Co., Chicago; G. E. Ryder, Locomotive Superheater Company, New York City; D. E. Sawyer, Illinois Steel Company, Chicago; Harold N. Scott, Griffin Wheel Company, Chicago; L. B. Sherman, Railway Age Gazette, Chicago; A. B. Wegener, Camel Company, Chicago.

George R. Carr, chairman of the committee, was born at Argenta, Ill., where he attended the public schools. In the fall of 1893 he moved to Chicago, where he has since lived and where he attended the Austin High School. He was graduated at the University of Illinois, School of Chemistry, in 1901. Immediately after graduation he entered the service of the Dearborn Chemical Company in the sales department and has been with that company in various capacities continuously since that time. He was elected vice-president and general manager in the spring of 1908, which position he now holds.

TRANSPORTATION COMMITTEE.

This committee has charge of all matters referring to transportation and is headed by George T. Cooke, Chicago Car Heating Company, New York City. The other members of the committee are E. A. Averill, Standard Stoker Company, New York; W. Anderson, The Pantasote Company, Chicago; J. T. Anthony, American Arch Company, New York; R. W. Benson, American Flexible Bolt Company, New York; C. C. Bradford, U. S. Light & Heating Company, Niagara Falls, N. Y.; D. L. Clement, Pratt & Lambert Company, New York; H. Chamberlain, Transportation Utilities Company, New York; A. N. Dugan, Bronze Metal Company, New York; L. S. Hungerford, Jr., Peerless Rubber Manufacturing Company, Chicago; A. S. Lewis, Chicago-Cleveland Car Roofing Company, New York; A. L. McNeill, Central Electric Company, Chicago; T. P. O'Brian, O. M. Edwards Company, New York; H. K. Porter, U. S. Metal & Manufacturing Company, Atlanta, Ga.; J. L. Randolph, Economy Devices Corporation, New York; C. C. Schumaker, The Carborundum Company, Chicago; L. S. Wright, National Malleable Castings Company, Chicago.

The chairman, George T. Cooke, was born in Chicago, May 28, 1883, and was graduated from the grammar and high schools of that city, after which he received a mechanical training and entered the service of the Pullman Company as a draftsman in 1901. Later he was made chief draftsman of the repair department, then chief repair inspector, and finally mechanical inspector. In 1911 he resigned his position with the Pullman Company to accept a position with the Chicago Car Heating Company as southern manager, with headquarters in Atlanta, Ga. This position he held for two years, and in 1913 was transferred to New York as eastern manager, which position he now holds.

ENROLLMENT COMMITTEE.

Harold A. Brown, eastern representative of the Pocket List of Railroad Officials, New York, is chairman of this committee for the second time, having held the same position last year. A sketch of Mr. Brown's career was published in the *Daily* of June 10, 1914, page 1265. The work of the enrollment committee is most exacting, and during the past few years a considerable improvement has been made in organizing it so as to distribute it more evenly among the various members and thus not demand too much of any one of them.

The other members of the committee are F. N. Bard, The Barco Brass & Joint Company, Chicago; G. A. Barden, Chicago Pneumatic Tool Company, Philadelphia, Pa.; C. W. Beaver, Yale & Towne Manufacturing Company, New York; W. J. Fleming, Jr., Automatic Ventilator Company, New York; Charles H. Gayetty, Quaker City Rubber Company, Philadelphia, Pa.; L. D. Mitchell, Detroit Graphite Company, Chicago; R. F. Moon, Westinghouse Electric & Manufacturing Company, Philadelphia; E. T. Sawyer, Commercial Acetylene Railway Light & Signal Company, New York; F. H. Smith, Gold Car Heating & Lighting Company, New York; T. D. Starr, Wm. C. Robinson & Son Co., Philadelphia; J. A. Stevens, F. W. Devoe & C. T. Raynolds Company, New York; and H. G. Thompson, Edison Storage Battery Company, Orange, N. J.

BADGE COMMITTEE.

C. B. Yardley, Jr., is chairman of this committee, of which Oscar F. Ostby and George H. Porter are the other two members, all being members of the executive committee. Mr. Yardley has been president during the past year of the Railway Materials Association, associated with the Railway Storekeepers' Association. A sketch of his career appeared on page 1266 of the *Daily* of June 10, 1914. Since that time he has been connected with William C. Robinson & Son Company, and on the first of this month went with the Lubricating Metal Company, New York, as manager of the railway department.

COMMITTEE ON BY-LAWS

C. F. Elliott is chairman of this committee, with F. E. Beal and George H. Porter as the two other members, all three being members of the executive committee.

HOTEL COMMITTEE

Oscar F. Ostby, vice-president of the Association, is chairman of this committee, with S. M. Dolan and P. J. Mitchell, both of the executive committee, as his associates.

FINANCE COMMITTEE

F. M. Nellis, who last year was chairman of the committee on by-laws, is this year chairman of the finance committee and has as his associates J. C. Currie and C. F. Elliott. A brief sketch of Mr. Nellis' career appeared in the *Daily* of June 10, 1914, page 1266.

MOTT SHERWOOD KILLED

M. E. Sherwood, master mechanic of the Michigan Central at Jackson, Mich., was shot and killed while automobile riding with his wife and a party of friends in the fair grounds at Jackson last Friday evening at 9.30 o'clock. It was at first believed that he had died of apoplexy, but examination later developed the fact that a bullet had entered the back just below the left shoulder and passed through the heart. Apparently the shot was fired by boys in the grand stand who were shooting at the lights and tires of passing automobiles. Mr. Sherwood entered the employ of the Michigan Central about 25 years ago as a mechanic and was made a master mechanic five years ago. He was 46 years of age and is survived by a widow and a son, William.

ROLLER CHAIRS

The Transportation Committee has issued the following instructions for the use of roller chairs during the conventions.

"Roller chairs will be furnished free from the following four stations at the periods noted and only to members wearing the official badges:

The Pier	9.00 A. M.	to	6 P. M.
Marlborough-Blenheim	9.00 A. M.	to	6 P. M.
Chalfonte Hotel	9.00 A. M.	to	6 P. M.
Strand Hotel	9.00 A. M.	to	6 P. M.
To both informal dances on pier	8.30 P. M.	to	10 P. M.

"Unoccupied chairs may be stopped at any point on the Boardwalk, except between the Marlborough-Blenheim and the Pier, and they may be used in either direction, but must be reported at the first checking station passed. Convention chairs are not allowed to wait more than fifteen minutes.

"Any of Shill's chairs may be had after hours for a continuous trip in any one direction for 25 cents per person. Hourly riding can be arranged for on the regular rate basis. Private chairs may be secured at special rates through the Transportation Committee only."

MASTER MECHANICS' REGISTRATION

Aldcorn, Thomas, Chicago Pneumatic Tool Co.; Shelburne.

Storey, J. W., C. D., C. of Ga.; Arlington.
Wightman, D. A., Dennis.

THE GOLF TOURNAMENT

The second annual golf tournament, open to members of the A.R.M.M.A., M.C.B.A., R.S.M.A., and official registered guests, will be held on June 13 at the Sea View Golf Club. The tournament will consist of two contests run simultaneously, one an 18-hole Medal Play Handicap, the other an 18-hole Kickers Handicap. Loving cups will be presented to the three low men in each contest.

The winning score in the Kickers Handicap will be between 71 and 76 inclusive. Each participant in this tournament will have the privilege of selecting his own handicap prior to starting, with a view of securing a net score from 71 to 76 inclusive. Net scores under or over 71 to 76 respectively will be disqualified. In case of ties in either the 18-hole Medal Play Handicap

Reproduction of the Golf Tournament Poster

or in the 18-hole Kickers Handicap additional rounds will be played by those who are tied, either on Monday, June 14, or Tuesday, June 15, at the Sea View Golf Club.

The Sea View Golf Club is a private course, and it is through the personal invitation of its President, Clarence H. Geist, that our associations are privileged to hold the tournament there. No entrance fees for the tournament will be charged by the Association, but the club will levy the usual greens fee of $1.00 per day per person.

Entries for both tournaments can be made to any of the members of the golf committee, prior to June 13, or can be made at the first tee on June 13, prior to starting. The golf committee consists of E. H. Bankard, Jr., chairman; L. B. Sherman, C. D. Jenks, D. E. Sawyer, H. N. Scott, M. G. Baker, R. H. Gwaltney, and C. R. King.

In order that adequate luncheon preparations may be made at the club Sunday noon, the manager of the Sea View Golf Club has been advised that between 75 and 100 golfers will probably have luncheon there. It will therefore be wise to make reservations for tables, etc., as early as possible.

The Bergdoll Taxicab Company has agreed to take any number of persons up to six in a car to the Sea View Golf Club and return for $5.00. If the party requests a layover, a charge of $2.00 for each hour of the layover will be added to the round trip rate. The golf committee suggests that in order to make transportation to and from the club as economical as practicable, those desiring to play golf shall make up parties of six or less in advance, and the taxicab company will deliver its cars wherever it is instructed to.

RECTANGULAR EXHAUST NOZZLE

The illustration shows a rectangular exhaust nozzle which is being exhibited by the Economy Devices Corporation. This nozzle is claimed to produce a jet, the gas entraining surface of which is increased 20 per cent over that of the circular nozzle having an equivalent area, the production of draft being thus increased without resort to bridges or other obstruction which impede the flow of steam and result in

Rectangular Exhaust Nozzle

increased back pressure. It is also claimed that the jet formed by this nozzle is better adapted to fill the stack under all conditions than the usual jet of circular section. Under ordinary operating conditions the horsepower required to produce draft often forms a considerable portion of the total output of the engine and any means whereby the necessary draft may be produced with a decreased back pressure may be expected to result in a saving in fuel consumption.

CHILEAN RAILWAY CONSTRUCTION.—The following railways are in course of construction in Chile at the present time: Iquique-Pintados, 842 men, beginning excavation; Rancagua-Donihue, 60 men, rail laying completed; Alcones-Pichilemu, 217 men, grading; Linares-Colbun, 69 men, grading; Pinto-Recinto, 88 men, track is laid; Confluencia to Tome and Penco, 1079 men, track is laid to kilometer 78; Selva Oscura-Curacautin, 129 men, grading; Cajon-Llaima, 155 men, track laid to kilometer 52.5.

A Passenger Locomotive of Unusual Interest

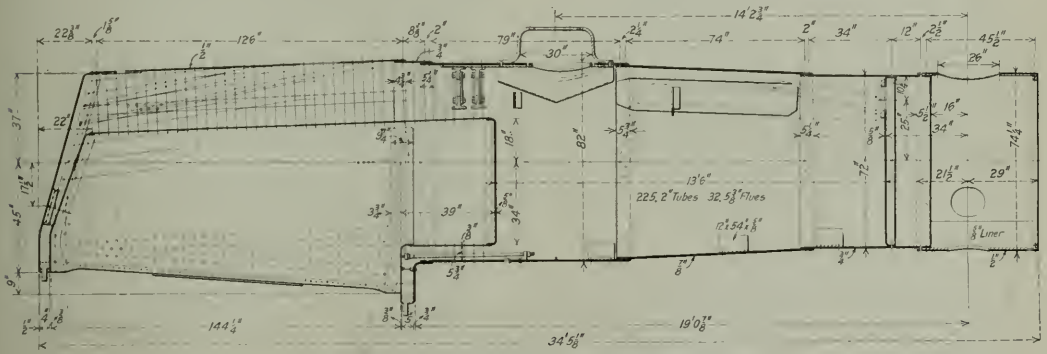
New Reading Engine of the 4-4-4 Type Has a Weight of 73,000 lb. per Driving Axle; Large Firebox Heating Surface

The Philadelphia & Reading has on exhibition at the conventions a locomotive of a new type, which has been designated as the "Reading" type, and has a 4-4-4 wheel arrangement, a four-wheel truck being employed under the firebox. This truck is interchangeable with the leading truck. The locomotive is the first of four which were designed and are being built at the company's shops at Reading, Pa., for heavy, fast passenger service.

These engines have a number of interesting and unusual features, apart from the wheel arrangement. These include a special design of back frame and ashpan, hallow axles with an unusual amount of metal removed from the centers, a cable-operated reverse gear and a weight on drivers of 146,200 lb., or 73,100 lb. per axle. Heat-treated steel has been liberally employed to reduce weight, and aluminum was resorted to for this purpose in the crossheads and some other parts.

A back frame is placed longitudinally under the central portion of the firebox. This frame is constructed of two rolled plates 1 in. by 30 in. by 16 ft. 9¼ in., flanged to a pulling casting to its back end. This back frame provides a passage-way for a reversing cable and piping, five lines of piping passing through it.

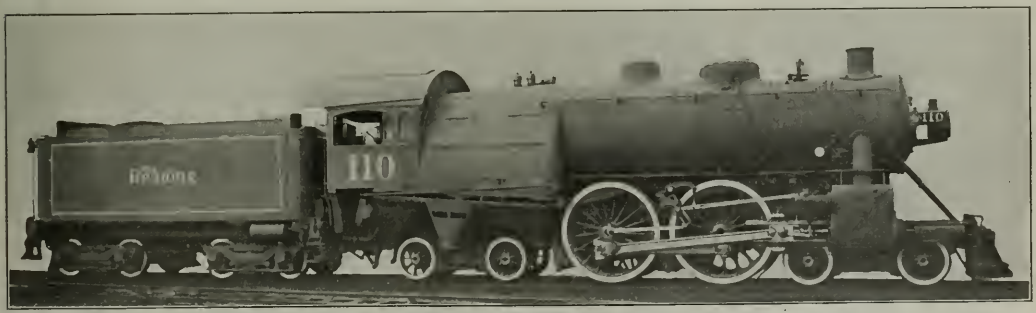
Three conical ashpans are provided on each side of the locomotive, giving large, self-cleaning receptacles, which also provide ample air openings at a considerable distance below the grates. Flatly flaring sides, where ashes can collect, are eliminated. The middle pans on each side catch the light rakings, which, in emptying the pans, can be dropped to the side of the track outside the rails, or deflected between the rails into the pit, by means of a short chute. The front and back pans receive the fire and ashes from the front and back drop-grates, when the fires are cleaned, and discharge it into the pit between the rails, ahead of and behind the truck.



The Boiler of the Reading 4-4-4 Type Locomotive

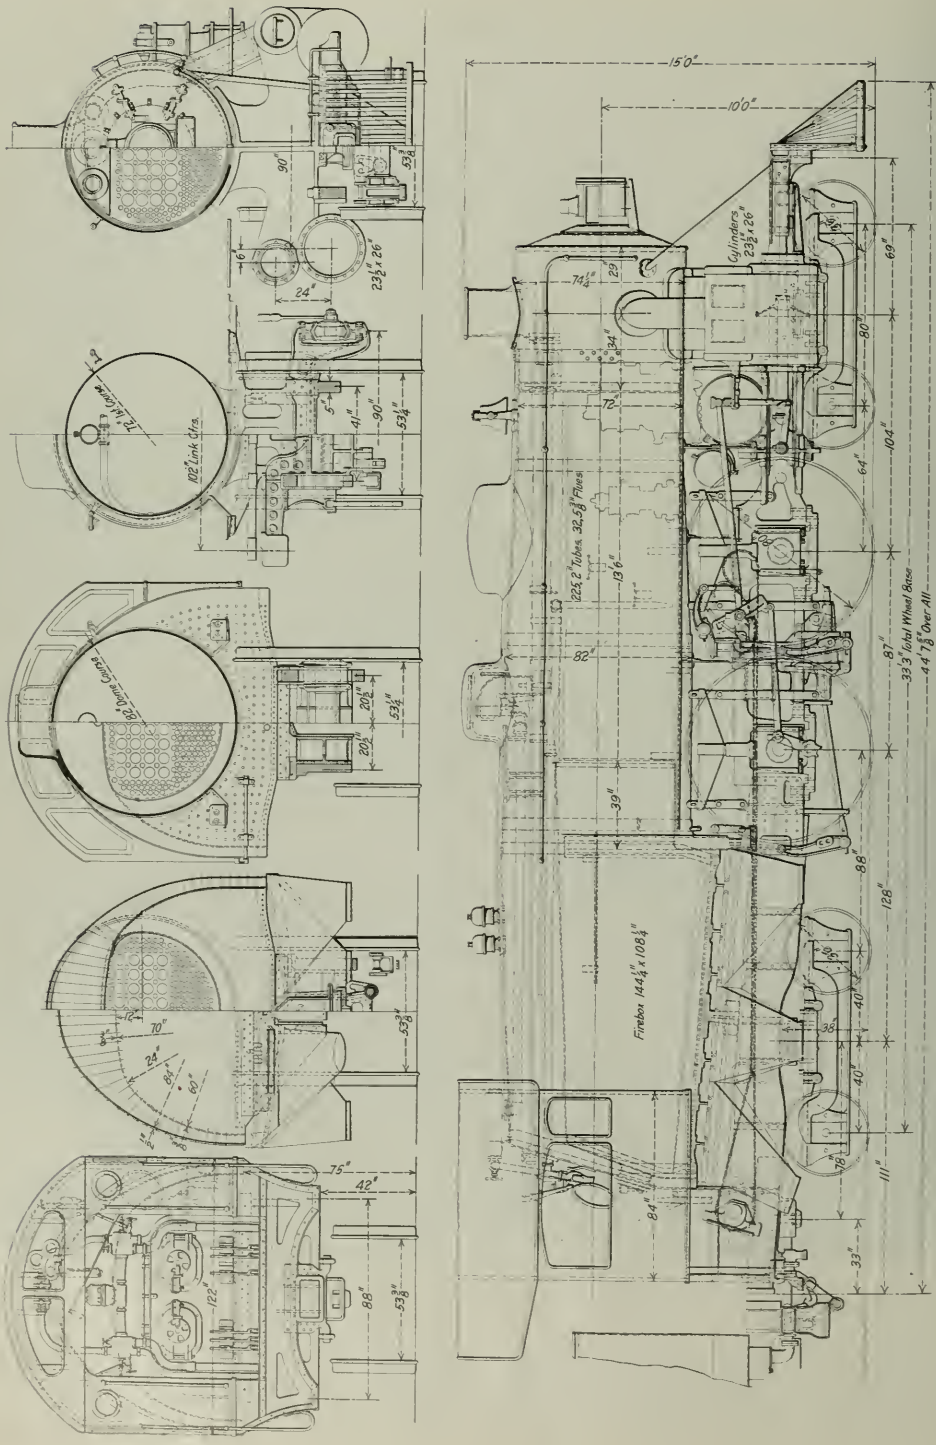
A rear cab arrangement of ample dimensions is combined with a very wide Wootten type firebox, for burning anthracite coal, without creating excessive weight at the rear of the locomotive. This permits the engineman and fireman to be together.

The firebox and grate surface is probably the largest of the prevailing types ever applied to a passenger locomotive, and, with a few exceptions, as large as any ever applied to a freight locomotive. The firebox and combustion chamber heating surface is 292 sq. ft., which is equivalent to 8.32 per cent of the total heating surface. As a square foot of firebox heating surface is ordinarily considered equivalent to five



Passenger Locomotive of the "Reading" or 4-4-4 Type

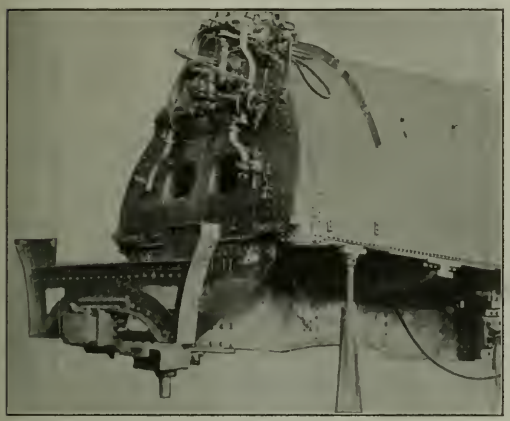
suitable shape and spaced 10 in. apart by spacers of a channel section, to which they are riveted. The main frames terminate under the front of the firebox, where they are tied together by means of a cross-brace casting, into which the back central frame is fastened. A center plate is riveted under the middle portion of the back frame, and a



Elevation and Sections Showing General Arrangement of the Reading 4-4-4 Type Locomotive

or six square feet of tube heating surface, ample steaming capacity is expected from the boiler.

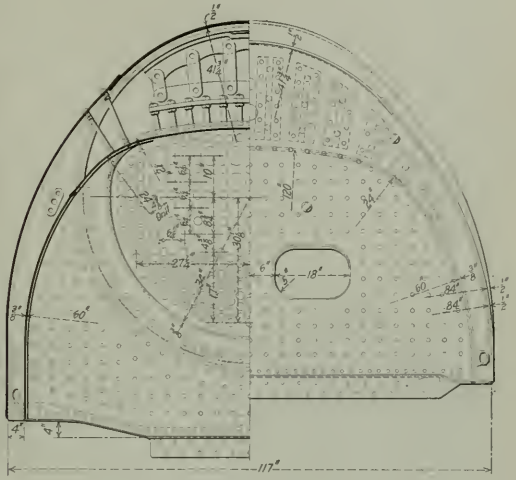
This large firebox is of advantage in burning low grades of anthracite coal. The 9 ft. by 12 ft. grate gives one square foot of grate for every 32.5 sq. ft. of heating surface in the boiler, which approximately equals what is considered good practice for stationary work in burning anthracite coal. This large proportion of grate surface to heating surface should also be advantageous in burning low grades of bituminous coal.



Firebox and Back Frame During Construction

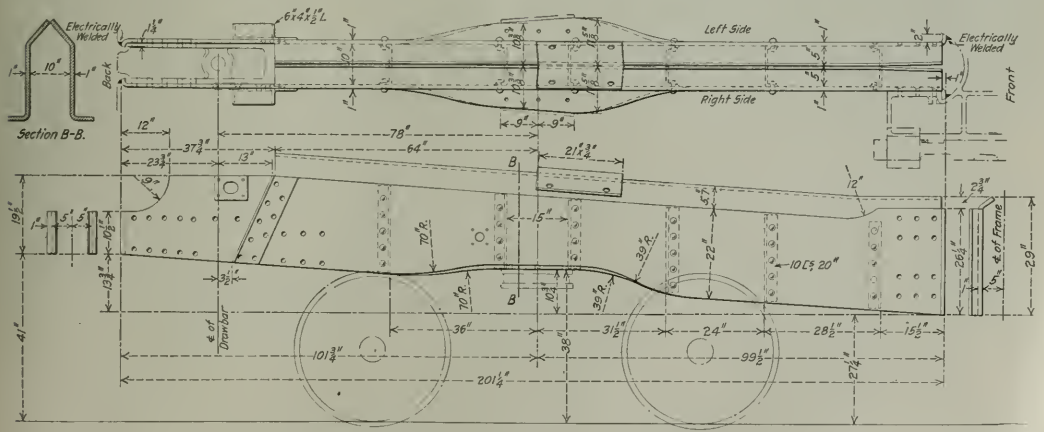
An anti-clinker device provides for the introduction of steam to the ashpan under the grates from the exhaust cavity of the cylinders and from the air pump, with means in the cab for turning this steam supply either under the grates or into the locomotive stack. This device assists the burning of low grade coal which runs together forming clinker and thus interferes with the operating of the grates and the working of the fire.

A special study has been made to obtain lightness in every part of the locomotive, so that all available weight could be put into the boiler. All castings and forgings have been designed with this in view. Heat-treated steel and high-grade materials have been used, with the result that this locomotive has a larger boiler than any other passenger locomotive now in service on the Reading, while at the same time the total weight of the locomotive is less than that of some engines of other types now in heavy passenger service; nevertheless, a greater weight is carried on the drivers, the result being a comparatively light but powerful locomotive with a large boiler capacity.



Cross Section and End Elevation of the Reading Locomotive Boiler

Mayari chromium-nickel heat-treated steel is used in the following parts: main and side rods, driving and engine truck axles, main crosshead guides, piston-rod-extension guides, crosshead centers, pistons and piston rods, valve motion parts, and a number of minor parts where special strength was required with a minimum of metal. Aluminum is used for the main crosshead shoes, crosshead for piston-rod-extension, main steam valves, valve-stem crosshead, hand reversing wheel, cab window frames and smokebox door clips.



Details of the Back Frame for the Reading Locomotive

Hollow driving and engine truck axles are used. The main driving axles have 6-in. holes, and the engine truck axles

3½-in. holes, which is much in excess of anything heretofore used. This feature lightens the parts and greatly assists in the heat treatment of the metal.

V-shaped guides are used for the crossheads and piston-rod-extension crossheads. These guides are made from bent plates of heat-treated steel, the main guides being ½ in. thick and the front guides 3-16 in. thick. The V shape gives a strong guide with large bearing surface, and allows the crosshead to be made much smaller and lighter than other constructions now in general use. The crosshead has a heat-treated steel center portion which contains the wrist pin hole and the piston rod key slot. Aluminum upper and lower shoes are cast solidly to this center, these aluminum shoes being provided with babbitt wearing faces. The piston is forged and turned to conical shape from a disc of heat-treated steel, and it is believed to be the lightest ever used for high pressure and heavy service. The web of this

The Assembled Frames

piston tapers from 5-16 in. thick, where it joins the outer rim, to ½ in. thick where it joins the center.

The reciprocating parts, throughout, are very light. This allows a great weight to be carried on the driving wheels without creating excessive loads at the higher speeds.

A hand wheel is used to operate a cable reversing mechanism connected to the tumbling shaft. A 7-16 in. steel cable runs through the duct formed by the back frame, from a drum under the cab to an arcuated lever on the tumbling shaft. A counterbalance is attached to this cable, to balance the weight of the lifted parts. An advantage is claimed for this cable mechanism over the ordinary reverse lever, in that it moves the valves easily under all operating conditions of the locomotive. It is also believed to have an advantage over the power-operated reversing devices, in that it indicates to the engineman the condition of the lubrication of

Weight in working order	230,800 lb.	240,000 lb.

*Equivalent heating surface = total evaporative heating surface + 1.5 times the superheating surface.

EXCEEDING THE SCHEDULE

Secretary Joe Taylor has lots of trouble keeping the convention sessions up to the program schedule. It is just as bad to run too fast as too slow. Railroads are sometimes worried with this same problem of keeping the trains from running too fast. An instance of this sort is described in the following letter which was recently received by the general claim agent of a southern road:

"Repleighing to your leter the 29 Beg to say we ar awair of the fack that X and Y dus not run fas enuf to endangur the life of a hog when it is runing skedul, but i am in possisshun to pruve that the trane maid a extrey effurt tow ketch this animule and exseyded ther spead limet having thur advantatige of the po hog by its being down graid the hog dun all in hets power to eskape but was overtucked by the enjine en put to deth. so i shal cuntend for the value of this animule as it is noan hear that the X and Y dus not pay for enything in thur weigh of stoc if it can avoyd so i am tuning this over to My atturneigh unles setle by return male."

LITTLE INTERVIEWS

J. Will Johnson, president of the Railway Supply Manufacturers' Association, remarked yesterday that the most marked tendency which he had noted during the ten years that he has been coming to the conventions, has been a growing disposition on the part of both the railway men and the supply men to make the conventions and the exhibits more efficient along purely business lines. "In the first place," said Mr. Johnson, "the railway men themselves have taken the conventions, and especially the exhibits, more and more seriously. The effect of this has been that the supply men have taken more pains to make their exhibits worth while. The proportion of improved devices or entirely new ones shown has increased until many concerns exhibit practically no others. The entertainment features have been modified until they occupy a very subordinate place as compared with the one they formerly occupied. The supply men co-operate together better than ever before, there being a better realization year by year that it is important to make not only the individual exhibits, but the exhibit as a whole, interesting and instructive. While the space used is reduced this year, owing to conditions with which all are familiar, I believe that the exhibit will be found to be at least as good as any we have ever had."

THE SWISS HAUENSTEIN BASE TUNNEL.—For a time, work on the Hauenstein Base Tunnel, the contractors for which are a German firm in Berlin, was interrupted, largely owing to the workmen having been called away to erect fortifications on the top of the range beneath which the tunnel runs. This having been accomplished, the men have been allowed to resume work on the tunnel, which is now completely excavated and which is expected to be lined by the end of May, the date of the opening having been provisionally fixed by the Swiss Federal Railways for October, 1915.

Conventionalities

J. W. Fogg, formerly master mechanic of the Baltimore & Ohio Chicago Terminal, comes to the convention this year for the first time in the guise of a supplyman. He is selling Boss nuts to all the "bosses" now.

W. O. Moody, mechanical engineer of the Illinois Central, with Mrs. Moody and friend, Miss Josephine Whalen, arrived Monday for the week. This is Mrs. Moody's first visit to the conventions. Mr. Moody reports a total of 75 locomotives and 1000 cars ordered by his road so far in 1915. Evidently the I. C. officers are no pessimists.

E. R. Hibbard, president of the Grip Nut Company, Chicago, will not be able to attend the convention this year. He, however, will be represented by his son Howard Hibbard, who this year for the first assumes the duties of official representative of his father's company.

Those many friends of "Tom" Dunbar of the Acme Supply Co., will be sorry to learn that owing to a recent operation for appendicitis in San Francisco he will be unable to attend

F. T. Hyndman, Superintendent Motive Power and Cars, Wheeling & Lake Erie

the conventions this year. We are glad, however, to report that he is well on the road to recovery, though for a time his condition was serious, this being his third operation.

C. D. Jenks, general manager for Edwin S. Woods & Company of Chicago, will be unable to attend the convention this year. He has had a serious case of iritis and his physician advises him to remain at home. His condition is improving. H. M. Perry of the same company, who has attended these conventions for many years, is here.

W. H. Cook, our genial English friend who has so well represented the Fastnut, Ltd., of London, was prevented at the last moment from visiting the conventions this year. He had booked passage on the Philadelphia, but owing to the sinking of the Lusitania, the berths were all taken, and furthermore, there seemed great difficulty about getting back, as it appeared that he would not be able to return to England until late in July.

G. W. Wildin, mechanical superintendent of the New York, New Haven & Hartford, Mrs. Wildin and their niece, Miss Josephine Fish, were among the arrivals on Tuesday. Mr.

Wildin was unable to get to the conventions last year because of a press of work in the car department, but says he hopes to be left in peace this year till both meetings are over.

George W. Lyndon, president of the Association of Manufacturers of Chilled Iron Car Wheels, made the trip to the conventions by easy stages. He came from Chicago to Pittsburgh, where he spent one night, and then to Philadelphia, where he spent another night. Last year Mr. Lyndon was accompanied to the conventions by his three daughters, but he is alone this year.

W. H. Lewis, superintendent of motive power of the Norfolk & Western and D. A. Wightman, formerly superintendent of the Pittsburgh Locomotive Works, were engaged in a fanning contest in the entrance hall on Tuesday while discussing old times. Mr. Lewis has been a member of the Master Mechanics' Association since 1876 and Mr. Wightman since 1878.

Dick Sawyer, of the Commercial Acetylene Railway Light & Signal Company, whose alibi is "E. T.," is not expected at the convention this year. Dick has been attending these conventions nigh unto nineteen years and but for a forced absence of one year on account of sickness, the string would be con-

H. C. Manchester (D. L. & W.) on the Job in His Office at Scranton

secutive. As a matter of fact, Dick just naturally grew into a place at these meetings because long before he was personally interested, his father used to bring him. For the past few years he has been active on the enrollment committee. His many friends will miss him this year.

E. W. Pratt, assistant superintendent of motive power and machinery, Chicago & Northwestern, and past president of the Western Railway Club, arrived Tuesday with Mrs. Pratt. Mr. Pratt is receiving congratulations as an A-1 star actor, he being the chief perpetrator and responsible for the recent "scandalous" performance at the annual meeting of the Western Railway Club. He is also receiving condolences from those who have not yet "bit." For full particulars see W. E. Symonds, the "villain" of the evening; Joe Taylor, or the members of the "Boosters' Committee" of the club.

Those of us who have to get here during the late afternoon of the Sunday before the convention opens, always find on the hotel register the names of certain members of the "old guard." We refer especially to Mr. and Mrs. D. C. Noble, of Pittsburgh; Mr. and Mrs. Scott Blewett, of St. Louis, and Mr. and Mrs. J. D. Hurley, of Chicago. And they usually stay to speed the last parting guest. Perhaps this leisurely way of doing things explains why none of them has aged a particle during the last ten years. Mr. Noble, however, is not feeling as fit as usual. Some of the facial nerves are disposed to be contrary, with the result that Mr. Noble suffers considerable pain at times.

One of the convention visitors for many years past who will be missed this year is A. R. Foley, of the Home Rubber Company. Mr. Foley was among the American citizens who were drowned when the Lusitania was sunk. He sailed for England, expecting to be gone only a few weeks, and had made his plans to attend the conventions. Mr. Foley had long been identified with the Stokes interests in Trenton, N. J., where he lived. He was born in England, came to this country when quite young, and early became connected with the Stokes Iron Works. When the Stokes interests organized the Home Rubber Company, he became its sales agent, and long traveled all over the United States. For the last three years he had been looking after the company's foreign interests. He was a jovial, big-hearted man, who had numerous friends among those who attend the conventions.

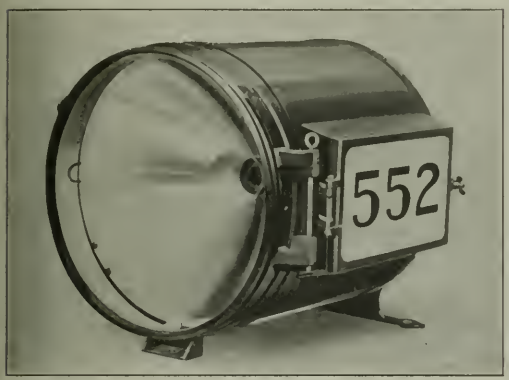
H. T. Bentley, superintendent motive power and machinery, Chicago & North Western, has lost his faith in Atlantic City. Having suffered with neuralgia due to Chicago's inclement month of May he came to the famous seaside resort extra early this year to get in fighting trim for the conventions. The god of storms, however, decided otherwise and Mr. Bentley has hardly seen the sun since his arrival. He and his daughter, Louise, were passengers on the ill-fated Lusitania on their return from England last summer, they arriving in New York July 31. Mr. Bentley reports that the North Western was one of the first to enter the pulverized fuel game. Orders have been placed with the Locomotive Pulverized Fuel Company for equipment for a 21 in. by 26 in. Atlantic type superheater engine. This engine will be equipped within a month and will operate on the Galena division out of Chicago. The purpose of the installation is to test out the possibilities of this fuel for eliminating smoke, noise and cinders, the city ordinances of Chicago being quite rigid in this respect.

For the first time in 25 years L. B. Sherman, vice-president of the *Railway Age Gazette,* is not among the visitors at the conventions this year. His absence is due to a very serious illness, from which he is slowly but steadily recovering. Mr. Sherman had already had several attacks of illness, from which he speedily recovered, when in the early part of last March, he was suddenly stricken at his home at Hubbard's Woods, a suburb of Chicago. He was hurried to St. Luke's Hospital and an operation performed. The surgeons found his condition so critical that all hope of his recovery was given up, but he pulled through the day following the operation and, although there were several days when his condition seemed to be almost hopeless, he showed a remarkable vitality, which carried him through. He was well enough last week to play a game of golf, the first since his illness. He is still somewhat weak, however, and will probably not be back at work until the late summer or early fall. Mr. Sherman is probably one of the best known men who attend the conventions. He was formerly secretary of the Railway Supply Manufacturers' Association, he has served on various committees of the association, he was a member of the Entertainment Committee for this year, and he was one of the prime movers in arranging for the first golf tournament in connection with the conventions, which was held last year. He has been one of the most efficient workers on *The Daily* ever since it has been under its present management, and he will be greatly missed this year by all his friends, and especially by his associates on *The Daily.* However, the regret caused by his absence is compensated for by realization of the fact that he soon will be well again.

INCANDESCENT HEADLIGHT EQUIPMENT

A recently-developed incandescent headlight equipment designed especially for use in switching service is being exhibited by the Pyle-National Electric Headlight Company, Chicago.

The new equipment is known as type "K," and the generating unit has a normal capacity of 300 watts; it weighs only 120 pounds, and occupies but little space, so that it can be mounted in any convenient place on the locomotive. The



Special 14-in. Incandescent Headlight Case

general outline is similar to the type "E" equipment, except that it is of smaller dimensions and has a number of new features.

The entire unit is self-contained, and shows a very high efficiency for a turbine of this size. The governor is well designed and controls the turbine speed within two percent, maintaining practically a constant voltage, which is absolutely necessary for incandescent illumination. The turbine operates on all steam pressures ranging from 60 lb. up and on

Method of Focusing the Lamp in the 14-in. Headlight Case

superheated as well as saturated steam without adjustment. The turbine is fed by a ⅜-in. pipe, and the exhaust outlet is fitted with a 1½-in. pipe. The rotar revolves in a partial vacuum, this tending to insure a high efficiency in the use of steam.

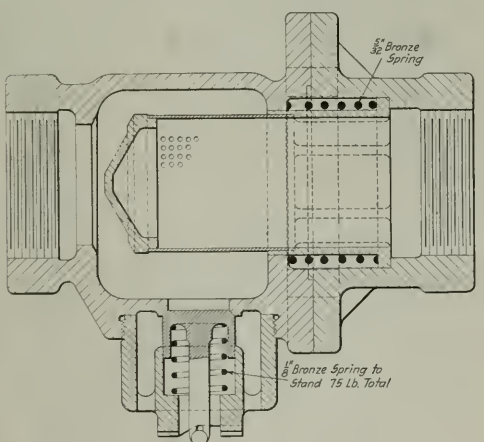
The generator is wound for 32 volts. With this voltage it is possible to obtain lamps of almost any desired candle power. This voltage has been recognized as standard, and has been proven to be the most desirable for locomotive illumination. The armature and commutator are mounted on the shaft, and are held in place by one screw. The brush holder attachment is fixed, and it is impossible for the brushes to get out of adjustment.

A special 14-in. headlight case has been designed in connection with this equipment, in which the lamp is supported horizontally from the back of the reflector. The goggle is hinged at both sides and may be readily removed. The reflector and slide are mounted on guides, and may be withdrawn from the front of the case, the electrical connections being made automatically by blade contacts when the reflector and slide are in place. The method of adjusting the lamp for focusing is clearly shown in one of the illustrations, the three adjustments being entirely independent of each other.

For switching service a 100-watt nitrogen lamp is supplied, with which it is said to be possible to distinguish objects clearly for a distance of 800 ft. For road service where a modified light is desired a 150-watt lamp of the same type is used. This is said to increase the range of distinct vision to 1200 ft.

COMBINED WATER STRAINER AND STRAINER CLEANER

The tank hose strainer shown herewith has recently been developed by the Barco Brass & Joint Company, Chicago, and is included in its exhibit on the pier. The strainer has the usual perforated cylinder through which the water passes from outside to inside. The strainer cylinder is secured at one end to a movable sleeve and at the other to a cone shaped valve which seats against the inner end of the water connection. Should the strainer become clogged it may be cleaned by merely turning steam pressure back through the injector suction pipe. This moves the strainer cylinder and



Tank Hose Strainer with Automatic Cleaning Device

sleeve towards the water connection, which it closes, thus preventing the flow of steam back through the hose. The pressure of the steam will blow the dirt from the strainer hose and will unseat the check at the bottom of the strainer body, allowing the dirt and water to be blown out to the ground. As soon as the steam pressure is turned off the springs will cause the return of the parts to their normal operating positions. In order to provide for the entrance of steam to the tank hose to prevent freezing in winter, the seat of the strainer may be scored or the end drilled to provide a small passage to the water compartment.

Railway Supply Manufacturers' Association Exhibit

Includes Names of Exhibitors, Brief Descriptions of the Exhibits, Names of Representatives, and Space Numbers

The exhibit this year is a little smaller than that of last year, but from the standpoint of the number of new devices and educational value probably averages higher. Its more important features are commented on in our editorial columns. Following is a list of the exhibitors, with data as to the devices exhibited, names of representatives, and location of exhibit:

Acme Supply Company, Chicago, Ill.—Acme simplex diaphragm; Acme reverse unifold diaphragm; Acme vestibule curtain outfit; Acme diaphragm opening attachments; Acme vestibule curtain revolving shield and sash locks; duplex weatherproof window; Regal revolving shade box; Kass safety step tread; Acme safety step box; Acme steel freight car ladder; Gosso beds for hospital bunk and caboose cars; Chanarch steel flooring; Acme steel passenger car doors; Faultless steel baggage car doors; Peerless steel baggage car doors; Acme anti-pinch hinge shield; Crown and Gem pinch handle curtain fixtures; Acme fool-proof curtain fixture; Acme friction roller curtain fixture; drawn steel mouldings. Represented by H. U. Morton, S. W. Midgley and R. C. Munro. Spaces 568-569.

Allegheny Steel Company, Pittsburgh, Pa.—Forsyth forged steel truck side frames; steel ties; continuous tie plates; rail braces; anti-creeping devices; spring plates; journal box lids; pressed steel specialties. Represented by W. D. Forsyth, Ralph McCarthy and L. C. Farquhar. Space 189.

Alston Saw and Steel Company, Folcroft, Pa.—Unbreakable hack saw blades in operation. Represented by Oscar W. Alston and William J. McArdle. Space 369.

American Abrasive Metals Company, New York, N. Y.—Feralun slip-proof treads for car steps, vestibule floors and door sills; Standard door sills for subway cars; new perforated slip-proof step tread for general use as passenger coach step; Feralun slip-proof floor plates; Feralun wheel truing brake shoes. Represented by William H. Sayre and Ellsworth Burger. Space 626.

American Arch Company, New York, N. Y.—Security sectional arch; Gaines combustion chamber. Represented by LeGrand Parish, John P. Neff, Harlow D. Savage, J. T. Anthony, George Wagstaff and R. J. Himmelright. Spaces 408-410.

American Balance Valve Company, Jersey Shore, Pa.—Valve motion models. Full size valves which have been in service and models of Jack Wilson high pressure slide and semi-plug piston valves, both adapted to old power as well as new. Represented by J. T. Wilson, Frank Trump and C. C. Young. Space 383.

American Brake Company, St. Louis, Mo.—Reception booth. Represented by R. E. Adreon and T. L. Burton. Spaces 19-29.

American Brake Shoe & Foundry Company, Mahwah, N. J.—Locomotive and car brake shoes illustrating modern practice. Represented by F. W. Sargent, W. S. McGowan and R. M. Brower. Space 416.

American Car and Foundry Company, New York, N. Y.—Cast iron wheels. Represented by William C. Dickerman, Scott H. Blewett, Clark D. Eaton, A. E. Ostrander, John McE. Ames and Benj. Wilson. Space 619.

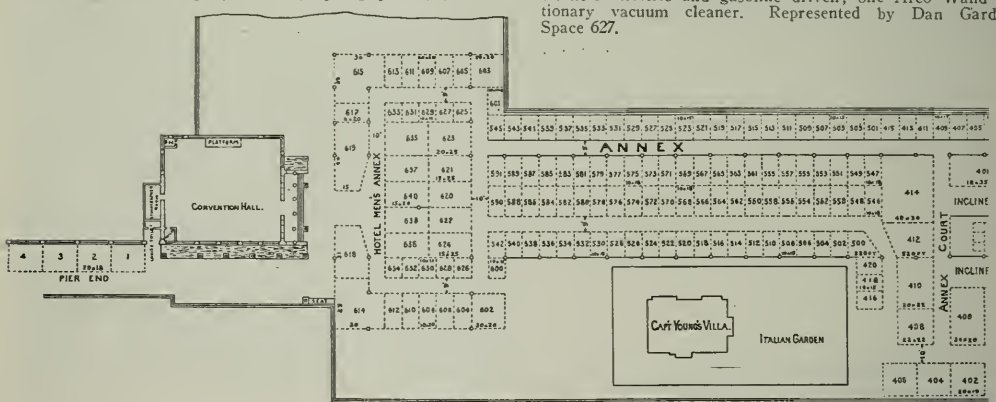
American Car & Ship Hardware Manufacturing Company, New Castle, Pa.—The Babcock safety water gage protector; bronze bushings. Represented by F. H. Babcock and P. J. Flaherty. Space 373.

American Flexible Bolt Company, Pittsburgh, Pa.—American staybolts; American staybolt bushings; U. S. self-locking bolt. Represented by C. A. Seley, R. W. Benson, H. T. Frauenheim, J. A. Frauenheim and L. W. Widmeier. Space 174.

American Malleable Castings Association, Cleveland, Ohio.—Walker wedge testing machine; photo-micrographs of malleable iron in its various stages of manufacture and sample castings and specimens of malleable iron. Represented by John C. Nulsen. Spaces 113-115.

American Mason Safety Tread Company, Lowell, Mass.—Mason safety treads, lead and carborundum filled, steel and brass base; Mason structural steel treads; Empire safety treads; Stanwood non-slipping, self-cleaning car steps and treads; Karbolith composition car flooring for steel cars; Mason non-slip safety ladder shoes; Mason non-slip "Dentil" nosing. Represented by Henry C. King and Ralph C. Davison. Space 542.

American Radiator Company, Chicago, Ill.—Arco Wand vacuum cleaners—electric and gasoline driven; one Arco Wand stationary vacuum cleaner. Represented by Dan Gardner. Space 627.



Arrangement of the Exhibit Spaces at the Ocean End of the Pier

American Saw Mill Machinery Company, Hackettstown, N. J.—Portable saw mill machinery; variety woodworker; saw tables for railroad shop use; circular saws. Represented by H. H. Hirschfeld and M. C. Hall. Spaces 162-164.

American Steel Foundries, Chicago, Ill.—The Vulcan truck; Andrews side frames; cast steel bolsters; Simplex bolsters; Simplex couples; American coupler pocket, Economy draft arms; Davis cast steel wheels; brake beams; springs; Susemihl roller side bearings; miscellaneous steel castings. Represented by R. P. Lamont, G. E. Scott, W. J. Lynch, J. V. Bell, G. F. Slaughter, W. Ross Gravener, D. T. Harris, T. H. Hopkirk, R. E. Janney and L. E. Jones. Space 193.

Anchor Packing Company, The, Philadelphia, Pa.—Packing for air pumps; throttles and general railroad purposes. Represented by W. R. Haggart, L. E. Adams, D. J. P. Murray, E. C. Adams and B. J. Miller. Space 371.

Armstrong Cork & Insulation Company, Pittsburgh, Pa.—Nonpareil corkboard insulation for cars and cold storage rooms; Nonpareil insulating brick; Nonpareil high pressure covering; cork covering for drinking water lines, brine and ammonia lines and cold pipes; Linotile for floors. Represented by C. H. Young and S. L. Barnes. Space 170.

Ashton Valve Company, The, Boston, Mass.—Master mechanic standard locomotive muffler and open pop safety valves; locomotive steam and air gages; wheel press recording gages; whistles; dead weight gage testers; piston Schwabs; locomotive boiler appliances. Represented by A. C. Ashton, J. F. Gettrust, H. O. Fettinger and J. W. Motherwell. Space 518.

Automatic Ventilator Company, New York, N. Y.—The Automatic car ventilator, as applied to monitor-deck and arched-roof steam and electric cars, shown by means of full sized and miniature demonstrating models. Represented by George H. Ford, Wm. J. Fleming, Jr., George H. Bryant and Frank A. Barbey. Space 313.

Baker & Company, Inc., H., New York, N. Y.—High speed and tool steel; metal specialties. Represented by A. W. Stephenson, A. S. Reeder and F. R. Decker. Space 364.

Barco Brass & Joint Company, Chicago, Ill.—Barco flexible joints; engine tender steam air and oil connections; metallic steam heat connections for cars; terminal car heating and air sets; water strainer; gage bracket; smoke box blower fitting; drip valves. Represented by F. N. Bard, C. L. Mellor and L. W. Millar. Space 609.

Beggs Signal Company, Julian, Terre Haute, Ind.—Automatic speed control. Represented by Stephen Smith. Space 183.

Besly, Charles H. & Company, Chicago, Ill.—One No. 15-30 inch C. Besly direct connected motor driven pattern makers' disc grinder. One No. 51-26 inch G Besly motor driven disc grinder with 18 inch helmet pressed steel ring wheel chuck. Represented by Edward P. Welles, Charles A. Knill and William H. Allen. Space 148-150.

Bettendorf Company, The, Bettendorf, Iowa.—Bettendorf all steel box car; 42 foot 40-ton steel box car underframe; section of improved refrigerator car underframe; single center sill for 40 foot 50-ton car; semi equalized 70-ton freight car truck; Bettendorf standard 40-ton freight truck. Represented by J. H. Bendixen, A. F. Macpherson, F. K. Shults, P. P. Beck, E. E. Silk, C. J. W. Clasen, W. G. Ransom and A. K. Reading. Space 200.

Bird-Archer Company, The, New York, N. Y.—Samples of polarized metallic boiler chemicals; anti-foaming chemicals; anti-leak chemicals. Tubes drawn from engines having used the Polarized treatment. P. B. Bird, C. A. Bird, J. A. McFarland, L. F. Wilson, H. V. Bootes, John Barnes and C. J. McGurn. Space 37.

Blackall, R. H., Pittsburgh, Pa.—Blackall drop handle ratchet; flat car type ratchet; improved Lindstrom brake lever; old style Lindstrom ratchet with back-off cap; pull-up ratchet arrangement with beveled gears and vertical shaft; tunnel brake ratchet arrangement using chain instead of shaft and separate winding drum for chain; Blackall trap door for vestibules. Robert H. Blackall and E. Emery. Space 588.

Buckeye Steel Castings Company, The, Columbus, Ohio.—Two 50-ton cast steel Buckeye type truck bolsters; one 50-ton cast steel pedestal type side frame; one 50-ton cast steel Buckeye Andrews type side frame; one Buckeye cast steel yoke for friction gear; one Buckeye cast steel yoke for tandem gear; cast steel journal boxes; Major coupler. Represented by S. P. Bush, C. B. Goodspeed, G. A. Macpherson, J. C. Whitridge, J. G. Bower, F. H. Bonnet, E. W. Campion, Geo. Groobey, G. T. Johnson and A. H. Thomas. Spaces 603-605.

Buffalo Brake Beam Company, New York, N. Y.—Buffalo freight brake beams for all classes and capacities of equipment. Truss beams with either malleable iron or forged steel struts to M. C. B. standards; also beams for E. & L. equipment and all classes and capacities of tenders and electrical equipment for standard broad and narrow gage. Buffalo passenger brake beams for all classes of service, including P. C. and L. N. equipment with automatically adjustable heads and safety locks. S. A. Crone, E. Strassburger, R. C. Fraser and O. W. Meissner. Spaces 550-551.

Burr Company, The, Champaign, Ill.—Dynamometer car Southern No. 2 track exhibit. Represented by E. M. Burr and L. R. Gulley. Space 632 and on track at Mississippi Avenue and Boardwalk.

Burroughs Adding Machine Company, Detroit, Mich.—Burroughs Master Car Builders machine. Represented by F. A. Willard. Space 534.

Byers & Company, A. M., Pittsburgh, Pa.—Wrought iron pipe. Represented by W. W. Williams, T. L. Lewis, R. A. Bruce and R. W. Kenney. Space 625.

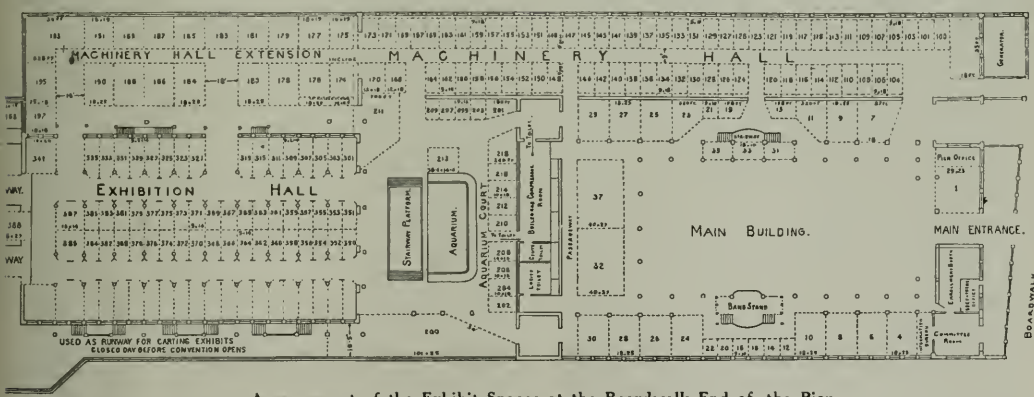
C. & C. Electric & Manufacturing Company, Garwood, N. J.—One 400 ampere C. & C. electric arc welding outfit complete with main control panel and three separate single welding panels, equipped with their patented system of automatic control throughout. This is an operating exhibit. Represented by Geo. W. Cravens, C. H. Florandin, John E. Chamberlin and Francis Caldwell. Space 2 pier end.

Cabot, Inc., Samuel, Boston, Mass.—Car insulation; fireproof car quilt; wood preservative; shingle stains; protective paints. Represented by John C. Donnelly. Space 381.

Cambria Steel Company, Philadelphia, Pa.—Slick draft gear. Represented by C. B. McElhany, W. S. Ottinger, H. G. Uphouse, L. B. Morris and R. V. Sage. Spaces 514-516.

Camel Company, Chicago, Ill.—Reception booth. Represented by J. F. Comee A. B. Wegecier J. M. Hopkins and P. M. Elliott. Space 536-538.

Carnegie Steel Company, Pittsburgh, Pa.—Schoen steel wheels, for steam railway service; Slick wheel products consisting of gear blanks, gear ring, gear rim blanks, turbine disc blanks, industrial wheels, street car wheels, rolled steel pipe flanges, submarine signal disc blanks, bevel roller blanks, automobile fly wheel blanks shaft couplings crane track wheels, and rolled steel locomotive pistons, together with exhibit of ingots and discs from which wheels are made. Standard steam railway ties, joints and fastenings. Alloy steels. Steel sheet piling. Represented by Wm. G. Clyde, I. W. Jenks, R. B. Woodworth, W. W. Scott, Jr., N. B. Trist, T. W. Williams, A. R. Willard, C. B. Friday and D. E. Sawyer. Space 414.



Arrangement of the Exhibit Spaces at the Boardwalk End of the Pier

Chambers Valve Company, New York, N. Y.—Chambers throttle valve. Represented by Frank H. Clark and J. M. Coffey. Space 418.

Chase & Company, L. C., Boston, Mass.—Chase mohair car plushes; Chase artificial leather for car seats. Represented by W. P. Underhill and H. T. Wight. Space 10.

Chicago Car Heating Company, Chicago, Ill.—Multiple regulation vapor system of car heating; Positive lock steam train line couplers; steam and hot water car heating specialties; emergency stoves. Represented by Egbert H. Gold, J. E. Buker, B. A. Keeler, R. P. Cooley, Eugene E. Smith, Elmer W. Rietz, Geo. T. Cooke, Harry F. Lowman, Frank F. Coggin, Edward A. Schreiber and A. D. Bruce. Spaces 212-214-216-218.

Chicago-Cleveland Car Roofing Company, Chicago, Ill.—Car roofs; steel carlines; composite box car ends: all steel ends. Represented by R. C. Dudley, T. N. Russell, J. L. Stark and A. S. Lewis. Space 506.

Chicago Varnish Company, Chicago, Ill.—Panels exemplifying their Ce-Ve process of painting railway coaches and engines. Represented by George S. Bgelow, Harry S. Whitehair and S. M. Dolan. Space 535.

Coe Manufacturing Company, W. H., Providence, R. I.—Coe's ribbon leaf and gilding wheels. Represented by E. J. Arlein and S. H. Swallow. Space 633.

Commonwealth Steel Company, St. Louis, Mo.—Catalogs, folders, drawings and a few models, all pertaining to the Commonwealth specialties. Represented by Clarence H. Howard, Harry M. Pflager, Geo. E. Howard, Boone V. H. Johnson, C. S. Shallenberger and W. P. Stout. Spaces 386-387.

Consolidated Car-Heating Company, Albany, N. Y.—Thermo-Vapor pressure system of heating; two-piece straight port steam couplers; steam traps; train line end valves; admission valves. Represented by C. C. Nuckols, Thomas Farmer, Jr., W. S. Hammond, Jr., Butler Keys and A. T. Harding. Space 179.

Consolidated Railway Electric Lighting & Equipment Company, New York, N. Y.—Type L-3 regulator with ampere hour meter control of the battery charging current and Type D-5 ball-bearing generator for car lighting. Represented by Thos. L. Mount, J. L. Watson and W. R. Hungerford. Space 588.

Crane Company, Chicago, Ill.—Crane locomotive pop safety valves; locomotive blow-off valves; locomotive cab valves; Crane railroad fittings, full line of globe, angle check and gate valves for railroad service, Crane-Erwood automatic stop and check valves; steam separators; steel valves for high pressure and superheated steam; automatic exhaust and relief valves; steam traps. Represented by F. D. Fenn and F. W. Venton. Spaces 552-554.

Crosby Steam Gage and Valve Company, Boston, Mass.—Locomotive safety valves; locomotive pressure gage; Johnston blow-off valve; recording gage for hydraulic presses; gage testing apparatus; indicators and their attachments. Represented by Edward C. Kenyon and H. B. Forbes. Space 630.

Curtain Supply Company, The, Chicago, Ill.—Car window and vestibule curtains; diaphragms and sash balances; ring fixtures; Rex rollers; Rex vestibule outfit and steel diaphragms. Represented by R. F. Hayes, G. E. Fox, W. H. Bentley and F. M. Egolf. Space 638.

Damascus Brake Beam Company, The, Cleveland, Ohio.—Forged steel fulcrums; adjustable brake heads; Brascott freight car ladder; Damascus water glass protectors. Represented by John F. Schurch and Albert Waycott. Space 555.

Dearborn Chemical Company, Chicago, Ill.—Water treating preparations scientifically prepared to suit conditions shown by analyses of the boiler water supplies, for prevention of scale, corrosion, pitting and foaming. Represented by Robert F. Carr, George R. Carr, J. D. Purcell, Grant W. Spear, Wm. H. Kinney, J. H. Cooper and A. W. Crouch. Spaces 6-8.

Delaware Railway Specialty Company, Wilmington, Del.—Parson's system of combustion. Represented by William H. Savery. Space 370.

Detroit Lubricator Company, Detroit, Mich.—Bullseye locomotive lubricators; flange lubricators; air cylinder lubricators; sight feed lubricators; force feed oilers; Detroit packless radiator valves. Represented by H. I. Lord, A. D. Homard and A. C. McChesney. Space 637.

Dixon, Joseph, Crucible Company, Jersey City, N. J.—Specimens of scale removed from locomotive boilers obtained through the use of Dixon's boiler graphite; photographs of various types of structures protected by Dixon's Silica-graphite paint; samples of Dixon's graphite lubricants especially adapted for railroad work; instruction cards. Represented by H. A. Chase, J. A. Tucker, H. A. Neally, W. H. Houston and L. H. Snyder. Space 24.

Draper Manufacturing Company, The, Port Huron, Mich.—Pneumatic locomotive turn-table motors; pneumatic flue welders; pneumatic superheater tube welders; tools for repairing superheater units; valve facing tools; ball check valves; hollow brass balls. Represented by Thos. Draper and Thos. Robinson. Space 528.

Duff Manufacturing Company, The, Pittsburgh, Pa.—Genuine Barrett track jacks; Duff high speed ball bearing screw jacks; Barrett car jacks; Duff improved geared ratchet jacks; Duff-Bethlehem forged steel hydraulic jacks; Duff journal box jacks. Represented by T. A. McGinley, E. A. Johnson, C. A. Methfessel, C. N. Thulin and G. E. Watts. Space 401.

DuPont Fabrikoid Company, Wilmington, Del.—Fabrikoid car window curtain material; Fabrikoid vestibule curtain material; Fabrikoid car seat upholstery material. Represented by C. Hallock Silkman, J. W. Stark and J. K. Rodgers. Spaces 548-549.

Durbin Automatic Train Pipe Connector Company, St. Louis, Mo.—Automatic train pipe connector; automatic safety car coupler; these will be operated by compressed air to show operation. Represented by V. S. Durbin and C. W. Durbin. Space 168.

Eagle Glass and Manufacturing Company, Wellsburg, W. Va.—Oilers, torches, supply cans, tallow pots, etc. Represented by J. L. Fusner and S. O. Paull. Space 600.

Economy Devices Corporation, New York, N. Y.—Ragonnet power reverse gear; Casey-Cavin power reverse gear; Universal valve chest; "Economy" exhaust nozzle; models of radial buffer; "Economy" engine truck; Woodard centering arrangement; bulletins, blueprints and drawings of Economy engine truck; four wheel Economy tender truck; multiple pipe clamps; Cole extended main driving box. Represented by H. F. Ball, J. L. Randolph and Hal R. Stafford. Spaces 408-410.

Edison Storage Battery Company, Orange, N. J.—Edison storage batteries for train lighting; industrial shop and baggage trucks; multiple unit control; locomotive headlights; railway signaling; inspection lamps. Represented by H. G. Thompson, F. V. McGinness, W. F. Bauer, C. A. Luckey and O. R. Hildebrant. Space 636.

Edwards Company, Inc., The O. M., Syracuse, N. Y.—Window fixtures; extension platform trap doors; sliding trap doors for high station platforms; all metal sash balances and shade rollers; weather stripping, and railroad padlocks. Represented by O. M. Edwards, E. W. Edwards, W. A. LeBrun, E. F. Chaffee, C. H. Rockwell, W. C. Bradbury and T. P. O'Brian. Spaces 527-529-531.

Elastic Car Waste Company, Philadelphia, Pa.—Packing for car journals. Represented by A. B. Birch, Jas. Gibson and A. Ahrens, 3d. Space 363.

Electric Controller & Manufacturing Company, The, Cleveland, Ohio.—Youngstown safety limit stop; crane switchboard with overload release; automatic machine tool controllers; push button controllers for wood working machinery; drum type controllers; cast grid resistance, literature of lifting magnets handling scrap iron, rails, etc. Represented by R. G. Widdows, E. C. Ryan and W. C. Jackson. Space 135.

Electric Storage Battery Company, The, Philadelphia, Pa.—E. S. B. constant voltage axle lighting system in operation; Hyray-Exide low voltage isolated plant for country home electric lighting, in operation; Chloride Accumulator and Ironclad-Exide cells for car lighting; Exide, Hycap-Exide; Thin-Exide and Ironclad-Exide cells for vehicle propulsion; Exide automobile starting and lighting batteries. Represented by J. Lester Woodbridge, J. MacBurney, F. G. Beetem and H. E. Hunt. Space 624.

Enterprise Railway Equipment Company, The, Chicago, Ill.—Car models showing all types of dump cars and door mechanism for same, including hoppers, gondolas, general service, divertible ballast and coal, convertible ballast or coal, plow gondola or ballast; also one convertible general service or ballast car on exhibit track at Mississippi Avenue. Represented by Argyle Campbell and A. E. Zimmer. Spaces 584-585.

Equipment Improvement Company, New York, N. Y.—Markel solid main rod end, lateral motion plate, shoes and wedges, removable driving box; Trojan packing; Wine roller side bearing. Represented by Frank H. Clark, C. W. Cross and E. C. Sawyer. Space 418.

Esterline Company, The, Indianapolis, Ind.—Golden Glow locomotive headlights; mine locomotive headlights; electric railway headlights; marine, dock and industrial searchlights; Esterline graphic meters. Represented by W. McKay White. Space 382.

Ewald Iron Company, Louisville, Ky.—Reception booth. Represented by R. B. Hickman, S. F. Sullivan, R. F. Kilpatrick, E. V. Shackleford and H. E. Pierce. Spaces 537-539.

Fastnut, Ltd., New York, N. Y.—Fastnut devises—washer, key and wrench. Represented by A. L. Story and J. D. McGrath. Space in passageway between ballroom and court.

Flannery Bolt Company, Pittsburgh, Pa.—Tate flexible staybolts, including standard water space stays, flush type, adjustable crown stays, section of boiler showing typical installations, tools for installation of Tate bolts, photographic views of various installations and display at the Panama Pacific Exposition. F. B. C. nut locks for freight and passenger cars. Represented by J. Rogers Flannery, B. E. D. Stafford, Charles Hyland, Geo. E. Howard, W. M. Wilson, Thos. J. Leahey, Barton H. Grundy and Jas. J. Flannery. Spaces 590-591.

Fort Pitt Malleable Iron Company, Pittsburgh, Pa.—Reception booth. Represented by Frank J. Lanahan, J. S. Lanahan and A. M. Fulton. Space 619.

Franklin Railway Supply Company, New York, N. Y.—Franklin fire door; Franklin water joint. Represented by J. S. Coffin, Sr., S. G. Allen, W. H. Coyle, R. G. Coburn, C. W. F. Coffin, J. S. Coffin, Jr. and H. M. Evans. Spaces 408-410.

Frost Railway Supply Company, The, Detroit, Mich.—Harvey friction spring gears; Detroit metal weather strip. Represented by Harry W. Frost, George A. Cooper and George L. Harvey. Space 560.

Galena-Signal Oil Company, Franklin, Pa.—Reception booth. Represented by S. A. Megeath, C. C. Steinbrenner, E. H. Baker, Barton H. Grundy, William Holmes, George L. Morton, William A. Trubee, William J. Walsh, J. E. Linahen, J. G. Arn, W. E. Brumble, J. W. Bunn, B. P. Corey, E. W. Grieves, E. G. Johnson, G. E. McVicar, P. H. Stack, W. O. Taylor, J. F. Walsh and J. A. Whalen. Space 32.

Garlock Packing Company, The, Palmyra, N. Y.—Air pump and

throttle packings; air brake and triple valve gaskets; special packings for accumulators and compressors; general line of shop packings. Represented by H. N. Winner, J. P. Landreth, W. G. Cook, Geo. T. Ramsey, T. P. Dunham, L. P. Duggan and F. W. Moore. Space 508.

General Brake Shoe & Supply Company, Chicago, Ill.—Brake shoes for use on all steam railway service. Represented by H. H. Hiland, C. E. Stecher, J. V. Valleau, B. J. Meyer, Ira C. Hubbell, John J. Stevens, Jr. and Wm. B. Neal. Space 4.

General Electric Company, Schenectady, N. Y.—Electric arc welding equipment; electric furnace; electric oil tempering bath; several types of motors; control; flow meters; incandescent lamps. Represented by W. J. Clark, P. A. Dyer, F. S. Hartman, W. O. Kellogg, C. A. Raymond, C. C. Peirce, B. F. Bilsland, J. A. Seede, C. Fair, J. Eaton, R. E. Woolley and L. W. Shugg. Spaces 157-173.

Gold Car Heating & Lighting Company, New York, N. Y.—M. C. B. standard steam hose couplers; vapor system; combination pressure and vapor system; automatic temperature control for steam heated trains; automatic temperature control for electrically heated trains; packless quick opening supply valve; steam traps; pressure regulators; ventilators. Edward E. Gold, E. B. Wilson, A. B. Strange, W. H. Stocks, J. M. Stayman, J. O. Brumbaugh, E. J. Ronan, A. E. Robbins, F. H. Smith and F. T. Kitchen. Spaces 301-303-305.

Goldschmidt Thermit Company, New York, N. Y.—All materials for welding locomotive frames and other broken locomotive parts; large sample welds on crank shafts; photographs of important welding operations; demonstrations of the process as applied to pipe welding and samples of metals and alloys produced free from carbon by the Thermit process. Represented by W. C. Cuntz, W. R. Hulbert, J. G. McCarty, William Aldrich, F. W. Cohen, H. S. Mann and H. D. Kelley. Spaces 137-139.

Goodwin Car Company, New York, N. Y.—Full size and working model of automatic dump and ballast car. Represented by Joseph Thayer Gilman, O. B. Gilman and Howard Van Scoy. Space 207—also track exhibit.

Goodyear Tire & Rubber Company, Akron, Ohio.—Samples of the Subers hose. Represented by L. H. Conger. Space 9.

Gould Coupler Company, New York, N. Y.—Gould cast steel jaw type side frame; high capacity freight friction draft gear 2½ in. travel, 250,000 capacity; fraction draft gear 3¼ in. travel, 300,000 capacity; fraction buffer for heavy steel passenger equipment; friction draft gear for passenger equipment, 2½ in. travel, 125,000 to 150,000 capacity; intermediate type of freight coupler; new type passenger coupler with all cast steel shank; pinless lid journal box; simplex system electric car lighting; storage batteries. Represented by F. P. Huntley, Geo. G. Milne, Clarence E. Rood and Geo. R. Berger. Spaces 608-610-612.

Greene, Tweed & Company, New York, N. Y.—Palmetto braided packing for piston rods; twist packing for globe valves, etc.; packing in sets for air pump service; packing in sets for throttle valve service; Manhattan packing for hydraulic pressures; Favorite reversible ratchet wrench for nut turning. Represented by H. S. Demarest, V. B. Nickerson and F. M. Thomson. Space 628.

Greenfield Tap and Die Corporation, Greenfield, Mass.—Motor driven bolt cutter; Acorn screw-cutting dies; reversing tapping chucks; automatic opening die head; reamers of all descriptions; new style or gun tap; friction tapping chucks; gages; hand taps and stay bolt taps. Represented by F. W. Strecker, F. C. Hoffman and W. A. Cook. Space 147.

Griffin Wheel Company, Chicago, Ill.—Car wheels on standards. Represented by C. K. Knickerbocker, H. N. Scott and A. A. Hale. Spaces 153-155.

Hale & Kilburn Company, Philadelphia, Pa.—Walkover car seats, latest styles; all-steel standard passenger coach seats; parlor and reclining car chairs; interurban car seats; metal doors for coaches and baggage cars; Steel integral window frame; Steel interior finish for coaches, parlor, dining and sleeping cars; Pressed steel mouldings, posts and parts for car construction. Represented by F. C. Edson, B. H. Forsyth, C. W. Laskay, A. F. Old, R. H. Pilson, F. F. Robb, H. R. Rochester and W. von Schlegell. Spaces 404-406.

Hammett, H. G., Troy, N. Y.—Trojan metallic packing; Trojan bell ringers; machine for expanding and beading copper pipe to coupling sleeves. Represented by H. G. Hammett and A. O. Van Dervort. Space 420.

Haring, Ellsworth, New York, N. Y.—E-H double X high speed steel, tool steels and specialties. Represented by Ellsworth Haring. Space 158.

Harrington, Son & Company, inc., Edwin, Philadelphia, Pa.—Chain hoists and travelers for overhead track. Represented by W. J. Somerset and Roger Sherron. Spaces 149-151.

Heywood Brothers & Wakefield Company, Wakefield, Mass.—Car seats for steel coaches. Represented by E. C. Lang, C. W. H. Frederick, Bertram Berry and Frank N. Grigg. Space 575.

Hunt Spiller Manufacturing Corporation, South Boston, Mass.—Cylinder bushings; cylinder packing; piston heads; valve bushings; valve packing; valve bull rings; eccentrics and straps; crosshead shoes; driving boxes; pedestal shoes and wedges; rod bushings. Represented by W. B. Leach, Frederic Parker, John G. Platt, A. B. Root, Jr., V. W. Ellet, J. M. Monroe, E. J. Fuller and H. McB. Parker. Spaces 562-563.

Hutchins Car Roofing Company, Detroit, Mich.—Half-tone cuts of all steel car roofs. Represented by F. M. Whyte, M. F. Ryan, D. W. Hawksworth and W. D. Thompson. Space 523.

Hulson Grate Company. Space 365.

Illinois Steel Company, Chicago, Ill.—Samples of heat treated track and crossing bolts with physical tests. Represented by D. E. Sawyer Space 414.

Imperial Car Cleaver Company, Newark, N. J.—Cleaners for cane seats and plush cushions. Represented by J. MacMarell Wilson, Frank Sherritt, J. Whitney Wilson and J. T. Hartnagel. Space 213.

Independent Pneumatic Tool Company, Chicago, Ill.—Reception booth. Represented by James Buchanan Brady, John D. Hurley, R. T. Scott, R. S. Cooper, H. F. Finney, Vernon Job and W. H. Rosevear. Space 574.

Ingersoll-Rand Company, New York, N. Y.—Little David pneumatic chipping and riveting hammers; jam riveters; holderons; pneumatic drills; Crown sand rammers and Imperial motor hoists. Represented by George A. Gallinger, E. H. Hinkens, M. O'Connor, Phil. Weiss, George S. Johnston, P. J. Christy, R. C. Cole, A. L. Wilhelm, C. R. Hewitt, W. A. Johnson, C. F. Overly and Wm. Wilhelm. Spaces 582-583.

International Oxygen Company, New York, N. Y.—I. O. C. system of oxy-hydrogen generators and accessories; I. O. C. stud valves; oxygen testing apparatus; high pressure oxygen cylinders. Represented by E. W. Erwin, P. J. Kroll and D. J. Tonkonogy. Space 341.

International Steam Pump Company, New York, N. Y.—One 12x7x10 Laidlaw Feather Valve air compressor, direct connected by close belt drive to 50 H. P. General Electric Motor; model of Glenora triple plunger deep well pump; Jeanesville horizontally split case turbine centrifugal pump. Represented by Paul B. Fenlon, C. Troutman, Thomas C. McBride and LeRoy Hilyard. Space front of Machinery Hall.

Jacobs-Shupert U. S. Firebox Company, Coatesville, Pa.—Models; photos; illustrations and circulars. Represented by C. Ducas, A. W. Whiteford, H. W. Jacobs, L. M. Henoch, Geo. R. Boyce, J. H. Smythe, G. T. Schnatz, F. H. Gordon, H. S. Coleman. Space 621.

Jenkins Bros., New York, N. Y.—Jenkins Bros. valves in brass, iron body and cast steel, for all pressures and purposes; round house valves; equalizing stop and check valves; mechanical rubber goods; sheet packing; gaskets; valve discs and rings; new oil-proof sheet packing, car heating discs. Represented by Frank Martin and B. J. Neely. Space 553.

Jessop, William & Sons, Inc., New York, N. Y.—Jessops steel tools. Represented by J. E. Sandmeyer, E. M. Britton and O. H. Reynolds. Space 504.

Johns-Manville Co., H. W., New York, N. Y.—Magnesia lagging; fire felt lagging; vitribestos; pipe coverings; air pump and throttle packing; sheet packing; gaskets; millboard; Transite and Ebony asbestos wood; asbestos shingles; friction and rubber tapes; electrical materials; fibre and sectional conduit; dry batteries; asbestos roofings; asbestos corrugated roofing; waterproofing and mastic; J-M expander rings; hair felt insulators; passenger and refrigerator car insulations; Vulcabeston; high temperature and insulating cements; smoke jacks; cork; armored hose; brake band lining; asbestos-metallic brake blocks. Represented by J. E. Meek, J. C. Younglove, G. A. Nicol, H. G. Newman, P. C. Jacobs, Geo. Christenson and F. J. Horne. Spaces 572-573.

Jones & Laughlin Steel Company, Pittsburgh, Pa.—Reception booth. Represented by Roland Gerry, Frank S. Slocum, George B. Mitchell and J. K. Barker. Space 409.

Kernchen Company, Chicago, Ill.—Kernchen siphonage ventilators. Represented by M. W. Hughes and P. R. Simmonds. Space 368.

Kerite Insulated Wire & Cable Company, The, New York, N. Y.—Kerite insulated wires and cables. Represented by R. D. Brixey, Azel Ames, P. W. Miller, J. W. Young and J. A. Renton. Space 510-512.

Keyoke Railway Equipment Company, Chicago, Ill.—Murray all cast steel friction draft gear and cast steel coupler yoke. Represented by George C. Murray and R. J. Cook. Space 321.

Keystone Equipment Company, Philadelphia, Pa.—Keystone driving box and assortment of Keystone tool holders. Represented by A. C. Buzby, H. A. Buzby and J. N. Mowery. Space 543.

Landis Machine Company, Waynesboro, Pa.—One 4 in. pipe threading and cutting off machine; chaser grinder; one 2 in. single spindle bolt cutter, belt driven; one 1½ in. double spindle bolt cutter, motor driven; one 2 in. stationary type pipe die

head; one 8 in. stationary type pipe die head; one 1¼ in. automatic screw cutting die head; one 1 in. solid adjustable die head. Represented by C. F. Meyer, F. C. Delcher, Dorsey Thompson, F. W. Heefner and J. W. Willis. Spaces 117-119.

Lehon Company, The, Chicago, Ill.—Roofing for railroad buildings; plastic car roofing; insulating paper; waterproof canvas for passenger coach, cab and caboose roofs; saturated burlap for waterproofing concrete construction work; paint for waterproofing, roofing and metal work. Represented by Tom Lehon. Space 18.

Liberty Manufacturing Company, Pittsburgh, Pa.—Turbine cleaners for arch tubes operated by steam, air and water. Represented by H. A. Pastre. Space 416.

Locomotive Stoker Company, Schenectady, N. Y.—One type "C" Street locomotive stoker. Represented by W. S. Bartholomew, Clement F. Street, W. G. Clark, J. J. Hannahan, O. B. Capps and J. J. Byrne. Spaces 403-405-407.

Loco-Light Company, Indianapolis, Ind.—One 32 volt incandescent headlight equipment. Represented by Robert H. Pyle. Space 614.

Locomotive Superheater Company, New York, N. Y.—Locomotive superheaters and accessories. Represented by Geo. L. Bourne, R. M. Ostermann, F. A. Schaff, G. E. Ryder, H. B. Oatley and W. A. Buckbee. Spaces 408-410.

Long, Charles R. Jr. Company, Louisville, Ky.—Railway paints of all kinds for locomotive and car departments. Represented by Charles R. Long, Jr., Harry Vissering, G. S. Turner, S. W. Russell and W. H. Heckman. Spaces 577-576.

Lubricating Metal Company, The, New York, N. Y.—Noheet bearing metal; Noheet metallic packing. Represented by C. B. Yardley, Jr., and Thatcher H. Soule. Space 367.

Lucas Machine Tool Company, Cleveland, Ohio.—Number 32 "Precision" horizontal boring, drilling and milling machine. Represented by W. L. Cheney, J. A. Leighton, Jr. and F. P. Sprague. Space 121.

Lukens Iron & Steel Company, Coatesville, Pa.—Reception booth with photographs of mill operation. Represented by Chas. Ducas, A. W. Whiteford, Henry W. Jacobs, L. M. Henoch, Geo. R. Boyce, J. H. Smythe, G. T. Schnatz and F. H. Gordon. Space 621.

Lundie, John, New York, N. Y.—The Lundie tie plate. Represented by John Lundie. Space 158.

Lunkenheimer Company, The, Ohio.—High grade steam engineering and motor accessory appliances; valves, bronze, iron body brass mounted, puddled semi-steel and crucible cast steel; whistles, water gages and gage cocks; ground key specialties; oil and grease cups; lubricators and oiling devices. Represented by Howard J. Evans and Andrew Lauterbach. Spaces 517-519.

M. C. B. Committee on couplers. Space, pier end.

MacRae's Blue Book Company, Chicago, Ill.—MacRae's blue book; the railway supply index catalogue. Represented by Albert MacRae, Alex. Smith and R. S. Lundy. Space 13.

Mahr Manufacturing Company, Minneapolis, Minn.—Mahr patent portable torches for car repair; boiler shop, foundry, brazing, paint burning and oil burning rivet forge work. Represented by J. A. Mahr, H. A. Warner and R. B. Ecker. Space 3, pier end.

Manning, Maxwell & Moore, Inc., New York, N. Y.—And subsidiary companies, comprising the Putnam Machine Company, Ashcroft Manufacturing Company, Consolidated Safety Valve Company, Hancock Inspirator Company and Hayden & Derby Manufacturing Company—Putnam latest car wheel boring mill; latest pattern 36 in. geared head lathe; No. 4 new pattern double axle lathe; journal turning lathe; National Machinery Company's latest type machines for forging and bolt cutting; a complete exhibit of brass goods consisting of Hancock inspirators, check valves, steam valves, hose strainers, boiler washers and other locomotive appliances; Metropolitan injectors; Consolidated safety valves; Ashcroft gages; Tabor indicators and instruments for measuring steam, water and gas. Represented by A. J. Babcock, James B. Brady, J. N. Derby, P. M. Brotherhood, F. P. Smith, Chas. L. Brown, Jos. H. Bush, R. A. Bole, F. J. Baumis, H. F. Brandes and E. R. Frost. Spaces 104 to 130.

Massachusetts Mohair Plush Company, Boston, Mass.—Car seat plushes and friezes and railway car seats. Represented by William W. Melcher. Space 22.

McConway & Torley Company, The, Pittsburgh, Pa.—Pitt passenger couplers; Pitt 3-stem passenger coupler equipment; Pitt freight coupler; Penn freight couplers of top and side operating designs. Represented by Stephen C. Mason, E. M. Grove, Wm. McConway, Jr., H. C. Buhoup, I. H. Milliken and W. J. Regan. Spaces 501-503-505.

McCord & Company, Chicago, Ill.—Steel and malleable journal boxes; force feed locomotive lubricators. Represented by A. C. McCord, D. W. McCord, J. A. Lamon, Morrell Dunn, W. J. Schlacks and H. E. Creer. Space 509-511.

McGraw Publishing Company, Inc., New York City.—Copies of Electrical Railway Journal; Electrical World, Engineering Record; Metallurgical & Chemical Engineering. Represented by Messrs. H. W. Blake, F. Kingsley, C. A. Babtiste, S. T. Henry, W. K. Beard, C. A. Henley and F. H. Behrens. Space 7.

McKinnon Chain Company, Buffalo, N. Y.—Electric welded chain. Represented by Geo. J. Armstrong. Space 366.

Midvale Steel Company, The, Philadelphia, Pa.—Reception booth. Represented by H. M. Deemer, Samuel Griffith, T. W. Illingworth, F. H. Philbrick, R. L. Williams and W. S. Edger. Space 640.

Miner, W. H., Chicago, Ill.—Friction draft gears; side bearings; centering devices and other railway specialties. Represented by W. H. Miner, A. L. Canavan, S. R. Fuller, Jr., J. R. Mitchell, W. E. Robertson, J. F. O'Connor, G. I. Haight and G. A. Johnson. Spaces 584-587.

Monroe Calculating Machine Company, New York, N. Y.—Machine which multiplies, divides, adds and subtracts without the use of complements, reciprocals or complicated manipulations of any kind. Represented by E. S. Maulsby and R. B. Hays. Space 558.

Mudge & Company, Chicago, Ill.—Mudge-Slater spark arrester model and Mudge-Peerless car ventilator. Represented by Burton W. Mudge and George W. Bender. Space 201.

Nathan Manufacturing Company, New York, N. Y.—Number 10 "XX" Monitor injector; number 11 Simplex injector type "R" flanged; number 10 Nathan injector, flanged; number 10 Simplex "HW" nonlifting injector flanged; 3-feed "BE" cup with cut out with booster; never leak gauge cock; coal sprinkler; balanced starting valve; 2-in. double boiler check type "T," 2-in. starting valve flanged; 2-in. intermediate steam valve; Locomotive pumps with 4 feeds; type "B" stationary pump 1 quart, 3-feed; type "A" pump 1 pint; type "A" pump ½ pint; balanced steam valve flanged bonnet; quadruple "BE" type 166 with cut out; quintuple feed "BE" 166 with cut out; single and double air cylinder attachment; never-leak gauge cock; 3-sided Delco water gauge guard; 4-sided Delco water gauge guard; Klinger water gauge guard number 4; Sectional model of type "B" pump; Woods pump 1 quart, 3-feed. Represented by E. S. Toothe, J. S. Seeley, J. C. Currie and Robert Wood. Space 578, 579.

National Boiler Washing Company, Chicago, Ill.—Safety first fire doors; photographs of the National boiler washing system. Represented by W. White, H. A. Varney and E. B. White. Space 629.

National Brake Company, Inc., Buffalo, N. Y.—Peacock passenger, freight and baggage car brakes. Represented by Frank D. Miller and W. D. Brewster. Space 385.

National Car Wheel Company, Pittsburgh, Pa.—"Star special" cast iron car wheels. Represented by John Howard Yardley, J. Baueis Weisbrod, James D. Rhodes, H. E. McClumpha, R. H. Tate, C. A. Maher, George P. Rhodes and E. H. Chapin. Spaces 530-532.

National Graphite Lubricator Company, Scranton, Pa.—Graphite lubricators for locomotives and stationary engines. Represented by Edward L. Pollock, Lewis S. Watres, Thornton N. Motley, C. B. Flint and David J. Lewis. Space 307.

National Lead Co., New York, N. Y.—Red lead in paste form; steel cars (models) painted with paste red lead. Represented by F. M. Hartley, Jr., and Chas. Barr Field. Space 329.

National Lock Washer Company, The, Newark, N. J.—Models of car curtains; curtain and window fixtures; National lock washers; Hipower nut locks. Represented by F. B. Archibald, J. Howard Horn, R. F. Horsey and Daniel Hoyt. Space 541.

National Malleable Castings Company, The, Cleveland, Ohio.—Couplers; journal boxes; brake staff mechanism; malleable iron castings. Represented by T. W. Aishton, C. A. Bieder, J. J. Byers, W. E. Coffin, Chas. Gaspar, R. T. Hatch, J. H. Jaschka, O. W. Loomis, G. V. Martin, B. Nields, Jr., Jas. A. Slater, J. H. Slawson, S. L. Smith, E. O. Warner and L. S. Wright. Spaces 613-615.

National Railway Devices Company, Chicago, Ill.—Shoemaker fire door; National release rigging and single link release rigging. Represented by Jay G. Robinson and Percy P. Hinckley. Space 187.

National Tube Company, Pitsburgh, Pa.—Reception booth. Represented by L. F. Hamilton, G. N. Riley, P. J. Conrath, J. F. Goodwin, J. W. Kelly and W. S. Bitting. Spaces 548-549.

Newkirk, W. P., Portsmouth, Ohio.—Portable blue flag derail. Represented by W. P. Newkirk. Space 631.

New York Air Brake Company, The, New York, N. Y.—Reception booth. Represented by Scott R. Hayes, B. Pratt, O. E. Moore, C. E. Leach, Thomas O'Leary, Jr., H. F. Bickel, N. A. Campbell and William Owens. Spaces 374 to 377.

Niles Bement Pond Company, New York, N. Y.—Niles 44 inch vertical boring and turning mill; Bement 60 inch duplex horizontal borer, driller and miller. Represented by James K. Cullen, Edward L. Leeds, Geo. F. Mills, Chas. L. Lyle and D. J. Normoyle. Spaces 134-136-138-140-142-144.

Norton, A. O., Inc., Boston, Mass.—Self lowering high speed jacks. Represented by A. O. Norton, Harry A. Norton, J. O. St. Pierre, Henry J. Wilson, F. L. Gormley, R. L. Skidmore and Chas. H. Smith, Jr. Space 559.

Nuttall Company, R. D., Pittsburgh, Pa.—Flexible gears and pantograph trolley as installed on Pennsylvania Railroad motor cars Philadelphia to Paoli electrification; locomotive rings, gears and third rail pantograph trolleys; ten inch trolley wheel and harp for high speed interurban and locomotive service; display of heat treated steels as applied to railway gears and pinions. Represented by Milton Rupert, W. H. Phillips and L. H. Keim. Spaces 143-145.

Nutter & Barnes Company, Hinsdale, N. H.—Automatic cold sawing machines; abrasive wheel metal cutting machines; automatic metal saw sharpeners, universal tool grinders; hydraulic plain cylindrical grinders; saw-gear and milling cutter sharpeners; motor driven. Represented by W. S. Howe and A. E. Champagne. Space 156.

O. and C. Company, The, New York, N. Y.—Emergency knuckles; skid shoes; car and engine replacers; diaphragms; E. M. Smith, Edmund Quincy and F. F. Kister. Space 187. Ross-Schoefield system of boiler circulation; snow flangers. Represented by C. F. Quincy, C. F. Pierce, J. V. Wescott.

Okonite Company, The, New York, N. Y.—Reception booth. Represented by F. J. White and W. T. Kyle. Space 500.

O'Malley-Beare Valve Company, Chicago, Ill.—Multiplate; full line of round house service valves, globe, angle and checks; locomotive special valves; duplex blow-out valves. Represented by Edward O'Malley and Thos. O'Malley. Space 210.

Pantasote Company, The, New York, N. Y.—Agasote headlining and panelling; Pantasote curtain material and upholstery leather. Represented by Wm. Anderson, Wm. A. Lake and John M. High. Space 400.

Parkesburg Iron Company, The, Parkesburg, Pa.—Charcoal iron boiler tubes; safe ends; arch tubes and locomotive superheater tubes; and Lohmannized boiler tubes. Represented by H. A. Beale, Jr., George Thomas, 3rd, W. H. S. Bateman, J. A. Kinkead, J. R. Wetherald and G. W. Denyven. Space 388.

Paxton-Mitchell Company, The, Omaha, Neb.—Piston rod, valve stem, air pump and cylinder packing. Represented by James L. Paxton and Wm. Leighton. Space 209.

Philadelphia & Reading Railway.—Reading or 4-4-4 type of passenger locomotive. Space on exhibit track at Mississippi Avenue.

Pilliod Company, The, New York, N. Y.—Engine model with Baker valve gear. Represented by R. H. Weatherly, K. J. Eklund, F. S. Wilcoxen, C. M. Jennelle, R. G. Graham and F. E. Pilliod. Spaces 556-557.

Pocket List of Railroad Officials, The, New York, N. Y.—The pocket list of railroad officials. Represented by J. Alexander Brown, Charles L. Dinsmore and Harold A. Brown. Space 7.

Power Specialty Company, New York, N. Y.—Full size model of Foster locomotive superheater. Represented by L. B. Nutting, G. B. Ferrier, Jr. and Frank Page. Space 635.

Pressed Steel Car Company, New York, N. Y.—Photographs of products. Represented by O. C. Gayley, J. F. MacEnulty, J. H. Regan, C. A. Lindstrom, C. E. Postlethwaite, J. H. Mitchell, L. O. Cameron, J. C. Anderson, J. S. Turner, W. H. Wilkinson, M. S. Simpson, H. S. Hammond, G. W. Ristine and F. L. Johnson. Spaces 545-601.

Pyle-National Electric Headlight Company, Chicago, Ill.—Type "E" arc headlight equipment, with special headlight case; type "K" incandescent headlight equipment, with special headlight case; Young locomotive valve gear; Young locomotive reversing gear; Young locomotive piston valve; Van Dorn sectional and one piece steel car ends. Represented by J. Will Johnson, J. E. Kilker, C. E. Miller, Wm. Miller, C. P. McGinnis, R. C. Vilas and O. W. Young. Spaces 602-604-606 and 90.

Pyrene Manufacturing Company, New York, N. Y.—Pyrene fire extinguisher for railway coaches, freight platforms, signal towers, buildings, offices, oil houses. Represented by E. L. Kent, W. H. McKinnon and O. E. Meske. Space 203-205.

Railway Age Gazette, New York, N. Y.—Publications Railway Age Gazette; Mechanical Edition Railway Age Gazette; Signal Engineer; other publications devoted to the transportation industry. Represented by E. A. Simmons, Samuel O. Dunn, Roy V. Wright, R. E. Thayer, A. C. Loudon, C. B. Peck, Geo. Mitchell, C. W. Foss, F. W. Kraeger, A. R. Gegen, M. E. Christy, C. R. Mills, Henry Lee, F. H. Thompson, A. F. Ashbacker, W. M. Ford, H. H. Marsh, W. D. Horton and F. S. Dinsmore. Space 1.

Railway Devices Company, St. Louis, Mo.—"Western" angle cock holder; Perfect drop brake handle; "Iron Horse" or pedestal; "Spiral" pipe clamps; "Interlox" brake mast ratchet and pawl. Represented by Louis A. Hoerr and Sterling Campbell. Space 618.

Railway Master Mechanic, Chicago, Ill.—The publication itself. Represented by Charles S. Myers and Laurence A. Horswell. Space 20.

Railway Materials Company, The, New York, N. Y.—Brake shoes. Represented by T. B. Cram, George Hoeffle, E. C. Folsom, I. B. Lesh and G. F. Allen. Space 561.

Railway Review, Chicago, Ill.—Railway Review current issues and files of previous issues. Represented by Willard A. Smith, Arthur E. Hooven, J. E. Gougeon, Jno. M. Lammedee and Clyde F. Burns Spaces 12-14.

Railway Utility Company, Chicago, Ill.—Various types of honeycomb ventilators for Monitor and arch roof cars; thermostat control for steam and electric heat. Represented by W. J. Pine and G. E. Pratt. Space 380.

Ralston Steel Car Company, The, Columbus, Ohio.—Model "Ohio flush side door." Represented by J. S. Ralston, A. Becker, A. D. McAdam, F. E. Symons, J. R. Forney, W. T. Sheldon, R. R. Weaver and C. S. Rea. Space 607.

Readng Specialties Company, Reading, Pa.—Rail benders; rail joints; guard rail clamps; rerailers. Represented by J. Turner Moore, M. G. Moore, B. J. Buell and R. G. Ross. Space 315.

Remy Electric Company, Anderson, Ind.—American 6 and 32 volt incandescent headlight. Represented by Thomas B. Arnold. Space 614.

Robinson Company, The, Boston, Mass.—Robinson exhaust nozzle. Represented by Frederic Parker and Frank Robinson. Spaces 564-565.

Rochester Germicide Company, Rochester, N. Y.—Automatic disinfecting appliances; general line of disinfectants; bubbling drinking fountains; liquid soap; soap dispensers. Represented by C. J. Pearson and D. N. Calkins. Space 502.

Rome Merchant Iron Mill, Rome, N. Y.—Rome "Superior" stay bolt iron and "Perfection" engine bolt iron. Represented Weston Jenkins. Space 614.

Ryerson & Son, Joseph T., Chicago, Ill.—Ulster special staybolt iron; Ulster engine bolt iron; Nikrome locomotive forgings; photographs and drawings of special railroad shop machinery. Represented by Geo. M. Basford, H. A. Gray, J. B. Warren and E. W. Kavanagh. Space 176.

Safety Car Heating & Lighting Company, New York, N. Y.—Safety "Under-frame" car lighting equipment; Pintsch mantle car lighting equipment; gas and electric car lighting fixtures; safety electric fan; Oxy-Pintsch metal cutting and welding equipment. Represented by R. M. Dixon, J. A. Dixon, A. C. Moore, G. H. Chadwell, W. L. Garland, J. S. Henry, R. C. Shaal and G. E. Hulse. Space stairway platform.

Safety First Manufacturing Company, Chicago, Ills.—Safety first combustion chamber; caboose stove; angle cock bracket; armored hose; safety parcel rack for passenger coaches; perfection door guide and seal; Fitch check holders for passenger cars; asbestos and magnesia products. Represented by Fay E. Posson and L. L. Cohen. Space 175.

Sargent Company, Chicago, Ill.—Sargent safety water guage; Wirth automatic safety water glass cocks; Sargent blow-off valve; safety valves; Loeidge quick acting blower valve; Lenz safety lathe dog. Represented by Frank G. Dunbar and George H. Sargent. Space 738.

Sellers, William & Company, Inc., Philadelphia, Pa.—Reception booth. Represented by Strickland L. Kneass, John D. McClintock, Charles T. Wilson, E. L. Holljes and L. H. Burns. Space 623.

Simplex Air Brake and Manufacturing Company. Space 614.

Southern Locomotive Valve Gear Company, Knoxville, Tenn.—Miniature locomotive and model equipped with the Southern valve gear. Represented by E. L. Chollman. Spaces 522-524.

Standard Asphalt & Rubber Company, Chicago, Ill.—Permanent waterproofing; mineral rubber pipe coating; mineral rubber floor. Represented by Chas. V. Eades. Space 634.

Standard Car Truck Company, Chicago, Ill.—One 50-ton truck and one 70-ton truck full size; one 70-ton car on exhibit tracks; 12 various models; 6 various parts. Represented by J. C. Barber, J. T. Milner, F. L. Barber, L. W. Barber and E. W. Webb. Spaces 178-180.

Standard Coupler Company, New York, N. Y.—Reception booth. Represented by Geo. A. Post, E. H. Walker, Geo. A. Post, Jr., R. D. Gallagher, Jr., and A. P. Dennis. Space 617.

Standard Heat & Ventilation Company, Inc., New York, N. Y.—Car heating apparatus of all kinds; Passenger car ventilators; steam hose couplers; end train line valves; automatic traps and regulators; Standard Econotherm. Represented by Samuel Higgins, C. F. McCuen, C. H. McCormick and L. B. Rhodes. Space stairway platform.

Standard Stoker Company, Inc., New York, N. Y.—Mechanical stokers for locomotives. Represented by Frank L. Connable, James A. Carey, Eugene duPont, David T. Williams, E. A. Averill, F. H. Cunningham and Walter Coopey. Space 211.

Stark Car Coupler Corporation, Washington, D. C.—The Stark car coupler and two miniature cars equipped with the coupler. Represented by C. H. Kadie and L. A. Shepard. Space 174.

Stockbridge Machine Company, Worcester, Mass.—One machine tool—20 inch Stockbridge patented two-piece-crank motion

motor driven shaper. Represented by A. W. Beaman and Radford Stockbridge. Space 132.

Summers Steel Car Company, Pittsburgh, Pa.—One freight car truck equipped with Summers arch bar side frame. Represented by E. W. Summers and J. M. Summers. Space 111.

Superior Oxygen Company, Pittsburgh, Pa.—Oxygen and oxy-acetylene welding and cutting apparatus. Represented by J. A. Warfel. Space 515.

Symington Company, The T. H., Rochester, N. Y.—Reception booth. Represented by C. J. Symington, A. H. Weston, C. R. Naylor, D. F. Mallory, R. H. Gwaltney, W. W. Rosser, T. C. deRosset and I. O. Wright. Spaces 570-571.

Transportation Utilities Company, New York, N. Y.—National steel trap doors; Flexolith composition flooring; metallic steel sheathing; Imperial car window screens; National standard roofing; Resisto insulation; Reliance and Perfection sash balances; deck sash ratchets. Represented by D. W. Pye, W. L. Conwell, Garrett Burgert, H. B. Chamberlain, F. N. Grigg and W. S. Humes. Spaces 566-567.

Union Draft Gear Company, Chicago, Ill.—Draft gear and side bearings. Represented by Jas. R. Cardwell, L. T. Canfield, J. W. Hathaway, W. G. Krauser, Jas. E. Tarelton and H. Barnard. Space 409.

Union Railway Equipment Company, Chicago, Ill.—Pries metal roofs; Union drop brake shaft; Pries refrigerator radiators; Pries brine tank valves. Represented by W. B. Hall. Space 507.

Union Spring & Manufacturing Company, Pittsburgh, Pa.—Kensington pressed steel journal boxes; coil and elliptic springs for any service on steam and electric roads; machinery and agricultural implement springs; pressed steel spring plates and journal box lids; pressed steel shapes of various designs. Represented by L. G. Woods, C. S. Foller, A. C. Woods and H. F. Ayres. Space 620.

United Engineering & Foundry Company, Pittsburgh, Pa.—Photographs of forging press installations in railroad and other forge shops. Represented by Arnold P. Bark. Space 540.

United States Graphite Company, The, Saginaw, Mich.—Graphite products for railroad use; Mexican boiler graphite; number 205 lubricating graphite. Represented by J. W. Eviston, W. W. Lampkin, C. M. Williamson and A. B. Turnbull. Space 526.

U. S. Light & Heating Company, Niagara Falls, N. Y.—Complete U-S-L electric lighting equipment for railroad cars, in operation; U-S-L axle generators in various sizes, each a unit in an equipment; U-S-L storage batteries in types for car lighting; U-S-L storage batteries in types for operation of automatic signals. Represented by L. R. Pomeroy, H. A. Mathews, J. A. White, R. C. Haley, W. L. Bliss, C. C. Bradford, E. F. Oates, Wm. G. Davis, J. Allan Smith, A. H. Ackermann, W. A. Turbayne and L. S. Cunny. Spaces 333-335.

U. S. Metal & Manufacturing Company, New York, N. Y.—Cayuta ball and cone bearing screw jacks, high speed and standard; ratchet jacks, pressed steel seamless gear case; Linofelt and Fibrofelt. Represented by B. A. Hegeman, Jr., Chas. C. Castle, F. C. Dunham, H. A. Hegeman, H. K. Porter, H. S. Norris, E. D. Hillman, H. A. Stone and W. T. Goodnow. Space 622.

U. S. Metallic Packing Company, The, Philadelphia, Pa.—King metallic packings; Leach sanders; Gollmar bell ringers. Represented by Morris B. Brewster, H. M. Wey, John S. Mace and R. R. Wells. Space 525.

Universal Car Seal & Appliance Company, Albany, N. Y.—Universal line of car door fasteners for wood or steel construction and standard for any car seals; "Universal" car seals. Standard for any car door fasteners. Represented by Wm. C. Martineau and Allston Headley. Space 520.

Universal Draft Gear Attachment Company, Chicago, Ill.—Full sized model cast steel draft arms, with twin spring key connected draft gear; keyed yokes for friction and tandem draft gears; lock yokes for friction draft gears; one-piece cast steel riveted yokes for friction and spring draft gears; miscellaneous malleable iron and cast steel draft plates; lugs, etc. Represented by C. J. Nash and C. C. Kinsman. Space 521.

Valentine & Company, New York, N. Y.—Valentine's Valspar railway finishing varnish; panels showing our various systems of painting wood and steel railway equipment; various tests showing action of weather, moisture, car soaps and cleaners on various grades of varnish, panels showing our signal enamels. Represented by Langdon B. Valentine, Irving H. Munford and Harry L. Bell. Spaces 580-581.

Vissering & Company, Harry, Chicago, Ill.—Viloco locomotive sanders; duplex engineers' valve; bell ringer; bell ringer throttle valve; one piece brake step; Crescent metallic packing. Represented by Harry Vissering, Chas. R. Long, Jr., Guilford S. Turner and Wm. H. Heckman. Spaces 576-577.

Walker Company, Inc., Sheridan A., New York, N. Y.—New improved all-steel railroad car-seats. Represented by A. H. Flint and S. A. Walker. Space 589.

Warner & Swasey Company, The, Cleveland, O.—One number 2A universal hollow hexagon turret lathe, operating on bar work; one number 3A universal hollow hexagon turret lathe operating on chucking work. Represented by A. C. Cook, L. K. Berry and H. E. Witham. Space 123-125.

Waugh Draft Gear Company, Chicago, Ill.—Draft gear. Represented by C. H. Osborn. Space 513.

Wayne Oil Tank & Pump Company, Fort Wayne, Ind.—Hand and power driven self-measuring pumps and storage tanks. Represented by W. M. Griffin, Edward H. Barnes and B. F. Geyer. Space 11.

West Disinfecting Company, New York, N. Y.—Liquid soap dispensers and liquid soap; Formosal fumigators; automatic drip machines; Protectus machines; sanitor closet; West portable steam sterilizer; fumigating lamps; Coro-Noleum. Represented by Geo. L. Lord, H. E. Daniels and Dr. Hyde R. Fussell. Space 26.

Western Railway Equipment Company, St. Louis, Mo.—Western brake jaws; Acme pipe clamps; Security dust guards; Western steel carline; Linstrom syphon; Acme brake adjuster. Represented by Louis A. Hoerr and Sterling Campbell. Space 618.

Western Steel Car & Foundry Company, New York, N. Y.—Photographs of products. Represented by O. C. Gayley, J. F. MacEnulty, J. H. Regan, C. A. Lindstrom, C. E. Postlethwaite, J. H. Mitchell, L. O. Cameron, J. C. Anderson, J. S. Turner, W. H. Wilkinson, M. S. Simpson, H. S. Hammond, G. W. Ristine and F. L. Johnson. Spaces 545-601.

Westinghouse Air Brake Company, Pittsburgh, Pa.—Reception booth. Represented by A. L. Humphrey, Walter V. Turner, E. A. Craig, J. R. Ellicott, C. P. Cass, C. J. Olmstead and F. V. Green. Spaces 19-29.

Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.—Reception booth. Lighted with 200-watt type C Mazda Lamps. Represented by J. C. McQuiston, W. H. Patterson, J. H. Bryan, H. W. Beaumont, R. F. Moon, R. J. Ross, H. C. Mode and L. W. Popp. Spaces 19-29.

Westinghouse Friction Draft Gear Company, Pittsburgh, Pa.—Reception booth. Represented by Robert Burgess, H. E. Chilcoat and S. J. Kidder. Spaces 19-29.

Westinghouse Lamp Company, East Pittsburgh, Pa.—Reception booth. Represented by Elliott Reid. Spaces 19-29.

Westinghouse Machine Company, East Pittsburgh, Pa.—Reception booth. Represented by E. H. Sniffin, M. C. McNeil and R. E. Miller. Spaces 19-29.

Westinghouse Pacific Coast Brake Company, Emeryville, Cal.—Reception booth. Represented by S. G. Down and C. C. Farmer. Spaces 19-29.

Westinghouse Traction Brake Company, Pittsburgh, Pa.—Reception booth. Represented by F. M. Nellis. Spaces 19-29.

Wheel Truing Brake Shoe Company, Detroit, Mich.—Samples of abrasive brake shoes for truing up car wheels and locomotive driver wheels. Represented by J. M. Griffin. Space 533.

White American Locomotive Sander Company, Roanoke, Va.—Combined pneumatic track sander and pipe cleaner. Represented by W. H. White, John E. Graham and R. J. Donahoe. Space 379.

Willard Storage Battery Company, Cleveland, Ohio.—No-wash train lighting storage battery and parts. Represented by W. E. Ballantine, R. N. Newolt, F. S. Gassaway, Louis Sears and E. L. Myers. Space 611.

Wilson Remover Company, Newark, N. J.—Wilson removers and appliances. Represented by J. MacMaull Wilson, J. Whitney Wilson, Frank Sherritt and J. T Hartnagel. Space 213.

Windsor Machine Company, Windsor, Vt.—Reception booth. Represented by F. L. Cone and Thomas F. Du Puy. Space 101, 102.

Wray Publishing Company, Chicago, Ill.—Periodical; Railway Electrical Engineer; monthly. Represented by Edward Wray and C D. Sperry. Space 16.

Wright Safety Air Brake Company, Greensboro, N. C.—Automatic train stop; air brake. Represented by J. E. Latham, J. B. Wright, F. O. Lawson, F. H. White and J. C. Watkins. Space 384.

Yale & Towne Manufacturing Company, The, New York, N. Y.—Yale triplex hoists, trolleys, electric hoists, battleship projectile hoists, Yale coach door closers. Represented by C. W. Beaver and W. A. Hall. Spaces 152-154.

COAL IN SPAIN.—An article in a Spanish journal states that in 1913 the coal basins in Spain were found to cover an area of about 494,000 acres, containing 3500 collieries, of which 762 only were working, embracing an area of 98,000 acres. The probable quantity of coal existing in the province of Asturias alone has been estimated at 5000 million tons.

BUSINESS DEPARTMENT REPRESENTATIVES
CECIL R. MILLS, FRANK S. DINSMORE, F. H. THOMPSON, H. H. MARSH, W. M. FORD, A. F. ASHBACKER, W. D. HORTON

Subscriptions, including 52 regular weekly issues and special daily editions published from time to time in New York, or in places other than New York, payable in advance and postage free:

United States and Mexico.....$5.00
Canada 6.00
Foreign Countries (excepting daily editions)..... 8.00
Single Copies .....15 cents each

Engineering and Maintenance of Way Edition and four Maintenance of Way Convention Daily issues, North America, $1.00; foreign $2.

Entered at the Post Office at New York, N. Y., as mail matter of the second class.

WE GUARANTEE that of this issue 10,011 copies were printed; that of those 10,011 copies 8,572 were mailed to regular paid subscribers to the Railway Age Gazette and the Railway Age Gazette, Mechanical Edition; 150 were provided for counter and news companies' sales; 189 were mailed to advertisers; 100 were provided for bound volumes, and 1,000 for distribution at Atlantic City.

The RAILWAY AGE GAZETTE and all other Simmons-Boardman publications are members of the Audit Bureau of Circulations.

The discussion of the report of the Committee on Mechanical Stokers brought out very definitely that the stoker manufacturers, or at least some of them, do not claim a saving in fuel by the use of stokers. They do, however, claim a marked increase in locomotive capacity; that is, a locomotive can haul a greater tonnage at a higher speed when stoker-fired than when hand-fired, and all the testimony seems to bear this out conclusively. Statements made during this discussion to the effect that stokers have been known to fire as high as 15,000 lb. of coal per hour, also show that there need be no limitation placed on locomotives as far as fuel consumption is concerned, as the stoker can be made to supply any amount of fuel which can be consumed on the grate. The particular field, therefore, of the mechanical stoker is not direct saving in fuel but increased tonnage.

Stokers and Increased Capacity

President Gaines made an excellent suggestion in his address when he directed attention to the fact that many of the associate and honorary members of the association, who are in position to help considerably in the investigations of the various committees and in preparing the reports, are being overlooked. If the work of the association is reviewed it will be found that certain associate members, because of their special knowledge or because of having time to devote to the work, have helped to prepare some of the most important and valuable of its reports and papers.

Make Better Use of Associate Members

Of course there may be subjects which, because of their nature, must be handled entirely by men in responsible positions in actual service, but these are comparatively few in number and there is hardly a committee in either the M. M. or M. C. B. Association which could not use the services of some of these members to excellent advantage. The matter can be easily adjusted if the executive committee will keep it in mind in outlining the work of the coming year.

In explaining the attitude of the Interstate Commerce Commission on the subject of autogenous welding in boiler work, Frank McManamy, chief boiler inspector, said that some of its over-enthusiastic friends are using it for purposes which will result only in retarding its development and restricting its legitimate field. Among the uses mentioned as not meeting with approval was that of repairs to boiler sheets that are wholly in tension, without any staying to assist in their support or in the absorption of stresses. We do not know to what extent this practice is being followed, but we have seen autogenous welding methods employed in repairing parts of locomotives which were in direct tension, and the practice would seem to have many possibilities for producing serious results. Autogenous welding processes are not a cure-all for all locomotive breakages and their use for some of the purposes indicated is likely to prove a set-back to their development along legitimate lines.

Restrictions on Autogenous Welding

That the prevention of locomotive smoke is an all-absorbing and important question to roads operating in cities which have smoke ordinances there is no question. The roads that are not now handicapped with city ordinances should profit by the experience of those that are and see to it that the cities which they serve do not find it necessary to even think of smoke ordinances. This can only be done by concerted action on the part of all the roads. It will be found much more satisfactory, and far cheaper, for the railways to show a sincere disposition to keep the locomotive smoke as unobjectionable as possible. While the report of the committee on Smoke Prevention discloses very amicable relations between the city smoke inspection bureau and the railways in Chicago, it will be realized that this is possibly more of an exception than the rule. The committee describes clearly the method followed by the railways entering Chicago and it could very well serve as a guide to those roads that are farsighted enough to get together and forestall objectionable ordinances.

Locomotive Smoke Prevention

If there were any doubts as to the success of the mechanical stoker in locomotive service, they would be removed by a perusal of the committee report presented at the recent convention of the International Railway Fuel Association and the report of the stoker committee of the Master Mechanics' Association. In the words of the former committee, "the stoker has arrived." Concerning fuel consumption, there seems to be as yet very little definite information, but there is no question that stoker-fired locomotives are capable of hauling greater tonnage than the same engines hand-fired because of the stoker's ability to maintain steam pressure under conditions beyond the physical limitations of the fireman. Like all new machinery, the mechanical stoker has had to pass through a period of development; some parts have had to be strengthened, some eliminated and others added. Because of this development work the cost of stoker maintenance, as referred to in the Master Mechanics' committee report, has not been reduced to the point which might have otherwise been reached. But it is encouraging in this respect to learn that efforts are being made to confine the failures to

The Mechanical Stoker

places where repairs can be conveniently made. Attention is also being given to the matter of a better arrangement of the parts of the locomotive which are affected by the application of a stoker. It would seem that in the case of new locomotives which are to be equipped with stokers, opportunities are presented for simplifying and otherwise improving the machine by co-operation between the locomotive and stoker designers. The stoker designer is frequently confronted with severe limitations in applying a stoker to an existing locomotive, but there does not seem any good reason why he should not be given a better chance in the case of new power. The report of the Master Mechanics' committee also disposes effectively of the doubt as to the possibility of producing a stoker that will handle run-of-mine coal.

Centralized Control of Associations

The recommendation of President Gaines in his opening address, for the formation of one mechanical association to assume direction and control of the various associations now in existence, seems a good one. Just how the plan would be worked out would, of course, have to be determined by conferences of all those concerned; but there does not seem any reason why the various associations should not retain their individuality to a considerable extent, while the centralized control of such matters as the subjects acted on by the various committees and presented for discussion should be the means of eliminating much of the duplication of effort and working at cross-purposes which is now evident to anyone who attends many of the mechanical conventions. We believe that much good could come from such an organization and that this recommendation should not be set aside without further attention, but that on the contrary every effort should be made to develop some logical plan to concentrate the efforts of the various associations to a much greater extent than is now possible.

RECLAMATION OF MATERIAL

IN the *Railway Age Gazette* of May 21, 1915, page 1039, there was published an abstract of the Railway Storekeepers' Association committee report on the reclamation of material. The discussion of the report brought out a number of points which seem worthy of the most careful consideration. One of the principal of these was that of applying the recommendations of the committee to any particular road. It should be remembered in connection with reports of this nature that because of the great number of plants which are visited and taken into consideration, with conditions varying in many respects, the findings cannot be anything but general in character, and while they should be of the utmost value as a guide for anyone wishing to install a reclamation plant, they should be used as a guide only and no attempt be made to adhere rigidly to the recommendations when conditions may be so different as to make this impracticable. This is particularly true in the case of labor conditions, which vary so in different parts of the country and on different roads, that methods which give satisfaction on one road might prove inapplicable on another. The report of this committee and the various published articles dealing with reclamation work on different roads throughout the country may be made of great value in the installation of a plant on any road, but if such a plant is to be a success the final details will have to be worked out to meet the local conditions.

Another point that should be borne in mind is that the foreman of a plant for reclaiming material is naturally anxious to make as good a showing as possible, and his overenthusiasm may, in consequence, lead him into practices that are not economical. Cases are not wanting where material has been "reclaimed" only to be found useless after a considerable expense has been involved in the work of reclaiming it. It is easy to imagine a reclaiming plant, because of such practices, wasting a considerable percentage of what the plant is saving in other directions. There is a difference between reclaiming material and repairing it. There is a great deal of material now going through reclamation plants for which credit is being taken for reclamation when, as a matter of fact, the material is only repaired, and cannot in any sense be considered as scrap reclaimed. Carrying this a little further, there is much material now being reclaimed which should never have been scrapped at all, much of it being in first-class condition. The reclamation of scrap material has been proving of great value as a money saver to those railways that have put it into effect, but it should be remembered that, like almost anything else, it can be overdone, and it is well for those who are in touch with this work to keep in mind such points as those above indicated.

THE MECHANICAL DEPARTMENT AND OPERATING RESULTS

IT behooves every railway officer to look about him frequently and take account of himself and of the results he is producing for his company. To be sure, if he is not producing reasonably satisfactory results, he will be told of it by those above him in no uncertain language. But there is, or should be, more to the question of "satisfactory results" than the mere matter of a man's pride or self-satisfaction in the knowledge that he is keeping up his end of the game about as well as anyone else on the road. Are these results, that are approved by the higher officers, as satisfactory to you as they might be? Are the methods employed in obtaining them the best you can develop? Are you trying only for results that will "get by," or are you extending every effort to produce real economy and at the same time improve operating conditions?

A certain division operates for three months without an engine failure. Naturally the master mechanic is proud of it. But he may be of the type of men who are content to rest on this record; he may believe that his organization is so perfected that his division will continue to operate with a minimum of failures. If he is wise he will look carefully into the matter to see where he can find possibilities for improvement—breaks in his fences which, if left unheeded, may produce an engine failure record of another character. The time has never been, and certainly is not now, when a railway man can afford to view his achievements as the best possible under the conditions: if he is going to keep up with the game he must be just a little bit ahead of it all the time.

On the methods pursued in building up and maintaining an organization depends much of its success. We are all used to hearing railway men say, "We have very bad labor conditions on our road." Undoubtedly, labor conditions are bad on very many roads; but, Mr. Mechanical Department Officer, what steps are you taking to improve them? Are you following the policy of let well enough alone, and trusting that nothing will arise to start any trouble? Or are you ever on the alert, in close touch with the conditions on your road and making every step count toward better relations with the men? The labor problem cannot be solved over night by any one man; but every mechanical department officer can help toward better relations between the company and its employees. The road foreman of engines can accomplish much with enginemen: haggling over little things of minor importance does much to antagonize this class of men. Engine house foremen and shop foremen can assist the road foreman in this respect, and can also go far toward building up a better feeling among the shop men.

On the master mechanic rests the responsibility of either finding or developing the right kind of foremen—men of character and with ability to control those under them without antagonizing them. And for the higher officer there is the necessity of making a wise choice of his immediate subordinates and instilling the spirit of harmony into the entire force, for his attitude is more than likely to be directly reflected in the attitude of those under him. In the final analysis, the type of man who holds a minor official position depends on the type of man at the head of the organization.

TODAY'S PROGRAM

Discussion of reports on:

Locomotive headlights	9.30 A. M. to 10.15 A. M.
Design, construction and inspection of locomotive boilers	10.15 A. M. to 10.30 A. M.
Standardization of tinware	10.30 A. M. to 10.45 A. M.
Superheater locomotives	10.45 A. M. to 11.30 A. M.
Fuel economy	11.30 A. M. to 12.00 M.

Individual paper on:

Variable Exhausts. By Mr. J. Snowden Bell	12.00 M. to 12.30 P. M.

Topical discussions:

Tender derailments, causes and remedies. To be opened by Mr. H. T. Bentley	12.30 P. M. to 12.45. P. M.
Road instructions for enginemen and firemen	12.45 P. M. to 1.00 P. M.
Cross-head design. To be opened by Mr. A. R. Ayers	1.00 P. M. to 1.30 P. M.

ENTERTAINMENT

10.30 A. M.—*Orchestral Band Concert.* Entrance Hall, Million-Dollar Pier.

3.30 P. M.—*Orchestral Band Concert.* Entrance Hall, Million-Dollar Pier.

9.30 P. M.—*Informal Dance.* Special Feature, Costume Recital, Miss Betty Lee. Ball Room, Million-Dollar Pier. Don Richardson Orchestra.

TINWARE EXHIBIT

The Committee on Standardization of Tinware announces that it has arranged with the American Car & Foundry Company to exhibit the standards recommended in its report at the exhibit space of that company. The exhibit was provided through the courtesy of the Johnson Manufacturing Company. I. G. Johnson is in charge of the exhibit.

COMMITTEE ON OBITUARIES

The following members were appointed to act on the Committee on Obituaries: For Mott E. Sherwood, of the Michigan Central, D. R. MacBain, E. W. Pratt and L. R. Pomeroy. For C. Phillips, of the New Orleans and Northeastern, C. F. Giles.

R. S. M. A. DISTRICT MEETINGS

Four new members of the Executive Committee of the Railway Supply Manufacturers' Association will be chosen on Saturday, June 12. The voting place will be the room, adjoining the enrollment booth, in which the executive committee holds its meetings; and the polls will be open from 10 o'clock A. M. to 12 noon.

LOCOMOTIVE ORDERS

The New York, Ontario & Western has ordered twelve 2-10-2 type locomotives from the American Locomotive Company to be equipped with Street stokers.

The Denver & Salt Lake has ordered eight Mikado locomotives from the Lima Locomotive Corporation.

CLEANING OUT THE BOOTHS

The Exhibit Committee calls attention to the fact that it is not necessary for exhibitors to bring men in from outside to clean their booths. A force of eight men and a foreman is employed by the committee to sweep all dirt from the aisles during the night, and the regular employes of the pier are expected to remove it from the aisles. Men are also kept on duty during the day to keep things clean. It is not only unnecessary, but undesirable to bring in cleaners besides those employed by the committee, because close supervision cannot be exercised over them, and in consequence things are likely to disappear from the booths. The committee requests that if the work of cleaning is not properly done complaint shall be made to it, and prompt attention will be given to the matter.

LOST

M. K. Barnum, superintendent motive power, Baltimore & Ohio, lost his Master Car Builders' Association ex-president's badge yesterday. It has his full name on it, and he will greatly appreciate the courtesy if the finder will return it to the *Railway Age Gazette* office.

SACRED CONCERT

As usual, a sacred concert will be given in the solarium of the Marlborough-Blenheim at 10.30 o'clock Sunday morning by the hotel orchestra. Through an inadvertence the announcement of this concert was not included in the printed entertainment program.

GET-TOGETHER MEETING OF NORTH WESTERN CLUB

An informal meeting of North Western Club will be held at the Shelburne Hotel at 8.30 o'clock Saturday evening. Its purpose is to enable all those attending the conventions who formerly were or are now employed on the Chicago & North Western to get together, and all of either class who are here are invited to be present.

PENNSYLVANIA TRANSPORTATION

The announcement was made at the meeting yesterday morning that transportation would be provided over the Pennsylvania if the request was made to the secretary of the association, Joseph W. Taylor. In accordance with the requirements of the law, such transportation must be limited to bona fide railroad officials only and cannot include members of boat lines, car lines or switching lines operated by industries.

HONORARY MEMBERS

The following were elected to honorary membership in the Master Mechanics' Association at the meeting of yesterday morning:

Rufus Hill, who joined the association in 1874 and continued as a member until 1880, when he resigned. He renewed his membership in 1892 and has maintained it to the present time. Mr. Hill is now past 80 years of age.

H. G. Beckhold, who has been a member of the association for 22 years.

SOCIAL GATHERING AND DANCE

The social gathering and informal dance held on the pier last night proved to be most enjoyable. As was predicted in The Daily, the change to holding this affair on the pier with its spacious dance floor proved a marked success. The program rendered by Don Richardson's Orchestra was the last word from New York, and the costume recital of Miss Betty Lee the finished expression of an artist. The committee in charge was composed of Burton W. Mudge, chairman; C. D. Eaton, C. D. Jenks, C. W. F. Coffin, H. W. Hegeman, A. MacRae, J. P. Landreth and L. Ingraham.

R. S. M. A. NOMINATIONS

The nominating committee, composed of A. L. Humphrey, Westinghouse Air Brake Company (chairman); Scott H. Blewett, American Car & Foundry Company; Walter B. Leach, Hunt-Spiller Manufacturing Corporation; H. I. Lord, Detroit Lubricator Company; E. P. Welles, Charles H. Besly & Company; George L. Morton, Galena Signal Oil Company, and J. Allan Smith, U. S. Light & Heating Company, has recommended the following for officers: For president, Oscar F. Ostby, Commercial Acetylene Light & Signal Company, New York; for

vice-president, Edmund H. Walker, Standard Coupler Company, New York. The nominees will be voted for at the annual meeting of the Railway Supply Manufacturers' Association, to be held in Convention Hall, Million-Dollar Pier, at 12 o'clock noon Saturday, June 12.

TURN IN YOUR GOLF HANDICAPS

Those intending to play in the golf tournament on Sunday are requested to give their club handicaps, club pars and average scores to F. H. Thompson at the booth of the *Daily Railway Age Gazette*. A large number of prospective players sent their handicaps to E. H. Bankard, Jr., who was to have served as chairman of the golf committee. Mr. Bankard unfortunately is unable to attend the conventions and it will therefore be necessary for those who sent their handicaps to him to turn them in again. D. E. Sawyer will serve as chairman of the golf committee in place of Mr. Bankard.

It is desired to have as many as practicable participate in the tournament. Those who have not brought clubs can rent them at the Sea View Club for a nominal sum. While it is desired to have the entries made early, they will be accepted at the first tee on the course up to the beginning of play on Sunday morning.

STREET STOKERS IN SERVICE

C. F. Street, vice-president of the Locomotive Stoker Company, states that there are now in actual service 583 locomotives equipped with the Street stoker. Of these 583 stokers, 184 are applied to Mallet locomotives, 287 to Mikados, 75 to engines of the Santa Fe type, 27 to Consolidations, 6 to Pacific type passenger locomotives, 3 to Mountain type locomotives and 1 to a locomotive of the Centipede type. In addition this company is delivering 34 stokers to the Chesapeake & Ohio, 24 of which are for new locomotives and 10 for application to existing engines, and has an order for the application of stokers to the 12 locomotives of the 2-10-2 type which are to be built for the New York, Ontario & Western.

A. E. MANCHESTER'S FIFTIETH ANNIVERSARY

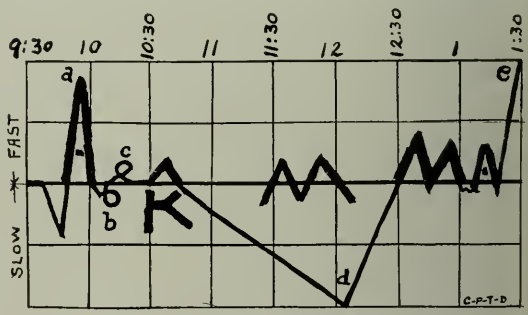
A. E. Manchester, superintendent of motive power, of the Chicago, Milwaukee & St. Paul, celebrated his fiftieth anniversary of continuous service with this road at Milwaukee on December 16, 1914. He was tendered a banquet by 250 of his associates and friends. J. F. DeVoy, assistant superintendent of motive power, was the toastmaster and the address of the evening was made by Burton Hanson, general solicitor of the road. Mr. Manchester was presented with a loving cup and an autograph album containing the names of all officials under his jurisdiction. Later he received a bound volume of the addresses of the evening, together with various clippings from magazines and newspapers publishing an account of the banquet.

Mr. Manchester is 68 years old and started with the road as a machinist at Portage, Wis., now on the LaCrosse division, when the road operated but 46 locomotives. He has held, successively, the positions of roundhouse foreman, division foreman of engines and master mechanic, and was appointed assistant superintendent of motive power in 1893. He was appointed to superintendent of motive power June 15, 1901. He joined the Master Mechanics' Association in 1894 and the Master Car Builders' Association in 1907, having missed only two or three of the conventions since he started to attend.

The guests at the banquet included the Governor of Wisconsin, Emanuel Phillips; J. H. Hiland and E. D. Sewall, vice-presidents of the St. Paul road; J. W. Taylor, assistant to the president; J. T. Gillick, assistant to the general manager; W. S. Cooper, general superintendent, and several division superintendents; S. P. Bush, president of the Buckeye Steel Castings Company, and Mr. Manchester's predecessor, James McNaughton, vice-president, American Locomotive Company; Charles Ridell, Baldwin Locomotive Works; H. T. Bentley, superintendent of motive power and machinery, Chicago & North Western, and all of Mr. Manchester's subordinates who were able to attend.

JOE TAYLOR'S EFFICIENCY CHART

They made a lot of fun of Joe Taylor and his efficiency methods at the meeting on Wednesday morning, but at the end of the session Joe was able to get up and demonstrate that he had made a schedule for the first day's session which worked out with fairly good results, even if it did have a stormy time at various times during the morning. Some of the committee chairmen had to duck when Joe developed the fact that he was forced to lay out his program before all of the committee reports had been turned in. The meeting



(Puzzle: Can you find A. R. M. M. A.?)
Joe Taylor's Efficiency Chart

started out 15 minutes late but closed 10 minutes ahead of time. The following notes will explain the various kinks in the diagram:

a—High peak of President Gaines' address.

b—Treasurer's report—not "in the hole" as chart indicates.

c—Taylor's report—looping the loop.

d—Locomotive stokers—Time lost was due to no *failure*, but there were four makes of stokers on the engine and there was not coal enough to keep them all supplied—capacity, 15,000 lb. each.

e—The fog at this point of the chart represents only an infinitesimal part of the smoke prevention in Chicago.

ADDITIONAL EXHIBITS

We said that H. Baker & Company, Inc., were making an exhibition of tool steel in space 364 in our list of exhibitors yesterday. Everyone who knows anything about the tool steel business would know we meant H. Boker & Company, Inc.

The Camel Company announces the substitution of A. B. Wegener as attending the convention in its interests in place of A. B. Wegecier, as we stated in our list of exhibitors yesterday.

Jerome-Edwards Metallic Packing Company, Chicago, is to to be found in space 362 with models of super-heat packing. Geo. C. Jerome and N. Huggins are representing the company.

The Hulson Grate Company, whose home office is in Keokuk, Iowa, is showing a new device in locomotive grate at space 365. Mr. A. W. Hulson is explaining its merits.

A new coupler and samples of a new replacer are to be found in space 311, shown by the Kelley Railway Appliance Company, of Gradyville, Ga. The company is represented by A. C. Kelley and O. Starling.

The Simplex Air Brake & Manufacturing Company, of Pittsburgh, Pa., whose exhibit is to be found in space 614, is showing engine air brake equipment. Milton D. Hays, the president, and Peter Wertz, the inventor, are in attendance, assisted by J. N. Weaver, Adam Goodwin and James Wardley.

Master Mechanics' Association Proceedings

Includes President's Address, Report on Stokers and Discussion on Compounding and Tender Side Bearings

The first session of the forty-eighth annual convention of the American Railway Master Mechanics' Association was held in Atlantic City, June 9, 1915. President F. F. Gaines called the meeting to order at 9.45 a. m. The past presidents and the officers of both the American Railway Master Mechanics' Association and the Master Car Builders' Association were invited to take seats on the platform. The opening prayer was made by the Reverend Doctor Newton D. Cadwell, Pastor of the Olivet Presbyterian Church of Atlantic City.

ADDRESS OF PRESIDENT GAINES

In looking over the developments of the past year, I do not recall any radical departure in locomotive design. There have been, however, developments along other lines which I recommend to you for the most serious consideration.

F. F. Gaines
President, Master Mechanics' Association

I will admit that personally I have been somewhat against the idea of one mechanical railroad association heretofore, believing that there was sufficient work and a broad enough field for the existence of the present organization. However, I think that the time has now come when we should have, under whatever title we may choose, one organization only, divided into such sections as may be found advisable. Most of the members of the various associations come under the jurisdiction of the mechanical department of a railroad. It would seem to me not only advisable, but very desirable, that some such new association should be formed to take over to a certain extent control of all the others. They need not necessarily meet at the same time; in fact, I think it would be better to spread the meetings out as at present, but the executive committee of the supreme association should pass upon the work of the minor associations.

Heretofore, the great argument for consolidation has been the saving of time, and I will admit frankly that my objection to consolidation has previously been on the basis that little could be done along this line; however, whether time can be saved or not seems to me a minor consideration and one that can be determined later. It is rather a question of having one recognized supreme authority on all mechanical matters pertaining to railroad work.

Until very recently the work of the Master Mechanics' Association has been more of an educational character with very few standards and very few specifications. This situation is now, of course, being changed, but I wish most urgently to call attention to the advisability of having standards for such things as it is possible to standardize in the way of methods, and also specifications for all classes of material used in locomotive

E. W. Pratt
First Vice-President, M. M. Association

work. Our standing committee has done some very valuable work, but I do not think we have nearly completed the task. We should be in a position at any time to say that such and such is our standard practice; or, that we have a specification for such material.

I would also suggest to the Committee on Specifications that in drawing up specifications for material they be not too rigid in their requirements; in other words, we want to obtain a fair grade of material under such specifications, but we do not want the specifications of such a nature as to involve a greatly increased cost, which would have the effect of a majority of the railroads not using them. After we have gone further into the matter in the way of standards and specifications a committee should be appointed to confer with the American Railway Association; the committee now in existence on Relations between Railways and Legislation might try to get the Ameri-

can Railway Association to lend its efforts toward the adoption by the railroads of such standards and specifications as the Master Mechanics' Association, or its successor, may produce.

I have several times, from the floor, called attention to the committees not issuing their reports until just a few days before the opening of the convention. It is exceedingly important that the committees get to work early in the year and have their reports in the hands of the secretary in time, so that they may be published and distributed at least two weeks before the opening of the convention. Many times it would add to the value of the proceedings and the information of the members were these reports available a sufficient length of time to allow of gathering data and investigating practices, so as to be able to discuss them intelligently and, perhaps, produce further information. A more thorough discussion of the reports would also add very largely to the value of our proceedings and the amount of information obtained.

Another matter that is worthy of consideration, is the greater use on the various committees of associate and

William Schlafge
Second Vice-President, M. M. Association

F. H. Clark
Third Vice-President, M. M. Association

honorary members. Many of these have had an excellent technical training, are familiar with committee work and possibly have a greater amount of time at their disposal than men actually in railroad service. It has been suggested to me by one such member that he would be only too glad to work on any committee, help them get their reports in shape and lined up in such form as to be readily investigated and in the best form for discussion.

I would like to suggest to the incoming Executive Committee the taking up of the form in which reports are prepared for the association. It has been suggested that all reports should be indexed on the margin for ready reference, that the logical handling of the subject be followed through consecutively and that the report, in general, be made as clear and concise as possible.

We have now, to a greater or less extent, adopted the principle of representative membership in the Master Mechanics' Association. This should be further encouraged and those roads which have not taken out representative membership should be urged to do so, as there is no good reason why every railroad of any consequence should not recognize its obligations to make common cause for the common good and unite to consummate the objects for which the association exists, until we have practically a complete representative membership, the same as in the Master Car Builders' Association.

It would seem from reports that we are not giving thorough enough training to our inspectors who look after the Federal boiler law, safety appliance and other Interstate Commerce orders. It has also been recommended that the railroads pay more attention to the educating of road foremen of engines, enginemen and firemen, and provide a more thorough examination for firemen before promotion.

The University of Illinois has an elaborate testing plant, large enough and of sufficient capacity to take the heaviest locomotive that is built, and it has been suggested the matter of testing locomotives and appliances be conducted on this plant and the results furnished the members of the association, the railroads to bear the expense in proportion to the number of locomotives owned. A test under such conditions would be cheaper to make than if actual road tests were made by any single road, and on account of the locomotives being under cover and not subjected to the variations of temperature, etc., conditions would be practically uniform for all tests.

[Reference was made at this point to the promising outlook as the result of experimental work in the use of pulverized fuel and induced draft.]

Consideration should be given to the developing and refining of present types of locomotives on economic lines rather than size or weight solely. Furthermore, while this association discusses engineering questions and questions of locomotive practice; it does not go very deep in the discussion of whether investment in either equipment or appliances brings returns on the investment. Do we investigate sufficiently the question of what becomes of the dollar

that we spend for these items? Very little is heard concerning cost. It might also be well to give consideration to the cost of doing various standard classes of work in different shops, so that those of us who are working inefficiently may see just where the leaks are and make the necessary changes to reduce the expense. Every member of this association should put himself in the attitude of a business man towards a dollar. As items that would be of interest to all, I suggest a partial list: Cost of small tools and supplies; cost of power in power houses; comparative costs and results from using Thermit, oxy-acetylene end electric welding; cost of tube work, turning locomotives, staybolt renewals, spring repairs, turning driving wheels, and fitting up driving boxes, shoes and wedges. If basic figures could be obtained on these, we could work more intelligently towards reduced cost.

Do we know, when a new engine of a new type is put in service whether its increased weight, capacity and cost are justified? Do we follow up this matter and obtain sufficient data to justify our expenditures? Do we know when a new

Angus Sinclair
Treasurer, M. M. Association

and improved machine tool is purchased and placed in the shop whether or not the cost is justified by the output?

The theoretical advantages of the superheater are well known; the practical saving in cost that can be accomplished is well known; but do we know that we are getting anything like this in every day service? Do we keep behind our roundhouse foreman to see that tubes are cleaned, superheater surfaces kept clean, joints kept tight, and that the proper handling for best results on the road is being carried out? If we do make these investigations, do we keep the operating department informed of them? Do we keep them informed as to results of improved devices and designs? Do we give information as to costs to subordinates in correct form so that they may analyze the results and endeavor to make reductions?

ASSOCIATION BUSINESS

The minutes of the last meeting were approved by the association.

The secretary's report showed the following figures regarding membership: Active, 979; associate, 19; honorary, 47, making a total of 1061. The report of the treasurer showed a cash balance of $1,213.28.

The report of the treasurer was received and referred to an auditing committee consisting of W. E. Dunham (C. & N. W.); M. D. Franey (N. Y. C.), and M. H. Haig (A. T. & S. F.).

The secretary reported on the two students attending the Stevens Institute of Technology on the Association's scholarships, stating that there are two vacancies in the scholarships at this Institute. He also stated that Joseph T. Ryerson & Son have increased the amount of their annual donation to cover two scholarships of $300 each, to take the place of one scholarship of $500. It was also arranged to increase the number of educational institutions at which the scholarships would be available. One scholarship will be vacant in June, 1915. Another scholarship will be available in 1916.

J. W. Taylor
Secretary, M. M. Association and M. C. B. Association

The secretary also referred to the proposed change in the constitution submitted last year in regard to the payment of dues. It was proposed to change Article III, Sec. 3, to read as follows:

"All active and associate members of the Association excepting as hereafter provided, shall be subject to the payment of such annual dues as it may be necessary to assess for the purpose of defraying the expenses of the Association, provided that no assessment shall exceed $5 a year."

In Article III, Sec. 3, Paragraph 2, it is proposed to have it read as follows:

"A representative member shall pay in addition to his personal dues as above, an amount for each additional vote to which he is entitled, as shall be determined each year by the Executive Committee, prorated upon the cost of conducting

such tests as may be determined upon at each convention."

These amendments to the Constitution were adopted.

The President: We have been pretty hard pressed financially for the last three years; quite a large number of the roads in various parts of the country have taken representative membership, and that has helped us out to some extent, but many of the roads have not done so. I hope you gentlemen will urge whoever may be the proper party with whom to take up this matter, that they will approve of the members of the Association acquiring this representative membership, because it is quite necessary for us to have the money which such representative membership will bring if we are to prosecute the work of the Association in a diligent manner.

The Secretary: At a meeting of the Executive Committee held last evening the question of a change in the hour for holding the election of officers, which was referred, during the closing hours of the convention of 1914, to the Executive Committee, was considered. It was thought that the plan now in force in M. C. B. Association, should be adopted by this Association and to conform thereto changes in the Constitution have been proposed. These changes will lie over until the next convention, in accordance with the requirements of the constitution.

At a meeting of the Executive Committee held last evening it was decided to recommend that the dues of active and associate members be fixed at $5 per year and representative members at $7 per one hundred engines per year.

(The action of the Executive Committee was approved.)

The Secretary: I move that W. C. Hayes, as the representative of the Traveling Engineers' Association, be accorded the privileges of the floor during this convention. (The motion was seconded and carried.)

LOCOMOTIVE STOKERS

Another year's experience with the locomotive stoker strengthens the conviction that it is not only accomplishing its purpose but withstands the test of continuous service with remarkable durability. Designs are being studied with the view of fixing the point of failure where repairs can be conveniently made, preferably without a road delay, and when it so happens that repairs can not be made on the road, the emergency can be met by resorting to hand firing until terminal is reached. The theory that the parts of the stoker be amply strong and in excess of the strength of the engine has its advantages.

In the consideration of designs, attention is being given the

A. Kearney
Chairman, Committee on Mechanical Stokers

matter of accessibility of parts, as well as certain features of the locomotive that are now, in some cases, difficult to reach on account of the stoker. Any of the stokers now in extensive use will, it seems, occasionally become inoperative by clogging. Viewing the prevention of foreign matter reaching the vital parts of the stoker as probably impracticable, the use of a reversible engine has been advocated, and, in fact, is receiving attention.

Time and experience have brought progress in the way of improving the manipulation of the scatter-type stokers, both in the care of the machine, as well as in a more efficient use of fuel. Instructions and experience have effected marked improvement on the operation of the stokers, and now it is rather rare to find a fireman disturbing the grates so long as a sufficient steam pressure is maintained to handle the train efficiently and successfully. The maximum depth of the fire should vary with the physical character of the coal, and to a degree with the chemical constituents in the ash. The committee is of the opinion that where the fireman will use his judgment the operation can be successfully manipulated with less physical exertion, and this precaution will result in reducing loss of fuel through the grates and relief valves, as well as reducing the physical effort on his part.

The cost of stoker maintenance has been somewhat affected in the aggregate during the past year by the modifications, improvements and changes introduced currently. From data gathered from the scatter-type stokers in more extensive use, the cost per 100 miles ranges from 43 cents to 68 cents, and the miles run per failure from 1000 to 5000.

Since the advent of the locomotive stoker it has been an open question as to whether it is more economical to prepare coal at wharves or on the tender of the locomotive. The aggregate cost of maintenance of a crusher at a wharf may be less than that for a number of locomotives, and it should not be forgotten that while crushers may be obtained that will fairly well handle the major portion of foreign matter found in fuel, it is conceded difficult to cope with such conditions after it reaches the locomotive. Regardless of this, however, it may be economical to equip locomotives with individual crushers on account of the proportion or volume of fuel supplied.

During the past year the Norfolk & Western put in operation sixteen Hanna and thirteen Standard stokers. The twenty-nine stokers were provided with crushing facilities on the tender to handle run-of-mine coal. The first few months these stokers were in operation some trouble was experienced while using run-of-mine fuel containing a large proportion of lump, on account of the presence of foreign matter. This, however, has been practically eliminated, or at least very much reduced, by constructing the conveyor to carry such foreign matter within reasonable sizes through to the fire bed with the fuel.

The past year has been marked by the successful performance of the Hanna and Standard stokers, which at the time of the committee's last report had been in actual service but a few months. Fifteen Hanna stokers have been applied to Mallet engines (2-6-6-2), 72.2 sq. ft. of grate area, and twelve Standards to Mastodon engines (4-8-0), 45 sq. ft. grate area, on the same road. They are handling sometimes slack and in other cases run-of-mine coal, from which the product under 2½ in. has been screened. The locomotives equipped with these stokers have been put in general fast and slow freight service, and in many cases the hardest runs on the division for which the respective types of locomotives are selected. These stokers, as well as the Street, have continued their successful work, each having its characteristic features.

The following stokers are reported in active service: Crawford, Street, Hanna, Standard, Kincaid, and Ayers.

Crawford Stoker. (Underfeed.)—At the present time there are 282 Crawford double-underfeed stokers in operation on the Pennsylvania Lines West of Pittsburgh. The stoker is still the only underfeed type in service. In addition to these 2 are being tried experimentally on the Bessemer & Lake Erie, 4 on the Vandalia and 3 on the Pennsylvania Lines East of Pittsburgh, making a total of 291 in service. It is reported that a new pattern of the Crawford stoker, known as type "30," is being constructed for test.

Street Stoker. (Overfeed or Scatter Type.)—The Street stoker still shows the largest number in service, totaling 531, with 24 on order. The type *C* stoker, which is the latest design, has a variable-speed engine and a friction clutch, instead of differential gear that was employed in the earlier type machines. The type *A* machine carried a crusher on the tank, but in the latter designs the crusher was set aside, the conviction being it was better under certain conditions to supply the fuel that would pass through the 2½ in. mesh on the locomotive tender. These stokers are in operation on fifteen railroads. The Street stokers are operated in passenger, general fast and slow freight service, performing their work satisfactorily. The machines have done remarkable work, on account of their durability, and nothing more is needed in their favor than their record and applications made. The principle upon which the machine is designed and operates is very widely known.

Hanna Stoker. (Overfeed or Scatter Type.)—The Hanna stoker is equipped with durable crushing facilities on the tank, consisting of a heavy helicoid conveyor screw and a bulkhead containing a restricted opening, partly encircled by two stationary knives. Coal is forced through the restricted opening in the bulkhead by the revolving conveyor screw, assisted by the two stationary knives for breaking the larger lumps. This stoker handles slack as well as run-of-mine coal quite efficiently.

regardless of weather conditions and moisture of the fuel. In the event of one of the stokers breaking down, it does not necessarily mean a failure, as the stoker is provided with two distinct recourses to be utilized in such emergencies; first, if any part of the tender conveyor becomes inoperative, the conveyor can be thrown out of operation by means of a clutch and the coal can be shoveled into the locomotive hopper through an opening in the deck; secondly, if the entire stoker becomes inoperative, coal can be shoveled to the plate by hand, from which it is driven to any section of the firebox by means of a blasting chamber and distributing plate. With the assistance of the distributing wings, which is a feature of the machine, the use of the fire hook is materially decreased.

Standard Stoker. (*Overfeed.*)—The Standard stoker is equipped with adequate crushing facilities on the tank, consisting of a durable helicoid conveyor screw and a bulkhead having a restricted opening partly surrounded by fixed center-punches. Coal is forced through the opening in the bulkhead by the revolving conveyor screw, assisted by the stationary center-punches for crushing the larger lumps. The apparatus is so constructed that it will handle moist coal quite satisfactorily. During the past year 20 Standard stokers have been put in operation, making a total of 22 in actual service. These stokers are being operated in slow and fast freight service, and are working satisfactorily. As has been previously explained, the stoker is under the deck of the engine, leaving the deck and boiler head clear. The machine makes very little noise in its operation, has a good distributing feature, and is very simple in its control. The latest development of the stoker is the type *AB*, which we understand possesses a number of distinct improvements over the type *A* stoker.

Gee Stoker. (*Overfeed or Scatter Type.*)—The Gee stoker continues in service on a consolidation locomotive on the Pennsylvania Lines East of Pittsburgh. It is still undergoing development.

Kincaid Stoker. (*Overfeed or Scatter Type.*)—The Kincaid stoker, which for the past year has been under development on a Chesapeake & Ohio yard engine, continues to progress. The distributing features of this stoker are attached to the fire door. Coal is shoveled into a hopper elevated in front of and attached to the door, from which it gravitates to a distributing apparatus and is delivered to the firebox. It is reported that a conveyor has been worked out and will be applied.

Elvin Stoker. (*Overfeed or Shovel Type.*)—The Elvin stoker is of rather novel construction, and is the only one that has not substituted some other device or devices for the scoop. A number of stationary tests have been made with the stoker, and it is thought that within the near future the machine will be tested out on a locomotive.

Raite Stoker. (*Underfeed or Overfeed.*)—The Raite stoker, claimed by the inventor to be either an underfeed or a scatter type, is the only one which the committee has any knowledge of that embodies a combination of the two methods. George B. Raite, of Indianapolis, advises that this stoker is still being developed and will soon be ready for application. The inventor further claims that special features were recently worked out which should materially improve the distribution of coal and aid combustion.

Ayers Stoker. (*Chain Grate.*)—The Ayers stoker, the sole member of the traveling-grate-type family, reports progress. Last summer and fall a number of experimental trips were made with this stoker as applied to a N. Y. C. engine, the results of which are reported to be encouraging. During the past winter the stoker has been further developed, and it is thought that it will soon be ready for service.

The following is a list of the operative stokers:

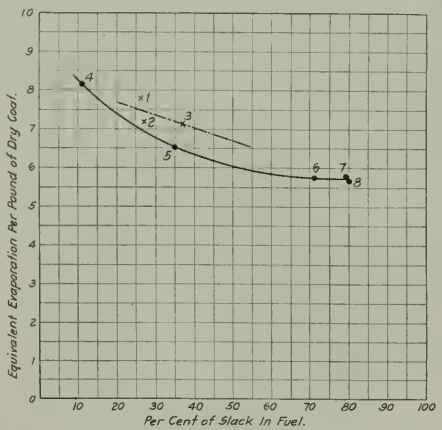
	Stokers in Active Service.	Stokers on Order.
Street	548	35
Crawford	301	31
Hanna	18	6
Standard	28	92
Gee	1	0
Ayers	1	0
Kincaid	1	0

Records have been taken during the past year with the scatter-type stoker in road service, and among others, observations were made on the Norfolk & Western, with a 4-8-0 locomotive having 24 in. by 30 in. cylinders, 200 lb. steam pressure, and a tractive effort of 52,437 lb.

Analyzing the results relating to fuel consumption, it was apparent that the amount of coal consumed varied according to its physical characteristics. The significance of the effect of the physical properties of the fuel stoker fired is shown in the accompanying chart, representing the relation between equivalent evaporation per pound of dry coal and the proportion of physically fine product in the fuel. It is found that the evaporative values of the coal vary inversely with the amount of the slack content. By the latter is meant the amount of fuel that passed through a 4-mesh-per-square-inch screen. It will be observed from the table giving the analysis of the different fuels considered that the variation in fuel consumption were hardly influenced by the difference in the quality of the fuel, except as it varied in physical properties.

For the Pocahontas nut fuel, which contains 11 per cent slack, the equivalent evaporation was 8.2 lb. of water per pound of dry coal, while for the Pocahontas slack, of practically the same heat value, but where the percentage of slack was about 80 per cent, the equivalent evaporation was only 5.6 lb. of water per pound of dry coal. Since these varying conditions of consumption were obtained while hauling the same identical train, with no change made in the drafting or any other feature of the locomotive, it was concluded that the fuel consumption with coal containing a higher percentage of the finer product took place, on account of a large percentage of the latter being carried through the flues and out through the stack before being completely consumed.

In conclusion it seems safe to say that the mechanical stoker has demonstrated by extensive service that it is capable of supplying coal to a locomotive firebox at a rate and under sufficient control to satisfactorily maintain the working steam pressure. It is also obvious, being a machine and working continuously, it should be capable of maintaining a more regular rate of steaming



All Fuel That Will Pass Through Four Mesh Per Sq. In. Screen Is Termed Slack.

Curve Showing Influence of Physical Properties of Fuel Upon Boiler Performance with Scatter Type Locomotive Stoker

with certain grades of fuel than might be obtained in average hand-firing practice. Greater work is done with the stoker, in terms of speed or tonnage, or both, under certain physical and operating conditions, while in another service with equally large engines and heavy tonnage, but under more favorable grade line and fuel conditions, as high efficiency has been obtained hand-firing.

As interesting as it would be to define the relation between hand and stoker firing, it is as difficult of determination as the fixing of the rate of efficiency for hand-firing. Many observations have been made and the range of possibility has been fairly well determined, but as can be appreciated, the enormous variable introduced by fuel and physical conditions makes the problem very complex.

The committee feels itself unable to point to any rule in terms of weight of engine or train load, or general conditions, where the stoker will always be applicable or necessary on account of the wide range of physical and operating conditions, as well as character of fuel, and the question of fuel is by no means a minor factor, for the reason that the choice of available coals demands consideration of their character as well as price, as the net result of using some of the finely divided grades of stoker-prepared or mixed coal may be offset by a more attractive rate of consumption, better evaporation, and lower cost per ton-mile

with run-of-mine after it has been crushed to the desired grade.

The report is signed by:—A. Kearney (N. & W.), Chairman; M. A. Kinney (H. V.); T. R. Cook (Penn. Lines); J. W. Cyr (C., B. & Q.); A. J. Fries (N. Y. C.); J. T. Carroll (B. & O.), and J. R. Gould (C. & O.).

DISCUSSION

A. Kearney (chairman): Some reference is made indirectly in the report to the damage to coal handled through the stokers. You will notice the committee speaks of run-of-mine coal being handled through the stoker, as compared with the same coal hand fired. That is on account of the further crushing of the coal as it passes through the helicoid screw. That is quite reasonable, and it was also noticeable in the results.

W. C. Hayes, Erie: I would like to ask if attention has been given to the question of the relative difference in the cost of the stokers and their value to the roads on which they are used.

Mr. Kearney: In order to get at the figures Mr. Hayes has mentioned, we would probably have to make a determination as to just how far we will be justified in spending money for a stoker. That has never been worked out.

L. R. Pomeroy: A locomotive with from 4,500 to 5,000 sq. ft. of heating surface, would require over 8,000 lb. of coal per hour. If it established that the stokers could easily handle 8,500 lb. of coal per hour, and the ordinary fireman can only handle 4,500 lb., the difference ought to be a measure by which you could compare and rate this economy and value of the stoker.

Mr. Kearney: On our stoker engines we have run up to about 12,000 lb. per hour.

D. R. MacBain (N. Y. C.): The mechanical stoker will increase the hauling capacity of the large locomotive, on such as they are installed, anywhere from 250 to 500 tons over what can be hauled with a fireman, and it seems to me that when you get into figures of that kind, that a few hundred dollars in the initial cost of the stoker applied to the locomotive might very consistently be lost sight of for the time being, while the developing is going on.

W. C. A. Henry (Penn. Lines): The Pennsylvania Lines West, within the last month, have ordered 50 consolidation locomotives having a tractive power of 53,000 lb. They were all to be equipped with the Crawford stoker. The stoker enables us to get about 8 to 10 per cent more ton miles per hour on the road, which makes it an attractive proposition. None of these locomotives have brick arches. Our passenger locomotives, however, where the fire box is deep enough to permit it, have arches. We have found the reversing mechanism for the stoker to be very nice, and all are being equipped with a very simple mechanism, by which the direction of the travel of the piston can be reversed at any time. There is no special preparation required as we simply use run-of-mine coal. The conveying mechanism, however, is so constructed that in case of a lump of such size that would interfere, the conveyer will not find it. If it finds its way to the opening of the conveyer mechanism, it will be broken.

M. K. Barnum (B. & O.): Stoker failures on the Baltimore & Ohio are very rare. From memory I should say that with about 223 stokers we are not having more than one or two failures a month, and those are of minor importance. We are getting excellent results on our power and in fact are operating some 2-10-2 locomotives with the stoker, which are probably larger than we could operate by hand firing, and get anything like satisfactory results.

W. E. Symonds: In connection with the item of the relative cost of the stoker; it has occurred to me to be not improper to suggest that the cost of a stoker at present might properly be compared with the salary of an additional fireman, which would be necessary on the large type of locomotives in order to work them to their capacity with hand firing.

C. F. Street (Loco. Stoker Co.): The important feature of the stoker is this question of increased capacity, and all these other features sink into insignificance when compared with it. I have never claimed that the locomotive stoker would save fuel. On the other hand, there are a great many devices which are put on the locomotives which will save fuel but are being used as economy increasers instead of fuel savers. The superheater is first and essentially a capacity increaser in actual service. Theoretically it is also a fuel saver. The stoker is essentially and only a capacity increaser. The stoker has made possible the building of locomotives which could not be run without stokers. I think none of the 2-10-2 types of locomotive, which have been introduced within the last year, and which was referred to by the president in his address, would ever have been built, had it not been known that a stoker could be secured for firing.

This increased tonnage possible with these larger locomotives is best illustrated by a remark made by A. N. Willsie, of the Chicago, Burlington & Quincy, at the recent convention of the International Railway Fuel Association held at Chicago, where he made a statement that the 2-10-2 type of locomotive, stoker fired, will haul 1,483 more tons than with a hand-fired Mikado, and that is a Mikado having 60,000 lb. tractive power. I said the stoker is not a fuel saver. He said the cost of coal per 10,000 ton miles is 34 cents, as against 45 cents for the Mikado, hand-fired.

Regarding the question of maintenance, we have been aiming at 50 cents per 100 miles and that varies in accordance with the manner in which the records are kept. Some roads keep records which include the cost of inspection in the cost of maintenance, and some would ignore that. It just depends on the way the records are kept. The same thing is true with regard to failures. I cannot help think that the miles run per failure of 1,000 to 5,000 is pretty low. I had a report recently from a superintendent of motive power, saying that his stoker fired locomotives had made 90,000 miles without a record of stoker failure at the present time. It just depends on what you call a stoker failure.

This report gives a curve which shows that the rate of fuel consumed, the water evaporated, varies in proportion to the amount of slack in the fuel. That is absolutely true up to a rate of burning of from 60 to 70 lb. of coal per square foot of grate. The water evaporated per pound of coal up to that point is not affected materially by the amount of slack in the coal, but when you get up to burning 120 to 150 lb. of coal per square foot of grate, the efficiency falls off in proportion to the amount of slack in the coal; and exactly the same thing is true in hand firing. I have seen reports of tests where there was an increase in the coal consumption of 20 per cent, owing only and absolutely to the amount of slack that there was in the coal used for hand firing. The difference probably is about the same with stoker firing, but only at the high rates of burning. With the stoker there is no condition of a steam failure no matter how high a rate of burning is used, while with hand firing when you get above a certain proportion of slack in the coal, it is impossible to maintain steam pressure. With the stoker it makes no difference how much slack there is in the coal; in fact, it is possible to stoke a fire and maintain steam pressure with coal that needs no lumps in it at all any larger than a finger nail, but of course it will take a larger amount of coal to produce those results.

Another feature which is important, in the development of the stokers, is the ability to use a much lower grade of fuel. This condition obtains in the West more than in the East. I have seen 15,500 lb. of coal put through a stoker in an hour; this was for a short time. Under those conditions of course the locomotive did not burn it economically.

I would not say that under all conditions on large locomotives, that the application of a stoker would enable increased tonnage. There are undoubtedly conditions under which large locomotives are working at slow speeds, where the stoker will not give you any marked increase in tonnage. The important feature is increased tonnage and increased average speed of heavy freight trains. That is what the stoker has actually accomplished.

Mr. Kearney: The committee mentioned here that the stoker failures ran between 1,000 and 5,000 miles per failure. The information is obtained from the firemen, and it is obtained after going over the record very critically. Last year the failures were taken from the despatchers' sheets and there they ran up four times the figures now published.

(Mr. MacBain called attention to the importance of providing ample diameter of stack.)

E. A. Averill (Standard Stoker Co.): I would like to emphasize what Mr. Street has been saying in his remarks in connection with the stoker on locomotives, which is primarily a matter of increased power or the opportunity given to use the power that is in the locomotive. In one case where tests were made, carefully conducted tests, it developed that the application of stokers on that particular division, to those particular engines, would result in saving approximately $100. per engine per month. That was very largely due to increased tonnage, and partially due to the elimination of the second fireman during the hot months. The report states: "If now the same grade of run-of-mine coal is retained for hand-firing, and in comparison we use the same coal with the stoker, crushing it on the locomotive, we might expect to find a difference of probably ten per cent in evaporated efficiency in favor of hand-firing." It may be true, of course, in some cases, but the tests I have been on and several others have shown under those conditions mentioned, using the same coal, and crushing it on the tender, the stoker does not use any more coal hand-firing, and on another test, it ran as high as 7 or 8 per cent in favor of the stoker in equivalent evaporation per pound of dry coal. These deductions were gained from two separate tests. These tests indicate that the conditions in arranging for the test were

such that the stoker was not extravagant in fuel, and did not use any more fuel than in hand-firing. In the case where it was given the opportunity of developing the full capacity of the locomotive it showed an evaporated efficiency as high as 11 or 12 per cent on the same basis.

Mr. Kearney: Do not forget there is quite a difference between Pocahontas and the higher volatile coals, and that was particularly mentioned in the report, and it was stated that in other fields an entirely different condition would obtain from that which is obtained with the use of Pocahontas coal.

REVISION OF STANDARDS AND RECOMMENDED PRACTICE

After consideration of the present Standards and Recommended Practices of the Association, together with the replies received to the Circular of Inquiry sent to the members, and instructions and other information received from the Executive Committee and from the Secretary of your committee, would submit the following report:

[Only the most important changes which were approved of by the committee are given below.—EDITOR.]

SPECIFICATIONS FOR STEEL AXLES FOR LOCOMOTIVE TENDERS (Standard)
Page 475.

The committee recommends the revision and modification in form of the present Specifications for Steel Axles for Locomotive Tenders, the requirements agreeing with the Standard of the M. C. B. Association.

JOURNAL BOX, BEARING AND WEDGE. (Standard and Recommended Practice)

For journals 6 in. by 11 in. Sheets M. M. L M and N.
Page 479.

A member suggests advancing these details to Standards from Recommended Practices. The committee concurs in the suggestion.

SPECIFICATION FOR BOILER AND FIREBOX STEEL. (Standard)
Pages 490-492.

The committee recommends the revision and modification of the present specifications for boiler and firebox steel as shown in Appendix *A*.

SPECIFICATIONS FOR LOCOMOTIVE DRIVING AND ENGINE TRUCK AXLES. (Standard)
Page 499.

SPECIFICATIONS FOR LOCOMOTIVE FORGINGS. (Standard)
Page 500.

The committee recommends the revision and modification of the present specifications for locomotive driving and engine truck axles and the present specifications for locomotive forgings and combining them in one, specifications for annealed and unannealed carbon-steel axles, shafts and other forgings for locomotives as shown in Appendix *B*.

SPECIFICATIONS FOR LOCOMOTIVE CYLINDER CASTINGS, CYLINDER BUSHINGS, CYLINDER HEADS, STEAM CHESTS, VALVE BUSHINGS AND PACKING RINGS. (Standard)
Pages 503-504.

The committee recommends the revision and modification of the present specifications for locomotive castings, cylinder bushings, cylinder heads, steam chests, valve bushings and packing rings as shown in Appendix *C*.

SPECIFICATIONS FOR CAST-STEEL LOCOMOTIVE FRAMES. (Recommended Practice)
Page 504.

The committee recommends the revision and modification of the present specifications for cast-steel locomotive frames substituting for them the specifications for steel castings for locomotives, as shown in Appendix *D*.

INSPECTION AND TESTING OF LOCOMOTIVE BOILERS. (Standard)
Pages 531-538.

The committee recommends the revision of these standards to conform to the latest revision in the Federal Regulations for the Inspection and Testing of Locomotive Boilers and their appurtenances.

NEW BUSINESS

Through the Secretary a communication was received advising that the Arbitration Board of the Master Car Builders' Association had been called upon for some rule in the Code to cover the use of brakes on locomotives handled dead in train and offered in interchange. An expression on this subject was requested from the A. R. M. M. Association, the details being referred to this committee. After considerable investigation the committee recommends the following regulations covering the operation of brakes on engines and tenders handled dead in train and offered in interchange:

1. All engines equipped with side rods must have them applied, when handled dead in trains, suitable washers, of wooden blocks clamped together with bolts, being used where necessary on main rod bearings to keep the side rods in place.

2. All engines and tenders hauled dead in trains must have the air brakes cut in and operative on drivers, trailers and on tender trucks.

3. Engines and tenders equipped with the Westinghouse ET, or New York LT brake must have the safety valve on the distributing valve, or control valve, adjusted to not less than 25 lb. or more than 30 lb.

4. Engines and tenders equipped with the automatic and straight air combined must have the safety valve in brake cylinder pipe adjusted to not less than 25 lb. or more than 30 lb.

5. Engines equipped with Westinghouse ET, or New York LT brakes, or with straight air must have positive stops applied to handles of automatic and independent valves to secure these handles in running position.

6. Engines and tenders equipped with high speed brake without the straight air, must have the high speed reducing valve set to reduce the brake cylinder pressure to not less than 25 lb. or more than 30 lb., or must have a safety valve applied to the brake cylinders or the brake cylinder pipe set to not less than 25 lb. or more than 30 lb.

7. Engines and tenders equipped with only the automatic brake must have a safety valve applied to the brake cylinders or the brake cylinder pipe set to not less than 25 lb. or more than 30 lb.

W. E. Dunham
Chairman, Committee on Revision of Standards and Recommended Practice

8. Engines fitted with power brakes other than air must be equipped with an air train line and connections.

9. Delivering line will be held responsible for flat spots on driving tires, trailer tires and tender truck wheels.

10. Owners shall be responsible for any special application of safety valves as required in Sections No. 3 to 8, inclusive.

The report is signed by:—W. E. Dunham (C. & N. W.), chairman; A. R. Ayers (N. Y. C.); M. H. Haig (A. T. & S. F.); A. G. Trumbull (Erie), and C. D. Young (Penn.).

APPENDIX A

SPECIFICATIONS FOR BOILER AND FIREBOX STEEL FOR LOCOMOTIVE EQUIPMENT

1. Scope.—These specifications cover two grades of boiler steel and shall be designated as flange steel and firebox steel.

MANUFACTURE

2. Process.—The steel shall be made by the open-hearth process.

CHEMICAL PROPERTIES AND TESTS

3. Chemical Composition.—The steel shall conform to the following requirements as to chemical composition:

	Flange.	*Fire-box.*
Carbon		0.12–0.25 per cent
Manganese	0.30–0.60 per cent	0.30–0.50 per cent
Phosphorus, not over	acid 0.05 per cent	0.04 per cent
	basic 0.04 per cent	0.035 per cent
Sulphur, not over	0.05 per cent	0.04 per cent
Copper, not over		0.05 per cent

4. Ladle Analysis.—An analysis shall be made by the manufacturer from a test ingot taken during the pouring of each melt, a copy shall be given to the purchaser or his representative. This analysis shall conform to the requirements in Section 3.

5. Check Analysis.—Analysis may be made by the purchaser from a broken tension test specimen representing each plate as rolled, which shall conform to the requirements specified in Section 3.

III. PHYSICAL PROPERTIES AND TESTS

6. (a) The steel shall conform to the following requirements as to tensile properties:

	Flange.	*Fire-box.*
Tensile strength lb. per sq. in.	56 000—85 000	52 000—62 000
Field point lb. per sq. in.	0.5 tens. str.	0.5 tens. str.
	1 560 000	1 500 000
Elongation in 8 in. min. per cent	Tens. str.	Tens. str.

(b) The yield point shall be determined by the drop of the beam of the testing machine.

7. Modification in Elongation.—For material over ¾ in. in thickness a deduction of 0.5 from the percentages of elongation specified in Section 6 (a) shall be made for each increase of ⅛ in. thickness above ¾ in. to a minimum of 20 per cent.

8. Bend Tests.—(a) COLD-BEND TESTS.—The test specimen shall bend cold through 180 deg. without cracking on the outside of the bent portion as follows: For material 1 in. or under in thickness, flat on itself, and for material over 1 in. in thickness, around a pin the diameter of which is equal to the thickness of the specimen.

(b) QUENCH-BEND TESTS.—The test specimen, when heated to a light cherry red, as seen in the dark (not less than 1200 deg. F.), and quenched at once in water, the temperature of which is between 80 and 90 deg. F., shall bend through 180 deg., without cracking on the outside of the bent portion as follows: For material 1 in. or under in thickness, flat on itself, and for material over 1 in. in thickness, around a pin the diameter of which is equal to the thickness of the specimen.

9. Homogeneity Tests.—A sample taken from a broken tension test specimen shall not show any single seam or cavity more than ¼ in. long, in either of the three fractures obtained in the test for homogeneity, which shall be made as follows: The specimen shall be either nicked with a chisel or grooved on a machine, transversely, about 1-16 in. deep, in three places about two inches apart. The first groove shall be made 2 in. from the square end; each succeeding groove shall be made on the opposite side from the preceding one. The specimen shall then be firmly held in a vise, with the first groove about one-fourth inch above the jaws and the projecting end broken off with light blows of a hammer, the bending being away from the groove. The specimen shall be broken at the other two grooves in the same manner. The object of this test is to open and render visible to the eye any seams due to failure of weld or to interposed foreign matter, or any cavities due to gas bubbles in the ingot. One side of each fracture shall be examined and the length of the seams and cavities determined, a pocket lens being used if necessary.

ALLOWABLE EXCESS (EXPRESSED AS PERCENTAGE NOMINAL WEIGHT).

Thickness Ordered. In.	Nominal Weight Lb. per Sq. Ft.	For width of Plate, as follows: Under 50 in.	50 to 70 in. excl.	70 in. or over	Under 75 in.	75 to 100 in. excl.	100 to 115 in. excl.	115 in. and over.
1/8 to 5/32	5.10 to 6.37	10	15	20	.....	.....	.....	.....
5/32 to 3/16	6.37 to 7.66	8.5	12.5	17	.....	.....	.....	.....
3/16 to 1/4	7.65 to 12.20	7	10	15	.....	.....	.....	.....
1/4	10.20	.....	.....	.....	10	14	18	.....
5/16	12.75	.....	.....	.....	8	12	16	.....
3/8	15.30	.....	.....	.....	7	10	13	17
7/16	17.85	.....	.....	.....	6	.....	10	13
1/2	20.40	.....	.....	.....	5	7	9	12
9/16	22.95	.....	.....	.....	4.5	6.5	8.5	11
5/8	25.50	.....	.....	.....	4	6	8	10
Over 5/8	.....	.....	.....	.....	3.5	5	6.5	9

11. Number of Tests.—One tension, one cold-bend and one quench-bend test shall be made from each plate as rolled and in addition one homogeneity test shall be made from each plate made into fire-box material.

(b) If any test specimen shows defective machining or develops flaws, it may be discarded and another specimen substituted.

(c) If the percentage of elongation of any test specimen is less than that specified in Section 7, and any part of the fracture is outside the middle third of the gaged length, as indicated by the scribe scratches marked on the specimen before testing, a retest shall be allowed.

IV. PERMISSIBLE VARIATION IN WEIGHT AND GAGE

12. Gage.—The thickness of each plate shall not vary more than 0.01 in. under that ordered.

13. Weight.—An excess over the nominal weight corresponding to the dimensions on the order shall be allowed for each plate, if not more than that shown in the preceding table, 1 cu. in. rolled steel being assumed to weigh 0.2833 lb.

[NOTE:—Only the more important paragraphs of these specifications are printed here.—EDITOR.].

APPENDIX B

SPECIFICATIONS FOR ANNEALED AND UNANNEALED CARBON STEEL AXLES, SHAFTS AND OTHER FORGINGS FOR LOCOMOTIVES

1. Basis of Purchase.—(a) These specifications cover annealed and unannealed carbon steel driving axles, engine and trailer truck axles, main and side rods, piston rods, crank pins and miscellaneous forgings.

(b) The manufacturer may, at his option, furnish annealed forgings when unannealed forgings are specified by the purchaser, provided they conform to the requirements specified for unannealed forgings.

I. MANUFACTURE

2. Process.—The steel may be made by the open-hearth or other process approved by the purchaser.

3. Discard.—A sufficient discard shall be made from each ingot to secure freedom from injurious piping and undue segregation.

4. Prolongation for Test.—The manufacturer and the purchaser shall agree upon forgings on which a prolongation for test purposes shall be provided.

5. Heat Treatment.—For annealing, the forgings shall be allowed to become cold after forgings. They shall then be uniformly reheated to the proper temperature to refine the grain (a group thus reheated being known as an annealing charge) and allowed to cool uniformly.

II. CHEMICAL PROPERTIES AND TESTS

6. The steel shall conform to the following requirements as to chemical composition:

Carbon	0.38—0.52 per cent
Manganese	0.40—0.75 per cent
Phosphorus, not over	0.05 per cent
Sulphur, not over	0.05 per cent

7. Ladle Analysis.—(Same as in Appendix *A*).

8. Check Analysis.—Analysis may be made by the purchaser from a forging representing each melt, which shall conform to the requirements specified in Section 6. Drilling for analysis may be taken from the forging or from a full-sized prolongation of the same, at any point midway between the center and surface, or turnings may be taken from a test specimen.

III. PHYSICAL PROPERTIES AND TESTS

9. Tension Tests.—(a) The forgings shall conform to the following minimum requirements as to tensile properties: For forgings whose maximum outside diameter or overall thickness is not over 12 in. when unannealed and not over 20 in. when annealed.

UNANNEALED

Size, Outside Diameter or Overall thickness	Tens. Str. lb. per sq. in.	Yield point lb. per sq. in.	Elongation in 2 in. per cent. Inverse Ratio	Elongation in 2 in. per cent. Not under	Reduction of area per cent. Inverse Ratio	Reduction of area per cent. Not under
Not over 8 in.	75 000	0.5 tens. str.	1 600 000 / tens str.	18	2 200 000 / tens str.	24
Over 8 to 12 in. inclusive	75 000	0.5 tens. str.	1 500 000 / tens str.	17	2 000 000 / tens str.	22

ANNEALED

Not over 8 in.	80 000	0.5 tens. str.	1 800 000 / tens. str.	20	2 800 000 / tens. str.	32
Over 8 to 12 in., inclus.	80 000	0.5 tens. str.	1 725 000 / tens. str.	19	2 640 000 / tens. str.	30
Over 12 to 20 in., inclus.	80 000	0.5 tens. str.	1 650 000 / tens. str.	18	2 400 000 / tens. str.	28

(b) The classification by size of the forging shall be determined by the specified diameter or thickness which governs the size of the prolongation from which the test specimen is taken.

(c) The yield point shall be determined by the drop of the beam of the testing machine.

(d) Tests of forgings shall be made only after final treatment.

10. Tension Test Specimens.—(a) Tension test specimens shall be taken from a full-sized prolongation of any forging. For

forgings with large ends or collars the prolongation may be of the same cross section as that of the forging back of the large end or collar. Specimens may be taken from the forging itself with a hollow drill, if approved by the purchaser.

(b) The axis of the specimen shall be located at any point midway between the center and the surface of the forging, and shall be parallel to the axis of the forging in the direction in which the metal is most drawn out.

(c) Test specimens shall be of the form and dimensions shown in the former specification.

11. Number of Tests.—Unless otherwise specified by the purchaser, tests shall be made as follows:

(a) For unannealed forgings one tension test shall be made from each melt.

(b) For annealed forgings one tension test shall be made from each annealing charge. If more than one melt is represented in an annealing charge, one tension test shall be made from each melt.

(c) If more than one class of forgings by size is represented in any lot, one tension test from a forging of each class by size shall be made as specified in Sections 9 and 10.

(d) If any test specimen shows defective machining or develops flaws, it may be discarded and another substituted.

(e) If the percentage of elongation of any tension test specimen is less than that specified in Section 9 (a), and any part of

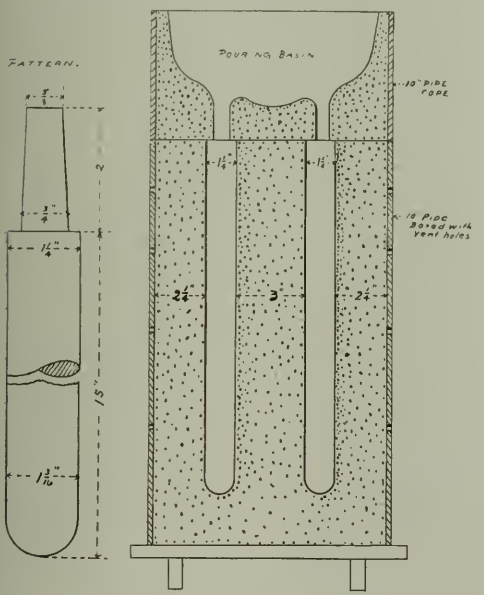

Fig. 1.—Mold for Arbitration Test Bar

the fracture is more than ¾ in. from the center of the gage length, as indicated by scribe scratches marked on the specimen before testing, a retest shall be allowed.

12. Retests.—(a) If the results of the physical tests of any test lot do not conform to the requirements specified, the manufacturer may reanneal such lot, but not more than three additional times unless authorized by the purchaser, and retests shall be made as specified in Section 11.

(b) When annealed forgings are specified, if the fracture of any tension test specimen shows over 15 per cent. crystalline, a second test shall be made. If the fracture of the second specimen shows over 15 per cent. crystalline, the forgings represented by such specimen shall be reannealed.

[NOTE:—Only the more important paragraphs of these specifications are printed here.—EDITOR].

APPENDIX C

SPECIFICATIONS FOR LOCOMOTIVE CYLINDER CASTINGS, CYLINDER BUSHINGS, CYLINDER HEADS, STEAM CHESTS, VALVE BUSHINGS AND PACKING RINGS

I. MANUFACTURE

1. Process.—Locomotive cylinders, cylinder bushings, cylinder heads, steam chests, valve bushings and packing rings shall be made from good quality close-grained gray iron cast in a dry mold.

II. CHEMICAL PROPERTIES AND TESTS

2. Chemical Composition.—Drillings taken from the fractured end of the transverse test bars shall conform to the following limits in chemical composition:

Phosphorus, not over	0.90 per cent
Sulphur, not over	0.12 per cent
Manganese, not over	0.70 per cent
Silicon for cylinders only, not over	1.60 per cent
Silicon for bushings, heads, chests and rings	1.50 to 1.80 per cent

3. Check Analysis.—A check analysis of drillings taken from the transverse test bar may be made by the purchaser, and shall conform to the requirements specified in Section 2.

III. PHYSICAL PROPERTIES AND TESTS

4. Transverse Tests.—When placed horizontally upon supports 12 in. apart and tested under a centrally applied load, the arbitration test bars, specified in Section 6 (a), shall show an average transverse strength of not less than 3200 lb. and an average deflection of not less than 0.09 in. The rate of application of the load shall be from 20 to 40 sec. for a deflection of 0.10 in.

5. Chill Test.—Before pouring, a sample of the iron shall be taken and chilled in a cast-iron mold, as specified in Section 6 (b). The sample shall be allowed to cool in the mold until it is dark red or almost black, when it may be knocked out and quenched in water. The sample, on being broken, must show a close-grained gray iron, with a well defined border of white iron at the bottom of the fracture. The depth of the white iron must not be less than 1-16 in. as measured at the center line.

6. Molds for Test Specimens.—(a) The mold for the arbitration bars is shown in Fig. 1. The bottom of the bar is 1-16 in.

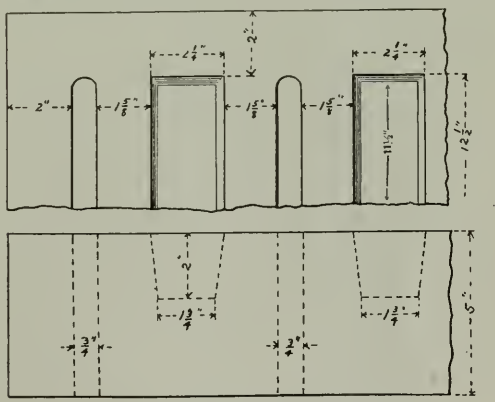

Fig. 2.—Mold for Chill Test Specimen

smaller in diameter than the top, to allow for draft and for the strain of pouring. The pattern shall not be rapped before withdrawing. The flask is to be rammed up with green molding sand, a little damper than usual, well mixed and put through a No. 8 sieve, with a mixture of 1 to 12 bituminous facing. The mold shall be rammed evenly and fairly hard, thoroughly dried and not cast until it is cold. The test bar should not be removed from the mold until cold enough to be handled. It shall not be rumbled or otherwise treated, being simply brushed off before testing.

(b) The form and dimensions of the mold for the chill test specimen shall be in accordance with Fig. 2.

7. Number of Tests.—(a) Two arbitration test bars, cast as specified in Section 6 (a), shall be poured from each ladle of metal used for one or more cylinders.

(b) One chill test, cast as specified in Section 6 (b), shall be poured from each ladle of metal used for one or more cylinders. The chill specimens may be cast in adjacent molds, but in such cases a space must be provided between the molds. (See Fig. 2.)

[NOTE:—Only the more important paragraphs of these specifications are shown here.—EDITOR].

APPENDIX D

SPECIFICATIONS FOR STEEL CASTINGS FOR LOCOMOTIVES

1. Basis of Purchase.—These specifications cover steel castings for locomotive frames, wheel centers and miscellaneous castings.

I. MANUFACTURE

2. Process.—The steel may be made by the open-hearth, crucible or other process approved by the purchaser.

3. Heat Treatment.—Castings shall be allowed to become cold.

They shall then be uniformly reheated to the proper temperature to refine the grain (a group thus reheated being known as an annealing charge) and allowed to cool uniformly and slowly. If, in the opinion of the purchaser or his representative, a casting is not properly annealed, he may at his option require the castings to be reannealed.

II. CHEMICAL PROPERTIES AND TESTS

4. Chemical Composition.—The steel shall conform to the following requirements as to chemical composition:

TABLE I

	Frames		Wheel Centers and Miscellaneous Castings
	Grade A	*Grade B	
Carbon	0.25—0.37 per cent	0.37—0.50 per cent	0.22—0.35 per cent
Manganese	0.40—0.75 per cent	0.40—0.75 per cent	0.40—0.75 per cent
Phosphorus, not over	0.05 per cent	0.05 per cent	0.05 per cent
Sulphur, not over	0.05 per cent	0.05 per cent	0.05 per cent

*When high carbon steel frames are specified this grade shall be used.

5. Ladle Analysis.—An analysis shall be made by the manufacturer from a test ingot taken during the pouring of each melt, a copy of which shall be given to the purchaser or his representative. This analysis shall conform to the requirements specified in Section 4.

6. Check Analysis.—Analysis may be made by the purchaser from a test piece and also from any casting selected at random, and shall conform to the requirements specified in Section 4.

III. PHYSICAL PROPERTIES AND TESTS

7. Tension Tests.—(a) The steel shall conform to the following minimum requirements as to tensile properties:

	Frames		Wheel Centers and Miscellaneous Castings
	Grade A	Grade B	
Tensile strength lb. per sq. in.	65 000	75 000	60 000
Elastic limit lb. per sq. in.	30 000	35 000	25 000
Elongation in 2 in., min. per cent.	20	15	22
Reduction of area, min. per cent.	28	22	30

(b) The elastic limit shall be determined by an extensometer.

8. Alternative Tests to Destruction.—In the case of small or unimportant castings, a test to destruction on three castings from a lot may be substituted for the tension tests. This test shall show the material to be ductile, free from injurious defects and suitable for the purpose intended.

9. Test Specimen.—(a) Sufficient test bars shall be furnished from which test specimens required in Section 7 may be selected. They shall be attached to castings weighing 500 lb. or over, when the design of the castings will permit. If the castings weigh less than 500 lb., or are of such a design that test bars cannot be attached, two test bars shall be cast to represent each melt; or the quality of the casting shall be determined by testing to destruction as specified in Section 8. All test bars shall be annealed with the castings they represent.

(b) The manufacturer and the purchaser shall agree whether test bars can be attached to castings, on the location of the bars on the castings, on the castings to which bars are attached, and on the method of casting unattached bars.

(c) If the purchaser, or his representative, so desire, a test specimen may be cut from a finished casting, such casting so destroyed shall be paid for by the purchaser.

(d) The purchaser shall have the privilege of taking drillings for analysis from a casting, so long as it does not destroy or weaken the casting.

(e) Tension test specimens shall be of the form and dimension shown in the previous specifications. Annealing coupons shall be located at points agreed upon by the manufacturer and the purchaser.

10. Number of Tests.—One tension test shall be made from each locomotive frame, and in the case of wheel centers and miscellaneous castings, from an annealing charge, or from each melt if more than one melt is in an annealing charge.

IV. VARIATION IN WEIGHT

11. Weight.—All castings shall come within the maximum and minimum weight, where shown on the prints, and when castings weighing more than the allowable maximum weight are presented, such castings shall be accepted at the maximum weight provided they meet all other tests, the excess weight being at the expense of the manufacturer.

[NOTE:—Only the more important paragraphs of these specifications are printed here.—EDITOR].

DISCUSSION

C. D. Young (Penna. Lines): The committee in rendering the report incorporates the original silicon requirement for bushings, heads, chests and rings. With the increasing use of super-heated steam, it is becoming very desirable to have a close grained hard iron for this purpose and I believe the time has arrived when we should reduce the silicon requirement to make it agree with the silicon mixture requirement. I move that the bushings, heads, chests and rings have the same silicon requirement as that which is specified for cylinders, namely, 1.60 per cent.

(The motion to accept the report of the committee as amended, was put to vote and carried.)

SAFETY APPLIANCES

M. K. Barnum (B. & O.): The committee has only a verbal report to make. The committee met with the special committee on Relation of Railway Operation to Legislation and the subject was discussed at some length, but it was not thought necessary to make any written report, in view of the fact that the time limit expired several years ago for the full equipment of locomotives with the safety appliances which had been prescribed. The committee would therefore respectfully recommend that it be discharged.

(The report of the committee was accepted and the committee discharged.)

COMPOUNDING SUPERHEATER LOCOMOTIVES

Lawford H. Fry, (Baldwin Loco. Works): The conclusions which I wish to offer for discussion this morning are, first, the fact that compound cylinders applied to a single expansion locomotive will show a saving in fuel and water of from 15 to 25 per cent, whether saturated or superheated steam be used. I wish further to show that in securing the saving some additional complication is introduced, and the question as to whether compounding is practically worth while or not can only be answered after studying the local conditions in each case. Take first the process by which compounding effects a saving in steam consumption. If any given range of expansion be divided between two cylinders instead of being carried out in one, the same amount of work can be obtained with a smaller consumption of steam. This is due to the fact that the range in temperature in the steam coming in contact with any one portion of the cylinder will be reduced, and consequently the thermal losses, in initial condensation, will be less. In addition to this, compounding offers a further opportunity for economy, by making it feasible to use a higher ratio of expansion than can be efficiently done with a single expansion engine.

In a single expansion locomotive it will be found that the greatest economy is obtained with a cut-off at about 30 per cent of the stroke and that with a shorter cut-off in spite of the theoretical advantage of a higher expansion the practical result will be a decrease in efficiency. Take for example, the K-29 superheater, Pacific type locomotive of the Pennsylvania Railroad, tests of which are described in the Company's Bulletin No. 19. The diagram on page 98 of this Bulletin shows that while the rate per indicated horse-power-hour was 18 lb. for cut-offs between 30 per cent and 35 per cent, it grows to 20 lb. when the cut-off was shortened to 25 per cent. This is largely due to the action of the valve gear, which, if it is to be adapted to all the requirements of locomotive service, cannot operate economically at very short cut-offs. To quote from the Bulletin referred to above—"The ideal conditions in regard to the expansion of steam in the cylinder would be to admit steam up to the cut-off point and then expand it to the atmospheric pressure before release. With the necessity for draft on the fire and the practical limitations of valve gears this is not possible and the steam must be discharged at a comparatively high pressure." The Bulletin then gives figures showing that the number of expansions (that is the volume of steam at release divided by the volume at cut-off) is 1.37 for a cut-off of 45 per cent, 1.75 for a cut-off at 30 per cent, and 2.0 for a cut-off at 25 per cent. This means that at the most economical cut-off of 30 per cent, the steam is being released at a pressure of about 51 lb. per sq. in. As this steam may carry some superheat, or at least is perfectly dry, there would obviously be considerable advantage in expanding it further. The use of compound cylinders will enable the effective ratio of expansion to be practically doubled.

It should be noted that it is not only the limitations of the valve motion which prevent a high ratio of expansion in a single cylinder on a locomotive. If the valves were modified so as to make efficient the use of a high expansion in a single cylinder, there would still be a mechanical advantage in dividing the expansion into two cylinders so as to produce a more uniform cylinder tractive force. With a high ratio of expansion in a single cylinder there will be a wide difference between the initial and the final pressures, and consequently a considerable difference between the tractive force during admission and the mean tractive force average throughout the stroke. Therefore, if the cylinders be made large enough to allow the mean tractive force to utilize a proper proportion of the weight on drivers, there will be a danger of slipping during the time of maximum cylinder pressure while steam is being admitted. By dividing the expansion, the difference between

maximum and minimum pressure in each cylinder is reduced, and with the cylinders quartered a more uniform tractive force is obtained. Practically all of the foregoing applies equally whether the locomotive uses saturated or superheated steam, but the last point is of special importance in connection with superheated steam, since with this medium there is more to be gained by a high ratio of expansion. In fact, if the expansion is insufficient the steam when exhausted will still be superheated, a condition which represents avoidable waste. Having stated briefly the reasons for expecting economy in steam consumption with compound cylinders, let us now see what results are being obtained in practice. In Europe there is a growing tendency to use compound cylinders with superheated steam, and all reports show that the results are satisfactory.

In France five of the six principal railways have adopted four-cylinder compound superheater engines as standards for both freight and passenger service, and after comparative trials are abandoning the single expansion cylinders. A paper by Mr. Sauvage before the English Institution of Mechanical Engineers reports that the Paris-Lyons and Mediterranean Railway in tests of Pacific type engines in service found that the single expansion consumed from 19 to 21.5 lb. of water per 1 h. p. per hour, and the compound from 13.5 to 15.0 lb., a saving of nearly 30 per cent.

In Germany, during the past three years compound cylinders have been reintroduced for the latest high speed passenger engines of the 4-6-0 type, and are reported as giving satisfactory results. Comparative tests have shown a water consumption per horse power hour of 23.8 lb. for the single expansion and 18 lb. for the compound, approximately 25 per cent saving.

In England the majority of superheater engines have single expansion cylinders, but some of the railroads are trying compounding, and Mr. Fowler of the Midland Railway, in a paper read before the Institution of Civil Engineers, last year, gave some results of comparative tests between four engines, all similar except for the quality of steam used and the number of cylinders. Two of the engines were two-cylinder single expansion, one using saturated and one superheated steam, while the other two were three-cylinder compounds, one was saturated, the others with superheated steam. Taking the performance of single-expansion saturated steam locomotive as a basis of comparison, the following savings in coal were observed: Compounding alone, 15 per cent; superheating alone, 25 per cent; compounding and superheating, 37.5 per cent.

Having seen the evidence that the saving can be obtained, let us consider the difficulties to be overcome in order to secure it. In the first place there will be a slight increase in first cost, and an increase in weight of 2 or 3 per cent, the latter being offset, however, by the better balance to be obtained with 3 or 4 cylinders. There will be more pistons, rods, valves, etc., requiring increased attention and maintenance, but the division of power between more than two cylinders may prove advantageous by reducing the power to be transmitted by each rod. In addition to this multiplication of parts the designer must provide for a crank axle and must find space for the large low pressure cylinders. These problems have been solved in European practice; and although the difficulty is increased by the size of the locomotives in this country, their solution should not be beyond the power of our American designers.

There is one further point of importance to be considered if a compound is to run at anything more than a slow speed, and that is the question of back pressure, the larger area of the low pressure cylinder makes the engine more susceptible to the evil effects of back pressure. In order that the engine may work successfully and efficiently at high speed the blast pipe must operate with the lowest possible pressure and the exhaust passage be designed to offer the least possible resistance to the steam.

With expensive fuel and ample opportunities for supervision and maintenance, the conditions will favor compounding, but whether the saving is practically worth while or not will depend on local conditions.

George R. Henderson, (Baldwin Loco. Works): We all know the principal gain in compounding is by eliminating cylinder condensation. We also know that the superheater gets its main value in reducing or doing away with the cylinder condensation, and if we do away with the condensation by one means, it hardly looks reasonable that we can expect still to get the same amount of economy by trying to do away with it a second time. It would be very easy to make a compound locomotive more economical by the use of superheated steam, more so than to make a superheater locomotive more economical by compounding. What I mean is that a certain temperature, up to 200 or 250 degrees of superheat will prevent any condensation in the simple cylinder up to probably one-fifth cut-off, or five expansions normally. Now, if we go ahead and increase our superheat still greater, we increase the volume of our steam, it just happens that we get about the same ratio of increased work. If we go so far as to have superheated steam at the moment of exhaust, we have so enlarged our volume per pound of steam or water, that we cannot go on with the increasing amount of superheat and get a corresponding amount of economy. These things look to the fact that it is necessary in the tests mentioned by Mr. Fry to know whether in all cases the amount of superheat, that is the temperature of the steam, was the same, and whether all the conditions were strictly comparable.

Mr. Fry: I have very complete data on the English tests here, and so far as I can see they were as nearly comparable as possible. In regard to the point Mr. Henderson made about the opportunity for saving being less because the initial condensation is done away with, I think the superheater makes a saving at the other end of the stroke. With the single expansion engine the compounding cuts down the initial condensation. With the superheater engine it tends to save the steam you would throw away dry or slightly superheated. With the single expansion superheater, you do not get much initial condensation, but you have to throw away good dry steam at a fairly high pressure, but if you put another cylinder on behind that you can make that steam still do some work.

C. D. Young (Penn.): I think the conclusions Mr. Fry has drawn are quite correct, except that I would like to add that there hardly seems the possibility in this country, with our operating conditions, that we will go to compounding to any great extent on high speed engines. High speed carries with it a fairly high maintenance of the parts, which, as you all know, is rather difficult to obtain. Whether compounding or superheating would give you as fast an engine, with equivalent draw-bar pull, as the simple superheater engine, I much question. Even though you may have superheated steam with the compounding, you still have the problem of getting rid of a large quantity of steam from the low pressure cylinder, and also of obtaining a sufficient amount of steam to supply the high pressure cylinder, in comparison with the amount you must furnish to the low pressure cylinder. It seems to me for American practice, it is a question whether we will use compounding, for passenger work particularly. The requirements of slow speed lend themselves to compounding, and it is the ideal thing to have.

I believe if we could provide a valve design that would withstand a temperature of 800 deg. F., and you could obtain superheat in that vicinity, you would then get a proportional increase that would warrant a higher superheat than we are getting today with the average modern locomotive. I believe if that matter is to be met, so far as economy is concerned, it will have to be met in that direction. We are getting experience every year in the maintenance of parts subject to high superheat, and our experience in that direction should lead to the development of an efficient valve, different from the piston type of valve, perhaps a pocket type of valve, made of material which will withstand high superheat.

Prof. L. E. Endsley (Pittsburgh University): I think Mr. Young's point regarding the increasing of the superheat is important. We must, however, take care of the lubrication and some other things, and if we can do that, the gain of the last 100 degrees is going to be more than the gain of the first 100 degrees of superheat. In tests from 80 degrees to 240 degrees superheat, making three steps—80, 160 and 240, at three different temperatures—the last 80 deg. is worth three times as much as the first 80 deg. If I could go to 320 deg. the last 80 deg. would be worth considerably more.

I do not think we will get much advantage through compounding our American locomotives, if we get a large enough cylinder in the simple engine. All we want to do is to reduce pressure in our steam down to the point where it will get enough draft to steam the locomotive, and if you put on a compound cylinder and reduce it too low, to make the engine steam, you will not get the increased power we are getting today, by reason of the superheat. I think it is important that we get something to carry a higher degree of superheat, and then we will not have to go to the compounding and add to our troubles by the employment of a double set of cylinders and other things.

William Flynn (M. C.): We have 90 compound engines on our division, and at the present time we have about 12 of these engines equipped with superheaters. The results have so pleased the mechanical department, as well as the operating department, that I think I am safe in saying that we will apply superheaters to the balance of those locomotives. On the division where we conducted one of our most important tests we found we could increase the tonnage of the superheater compound over the saturated compound 15 per cent. That seems an astonishing figure, but it is true; and the superheater compound would

handle that increased tonnage more satisfactorily than a saturated compound would do it, and not burn quite as much coal. These are used in slow speed freight service. We had occasion to put one of these superheater compounds on a passenger train, and we found the engine would run about 10 or 12 miles faster than an engine of the same class without the superheater-compound arrangement.

Mr. Henderson: There is a difference between superheating compounds and compounding superheaters. With Mallet locomotives, for instance, there is a great advantage in the compounding feature, one being that the flexible pipes carry steam of moderate pressure, about 100 lb. The superheater is a great advantage there, because there is certainly some loss in temperature in passing through the receiving pipe, and you can put in a superheater in that engine, to make up for cylinder expansion and also loss of temperature in your pipe, and there is no question in such an engine it is a great advantage to have low pressure in the flexible pipes. I feel that if we need a little more economy, we had better get a little more superheat. The problem of superheating compounds is more logical than that of compounding superheaters.

Mr. Fry: Before compounding superheater locomotives over here we must weigh very carefully the disadvantages of the increased complication, and as a general proposition I doubt very much if it will be widely adopted in this country.

SMOKE PREVENTION

[The committee report on this subject covered very thoroughly the system employed by the railways in Chicago in handling the smoke problem. This system has been quite thoroughly described in these columns and special attention is called to the abstract of the paper on Smoke Prevention presented before the International Railway Fuel Association, published in the *Railway Age Gazette* of May 21, 1915, and the *Railway Age Gazette, Mechanical Edition* for June.—Editor.]

DISCUSSION

M. D. Franey (N. Y. C.): Speaking for the Fourth District of the New York Central Lines, we have a smoke washing device at our Englewood engine house. We handle approximately from 80 to 100 locomotives at that point each 24 hours. The smoke washing device consists of a 78-in. steel blade fan, motor driven. The house is piped with a conduit or duct extending over the portion of the house that is usually occupied by the smoke jackets. Connecting each pit with this smoke jacket is an adjustable telescope jack that fits down with a funnel over the smoke stack of the locomotive. The smoke is drawn up by means of the fan through the jacks and ducts and delivered at high velocity into vats of heated water, heated by steam. The action is such that it produces a wave motion and envelops the smoke and gases several times as they pass out through baffles and finally disappear through the stack. The solids, carbons, etc., are gathered on the top of the water in the form of a foam. The other gases pass out with steam whiteness from the top of the stack, and as they disappear it is very evident that the carbon is taken from the smoke. We obtain from eight to ten barrels of carbon out of the smoke,—this is pure carbon—and the whole plant is working very satisfactorily.

We have this disadvantage, that the acids produced are very injurious to the metals, and it even will eat out the concrete of which the duct or vat is composed. We have found it necessary in making the ducts, to make them of transite—that is the best product we have obtained so far. I am not prepared at this time to give you official figures, but from tests we have made, unofficial tests, the figures seem to be satisfactory and show a saving in fuel on engines stored in the engine house.

L. R. Pomeroy: Is there any salvage from the by-products of these plants?

Mr. Franey: We have deposited considerable of the carbon, but I am not prepared to say to just what extent it has been made a paying proposition.

Wm. Elmer, Jr., (Penna. Lines): I can say a word about Buffalo. The city council has endeavored for a year or more to agree on some ordinance, which would be acceptable to the manufacturing industries and to the railroads, regarding smoke prevention. Without an ordinance the railroads have done a good deal toward reducing the amount of smoke which the engines are making. All the railroads are alive to the situation and making every possible effort to prevent the making of very dense smoke, so as to forestall any drastic efforts of the part of the Council.

E. W. Pratt: I do not think there is anything special to say except to urge on those who have not had to go through the experience we have gone through, to cut down the smoke nuisance as much as they can before the authorities take action. If we had done that in Chicago we would not now be up against the expensive problem of electrification. The final report on that matter has not yet been made public but will cost approximately $192,000,000 for the cost of the electrification, and another $100,000,000, or $200,000,000, for incidental betterments due to changes in motive power. We will have to do some business to provide the interest on that $300,000,000.

LITTLE INTERVIEWS

The expert on car wheels leaned back and remarked, "Some of the desirable features of a car wheel are inadvertent, as you may say. Do you see that street car wheel? The holes in the body of the wheel are extremely useful, but they do not in any degree serve the purpose for which they were first introduced. Originally the street car wheel was cast with spokes. As equipment became heavier the wheel was cast solid. The solid wheel was objectionable; in cities there was complaint that it rang. These holes it was hoped would deaden that ringing. Now, in my opinion, the wheels continue to ring just the same, but the holes in the wheel are retained since they are so convenient to hook chains into to drag the car and truck around when a wheel is broken."

Conventionalities

Burton W. Mudge came to the conventions alone this year. Burton, Jr., was in school, it was not desired to take him out, and Mrs. Mudge decided to stay at home with it.

L. A. Richardson, mechanical superintendent first district, Chicago, Rock Island & Pacific, Des Moines, Iowa, who arrived

B. P. Flory, Superintendent Motive Power, New York, Ontario & Western

on the Chicago special Tuesday, is accompanied by his daughter, Miss Dorothy. They are stopping at the Traymore.

John P. Landreth, of the Garlock Packing Company, is accompanied this year by Mrs. Landreth and little daughter. The fact that the little girl is familiarly known as "Ginger"

Hugh Montgomery of the Bangor and Aroostook, and George Wildin of the New Haven

indicates correctly that she has certain of the qualities of her energetic father.

F. W. Brazier, superintendent of rolling stock of the New York Central, is down a little early this year in order to get rested up in time to get in his usual hard work at the M. C. B. Association next week. He has been a little bit "under the weather" lately.

The Q. & C. Company has unintentionally been exalted by the "printer's devil." In the list of exhibitors yesterday it was shown as the O. & C., and for a little while, not being able to find the name, friends of the company were afraid that their exhibit had not arrived safely.

President Gaines of the M. M. Association has been ill for the past two or three weeks and has not yet fully recovered his strength. He found it necessary to have Secretary Taylor read his address yesterday morning, but was able to preside over the remainder of the session.

Friends of W. L. Allison, vice-president of the American Arch Company, were asking yesterday morning why it was that "Bill" had not come to the conventions this year. They will be glad to know that he is here and on the job, his name being omitted from the list of representatives of his company through an oversight.

George Wagstaff, of the American Arch Company, in "Uncle George's Primer," specifically states in the preface that it is not his intention to be technical. Is this a joke? The first part of the answer to the third question, for instance, reads: "By virtue of its position the brick arch

J. S. Sheafe, Master Mechanic, Baltimore & Ohio

becomes an incandescent refractory barrier between the furnace chamber and the outlet of the products of combustion, etc."

W. E. Symons, consulting engineer, has been pretty busy lately in connection with investigations into the proportion of operating cost which should be assessed against locomotives and cars for terminal and road charges. On the basis of these studies he has testified at several of the law suits in southwestern states to good effect.

J. C. Little, mechanical engineer of the Chicago & North Western, has been leading a strenuous life for the past few weeks. The building in which his office was located was burned some time ago and about 1,200 tracings which were not in the vault were destroyed. Among these was a set of drawings for a new stock car which was just being designed and of which no copies had been made. Outside of this, however, it is hoped that with the aid of an extra staff of draftsmen the other drawings will be fully replaced within a short time.

Jack Daly, a boilermaker on the Philadelphia & Reading, has the distinction of having built a model locomotive which is attracting considerable attention both because of the neatness and care with which the details have been worked out and

the circumstances under which it was built. The model forms a part of the Q. & C. Company's exhibit, where it is in operation with Mr. Daly at the throttle. To complete the engine required four years of his spare time in the basement of his own home. At the time his wife was in a sanitarium recovering from a protracted illness and he was left in charge of two growing boys. With the exception of a small lathe and drill press only hand tools were used and these by a novice in all but the boilermaker's trade. The result is worthy of a skilled mechanic.

While we all know J. D. Hurley as a maker of pneumatic tools, it happens that he is also responsible for the Thor motorcycle. Like many other normally peaceful citizens of the railway supply fraternity, Mr. Hurley has been repeatedly asked to bid on implements of war needed by the allies. His latest inquiry was for a price on "one hundred motorcycles fitted with gun brackets," without specifications of any kind—just as though we were all in the habit of going about the country on power cycles fitted with guns. Many other requests for prices are fully as indefinite. They remind us of the days when foreign railways first began to buy American built locomotives in any considerable number. Most of the New York export houses at once jumped into the breach

F. H. Clark, General Superintendent of Motive Power, Baltimore & Ohio

and asked for quotations on for example, "ten Forney type engines." Some of the war munitions inquiries are equally absurd.

The Rock Island lines are unusually well represented at the conventions this year. The delegation is headed by W. J. Tollerton, general mechanical superintendent, and includes the following: L. R. Richardson, mechanical superintendent first district, Des Moines, Ia.; G. W. Lillie, mechanical superintendent second district, Topeka, Kans.; R. S. Stewart, mechanical superintendent third district, El Reno, Okla.; George S. Goodwin and C. G. Chenoweth, mechanical engineers, Chicago; George W. Hartman, general air-brake inspector, Chicago; S. W. Mullinix, superintendent of the Silvis shops; J. N. Milton, superintendent car department, Chicago, and F. O. Bunnell, engineer of tests, Chicago. Two or three of the general car foremen will be here for the Master Car Builders' convention. Mr. Tollerton served as a member of the conference committee of managers which represented the western railways in the recent arbitration of their differences with their engineers and firemen. The result of the arbitration was that certain classes of employees were given increases in pay, but on the whole it was a victory for the railways.

TOOL HOLDER FOR HIGH SPEED STEEL CUTTERS

The tool holder shown in the illustration was designed by the Keystone Equipment Company, 21st and Clearfield streets, Philadelphia, Pa., with a view to protecting the cutting edge of the tool against both vertical and lateral strain. It is made of cold drawn steel and is case hardened to insure durability. In the top is a slot in which the high speed cutter is placed, set screws being provided through one side of the slot to hold the cutter in place. At the end where the cutting edge projects beyond the slot the body of the holder is extended below the tool and is so shaped as to form practically a continuation of the cutter itself. To protect the tool against the side pressure due to the feed, the back side of the slot is extended behind the projecting end of the tool.

The upper face of the cutter projects about 1-32 in. above the top of the holder and when clamped in the tool post the pressure is exerted directly against the cutter, firmly holding the tool in place. The only purpose of the set screws is to

Keystone Tool Holder

hold the cutter in the holder when not in place in the tool post.

The reinforcement provided by this holder is claimed to make possible the use of as high speeds and feeds with the small high speed steel cutter as are possible with a solid forged tool of the same size as the holder. The method of inserting the tool also reduces the waste of cutting steel since the tool may be used until it is too short to catch the set screw or clamps on the tool holder. Owing to the large area of contact between the cutter and the holder the transmission of heat from the cutting edge to the body of the holder is claimed to be especially rapid and to add to the life of the cutting edge.

The Keystone tool holders are made both right hand and left hand and for both round and square nose tools in 14 different sizes. A complete set of these tools is on exhibit at the booth of the manufacturer.

SEAMLESS DRAWN STEEL GEAR CASE.—A seamless and rivetless drawn steel motor gear case for use on electric cars has been developed which is adapted to withstand the vibration to which this part of the electrical equipment is constantly subjected. The manufacturing methods used in constructing these cases combine the operations of pressing and drawing in such a manner that the metal of the finished case is of uniform thickness and therefore well adapted to withstand vibration. These cases have been applied by the Pennsylvania Railroad on electric passenger cars for use on main line electrification. One of the Pennsylvania gear cases, which are of unusually large size, is being exhibited by the U. S. Metal and Manufacturing Company, New York, representing the manufacturers, the Chillingworth Manufacturing Company, Jersey City, N. J., in the southern and New England States.

VOLUME 58 JUNE 11, 1915 NUMBER 24

Contents

*Illustrated.

The Gretna train wreck, May 22, killing nearly 200 soldiers before they had even seen a battlefield, is briefly reported in another column. The British railway system, with the reputation of being the safest in the world, now records almost the worst train wreck ever known. Once more "a very small error produces a very great horror." The causes, in detail, are not fully explained; but there is enough explained so that it is easy to tell what American railway officers will say; they will congratulate each other on the popularity, and the extending use, in this country, of the track circuit and of automatic signals. Track circuits for a quarter mile at Quintinshill interlocking would have held the signals against that troop train. The track circuit system does indeed, show a percentage of failures, but the decimal has to be extended out with a good many ciphers to make the percentage comprehensible; and comparisons of automatic and non-automatic block signals, where comparisons are possible, show that proportionately the men make many more mistakes than do the machines. The English roads have made extensive installations of track-circuit locking at stations during the last few years, and this disaster undoubtedly will be followed by a rapid extension of this simple yet wonderful safeguard. This is the outstanding lesson of the calamity, far transcending all others.

The Railroad Disaster at Gretna

In an editorial in these columns last week a comparison was made between the mileage and capitalization of roads in the hands of receivers at present, and on June 30, 1896, and the erroneous statement was made that the mileage of roads in the hands of receivers in 1896 was the greatest in the history of the United States. As a matter of fact, in 1895 there were 37,805 miles of road in the hands of receivers and in 1894, 40,817 miles, as against 30,475 miles in 1896 and approximately 30,500 miles at present. The comparisons of conditions in 1896 and at present, as given in the editorial last week, are of course correct, but the fact that there was 30 per cent more mileage in the hands of receivers two years previous to 1896 than in that year, is a fact which should have been stated in the editorial last week.

Roads in the Hands of Receivers

On June 2 the eastern roads put into effect rules requiring all persons checking baggage for interstate transportation to sign a declaration of its value, and similar regulations are to be applied by the western lines. If the value of the baggage is declared to be in excess of $100 a charge of 10 cents for each $100 or fraction thereof over that amount will be made for insurance. This is one of the unexpected and probably unintended results of the Cummins amendment, which was jammed through Congress in the closing hours of the session which adjourned on March 4. Although the law has gone into effect without causing the general increase in freight rates which for a time it was thought would result from the careless way in which it was drawn, its application to baggage will hardly tend to increase the popularity of the senator whose name is attached to it. Heretofore the carriers have limited their liability for loss of or damage to baggage to $100. The Cummins act prohibits any limitation of their liability for property transported with the proviso that "if the goods are hidden from view by wrapping, boxing or other means, and the carrier is not notified as to the character of the goods, the carrier may require the shipper to specifically state in writing the value of the goods, and the carrier shall not be liable beyond the amount so specifically stated. The Interstate Commerce Commission has ruled that the provisions of the law apply to baggage. The railroads therefore cannot limit their liability for baggage unless they obtain a declaration of its value, which then constitutes the maximum amount recoverable from the company. If the new rules result in inconvenience to the traveling public, as they doubtless will, the public can place the blame not on the railroads, but on its representatives in Congress who passed such a law without taking time to consider the conditions to which it applied. The railroads have endeavored to work out rules which will avoid the inconvenience to passengers as much as possible. The Pennsylvania has announced that it will require the declaration only where specifically required by the law—on baggage checked for interstate transportation—although some roads have taken the position that it will be simpler to apply the rules to both state and interstate transportation. Small blanks have been prepared on which the declaration may be made and signed, but once for several pieces of baggage at one time.

Passengers Must Declare Value of Baggage

The act makes it a misdemeanor for passengers to misrepresent the value and under the rules, if the baggage masters for any reason fail to obtain a declaration the baggage will not be forwarded. The roads will not insist, however, that the owner make out the declaration in person. It may be done by a servant or member of the family. Strong protests are already being made by commercial travelers, especially those who carry samples of high value, and who will be required to pay the insurance charge each time they check baggage. One result of the rules will be that passengers will have to allow themselves more time for the checking of baggage at stations and the railroads are making every effort to secure full publicity, so that passengers may be prepared. The railroads, of course, as an offset to the revenue they will derive from the insurance, will be subjected to greater expense by the increased liability they are required to assume and the additional clerical expense of obtaining and recording the declarations which will have to be preserved for six years.

CHICAGO, ROCK ISLAND & PACIFIC HEARING

THE important points which were raised at the hearing before the Interstate Commerce Commission last week in regard to the Chicago, Rock Island & Pacific Railway Company's receivership were:

The immediate necessity of the appointment of a receiver and the propriety of the application for a receivership by some of the directors without consultation with the other directors or with the Sheldon Committee; the sharp and crazy advance in the Railway company's stock on the New York Stock Exchange in the latter part of March and early part of April and its sudden collapse after the receivership; the question as to the fundamental necessity of the appointment of a receiver at all; and the Interstate Commerce Commission's relations with this whole affair.

Roberts Walker, who has since been appointed general counsel for the receivers, took largely the responsibility for the application for receiver. This application was made nominally by a supply concern and was for a comparatively trifling sum. The company consented to the receivership and as was brought out at the hearing it was at the instigation of the company that the application was made. There is nothing inherently improper in this sort of proceeding. It is often necessary to have a creditor for a small sum bring proceedings in order to forestall an unfriendly receivership. On the other hand, Mr. Amster, who was a newly-elected director, felt that he should have been consulted before the application was made. The Sheldon committee which had co-operated in getting proxies for the annual meeting which took place in March was not consulted. The facts of the matter are probable that if the intention of the company to submit to receivership had been known by Mr. Amster and his counsel, every possible legal difficulty would have been placed in the way of the appointment of receivers. This accounts for the decision not to take Mr. Amster into the confidence of the majority directors. As has been previously pointed out in these columns, there are numerous conflicting interests within the majority Rock Island directorate. It was this conflict of interests which led to the application without consultation with the Sheldon committee, but while this is probably the real explanation, it does not make the manner of application for the receivership defensible.

The Missouri Pacific's tangled affairs are being straightened out by co-operation and consultation between the various interests affected. It is to be regretted and very much deplored that in the matter of the Rock Island receivership a similar course could not have been followed.

Mr. Amster claims that he could have raised $6,000,000, to do which he would have had to pay off a lien of $4,100,000, which was secured by collateral on which he had planned to raise $6,000,000. This would have left $1,900,000 net new money. The receivers have found it necessary to issue $1,494,000 receivers' certificates and to keep in the treasury $505,000, which would have had to be paid on equipment notes May 1, but which has been deferred under the period of grace provision in the indenture. This is a total of $1,999,000 which the receivers found immediately necessary against $1,900,000 which Mr. Amster would have raised, to temporarily tide over the May 1 crisis. While the consideration of these facts is not entirely conclusive in answering the first point mentioned above as having been raised by the Interstate Commerce Commission's hearing, it would lead nearly any fair-minded outsider to the belief that there was no more immediate reason for the appointment of receivers on April 1 than on April 20, at least insofar as the company's interests as distinguished from the private interests of the directors were concerned. Furthermore, the method of application was questionable, and coming as it did from the interests which have already been so severely criticized for their theories of high finance is to be deplored.

Samuel Untermeyer, who plays a somewhat dual role in this Rock Island investigation, as protector of minority stock holders and aid to Gov. Folk, the Interstate Commerce Commission's counsel, insinuated that the high stock prices for the Chicago, Rock Island & Pacific the latter part of March were the result of the rigging of the market by speculators associated with the Reid-Moore people. It was obvious to anyone that the market in Rock Island shares, when they were selling up to 39, was an artificial one. There was no testimony which was undeniably conclusive that any of the insiders helped to create this high price. On the contrary, Mr. Amster and his counsel have accused the Moore-Reid people and President Mudge of giving out bearish interviews in regard to their own stock. The whole stock movement looked far more like an attempt of a clique of comparatively small speculators to put up the price than any attempt on the part of the controlling interests to make a market on which they could unload their holdings.

As to the fundamental necessity for the receivership for the Chicago, Rock Island & Pacific, the *Railway Age Gazette* has already expressed some views in the issue of April 23. The Sheldon committee when they first began to ask for proxies for the annual meeting had an expert make a report on the physical needs of the property and previous to that the management had come to the conclusion that a very considerable amount of new capital would have to be raised to conserve the assets of the company and to eventually increase its earning power to an extent which would make it possible to show a margin of safety above its interest charges. Against this expert testimony there is only the general statement of Mr. Amster and his associates that the property is a "fine property." It would appear to any disinterested student of Rock Island affairs that some readjustment of its finances was absolutely necessary. Whether or not such a readjustment could have been made without the receivership if the conflicting interests had been willing to co-operate in the best interests of the property, it is impossible to say. Without passing final judgment one way or the other, it would appear that strong banking support and unity of interests could more easily have kept the Chicago, Rock Island & Pacific out of the hands of the receiver than the Missouri Pacific. But the Missouri Pacific had the strong banking support and the Rock Island didn't, and the consequence has been that the Missouri Pacific is in a fair way to be reorganized without a receivership, while the Rock Island had to seek the protection of the courts. That Mr. Amster's $1,900,000 could have been anything more than a temporary and extremely frail support is inconceivable. Various plans were put forward, but no one of them promises success, nor could any assurance be given that the stock-holders would raise the needed money, and in the meantime it was thought best to have the court's protection.

One thing must appear most unfortunate to anyone who really has the best interests of the thousands of security holders of the Chicago, Rock Island & Pacific, as well as the interests of the hundreds of thousands of other railroad security holders at heart, and that is that this sort of a tangle should have come up before the Interstate Commerce Commission. There are now

three proceedings in the courts. One an application to intervene in the receivership proceedings by minority stockholders represented by Mr. Amster. One a suit to recover from the directors approximately $7,500,000 which was lost when the St. Louis & San Francisco was divorced from the Rock Island, and the third a general suit in equity to prove that the April 12 meeting was illegal under the Illinois construction.

These are questions in which the courts will see that the minority stockholders and other security holders have a fair and open hearing, and it is in these suits that the wrong doing, if wrong doing there has been, of the Reid-Moore people can be and should be brought out and redress exacted.

LATERAL STRESSES IN RAILS

THE magnitude of the stresses, both vertical and lateral, created in rails by locomotives of various types running under different conditions has been the subject of serious discussion for many years. Such conclusions as have been drawn have been based largely on conjecture supported by occasional evidences of excessive stresses revealed by some accident or injury to the rail. As there has arisen during recent years a general feeling that we are approaching the limit of safety in the relation of wheel loads to track structure, there is a greater demand for accurate information regarding the stresses actually created in the track under service conditions. George L. Fowler's series of experiments, described in another column, is one of a limited number which have been undertaken recently to this end. While confined to a small number of measurements of the lateral stresses only at one location on tangent track, with one form of roadbed conditions and track construction, these experiments nevertheless bring out interesting and valuable information on a relatively unexplored subject. The tentative conclusions that the lateral stresses imposed on the rail at any particular point are dependent more on the condition of the roadbed than of the locomotive, and that track conditions are the controlling elements in track stresses, provide food for serious reflection on the part of maintenance of way officers. While the experiments could only approximate some of the unfavorable conditions with which a trackman has to contend continually, the uniformity of results secured gives weight to the conclusions reached. The insertion of a hump in one rail with a relatively long run-off, or of a hump in each rail not directly opposite, approximating a condition found where the track is out of surface or where low joints are prevalent, increased the lateral stresses very materially, particularly on the rebound. While the maintenance of surface has naturally been given the greatest attention on lines carrying high class passenger service to secure improved riding qualities, the increased stresses introduced in the rails because of rough track are a matter of serious concern under freight trains as well.

The effect of wide gage is also strikingly shown in the increased lashing of the engine and the accompanying increased intensity of the lateral stresses introduced, especially at the higher speeds. This is what one would expect and coincides with the increased wear of the rail under such conditions, observations of which have recently caused some roads to pay greater attention to this subject on tangents and to reduce the increased width formerly allowed on curves.

Studies such as this are not only valuable for the information they bring out directly, but for the light they shed on the general design of track and locomotives and the relations they bear to each other. While our track structure of today is not the result of theoretical design, but rather of rule-of-thumb practical methods which have been developed in the light of past experience, the continuance of tests such as these, and such as those being inaugurated by the joint committee of the American Railway Engineering Association and the American Society of Civil Engineers, will do much to harmonize practice and theory and to develop a more rational design of track.

CO-OPERATION WITH THE PRESS IN A GOOD CAUSE

JAMES A. McCREA, general manager of the Long Island, is conducting a campaign of public education in an attempt to cut down the quite appalling number of automobile accidents that occur at grade crossings each summer on Long Island. A brief description of the first steps which have been taken is published elsewhere in this issue. One of the most remarkable things, however, about this campaign is the success which has been met with in getting the whole-hearted co-operation of the newspapers published in New York. Every paper of any size is giving its support either through a description or picture of the signs which the Long Island is putting up, or by such a description and editorial comment. Such unanimous support as this is interesting and encouraging. It is primarily the result of two factors: a good cause and the devotion to this cause of the personal time and interest of Mr. McCrea. After a great deal of thought and care had been given to the campaign Mr. McCrea decided to give up two days of his own time entirely to talking over with newspaper editors the aims of his company and the methods which were to be used to further them. As a matter of fact it was probably more nearly a week than two days which was given up to this work, but it has already proved to be time well spent.

Of course, no campaign of publicity and of education could entirely eliminate reckless automobile driving and resulting accidents at grade crossings. On the other hand it is safe to say that there are many thousand automobile drivers on Long Island who are thoughtless rather than wantonly reckless. It is at this class of driver that the railroad's campaign of education is aimed, and the annals of advertising prove pretty conclusively that when a cause is as good as this one, and when it gets the amount of newspaper discussion that is being given to the Long Island's Safety First campaign, results almost inevitably follow.

After all it must be a rather careless and habitually reckless man who can pass a sign 50 ft. long with the reminder staring him in the face that the heeding of that sign may save his life today, who is not just a bit more careful, for a few hours at least, in approaching grade crossings. So far as the Long Island Railroad is concerned, the success which the officers hope to obtain in cutting down the number of accidents at grade crossings is a thing of paramount interest and the methods by which this success is obtained are of secondary interest.

To other railroad men, however, whose particular problems in this respect may be quite different and to whom the grade crossing problem may not necessarily be the most important problem for the solution of which they must obtain the co-operation of the public, the chief interest in the Long Island's campaign of education is the method by which the railroad corporation has obtained this great measure of newspaper support. There is an important lesson in the experience of the Long Island which is almost as old as the history of railroads in this country. Each time, however, that the principles which underlie the Long Island's success are demonstrated in practice the results obtained come almost as a revelation. This is because these principles are applied on a large scale by railroad companies in comparatively few instances. Of course in the main this is necessarily so. A routine has to be followed and there is no "news" in routine. It is in exceptional cases that there is "news."

The editor or managing editor of a large metropolitan daily newspaper ranks in intelligence with the president or the general manager of a large railroad company. The daily newspaper editor is more open to conviction than the ordinary business man. His outlook is generally far broader, and his profession, like the railroad man's, is "public service." A public service corporation can almost invariably get the co-operation of the better class of newspapers, if not of all newspapers, if the railroad man is willing to discuss his cause with the newspaper man and set it forth in such a way that it stands on its own merits.

ELECTRIFICATION OF THE NORFOLK & WESTERN

WHILE the electrification of the New York, New Haven & Hartford from New York to New Haven is for freight as well as passenger operation, it was brought about primarily by the necessity for the elimination of steam locomotives in passenger service at the Grand Central Terminal, New York City. Similar conditions have led to electrification at other points. The Norfolk & Western electrification between Bluefield, W. Va., and Vivian, described in the *Railway Age Gazette* of June 4, was not decided on because of conditions such as these, but to secure an increase in track and tunnel capacity and in economy of operation. While the Chicago, Milwaukee & St. Paul is now electrifying 220 miles of its main lines in Montana for reasons of economy, the Norfolk & Western is the first trunk line to adopt electric operation on a portion of its main line for these reasons.

Only 30 miles is electrified at this time, but this section is adapted to electric operation, because for most purposes it comprises a separate division. Over 72 per cent of the freight traffic of the Norfolk & Western consists of coal and coke, and this percentage is increasing steadily. Practically all of this business originates within the limits of the electrified zone. Over 23,000,000 tons of revenue coal alone was handled last year. When business is normal, about 2,000 cars are loaded daily. This 30 miles of line is, therefore, one of intensive traffic development. Nearly all of this coal originates west of Elkhorn tunnel, about 40 per cent of it going east. Over 700,000 tons was unloaded over the Lamberts Point, Norfolk, coal pier alone last month. This coal must be brought from the mines to the main line, the eastbound loads separated from the westbound, and the former hauled up the 2 per cent grade through Elkhorn tunnel to Bluefield. The westbound coal is taken to Eckman yard, a short distance east of Vivian, where it is made up into trains for further movement. Thus, for this coal traffic the electric locomotives will entirely replace steam without increasing the constructive mileage for steam locomotives, as has so frequently resulted.

From the standpoint of increased capacity, the article on this project in the issue of June 4 showed that the time required to clear the block through the single track tunnel is reduced one-half by electric operation, while the speed of the tonnage trains up the grades is similarly increased. The desirability of securing this greater expedition in the movement of trains is indicated by the fact that the total revenue coal traffic of the Norfolk & Western increased from 13,986,054 tons in the fiscal year 1910, to 23,221,742 tons in 1914, or 66 per cent, while that over the piers at Norfolk alone increased from 4,293,087 tons in 1910 to 5,986,910 tons in 1914, or 40 per cent. It is thus clear that the saving in the cost of constructing additional track facilities to provide the same increase in capacity will to a considerable extent pay for the electrification. Railway men will watch with much interest the actual results secured from the installation, since it is the first placed in operation to secure advantages from the purely railway standpoint, without other complicating features.

NEW BOOKS

A History of Travel in America. By Seymour Dunbar. The Bobbs-Merrill Company, Indianapolis. Four volumes, 400 illustrations, 1,600 pages. Bound in cloth. Price $10.

This is an interesting set of volumes showing the evolution of passenger transportation in America from the days of the Indian trail to the days of the railroad. The book has an historical value, for, although it, perhaps, touches primarily upon the more romantic and striking characteristics of its subject, it nevertheless conveys a remarkably clear idea of the effect of transportation upon the gradual extension of this nation westward from the Atlantic coast to the Pacific. The early part of the book, naturally, does not deal with railroads. The experiences of our forefathers who had to entrust themselves to Indian canoes, flat boats, river barges, or stage coaches and Conestoga wagons were so spectacular, however, that the first two volumes cannot fail to have their appeal to modern makers of transportation.

The book contains a detailed description of the introduction of the steamboat, emphasizing the fact, not too well known, that Fulton was by no means the real originator of water craft propelled by steam. The story of the introduction of the steamboat on the western waters of the country is especially attractive despite the emphasis placed upon the unsafe character of early river travel. The book tells also in detail of the many projects for canals, treats of their success or failure and gives a carefully compiled list of those that were completed. It describes travel upon the canal boats which at one time were very popular. These boats traveled at the prodigious speed of 3 or 4 miles an hour and the passenger paid usually 5 cents a mile including meals and bed.

The story of our railroads occupies a large portion of the books, but nevertheless not all that it deserves. The account is carried through from the beginning of rail transportation to the completion of the first transcontinental railroad. Definite data is given relative to the first railway, the first locomotives, the first trains, this being information that is always in demand and always hard to find in concise form.

The book treats carefully of the several early railroad lines. It names their routes, describes the early methods of track construction, tells of the difficulties with motive power and cars and treats of the lack of standard gages. It would, perhaps, be much more valuable in this connection did it contain maps showing these many lines, and it is a serious fault that these early railroads are not identified with the systems of which they are now parts.

In following the history of the early railroads, it is most interesting to observe the gradual introduction of new ideas. The first railroads had to choose between horses and steam locomotives. The first cars were stage coaches, and it was only gradually that the stage coach equipment evolved into a modern car with perpendicular lines and center aisles. The book does not neglect to mention the introduction of dining and sleeping cars and the various other modern necessities of our transportation system.

The reader is at a loss, however, to know why the author's treatment of our railroads should end at 1869. Surely the romantic features did not cease with the construction of the first transcontinental railway. The introduction of our signal system, a subject which is hardly touched upon, in itself should surely be of greatest interest. Nor does the book say a word about the part played by the railroads in the Civil War. One can well imagine how rich such material would prove at present.

Several chapters in the four volumes are devoted to the effects of the extension of the various new methods of transportation upon the settlement of the West, and it is from this that the book secures historical value. It is somewhat unfortunate, however, that so many chapters should have been set aside for consideration of the Indian problem. While that is an interesting and vital chapter of this country's history, it is not necessarily as important a part of the history of its transportation. A large part of the space used for the treatment of this subject could, therefore, perhaps be better used for a more adequate treatment of the public land policy, as the latter is certainly more closely related to the history of this country's transportation, particularly in so far as railroads are concerned.

The four volumes are most profusely illustrated. That part of the book which deals with the early history of the railroads, however, suffers slightly because in many chapters the illustrations are placed 100 or more pages ahead of the reading matter to which they are related.

To the person who desires to obtain a clear idea of the advance in the art of passenger transportation in this country the book is of greatest value. Its illustrations, the typographical work and the well chosen language make it most interesting.

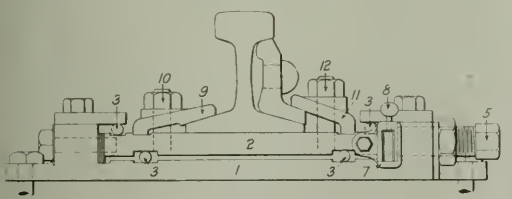
Lateral Stresses in Rails on Straight Track

Several Types of Locomotives Were Experimented With at Varying Speeds and Under Different Conditions

By George L. Fowler
Consulting Mechanical Engineer

The lateral stresses imposed on rails by running locomotives and cars have been the subject of much conjecture, some calculation and a little experimentation for a number of years, and the little of the last tends to show the unreliability of the other two methods of determination. It has been my good fortune to have conducted a series of investigations, the results of which may serve as indications of what probably exists, even though they may not be accepted as a final demonstration from which there can be no question.

The investigations were limited, for the most part, to the determination of the stresses imposed by locomotives. They may be divided into two parts: one in which the thrust of the locomotive as a whole, was measured on a tangent track, and the other in which the thrust of each individual wheel was measured on the outer rail of curves. In the case of the thrusts on the tangent it was the total lateral thrust that was measured and not the individual thrust of each wheel. Also, from the methods employed, it is impossible to state positively whether the records obtained were



Apparatus Used for Registering Lateral Stresses on Rails

those resulting from a single impact of a wheel against the rail or from the accumulated results of a series of impacts. But for the purposes of discussion they are considered to be the result of the impact of the engine as a whole.

THE TEST APPARATUS

The apparatus used for measuring the stresses is shown in the drawing. The rail was rigidly clamped to the plate 2 by the clamps 9 and 11 and the studs 10 and 12, a variation in form being made according to location, with provision for clasping the flange of the rail itself, or the splice bar at the joints. The whole was carried in the cast steel base 1, which was bolted to the tie in place of the usual tie plate. Plate 2 was floated on this base, being carried and held down by the rollers 3. When the apparatus was not in use the rail was adjusted to gage and held by bolts in place of those marked 5. When in service the bolt 5 was inserted, which carried a 1 in. hardened steel ball at its inner end. The clamp 7 attached to the plate 2 was provided with a thumb screw 8 for holding a cold drawn steel strip. This steel strip was interposed between the plate 2, against which it had a bearing and the ball on the end of the bolt 5. The bearing of this ball on the steel strip was all that prevented the spreading of the track as the locomotive passed. The result was that the outward pressure set up by the locomotive caused the ball to make an indentation in the strip the size of which indicated the amount of pressure exerted.

There were 120 of these units. The rail was of 85 lb. section. The ties were spaced 22 in. between centers and were laid in gravel ballast that came up flush with the top; the depth of the ballast beneath the ties was about 12 in. The location was on a fill about 5 ft. high, built on a muskeg foundation that was very elastic. A passing train produced a wave motion of the whole track that was quite visible to the eye, but no measurements were made of the height of the waves.

In placing the apparatus, great care was exercised that there should be no disturbance of the ties or ballast, and the bases 1 were allowed the same freedom of vertical motion on the ties that obtained in the track with the rails spiked down on the usual tie plate. In this way the rail conditions remained the same as in the normal track, with the single exception that they were raised 2 in. above the ties by the apparatus.

The steel plates used for the records were of cold drawn steel of a homogeneous structure, measuring ⅜ in. by 1¼ in. The metal was carefully calibrated to determine the relationship between the size of the indentation and the pressure required to produce it. The readings of the diameters of the impressions on the strips were made with a microscope worked with a micrometer screw reading to thousandths of an inch, but on which ten-thousandths were readily estimated.

The units or chairs were of such dimensions that the rail resting thereon was raised 2 in. above the ties. This necessitated a gradual rise from the regular track level to that of the apparatus. This run-off extended over a distance of three rail lengths in each direction, or at the rate of rise of 2 in. in 99 ft., or about 0.17 per cent. The run-off was carried on shims of varying thickness, so that there was no disturbance of the ties either at this point or under the units of the apparatus. The track was laid in a gravel ballast that dried out quickly after a rain. The ballast was well up to the tops of the ties at all points. The roadbed was springy and the whole surface of the ground and ties received a wavy motion under a passing train.

The tests were made in the month of August and during the whole period the weather was fair and dry and the condition of the roadbed uniform.

A speed recorder placed in the cab of the locomotive enabled the engineer to traverse the test track at any desired speed. The speeds selected for the tests were 30, 40 and 50 miles an hour for freight locomotives of the Consolidation and Mikado classes, and 30, 40, 50 and 60 miles an hour for passenger locomotives of the Pacific and Ten-wheel classes. The tests may be divided into two groups: those in which the rails and tracks were maintained in the regular, normal conditions of operation, and those in which humps or distortions were introduced in one or both rails.

It was found that there was a peculiar harmony in the range of high and low thrusts at the several units. A heavy thrust was apt to occur at the same tie in each of a series of runs and the same held for the lighter thrusts. When this recurrence became quite evident an explanation was sought in the vertical movement of the ties under the passing locomotives, but the improvisation for the work was too crude to give reliable results.

Following are some general data for the engines used in the tests:

	Mikado	Consolidation	Ten-Wheel	Pacific
Total weight, lb.....	225,000	226,000	167,000	219,000
Total wheel base....	35 ft. 5 in.	25 ft. 5 in.	24 ft. 11 in.	33 ft. 7 in.
Rigid wheel base....	16 ft. 5 in.	16 ft. 6 in.	14 ft. 6 in.	13 ft. 0 in.

All the locomotives had the standard Master Mechanics' Association tread, and each was surveyed to determine the amount of

lateral play in the journal boxes. All records were made with the engines using steam.

DETAILED RESULTS OF TESTS

An examination of the diagrams plotted from the records shows that, in no case when the track was in its normal position, was there any indication of a tendency on the part of any of the locomotives to nose, that is, to move from one rail to the other and thus exert a maximum pressure on one, and a minimum pressure on the other. There was considerable lashing or dealing of heavy blows on one side or the other, but there was no uniformity in this, in so far as the delivery of a heavy blow at one end of the tie was accompanied by a slight blow at the other end.

Again, if we examine the averages of all blows struck on either rail they will be found to be remarkably uniform and with but a slight, if any, tendency to rise with the speed. The same statement holds for the maximum blow. It is noticeable that from August 5 to 8, inclusive, the highest average of blows was on the north rail; while from August 10 to 14, inclusive (the date of the last runs with the normal track) the higher average of blows was on the south rail, regardless of the class of locomotive tested. There was no marked difference between the averages of pressures exerted by the different classes of locomotives.

EFFECT OF SIDE PLAY IN JOURNALS

In the tests on the normal rail two of the locomotives were new. One was a Mikado, No. 5034. If the diagrams of this new locomotive are compared with those of No. 5012, on which there was an accumulated side play of something more than three times as much for the total of all of the wheels, it will be found that there was a marked increase in the steadiness of motion of the engine with the greater amount of side play. In the old engine the lash was moderate and uniform up to 50 miles an hour, with but a slight tendency to increase up to that point. At 60 miles an hour the lashing was notably more severe than at the lower speed. In the case of the new locomotive, No. 5034, the lashing was severe throughout the whole range of the tests, but was not markedly greater at high than at low speeds.

Consolidation engine 3950, tested on August 6, was also new, and Consolidation 3813, tested on August 13, was an old engine that had accumulated something more than three times the total amount of side play in the journal boxes obtaining on 3950. The same differences are to be noted as in the case of the Mikado just referred to. The worn engine, 3813, ran with remarkable smoothness showing a slight but gradual tendency to an increase of intensity of lashing as the speed was increased. The new engine, 3950, on the other hand, was very severe in its lashings, which also showed a slight tendency to increase as the speed was increased. Yet the average and maximum pressures exerted were not greatly different on the two engines, the difference between the two lying in the

rapid succession of blows which varied considerably in their intensity.

Basing the statement solely on these comparative records, it appears that the locomotive is easier on the rail after it has developed some side play in the axle boxes than when it is just out of the shops.

EFFECT OF DIFFERENT TYPES OF LOCOMOTIVES

As to the difference in the various types of locomotives, a comparison is possible between Pacific No. 1028; Consolidation Nos. 3921 and 3922; Mikado No. 5012 and Ten-wheel No. 919, all of which were fitted with the same type of trucks, and between Pacific No. 2229 and Consolidation No. 3819 which were fitted with another type.

Of these engines the smoothest diagrams were made by Ten-wheel No. 919, followed very closely by the Mikado No. 5012. There is very little to choose between the other three locomotives. On some runs the Pacific gave a slightly smoother record; on others it was in favor of the Consolidations. Considered together, the diagrams show the Pacific to be between the two Consolidations. From the diagrams it appears that the maximum blows in pounds delivered by the several locomotives on a normal track was as follows:

	Speed in Miles per Hour			
Type	30	40	50	60
Mikado—				
New	12,500	12,500	12,500	12,500
Worn	10,000	10,500	11,500	12,250
Consolidation—				
New	11,000	14,000	15,000	.....
Worn	10,250	13,500	12,750	.....
Pacific—				
Worn	13,250	14,000	12,250	12,250
Ten-Wheel—				
New	8,750	14,250	10,750	11,250

It was quite impossible to detect any consistent effect of rail joints. In some cases the greater thrust was at the last tie of the delivering rail, while on others it was on the first tie of the receiving rail, so that the effects were probably due to ballast and general track conditions rather than to the joints.

At the conclusion of the tests on the normal track, that is a track in which the average running conditions of a straight track were maintained as to the level of the two rails and the gage, it was decided to test the effects of a distorted track and various conditions were tried.

EFFECTS OF DISTORTED TRACK

The first change made was that of raising one (the south) rail ½ in. on the third tie in advance (east) of the apparatus or about 4 ft from it. There was a run-off at each end of about 4 ft. Two runs were made with the track in this condition at 30 and 40 miles an

hour respectively. The passage over the hump was not noticeable on the locomotive. The rise of the wheels was taken up by the compression of the springs, and the general appearance of the diagrams was unchanged. An examination of the two sets of diagrams of engine No. 5012 on the normal track at 30 and 40 miles an hour, shows them to be severally very similar, even in the details of their indications. The introduction of the hump disturbed this uniformity of action, but had no appreciable effect on the intensity of the blows delivered.

Owing to the slight effect produced by this distortion, the hump was raised to ¾ in. at the same place and engine No. 5012 was run over it at a speed of 30 miles an hour. This produced no more perceptible effect than the first distortion either on the engine or on the track.

The results of this distortion were that with engine No. 5012 running over the first hump of ½ in., which was short, at speeds of 30 and 40 miles an hour, there was no perceptible effect produced on the locomotive, when viewed from the track, nor was it perceptible on the engine. This held true also for the ¾ in. hump at the third tie when traversed at a speed of 30 miles an hour, making it evident that the momentary lifting of the wheels was cared for by the springs without moving the body of the locomotive itself, because of the short space of time during which the lifting force was in action.

In order to increase this time and give the springs an opportunity to act the hump was extended back from the third tie in advance of unit No. 2 for a full rail length at a height of ¾ in., and engine No. 5012 was run over it at speeds of 41 and 50 miles an hour. This produced an effect perceptible to the men on the engine, who could feel it rise, but did not feel any decided lateral blow when leaving the hump, nor was there any marked change in the character or intensity of the blows as indicated by the diagrams of the record.

Owing to the failure to produce results with a single short hump it was decided to introduce two humps, one on each rail. The north rail was raised for a length of 50 ft. and the south rail was raised for the same distance in advance of the apparatus. Mikado No. 5012 was run over it at speeds of 30, 41 and 49½ miles per hour.

While this arrangement did not produce effects that were noticeable on the engine, it is evident from the diagrams that the lateral thrusts were very materially increased over those obtained on the normal track. On one run at 30 miles an hour a blow of 15,000 lb. was received on the south rail, and on both runs there was an increase of the heavy blows, especially on the south rail, with the engine running very steadily over the last half of the apparatus. These same results obtained at 41 miles an hour with a mere variation of the details. At 49½ miles an hour the lashing was increased and continued for the whole length of the apparatus. This showed that inequalities in track level, especially when alternating from

one rail to the other, can set up side thrusts of considerable moment.

The next move was to place a hump in the north rail carrying it onto the apparatus itself and moving the two previous humps to the east or approaching side. This track was traversed at speeds of 30, 40, 45 and 46 miles an hour. At the higher speeds the engine was rolling to such an extent as to make it inadvisable to run any faster. Here we see, in a very marked manner the effect of throwing the engine over against the south by the hump in the north rail. The engine on entering the apparatus was dropped from the hump in the south rail and was lifted by that in the north. The result was a low pressure against the north rail and high ones against the south, rising to 15,000 lb. This was followed by a severe lashing that lasted throughout the whole length of the apparatus, causing a series of heavy blows, which while they did not raise the average or go very much above the maximum of the same engine on normal track, did show that the running of the engine was greatly disturbed.

Lateral Track Stresses for Mikado Locomotive No. 5012 on Track with Two Humps Alternating on the Two Rails for 100 Feet East of Apparatus; Speed 30 Miles Per Hour; Test Made August 15, 1913

A run was made over the track in this same condition on August 16 with Consolidation No. 3813 at 30 miles an hour. The results were identical with those obtained with the Mikado.

The track was again changed. The humps were taken out of the north rail and one long hump was put in the south rail extending well out on the apparatus. The purpose of this was to give the springs ample time to lift the engine and assume a condition of equilibrium, before the engine left the hump. The elevation of the south rail was ¾ in., and this extended for about 100 ft.

Runs were first made over this track with a Consolidation locomotive. The effect was very apparent and striking. The hump in the south rail threw the engine over against the north rail, with the result that the pressure against the south rail was very light, while that against the north rail was comparatively heavy. This held true to unit 14, where the hump practically disappeared, and there was a sudden rise in the thrusts against the south rail, culminating in a very heavy blow on unit No. 42. This showed clearly on the 30 mile diagram, increased very markedly at 39 and 40 miles an hour, and reached a maximum at 47 and 50 miles per hour.

After the engine had been thrown back against the south rail at 47 and 50 miles an hour, it maintained that position to unit No. 88, when it had crossed to the north rail. This tendency was also shown at 30 and 40 miles an hour, but not quite so markedly. While the averages of the thrusts were not much higher with the hump than they were with the normal track the maximum blows were very much higher. If, however, the average of the thrusts received are taken for the por-

tion of the track after the engine left the hump they are considerably higher than with the normal track. This shows that while an engine is traversing a single long hump, it is thrown over against the low rail and the side stresses on the latter are less than on a normal track with both rails level; while on the high rail they are inappreciable. But when the engine leaves the hump it is thrown violently against the rail in which the hump was situated and will deliver thrusts of from 20 to 30 per cent in excess of those delivered on a normal track with the two rails level.

Again the hump was extended, this time to unit No. 26. This hump was traversed by Consolidation locomotive No. 3950 at 30, 40, 46, 48 and 50 miles an hour. The effect was essentially the same as before. The engine lay over against the north rail, putting comparatively little pressure against the south rail up to unit No. 26, the end of the hump, when it crossed quickly to the south rail and put on high pressure, crossing at the higher speeds to the north rail and again imposing comparatively heavy loads there, and at the same time extending the lashing for the whole length of the track.

Pacific locomotive No. 1028 was run over the track in the above condition at 30, 40, 50, 50½, 60 and 61 miles an hour. The same general effect was produced as with Consolidation No. 3950, but more pronounced. The Pacific locomotive developed a heavier lashing than the Consolidation, and on this distorted track it carried the low pressure on the south rail out to the end of the hump on unit No. 26, and was then thrown back on that rail. It lay against it for nearly the whole length of the apparatus, only crossing back to the north rail at about units No. 100 to 106. This action appeared at 30 miles an hour, and increased to prominence as the speed increased until at 60 and 61 miles an hour there was a wide gap between the pressures on the two rails, and it was found that the Pacific locomotive put a much heavier stress on the south rail than the Consolidation. Evidently, too, the Pacific was much slower than the Consolidation in swinging from one rail to the other.

EFFECT OF WIDENING GAGE

The gage was then widened over the whole length of the apparatus by from 3/16 to ¼ in., and four runs were made at speeds of 30, 40, 50 and 58 miles an hour. The effect of the widening of the gage was not especially noticeable at 30 miles an hour. But as the speed increased the gap between the south and north rails increased, although the maximum blows delivered were not more. Apparently the extra play between the flanges and the rails, produced by the widening of the gage, gave the engine a chance to be thrown back against the south rail with enough greater force to hold it there with greater steadiness and relieve the north rail of a portion of its load, indicating that a loose gage tends to increase the lateral stresses which a locomotive will put on the track.

OTHER TESTS

The track was changed again by bringing the rails back to standard gage, but leaving the long hump extending down to unit No. 26, as in its first condition. Mikado locomotive 5012 was again run over the track with the long hump. The effect was the same, but less pronounced than with the Pacific loco-

Lateral Track Stresses for Consolidation Locomotive No. 3813 on Track with Long Hump in South Rail to Unit No. 4; Speed 50 Miles Per Hour; Test Made August 16, 1913

motive. The same steadiness of motion that characterized the Mikado on the normal track was found here, except that, when it left the hump, it lay over against the south rail and continued to put an excess of pressure on that rail, as compared with the north rail, out to unit No. 105, when it sometimes crossed to the north rail, though it usually held to the south rail to the end.

Taking the results obtained with the Pacific and Mikado locomotives, as compared with those of the Consolidations, it would appear that the trailer truck has a markedly steadying

effect to prevent lashing, and tends to hold the engine to the rail against which it has been thrown by running off from the hump. The hump, however, did not serve to raise the average thrusts of the engine on the north rail or the maximum for either rail to any extent, although the average for the south rail was higher for that portion after leaving the hump than when the track was in its normal condition.

On August 20, Pacific locomotive No. 2229 was run over the track. It was on this day that the rail deflections for each tie for each run were measured. A careful comparison of these deflections, as measured with the diagrams, fails to show any connection between the two. This, however, must not be taken to imply, in any way, that there is no connection, since the deflections were taken very crudely and cannot be assumed to represent the depression of the ties or the actual depression of the rail.

Pacific locomotive No. 2229 was also tested. It showed a general tendency that has already been noted, to lay over against the south rail after leaving the hump, but to a lesser degree. This engine had a swing link truck and a total side play in the axle boxes of 3 7/32 in., averaging 17/32 in. per axle. On the normal track it was quite steady and this same steadiness obtained when subjected to the action of the hump. The lashing effect increased with the speed and was quite severe at 50 miles an hour.

Average thrust, north rail..... 5,704 lb. Maximum thrust, north rail..... 9,750 lb.
Average thrust, south rail..... 5,333 lb. Maximum thrust, south rail..... 17,750 lb.

Lateral Track Stresses for Ten-Wheel Locomotive No. 919 on Track with Long Hump in South Rail to Unit No. 26; Speed 49½ Miles Per Hour; Test Made August 22, 1913

Runs were made with Consolidation locomotive No. 3925 at 30, 39, 40 and 48 miles an hour. The records of this engine may be compared with those of No. 3921. The diagrams showed the same low pressures against the south rail up to the end of the hump at unit No. 26, and beyond. Then there was a transference of the pressure to the south rail, with the engine laying up against it to the end of the apparatus. The run of maximum blows was higher than with No. 3921 on the normal track, and the lashing was somewhat more severe at the highest speeds, decreasing as the speed decreased down to 30 miles an hour. Engine No. 3925 has a total side play of 5 13/16 in. ranging from 9/16 in. in the second driver to 2 9/16 in. in the truck axle.

Attention has already been called to the smooth running of the Ten-wheel engine, No. 919. This engine was tested again on the humped track at speeds of 30, 40, 49½, 59½, 60 and 61 miles an hour. When running on the hump it showed the same low even pressure on the south rail that all of the others had, then a crossing at the end of the hump to put the higher pressure on the south rail; but, beyond that, there was an almost entire absence of the heavy lashing effect of the other types of engines at high speeds. Even at 60 miles an hour the engine was very steady. The only exception was to be found at 49½ miles an hour, where a blow of 17,500 lb. was struck at unit No. 72, but the engine quieted down immediately and showed no further tendency to lash, out to the end of the apparatus. Hence here, as on the normal track the Ten-wheel engine showed that it tended to put less stress on the track than any of the other classes.

Finally a Consolidation locomotive was backed over the apparatus at a speed of 30 miles an hour. The effect of the hump on this locomotive was very marked when running ahead. Not only were the maximum blows delivered higher than those of the same engine on the normal track, but the plunge over to the south rail, when it ran off the hump, was very decided. This was indicated especially by a blow delivered to unit No. 42, a blow that increased with the speed and was sometimes followed by a heavy blow on a succeeding unit. Evidently the engine went back to the north rail as unit No. 87 gave evidence of heavy blows.

Contrary to the action of the Consolidation locomotives when backing over curves, the action of such an engine backing on a straight track does not differ essentially from its action when moving forward. In fact, in the latter case, the stresses was much more severe when running forward than when running backwards.

As in the previous trial with the widened gage, the effect was not noticeable at 30 miles an hour. At 40 miles an hour, it was more distinctive, showing the same tendency to increase the lateral stresses as the speed increased.

GENERAL CONCLUSIONS

Reviewing the whole series of tests they may be said to furnish the following indications, although the work has not yet been carried to the point where the conclusions reached can be said to have been demonstrated.

The probability is that the blow delivered or the stress imposed at any particular point is dependent more on the condition of the roadbed than of the locomotive. This is shown by the marked similarity of the diagrams of any particular locomotive, whereon it will be seen that the heavy and light blows are apt to occur at the same unit respectively, regardless of the speed at which the engine may be running. This checks with observations made elsewhere.

There is no tendency for locomotives to nose, that is to go from one rail to the other at regular or irregular intervals, and, in so doing put a heavy pressure on one rail while there is a light one on the other. Nor when the engine or wheels come up against the rail is it usual for the pressure to increase gradually over a number of ties. The maximum pressure is apt to follow a comparatively low pressure on the same rail. In fact, it is quite characteristic of the diagrams to show an excessively high pressure immediately succeeding an abnormally low one.

A goodly amount of side play in the axle boxes evidently serves to relieve the lateral thrust of the wheel on the rail. It is as though the wheels and axles were free to move from side to side of the track while the main body of the engine continues on in a straight line undisturbed by the side movement of the wheels.

Judging from the diagrams presented, the order of severity of stresses put on the rails by the locomotives tested, indicates that they stand in the following order: Ten-wheel, Mikado, Pacific, Consolidation, increasing from the first to the last.

As already intimated track conditions are evidently of great importance in the development of lateral stresses, but no data was obtained showing what the effect in detail of track deflection or yielding may have upon the lateral stresses. Nor was any determination possible, from the data obtained, as to the effect of rail joints. There were, of course, no low joints on the apparatus used.

As far as the riding qualities of the engine, or the development of lateral stresses, a short hump or elevation of one rail has no appreciable effect, even though that rise be as much as ¾ in.

With two humps, one on each rail and alternated, so that the engine is not on both at the same time, there is an appreciable rise in the intensity of the lateral stresses.

With three humps, two on one rail and one on the other, alternated in the same manner, the engine will be given a rolling motion, which may become dangerous at high speeds, and which will produce a very marked increase in the intensity of the lateral stresses imposed on the rail.

Where one rail is elevated above the other for a considerable distance, giving the springs time to lift one side of the engine and come to a state of equilibrium, the effect is to cause the engine to strike against the rail in which the hump is located, when the engine leaves it. This may be followed by a rebound against the other rail. A widening of the gage tends to increase the lashing of the engine.

Contrary to its effect on curves, there is no appreciable increase of lateral thrust caused by backing a Consolidation locomotive over a straight track. This seems to hold, at least for moderate speeds.

While no demonstrative evidence to that effect was obtained, the impression left by these tests is that the track conditions are the controlling elements in track stresses. As to just what these may be, in detail, no statement can be made.

From these tests, as well as from those made on curves, it is evident that no prediction is yet possible as to what will be the effect of any individual locomotive, at any speed on any track, curved or straight. It can only be assumed that the performance of the engine will fall within the limits that are characteristic of its type.

In connection with these tests it is to be noticed that most of the locomotives tested had dissymmetrical wheel bases; that is to say, the number of truck wheels on either side of the drivers was unequal. This holds for all of the engines except the Mikados. It has been found in other investigations, that locomotives with dissymmetrical wheel bases are easier on the track and more stable than those having symmetrical bases.

QUARTERLY ACCIDENT BULLETIN No. 53

The Interstate Commerce Commission has issued Accident Bulletin No. 53, containing the record of railway accidents in the United States during July, August and September, 1914. The number of persons killed in train accidents was 181, and of injured 2,555.

The total number of casualties of all classes reported, including industrial accidents, was 2,748 killed and 47,215 injured. The accidents are summarized as follows:

Table No. 1—*Casualties to persons—Steam railways*

Causes.	Passengers		Employees (including employees not on duty)		Other persons (trespassers and non-trespassers		Total persons	
	Killed	Inj'd	Killed	Inj'd	Killed	Inj'd	Killed	Inj'd
Train accidents.								
Collisions	37	606	27	405	5	28	69	1,039
Derailments	36	850	39	381	28	59	103	1,290
Miscellaneous, including boiler explosions	...	10	8	213	1	3	9	226
Total	73	1,466	74	999	34	90	181	2,555
Other than train accidents.								
Accidents (229) to roadway or bridges not causing derailment	...	...	...	1	...	...	...	1
Other accidents (classes C3 to C12, inclusive)	44	2,215	470	10,200	1,954	3,640	2,468	16,055
Total	117	3,681	544	11,200	1,988	3,730	2,649	18,611
Industrial accidents to employees.								
While working on tracks or bridges	...	...	42	7,548	...	...	42	7,548
At stations, freight houses, engine-houses, etc.	...	...	19	6,304	...	...	19	6,304
In and around shops	...	...	17	13,177	...	...	17	13,177
On boats and wharves	...	...	9	432	...	...	9	432
At other places	...	...	12	1,143	...	...	12	1,143
Total	...	...	99	28,604	...	...	99	28,604
Grand total	117	3,681	643	39,804	1,988	3,730	2,748	47,215

The comparisons with the quarterly bulletin covering the corresponding quarter of the previous year shows* an increase in passengers killed in train accidents of 40 (33 to 73); employees killed (on duty) all causes, a decrease of 296 (759 to 463); employees killed in industrial accidents, a decrease of 33 (132 to 99) and a decrease in total persons killed, all classes, of 425 (3,173 to 2,748). The quarter now reported included three notable accidents: Tipton Ford, Mo., August 5, passengers killed, 36; Lebanon, Mo., September 15, passengers killed, 27; Livingston (Klondyke), Ala., September 18, passengers killed, 9.

The total number of collisions and derailments reported was 3,085 (1,095 collisions and 1,990 derailments), of which 97 collisions and 168 derailments affected passenger trains. The damage to cars, engines and roadway amounted to $2,342,511. A comparison with the same quarter in preceding years shows:

	Number	Killed	Inj'd	Damage
Total collisions and derailments this quarter	3,085	172	2,329	$2,342,511
Total for same quarter of 1913	3,913	208	3,760	3,239,159
1912	3,935	276	4,100	3,366,401
1911	3,034	189	3,776	2,533,170

The bulletin gives the usual tables classifying certain kinds of accidents in detail.

Fifteen accidents were investigated by the inspectors of the commission during this quarter, and the reports of these investigations fill 23 pages of the bulletin. These accidents occurred as follows:

Chicago & Alton	Lockport, Ill.	Jan. 3,	Derailment
Chic. St. P. Minn. & O.	Bigelow, Minn.	Feb. 9,	Derailment
Detroit, Jackson & Chic.	Michigan Center, Mich.	July 1,	Butting collision
Virginian	Fairmount Park, Va.	July 17,	Collision (st. cars)
Pennsylvania	Shannon, Pa.	July 23,	Derailment
Kansas City So.	Tipton Ford, Mo.	Aug. 5,	Butting collision
Tennessee Central	Green Hill, Tenn.	Aug. 13,	Derailment
Denver & Rio Grande	Thistle, Utah	Aug. 14,	Derailment
Chic. R. I. & P.	Talloway, Ark.	Aug. 21,	Derailment
Chic. St. P. Minn. & O.	Peak, Neb.	Aug. 27,	Butting collision
St. L. Iron Mt. & So.	Watson, Ark.	Sept. 14,	Butting collision
St. L. & S. F.	Lebanon, Mo.	Sept. 15,	Derailment
M. K. & T. of Texas	San Marcos, Tex.	Sept. 16,	Derailment
Alabama Great So.	Livingston, Ala.	Sept. 18,	Derailment
St. L. Iron Mt. & So.	Rixey, Ark.	Sept. 22,	Derailment

Electric railways reporting to the commission (not included in the foregoing statistics) had 125 persons killed during the quarter and 1,686 injured; and there were 44 collisions and 23 derailments. Train accidents are charged with 6 fatalities. The total number of passengers killed from all causes was 12, and of employees 15 (4 in industrial accidents). The number of trespassers struck or run over by cars was 49; 27 killed and 22 injured.

British Rail Exports.—The war is naturally telling upon English rail exports, the aggregate shipments to April 30 having fallen to 78,462 tons, as compared with 164,277 tons and 157,507 tons in the corresponding periods of the two former years.

Baghdad Railway Bridge Opened.—A Constantinople telegram states that the great bridge across the Euphrates near the railway station of Djerabulus, on the Baghdad Railway, has been opened for traffic.

*Preceding bulletins have been noticed in the *Railway Age Gazette* as follows: No. 52 (yearly), February 19, 1915, page 299; No. 51, December 11, 1914, page 1081; No. 50, July 24, 1914, page 170; No. 49, May 15, 1914, page 1072.

Federal Regulation of Railroads—A Suggestion

Division of the Country Into Districts and With Sub-Commissioners With Jurisdiction Over These Districts

By J. G. Code
General Manager, Wabash-Pittsburg Terminal

The "Act to Regulate Commerce," taking effect early in the year 1887, and based upon the constitutional authority of Congress to regulate foreign and interstate commerce, inaugurated a system of federal regulation and control of business interests of the greatest magnitude in themselves and so closely interwoven with the business and social activities of all the people as to make the manner, extent and character of regulation of vital importance as related to national welfare. The commission in its first annual report directed attention to this fact in the following words:

> The regulation of no other business would concern so many or such diversified interests or would affect in so many ways the result of enterprise, the prosperity of commercial and manufacturing ventures, the intellectual and social intercourse of the people, or the general comfort and convenience of the citizen in his every-day life. The railroads provide for the people facilities and convenience of a business and social nature which have become altogether indispensable, and the importance of so regulating these that the best results may be had, not by the general public alone, but by the owners of railroad property also, is quite beyond computation.

In the same report rendered after the act had been in operation about eight months it was noted that "one immediate effect was to cause inconvenience in many quarters," which comment is probably equally applicable to the situation after twenty-eight years of experience. This, however, is no indication that progress has not been made, nor good results obtained, as any restriction of individual or corporate action is practically certain to inconvenience some, even while generally beneficial.

The tremendous expansion of our resources in agriculture, mining, manufacturing, etc., during the latter half of the nineteenth century was made possible only by the rapid development of transportation facilities which, in many notable instances, proceeded materially in advance of actual needs, but in a manner to promote the opening of remote areas to population and all the activities of civilization. That in the public interests federal regulation became necessary, was adopted, justified its adoption, is therefore properly adhered to, and will be continued and made more extensive by the will of the people, are facts of the situation which for purposes of this discussion are assumed to be settled. I am also assuming and firmly believe that government ownership is not seriously considered by any great number of our people, and will not be until or unless the policy of regulation by commission has absolutely failed.

There is an old Scotch fairy tale of an enchanted flag given by a fay to a member of the Macleod clan. Thrice it would save him from the worst danger, but only thrice. After that it would be useless and must be burnt. As the story goes, Macleod waved the flag twice, once when his child heir was lost, again when the clan was hard pressed by enemies—but he never waved the flag the third time! Furled it lies in the treasure chamber of Dunvergan, while generations of Macleods bravely live and bravely die. No one of them will use the fairy's charm for the last time.

Government ownership is the last resort and its flag may well be kept in the treasure room of our castle, to be unfurled only when there is no other way to turn. Unlike the fairy banner, we can use it not thrice, but only once and must then abide the consequences.

Until very recently the repressive function of regulation has predominated. Naturally those features of the act aimed at the correction and prevention of abuses have been thoroughly worked to conclusion. There are now gratifying indications of an understanding that the function of repression of evil must be accompanied by cultivation of good through our instrumentalities of regulation if the people at large are to continue to enjoy the benefits of efficient transportation facilities. A broader conception of the duty devolving upon governmental authority will result in an extension of the powers of the commission, and a very considerable increase in the amount of work to be performed by it.

The suggestion which I wish to advance relates solely to the situation as it exists and to the very probable extension of the authority of the commission, and consequent increase in the amount of labor. Even though, as it now stands, a tremendous amount of business is handled by the commission, which docketed in the year 1913, 16,764 cases. There were conducted 1,401 hearings, in the course of which approximately 140,000 pages of testimony were taken, which represents a good sized printed volume for every working day in the year.

There has been no material change in the organization other than an increase in membership from five to seven and which it is now proposed to increase to nine. The quality of its membership has been well maintained, so that notwithstanding many acute differences of opinion, it must be conceded that we have a board composed of men ranking very high in ability, capacity, sincerity and devotion to the manifold tasks upon which they are continuously engaged.

The reference before made to the number of cases docketed, while indicating in a manner the volume of work directly handled or reviewed by the members of the commission, does not cover the entire work performed under the authority of the commission by its subordinate employees or bureaus, as of locomotive inspection, accounts, statistics and tariffs.

In working out the enforcement of the boiler inspection law it has been found desirable to locate the inspectors of this division at various points throughout the country in such a manner as to insure frequent observation of the locomotive boilers and appliances. That this organization is effective most of us know. The men are "on the job" and the figures reported by the chief inspector in his 1914 annual report showing 32 per cent decrease in the number of accidents, 36 per cent decrease in deaths and 32 per cent decrease in injuries as compared with the previous year are at least prima facie evidence of efficiency.

The division of accounts now maintains representatives in seven of our principal cities, where they are in close touch with the accounting features of our principal railroad systems. These men too are "on the job" and the theory of uniform accounting is being evolved into fact.

For valuation purposes the country has been divided into Eastern, Central, Western, Southern and Pacific divisions, with headquarters in four principal cities outside of Washington.

In the matter of hearings and investigations, however, the commission has no fixed local representation. Its principal office is in Washington and there is provision for the conduct of hearings and investigations by one or more commissioners in any part of the United States. This circuit riding feature was for a number of years frequently operative and it was quite the usual thing for members of the commission to conduct hearings at various points in the territory immediately concerned in the matters at issue. But as the work

*An address delivered before the Railway Club of Pittsburgh.

increased it became exceedingly difficult for members of the commission to absent themselves from headquarters at Washington until it is a rare occasion when a member of the commission takes direct charge of any proceeding at an outside point. Such are almost invariably conducted by subordinate representatives of the commission, known as lawyer examiners, who report to the commission for its review and action the evidence adduced, briefs filed and recommendations.

On account of the large amount of work and the probability that it will continue to increase, further addition to the membership of the commission has been proposed, and if it were wholly practicable to subdivide and assign to certain members a particular share of the duties, the end might be attained in this manner, which is workable, however, only in some minor matters.

Are not the work and territory involved and interests affected now great enough to subdivide in a more rational manner? I believe such to be the case, particularly as the development of successful regulation will require greater authority in the regulatory body, coupled with a greater degree of accountability to the whole people.

My suggestion, which I hope may be considered in the line of progress, is:

1. Divide the country into six districts—Eastern, Central, Southern, Southwestern, Northwestern and Pacific.

2. Assign to each district three sub-commissioners, with headquarters at convenient geographical locations in each district.

3. Let all hearings and investigations be conducted by these boards of sub-commissioners singly when intraterritorial, and by joint representation when interterritorial.

4. Forward to the Washington commission for review and decision the record of hearing and investigation, lawyers' briefs and sub-commissioners' recommendations as is now done in cases conducted by examiners.

5. Relieve the Washington commission generally of the direct conduct of hearings and investigations, except in cases of such importance as in their judgment may make it desirable for one or more of their members to sit with the local commissioners.

The personnel of all commissions is of vital importance. Salary and tenure of office should be such as to command experience, ability and honest devotion to the work. One member for each of the sub-commissions may well be assigned from the commission's corps of examiners, whose experience qualifies them to produce results. Give them a chance to settle down and get a thorough acquaintance with the transportation and business needs of a particular territory and they can do better work and more of it. One member on a sub-commission should certainly have general experience in the conduct of railway operations. A third member should be a representative of general business or shipping interests.

The benefits of such an organization are readily manifest. Among them may be cited:

1. Washington commission can give more concentrated and thorough attention to the larger problems and policies of regulation and control.

2. Washington commission can serve more efficiently in advisory capacity to Congress and the president. The chairman of the commission should be ex officio a member of the president's official family and on the same footing as a cabinet officer. The president and the Congress should have the benefit of the expert knowledge possessed by the commission in considering proposed legislation.

3. Local commissions should foster a better understanding and closer relationship and co-operation among all interests, including what is extremely important, state and other local regulatory commissions.

4. Business can be handled with greater expedition and we will have less standing still and marking time while waiting for action.

5. Much loss of time and long distance traveling may be avoided.

6. The commission will be "on the job."

SAFETY FIRST ON THE LONG ISLAND

The latest phase of the campaign for safety on the Long Island Railroad is the posting of signs on the highways, warning automobile drivers to be more careful at grade crossings. One of these signs, painted on a bridge, is shown in the accompanying engraving. This is at Broadway, Flushing, N. Y. It is 50 ft. long and about 10 ft. high. Other signs will be put on bridges at Winfield, Jamaica and other places, and also at places near grade crossings where the warning is likely to be useful. The signs are of different sizes, a common shape being 10 ft. wide and 10 ft. high. Some of the signs will be lighted at night. More than $15,000,000 has been spent already in the elimination of grade crossings on the Long Island, but there are still 631 crossings on the lines of this one railroad company. Work on the elimination of 32 more crossings is now in progress.

Coincidently with the posting of the signs the railroad company is publishing advertisements in the local newspapers. From

Sign on Broadway Bridge, Flushing, N. Y.

a series of several advertisements, the publication of which is to be spread over several weeks, we make the following extracts:

This is the first of a series of advertisements the sole purpose of which is to save life—your own life it may be or the lives of your family or friends. The automobile touring season is just beginning. Every year brings an increase in automobile accidents at grade crossings on Long Island. We have tried many ways to get people to be careful, but reckless driving is as common as ever. . . . We shall keep putting up more signs wherever they can do any good. *Look for them.*

A large percentage of the people hurt in grade crossing accidents on Long Island are people who are not familiar with the roads. Remember this when motoring on Long Island: When you see a railroad crossing sign, respect it! It may mean the saving of your life. You cannot miss the crossing sign. . . .

To take a chance at a crossing; to trust to luck to get across is worse than foolhardy; it is criminal. Let the sight of a grade-crossing sign instantly convey to you the warning to slow down or stop. It's the only way to be safe.

Even if you know none of the victims, there is a shock in reading the details of an accident to automobilists at grade crossings. . . . But how often do you take home the lessons your daily paper so constantly conveys? . . .

A train approaches a grade crossing. The gates drop, the automatic bells sound, or the flagman appears with his warning

lantern. But the chauffeur deliberately speeds up his car, smashes through the gates, and whirls across the tracks a hair's breadth ahead of the engine. Couldn't happen, you say? It happens at least once a week on Long Island. . . .

Remember where the grade crossings are and slow down or stop before you approach them. As fast as possible we are abolishing them. This is our part. Yours is the exercise of caution.

If you would always associate the sight of a grade crossing with the instant application of your motor's brakes—accidents to automobilists at grade crossings would soon be scarce. . . . Trains must run on tracks and on time. Their operators have no choice of routes. But the automobilist can choose his road and regulate his rate of speed.

Five hundred flagmen are on duty day and night at this railroad's grade crossings. We keep them there for your protection.

At the sight of a warning flag or lantern—stop your automobile.

STATISTICS OF ENGLISH RAILWAYS IN WAR TIME

By Julius H. Parmelee
Statistician, Bureau of Railway Economics

The virtual nationalization of the railways of Great Britain for the period of the European war has effected curious results, as regards both management and statistics of operation.

On August 4, 1914, the very day Great Britain and Germany locked horns, an Order in Council provided that the government should assume control of the railways of the United Kingdom. For this purpose an executive committee was created, composed of the general managers of a dozen selected railway companies, with the president of the Board of Trade as chairman ex-officio, and the general manager of the London & South Western as acting chairman. Beginning August 5, the railways have been administered as one system under the control of the government and in conjunction with the war office and the admiralty.

The annual reports of the English railways for the year ended December 31, 1914, reflect this government control in a number of aspects. By an arrangement perfected at the commencement of the period of control, the government agreed to compensate the railways for their services in connection with naval and military transport by guaranteeing them the same net revenues as were earned from rail operations during the corresponding period of the preceding year. In return, the railways have placed their facilities primarily at the disposal of the military organizations, and only secondarily at the disposal of the traveling public. All necessary expenditures are met by the railways, the government agreeing to make up any deficits and guaranteeing net revenues proportionate to those of the latest corresponding period of peace. Stating this differently, the government has practically commandeered the railways for its own use, paying therefor a sum equivalent to the deficit (if any) plus the normal net revenues of the period. The sole proviso is that if the net revenues for the first half of 1914 were less than for the corresponding period of 1913, a proportionate reduction is made in the net revenues for which the government stands guarantor.

Statistical interest centers in the form of accounts necessitated by these extraordinary conditions. The principal railways of England carry in their annual reports for 1914 a uniformly worded description of the arrangement with the government, and point out that the circumstances necessarily involve considerable alteration in the accounts and statistical returns for the year. The statements presented in these reports are prepared in the abridged form agreed upon with the Board of Trade.

The English railway reports for 1914 are, therefore, less detailed and contain fewer statistical tables than usual. None too enlightening at the very best, the reports now throw little light on actual operations. For example, the one vital account (No. 8, Revenue Receipts and Expenditure of the Whole Undertaking), which is the record of income and outgo for the year, is now made up almost wholly of two items. The income item is entitled "Receipts in respect of railway working, and of separate businesses carried on by the company, including estimated amount receivable under agreement with the government in respect of control of railways for the period August 5 to December 31, 1914," while the outgo item is entitled merely "Expenditures." These two heads cover transactions aggregating millions of pounds, without the slightest attempt at detail of any kind.

With the further sanction of the Board of Trade, the railways are varying the statutory form of accounts this year by omitting from their reports all accounts showing revenues and expenses in detail, especially the income account entitled "Receipts and expenditures in respect of railway working"; also statistical tables dealing with the auxiliary activities of the railways, such as the operation of omnibuses, steamboats, canals, docks, harbors, wharves, electric light and power plants, and so on; also the important records of passengers and freight carried, and the detailed traffic statistics. Whether these accounts are omitted for the sake of simplicity, or as a blind to the enemy, or to conceal actual conditions from the English public, is conjectural; but they serve to rob the reports of what little value they formerly possessed.

It is clear that the only item now remaining in the English railway accounts offering any index to business conditions is that of expenditures; for the traffic statistics have disappeared, and the income item is arbitrarily arrived at by adding expenses and normal net revenues. Comparison of the expenditures of the railways for the calendar year 1914 with those for 1913 is disappointing, therefore, in that little change is noted in either direction.

The available statistics cover 15,314 operated miles. The operating revenues for the calendar year 1914 amounted to $513,521,144, as compared with $505,656,203 in 1913; operating expenses in 1914 were $339,711,288, and in 1913 were $329,272,383.

A point of interest in the reports concerns the human side of the war—the enlistment of railway employees under the banners of the Empire. The London & North Western points with pride to 12,000 employees in the army and navy; "that they have acquitted themselves with honor is attested by the fact that their list of casualties to the latest recorded date, is, etc." Similarly, the Great Western takes satisfaction in 10,000 employees with the colors; the Midland in 9,000; and the North Eastern in 6,200. These roads, in common with others, are making allowances to dependent families of their employees while under arms, and will find positions for them on their return to civil life.

Another vital human touch is the official announcement of the North Eastern, in its annual report, that in the bombardment of Scarborough, Whitby and the Hartlepools 5 employees were killed and 32 injured.

Dining Car Service.—The railroads that have dining car service have a growing incentive to make that service all that the traveler could desire. Gastronomic expectations can be fulfilled with greater happiness and disappointed with greater bitterness than any other. There are two things that must be gone about in the right spirit. A "kick" by a patron, no matter how made, may represent a substantial cause for complaint which may have been going on unspoken for a long time, for not every one exercises his right to complain. In order that complaints may always be turned to good account, the invitation that they be made to the conductor is important. Try to make the kicker speak to the conductor, not to the waiter, for the latter can see it only as an effort to defeat his right to a tip. The other point is the strictest care to serve only fresh, well-prepared foods. Don't say, when a robust, healthy man has a sudden attack of ptomaime poisoning, that it is a matter you can't get at. A legislator can't get at it, but a good caterer can.—*The Railroad Herald.*

THE GRETNA DISASTER

The wreck of three passenger trains at Gretna, Scotland, on the Caledonian Railway, May 22, reported briefly in the *Railway Age Gazette*, May 28, page 1130, resulted in the death of 161 persons and the injury of 200 others. Nineteen passenger cars and 12 freight cars were wrecked and destroyed by fire, and four locomotives were damaged beyond repair. The English papers bring some details of the causes of the collision. The second smash, which occurred within about one minute after the first one, is more properly to be classed as a derailment, the northbound express train on the west track, running into the wreckage of the first collision, which had occurred on the southbound (east) track. A considerable number of the victims were soldiers who had alighted from the southbound train and were walking or standing on the northbound track. They were unable to escape from the oncoming express train because of the presence of freight cars on a side track west of the main line.

The collision occurred at a signal box known as Quintinshill, about a mile north of Gretna station. A northbound local passenger train was set off on the southbound track to allow two express trains to pass it. These expresses, when on time, leave Carlisle, a few miles south, ahead of the local. The local train would have been put on a siding, but for the fact that there was much congestion because of Whitsun traffic and the movement of troops. While standing on the east track the local was run into by a troop train coming from the north, at full speed, both the distant and the home signals being clear for it. As before stated, the northbound train then came on at high speed before there was time to send out an adequate warning. Flames broke out within a very few minutes, either from coals which fell from the fireboxes of the locomotives or from ruptured gas pipes. There was some use of fire extinguishers, but the testimony concerning the fire is rather indefinite and somewhat contradictory.

The collision occurred about 6:40 a. m., just as the night signalman was going off duty, and some confusion in the giving of information by the night man to the day man, or misunderstanding on the part of the latter, appears to be one reason why signals were cleared for the southbound troop train when the northbound local passenger stood in its way. Mechan, the night man, regularly remained on duty until 6:30, instead of going off at six, according to the regulations; this in order to enable the day man, Tinsley, to reach the cabin by a convenient train from Gretna, the very train which was standing in front of the cabin and which was run into. This irregular habit was concealed from the inspectors; the night man made no entries on the train sheet after 6 o'clock, leaving a memorandum from which these were made by the day man.

In the reports thus far at hand nothing is said concerning the qualifications or experience of either of the signal men.

When a northbound train is thus standing at a station on a southbound track the rules require that the signal man put a collar on the levers of the signals, so that he cannot absent-mindedly clear a signal for an approaching southbound train; but it appears that this use of the collar was habitually neglected.

The fireman of the local passenger train had gone into the cabin, and it was his duty to see that the collar was used, but this duty also was neglected.

A train of empty freight wagons, southbound, preceding the troop train had just arrived at Quintinshill, and had entered a side track. Whether the arrival of this train had been reported to the next station north appears to be in doubt; both the day man and the night man say that they did not make this report, which throws responsibility on Kirkpatrick, the block station next north; but the reports do not tell what happened there. The day man admits that he forgot all about the local passenger train, standing less than 100 ft. from his cabin. There was a freight train on a side track between the cabin and the main line which, however, does not appear to have formed a complete obstruction to his view of the passenger train.

The English papers refer to this disaster as the worst occurring on a railroad anywhere in the world since railroads were used, measuring, of course, by the number of persons killed and injured. So far as official records are concerned we have no facts at variance with this statement; but there was a wreck at Mailpois, Mexico, in June, 1881, which, according to the newspapers, resulted in the death of 214 persons and the injury of 50 others. A similar report from Santa Ana, Salvador, May 3, 1894, reported over 200 persons killed. A train wreck at Kobe, Japan, July 28, 1895, resulted, according to report, in 140 fatal injuries. In a train wreck at Maddur, India, September 24, 1897, the number of persons killed was reported as "five carloads." The longest death list in any train accident in the United States is that of the wreck at Eden, Colo., August 7, 1904, when a train broke through a bridge and 94 were killed.

RAILROAD LEGISLATION IN NEW YORK

The legislature of New York, recently adjourned, passed five laws affecting railroads, besides the items in appropriation bills for removing highway crossings. Senate bill No. 837, now chapter 281, amends the general law, section 52, requiring railroads to keep fences in good repair, by adding a clause including cattle guards, so as to make the railroad responsible for injuries to animals in case a cattle guard is not kept in good condition.

Senate bill 141, now chapter 240, amends the railroad law in relation to grade crossings by amending section 94, paragraph 7, so as to empower the Public Service Commission to authorize intermediate payments on an improvement taking a long time to carry out; and paragraph 8, requiring the legislature annually to appropriate $100,000 for paying the state's proportion of crossing changes, is cut out.

Senate bill No. 2112, now chapter 515, amends the banking law in relation to savings banks investments by an addition to paragraph a so as to make applicable to a consolidated road, like the New York Central, the provision requiring certain dividends to have been paid during the term of five years. In calculating the dividends all payments by all of the consolidating corporations may be included.

Chapter 559 amends the railroad law in relation to gates and flagmen at highway crossings, empowering the Public Service Commission to order the employment of a flagman or the erection of gates at any crossing where wayfarers on the highway cannot have a good view along the track when they come within 200 ft. of the crossing.

Chapter 564 empowers the Public Service Commission, on petition, to change the name of any railroad station.

A sixth law affecting railroads is that which gives the Public Service Commission authority over so-called "jitney bus" service in cities having less than one million population, the authority of the commission being made substantially the same as in the case of street railroads. The Long Island Railroad operates three trolley roads, and so is interested in this law. The company carries on this business without profit, for the general benefit of the people of Long Island. The law aims to prevent unfair competition on the part of automobiles with street cars.

The annual appropriation bill for the Public Service Commissions includes, for the elimination of highway grade crossings in the first district $200,000, and for the same purpose in the second district $552,000.

The Iron Cross.—The iron cross, the most highly-prized recognition of valor in the German army and navy, is not a casting, but is struck with steel dies in heavy coining presses. After being stamped out, the crosses are taken to the silversmith's, where the soldering is done, a fine silver border added, and the finishing completed. The silver border is polished on electrically-driven polishing and grinding motors.—*The Engineer.*

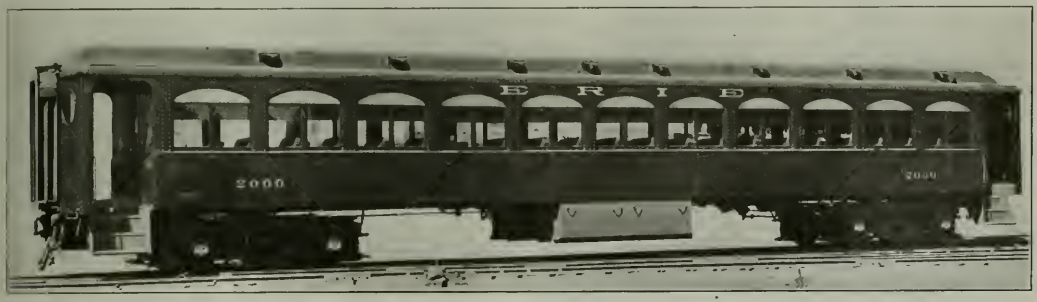
All-Steel Suburban Passenger Cars for the Erie

Coaches Have Seating Capacity of 86 and Are Exceptionally Light in Weight; Built for Future Electrification

A train of eight suburban passenger cars of all-steel construction, consisting of seven coaches and one combination baggage and smoker, has recently been placed in service by the Erie Railroad. The cars were built by the Pressed Steel Car Company, Pittsburgh, Pa., from designs prepared by L. B. Stillwell, consulting engineer, New York.

The design of these cars was made with a view to meeting the following conditions: Safety and comfort of passengers; low cost of operation; low cost of maintenance, and moderate weight per foot of over-all length, when compared with the lightest wooden cars in the same company's service.

The comparison per foot of over-all length is unaffected by the seat spacing, and is particularly interesting in this instance, as the new cars include heavy buffing and friction draft gears, as well as heavy draft sills, whereas the lightest wooden car has only the platforms and wooden draft sills with tandem spring draft gears. The light weight can be attributed to the exclusion of all unnecessary members. The deep and heavy center sill

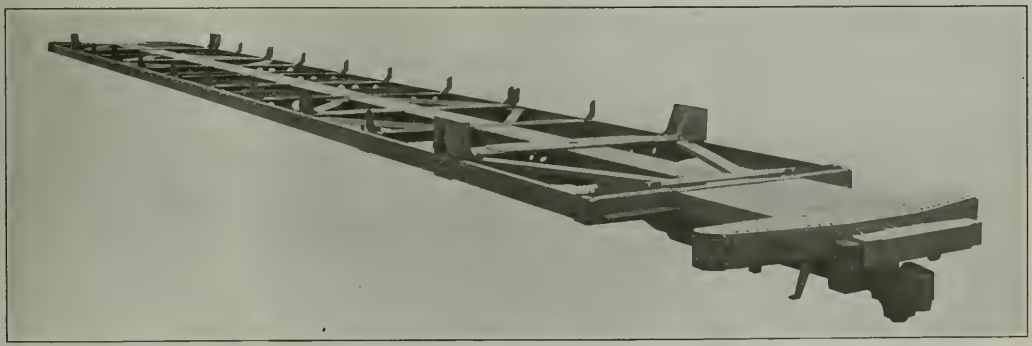


Erie All-Steel Suburban Coach

first cost. In general their construction is similar to that of the New York, Westchester & Boston electric suburban cars, described and illustrated in the June 14, 1912, issue of the *Railway Age Gazette*, and while they are built for steam operation, provision has been made for the ultimate addition of electric motive power equipment. One of the points of greatest interest in the construction of these cars is the arrangement of the superstructure, whereby all parts contribute to its strength to withstand shocks of derailment, overturning or collision. Other notable features are the light weight per seated passenger and the easy-riding qualities which have developed in service.

The coaches are 70 ft. 4 in. long over-all and weigh complete 95,400 lb. The table on page 1245 of comparative weights of Erie passenger equipment shows that the total weight is less than that of two classes of steel underframe passenger cars having a smaller seating capacity. It shows further that the all-steel car weighs less per seated passenger and closely approximates the construction of the fishbelly type has been dispensed with, and sills of uniform section are supported by the deep side frame through a system of crossbearers.

Provisions for application of electric motive power equipment consist in the suitable height and outline of roof to permit of application of overhead current collector if required; the arrangement of vestibule for application of platform control equipment; the arrangement of underframe members for the support of electrical motive power equipment in the most advantageous manner for operation and for thorough inspection and maintenance of apparatus, and the design of draft sills, bolster and of truck whereby clearance is provided for electric motors.



Underframe; Erie All-Steel Suburban Cars

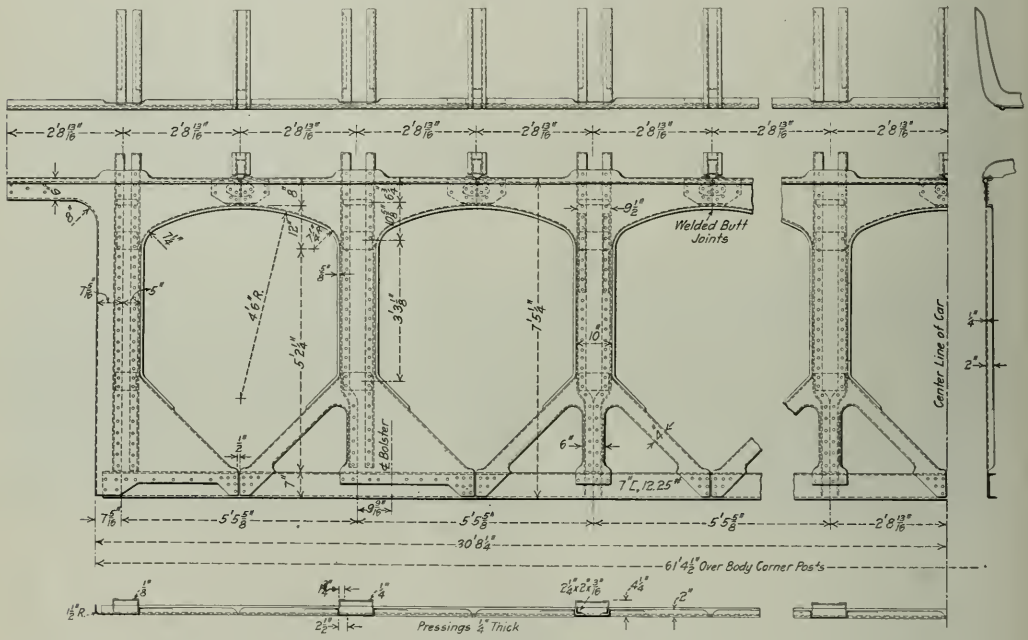
The center sill construction of these cars is of uniform depth and section between bolsters, and consists of two 8-in. 16.25-lb. channels spaced 14 in. back to back, with a 19-in. by ⅜-in. top cover plate and two 4-in. by 3½-in. by ⅜-in. angles reinforcing the bottom flanges. This gives a total section of 22 sq. in. Forward of

the bolsters deep pressed steel draft sills extending through the bolsters reinforce the center sills and at the point of maximum depth add 10 sq. in. to the section.

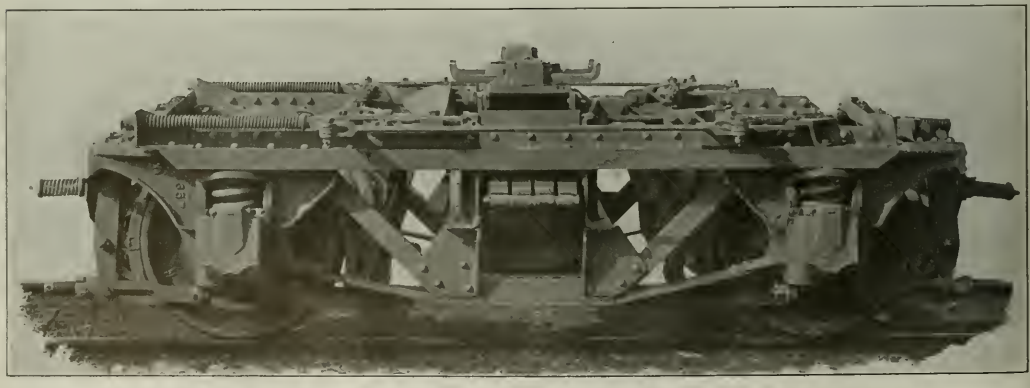
The center sill construction forward of the bolsters is supported by the high side frames through the body end sill and bulkhead construction. The bending moment occurring at this point due to the eccentric draft gear forces is resisted by the draft sills and is transferred by the body end sill and bulkhead to the high side frames. The center sill construction between bolsters is thus relieved of any eccentric loading from the draft gear forces, and the full section is available to resist the consequent direct compression because of the support afforded by the high side frames and heavy crossbearers placed under the side posts.

As the rigidity of an all-steel car underframe makes the use of a heavy draft gear practically imperative, and the installation of an effective buffing device equally necessary, the new Erie cars are fitted with a friction draft gear and buffing device calculated to be of sufficient capacity to absorb the most severe shocks received in service.

The side frames of the car are 7 ft. 5¼ in. from bottom of sill to top of side plate, and are 61 ft. 4½ in. long over body corner posts. The entire frame is designed as a girder, with a pressed steel compression member at the side plate and a 7-in. 12.25-lb. channel tension member at the side sill. The posts connecting these members are of 10-in. pressed channel form, ¼ in. in thickness, and are spaced 5 ft. 5⅝ in. between centers. They are furnished with integral diagonal braces below the windows.



Pressed Steel Unit Side Frame Construction of the Erie Suburban Cars



Truck Used on the Erie All-Steel Coaches

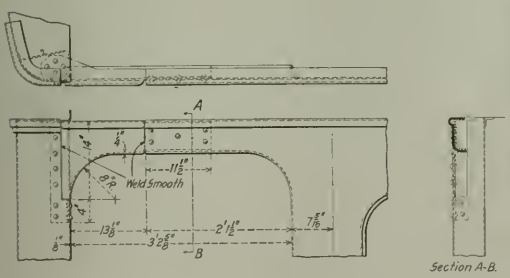
and with flanged gussets at the portal arches. The vestibule end posts consist of 9-in. I-beams framed into the sills and to the vestibule ceiling construction. The body end walls are fitted

Interior of Erie Steel Suburban Coach

with ¼-in. pressed steel corner posts 12 in. deep, with gusset connections to the side sills and to the side plates of flanged form ¼in. thick, thus bracing the end walls against collapse.

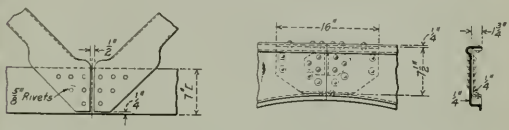
The roof structure is formed of pressed channel carlines, and is of the compound arch type. This form of roof is not only strong, light and inexpensive, but gives good ventilation good distribution of reflected light and is particularly suitable for the support of electric current collectors, should the cars later be fitted with electrical motive power equipment.

The trucks are 47 ft. 7½ in. apart from center to center and



Detail of Vestibule Corner Post Connection to Side Door Header

are of a non-equalized type, generally similar to those on the Westchester cars previously referred to. They are fitted with coil journal box springs and long quadruple elliptic springs under the bolsters. The proportioning of the springs is such as to produce the easy-riding qualities essential in steel car construction, not only for the comfort of the passengers but for the maintenance of equipment and roadbed. The trucks have an 8-ft. wheel base and complete, with clasp brakes and 33-in. wheels with 5-in. by 9-in. journals, weigh 12,500 lb. each. These trucks are designed with ample clearance for the application of electric motive power equipment, if at any future time their use in such service is required. Other features of interest on the trucks are Coleman bolster locking center pins which prevent the separation of car body from truck in case of derailment or collision, and



Details Showing Diagonal Brace Connection to Side Sill and Side Plate Splice

clasp brakes, which greatly reduce brake shoe and journal wear and facilitate smooth stops, which is an especially desirable feature in suburban service.

The illumination of these cars is secured by eleven electric fixtures arranged in center line of car, the form of ceiling outline being such as to reflect and distribute the light evenly over the seats and aisle without producing shadows. One 25-watt lamp is

Interior View of the Completed Framing; Erie Suburban Cars

used on each fixture. Power for lighting is furnished by a Wilson storage battery of 800 ampere hour capacity.

The equipment of the cars includes Miner friction draft gear and buffing device; Pitt couplers and Hale & Kilburn seats. Wherever renewals or maintenance require that a stock be kept on hand the railroad's standard parts have been used.

THE MEASUREMENT OF EFFICIENCY IN YARD OPERATION

By J. W. Roberts
General Superintendent of Passenger Transportation, Pennsylvania Lines West, Pittsburgh, Pa.

The results of efforts which may be directed toward the operation of terminal yards in accordance with appropriate efficiency standards, are affected either favorably or adversely by such a diversity of varying conditions that facts descriptive of the most minute details of the methods and practices of one yard, and apparently well adapted to its requirements, may not be accepted as conclusive evidence of a high standard of operation, but merely as one of numerous factors which enter into the formation of a correct measure of efficiency. Such results do not necessarily represent even the more prominent factors which a measure of terminal yard efficiency must embrace, but on the contrary owing to the wide range of view points as to the real functions of a terminal yard as part of a railway system, an achievement in the form of a comparatively low unit cost of operation at one point might in reality constitute the cause of legitimate criticism relative to unsatisfactory operation at other points because keen competition, irregular inbound and outbound train and interchange movements of cars, or inadequate car repair facilities and other like conditions may necessitate radical deviations from methods and practices calculated to produce a minimum unit cost of operation.

The classification of forces, assignment of shifting locomotives, selection of supervising assistants, and estimates of period appropriations, are all duties devolving upon the head of a terminal yard organization, which he cannot perform, correctly at least, in accordance with observations, but which demand reports descriptive of the exact situation in each part of the yard.

A very great variety of report and record forms have been designed to meet the three-fold requirement of measurement of service to be performed—measurement of member or unit capacity, and measurement of results obtained. Some of these forms doubtless serve the desired purpose, but as a principle it is safe to state that, to be most efficient, reports and records should be as brief and simple as possible consistent with the information they are expected to express, and should harmonize in all respects with the unit of service regardless of its character.

In the terminal yard this unit is the car, hence the current reports, records and permanent statistics should be based upon the *number of cars* handled in *each class of switching service* as illustrated by the accompanying report and record forms designated "A" and "B."

The reports and records relative to terminal yard operation which seem to be most popular among both large and small roads, are limited to information as to the *total* number of cars handled in and out of a terminal yard, including cars delivered to and received from connecting lines, and the direct operating expenses per car so handled. Such reports and records are fundamentally wrong and have no value as a gage of efficiency or proper unit expense. They do indicate whether the cost of handling a car varies within each of two corresponding periods when the business and other prevailing conditions generally are about the same, but the result when available is meaningless for the reason that within one period industrial switching service may have been very heavy, and through or interchange switching service very light; while within the other period involved by the comparison the directly opposite situation may have obtained. If reports and records do not meet the requirements of a single terminal yard, they can not possibly be employed to any advantage in connection with comparisons of the results of operations of different terminal yards of one railway system or of different railway systems.

The combination report and record forms "A" and "B" are designed to accommodate information showing the *total* number of cars handled by *each* switching crew in *each* of the four *distinct classes* of terminal yard service, and the total number of hours performed by *each* crew within a calendar day; the details specified and the total direct or the total direct and indirect expenses incidental to operations, constituting the measure of, (1) cost per car of all cars handled by each crew in each class of switching service within the limits of each district, and within the limits of the entire terminal yard; (2) cost of handling a car from the time it enters a terminal yard until it departs therefrom; (3) cost per car for the handling of cars to or from a particular industry or private track, and (4) causes of differences between items of cost referred to in sections (1) to (3) inclusive, as applied to different districts in the same terminal yard, to different terminal yards of a system, or to terminal yards of different systems.

Form "A" is intended to serve the three-fold purpose of a crew conductor's daily report of operations to his yardmaster, the yardmaster's daily report of district operations to the terminal yard organization head, and the basis for the maintenance of daily records on the form designated "B" by the crew conductor to measure operations under his immediate charge, the yardmaster to measure operations within the district under his immediate jurisdiction, and the terminal yard organization head to measure operations of the various branches or sub-departments of his organization.

Note.—Record to be in book form so that the opposite page will in all cases indicate details of the corresponding day, week or month of the preceding year.

Both forms are in harmony with the theory that there is a unit in each class of service; that the supervisor over a service must know not only the capacity of his assistants, but the causes of variations in results of their efforts, and thus be in position to direct adjustments in forces and expenses immediately after conditions warranting that action become apparent; that the exhibited comparative results of member, branch or sub-department, and department operations are an essential part of a system of educating employees and creating interest in their work;

and that a terminal-yard organization head should be prepared at any time to make a very close estimate of the cost per car of all cars handled in each of the different classes of switching service; in any one of the classes of switching service, or to or from a particular industry or private siding. The latter detail is one which is very closely related to the service of "spotting cars," while the measure of switching cost is certainly the *right measure* also of the switching rates.

The four different classes of switching service as indicated are common to all terminal yards, which is likewise true of certain of the subdivisions of classes two and four as indicated. The classes which represent the movements of cars to and from mines, the handling of passenger cars, and classification through hump yards, are not common to all terminal yards, and since refinements with respect to cost more extensive than the four distinct classes of service might be required, the record and report forms provide for them.

A very natural criticism of the report and record forms referred to is that their use will entail considerable labor on the part of the supervising heads, in which criticism advocates of the theory that efficiency may be obtained without supervision other than observations will readily concur; the other side of the same proposition being that economical operations demand interest and efforts of employees to the extent of reliable current measurements of accomplishments, and that the results warrant the little additional labor necessary to obtain them. Inasmuch as the performance to be reported and recorded refers to *totals* in all cases, a loyal head of a branch or sub-department, informed as to the purpose of the reports and records in their relationship to his personal service and standing, should resent instructions prohibiting him from giving in that form evidence of his relative capacity, worth, and rights when the opportunities for advancement are presented. Furthermore, to maintain the records, which would be neither difficult nor expensive as proven by experiments in a large terminal yard, would be to anticipate requirements in the nature of measures for: (1) Switching rates sufficiently large to yield a fair profit, and represent a proportion of through transportation rates; (2) charges sufficient to cover the cost of handling carload shipments between loading or unloading points on private sidings, and reasonable distance limits from stations to or from which transportation rates apply; (3) charges representing at least the cost of switching and handling of cars at different points incidental to reshipments, reconsignments, etc., as authorized by published tariffs.

OVERHEAD CHARGES IN VALUATION

By Richard Hoadley Tingley

The scrap-heap, into which is thrown all items of construction expense that cannot find lodging in any other classification, is commonly known as the "Overhead." There are almost as many different ideas as to the make-up of this classification, and the value of the units that go into it, as there are commissions having to do with it. The truth of the matter is that the term "Overhead" has no clearly defined, well recognized definition; no really official standing in valuation nomenclature. The official classification of the Interstate Commerce Commission does not mention this term, but provides for "General Expenditures," into which must be placed all items of expense not specially mentioned as belonging elsewhere. Nevertheless, the term overhead has come into such general use; is so often spoken of and written about when reference is made to the valuation scrap-heap, and has occupied such an important position in the decisions of courts and commissions, that a brief study of its real meaning and significance may be instructive.

In the broadest acceptance of the term, overhead charges include: Engineering and superintendence, contingences, contractors' profit, promotion costs, bond discount, piecemeal construction, brokerage and general expenditures.

In this last item, which is recognized as one of the three grand sub-divisions of construction accounting by the Interstate Commerce Commission, is included further overhead items as follows: Organization expenses, general officers and clerks, law, stationery and printing, taxes during construction, interest during construction and other general expenses. To these may be added two more items which, although not fully recognized by commissions generally, are really members of the overhead family in certain classes of valuation, development costs, going value and franchise value.

There is no uniformity among the different commissions as to the acceptance or rejection of the above items, each choosing its own course irrespective of others.

Not only in the matter of looseness of definition is overhead noticeable. It is the weak point in valuations today; the feature about which the least amount of definite knowledge exists. Other elements of value have been and are being accurately determined. Inventories of visible assets have been and are being made with great care and scrupulous nicety. Land values have been and are being scrutinized by experts, and courts are deliberating and ruling on whether or not the unearned increment represented thereby shall be allowed as value. The subject of depreciation is being widely discussed with a view to ascertaining what place, if any, it has in valuations for rate making or other purposes, yet, except in a few cases of appraisal of water works properties, it is apparent that overhead has so far received no really careful study; no attention to compare in any way with the thought that has been given to other elements of value. Its importance warrants better treatment.

Professor M. E. Cooley says in the Journal of the American Electric Railway Association, 1911: "Depending on the locality, and whether certain of the items discussed may or may not be included in the cost without being separately stated, the total overhead charges may vary from 20 to 25 per cent, and from 50 to 60 per cent, of the cost as determined by inventory; that is to say, the total cost of the property will vary from 120 or 125 per cent to 150 or 160 per cent of the cost as determined by inventory of the physical elements alone." In this Professor Cooley writes from general knowledge only, and it must be admitted that the range is wide indeed. It is true, however, that such a range exists, though perhaps Professor Cooley has overdrawn it. Moreover, the determination of whether 20 per cent or 60 per cent of the inventory cost shall be added to appraisals is little better than one man's judgment as against another's, for no better information exists, and one expert's judgment, estimate or guess is as good as another's.

In an arbitrary manner the different state commissions have adopted certain percentages to be added to inventory costs to cover overhead. In practically no case does the determination of these percentages rest on a solid basis. In each case it is an assumed basis resting on general knowledge and a limited amount of actual data.

Many state commissions do not recognize development costs or going value as elements in valuations, and many, too, give no room as such to contractor's profit, contingences, etc., reasoning that in inventory costs these latter items have already been taken care of. If, however, full consideration is given in valuations to development costs, a much wider range of possible percentages to be applied to overhead will appear than that brought out by Professor Cooley. A lack of understanding as to what is included under this heading is responsible in some measure for the situation, and some distinction is made with respect to the purposes of the valuation. In several cases of valuation for purchase and sale the courts have upheld an addition of from 10 to 25 per cent to the inventory cost to cover going value, but in rate cases there has been a tendency to exclude this feature as well as development costs. The Wisconsin Commission usually gives full recognition to development costs, and in certain rate cases has allowed as high as 20 per cent of the cost of reproduction. L. R. Nash says in Stone and Webster Public Service Journal for October, 1912: "It will be of interest to consider the aggregate of all overhead costs as

compared with structural cost. The successive addition of percentages applying to physical property gives a cost of reproduction from 129 per cnt to 158 per cent of the structural cost. The further addition of percentages connected with the organization of the company gives totals of 131 per cent to 163 per cent of the structural cost. The final addition of percentages to cover development costs gives an undepreciated fair value from 141 per cent to 188 per cent of the structural cost. It thus appears that it is by no means inconceivable that such fair value in certain cases may be double the structural cost, if development costs are considered."

Robert H. Whitten says in his Valuation of Public Service Corporations: "The trouble with overhead is that nobody has yet taken the pains to study it, and that there is no uniformity of practice in the different states and commissions as to what items go to make up its total. In giving testimony the experts on behalf of both sides freely admit that they have no definite knowledge of the subject nor of the figures they are presenting to cover overhead. In summing up valuation cases and in rendering opinions, commissioners also are equally free in acknowledging their ignorance, and in stating that 'general knowledge' rather than definite and precise information governs." In reviewing opinions and findings of commissioners one frequently finds such references as the following: In the Public Service Commission of New York, First District, opinion and order of commission, October 20, 1911, Mayhew vs. Kings County Lighting Company: "It might be expected that the company itself would have data on which to base an estimate of a reasonable allowance for these terms (overhead). In this case the company has produced no such data. A request was made for the early records of the Kings County Gas & Illuminating Company, the predecessor of the present company, but they were not presented. An estimate must therefore be based upon general knowledge and experience." The theoretical figures of the company were then discussed, and the opinion goes on to say: "In the absence of data as to actual expenditures by the company, this amount is considered generous, probably too large." Again, in an opinion of the Los Angeles Board of Public Utilities is found. "The usual 20 per cent of cost, to cover engineering, supervision, interest and contingencies during construction," was allowed.

It seems to be apparent that in most cases a company should be able to substantiate its claims for overhead allowances by actual vouchers and other records of such expenses incurred in the construction of the property. There is no necessity for leaving this important matter entirely to expert opinion as to such costs, based on hypothetical conditions of assumed reconstruction. Suppose, for instance, that in the federal valuation of the railroads now in progress the matter was allowed to remain in its present chaotic state. The Interstate Commerce Commission, contending probably for low values, at least not for high ones, might be 10 per cent, or even 20 per cent, apart from the overhead value determined by the railroads, and in a total figure represented by many billions of dollars such a discrepancy would be serious indeed, and each faction would have as clear a title to its opinion as the other. Such a difference would render worthless all the carefully prepared inventories of visible assets, and would throw into disrepute the entire valuation matter. Its enormous expense would have been of no practical value. It would be like straining at a gnat and swallowing a camel.

The remedy for the troubles in overhead is quite clear. The National Association of State Railroad Commissioners has produced much valuable data bearing on valuation practice generally, in the different states. It might well occupy itself in defining the meaning and scope of overhead, and in determining and agreeing upon just what items of expense properly belong to this classification in valuations for the different purposes, rate adjusting, taxation, capitalization, purchase. This would insure at least uniformity. Furthermore, the state commissions, the Interstate Commerce Commission, and the various committees from the railroads might, and eventually must, occupy themselves, either jointly in one grand committee or separately, each for itself, in solving the greater overhead question; that of fixing upon a series of percentages that can safely be added to inventory costs to cover the various types of cases that present themselves in valuations. This field has never yet been covered. An organized search by experts of the books, accounts, histories and records of the railroads and utilities plants under review would be productive of illuminating results, and by covering a very large field, as in the case of the federal valuation of the railroads, and by carefully analyzing and tabulating results, a series of percentages could be arrived at that would mean something. As the matter now stands, a series of arbitrary percentages are applied to inventory costs to determine the overhead that mean little or nothing; somebody's opinion. As it might be worked out by the plan I have suggested, actual costs of overhead could be determined in a sufficient number of cases, so that the reverse would be the case: actual figures would then govern percentages. Such well digested and authenticated percentages could then be applied to plants and properties where no record exists, and where etsimates must of necessity prevail.

A NEW LUNCH COUNTER CAR

The Chicago & North Western on June 5 put in service a lunch counter car in connection with its "Golf Special" train, which leaves the Chicago passenger terminal daily, except Sunday, at 12:20 p. m., and reaches nearly a score of golf clubs located along its line on the north shore between Chicago and Waukegan. Returning the train reaches Chicago at 7 p. m.

Interior of the Lunch Counter Car

The car will be ready to serve a high grade lunch at popular prices at 12 noon, 20 minutes before the leaving time of the train, and thus will be a great convenience to the patrons of this train. The car contains a lunch counter running lengthwise of the train and occupying the entire length of the car, except for a short kitchen at one end. Seats are provided for 27 persons.

Signals on the Victoria Railways.—On the Victoria government railways 74.49 per cent of the stations, junctions and siding connections are interlocked. During the year ended June 30, 1914, fifty new electric train staff sections were brought into use and thirty-two tablet sections were replaced by the electrical train staff.

The Mechanical, Purchasing and Stores Departments*

Relations Between These Three Departments. Organization Necessary to Get Both Economy and Co-operation

By H. C. Pearce
General Purchasing Agent, Seaboard Air Line

There should be no division of responsibility between the purchasing and stores departments. These departments are logically one, and should more properly be termed the "Supply Department."

Our maintenance departments are organized and maintained primarily for the purpose of maintaining the equipment and roadway and structures in the best possible physical condition. Their unit of measure is the condition of the equipment and permanent way. They are not vitally interested in the investment for materials, or in any of the problems of purchasing, storing, distributing and accounting.

The supply department is organized for the purpose of providing, caring for, delivering and accounting for materials, and the assembling and disposing of the salvage. Its unit of measure is its ability to provide suitable materials promptly for the work at the lowest cost, and with the smallest permanent investment.

By a careful analysis, it will be found that the real cause of the unsatisfactory conditions which have prevailed, generally, is due to imperfect organization and supervision. The supply department should be so organized that it knows with reasonable accuracy what material will be needed, what quality is best suited for the work, and be in position to provide it promptly to the users when needed; recover and reclaim everything possible for re-issue, and market the salvage to the best advantage. In order to do this, there must be a well defined, practical plan, proper facilities and a sufficient number of trained men to handle the work. It is not expensive buildings and supply depots that are needed so much as sufficient room to properly segregate the material and protect it from the elements; facilities for handling and delivering economically, and, above all, a well trained organization that is in position to anticipate the requirements and provide for them in the shortest possible time, with the least expense, and with the smallest amount of material on hand.

The store delivery system, properly installed and supervised, offers the only practical way of keeping in touch with the actual needs and is the only economical method of delivering materials to the users in shops. The plan has as its basis a store delivery foreman with sufficient messenger boys and men to place the material in the hands of the users as wanted, and the bringing back to the storehouse of repaired and manufactured articles. The foreman in charge of this work should be a thoroughly competent man and be in close touch with the foremen of the different departments at all times. The messengers and delivery-men, by being in actual personal touch with the users of the material, become efficient and useful. The foremen and mechanics are able to confine themselves to the actual work at hand, thus saving the present loss of time of mechanics and helpers going back and forth from the storehouse for material, loss of the use of machinery; etc.; but, above all, it places the supply in touch with the actual needs

The supply train offers the only practical means of knowing what is needed for ordinary maintenance on the line, and is the most economical method of delivering material and collecting the salvage. The plan consists in moving the necessary supplies for all ordinary maintenance and operation on a regular schedule. The material and supplies in this train are so arranged that they can be issued in the least possible time. The crew consists of a supply car storekeeper and the necessary help or helpers to unload and deliver to the agents, telegraph officers, pumpers, section foremen, signal maintainers, etc., such material and supplies as will be needed to last until the next regular schedule of the train, after a thorough check has been made of what is actually on hand.

This train picks up all surplus material which may have been collected for any reason, materials and tools which can be reclaimed and repaired, and the scrap or salvage. It should be accompanied by the division engineers, roadmasters, and, whenever possible, by the superintendents. It will be found to be the most practical way of making a careful inspection of conditions by division officers. On railroads, districts, or divisions where the amount of supplies required does not make up a full train, dead-empties and loads can be moved to make up the tonnage. Engines moving light can be used to handle this train to advantage. The schedule should be prepared with this object in view. On railroads, districts, or divisions where these cars can be operated in locals during daylight, there is no objection to so doing, but the full usefulness of this train cannot be obtained unless it is operated properly.

These two branches of the service are fundamental to any efficient supply organization.

The organization should be such that the requisitions will be prepared so that they will go to the purchasing agent complete in every detail. The purchasing agent should so organize his office that only in exceptional cases should it be necessary to secure bids after the requisitions are received. In the majority of cases, agreements and contracts can be made to cover all standard supplies so that the orders can be placed immediately for most standard materials. It should not even be necessary to rewrite the orders. They should be made up complete at the time the requisition is prepared in the general storekeeper's office. Every day consumed from the time the requisition is prepared until the order is placed is time lost, without any contributing advantage. For the same reason the purchasing power should be used to its fullest extent to procure regular and uniform deliveries.

The maintenance departments should combine their technical knowledge and experience in the preparation of the specifications and standards. Probably no one thing is so badly needed on most of our railroads as carefully prepared, practical specifications and inspection. The specifications, when drawn, should combine the best practice and experience of the maintenance officers of our railroads, as well as the manufacturers.

Specifications, like organizations, should be flexible enough and broad enough to meet all conditions. Specifications are essential for the economical purchase and supply of materials. Specifications offer many advantages: They enable the manufacturers to produce their products at the lowest cost and place them in position to regulate their purchases of raw material and systematize their organizations so as to greatly reduce the costs and furnish better and more uniform material. They enable the supply department to arrange for its source of supply in advance and obtain it regularly. It is the only fair way to purchase materials, as it places all manufacturers on an equal basis.

Specifications, to be useful, must be prepared on the basis of service performed. Our chief engineers, mechanical engineers and engineers of permanent way have an opportunity to procure very valuable service records which should be

*From a paper read at the March meeting of the Southern and Southwestern Railway Club.

greatest service to the purchasing officer in arranging for materials.

Inspection is of fundamental importance, and should be thorough and complete. Material purchased to specifications and drawings should be inspected by the mechanical engineer or engineer of tests, and a certificate issued before it is accepted. Other material can be given a practical inspection by the section storekeeper who receives it. These men must be practical men and thoroughly informed regarding the materials for which they are responsible. Their knowledge of the purpose for which the material was ordered, and the purpose for which it is used, enables them to make a practical and useful inspection at the time they check it for quantity.

The manufacturing and repair departments of our railroads should be required to give as good service as any outside industry, and should be held responsible for regular and prompt deliveries. Proper regulation and supervision of this branch of the service will give great relief to the supply department and overcome many of the present complaints. This is particularly true of repair work, which is generally not given proper consideration. The manufacturing and repair departments on our railroads should be operated for the benefit of the railroad as a whole, and not for a particular department.

The maintaining of standards is of the greatest importance. Standards should not be so rigid as to destroy their usefulness, but they should not be changed until the benefits can be shown to fully offset all of the expenditures incidental to the change. A standing committee on standards, consisting of the chief maintenance, construction and supply officers, to which should be referred all recommendations for change in standards, will be found of great assistance and of practical value. The chief supply officer is conversant with manufacturers' standards, markets and other matters which would be of use to the committee. In addition to passing on standards, this committee could direct the preparation of specifications, arrange for the use of surplus and obsolete material, either for application to the company's requirements or by exchange agreements with the manufacturers.

All matters referred to in this paper apply equally to the maintenance of way as well as the maintenance of equipment department. There is a disposition on some railways for the maintenance of way department to consider its operations such that it should handle its own material, while the maintenance of equipment department, for some reason, is inclined to believe it should be the custodian of the stores.

In conclusion, from a broad viewpoint, the relations which should exist between these departments is one of useful, intelligent co-ordination. It may be truly said that the best organization is the one that requires each department to thoroughly understand its responsibilities and perform its duties, and I am firmly of the opinion that the relation between the mechanical, purchasing and stores departments on our railroads will be best improved and more efficiently administered by having each of these departments carry out every day the details of their organization in a careful and thorough manner, supervised by broad and experienced officers. The truest co-operation is that which comes from respect.

DESIGN OF STEAM PIPING.—Correctly designed steam lines skillfully erected are no more likely to fail and interrupt the service than other features, not duplicated. It is a matter of common experience that the hydraulic piping in a plant causes less trouble than the low-pressure house-service piping, because of the difference in installation. The same is applicable to steam piping.—*Power.*

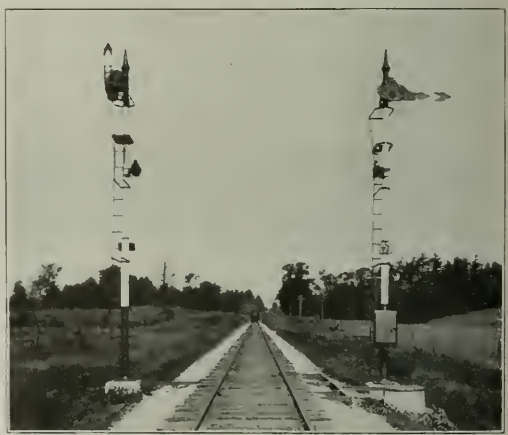
TORONTO, HAMILTON & BUFFALO

During the summer of 1911 the Toronto, Hamilton & Buffalo began its first automatic block signal installation on a short stretch of track, nine miles long, from Kinnear, Ont., to Vinemount. In 1913 this signaling was extended from Vinemount eastward to Welland, a distance of 26 miles, and in 1914 signals were installed on the west end from Hamilton to Brantford, a distance of 25 miles. There remains approximately 16 miles of single track between Brantford and Waterford which is not equipped with automatic block signals.

As shown in the accompanying map, the T., H. & B. forms a connection between the New York Central Lines on the south and the Canadian Pacific on the north. The traffic is heavy, the average being 32 trains a day, and the maximum 52 trains a day, as follows:

	Average.	Maximum.
Freight westward	6	10
Passenger westward	10	16
Freight eastward	6	10
Passenger eastward	10	16
Total	32	52

Trains were formerly operated by the telegraph block system in connection with train-order boards, and in some cases by



Double Signal Location Between Cainsville and Jerseyville

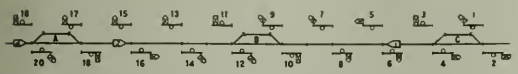
standard semaphore train-order signals. Trains following a passenger train were held at train-order stations until the passenger train was clear of the block, and a time interval of five minutes was maintained at train-order stations between following freight trains. Train orders and instructions regarding train movements are transmitted by telephone, and there is a telephone at each passing siding so that trainmen can communicate direct with the despatcher when occasion requires.

The system of signaling is the General Railway Signal Company's absolute permissive block, in which the block for opposing trains is from siding to siding, and for following trains from signal to signal as in double-track signaling. Signals governing movements from passing sidings into adjoining blocks are in all cases absolute, and, when in the stop position, must not be passed, as the block may be occupied by an opposing train. Signals governing trains approaching the siding are permissive, and, when in the stop position, may be passed after a stop has been made in accordance with the rules. Intermediate signals are permissive. Ordinarily there are two or three pairs of intermediate signals between passing sidings, but in some cases there is only one pair, in which case the intermediate signals are staggered in order to provide an adequate margin of safety if a train

should disregard an absolute stop indication and enter a block occupied by an opposing train.

The diagram herewith shows opposing trains 1 and 2 approaching a meeting point at siding B, and illustrates one of the important features of this system, the double distant or caution indication, signals 7 and 9, and signals 12 and 14, which affords maximum safety at meeting points, and insures proper signal indications. Owing to the arrangement of the control circuits it would be practically impossible for train 1 to pass signal 7 at clear and then find signal 9 at stop, or for train 2 to pass signal 14 at clear and then find signal 12 at stop. Absolute signals 10 and 11 protect against opposing trains.

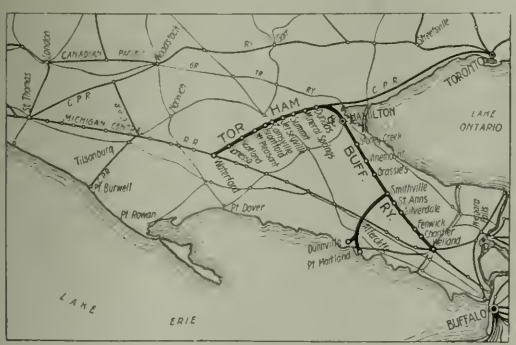
Intermediate switches are, in most cases, equipped with push-button indicators of the semaphore type and normally indicate that the block is not clear. Before opening the main line switch, trainmen are required by rule to press the push button; if con-



A. P. B. Signal System on T. H. & B. Showing Two Trains Approaching a Meeting Point

ditions are such that it would be safe to enter the main track, the indicator blade operates to the vertical position and indicates that the block is clear. If the block is not clear, the indicator blade remains in the normal position. This arrangement of de-energized switch indicators reduces to a minimum the chance of false clear indications. The push button operates two contacts which make and break both sides of the energizing circuit. The resistance ot the indicators is 690 ohms. Main line switches are equipped with model 5 switch-circuit controllers through which, in some cases, the control circuits are broken, and, in other cases, the track circuits are shunted.

Absolute signals are distinguished by a square-end red blade and by a red marker light below and in the same vertical plane as the active light. Permissive signals are distinguished by a pointed-end red blade and by a red marker light below and to



T. H. & B. Single Track Line Recently Equipped with Automatic Block Signals

the left of the active light. The roundels are R. S. A. standard, the colors being red for stop, yellow for caution and green for clear. The automatic signals are numbered according to their mile-post locations. The top and bottom parts of the signal masts and fittings are painted black, and the intermediate part white, making a conspicuous signal which stands out clearly against the usual backgrounds. Semaphore lamps are R. S. A. standard and are equipped with long-time oil burners.

The railway company furnished and installed in place insulated joints, insulated switch rods and connections and line-wire supports, and the General Railway Signal Company manufactured and installed the signals and signal appliances. R. L. Latham, chief engineer of the Toronto, Hamilton & Buffalo, had general charge of the installation, which was performed under the immediate supervision of A. A. Hurst, supervisor of signals.

Suitable rules governing the use of the automatic signals were adopted by the railway officers, and were printed in the back of the employees' time table with the operating rules. About the time the signals were ready for service, the railway officers held several meetings for instruction of the trainmen at Hamilton, the division headquarters, at which the signal aspects and indications were elucidated and discussed, as were also the rules governing their use. At these meetings lantern slides of the signal aspects and indications were thrown on a screen to illustrate the explanations, and a model 2-A signal mounted on a short mast, an indicator, a switch-circuit controller and other signaling appliances were operated as if under service conditions to afford a practical demonstration of the signal system and to fix the essential features firmly in the minds of employees.

The maintenance of these signals is in charge of a signal supervisor whose force consists of two maintainers, four battery men and two lampmen, who make a daily inspection of the signals and appliances on their respective districts. Each man is provided with a velocipede car on which he carries the necessary maintenance supplies and a kit of tools. Improper operations of the signal system are reported by the maintainer by joint wire to the chief engineer, the superintendent and the signal supervisor. Copies of the report are forwarded by railroad mail to the signal supervisor with full explanation of the cause. The signal supervisor investigates each case personally and works up a record which shows the performance of the entire signal system month by month.

The signal supervisor also keeps an accurate record of all labor and material chargeable to signal maintenance, so that maintenance costs can be determined for the entire system or any part thereof. The cost of maintenance per mile per month is about $16. Ordinary maintenance supplies are carried in stock at the general storehouse situated at Hamilton, and a few emergency supplies are kept on hand at maintainers' headquarters.

The officers of the T., H. & B. are well satisfied with the results obtained by the automatic signals, summarized as follows: (1) Under proper observance of the indications, the signals provide for opposing, as well as following movements, a definite space interval which reduces the likelihood of collisions to a minimum; (2) misplaced switches, broken rails, or any breaks in the continuity of the track cause the display of a stop indication at the signal governing entrance to the block, thus greatly reducing the likelihood of derailments; (3) the signals increase the traffic capacity of the line, as one train can follow another as soon as the first train passes the signal in advance, which is accomplished in considerably less time than the prescribed time interval of the telegraph block; (4) the signals afford maximum protection at meeting and passing points, serving as a check on despatchers' orders, also as a reminder to trainmen at scheduled meeting and passing points; (5) the signals more than double the safety factor in connection with flagging, as an approaching train would, in most cases, meet a caution or stop indication before the flagman could go out far enough to insure adequate protection; (6) owing to the high degree of protection which the automatic signals afford, "19" orders may be used in many cases where "31" orders would otherwise be required.

Crude Oil.—California's crude oil production in 1914 was 103,623,695 barrels, as compared with 97,867,147 barrels in 1913.—*Power.*

Cab Signals in England.—Among the English railway companies which are known to have commenced experimenting with locomotive cab signals are the Lancashire & Yorkshire, the Great Central, and the South-Eastern & Chatham. The Great Western and North Eastern have them in regular use, and the Midland has been trying two systems for some time.

By H. R. Kurrie

President of the Chicago, Indianapolis & Louisville

Entirely apart from the question of the legal duty of the state is the question of the best interest of the state. I maintain that no state can afford to gain the reputation, among men of large means, as being one that will add burdens to already overburdened existing investments without careful inquiry disclosing conditions which will appeal to any reasonable mind as justifying the increased burden.

Now, what has happened in the state of Indiana in the last 10 years relating to railway properties? In the first place, and without fear of contradiction, I make the statement (aside from the law limiting free transportation) the state has not done one single thing which will increase the revenues of the railway companies or reduce the expenses of doing business. Everything that the state has done has been in the way of adding a burden to an already over-burdened investment. In the year 1905 the law commonly known as the "railroad commission" or "public utilities law" was passed. Without going into detail, it is sufficient to say that this law brought improved methods of doing business at a substantially increased cost. In the same year, laws were passed which authorized certain cities to require track elevation. Track elevation means a very large outlay with no increased return, and while in many cases the condition justifies the separation of grades, yet the point which I am making is that the effect of the law was to add materially to the railroad expense in the state of Indiana. In 1907 a law was passed which materially reduced the charge of railway companies for handling excess baggage. A law was also passed limiting the hours during which the employees could be kept on duty. A law, commonly known as a "full train crew law," was passed. On the heels of this law the legislature passed a law requiring railroads to equip their lines with automatic block signals. This is the best known method of spacing trains, and avoiding collisions, and it also gives warning of a broken rail, an open switch, or any other track condition which imperils the advancing train, and in every case it gives warning in ample time. It is a silent sentinel, Argus-eyed, ever watchful and unfailing. The flagman is a duplication in a most crude and inefficient way of this protection. The crowning effort of 1907 was the enactment of the two-cent fare law. This was a horizontal reduction of 33⅓ per cent in the passenger fare. The legislature passed this law without any investigation of the value of these investments or whether the return at the time enjoyed was excessive. It was a sort of climax to an avalanche of hostile legislation which was directed at this form of investment—a frenzy in which the desire to apply the lash was much more in evidence than a sense of fair dealing.

It is a common impression now that when the fare was reduced from three cents to two cents, increased travel resulted, so as not only to overcome the apparent loss, but actually to make the two-cent fare more profitable to the railroads than the three-cent fare. On the Monon this is what actually happened: In the year 1908, which was the first year of the two-cent law in Indiana, the actual cash receipts were $103,000 less than in the last year under the three-cent law, while the passengers carried one mile increased in 1908—1,200,000. In other words, this increased service was rendered for $100,000 less money. In 1909 there was an increase of 4,500,000 in passengers carried one mile, while the revenues were $83,000 less than the last year of the three-cent law. In 1910 the receipts were $17,000 more than in the last year of the three-cent law, but the passengers carried one mile were 9,500,000 in excess of the last year of the three-cent law, so that the increased business was actually transacted at an increase of only $32,000 in the revenue. In 1914 the passenger receipts amounted to $300,000 more than in the last year of the three-cent law, but there was an increase of ing which the two-cent law has been in effect the passenger miles increased 22,000,000. In the seven years immediately preceding the two-cent law; or, in other words, the last seven years of the three-cent law, the passenger miles increased 21,300,000, so that the increase in the last seven years of the three-cent fare was considerably more than the increase in the seven years of the two-cent law. These figures show to a certainty, from the business actually handled, that the increase under the two-cent law was less than the increase in the same period under the three-cent law. It was a perfectly natural increase, due to the increase in population and not to the decrease in the rate, just as there has been an increase in every line of business.

This particular action on the part of the state has been made the subject of pretty careful investigation by the Interstate Commerce Commission of late. The commission points to the fact that the rate of fare as fixed by this law and other state laws of a similar nature, is too low and that if the carriers are to be allowed to earn the return which they are entitled to earn under the Constitution of the United States, it can only be by increasing the rates for other transportation service. It is the law that the state traffic must bear its fair share of the earnings of the transportation company; that the state traffic cannot be handled at cost, or less than cost under state-made rates and the interstate traffic compelled at substantially increased rates not only to pay the cost of its transportation, but also to create enough net earnings to pay interest on the value of the whole investment. That is what is actually happening now, at least insofar as the passenger traffic is concerned, and it seems to me that this policy on the part of the state, entirely apart from the fact that it is inconsistent with its own best interest, is certain to result finally in the United States taking jurisdiction over the entire transportation service.

If the state takes advantage of its authority to fix rates to handicap the United States in its action relating to interstate rates, then the United States, in order to make its own action effective and just, in the very nature of things, must take jurisdiction of the entire subject and the right of the states will disappear. There can be no doubt in the world that the United State has authority to assume jurisdiction of the entire subject of railroad regulation. Each year we find certain invasions by the United States into the authority which has been exercised by the state through the acquiescence or inactivity of Congress.

In line with the suggestion of the Interstate Commerce Commission, the railway companies of Indiana, last fall, began to appeal to the people of the state for a repeal of the two-cent fare law. These meetings were held in practically every important city and town in the state and with the exception of three cities, resolutions were passed in favor of the repeal of the two-cent fare law and the enactment of a two and one-half cent fare law to take its place. When the legislature convened a bill was introduced for the purpose of putting in the form of a definite law the public sentiment which was expressed in these resolutions. These resolutions were submitted to the members of the legislature and were made the subject of a great deal of comment by the publications throughout the state, and almost without exception that comment was in favor of the enactment of that law, but when it came to a vote, it was perfectly clear that the law would not pass. When this situation was brought home to the railroads, having full confidence in the merits of their case, they asked the legislature to pass a law authorizing the Public Service Commission of the state to inquire into the question of whether the rate of two cents was fair and if a greater rate was required to fix such rate. The legislature refused to entertain this proposition. The fact is that those who were charged with the responsibility of making this public opinion in the form of a law considered more the political future than the merits of the proposition. Investments can, through the slow but certain process of litigation, secure definite relief from the existing law, but the people of the state are interested in its industrial development; they are inter-

*From an address before the student body of the University of Indiana, at Bloomington, Ind., on May 12, 1915.

means that capital invested in the state will be fairly dealt with. In this case the largest single investment in the state was refused an opportunity to show that it was being unfairly dealt with. When you get down to the practical question of men investing their means in the state in the future, you can appreciate that men to whom this action has been brought home will withhold investments in this state.

The thing that is most important of all, in dealing with capital, and especially foreign capital, is to invite confidence, and that certainly cannot be done by imposing upon capital which is already here a burden the unfairness of which has been conceded by local action in practically every community in the state.

It seemed inconceivable when the state is so much interested in having men feel that they can come with confidence and permanently invest their money in this state, that the state would say to the owners of these properties, which represent the largest single investment in the state, that only two cents per mile will be allowed for passenger travel and that the question of whether that is or is not sufficient will not be open for investigation. The state cannot afford in its own interest to continue any such attitude.

In 1909 the legislature passed a law requiring electric headlights on locomotives. In 1911 it passed laws increasing the liabilities for loss of freight and for injuries to persons; also, a law providing for separation of grades in smaller cities. In 1913 the law with reference to separation of grades was further amended so that now practically any city having a population of more than 19,000 can have grade separation. Numerous other laws were passed adding less important burdens to railroad operation in 1914.

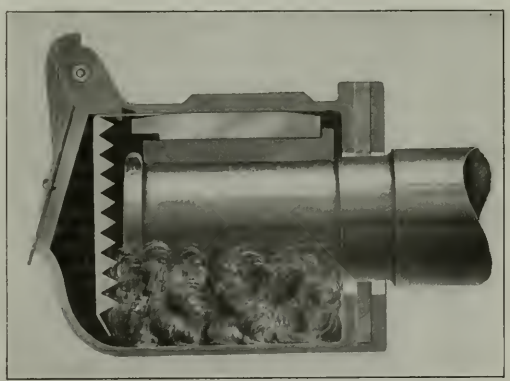
No one can successfully maintain that the Indiana railroads are earning what they should. Take the Monon—and I am giving figures which are taken from public record: In 1914 the cash investment in the Monon was $8,852,454 more than it was in the year 1900. In the year 1914, after the actual operating expenses had been paid, the amount which was left to take care of interest on bonded debt and to pay an income to the stockholders was less than the amount which remained in 1900. In other words, on this added investment of nearly $9,000,000, which had been made in the 14-year period, not one cent was earned for those who had made the investment. In the same period the state levied as its share of this return in 1900, $184,000; in 1914, $333,000. The increase in the amount of the income which the state has taken was 80.47 per cent. The increase in the property investment was 29.8 per cent.. The actual income to the owners of the property decreased 2 per cent.

It is interesting, as we observe now the avalanche of assaults which the state has been making on these investments, to hark back to the fact that in the beginning the state regarded the construction of railways so important to its internal development that it began the construction of what is now some of the important lines of railroad in the state. The first railway construction in Indiana was known as the Lawrenceburg & Indianapolis line, which was one and one-quarter miles long and opened in 1834. Its rolling stock consisted of one car which cost $222.12½, and a horse of unknown value. On the first day the total operating expenses were $12.62. The net receipts were $60. At sundown the first day a meeting of the board of directors was held and the amount remaining after paying the day's operating expenses was paid out to the owners of the property as a dividend, much to their satisfaction. That railroad was owned by citizens of the state. The first serious effort toward railroad construction in the state was the Madison & Indianapolis road. This was one of the lines the construction of which was undertaken by the state. This railroad was opened in 1838 and it had 18 miles of track completed by the month of April, 1839, and 10 miles were added later. The cost to the state of the construction of this 28 miles was $1,624,603, or $56,235 per mile. The locomotive for this particular railroad was on shipboard, taken down the Delaware bay into the Atlantic Ocean and was to be carried by the way of the Gulf of Mexico, Mississippi and Ohio rivers to Madison, Ind. It never arrived. The ship was sunk, and the first locomotive constructed for an Indiana line is still resting somewhere on the bottom of the sea. After the state had constructed this 28 miles at this excessive cost, it was very glad to relinquish its interest in the property to private interests, willing to complete the construction of the road.

I speak of this to show that there has been a decided reversal of state policy. This is an exceedingly important public question. If it is fairly dealt with, notwithstanding what has occurred in the past 10 years, I believe that it will be possible for our railroad credit to be restored, and fresh capital secured for our large industrial development. I do not believe that the citizens of this state can expect to have a further immigration of foreign capital unless they together join in an effort to bring about a distinct reversal of the state policy of the last 10 years, and assure fair treatment for the large investments which we find here now.

JOURNAL BOX PACKING GUARD

A packing guard for use in journal boxes which holds the packing under the journal and prevents it from working out between the lid and the box has been placed on the market by the Nuway Packing Guard Company, Tuscaloosa, Ala. It is formed from No. 14 gage steel with teeth extending back from the sides and bottom. A tongue extends back from the top of the guard, by means of which it is secured in the journal box. In applying the guard the weight of the car is raised from the journal and the box packed, the packing being pushed well back against the dustguard and the box filled only to the end of the journal. The guard is then placed in the box with the tongue, which is formed to fit the lugs at the top of the box, between the box and the wedge. When in position the weight of the car is let down on the journal, thus securely holding the guard in place. A small quantity of packing is then pushed around the sides of the guard. Holes are provided in the packing guard through which oil may be applied should the packing become dry. The guard is manufactured in different sizes and to fit the various types of journal boxes.



Packing Guard for Journal Boxes

ROLLING STOCK ON THE IRISH RAILWAYS.—The railways of Ireland on December 31, 1912, owned 901 locomotives, 3,302 passenger train cars, 22,151 freight cars and 1,030 other cars.

General News Department

The Clearing yard, near the southwest city limits of Chicago, was placed in service for the traffic of the Belt Railway only, on June 1. Interchange traffic between the 12 roads owning the Belt Railway will not be handled through this yard for the present.

A new wage schedule carrying higher pay for certain classes of trainmen on the Northern Pacific and a number of changes in working conditions has just been agreed upon by representatives of the company and of the employees, after 18 months of negotiation.

Near Lake City, Minn., on June 6, seven persons were killed, including four passengers, and several more were injured, when a passenger train on the Chicago, Milwaukee & St. Paul went through a bridge which had been weakened by a washout. Three of the cars fell into the Mississippi river.

The "Sunset-Central Boys' Educational Association" has been formed by officers of the Sunset Central Lines at Houston, Tex., for the purpose of organizing classes of office boys and messengers to study penmanship, arithmetic, typewriting and shorthand. Similar educational advantages are to be afforded to the young women employed by the company, of whom there are in Houston about 250.

The New York State Public Service Commission, Second district, announces that the statement published last week (page 1176) concerning the law to regulate the "jitney bus" had to do only with the second district. The law does not exempt the city of New York from its requirements. Under its provisions bus lines carrying passengers for fifteen cents or less in any city of the state must obtain certificates of public convenience and necessity.

In the Federal Court at Charleston, W. Va., June 4, three railroads, the Baltimore & Ohio, the Coal & Coke, and the Lewisburg & Ronceverte (electric) were fined for violation of the federal laws; the Baltimore & Ohio $1,000 for failure to observe the twenty-eight hour law relative to feeding livestock; the Coal & Coke $3,500, for violating the sixteen-hour law for employees, and the electric road, which is only four miles long, for not conforming to the federal rules regarding fittings on cars.

Among the employees of the Pennsylvania Railroad retired on pension May 1 last was William Watson, staybolt inspector in the shops at Altoona, who had been in the service of the company 34 years and for over 20 years was inspector of flues in locomotives. A portrait of Mr. Watson is given in the bulletin issued by the company, and it is calculated that during his twenty years of service in this occupation he had crawled through the fire doors of 20,000 locomotives, and had inspected 6,440,000 flues.

The Baltimore & Ohio reports that for the month of May the Shenandoah district of the road, embracing the line through the valley of Virginia from Harper's Ferry to Lexington, made a perfect record for punctuality of passenger trains; 300 passenger trains having arrived at their terminals on time. For several months the record for punctuality of trains on this road has been watched with special interest. Rivalry has been displayed by the employees to such extent that an act of negligence resulting in a delay is regarded as an offense against all of the co-workers of the district.

Railroads' Position on Mail Pay Question

The railway presidents who, to consider the question of mail pay, met in New York, following the May meeting of the American Railway Association, adopted unanimously the following resolutions:

"Resolved, that the position of the Committee on Railway Mail Pay has the approval of the representatives of the railroads present at this meeting, and that the railways of the United States continue to give their united support to the committee in its efforts to secure to the railways adequate compensation for transporting the mails.

"Resolved, further, that we believe the so-called space basis as proposed in the last Congress is wrong, and susceptible in practice of grave injustice to the railways in denying payment for services rendered.

"Resolved, further, that we endorse the views of the committee on the superiority of the existing weight basis, amended by annual weighing, payment for apartment cars and payment for or release from side or terminal messenger service.

"Resolved, further, that the Committee on Railway Mail Pay is urged to continue its work on this basis, and to ask Congress to enact a law that will give the Interstate Commerce Commission the same jurisdiction over the mail traffic that it now has over all other traffic of the railroads."

The chairman of the meeting was Howard Elliott, president of the New York, New Haven & Hartford. All of the proposals of the roads' committee were fully discussed, and, as stated in the resolutions, were fully endorsed; and the meeting represented fully 90 per cent of the railway mileage of the country. Of the half dozen prominent companies which do not appear in the list of roads represented, all are known to hold the same views as those embodied in the resolutions.

THE GREATEST ASSET OF THE PENNSYLVANIA RAILROAD*

THE management of the Pennsylvania Railroad System believes that the Company's greatest asset is the loyalty and efficiency of its men.

* * *

In normal times the Pennsylvania System has 250,000 employees. The Company pays the highest prevailing rate of wages received by railroad employees in the territory in which it operates. The policy of the Pennsylvania System is to insure that all its relations with its men shall be characterized by fairness and friendliness.

* * *

The Pennsylvania System early realized the importance of training its own officers. This, of course, carries with it the training of its own men. To make the service attractive it is essential that employment, as far as possible, be permanent.

* * *

The man of today is the officer of tomorrow. The organization is in substantial respects a civil service.

* * *

This Company is endeavoring continually to develop its organization, to assure itself of the loyalty of its men, and to build up an efficient and economical transportation enterprise.

*A placard, 12 in. x 20 in., posted in Pennsylvania Railroad stations.

Michigan Legislation

Senate bill No. 234, providing for the inspection of boilers, was not passed by the lower house of the Michigan legislature, and our account of the bills which became law in that state this year, published May 28, page 1124, is erroneous in that particular.

Washington Railroads, 5166 Miles

The Public Service Commission of the state of Washington reports that 400 miles of new main line have been added by Washington railroads during the past year, showing an aggregate of 5,165 miles as of January 1, 1915, excluding logging roads and electric lines.

Including second track and sidings, the railroads now show 7,235 miles of track. The principal increases during the past

Interbay line built by the Great Northern; 103 miles by the Spokane "air line," 43½ miles by the Northern Pacific (the new Point Defiance line) and 13½ miles added to the North Yakima & Valley; 39 miles on the Chicago, Milwaukee & St. Paul; Willapa Harbor line and 29½ miles of the Seattle, Port Angeles & Western.

Following is the detailed statement mileage shown by the railroads in their 1914 and 1915 reports:

Railroad	1914	1915
Bellingham & Northern	49.5	49.6
Chicago, Milwaukee & St. Paul	*637.4	580.4
Colorado & Puget Sound	55.2	55.7
Great Northern	855.5	1,005.0
Northern Pacific	1,767.9	†1,863.2
North Yakima & Valley	†39.0	.....
Oregon Trunk	.7	.7
O. W. R. & N.	787.0	898.0
P. S. & Willapa Harbor	9.5	48.6
Spokane & B. C.	36.3	36.3
Spokane International	17.7	17.7
S. P. & S.	409.6	409.6
Tacoma Eastern	92.1	92.1
Washington, Idaho & Montana	3.3	3.3
Waterville Railway	5.1	5.1
Idaho & W. N.	.....	*70.8
Seattle, P. A. & W.	.....	29.5
Total miles	4,765.8	5.165.6

*The Idaho & Washington Northern is included with the C. M. & St. P. for 1914, and the (†) North Yakima & Valley is included with the Northern Pacific for 1915.

Report on Oakwood (Wis.) Derailment

The Interstate Commerce Commission has issued a report, dated April 28, on the derailment of a passenger train on the Chicago, Milwaukee & St. Paul at Oakwood, Wis., January 30, when 21 passengers were injured. The train was derailed at a crossover when running about 55 miles an hour, and Inspector H. W. Belnap concludes that the cause of the derailment was the breaking of a steel tired wheel of the baggage car, the middle wheel on the right-hand side of a six-wheel truck, the forward truck of this car. The wheel was of a built-up type, cast iron hub or spider, two rolled steel cheek plates and a rolled steel tire. The parts were held together by 39 bolts. The tire broke into four pieces and it was found that ruptures through the bolt holes had started, in each case, at the inner diameter of the tire, thence passing through the metal in an outward direction to the surface of the tire and through the flange. Considerable wear was found at the bearing between the plate and the tire. The mate of the broken wheel was taken apart and in it were found incipient cracks at each of the twelve bolt holes in the tire; and similar incipient cracks were found in other wheels examined. None of these cracks were visible until the outer circle of bolts was taken out or one of the plates removed. The broken wheel had not been overloaded. It had run 276,396 miles, having been changed from one car to another a half dozen times. The study of the broken wheel, and of others of the same type, was made by J. E. Howard, engineer. He concludes that tires of this type are sometimes loose, while yet the looseness is not detected by the ordinary inspections. His principal recommendation is for better inspection of the metal at the bolt holes, which means, of course, that wheels would have to be taken apart, as the cracks above referred to cannot be seen in an ordinary inspection.

Legislation Affecting the New Haven Road

[From a statement by Howard Elliott, president of the New York, New Haven & Hartford, issued on the final adjournment of the Massachusetts legislature.]

During the past year a large amount of work has been done by the officers of the company, the public service commissions, the legislatures and the state executives in studying the complicated corporate and financial relations of the New Haven system and the differences in the laws of Connecticut, Massachusetts and Rhode Island. As the result of this study and of numerous conferences between the public service commissioners and the officers of the company, various bills were drafted, which have been passed as follows:

In Rhode Island (March 28): A general law curing certain minor defects in the corporate stock status of the company and making legal under suitable restrictions the issue of preferred stock and of mortgage bonds.

In Connecticut (March 19): A law permitting the company for short-time loans.

A general law (May 19) reducing the powers of the New Haven company and providing for increased supervision by the public utilities commission of Connecticut; providing that at least two-thirds of the directors of the company shall live in Connecticut, Massachusetts and Rhode Island, and permitting, under suitable restrictions, the issue of preferred stock and of mortgage bonds.

In Massachusetts (May 31): A law prohibiting the issue of fractional shares of stock, making the practice in Massachusetts similar to that of Connecticut and Rhode Island.

A law (May 31) permitting the issue of preferred stock.

A law (June 4) removing the obstacles and defining the limits to the issues of mortgage bonds and evidences of indebtedness and permitting this kind of financing in accordance with modern business requirements.

A law (June 4) validating the New Haven securities as of May 15, 1915, and providing for an investigation by the public service commission of the capital expenditures, investments and contingent liabilities of the New Haven company and their validity under the laws of Massachusetts and under the laws of any other state in which the company is organized; their report to be made not later than February 1, 1916, at an expense not exceeding $10,000, to be paid by the New Haven company. Also, for an investigation by the public service commission, the port directors and the attorney-general, of the rates to and from the Commonwealth pier in Boston, under the contract of July 1, 1912, between the state and the New Haven and Boston & Maine companies.

The passage of these bills gives the company the legal right to submit to its stockholders some plan for financing its present floating debt and for obtaining money for future needs if business conditions justify.

Now that these bills have been passed there is much work to be done in preparing any plan and in obtaining the necessary approval of the public service commissions of the states.

In trying to harmonize the laws of these states, there have been some differences of opinion among interested parties. . . . The public service commissioners, the members of the legislature, the executives and the company have all yielded something, with the result that the bills, while not giving all that the various parties wanted, are a long step forward in putting the New Haven in a position to re-establish its credit and to perform its duty as a common carrier.

The validation bill calls for an investigation, and the company is anxious to have that work proceed rapidly. It hopes that the public service commission can complete their report in the late autumn and it will co-operate in every way. As a result of the recent investigation of the company's affairs by the Interstate Commerce Commission, the Congress of the United States and the department of justice, there is a very large amount of material ready, which is at the disposal of the commission.

The company is ready to submit all information and facts about the Commonwealth pier contract of July 1, 1912. The rates on business controlled by the New Haven company conform to the terms of that contract. . . . The New Haven is owned very largely in New England, and with a resumption of business a restoration of confidence and credit should receive financial nourishment and support from its owners and from the public who live along its lines. The business men of New England have given greater attention than ever before to the question of railroad transportation, and have loyally supported the management in its efforts to obtain the remedial legislation.

The great interest and cordial support of the press of New England were also most helpful elements in working out the problem. In fact, if the plans of the company had not been presented in considerable detail to the public and to the business men of New England, and if those plans had not appealed to their judgment, the bills probably never would have become laws. The legislative sessions have ended with improved and more cordial relations between the company, the public, many business organizations, and the representatives of the state governments, which is a source of gratification to the company and a valuable asset for the future.

For the company I desire to express its thanks for the co-operation of all. A most important result is that the passing of these laws marks the starting out of a course of constructive

land transportation business, the success of which is so essential to New England.

Some New Jersey Railroad History

As is well known to most persons traveling by rail between New York and the west, the lines reaching the west shore of the Hudson river, opposite the city, encounter a serious obstacle in the high ridge that extends north and south for a long distance a mile or two back of the river, a mountain of rock, Bergen Hill. The tracks of the Pennsylvania Railroad—the line which was built and for years operated by the New Jersey Railroad & Transportation Company—run through a deep cut at Marion, about two miles west from the river front, known today as Shanley's cut; the Erie and the Delaware, Lackawanna & Western get through the mountain by means of tunnels, and the Central of New Jersey passes around the south end of the ridge, through Bayonne. To most of the present generation all of these routes are old institutions; but from an article in the Erie Railroad Employees' Magazine, by John S. Bell, vice-president of the Morristown & Erie Railroad, it appears that at one time or another all of the roads named, as well as the Lehigh Valley, reached the Hudson river over the Shanley's cut route. Mr. Bell says:

"I find that many railroad men never heard of the old Bergen cut, so long used by the Erie Railroad. It was through this cut, after the passenger terminal at Piermont was abandoned, that the trains of the Erie Railroad reached New York, or rather the west side of the Hudson river opposite New York. All Erie passenger trains reached the Hudson river through this cut until April, 1861. This cut was made, in the construction of the New Jersey Railroad & Transportation Company's line, in the early thirties. That road extended to New Brunswick, 31 miles; where passengers transferred to the Camden & Amboy, which took them to Trenton, whence they went to Philadelphia over the Philadelphia & Trenton. In the early days there was a transfer by horse power both in Philadelphia and in Baltimore on the route to Washington.

"Before the consolidations which we know in the present day the companies running trains through the Bergen cut were the New York & Erie (now the Erie), the Northern Railroad of New Jersey, the Morris & Essex, the Central of New Jersey, the Hackensack & New York and the New York, Susquehanna & Western. [All lines from the west, except the Central of New Jersey, have connections one with another west of the Bergen Hill.] The only one of the roads named which did not at one time or another run trains through the cut with their own locomotives was the Central of New Jersey, which delivered its cars to the New Jersey Railroad & Transportation Company at Elizabeth. The trains of the Morris & Essex, in the early fifties, were coupled to the New Jersey Railroad trains at the foot of Centre street, Newark. The Morris & Essex afterward left this line, and in 1863 made a contract with the Erie; this line was used until 1876, when the Morris & Essex began using its own tunnel to the Hoboken terminus.

"The Erie Railroad ran through the cut from 1853 until 1861, when its own tunnel was completed. The Northern of New Jersey began running through the Erie tunnel in 1869. The New York, Susquehanna & Western continued using the Pennsylvania terminus for a number of years after coming under the control of the Erie, but about three years ago began using the Erie terminus. The Lehigh Valley, which now uses the terminus of the Central of New Jersey, connecting with the line of that road a few miles out, used the Pennsylvania terminus (and the Pennsylvania tracks from Newark) from the time of the completion of its New York line, until about one year ago."

The West Shore, which is comparatively young—only about 30 years old—has its terminus at Weehawken two or three miles up the river, but it ran a few trains to the Pennsylvania terminal, through the Bergen cut, until about four years ago. The Pennsylvania itself, which now runs substantially all its through passenger trains to and from Thirty-second street, New York City, passing under both the Bergen ridge and the Hudson river by its tunnel, has left its Jersey City passenger terminal comparatively deserted, and the Bergen cut enters on another chapter of its history. But, though the Jersey City passenger terminal has lost its importance the cut continues to be the channel for two main currents of traffic, namely, freight, including much express freight, to the Hudson river terminals between Park place, Newark, and Church street, New York city, which run through the Hudson & Manhattan tunnel.

Mr. Bell estimates that when all the roads entering Jersey City ran their trains through the cut the total number of passenger trains daily, out and in, did not exceed 100. At the present time he estimates that all of the roads, including the West Shore and those that reach New York through the tunnels under the river, have a total of over 1,300 trains a day.

The Erie and some of the other roads in the early days had tracks of 6 feet gage and the tracks through the cut had three rails. The broad gage engines had smokestacks painted black, while the standard gage engines had stacks painted red. All were wood burners. On the New Jersey Railroad all trains used the left hand track; and a single short blast of the whistle meant, not to put on the brakes, but to let them off; and in those days the whistle signal meant something, for the air brake had not been invented. Before the Civil War the time required for a passenger journey from Jersey City to Washington was twelve hours, and the single fare was $10. At present the price of a roundtrip ticket is $10, and the journey, one way, is made in five hours.

Railway Telegraph Superintendents

The thirty-fourth annual meeting of the Association of Railway Telegraph Superintendents will be held at the Powers Hotel, Rochester, N. Y., June 22, 23, 24 and 25. There will be an informal assembly in the hotel on Monday evening, the 21st. Among the subjects scheduled for discussion at the business meetings are: Primary versus dry battery for transmission on telephone lines; Screened cable conductors; Censorship of railway messages; Interference from high tension power lines.

United Yardmasters' Association

The program for the convention of the United Yardmasters' Association, to be held in Seattle from June 15 to 19, inclusive, provides for business sessions on June 15, 16, 17 and 19, with various entertainment features. The program includes papers by J. J. McCullough, superintendent of the Puget Sound division of the Northern Pacific on "Rough Handling of Freight"; G. H. Hunt, freight claim agent of the Chicago Great Western on the same subject; R. M. Calkins, general traffic manager of the Chicago, Milwaukee & St. Paul on "Duties of the Yardmaster Toward the Public"; J. M. Daly, former general superintendent of transportation of the Illinois Central, on the subject of "Per Diem"; A. J. Hillman, general agent of the Chicago, Milwaukee & St. Paul, on "Yard and Terminal Work"; C. S. Price, general yardmaster of the Great Northern at Seattle, on "Rough Handling of Cars." Each paper is to be followed by general discussion.

Railway Real Estate Association

This is the name of an association which has been formed by officers of a number of prominent roads and the purpose of which is perhaps sufficiently explained by the title, indicating the department to which these gentlemen belong.

From a statement issued by Frank C. Irvine, secretary, Pittsburgh, Pa., it appears that the association has been organized to comprise within its membership all officers, and their staffs, of the railways of America, Canada, Mexico and Cuba directly concerned in the various activities pertaining to the land of their respective corporations. Provision is made for the formation of sections, as "Tax Division," "Agricultural Division" and "Right of Way Division." The first meeting of the association is scheduled to be held in Chicago, October 13 next.

A constitution has been adopted; and, acting on the provisional organization, the following officers have been chosen: President, F. P. Crandon (C. & N. W.); first vice-president, J. D. McCubbin (B. & O.); second vice-president, B. A. McAllaster (Sou. Pac.); secretary, Frank C. Irvine (Pennsylvania Lines); treasurer, James G. Armstrong (W.-P. T.).

The following roads are represented in the roll of charter members of the association: Algoma Central & Hudson Bay; Baltimore & Ohio; Bessemer & Lake Erie; Buffalo Rochester & Pittsburgh; Canadian Pacific; Chesapeake & Ohio; Chicago, Burlington & Quincy; Chicago Great Western; Chicago, Rock Island & Pacific; Chicago & North Western; Cincinnati, Ham-

The enrollment fee is $5 and annual membership dues $3.

MEETINGS AND CONVENTIONS

The following list gives the names of secretories, dates of next or regular meetings, and places of meeting of those associations which will meet during the next three months. The full list of meetings and conventions is published only in the first issue of the Railway Age Gazette for each month.

AMERICAN ASSOCIATION OF DEMURRAGE OFFICERS.—F. A. Pontious, 455 Grand Central Station, Chicago. Next meeting, July 21, 1915, Milwaukee, Wis.

AMERICAN ASSOCIATION OF RAILROAD SUPERINTENDENTS.—E. H. Harman, Room 101, Union Station, St. Louis, Mo. Next meeting, August 19-20, 1915, San Francisco, Cal.

AMERICAN RAILROAD MASTER TINNERS, COPPERSMITHS AND PIPEFITTERS' ASSOCIATION.—W. E. Jones, C. & N. W., 3814 Fulton St., Chicago. Annual meeting, July 13-16, 1915, Hotel Sherman, Chicago.

AMERICAN RAILWAY MASTER MECHANICS' ASSOCIATION.—J. W. Taylor, 1112 Karpen Bldg., Chicago. Annual meeting, June 9-11, 1915, Atlantic City, N. J.

AMERICAN RAILWAY TOOL FOREMEN'S ASSOCIATION.—Owen D. Kinsey, Illinois Central, Chicago. Annual meeting, July 19-21, 1915, Hotel Sherman, Chicago.

AMERICAN SOCIETY FOR TESTING MATERIALS.—Prof. E. Marburg, University of Pennsylvania, Philadelphia, Pa. Annual meeting, June 22-26, 1915, Hotel Traymore, Atlantic City, N. J.

AMERICAN SOCIETY OF CIVIL ENGINEERS.—Chas. Warren Hunt, 220 W. 57th St., New York. Regular meetings, 1st and 3d Wednesday in month, except July and August, 220 W. 57th St., New York.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS.—Calvin W. Rice, 29 W. 39th St., New York. Next spring meeting, June 22-25, 1915, Buffalo, N. Y. Annual meeting, December 7-10, 1915, New York.

ASSOCIATION OF RAILWAY ELECTRICAL ENGINEERS.—Jos. A. Andreucetti, C. & N. W., Room 411, C. & N. W. Sta., Chicago. Semi-annual meeting with Master Car Builders' and Master Mechanics' Associations. Annual meeting, October, 1915.

ASSOCIATION OF RAILWAY TELEGRAPH SUPERINTENDENTS.—P. W. Drew, Soo Line, 112 West Adams St., Chicago. Annual meeting, June 22-25, 1915, Rochester, N. Y.

ASSOCIATION OF TRANSPORTATION AND CAR ACCOUNTING OFFICERS.—G. P. Conard, 75 Church St., New York. Next meeting, June 22-23, Niagara Falls, N. Y.

ENGINEERS' SOCIETY OF WESTERN PENNSYLVANIA.—Elmer K. Hiles, 2511 Oliver Bldg., Pittsburgh, Pa. Regular meetings, 1st and 3d Tuesday of each month, Pittsburgh.

FREIGHT CLAIM ASSOCIATION.—Warren P. Taylor, Traffic Manager, R. F. & P., Richmond, Va. Annual meeting, June 16, 1915, Chicago.

GENERAL SUPERINTENDENTS' ASSOCIATION OF CHICAGO.—A. M. Hunter, 321 Grand Central Station, Chicago. Regular meetings, Wednesday, preceding 3d Thursday in month, Room 1856, Transportation Bldg., Chicago.

INTERNATIONAL RAILWAY GENERAL FOREMEN'S ASSOCIATION.—Wm. Hall, 1126 W. Broadway, Winona, Minn. Next convention, July 13-16, 1915, Sherman House, Chicago.

INTERNATIONAL RAILROAD MASTER BLACKSMITHS' ASSOCIATION.—A. L. Woodworth, C. H. & D., Lima, Ohio. Annual meeting, August 17, 1915, Philadelphia, Pa.

MASTER CAR BUILDERS' ASSOCIATION.—J. W. Taylor, 1112 Karpen Bldg., Chicago. Annual meeting, June 14-16, 1915, Atlantic City, N. J.

NIAGARA FRONTIER CAR MEN'S ASSOCIATION.—E. N. Frankenberger, 623 Brisbane Bldg., Buffalo, N. Y. Meetings, 3d Wednesday in month, New York Telephone Bldg., Buffalo, N. Y.

PEORIA ASSOCIATION OF RAILROAD OFFICERS.—M. W. Rotchford, 410 Masonic Temple Bldg., Peoria, Ill. Regular meetings, 3d Thursday in month, Jefferson Hotel, Peoria.

RAILROAD CLUB OF KANSAS CITY.—Claude Manlove, 1008 Walnut St., Kansas City, Mo. Regular meetings, 3d Saturday in month, Kansas City.

RAILWAY SUPPLY MANUFACTURERS' ASSOCIATION.—J. D. Conway, 2136 Oliver Bldg., Pittsburgh, Pa. Meetings with Master Car Builders and Master Mechanics' Associations.

RAILWAY TELEGRAPH AND TELEPHONE APPLIANCE ASSOCIATION.—G. A. Nelson, 50 Church St., New York. Meetings with Association of Railway Telegraph Superintendents.

SALT LAKE TRANSPORTATION CLUB.—R. E. Rowland, David Keith Bldg., Salt Lake City, Utah. Regular meetings, 1st Saturday of each month, Salt Lake City.

SOUTHERN ASSOCIATION OF CAR SERVICE OFFICERS.—E. W. Sandwich, A. & W. P. R. R., Atlauta, Ga. Next meeting, July 15, 1915, Atlanta. Annual meeting, January, 1916.

SOUTHERN & SOUTHWESTERN RAILWAY CLUB.—A. J. Merrill, Grant Bldg., Atlanta, Ga. Regular meetings, 3d Thursday, January, March, May, July, September, November, 10 A. M., Piedmont Hotel, Atlanta.

TOLEDO TRANSPORTATION CLUB.—Harry S. Fox, Toledo, Ohio. Regular meetings, 1st Saturday in month, Boody House, Toledo.

TRAFFIC CLUB OF CHICAGO.—W. H. Wharton, La Salle Hotel, Chicago.

TRAFFIC CLUB OF PITTSBURGH.—D. L. Wells, Genl. Agt., Erie R. R., 1924 Oliver Bldg., Pittsburgh, Pa. Meetings bi-monthly, Pittsburgh. Annual meeting, 2d Monday in June.

TRAIN DISPATCHERS' ASSOCIATION OF AMERICA.—J. F. Mackie, 7122 Stewart Ave., Chicago. Annual meeting, June 15, 1915, Minneapolis, Minn.

TRANSPORTATION CLUB OF DETROIT.—W. R. Hurley, Superintendent's office, N. Y. C. R. R., Detroit, Mich. Meetings monthly, Normandie Hotel, Detroit.

UTAH SOCIETY OF ENGINEERS.—Frank W. Moore, 1111 Newhouse Bldg., Salt Lake City, Utah. Regular meetings, 3d Friday in month, except July and August, Salt Lake City.

Traffic News

The Southern Pacific announces that it has booked an average of one special train for every other day between now and the first of October to the Panama-Pacific Exposition at San Francisco.

The steamboat Steel City, which has just been put in service on the Illinois river and Mississippi river by the Chicago, St. Louis & Gulf Transportation Company, reached New Orleans on June 6, on its first trip, which is to be the beginning of a regular service.

The New York State Public Service Commission, Second district, has authorized the Long Island Railroad to equalize commutation ticket rates on the basis of four mills a mile; which will cause a small increase in monthly tickets between New York and points east of Bayport and Holtsville.

The lower house of the Illinois legislature has passed, on second reading, an amendment to the senate bill permitting the exchange of newspaper advertising for railroad transportation and to permit the issuance of passes to members of the general assembly. The bill was advanced to a third reading.

The midnight passenger trains between St. Louis and Kansas City, which were discontinued by several roads in January, 1914, were restored on June 1, by the Missouri Pacific and the Wabash, and on June 6, by the Chicago & Alton and the Chicago, Burlington & Quincy. Trains leave each city shortly before midnight and arrive at the other city early the next morning.

The Chicago, Milwaukee & St. Paul has announced that on June 20 it will put in service a new train to the Pacific coast via the Union Pacific and Southern Pacific to San Francisco. The train will be known as the "San Francisco Limited," and will leave Chicago at 9:35 p. m. On the same day a new train, the "Denver Special" will be put on between Chicago and Colorado.

A new passenger train between Chicago and California will be put in service on Saturday, June 19, by the Chicago & North Western, Union Pacific and Southern Pacific. The train will leave Chicago daily at 10:30 a. m., arriving at San Francisco at 9:30 a. m. the third day; and the eastbound train will leave San Francisco at 10:20 a. m., arriving at Chicago at 11:00 a. m. the third day.

A. O. Eberhart, former governor of Minnesota, has been elected president of the newly-organized River Terminal Association, with headquarters at St. Louis, Mo. As chairman of the executive committee of the association he has stated in a report that the construction of river terminals will be undertaken in at least 15 towns of the Mississippi valley during the present year.

The Pennsylvania and the Philadelphia & Reading both have reduced, from $75 to $62.50, the price of 150-trip tickets between Philadelphia and Atlantic City, Cape May and other points on the south Jersey coast. It appears that from Camden, N. J., across the river from Philadelphia, the rate for these tickets is $60, which rate could not be advanced because of the disapproval of the New Jersey Public Utilities Commission; and now because of the facility with which Philadelphia passengers can cross the river and avail themselves of the intrastate rate, the railroads have concluded to reduce the interstate rate. The distance from Camden to Atlantic City is 59 miles.

Freight Traffic Manager C. E. Perkins, of the Missouri Pacific, has notified station agents to refuse to allow consignees of bulk freight to peddle goods out of cars at destination. The use of cars as salesrooms, for the disposal of apples and other freight, has become too common to be tolerated; and the practice is now forbidden not only on account of considerations of economy, but also because of the possibility of bodily accident to persons doing business in, on or around freight cars. If a consignee does not unload his freight promptly within the free time agents are instructed to have the goods unloaded into public warehouses.

The lines operating from Key West to Chicago have made some good records recently on special trainload movements of Cuban pineapples. The cars are loaded in Havana and thence carried to Key West on the car ferry of the Florida East Coast. From Key West to Chicago the special trains are run over the Florida East Coast, the Atlantic Coast Line, the Central of Georgia, the Nashville, Chattanooga & St. Louis and the Illinois Central. The distance is 1,767 miles and four trains have been run through in an average time from Key West to Chicago of 86 hours. The fastest run was 81 hours, which, for the distance, made an average running time of 21.8 miles an hour, including stops.

Panama Canal Traffic in April

The Canal Record reports the total quantity of freight going through the Panama Canal in April as 522,841 tons; eastbound, 285,457 tons, and westbound, 237,384 tons. The total in March, the heaviest month on record, was 635,057 tons. Other interesting facts in the statement are the following:

Tolls in April	$442,415
Tolls since opening, net	$3,274,566
Commodities in April—	
Cacao from South America, tons	6,446
Canned fish from Washington, Oregon and California, tons.	5,544
Coal, tons	14,126
Copper from South America, tons	5,766
Flour from New York, tons	1,000
Flour from Puget Sound, tons	14,407
Gasoline, tons	6,462
Total westbound United States coasting trade, tons	68,271
Total New York to South and Central America, tons	22,515
Total New York to China, etc., tons	23,873
Total Europe to California, etc., tons	3,893
Total United States coastwise, eastward, tons	27,438
Total South America to Europe, tons	6,482
Total South America to New York, tons	3,544
Nitrates from South America, tons	68,027
Refined petroleum, Atlantic ports to Hawaii, China, etc., tons	22,297
Sugar, Hawaii to New York, tons	31,687

The average loading of all the vessels passing through the canal since its opening has been 5,156 tons.

New Railway Link Between Servia and Roumania.—It is reported from Rome that for several weeks past thousands of workmen have been engaged on the construction of a railway line between Negotin in Servia and Severinu in Roumania. This line, which is nearing completion, will link up the Roumanian railway system with Salonika. Russia and Roumania will then be able to receive supplies direct from Salonika, and send their cereals to other parts of Europe.

Discovery of Oxygen.—The discovery of oxygen is generally credited to Dr. Joseph Priestly, an English clergyman and scientist. The date, August 1, 1774, is commemorated as the birthday of modern chemistry. At about the same time two others made the same discovery: Scheel, a Swedish apothecary, who called it "fire air"; and Lavoisier, a French chemist, who called it oxygen, meaning "acid former." To Lavoisier is due the credit for the true explanation of combustion.—*Power.*

The Bagdad Railway.—The future of the near East is obviously a matter of the greatest practical interest to Russia, which is thus directly interested in the Bagdad Railway. A committee formed under the auspices of the "Society of Slavonic Reciprocation" has been studying this matter, and has recently made a report. The committee urges that under the terms of peace the Turkish Black Sea coast should belong to Russia, and that the Bagdad Railway, as regards both the sections already constructed and the concession for the building of the remainder, should be taken from Germany. At first, it will be desirable for the railway to continue to be operated and developed under the joint administration of England, France and Russia, while the selection of new lines and the final determination of the route of trunk and subsidiary lines must depend not so much upon political interests as has hitherto been the case, but on the economic interests of the three allied powers. The report recommends that, from the standpoint of Russian commercial interests, the roundabout route from Biredjik to Bagdad, chosen by the Germans for strategic reasons, should be straightened out in the form of a line on the right bank of the Euphrates, which happens to be the British plan. It is obvious that the Bagdad Railway, whose commercial and military importance is being much more generally appreciated than was formerly the case, will in the near future become a political factor of much importance.

Commission and Court News

INTERSTATE COMMERCE COMMISSION

Rates on Iron Pipe Found Reasonable

City of Charlotte, N. C., et al. v. Southern Railway Company et al. Opinion by the commission:

Rates on cast-iron pipe in carloads from East Radford and Lynchburg, Va., and Anniston, Ala., to Charlotte, N. C., and Rock Hill, S. C., not found to have been unreasonable. Fourth section applications named granted in part and denied in part. (34 I. C. C., 128.)

Spokane Lumber Rates Reduced

Wilson-Leuthold Lumber Company et al. v. Chicago, Milwaukee & St. Paul et al. Opinion by Commissioner Hall:

Rate of 20 cents per 100 lb. for the transportation of lumber in carloads from Spokane, Wash., to Butte, Mont., over the Northern Pacific and the Chicago, Milwaukee & St. Paul, found unreasonable. Reasonable maximum rate (17½ cents) prescribed for the future. (34 I. C. C., 146.)

Rates on Shingles to Points in Iowa

Board of Railroad Commissioners of Iowa v. Atchison, Topeka & Santa Fe et al. Opinion by the commission:

The commission finds that the present rates on cedar shingles from points in Oregon, Washington, Idaho and Montana to points in Iowa are discriminatory, and fourth section applications seeking authority to charge lower rates on this commodity from these points of origin named to Chicago and St. Louis than to intermediate points are denied. (34 I. C. C., 111.)

Westbound Transcontinental Refrigeration Charges

Opinion by the commission:

The commission finds that the carriers have not justified proposed new refrigeration charges on perishable commodities iced by the shipper and delivered to the carrier with specific notice not to re-ice in transit. Certain proposed increased charges per car for the re-icing in transit of perishable commodities shipped from Missouri river territory to the north Pacific coast, Spokane and Montana territories are, however, found to be justified. (34 I. C. C., 140.)

The Tap Line Case

Opinion by Commissioner Harlan:

The commission finds that joint rates on hardwood lumber from mills located on the Louisiana & Pine Bluff at Huttig, Ark., in excess of the rates on the same commodity from the station at Huttig on the rails of the St. Louis, Iron Mountain & Southern are unreasonable and discriminatory. The Louisiana & Pine Bluff is a subsidiary of the Frost-Johnson Lumber Company. The complainant is charged three cents a 100 lb. for the switching of the product of its mill to the Iron Mountain, a distance of but a few hundred feet to one connection and of less than three miles to another connection. (34 I. C. C., 116.)

Rates from Trebein and Leesburg, Ohio

Dewey Brothers Company v. Pittsburgh, Cincinnati, Chicago & St. Louis, et al. Opinion by the commission:

The commission finds that the maintenance of lower rates on grain and grain products from Trebein and Leesburg, Ohio, to Norfolk, Va., than to intermediate points west of and including Bluefield, W. Va., is not justified, and relief from the provisions of the fourth section of the act is denied. The rates from these points of origin to main-line points on the Norfolk & Western west of and including Bluefield are held unreasonable to the extent that they respectively exceed 15.4 and 14.9 cents per 100 lb. The rates to branch line points on the Norfolk & Western, both east and west of Bluefield are not shown to be unreasonable. (34 I. C. C., 135.)

The Illinois Public Utilities Commission has issued a decision holding that the "jitney bus" is to be considered as a public utility, and that proprietors must incorporate and seek certificates before operating.

The Illinois Public Utilities Commission held a hearing on Monday on the application of the Chicago & Milwaukee Electric Railroad for permission to increase its passenger fares from about 1.40 cents a mile to 1.75 cents.

The Colorado Public Utilities Commission has issued an order requiring railroads to file with the commission copies of their working time schedules, insofar as they affect the movement of passenger trains, and all changes therein at least five days before their effective date. It is also ordered that if any change is made in the time of arrival or departure of regular passenger trains, such information shall be posted in each station at least five days before the effective date. Notice to the commission is also required of the removal or abandonment of any station or agency at least ten days before the effective date.

PERSONNEL OF COMMISSIONS

William M. Brown, of Bangor, has been appointed chief inspector for the Public Utilities Commission of Maine, the appointment to take effect July 3. For seventeen years, up to 1912, Mr. Brown was superintendent or general superintendent of the Bangor & Aroostook. He was graduated from Bowdoin College in 1881 as civil engineer, and was engaged in the location and construction of several railroads in Maine between 1882 and 1895.

COURT NEWS

The judges of the United States district court at Detroit have declined to issue a temporary injunction at the request of the Ann Arbor, restraining the state of Michigan from enforcing the two-cent passenger fare law.

In the Federal Court at St. Louis, Mo., June 1, the Davidson Brothers Company of Des Moines, Ia., pleaded guilty to an indictment charging the presentation of fraudulent claims for damages to freight. Davidson Brothers are wholesale fruit dealers, and the offenses occurred in 1912.

Discrimination in Delivery from Spur Track

Under the Texas statute, defining and prohibiting unjust discrimination on the part of any railroad, the Court of Civil Appeals holds that a road, by refusing to deliver to one doing business on its spur track shipments from localities or persons not served by its own line, but by connecting lines, works an unlawful discrimination against such localities or persons that may be enjoined.—M. K. & T. v. Seeger (Tex.), 175 S. W., 713.

Texas Blacklisting Statute Held Unconstitutional

Following the decision of the Texas Supreme Court in St. Louis Southwestern v. Griffin, 171 S. W., 703, the Texas Court of Civil Appeals holds that the Texas blacklisting statute, requiring railroad companies to furnish discharged employees with a statement of the cause of their discharge, and to furnish employees voluntarily leaving the service with a statement to that effect showing whether their services were satisfactory, is unconstitutional. Galveston, H. & S. A. v. State (Tex.), 175, S. W., 1096.

Right to Relief from Passenger Service on Branch Lines

The North Dakota Supreme Court in a case against the "Soo Line," holds that in determining whether a railroad shall be granted relief under the North Dakota statute from maintaining a separate daily passenger service on a branch, the earnings and cost of operation of the branch line service must be determined as nearly as possible; and where it plainly appears that the cost of operating the branch line with separate daily passenger service installed greatly exceeded the road's revenues derivable from the operation of the branch line, the road is prima facie within the statutory exception, and prima facie is entitled to be permitroad cannot be compelled to operate a separate daily passenger service on a particular branch line at a great loss, and be compelled to make up such loss from its main line revenues. The intention of the statute is that the revenues from branch lines shall justify a daily passenger service independent of whether the road as a whole within the state is returning a fair dividend on its investment. In the present case the evidence showed that the Crosby-Berthold line of another company—the Great Northern—furnishes ample passenger service for four-fifths of the length of this line. It was held that a separate passenger service should not be forced for the convenience alone of the town of Ambrose and vicinity, when to do so would cause an additional annual expenditure of $14,000, added to a loss already sustained under mixed train service, the revenues being inadequate to meet even the expenses of a mixed train service. Minneapolis, St. P. & S. S. M. v. State Board (N. Dak.), 152 N. E., 513.

Exchange of Passes—Liability

The Indiana Appellate Court holds that passes exchanged between two interurban railroads for the use of their officers are supported by a valid "consideration," i. e., some right, interest or profit accruing to one party, or some detriment, inconvenience, loss, or responsibility given, suffered or undertaken by the other, and the stipulation for nonliability indorsed thereon cannot be enforced. Fort Wayne & Wabash Valley Traction Co. v. Justus (Ind.), 108 N. E., 754.

Safety Gates—Stop, Look, and Listen Rule

The Pennsylvania Supreme Court holds that, while safety gates are for the protection of the public, they do not absolve the public from exercising proper care to protect themselves. An automobile approached a crossing from the west, traveling 20 miles an hour, when it was 20 or 25 ft. from the crossing, the safety gates of which were raised. At that distance the chauffeur first saw a locomotive on the track, traveling 20 miles an hour. He made no effort to reduce his speed or stop the machine until he saw the engine. His machine was struck when it was at a standstill with its front part over the first rail of the northbound track. He was held to be guilty of contributory negligence barring recovery in not observing the stop, look, and listen rule. This rule has been enforced by the Pennsylvania courts since the decision in Pennsylvania Co. v. Beale, 73 Pa. 504, in 1873, and failure of a traveler to observe it is not mere evidence of negligence for the jury, but negligence per se and to be so declared by the court. Earle v. Reading (Pa.), 93 Atl., 1001.

Air Brakes—Switching Operations

Following the federal court's decision in United States v. Erie, C. C. A., 212 Fed. 853, where the question of the compulsory use of air brake equipment in switching operations was elaborately considered, the Pennsylvania Supreme Court holds that the safety appliance act does not compel the air coupling of cars in switching movements. Whalley v. Reading (Pa.), 93, Atl., 1016.

United States Steel Corporation Not Condemned

The United States Circuit Court of Appeals, at Trenton, N. J., June 3, handed down a decision refusing the application of the government for an injunction against the United States Steel Corporation as an organization maintained in violation of the anti-trust law. The decision, by Judge Buffington, is concurred in by Judges McPherson, Hunt and Woolley. Though unanimous in their decision, not all the members of the court are in complete accord as to the steps by which the result is reached.

As against the government the court refused to dissolve the corporation, holding that in acquiring its foreign and home trade the concern did not violate the Sherman anti-trust act; and it refused all the injunctions prayed for by the Department of Justice.

As against the Steel Corporation the court held that the committee meetings participated in by 95 per cent of the steel trade of the country, including the Steel Corporation, subsequent to the famous Gary dinners of eight or nine years ago, were unlawful combinations to control prices, but as these meetings had stopped before the government filed its complaint, in October,

1911, the judges held that there was no occasion for an injunction.

The opinion of the court suggests that such practices lie within the province of the new Federal Trade Commission, but adds that if their repetition is apprehended the court will on motion of the government retain jurisdiction of the case to deal with this feature.

Judge Buffington declares that the keynote of the entire opinion is "that this case, a proceeding under the Sherman anti-trust law, is largely one of business facts. . . . The real test of monopoly is not the size of that which is acquired, but the trade power of that which is not acquired. . . . If mere size were the test of monopoly and trade restraint, we have not one but half a dozen unlawful monopolies in the large department stores of a single city."

The court found nothing wrong in the Steel Corporation acquiring the Tennessee Coal & Iron Company during the financial panic in 1907. The output of the Tennessee Coal & Iron Company at the time was only 1.7 per cent of the country's total output; up to that time it had not been a business success; its principal product—rails—was made at a loss; its ultimate success was doubtful and involved a further outlay of $25,000,000, and the purchase of the Tennessee property, as well as that of several other steel concerns earlier in the history of the big corporation, was made in fair business course and was "the honest exertion of one's right to contract for one's benefit, unaccompanied by a wrongful motive to injure others."

With regard to Andrew Carnegie, who, the government charged, was a party to the "unlawful combination," and "took the bonds of the corporation with all the infirmities attaching to such participation," the court found that there is no proof that he accepted any other relation in the formation of the Steel Corporation than that of seller of his stocks and bonds.

On the filing of a formal decree the government will probably take an appeal to the Supreme Court.

Advance New York Suburban Fares Sustained

The New York State Court of Appeals on June 8 affirmed the decision of the Supreme Court, Appellate Division, handed down in January, 1914, approving an increase of fares, between New York City and points in Westchester county, made by the New York Central in 1910. The decision of the lower court was reported in the *Railway Age Gazette* January 30, 1914, pages 221 and 249. By this action the courts have reversed the decision of the Public Service Commission, second district, which had held that the very low rates formerly in effect should be continued as a matter of public policy; this conclusion, in an opinion by Chairman Stevens, having been reached in spite of the fact that no evidence was found showing the higher rates to be unreasonable in themselves.

The present decision is by Judge Hiscock, who says:

"The naked fact that a railroad has established and continued a rate for a limited time does not justify the conclusion that it was profitable. It may have been established at an unprofitable figure as a result of miscalculation, or because of compelling competition or of a policy which was willing to endure temporary losses in the hope that there might ultimately be developed a profitable traffic.

"In the second place, even if we should assume that these rates when established in 1907 were compensatory, the presumption did not follow that this condition and result would indefinitely continue."

The question what general policy should be adopted in developing suburban trade was one to be decided by the road and not by the state. The methods and rates which it would apply to the development of any policy were subjects for regulation, but the question whether the welfare of the road would be best subserved by one policy or another was a subject to be decided by the officers and stockholders of the corporation.

In April, 1914, the legislature passed a bill, applying both to the New York Central and to the New York, New Haven & Hartford (which has a similar suit pending) reducing the fares, in accordance with the view of the Public Service Commission; but this bill was vetoed by Governor Glynn, who, referring to the fact that the suit had been appealed to the higher court, declared that legislation to forestall a decision of the court was wholly unjustifiable.

The present decision foreshadows a similar conclusion in the New Haven road's case.

Railway Officers

Executive, Financial, Legal and Accounting

T. Cox has been appointed acting auditor of the Pacific & Idaho Northern, with headquarters at New Meadows, Idaho, succeeding H. W. Davies.

Samuel C. Stickney, assistant general manager of the Erie at New York, has been appointed assistant to vice-president of the Erie, the Chicago & Erie, the New York, Susquehanna & Western and the New Jersey & New York. Jason C. Tucker, assistant to general manager at New York, has been appointed assistant to vice-president, and John D. Cummin, assistant to general manager at New York, has been appointed assistant to vice president. All with headquarters at New York. The positions of assistant general manager and assistant to the general manager are discontinued. (See Operating Officers.)

John D. Cummin, whose appointment as assistant to the vice-president of the Erie has already been announced, was born October 11, 1870, at Babylon, New York. After a common school education he began railroad work on July 1, 1887, with the Long Island. Up to July 31, 1897, he held various positions under the general roadmaster, chief engineer and general superintendent, and for six of these years was in charge of work train service. From 1897 to 1901 he was out of railroad work, being superintendent of a news company. From 1901 to February, 1905, he was clerk and then chief clerk to the general superintendent, later the general manager, and later the vice-president of the Erie. From March to December, 1905, he was general agent of the Bath & Hammondsport Railroad and the Lake Keuka Navigation Company. From 1906 to August, 1909, he was assistant to the receiver of the Cincinnati, Hamilton & Dayton and Pere Marquette. In September, 1909, Mr. Cummin was appointed special agent in the vice-president's office of the Erie, and in January, 1914, assistant to the general manager.

Operating

T. E. Jamison has been appointed trainmaster of the Chicago division of the Baltimore & Ohio, with office at Garrett, Ind., succeeding D. F. Stevens, promoted.

O. C. Bishop has been appointed superintendent of sleeping and dining cars and news service of the Canadian Northern, western lines, with headquarters at Winnipeg, Man. J. M. Grieve has been appointed assistant superintendent of sleeping and dining cars and news service, with headquarters at Winnipeg, Man.

J. E. Snedeker, superintendent of the Central Kansas division of the Missouri Pacific-Iron Mountain System, has had his jurisdiction extended over the Colorado division, with headquarters at Osawatomie, Kan. A. J. Alexander, superintendent of the Colorado division, has been appointed assistant superintendent of the Horace district of the Colorado division, with headquarters at Pueblo, Colo. T. W. Collins has had his jurisdiction extended over the Hoisington district, with headquarters at Hoisington, Kan. R. E. Cahill has been appointed assistant superintendent of the Northern Kansas division, with headquarters at Concordia, Kan. The offices of assistant superintendent of the Kansas City and Northwestern district and the Leavenworth branch and of trainmaster of the Northern Kansas division have been discontinued.

Frederic B. Lincoln, general superintendent of the Erie and subsidiary lines east of Salamanca, at New York, has been appointed general manager of the Lines East of Buffalo and Salamanca, with office at New York. William A. Baldwin, assistant general superintendent at New York has been appointed general superintendent of Lines East of Buffalo and Salamanca, with office at New York. John B. Dickson, assistant general manager at Cleveland, Ohio, has been appointed general superintendent of Lines West of Buffalo and Salamanca, with office at Cleveland. George W. Kirtley, superintendent of transportation at New York, has been appointed general superintendent of transportation, and the offices of assistant general superintendent, Lines East, assistant general manager, Lines West, and superintendent of transportation, have been discontinued.

intendent of the Canadian Government Railways, with headquarters at Moncton, N. B., has already been announced in these columns was born on February 23, 1874, at Toronto, Ont., and was educated in the public schools and at Collegiate Institute, Lindsay, Ont. He began railway work in May, 1890, with the Grand Trunk and served as call boy and apprentice at Lindsay, until November, 1891, then as apprentice, locomotive fitter and machinist at Point St. Charles. In September, 1896, he entered the service of the Canadian Pacific as clerk in the chief despatcher's office, and subsequently served as chief clerk in the superintendent's office, also in the general superintendent's office, and as car service agent until March, 1903. He was then passenger car distributor in the car service department at Montreal, until September, 1907, when he was appointed assistant superintendent of the Toronto Terminals. The following July he was appointed superintendent of District No. 1, Ontario division at Toronto, Ont., and in February, 1909, was transferred to London as superintendent of District No. 2. From March, 1911, to February, 1913, he was superintendent of District No. 1, Eastern division at Farnham, Que., and then to June, 1914, was superintendent of the Montreal Terminals. He was then appointed superintendent at Montreal of District No. 3, Eastern division, remaining in that position until May, 1915, when he left the service of the Canadian Pacific to go to the Canadian Government Railways as general superintendent of the Intercolonial, the Prince Edward Island and the National Transcontinental east of Quebec, with headquarters at Moncton, N. B.

J. K. McNeillie

Frederic Bowen Lincoln, who has been appointed general manager of the Erie Lines East of Buffalo and Salamanca, with office at New York City, was born in October, 1867, at New York, and was educated in the public schools and at New York University. He began railway work on May 20, 1887, in the enginering department of the Erie, and to June, 1892, was consecutively rodman, transitman and assistant engineer. He was then, for over three years, assistant engineer of the Allegheny and Susquehanna divisions, and from November, 1895, to May, 1897, was trainmaster of the Toby branch, in charge of maintenance and operation of the same road. In May, 1897, he became agent of the Erie at Salamanca, N. Y., and from December, 1898, to March, 1902, was superintendent of the Tioga division of the same road and superintendent of the Blossburg Coal Company. He was then, to October, 1903, general manager of the Buffalo & Susquehanna Coal & Coke Company, and from October, 1903, to the following February was special agent for the vice-president and general manager of the Erie. In February, 1904, he was appointed superintendent of the Susquehanna division of the Delaware &

F. B. Lincoln

a short time he was superintendent of construction of the Delaware & Eastern. From October, 1905, to March, 1906, he was superintendent of construction of the O'Rourke Engineering Construction Company, New York, engaged on the New York Central & Hudson River terminal work, at Forty-second street, New York. On March 15, 1906, he became assistant to the receiver of the Pittsburg, Shawmut & Northern; in January, 1914, he was appointed general superintendent of the Erie grand division of the Erie, and now becomes general manager of the Lines East of Buffalo and Salamanca of the same road.

M. A. Mulligan, whose appointment as superintendent of the New York division of the Lehigh Valley has been previously announced in these columns, began railway work on that road as water boy for a track gang. He was later brakeman, conductor and then fireman. He left the Lehigh Valley to take a position as fireman on the Erie, and previous to 1910 filled the positions of yardmaster, and later general yardmaster of the New York terminals of the Erie. In December, 1910, he returned to the Lehigh Valley as general yardmaster of the New York division, and later was made trainmaster of that division. Some months ago he was appointed general yard inspector, making a study of the condition of all the larger yards on the system. He has now been appointed superintendent of the New York division, as noted above.

M. A. Mulligan

Traffic

F. B. McIlvaine has been appointed district freight claim agent of the Michigan Central, with headquarters at Chicago.

Engineering and Rolling Stock

T. L. Landers has been appointed resident engineer of the Intercolonial, with office at Truro, Nova Scotia.

W. H. Keller, assistant master mechanic of the Baltimore & Ohio Southwestern, at Cincinnati, Ohio, has been appointed master mechanic of the Indiana division, with headquarters at Cincinnati.

E. W. McGarvey has been appointed assistant supervisor of the Philadelphia division of the Eastern Pennsylvania grand division of the Pennsylvania Railroad, succeeding J. R. Scarlett, transferred.

John Ernest Lloyd, assistant division engineer of the Baltimore & Ohio, at Garrett, Ind., has been appointed division engineer, with headquarters at Cleveland, Ohio, succeeding A. A. Jackson, resigned.

B. B. Milner has been appointed engineer of motive power of the New York Central, in charge of locomotive design and construction, and the relation of locomotive standards to operation, with headquarters at New York.

Lee Highley, chief engineer of the Pacific & Idaho Northern, having resigned, the office of chief engineer is abolished for the time being. All correspondence regarding the engineering department should be addressed to the general manager.

E. N. Layfield, formerly chief engineer of the Chicago Terminal Transfer Railway, and more recently a consulting engineer at Chicago, has been appointed assistant secretary and editor of publications of the Western Society of Engineers, Chicago.

souri, Kansas & Texas at Sedalia, Mo., has been appointed general superintendent of the car department, with office at Dennison, Tex. William Walker, general foreman of the Sedalia shops succeeds Mr. Alquist.

A. F. Dorley, whose appointment as engineer of maintenance of way of the eastern district of the Missouri Pacific-Iron Mountain System, with headquarters at St. Louis, Mo., has already been announced, was born on April 8, 1875, at Lancaster, Pa. He was graduated from Mt. St. Mary's College, Emmitsburg, Md., in 1893, with the degree of A. B., and from Notre Dame University, South Bend, Ind., in 1900, with the degree of C. E. He entered railway service on June 21, 1900, and was rodman for the Baltimore & Ohio Southwestern until February 1, 1901, when he became assistant engineer of the Cleveland, Cincinnati, Chicago & St. Louis, at Indianapolis, Ind. From February 1, 1902, to April 1, 1903, he was assistant engineer of the Baltimore & Ohio Southwestern, at Chillicothe, Ohio. He was then made assistant division engineer at Washington, Ind., which position he held until April 1, 1906, when he came to the Missouri Pacific-Iron Mountain System as assistant engineer. From July 15, 1906, to December 10, 1910, he was consecutively division engineer at Kansas City, Mo., Osawatomie, Kan., and Omaha, Neb. On December 10, 1910, he was appointed engineer of water service, with office at St. Louis, Mo., and on April 1, 1914, was appointed principal assistant engineer, with headquarters at St. Louis, from which position he is now promoted.

A. F. Dorley

Purchasing

A. E. Hutchinson has been appointed general purchasing agent of the Oregon Short Line, with headquarters at Salt Lake City, Utah, succeeding G. H. Robinson, who has been appointed general storekeeper at Pocatello, Idaho, succeeding T. A. Martin, promoted.

OBITUARY

N. A. Waldron, general storekeeper of the Missouri, Kansas & Texas, with headquarters at Parsons, Kan., died in St. Louis, Mo., on May 30.

E. N. Brown, assistant superintendent of the Baltimore & Ohio Southwestern, at Chillicothe, Ohio, died in that city May 25, at the age of 46 years.

H. W. Cowan, chief engineer of the Colorado & Southern, whose death on May 29, at his home in Denver, Col., has already been announced, was born on April 27, 1862, at Bath, Me. After graduating from the Worcester Polytechnic Institute he entered railway service, and from 1883 to 1886 he was topographer and draftsman for the Winona, Alma & Northern. From June, 1886, to September, 1888, he was draftsman and topographer for the Colorado Railway, and from September, 1888, to February, 1894, was assistant engineer of the Colorado division of the Union Pacific. He was then appointed resident engineer of the Union Pacific, Denver & Gulf and the Denver, Leadville & Gunnison railways, at Denver, Col. In January, 1898, he was appointed chief engineer of the Colorado & Southern, successor to the Union Pacific, Denver & Gulf and Denver, Leadville & Gunnison Railways, and in January, 1907, was also appointed consulting engineer of the Colorado & Southern, and was later appointed chief engineer.

Equipment and Supplies

LOCOMOTIVE BUILDING

The Denver & Salt Lake has ordered eight Mikado type locomotives from the Lima Locomotive Corporation.

The New York, Ontario & Western has ordered 12 Santa Fe type locomotives, cylinders 28 by 32 in., driving wheels 57 in., total weight in working order 360,000 lb., from the American Locomotive Company.

CAR BUILDING

The Lehigh Valley is making inquiries for twenty 50-ft. steel underframe milk cars.

The International & Great Northern is negotiating for 1,000 cars, with the Mt. Vernon Car Company.

The Norfolk & Western has ordered 10 coaches from the Harlan & Hollingsworth Corporation, and 12 baggage and express cars and 2 postal cars from the American Car & Foundry Company.

IRON AND STEEL

The Chesapeake & Ohio Northern has placed an order for 2,000 tons of bridge material.

The Lehigh Valley has ordered 100 tons of steel from the American Bridge Company, for a turntable.

The Louisville, Henderson & St. Louis has ordered 3,000 tons of rails from the Illinois Steel Company.

The Chesapeake & Ohio has ordered 2,100 tons of bridge material from the Virginia Bridge & Iron Company.

The Virginian Railway has ordered 240 tons of bridge material from the Virginian Bridge & Iron Works.

The Lehigh Valley has ordered 2,000 tons of steel from the American Bridge Company for train shed and grade crossing work.

The Chicago, Milwaukee & St. Paul has awarded a contract for 359 tons of steel for a bridge at Tacoma, Wash., to the American Bridge Company.

The St. Louis & San Francisco has been authorized by Judge Sanborn in the Federal Court to spend $800,000 for rails for replacements on various portions of the system.

The Chicago, Indianapolis & Louisville has ordered 3,000 tons of rails from the Illinois Steel Company. This order was prematurely reported in our issue of May 7.

The Pennsylvania Lines West has ordered 300 tons of steel for elevated track work at Fort Wayne, Ind., from the Riter-Conley Manufacturing Company, Leetsdale, Pa.

The Pennsylvania Lines East and West of Pittsburgh has placed orders for 155,500 tons of rails. The orders call for 118,000 tons of 100-lb. rail and 37,500 tons of 125-lb. rail. An order for 12,000 tons had previously been placed, so that the present order makes the total Pennsylvania rail orders for the present year 167,500 tons.

MACHINERY AND TOOLS

The Missouri Pacific-Iron Mountain System has purchased four wood-working tools for its repair and machine shops at Pueblo, Colo.

The Gulf, Colorado & Santa Fe contemplates the purchase of the following new machinery at its shops at Cleburne, Tex.: One 4-ft. 8-in. by 8-ft. sash and door clamp; one 15-hp. power motor; one 22-in. by 12-ft. engine lathe; one ⅛-in. to 3½-in. twist drill wet grinder; one 4-in. pipe threading machine and one 28-in. rigid turret lathe. New machinery contemplated at Galveston, Tex., consists of one 24-in. crank shaper and one 26-in. by 14-ft. engine lathe.

Supply Trade News

The Union Twist Drill Company, Athol, Mass., is reported to have received a large order for rifles.

The Standard Underground Cable Company has begun the erection of an addition at Perth Amboy, N. J., to be used for drawing brass wire and copper tubing.

At a special meeting of the stockholders of the Burd High Compression Ring Company, Rockford, Ill., held on May 19, it was unanimously voted to increase the capital stock from $50,000 to $200,000. It was announced that the additional capital was voted because of large contracts which the company has been receiving and for the purpose of adding to equipment and enlarging the business.

C. H. Morse, Sr., the retiring president of Fairbanks, Morse & Company, who is being succeeded by his son, C. H. Morse, Jr., as has already been announced, was born in St. Johnsbury, Vt., in September, 1833. He began his business career at the age of 17, when he became clerk in the office of E. & F. Fairbanks & Co., scale manufacturers. In 1862 he became a member of the firm of Fairbanks, Greenleaf & Company, successors to E. & F. Fairbanks & Co. In 1872 the firm of Fairbanks, Morse & Company was established, Mr. Morse, Sr., being elected president, which position he held until May 19, when he resigned.

C. H. Morse, Sr.

J. B. Evans, recently with the General Railway Signal Company of Canada, Ltd., and formerly with the General Railway Signal Company, Rochester, N. Y., has been appointed general manager of the National Concrete Machinery Company, Madison, Wis. This company manufactures machinery for the production of concrete fence posts, and has a number of plants located on several of the large railways.

A. S. Hill, who was for a number of years at the head of Wm. E. Hill & Co., Kalamazoo, Mich., manufacturers of heavy saw mill machinery, has become connected with the American Saw Mill Machinery Company, Hackettstown, N. J., as the manager of the heavy saw mill department. It is the intention of the American Saw Mill Machinery Company to greatly amplify their line of heavy duty machinery under the supervision, designs and patents of Mr. Hill.

Six representatives of the Russian government, Maximillian Groten, Michael Bronikovfky, Michael Jurin, Nicolai Kemmer, Victor Kofhkin and Aready Martynoff arrived in New York last Friday on the Norwegian-American liner Bergensfjord for the purpose of making a tour of the United States and Canada to inspect the supplies, including railroad equipment and other material, recently ordered by the government. The commission of six inspectors will spend two weeks in New York, after which they will visit various manufacturing centers. They expect to stay on this continent about six months.

The Baldwin Locomotive Works is reported to have entered into a contract with the Remington Arms & Ammunition Company, whereby the locomotive company will turn over to the ammunition company certain new shops, the construction of which was recently started at Eddystone, for the manufacture of 1,500,000 rifles on an order from the Russian government. The ammunition company, according to the reports, will make the each rifle made, and at the completion of the order will turn the plant and equipment, valued at $1,500,000 over to the locomotive company, whereby the latter will have made $3,000,000 on the contract.

The business of the Wells Light Manufacturing Company, Jersey City, N. J., has been acquired by the Alexander Milburn Company, Baltimore, Md., manufacturers of high power portable lights and oxy-acetylene welding apparatus. Repair parts for Wells lights will be manufactured and supplied in the future by the Alexander Milburn Company from its Baltimore factory, and complete Wells oil lights will also be furnished where desired, in conjunction with the standard Milburn acetylene lights. The manufacture of Wells oil preheating burner outfits will be continued by the company and sold in connection with Milburn oxy-acetylene apparatus. The Wells lights and Wells preheating devices have been on the market for about 20 years, and have occupied a leading place among oil-burning equipment of their kind.

C. H. Morse, Jr., who has been elected president of Fairbanks, Morse & Company, succeeding his father, C. H. Morse, Sr., as has already been announced, is 41 years old. He was graduated from the University of Michigan in 1895, as a mechanical engineer. He first entered one of the Fairbanks, Morse & Company shops in order to get a practical knowledge of the building of gas engines, pumps, etc. He has been president of the Fairbanks, Morse Manufacturing Company, Beloit, Wis., in charge of manufacturing, for 10 years, which position he still holds. He has also been a director of Fairbanks, Morse & Company, Chicago, for 15 years, a director of Fairbanks, Morse Elecal Manufacturing Company, Indianapolis, Ind., for eight years. Eight years ago Mr. Morse was also elected a director of the Canadian Fairbanks, Morse Company for eight years.

C. H. Morse, Jr.

TRADE PUBLICATIONS

BUILDING CONSTRUCTION.—H. Edsil Barr, mechanical engineer, Erie, Pa., has issued a booklet describing his system of construction for warehouses, factories and industrial buildings. This form of construction, for which great economy is claimed, consists of concrete foundation, structural steel framework and brick pilasters with large window areas equipped with steel sash.

INSULATORS.—A recently issued 12-page pamphlet by the Brookfield Glass Company, New York, gives a brief list of insulators and insulator pins forming a part of its line of these products. Complete dimensions and specifications are given for each item. A more complete list of the products of this company is contained in its bulletin No. 56, which will be supplied upon request.

CHIMNEYS.—The Weber Chimney Company, Chicago, has issued a 48-page booklet describing its reinforced concrete chimneys and showing a large number of chimneys completed and in course of construction. It also contains a list of places where Weber chimneys have been erected throughout the United States and Canada with dimensions, and contains Kent's table of chimney sizes for steam boilers.

AIR COMPRESSORS.—Bulletin No. 34M, dated March, 1915, and issued by the Chicago Pneumatic Tool Company, describes the class O Chicago pneumatic steam and power driven compressors. The bulletin contains 36 pages, including detailed illustrations of the various parts of these compressors, as well as indicator diagrams showing the results obtainable by their use. Tables are included giving the principal data for the various sizes.

Steel Company, Pittsburgh, formerly the Des Moines Bridge & Iron Company, has issued a booklet describing its exhibit at the Panama-Pacific International Exposition, San Francisco. This booklet also contains a number of photographs and descriptions of installations of tanks for railway and other purposes. A list of tank installations with capacity and height is included.

Steel Reinforcement.—"Hy-Rib" is the title of a 144-page book issued by the Trussed Concrete Steel Company, Youngstown, Ohio, which contains a large amount of data showing the use of this steel sheathing in building constructions of various kinds. The book is well illustrated with a large number of photographs and drawings of representative structures in which this material has been incorporated, and should be of interest to the engineer and architect.

Heat Insulation.—A four-page folder recently issued by the Armstrong Cork & Insulation Company, Pittsburgh, Pa., deals with that company's high pressure covering for use on high pressure and superheated steam lines, boilers and other heater surfaces. This material is made up of a special form of silica of a minute cellular construction mixed with asbestos. Owing to the cellular nature of the silicious material it is said to be an exceptionally good heat insulator.

Speed Reducing Gear.—Catalog A of the Turbo-Gear Company, Baltimore, Md., is devoted to the Turbo reducing gear recently developed by this company for high ratio speed reduction. This gear consists of a stationary annular gear, a pinion cut integral with the high speed shaft, between which operate the intermediate gears, the shafts of which are secured to the cast steel close feed members. All the gears are of a double helical type and are enclosed in a cast iron housing.

Locomotive Stokers.—The Locomotive Stoker Company, Schenectady, N. Y., in its catalogue No. 14-B, issued in April, 1915, has compiled a list of locomotives to which the Street stoker has been applied. The catalogue is a neatly arranged booklet of some 50 pages, containing full-page illustrations of the locomotive classes, the principal dimensions, the number stoker fired in each case being shown on pages facing the illustrations. The catalogue brings out the fact that at the present time there are in service over 600 locomotives fired by Street stokers.

Sectional Steel Buildings.—A loose-leaf catalog recently issued by the C. D. Pruden Company, Baltimore, Md., is devoted to the line of portable and permanent sectional steel buildings designed and manufactured by this company. These buildings include garages, cottages and a variety of portable buildings suitable for construction camp and other temporary purposes. The buildings are fireproof and may be amply lighted and ventilated. Standard sizes are carried in stock for immediate shipment.

Intercolonial Railway of Canada.—The passenger department of the Canadian Government Railways has recently issued three exceedingly attractive folders relative to the scenic and other attractions of travel on the Intercolonial and the Prince Edward Island Railways. These booklets are entitled respectively; La Baie de Chaleur, Bras d'Or Lakes (Cape Breton), and "Abegweit." All three contain much interesting information and are well illustrated. The last, "Abegweit," deals with Prince Edward Island. It terms that island a "million acre farm," and says that although it does not now have a population as large as many Canadian cities, it could, nevertheless, on its 1,398,000 acres, support a population of over two million people. A fourth booklet, also of recent issue, names the 1915 summer excursion fares.

South African Notes.—The board of the South African Railways in a recent report says that during the past five years 1,446 miles of railway have been added to the South African system, representing an increase of over 20 per cent. The mileage at the end of last year was 8,486. In addition there are 647 miles of lines operated, but not owned by the administration. In 1910 the train mileage was 23,580,846, as against 29,701,991 in 1914, an increase of 6,121,345 train miles, or 25.9 per cent. There were under construction on December 31 last 973 miles of railway, the construction of all the lines sanctioned by Parliament having been started.

Railway Construction

Alabama Great Southern.—The new double track between Cuba, Ala., and Toomsuba, Miss., eight miles, has just been placed in service on the Alabama Great Southern. This track is to be used jointly by trains of the Alabama Great Southern and the Southern Railway.

Carolina, Greeneville & Northern (Electric).—Contractors have started work near Rader, Tenn., it is said, on this line. The plans call for building from Kingsport, Tenn., southwest, to Newport, about 75 miles, and there will be five steel bridges on the line. The company has under consideration the question of building an extension from Kingsport, east to Bristol, also an extension from Newport west to Knoxville. H. S. Reed, president, 205 Grant building, Los Angeles, Cal., and F. A. H. Kelly, chief engineer, Greeneville, Tenn. (January 19, p. 350).

Charleston Interurban.—This company has secured $750,000 through a sale of notes, it is said, and the proceeds are to be used for building the projected extension of the Kanawha Valley Traction from Charleston, W. Va., southeast via Marmet, Paint Creek, Cabin Creek, Coalburg and Handley to Montgomery, about 25 miles. Track has already been laid on about two miles. (March 12, p. 493.)

Kent Coal & Railway Company.—This company has been incorporated in New Brunswick, to build from Rexton, N. B., southwest to a point on the Intercolonial between Kent Junction and Adamsville, thence via Chipman to Minto, about 80 miles; also to build from Rexton to Richibucto Head. Inches & Hazen, solicitors, Fredericton, N. B. (April 23, p. 914.)

McConnellsburg & Ft. Loudon (Electric).—An officer writes that a contract has been let to Bennett & Smith, Greensburg, Pa., for the grading, track laying, etc., on the line from McConnellsburg, Pa., east to Ft. Loudon, 11 miles, and work is now under way. E. J. Post, president, McConnellsburg, Pa. (May 21, p. 1099.)

Meriden, New Britain & Hartford (Electric).—Work is to be started at once, it is said, on a line between Meriden, Conn., and Hartford, about 20 miles. Mayor D. J. Donovan, Meriden, is said to be interested.

North Carolina Traction.—An officer writes that this company will let contracts July 1 for building the projected line from High Point, N. C., via Winston-Salem to Christiansburg, Va., a distance of 137 miles. The work calls for the handling of about 300,000 cu. yd. of earth and about 63,000 cu. yd. of rock. There will be two steel bridges and a 21,897 ft. trestle and one 600 ft. tunnel. The company expects to develop a traffic in tobacco, timber and coal. B. D. Hammond, Box 21, Station A, Boston, Mass., is president.

Salt Lake & Utah (Electric).—This company, it is said, will open the line now under construction from Provo, Utah, to Springfield in July, and plans are under consideration for the immediate construction of the proposed extension to Payson.

Texas Roads.—The construction of a railroad from Dallas, Tex., northwest to Wichita Falls, is contemplated by A. A. Green, Jr., H. D. Lindsley and others. A tap line will first be built between Denton on the Missouri, Kansas & Texas of Texas, and Krum on the Gulf, Colorado & Santa Fe, and trackage rights will be secured over the Missouri, Kansas & Texas of Texas between Denton and Dallas.

Waycross & Western.—This company is considering the building of an extension from Milltown, Ga., its present southern terminus, to Ray's Mill, where a connection will be made with the Georgia & Florida.

West Virginia Roads (Electric).—According to press reports plans are being made to build an electric line between Fayette, W. Va., on the Chesapeake & Ohio and Beckley, about 35 miles. H. G. Scott, Charleston, W. Va., is said to be interested.

CHICAGO, ILL.—The Atchison, Topeka & Santa Fe has applied to the city council for the vacation of several streets and alleys to permit the construction of its proposed fruit terminal, located about one mile from the center of population of the city, between Sixteenth street, Wentworth avenue, Archer avenue, Twenty-second street and Grove street, along the south branch of the Chicago river. It is proposed to construct a banana warehouse, a fruit auction house and a large cold storage warehouse. In a letter to the local industries committee of the city council, President Ripley says of the plan that facilities will be open to the general shipping public and also will be made available to other carriers entering the city for the handling of perishable freight at the usual charge for such service, thereby enabling the receiver, if he so desires, to concentrate his business at one place.

CHICAGO, ILL.—The Chicago & North Western is having plans prepared for a new four-story office building to cost about $250,000, at the northeast corner of Ravenswood Park and Lawrence avenue, to accommodate some of the offices of the accounting department which are now located in the company's main office building downtown.

CHICAGO, ILL.—The Union Station Company, Chicago, has awarded contracts for the Monroe street bridge substructure to the Fitzsimons-Connell Dredge & Dock Company, Chicago, and for the superstructure to the Kettler-Elliot Erection Company, Chicago.

KANSAS CITY, MO.—The Chicago, Burlington & Quincy will replace its present bridge at this place with a double decked structure. The Union Bridge & Construction Company has been awarded the contract for the substructure.

KIOWA, KANS.—The Atchison, Topeka & Santa Fe is constructing a passenger depot at this place. It will be brick with stucco finish and tile roof. Swanson & Sons, Topeka, Kan., have been awarded the contract. The estimated cost of the depot is $18,000, and the track changes will amount to about $10,000.

PHOENIXVILLE, PA.—The Pennsylvania Railroad has asked bids on a concrete arch bridge at Campbell's Crossing, west of Frick's lock. The bridge is to consist of seven 84-ft. concrete arches for double track to take the place of the single-track four-span bridge now being used.

ST. PAUL, MINN.—The Chicago, St. Paul, Minneapolis & Omaha has awarded a contract to the Milwaukee Bridge Company, Milwaukee, Wis., for the superstructure of a counter balanced swing span 260 ft. long, with the long arm 175 ft. long. This is a bridge used jointly with the Chicago, Milwaukee & St. Paul, at St. Paul, over the Mississippi river. The contract for the deck plate girder spans was let some time ago. H. Rettinghouse, St. Paul, Minn., is chief engineer of the Chicago, St. Paul, Minneapolis & Omaha.

RAILWAY CONSTRUCTION IN SWEDEN.—A new railroad connection has been proposed between Goteborg and the province of Ostergotland, Sweden, on the Baltic. The connection will be made over an existing line from Goteborg via Boras, the cotton manufacturing center, to Halldarp. From Halldarp two new lines have been surveyed to Sommen, in Ostergotland. The two proposed lines coincide on the west side between Halldarp and Hoppebo, and on the east side between Sommen and Ostena. Between Hoppebo and Ostena one survey, known as the Jonkoping line, runs along the southern bank of Lake Vettern and through the town of Husqvarna and connects with Jonkoping, two important iron manufacturing centers. The other survey, the Tenhult line, runs through Lekeryd and Tenhult. The Jonkoping line, 88 miles in length, would cost $4,448,800 to build, or $935,320, more than the Tenhult line, because the grades are steeper and a narrow-gage line from Kojnoping to Gripenberg would have to be purchased and reconstructed. Either route would shorten the existing connection between Goteborg and the province of Ostergotland by about 30 miles. At present work is in progress to eliminate several sharp curves on the line from Goteborg to Boras, at an estimated cost of $804,000.

Railway Financial News

ERIE.—The Wall Street Journal says that the directors of the Erie have decided to furnish the stockholders with full information concerning the company's coal properties. An inventory will shortly be made of these properties and the results put before the stockholders.

MISSOURI PACIFIC.—It is said that the reorganization plan contemplates the consolidation of the Missouri Pacific proper and the St. Louis, Iron Mountain & Southern, and the probable elimination of the St. Louis, Iron Mountain & Southern stock, which stock is now held by the Missouri Pacific. An issue of preferred stock may be made, to be exchanged for collateral trust bonds which are now secured by a like amount of St. Louis, Iron Mountain & Southern stock; and a stock assessment of $30 per share may be made, for which consenting stockholders will be given new preferred stock.

NATIONAL RAILWAYS OF MEXICO.—As announced in these columns last week the $28,322,660 due June 1, including the principal of two year notes and interest maturities has not been paid. A formal announcement by the company says that owing to the continuance of the disturbing conditions in Mexico, it has been impossible for the company to make any arrangements for the payment of these obligations at this time. The operation of the property of the company is out of its hands. Holders of maturing obligations are asked to await the return to it of properties belonging to the system and the restoration of business to the Mexican nation, so that "the government and the company may be placed in a position to duly deal with the subject."

NEW YORK, NEW HAVEN & HARTFORD.—See President Elliott's statement in regard to the New Haven situation printed elsewhere in this issue.

PENNSYLVANIA.—The leasing of all the property and franchises of the Pennsylvania & Atlantic to the Pennsylvania Railroad has been approved by the New Jersey Board of Public Utilities Commissioners. The lease was dated April 14, 1915, and provided that it may be terminated at any time upon 60 days' notice in writing from either party.

WABASH.—It has been announced that more than 90 per cent of the $40,600,000 first refunding and extension mortgage bonds have been deposited under the reorganization plan, and the time for the deposit of these bonds has been extended to July 3.

OPENING OF THE MONT D'OR TUNNEL TO SWITZERLAND.—A new railway link between France, Switzerland and Italy—the Frasne-Vallorbe Railway, including the Mont d'Or tunnel through the Jura—was opened for traffic on Sunday, May 15, without any ceremony, the only railway officers present on the occasion being those of the Paris-Lyons-Mediteranean Company and the Swiss Federal Railways. Work has begun in September, 1910, and was expected to be completed in May, 1914, but was seriously delayed mainly by water-bursts in the tunnel, and also by the difficulty of obtaining a solid foundation for the embankment near Frasne. The original estimate for line and tunnel was $7,400,000, but the actual cost was about $6,437,250 a mile. The new line is about 15 miles in length, 13½ miles of which is in France and 1½ miles in Switzerland. It branches off from the Dijon-Pontarlier line at Frasne, and penetrates the Mont d'Or by a tunnel 6,670 yards long, joining the Pontarlier-Lausanne line at Vallorbe. By avoiding the circuitous route via Pontarlier the new line shortens the distance between Paris and Lausanne by nearly 10 miles, while other improvements have resulted in a gain of from 45 to 60 minutes in the journey between the same points, with a consequent quickening of the Paris-Simplon-Milan service. The curves of the new line are favorable for speed, and, in winter, the tunnels and pine forests are a protection against snowstorms. Vallorbe has become a customs station, and has been entirely remodeled, so that trains can now enter and leave without the engines having to be uncoupled and reversed.

United States and Mexico	$5.00
Canada	6.00
Foreign Countries (excepting daily editions)	8.00
Single Copies	15 cents each

Engineering and Maintenance of Way Edition and four Maintenance of Way Convention Daily issues, North America, $1.00; foreign $2.

Entered at the Post Office at New York, N. Y., as mail matter of the second class.

WE GUARANTEE that of this issue 10,011 copies were printed; that of those 10,011 copies 8,572 were mailed to regular paid subscribers to the Railway Age Gazette and the Railway Age Gazette, Mechanical Edition; 150 were provided for counter and news companies' sales; 189 were mailed to advertisers; 100 were provided for bound volumes, and 1,000 for distribution at Atlantic City.

The RAILWAY AGE GAZETTE and all other Simmons-Boardman publications are members of the Audit Bureau of Circulations.

It has been generally believed that there is little definite knowledge as to what actually takes place in the sheets and staybolts of a locomotive firebox, but the statements made by George L. Fowler in his discussion of the committee report on locomotive boilers on Thursday morning indicates that we know infinitely less than we thought we did. It appears from Mr. Fowler's investigations that the staybolts are always moving and always under stress; in fact, that they are practically subjected to the conditions of a vibratory testing machine. The effect of the rigid staybolt and the advantage of the flexible staybolt is indicated from the relative movement of the sheets, which is only half as great with the rigid as with the flexible bolt. The investigation also brought out some definite evidence of the cooling effect of the opening of the fire door, and the change in the movement of the tubes after the throttle is opened is one of the many astonishing features brought out in the investigation. The continuation of this experimental work with the improved apparatus which has been developed should bring out some valuable information as to just what is taking place in the firebox structure when the locomotive is working.

Movement of Firebox Sheets

Thin Fires for Stoker Engines

engines. The committee stated that there is sometimes a tendency to carry a fire that is too thin. A thick fire on a stoker engine and a thick fire on a hand-fired engine are two different things and must not be confused by those who have not had extended experience with stoker-fired engines. The operating conditions and the grade of fuel will govern the depth of fire. Where the use of the throttle is intermittent, it can be readily seen that a thin fire, which would require constant stoking to keep it alive, would tend to keep the pop open. On the other hand, with a heavier fire, it would be possible to maintain full pressure without continually feeding coal when the throttle is not open. One of the good features of the stoker is the thin fire it can carry, thus insuring more perfect combustion. But the conditions will determine the correct depth.

A Committee Report Well Presented

The Committee on Revision of Standards and Recommended Practice has received many congratulations on the splendid manner in which its report was presented on Wednesday morning. With its several appendices the report covered 26 pages. So skillfully did the chairman touch on the vital points, hardly using an unnecessary word, that the presentation was made in a few moments and yet the import of the recommendations was thoroughly grasped by all those who were interested. The report also conforms to the suggestions made to the Committee on Specifications by President Gaines that the standard specifications be not too rigid, but that they call for a fair grade of material which will prove satisfactory for general use. This will be less expensive than where each road has different requirements, some of them of a very special nature. The commitee has also kept in touch with other associations, and particularly with the American Society of Testing Materials, with the idea of having uniform specifications.

Superheat and Compounding

In the topical discussion on compounding superheater locomotives the point was brought out that the application of superheaters to compound locomotives and the compounding of superheater locomotives are entirely different matters, the results from which are not necessarily of equal benefit in increasing efficiency. The fact that considerable increase in efficiency may result from the application of superheaters to existing compound locomotives does not argue that the compound feature contributes the same share to the combined result, as indicated by the improvements which may be effected by its application to saturated steam locomotives. Theoretically, however, there seems to be little doubt that the compounding of superheater locomotives may effect an appreciable saving in fuel. This is clearly indicated by the results of the European tests referred to by Lawford H. Fry in opening the topical discussion on Wednesday morning. Undoubtedly similar results could be obtained in this country, but not with the standards of mainatenance now obtaining. The relative value of labor and fuel in European countries, and especially in France and Germany, where the compound superheater locomotive is finding its greatest use, is such that refinements in design intended to increase fuel economy are practicable, which would fail in this country because of the excessive cost of maintenance. The relatively high value of fuel in relation to the cost of labor in Europe as compared with this country, is the basis for the difference in practice existing between the two continents. In calling attention to

demanding increased attention, the cost of labor is also constantly increasing, and the advisability of the use of compounding in connection with superheated steam is unlikely to receive serious attention in this country until existing conditions have been greatly changed.

American and European Locomotive Design

In the refinements which have been and are being made in locomotive design in America, the designers, whether they know it or not, are to a considerable extent following the lines which European designers have followed for years. The restricted loading and clearance limits with which the railways of Europe have to contend forced their mechanical engineers to many expedients in order to reduce the weight of the frames and running parts to a minimum, the saving thus made being employed in increasing boiler capacity. The American designer did not adopt such methods until he was forced to it by the dimensions which American locomotives had reached; but the increasing use of heat-treated and special steels to increase strength and reduce weight is in direct line with European practice. That this development of the American locomotive will continue is certain and it would be well for those responsible for locomotive design to familiarize themselves with European practice, with a view to its adaption to our conditions.

Matters Worthy of Attention

President Gaines, in his opening address, asked some questions concerning motive power matters on which further emphasis may well be placed. Do we know when a new locomotive is placed in service whether its increased weight, capacity and cost are justified? There is too much designing and placing in service of locomotives without enough consideration being given to their suitability for the service in which they are to be used. Is the operating department kept informed of the results of investigations, if such investigations are made, into the means of obtaining the best results from locomotives on the road? This question is not difficult to answer. Such investigations are made infrequently and when made are too often of a nature which does not produce results that are worth keeping on record. How many operating department officers know in detail the savings effected by improvements in locomotives? Yet the operating officer is keenly interested in anything that affects the cost of conducting the operation. Again, how often are subordinates supplied systematically with information so that they may analyze the results of their work and endeavor to make reductions in expenses? These are only a few important items. They will suggest others to anyone taking the time to give them the consideration which they deserve, and are commended to the careful attention of motive power officers.

Cost of Hiring and Discharging Men

An investigation of the employment and discharge of all classes of employees at a number of factories disclosed the fact that of all those engaged during the year 1912 about 73 per cent. were new employees, never having worked in that particular factory previously. Managers stated that in their opinion the amount of money wasted in engaging and discharging employees in large numbers ranged from $30 to $150 per employee. The author of the investigation concludes that the apparently unnecessary engagement of 22,225 employees within one year in the factories investigated involved an economic loss of $774,139, which means that the cost of train-

methods for taking care of new employees, effective systems of apprenticeship and specialized training, and the regulation of commercial requirements so as to secure a fairly uniform production throughout the year. The effect of an efficient apprentice system in helping to correct such conditions is readily recognized, but the last suggested remedy is extremely difficult of application even in commercial establishments. When we consider the possibilities of its application to railway repair shops, the difficulties are, of course, greatly increased. Traffic conditions require the employment of every available unit of power at certain seasons of the year, while at others many locomotives are kept idle. The conditions at the large repair shops of necessity hinge to a great extent on this, but it seems probable that some improvement could be made in the assignment of locomotives for repairs so as to reduce the fluctuation in the amount of work throughout the year. If any marked improvement were to be made, it would require a careful study of all conditions and co-operation between departments; however, a study of the foregoing figures cannot but be of interest to mechanical department officers, and it is evident that any improvement which will tend toward reducing the number of men who are hired and discharged during the course of the year can have a direct effect on the condition of the company's treasury.

LOCOMOTIVE FUEL ECONOMY

THE problem of fuel economy, with all its ramifications, is without doubt one of the biggest questions with which the mechanical department has to contend. It includes the proper method of firing, the operation of the locomotive, its maintenance and desgin, and the use of fuel saving devices. Each one of these items is a large problem in itself and it would be impracticable to cover the entire subject in one committee report. This year the committee has, very wisely, confined itself to covering thoroughly one phase of the problem—instructions for enginemen and firemen—and has touched lightly on the other important items. These instructions are the first ever published by this association and are presented in a simple and concise manner so as to be readily understood by the engine crews.

Another problem concerning which but little detailed study has been made recently by this association, is that of the drafting of locomotives, this to include the progress of the air and gases from outside of the ash pan to the top of the stack. In a committee report at the recent Fuel Convention, M. C. M. Hatch, of the Delaware, Lackawanna & Western, showed a wide variation in the practices of the railways regarding ash pan opening, finding a difference of from 15.1 to 5.78 per cent in the ratio of air opening in the ash pan to the grate area. He found a difference of from 25.8 to 49.6 per cent in the ratio of air openings in the grate to the grate area. He also found that there is no one front-end arrangement in general use nor a general conforming to the Master Mechanics' Association's recommendation for proportioning the front end. Another feature, as brought out in the discussion by Lawford H. Fry, is that of the firebox volume. With the high volatile coal this is a most important feature. It is well known that the loss of available heat by incomplete combustion is very large and without sufficient firebox volume this will occur.

The effect of improper maintenance on the coal pile, in addition to the imperfect operation of the locomotive, should also receive consideration. Leaks in the flues, packing and front-end all contribute to the wasting of fuel. Worn pins in the valve gear, and improperly maintained bearings on both the cars and locomotives are also a drain on the fuel. These are but few of the many possible problems for a committee on fuel economy to consider.

9.30 A. M. to 1.30 P. M.

Individual Paper on:

Variable Exhausts by J. Snowden Bell.

Discussion of reports on:

Joint meetings with M. C. B. Association.

Revision of air-brake and train signal instructions.

Train resistance and tonnage rating.

Locomotive counterbalancing.

Maintenance and operation of electrical equipment.

Forging specifications.

Boiler washing.

Dimensions of flange and screw couplings for injectors.

Subjects.

Resolutions, correspondence, etc.

Unfinished business.

Election of officers, closing exercises.

Adjournment.

ENTERTAINMENT

10.30 A. M.—*Orchestral Band Concert.* Entrance Hall, Million-Dollar Pier.

3.30 P. M.—*Orchestral Band Concert.* Entrance Hall, Million-Dollar Pier.

9.00 P. M.—*Carnival Dance.* Special Feature, "Charlie Chaplin Fox Trot," Miss E. M. Kegel and Mr. Frank Carlin. Ball Room, Million-Dollar Pier. Don Richardson Orchestra.

ASSOCIATION OF RAILWAY ELECTRICAL ENGINEERS

The eighth semi-annual meeting of the Association of Railway Electrical Engineers will be held as usual at the Hotel Dennis, Atlantic City, on June 14. The meeting will be called to order at 9 a. m. and the various committees will present reports of progress.

ROLLER CHAIRS FOR DANCES

The announcement of the Transportation Committee that roller chairs would be provided free from 8.30 p. m. to 10 p. m., to both of the informal dances on the Pier refers only to the functions held last evening and to be held next Tuesday evening. Roller chairs will not be furnished free to the other informal dances.!

WHERE THE VAUDEVILLE SHOW WILL BE HELD

The vaudeville show on Saturday evening will be held in the Auditorium over Exhibition Hall on the Pier. Probably a good many people do not know just how to reach the auditorium. The way to get to it is to pass through the court and through Exhibtion Hall and up the incline. At the top of the incline members of the entertainment committee will be stationed to direct the crowd where to go.

TRANSPORTATION TO THE GOLF CLUB

The Entertainment Committee has arranged with the Bergdoll Taxicab Co. for special rates to and from the Sea View Golf Club a charge of $5.00 being made for six passengers each way. Machines will be parked at the Marlborough-Blenheim, Traymore and Chalfonte hotels for the convenience of those attending or participating in the golf tournament on Sunday, or machines may be ordered at any time by phoning the taxicab company, phone 600.

INFORMAL DANCE

The informal dance which was held on the Million Dollar Pier last night proved to be a most delightful affair and was very largely attended. The program was rendered by the Don Richardson Orchestra. Miss Betty Lee, who was announced to sing folk songs, has found it is impossble to render these to advantage because of the poor acoustic prop- of J. F. A. Comstedt, chairman; M. G. Baker, W. K. Krepps, G. E. Ryder, D. E. Sawyer, T. K. Dunbar, R. J. Faure, R. H. Gwaltney, A. B. Wegener and W. H. Bentley.

PURDUE UNIVERSITY DINNER

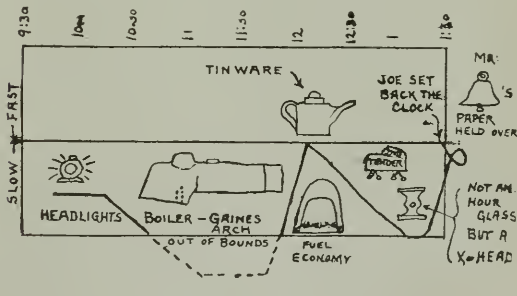
The annual convention Purdue Dinner will be held at 6.30 Saturday evening at the Shelburne. All Purdue men are requested to attend. Those who have not already signified their intention of attending should leave their names with Prof. L. E. Endsley, E. E. Silk or at the *Railway Age Gazette* booth, in order that proper arrangements may be made.

CORNELL DINNER

The annual dinner of the Cornell men attending the conventions will be held at Barney's to-night at 7.30 o'clock. All Cornell men who have not already signified their intention of being present are requested to register to-day at the booth of the Chicago-Cleveland Car Roofing Company, Space No. 506. The guest of honor at the dinner will be Professor Dexter S. Kimball, professor of mechanical engineering of Sibley College at Cornell.

YESTERDAY'S SESSION

We are indebted to Joe Taylor for the accompanying diagram, showing graphically the progress which was made at yesterday's meeting. It really needs no explanation.



COMPARATIVE REGISTRATION FIGURES

Below are given the registration figures for the first day of the conventions for the past four years. The figures for this year should be compared with those for 1913, as the M. M and M. C. B. conventions alternate from year to year in coming first.

	1912.	1913.	1914.	1915.
Members M. M. and M. C. B.	263	374	466	367
Special Guests	169	141	182	135
R. R. Ladies	211	222	200	163
Supply Ladies	164	221	350	163
Supply Men	1149	1264	1169	892
Totals	1956	2222	2367	1720

While there is a substantial decline in the figure for total registration, an analysis of the figures is encouraging rather than discouraging. From the standpoint of all concerned the attendance for railway men is the most important factor and it will be noted that the number of railway men registered the first day was only seven less than in 1913 and was much larger than in 1912. The heavy decline in the total registration is due to the reduction in the numbers of ladies and of representatives of supply companies here, the number of ladies who registered the first day being 119 less than in 1913 and the number of representatives of supply concerns 372 less. The relatively large registration of railway men shows that their interest in the conventions and the exhibit remains as keen as ever.

President Gaines called the meeting to order at 9.50 a. m. Thursday. The secretary read the reports of the auditing committee and the certified public accountants, which on motion were received and approved.

At the suggestion of D. F. Crawford, chairman of the Committee on Locomotive Headlights, who was unable to be present, the privileges of the floor were extended to J. L. Minick, who presented the report.

LOCOMOTIVE HEADLIGHTS

In connection with the incandescent lamp headlight, the committee feels that the following standards should be adopted in order to direct the development of this type of headlight.

Voltage.—The voltage of the system should be fixed at 6 volts, for the following reasons:

1. This voltage will permit the use of standard 6-volt automobile lamps in the cab, markers, etc. Lamps in the 25-34 volt class, of the proper candle-power for this service, are not now made, and they will be difficult to develop.

2. This voltage will permit the use of incandescent lamps having the strongest possible filament of the most rugged construction. A complete line of 6 and 7 volt lamps has been manufactured for some years past for automobile service. No new sizes need be developed for locomotive service, except that the size and form of filament winding in the headlight lamp will have to be changed slightly to give the proper distribution of light.

3. This voltage will permit the use of a small storage battery on the locomotive, if so desired. Sufficient space is not now available on steam locomotives for 32-volt storage batteries.

4. This voltage can be obtained from a small turbo-generator as readily as any other voltage.

Candle-power.—The Columbus tests show that an incandescent lamp of approximately 50 mean horizontal candle-power will give sufficient light to meet the recommended maximum requirements of 3000 apparent beam candle-power. Concentrated filament tungsten lamps are now regularly manufactured in candle-powers

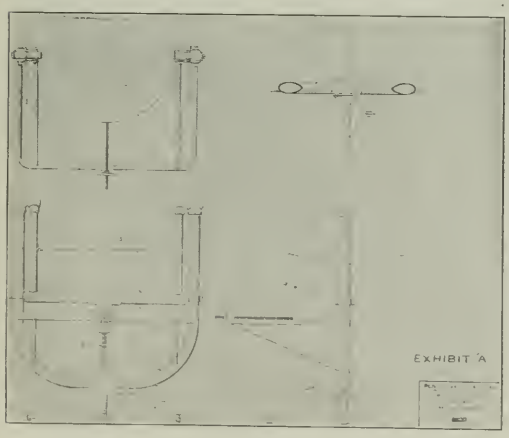


Fig. 1.—Photometer Table for Testing Locomotive Headlights

of 50, 100 and 160 at 6 and 7 volts, for headlight service. The two larger sizes are not deemed necessary by the committee. The committee recommends for use in the headlight a 50 candle-power, 7 volt, G-20 clear bulb, Edison screw base (style 100), loop-back tungsten filament, multiple burning, headlight lamp. (In case gas-filled lamps are used, the filament winding should be of such form and shape as to correspond closely with the form and shape of filament used in the lamp above described, and "gas-filled" must be specified when ordering.)

For use in the cab, markers, etc., the committee recommends a six candle-power, 7 volt, G-10 clear bulb, double-contact bayonet candelabra base (style 1000), tungsten filament, multiple burning lamp.

Standard bayonet double-contact sockets are recommended for bayonet base lamps. Standard Edison screw sockets, equipped with Benjamin lamp grip, or equivalent, are recommended for use with the headlight lamp.

When metal reflectors are used, the minimum nominal diameter

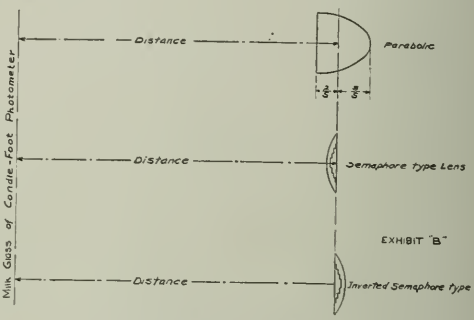

Fig. 2.—Method of Measuring Distance Between Milk Glass and Reflectors and Lenses

should not be less than 16 in. When parabolic glass reflectors or semaphore type lenses are used, the minimum nominal diameter should not be less than 12 in.

Method of Photometering.—A photometer table, constructed entirely of metal, has been developed, being so designed that it may be readily handled or moved about, and may be set up in

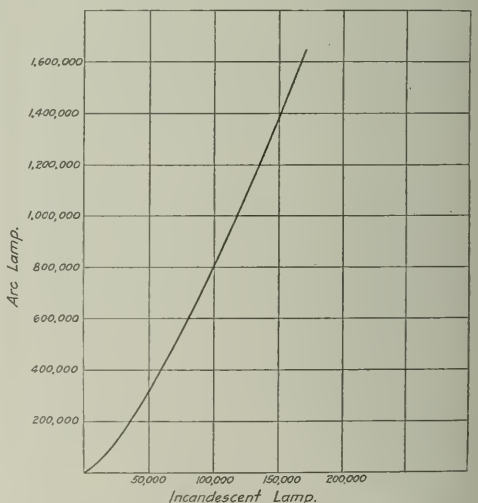

Fig. 3.—Ratio of Values of Arc and Incandescent Lamp Headlights

any location where sufficient floor space is available. This table is shown in Fig. 1. It consists of a platform (*A*) on which the headlight is mounted. This platform (*A*) is adjusted vertically by a screw (*B*) until the axis of the headlight corresponds with the point (*C*). The platform (*A*) and its adjusting-screw (*B*) are supported by a cradle (*D*), swinging in a vertical plane above a horizontal axis through the point (*C*), the whole being supported by a U-frame (*E*) of steel tubing. The U-frame is in turn supported by and rotated horizontally on a metal base (*F*),

may be rotated about three degrees in either direction for finding the optical axis of the headlight. The scale (*G*) indicated the vertical angle and the scale (*H*) the horizontal angle through which the headlight is rotated. Both of these scales should be provided with verniers for accurate reading.

Space not less than 9 ft. wide by 9 ft. high and 30 or more ft. in length, depending upon the type of headlight to be photometered, must be provided and enclosed on all sides with light, tight material. Heavy canvas or oilcloth may be used for this purpose, and all interior surfaces must be painted dull black to avoid reflection. A candle-foot photometer is mounted at one end and the headlight table at the other end of the room. Between these a series of at least three canvas screens, painted dull black on both sides, should be attached to the ceiling, floors and walls. A hole approximately 1 ft. square should be cut in each screen on the axis of the headlight. The candle-foot photometer is mounted outside the photometer room, the milk-glass tube pro-

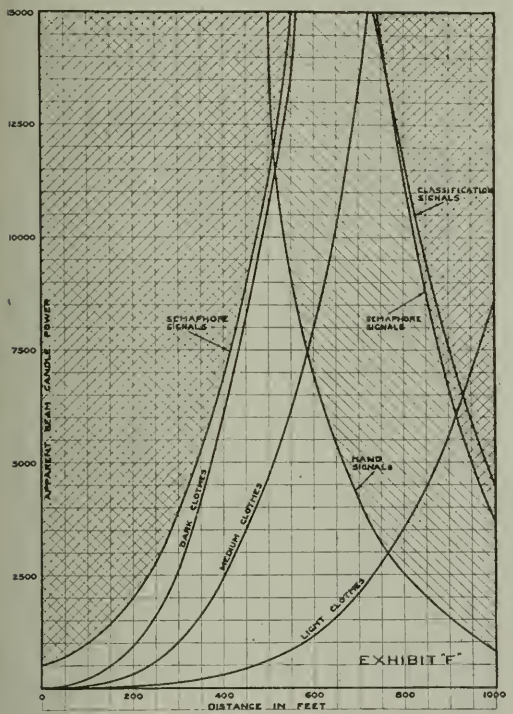

Fig. 4.—Dangerous Conditions for Various Apparent Beam Candle Powers.—The cross-sectioned space represents the danger zone

jecting through the end wall on the horizontal axis of the headlight.

The headlight should be set up at the following distances from the milk glass of the candle-foot photometer, depending upon the apparent beam candle-power of the headlight, as follows:

Apparent beam candle-power of headlight.	Distance of headlight from milk glass of candle-foot photometer.
1000 or less	15 ft.
1000 to 10,000	25 ft.
Above 10,000	50 ft.

The method of measuring this distance for parabolic reflectors, semaphore type of lenses, or inverted semaphore type of lenses is shown in Fig. 2. Readings are taken by rotating the headlight, both vertically and horizontally, to throw on the milk glass of the candle-foot photometer those rays of light corresponding to the reading stations recommended in last year's report.

As a matter of general information the committee has added Figs. 3 and 4. Fig. 3 is based upon the Columbus tests, and

light of 800,000 apparent beam candle-power may be seen just as readily with an incandescent-lamp headlight of only 100,000 apparent beam candle-power.

Fig. 4 is also based on the Columbus tests. All of the curves indicating dangerous conditions, as referred to in last year's report, have been reduced to a common scale and plotted on one sheet. The cross-sectioned space is the "danger" zone and the clear space is the "clear" zone. In selecting a safe headlight it is evident that its apparent beam candle-power value must lie within the clear space.

The Sixty-third Congress passed an amendment to the Locomotive Boiler Inspection Bill regarding the inspection of locomotives and tenders, including "all parts and appurtenances thereof." It is evident from the foregoing that this subject will be active for several years to come. For this reason the committee feels that it should be continued so as to collect for ready reference any new information that may develop or conduct any tests that may be desired.

The report is signed by:—D. F. Crawford (Penna. Lines), Chairman; M. H. Flynn (M. C.); C. H. Rae (L. & N.); F. A. Torrey (C., B. & Q.); H. T. Bentley (C. & N. W.); M. K. Barnum (B. & O.), and Henry Bartlett (B. & M.).

DISCUSSION

President Gaines: Have you tried the application of the incandescent lamp to the old arc outfits in any of your tests?

J. L. Minick: The equipment used consisted entirely of new reflectors. They were made up by several manufacturing concerns and we did not try the adaptation of incandescent lamps to reflectors which had formerly been used with arcs. We did use incandescent lamps with certain reflectors formerly used with oil. We got very reasonable candle powers. The Pennsylvania 16-in. reflector has quite large openings in the side for illuminating the locomotive numerals. The holes for the oil lamp are also very large. It was found that by closing first only the numeral holes the candle power of the headlight could be increased approximately 50 per cent, and by closing up the two holes used for the chimney it could be increased approximately 100 per cent by using an incandescent lamp.

J. L. Minick: There are about 2,000,000 six-volt starting and lighting generators used in automobile service. There are a great many turbo-generators of somewhat larger size used. They will vary anywhere from 500 to 600 watts up to 1,000 watts and apparently from the steam end these are working satisfactorily. It remains, therefore, to get a smaller turbine to drive the six-volt generator intended for use with the incandescent lamp, which does not require as much power as the arc light headlight. It is purely a matter of reducing the size of the turbine slightly. The difficulty in this lies in getting the steam nozzle small enough to deliver just the right amount of steam.

W. E. Dunham (C. & N. W.): In noting the number of states that now require the fifteen hundred candle power lamp, it would seem that there are a great many equipments now in use which it would not be desirable to throw away. In changing to the six-volt equipment and abandoning our thirty-volt equipment, it will be difficult to win the support of those who handle the pocketbooks of the railroads. We have been experimenting on the Northwestern with incandescent lamps of the 25 to 34-volt class and we are able to get good lamps and good results without changing the generators or any other part of our present equipment on the locomotive.

M. K. Barnum (B. & O.): It is quite probable that a plan could be worked out by which the present equipment can still be used in connection with lower voltage if they desire to do that, and if they do not desire to do that, there is nothing to prevent their continuing the present equipments as they are.

J. L. Minick: The statement of the committee is not to the effect that there are no thirty-two volt headlight lamps made. The statement is made that lamps of the proper candle power for use in the cab and as markers of the 25-34 volt class are not made. There is a series of incandescent lamps made for headlight service which correspond exactly to the size given for the six-volt lamps, that is 50, 100 and 160 candle power, and they can be substituted for the present arc light headlight equipment, but when it comes to cab lights and marker lights, you will either have to have special lamps made up or use lamps which are too large and consume too much power.

E. W. Pratt (C. & N. W.): We are buying for cab lights and markers 32-volt lamps, which cost 11 cents each. These are about 25-watt lamps.

J. L. Minick: That is equivalent to about 20 candle power, and not more than five or eight candle power is necessary. Five or eight candle power cab lights in the proper reflector will give as good results.

the incandescent light headlight in place of the arc light headlight. I would like to ask if these standard headlights can be rewound to six volts.

J. L. Minick: It would probably cost no more to buy the six volt equipment, than it would to go to the expense of rewinding the other.

J. A. Pilcher (N. & W.): Could not the cab lights and auxiliaries be run in series using low voltage lamps and in this way keep down the power?

J. L. Minick: That is possible.

J. H. Davis (B. & O.): If the committee's recommendations are accepted, how are we to comply with the law where it states that 1500 candle power, unreflected, shall be furnished? The maximum candle power of the lamps specified for six volts is 160 candle power.

C. E. Fuller (U. P.): It is presumed that there will be a federal law governing headlights, and in that case the best legal advice we have is that it will automatically wipe out all state laws. We now have such law, but there have been no requirements framed under it. We presume that when these requirements are framed they will be Federal requirements, so that all the railroads in the United States will be operating under the same requirements.

W. H. V. Rosing (St. L. & S. F.): We use the same kind and style of lamps in cabs as we do in train lighting, and it seems to me that the locomotive and the passenger train ought to be considered together. By using the same lamps in both engine and train, even though the higher voltage might be more expensive on the locomotive, that might be offset by not having to carry a separate stock of lamps at points where repairs would be required.

The committee was continued for another year.

DESIGN, CONSTRUCTION AND INSPECTION OF LOCOMOTIVE BOILERS

During the past year the committee has made a complete investigation of the methods in vogue for figuring stresses in locomotive boilers. The replies from 44 roads indicate that in some essential details, such as figuring efficiency of seams, there was no variation in methods, while in other details there was at times

C. E. Fuller
Chairman, Committee on Design, Construction and Inspection of Locomotive Boilers

a wide variance of assumptions. The following rules for determining stresses in locomotive boilers are presented as Recommended Practice:

RULES FOR DETERMINING STRESSES IN LOCOMOTIVE BOILERS.

Longitudinal Barrel Seams and Patches.

(a) In figuring net section of plate, use the actual diameter of rivet hole.

(b) In figuring rivet shear, use the actual diameter of the rivet after driven.

(c) In figuring stress in plate and shear in rivet, in case the barrel is not cylindrical where it joins the firebox wrapper sheet, use the maximum diameter. Surfaces subject to bending action

(d) When boiler shells are cut to apply steam domes or manholes, the amount of metal in the flange and liner shall be equal in strength to the metal removed. When a separate flange is used at the base of the dome, the entire net area of it shall be assumed as reinforcement. Where the dome sheet is flanged direct to the shell of the boilers, a vertical distance of 2 in. from the base of the flange shall be assumed as reinforcement, using the net area after the rivet holes are deducted and using 28,500 lb. tensile strength per square inch as the ultimate strength, if the dome sheet is welded vertically.

Longitudinal Gusset Braces and Flat Surfaces.

(a) In figuring stress in diagonal braces, allowance for the angularity of the brace shall be made.

(b) The sectional area of the brace and the strength of the attachment of the brace to the shell shall both be investigated and the lowest net strength shall be used.

(c) In determining the strength of the gusset braces for supporting the back head and tube sheets, use 100 per cent of the rivet-bearing area, 80 per cent of the rivet shear area and 90 per cent of the gusset plate area, measured at right angles to the longest edge of the gusset sheet, and of the three, select the minimum value.

(d) The calculation of stress in gusset braces shall cover both the section of the plate and the strength of fasteners, and the lowest net strength shall be used.

(e) In figuring flat stayed surfaces, such as back heads, the boundary of the unsupported flat surface shall be located at a distance equal to the outside radius of the flange measured from inside of the shell.

(f) No supporting value shall be assigned to the stiffness of flat plates on flat surfaces, as it is too small to be of material value.

(g) Reinforcing plates, such as back head liners, shall not be figured as having any staying or supporting value, but shall merely be considered as mechanical reinforcements for various attachments, such as longitudinal stays, staybolts, etc.

(h) The distance beyond the outer row of flues on tube sheets, assumed to be self-supporting, shall be 2 in.

(i) In calculating the area to be stayed on the front tube sheet, the area of the dry pipe hole shall be deducted.

(k) Tee irons or other members, when used subject to bending, shall be calculated without addition for the strength of the plate, and the stress in such beam and its abutments must not exceed 12,500 lb. per sq. in. The spacing of the rivets over the supported surface shall be in conformity with that specified for staybolts. No allowance for value of such beams shall be made in calculating the total area of longitudinal braces that may be attached thereto.

(l) Where there are a number of diagonal stays supporting a flat surface, such as the back head or front tube sheet, the proportion of area allotted to each brace shall be as follows: Divide the entire net area to be stayed by the entire net area of braces. If it is felt that any individual brace is so segregated as to receive more than its fair proportion of the load, it shall be investigated separately as to the area which it supports.

(m) Patches when applied to the barrel of a boiler shall be designed with longitudinal and circumferential seams at least equal in strength to the main longitudinal and circumferential barrel seams. Patches may be applied to flat stayed surfaces with properly designed single-riveted seams without impairing the strength of the sheet.

Staybolts—Radial Stays and Crown Bar Bolts.

(a) In figuring the net area of staybolts to obtain the stress, the area of the tell-tale hole shall be deducted.

(b) When figuring the area at the root of the thread, the area must depend upon the type of thread used, namely, United States V or Whitworth threads, as the case may be.

(c) In determining the area for figuring stress on staybolts, the area of one staybolt shall be deducted from the rectangular area included between any four staybolts.

(d) In boilers with crown bars supported on firebox side sheets and sling stays, the sling stays shall be considered as carrying the entire load.

The report is signed by: C. E. Fuller (U. P.), Chairman; M. K Barnum (B. & O.); J. Snowden Bell; C. B. Young (C., B. & Q.); D. R. MacBain (N. Y. C.); A. W. Gibbs (Penn.), and R. E. Smith (A. C. L.).

DISCUSSION

J. Snowden Bell: In justice to the committee and particularly to the chairman there should be a brief explanation made to the Convention of the brevity of the report and its failure to deal with the question of the design of locomotive boilers.

chanical Engineers appointed to formulate a code of specifications for the construction of steam boilers and other pressure vessels, which naturally included air-brake reservoirs, gas tanks, etc. That committee published and sent out a preliminary report. We also learned that they proposed to send copies of that report to the legislatures of seven different states, even before it had been approved by the society, with a view to guiding legislation. There were a great many very objectionable provisions in it regarding the factor of safety of pressure vessels other than steam boilers and stationary boilers, a large number of which are used by railroads. We deemed it to be most important to endeavor to obtain a modification of such of those provisions as were detrimental to the railroads and we met with this committee. There were four different meetings devoted entirely to a consideration of the proposed code.

There was also correspondence with the committee on the relation of railway operation to legislation, with which our committee was closely in touch. We succeeded in obtaining modification of the report, the first draft of which has been revised three times; and this morning I saw the fourth revision. We have not obtained all we wanted, but great improvement has been made upon the original drafts of the report.

J. A. Pilcher (N. & W.): It seems to me that item (i) in the report is wrong, because the pressure coming on the pipe itself is finally delivered on the front sheet around its circumference.

M. H. Haig (A. T. & S. F.): A great many of the boiler parts have already been figured, but there are still more to be figured. It is necessary from time to time to train men for calculating of the parts in reinforcing and maintaining boilers, and while the men responsible for the correct reports check them very carefully, their work must be supplemented by those trained to do the original figuring. Therefore I feel that the simpler these reports and explanations are, the greater their usefulness. Item (a) under Longitudinal Gusset Braces and Flat Surfaces I presume includes a bar brace or diagonal brace as well as the gusset. I think it would be well if this could be explained still further, to show just how that angularity is taken care of for the benefit of those who do the work. Referring to item (e) under the same heading, I would like to suggest that the unsupported flat surface be located a distance equal to the outside radius of the flange plus one inch. I think the additional area is well taken care of by the curve surface.

G. L. Fowler: A year ago when the report of this committee was presented it was announced that there were to be some investigations made during the year that might be of interest to the convention at this time. The results are tentative and I do not want them to be considered in the slightest as demonstrations. They are merely indications of what is happening in the locomotive fire box, and as the construction of the box is to a great extent dependent upon these conditions they are presented to you.

The object of the investigation was to determine the relative amount of movement between the two sheets of the side water leg of a locomotive fire box by which the amount of deflection of the staybolts might be determined. In addition to that we made an approximate determination of the temperatures of the two sides of the inside sheet. Of course the work at the start was entirely without any precedent. I had absolutely nothing to go by and it was a mere matter of guess as to where we were going to land. The credit for this work is due to D. R. MacBain, Superintendent Motive Power and Rolling Stock, New York Central. He supplied the two boilers for the purpose, with new fireboxes especially constructed. The fire-boxes had the grates about eight feet long and five feet wide. One firebox had a complete installation of one-inch rigid staybolts put in in the usual manner; the other had a complete installation of Tate flexible staybolts throughout. The first bolts tested were the top row at the front, just below the crown sheet. My apparatus was so designed that there was no lost motion in it and it was of such a character that I could multiply the motion between the outside and inside sheets indefinitely, using a radiating mirror and a reflected light. I started in one evening (the work was all done at night) and told the fireman to get up steam and to pay no attention to me. I wanted round house practice. I waited about twenty minutes and went to my apparatus to get a reading. I found that whereas my divided beam of light that carried the motion on the outside was there, the other one had absolutely disappeared. It was finally located off about five or six feet, so far away that the reading was useless. The next night I moved my instrument up closer to get the light beam under control, and then surprises began. That I may be understood in speaking of the expanding of the sheet downward, backward and forward movement, means that the inside sheet moves down or back or forward relatively to and expansion within a minute of the time the lighted waste was thrown in to light the fire. A curious thing about the performance was that they almost invariably went in the unexpected direction. The front corner of the sheet, instead of going up and forward, as we would expect with the heat applied, went down and back. It did not go much more than .001 in. and then it started up. It was a constant movement throughout the whole proceeding. At the end of about twenty minutes it had reached its maximum forward movement. Then as the steam began to rise it went up, and while we had steam pressure on it kept moving, coming down back practically to its original position when the boiler was blown down. This was the case in all of the investigations.

In our tests we carried 200 lb. pressure, which would be raised in from 55 minutes to 1½ hours, then the pressure was held, with both pipes blowing, for about 15 min., after which the fire was dumped and the pressure blown down through the blowers in the stack. When that was not enough I opened the controller. The pressure was reduced about one point per minute, so that it took about three hours to drop the steam pressure; and in no instance did the boiler come back to its original position until the steam pressure was all drawn. In some cases it did not come quite back. In making the comparison between a flexibly and rigidly stay boiler the amount of movement of the upper corner at the front end of the flexibly stay boiler in comparison with the rigidly stay boiler was as 31 to 13. That is, the maximum deflection for the stay bolt of a flexibly stayed boiler was .031 in., for a rigidly stayed boiler it was .013 in. Going to the back end of the same row of bolts the movement was toward the back, but practically the same. We then came to the middle bolt in the center of the boiler where we would expect to find the neutral zone of no motion; but it is only an instantaneous neutral zone. It is varying from front to back and up and down all the time, but the limitations of the movement with the flexibly and rigidly stayed boiler was very marked. The total horizontal motion of the rigid bolt was about .026 in.; the total movement of the flexible bolt was about .042 in., about twice as much. That the rigidly stayed boiler only moves about half as far as the flexibly stayed boiler represents a fair average of the results obtained. I found on the middle row of bolts and as I came farther down, a phenomenon that at first was difficult to explain. The first movement of the inner sheet was down and the downward movement increased as we approached the mud ring. My apparatus was so designed as to measure the apparent movement of the two sheets, so if there were a buckling of the sheets there might apparently be a very decided downward movement when there was none at all; but of course there was a bending of the sheet or of the stay. I have redesigned the apparatus to eliminate this weakness, and am pleased to say that the facilities will be afforded this fall to go into the same two boilers again with an apparatus that will measure not only the actual relative movement of the two, but any buckling that may occur in the inside sheet.

As far as we have gone we have determined that the staybolt is in constant motion during the entire time the boiler is hot; that it is always bent when it is under stress, and that the maximum deflection of the bolt occurs before any pressure appears on the gage. In addition I put gages in the throat sheet, in the roof sheet and in the back head, to measure the in and out movement between these sheets, and the back tube sheet, the crown sheet and the back sheet in the fire box. The indications from the throat sheet and the back head were not very consistent, but the consistency of the movement of the crown sheet to the roof sheet was remarkable. The very instant the fire is kindled and begins to throw out any heat the crown sheet begins to go up relatively to the roof sheet. It goes up quite rapidly until the first indication of pressure appears, when it begins to drop, and in almost every instance it dropped well below its normal position when we had reached full steam pressure. In addition an attempt was made to get at the relative movement of the back tube sheet to the shell. There was a washout plug located about three or four inches ahead of the back tube sheet. The apparatus was connected to a tube through this hole. Whether the motion of the tube was entirely transferred to the tube sheet, I cannot say, but indications are that it was. The moment that we built our fire the tube began to move back. We took the valves out of the engine, so that the throttle could be opened and the fire driven for about half an hour with the throttle wide open. When getting up steam, that tube moved back with very great steadiness, but the instant the throttle was opened the movement became very rapid and

and came back into its original position again at the time of reaching the steam pressure. When I was measuring in that front staybolt I said that the first movement of the sheet was to the rear. At the end of ten minutes after the fire had been built the sheet had moved back .002 in. When the apparatus was attached to the tube it also moved back .002 of an inch, showing that probably the first backward movement of the sheet was due to a direct thrust from the tubes.

We also made an attempt to get at the temperatures of the two sides of the sheet. That was done with ordinary thermocouples. I went up over the top of the arch for the first investigation. There conditions were found to be what I would consider normal: the temperature of the water side was a little above the water temperature. On the other side it was about 750 deg. F. The apparatus was next moved back towards the end of the fire-box and during the early parts of getting up steam conditions were normal. When pressure was up, however, I found that the fire side of the sheet was about 50 deg. F. colder than the water side. My first conclusion was that the apparatus was out of order until attention was called to the smoke tube holes at the side. The apparatus was located about six inches ahead of the back smoke tube hole. This was plugged, and in less than two minutes the temperature was up where it ought to be. The cold air coming through the tube, flowing along on the side of the sheet, had cooled the sheet locally until it was below the water temperature. The apparatus was then located back of the fire door. It was possible instantly to tell when the fire door was opened, from the cooling of the sheet. The cool air coming in from the smoke tubes and chilling the sheets explains the cracking which is apt to occur around these holes, and the effect of the opening of the fire door is a good argument for the use of mechanical stokers.

E. W. Pratt: I would like to ask Mr. Fowler whether the boilers tested had wide fire-boxes with straight side sheets, or narrow fire-boxes with O. G. curves, and whether sloping heads or straight heads?

Geo. L. Fowler: They were wide fire-box boilers with sloping sides and slightly sloping crown sheets.

(The report of the committee was accepted and the recommendations will be submitted to letter ballot.)

STANDARDIZATION OF TINWARE

The committee has carefully reviewed the report submitted one year ago and has made some corrections, though no important changes in the details of any of the articles submitted at that time have been made. It has corresponded with a number of the leading railroads, secured blue-prints of the tinware they are using in their various departments, and has incorporated in its report items that it feels would be of general interest. The committee, in preparing this report, has received some very valuable suggestions from the Storekeepers' Committee, the manufacturers of tin plate, and some of the manufacturers of tinware.

The committee can not hope to present dimensions that have not adopted a standard, and while the committee has studied principally the method of construction and the material to be used, it has also selected the dimensions that in its judgment will be most suitable for the service for which each article will be used.

In the prints submitted the committee has endeavored to cover every detail, making parts interchangeable where this is practical. It will be noted that the joints are double-seamed and the detail of the seam is carefully outlined. Fig. 1 gives the description and name of the joints used in the construction of this tinware. The material is specified, standard kettle ears are used, handles are wired for stiffness and the diameter of the wire is in proportion to the capacity of the article, the can tops are interchangeable in groups, and the spouts are carefully braced to withstand rough service. The following is a brief description of each part recommended:

M. D. Franey
Chairman, Committee on Standardization of Tinware

Fig. 2 is a one-pound emery can, with a small opening which directs the emery onto the spot where it is required. There is a remarkable saving in the amount of emery used with a can of this type.

Fig. 3 is a typical funnel which in sizes of one pint, one quart and one gallon should take care of all requirements in the mechanical department.

Fig. 4 is a typical measure which may be made in one pint,

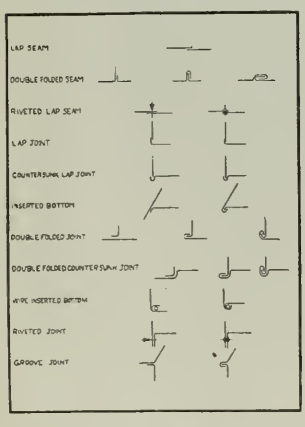

Fig. 1—Typical Seams and Joints

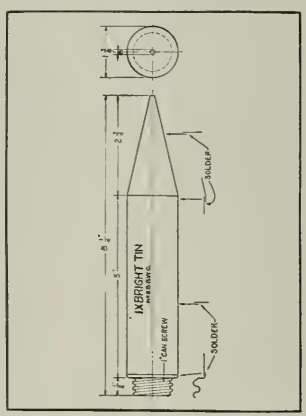

Fig. 2—One Pound Emery Can

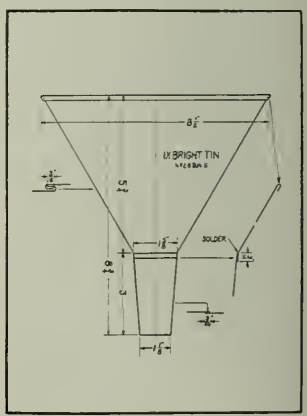

Fig. 3—One Gallon Funnel

diameter 5 5-16 in.; and for the one gallon size, a depth of 6 15-32 in. and a diameter of 6¾ in. The dimensions of the pint measure are shown in Fig. 4.

Fig. 5 is a plain and economical form of coal hod.

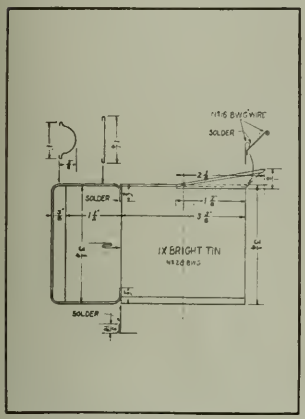

Fig. 4—One Pint Measure

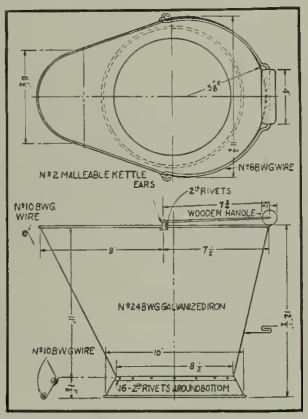

Fig. 5—Coal Hod

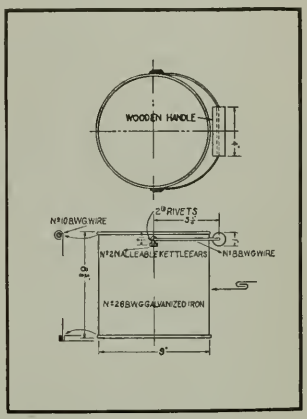

Fig. 6—Two Gallon Pail

Fig. 6 is a two-gallon pail. A four-gallon pail may be made similar to this with the depth of 10¼ in. and a diameter of 10¾ in.

Fig. 7 is a two-gallon journal oil can with a removable brass tip so that the size of the hole may be varied as required. The use of this oil can is not recommended in engine houses.

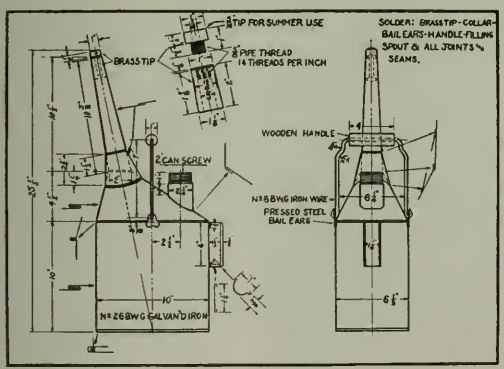

Fig. 7—Two Gallon Journal Oil Can

(Note.—The report also included illustrations of the articles submitted last year by the committee with a few minor changes and other lesser important articles—Editor.)

The report is signed by:—M. D. Franey (N. Y. C.), chairman; J. C. Mengel (Penn.); W. C. Hayes (Erie); G. S. Goodwin (C. R. I. & P.), and W. O. Moody (I. C.).

SUPERHEATER LOCOMOTIVES

[In view of lack of new material concerning superheater locomotives the committee did not present any written report. It submitted however the results of further tests made by the Pennsylvania Railroad on its Class E 6s engines as published in the P. R. R. pamphlet No. 27 with a recommendation that it be incorporated in the proceedings. This recommendation was adopted.—Editor]

That design of a locomotive boiler and firebox, together with the appurtenances, which will permit of the largest possible amount of evaporation from a given amount of combustible burned, has the maximum efficiency, and is, therefore, the best boiler from the standpoint of fuel economy. Greater attention is being given to the design of boilers, fireboxes, grates, ash pans and front ends than ever before, as all of these parts are interdependent and should bear a definite relation for the best results, and are influenced by the nature of the fuel available.

A study of certain ratios in locomotives constructed within the past 2 years, and in others built 10 or 12 years ago, shows the trend of locomotive design in those respects which have the greatest influence on fuel consumption and steaming capacity. The data shown below are the averages for a large number of bituminous and anthracite burning locomotives of the 4-6-2, 4-6-0, 2-8-0 and 0-6-0 types.

1.—Bituminous.

Type of Locomotive.	Ratio Total Evaporative Heating Surface to Grate Area. 1913	1903	Ratio Firebox Heating Surface to Total Evaporative Heating Surface. 1913	1903
4–6–2	65.9	70.9	6.4	5.4
4–6–0	52.3	62.8	7.8	6.5
2–8–0	53.3	60.1	6.7	5.7
0–6–0	53.0	71.8	8.3	6.0
Average	56.1	66.4	7.3	5.9
Per cent. change	Dec. 15.5 per cent.		Inc. 23.7 per cent.	

2.—Anthracite.

4–6–0	30.0	34.8	8.0	6.5
2–8–0	31.1	37.9	8.3	6.1
Average	30.5	36.3	8.1	6.3
Per cent. change	Dec. 16 per cent.		Inc. 28.5 per cent.	

The changes in these ratios are, without doubt, steps in the right direction.

The advantage of large heating surfaces and large grate areas in increasing the evaporation from a unit amount of fuel consumption over that from a similar locomotive with smaller heating surfaces and grate area, is clearly shown by an evaporation test recently conducted at the Pennsylvania Railroad testing plant at Altoona, between a Consolidation type and a Mikado type locomotive. The principal dimensions of the two locomotives and a summary of the data follow:

Principal Dimensions.

Item.	Consolidation.	Mikado.	Per Cent. Increase Favor of Mikado.
Cylinders	24 by 28 in.	27 by 30 in.	.....
Drivers	62 in.	62 in.	.....
Boiler pressure	205 lb.	205 lb.	.....
Smallest diameter of boiler	76¾ in.	76⅝ in.	.....
Length of flues and tubes	15 ft. 0 in.	19 ft. 0 in.	.....
Heating surface, flues and tubes	2 841.2 sq. ft.	3 746.8 sq. ft.	.....

Heating surface, total.....	4 201.5 sq. ft.	5 766.3 sq. ft.	37.2
Grate Area	55.1 sq. ft.	70.0 sq. ft.	27.1
Weight on drivers.....	219 900 lb.	235 800 lb.	.....
Total weight of engine.....	249 599 lb.	315 600 lb.	.....
Total tractive power.....	42 661 lb.	57 850 lb.	.....

SUMMARY OF TEST DATA.

Dry Coal Fired Per Hour, Lb.	Water Evaporated Per Hour, Lb. Consolidation.	Mikado.	Per Cent. Increase Favor of Mikado.
2 000	17 000	17 000	0.0
4 000	27 000	30 000	11.1
6 000	32 500	43 000	32.3
8 000	34 500	52 500	52.2

These figures clearly show the advantage of the large heating surface and large grate area, and that the economy increases with a decrease in the rate of combustion.

The above testing-plant figures are verified by the results obtained from a road test on the Chicago & North Western, reported in the *Railway Age Gazette* of January 15, 1915, pages 93-94. The locomotives compared were of the Consolidation and Mikado types, each equipped with superheater and brick arch.

Taking advantage of the opportunity afforded by locomotives with trailing trucks to increase the size of firebox and grate area over those proportions in locomotives without trailing trucks, affords a valuable means for reducing the fuel consumption on a ton-mile basis.

The design of exhaust nozzles to suit the various conditions, and as a factor in fuel economy, is very important. A number of roads have experimented with special types of nozzles, and claim a considerable saving in fuel as a result. The committee feels that the subject presents a fertile field for future investigation, due to changed conditions since previous reports were made.

The practice regarding the amount of air opening in ash pans varies between wide limits, ranging from 3 to 18 per cent of the gate area for bituminous and from 10 to 33 per cent for anthracite locomotives. These figures include all classes of service. The importance of air openings through the ash pan should not be overlooked, and it would be well to establish definitely the minimum opening in the ash pan as a percentage of the grate area. From the best data that the committee has been able to obtain thus far, it appears that this should not be below 12 per cent for locomotives having 70 sq. ft. of grate area, and this percentage should be increased with smaller grate areas.

The almost general application of superheaters and brick arches, not only to new locomotives, but also to many older ones, should not be lost sight of in this connection, as both are important factors in fuel economy and smoke reduction. The practice of welding flues into the back flue sheet is a step in fuel economy, because leaks in the firebox are reduced and the fire does not have to be drawn so frequently for repairs. Care should be taken in the design of all future locomotives to have the boiler capacity at least equal to, and, if possible, somewhat in excess of, the maximum power requirements of the cylinders.

SUPERHEATER LOCOMOTIVES.

When properly maintained and efficiently operated, the superheater is by far the most valuable mechanical aid to fuel economy ever applied to locomotives. By its use savings of 20 to 25 per cent in coal and water are obtainable in actual service. But if maintenance is neglected and careless handling of the device in service is permitted, the superheater may become almost useless, as far as performing its regular function is concerned. The question of superheater operation is extremely vital to the subject of fuel economy, and should be given careful consideration.

The method of handling the throttle on superheater locomotives is of more importance than is generally realized. The best results are secured by the use of a full throttle opening, with reverse lever control as far as service conditions will permit, the exceptions being, when starting a train, when using a very small quantity of steam while running at high speed on low grade or level track, and when drifting.

There are several conditions which will tend to reduce the amount of superheat added to the steam while passing through the superheater, some of which indicate improper inspection and maintenance, while others are within the control of the enginemen. The principal causes of loss of efficiency in the superheater are as follows:

1. When water is carried at too high a level in the boiler, priming is apt to result. When this occurs, water is carried over into the superheater and the water has to be evaporated.

2. If the fire is in poor condition, due to improper or excessive firing, or to holes in the fuel bed, there is bound to be a drop front end, will impair the efficiency of the superheater.

It would appear that to insure obtaining the best results from the superheater, a temperature indicator showing the degree of superheat is desirable. Among those who have had experience with such pyrometers is quite a difference of opinion regarding their value as an aid to the enginemen in improving locomotive operation. Of those replying to the questions relative to experience with pyrometers on superheater locomotives nine replies were unfavorable to the use of the pyrometer, except perhaps for tests or for limited application for educational purposes, and six replies were entirely favorable to the application of the pyrometer to all superheater locomotives.

On the road with which the chairman of this committee is connected, some experimenting has been done with the pyrometer, both in regular road service and on tests. It was observed that the enginemen were very enthusiastic over the results obtained with the device, and, as a rule, the fireman watched the pyrometer gage much more closely than he did the steam gage. In spite of its apparent delicacy of construction and adjustment, the instrument maintained its setting quite accurately. While the committee is not prepared to say that the cost of applying pyrometers generally would be justified by the savings resulting from their use, the device is not without merit, and, as an educational feature, the cost of a few applications would undoubtedly be amply repaid.

INSTRUCTIONS FOR ENGINEMEN AND FIREMEN.

In order to obtain the best operating efficiency and the greatest amount of fuel economy, careful attention to two fundamentals is absolutely essential. The design of locomotives must be such that economy is obtainable, and the enginemen and firemen must receive suitable instruction in order that the desired economies can be realized.

Foregoing portions of the report cover, in a general way, those factors of locomotive design which have the greatest influence on fuel economy. [The committee also presented a standard Manual of Instructions for Enginemen and Firemen, which embodied all the essential points of efficient locomotive operation, and at the same time was brief and free from technical data.—Editor.]

The report is signed by:—Wm. Schlafge (Erie), Chairman; W. H. Flynn (M. C.); D. M. Perine (Penn.); Robert Quayle (C. & N. W.); S. G. Thomson (P. & R.), and D. J. Redding (P. & L. E.).

DISCUSSION

C. D. Young (Penn.): The committee has covered the ground of instructions to the road employes in a very complete and concise way. I move that this part of the report go to the association for letter ballot for adoption as recommended practice. It might be well for the executive committee to consider the advisability of publishing this portion of the report in some small booklet form, so that these copies could be procured by the small roads who do not care to have more elaborate instruction, and distributed to their road foremen and to the men.

(The motion was carried.)

D. J. Redding (P. & L. E.): I hope that the manufacturers of pyrometers may be able to bring out in the near future some pyrometer which will record its performance over the entire trip and which will be of sufficiently rugged design that it will be satisfactory for locomotive service. The committee speaks of starting the lubricator at least fifteen minutes before leaving time. I think that could be made clearer.

Lawford H. Fry (Baldwin Loco. Works): There is one point I think might be brought out in connection with the ratios given of fire-box heating surface to grate area, and total heating surface to grate area, and that is the volume of the fire-box. The value of the volume is indicated where it says "When bituminous coal is applied to the fire the volatile or gaseous matter is expelled, and, if properly mixed with air and heated to a sufficient temperature in the fire-box, the mixture will ignite." Both space and time are necessary for the ignition, and it is necessary to give proper volume as proper grate area. If we analyze the figures we see that the fire-box heating surface per square foot of grate area which is a rough measure of the volume of the box per square foot of grate area, to be 11.3 in 1903, and was reduced to 7.7 in 1913 for the bituminous locomotives, indicating that with the increasing sizes of the locomotives it is more difficult to keep up the fire-box volume. While it has become more difficult, the fact that it is desirable to keep up the volume, I think should not be lost sight of.

Mr. Schlafge: It was not the intention of the committee to draft hard and fast rules, because we know that that would

we have got to meet these conditions as they come up, and I am a great believer in system. To me a system, be it ever so bad, is better than no system at all.

C. F. Baker: I think much more attention ought to be paid to the area of the air openings in the ash pans. I would suggest that either this committee or another committee make further investigation and report at the next convention on the proper area of air openings in locomotive ash pans.

SYMPATHY FOR MR. FOSTER

O. M. Foster, master mechanic of the New York Central at Collinwood, Ohio, recently lost his wife and daughter, and was badly injured himself, in an automobile accident. A motion was carried at yesterday's meeting conveying the sympathy of the M. M. Association to Mr. Foster.

UNIVERSITY OF VERMONT ALUMNI

Members of the University of Vermont Alumni held an informal luncheon at the Marlborough-Blenheim on Thursday. Those present were: H. B. Oatley, Locomotive Superheater Co.; M. C. Robbins, general manager of the Iron Age; H. H. Marsh, Railway Age Gazette, and G. M. Leach, Atlantic City Electric Co.

SOME FACTS ABOUT THE GOLF TOURNAMENT

Certain points regarding the golf tournament do not seem to be generally understood. One of the most important of these is that while there will be two contests, an 18-hole Medal Play handicap and an 18-hole Kickers' handicap, it will be necessary to play only 18 holes in order to take part in both of them. In other words, the player may enter both contests and have his score for 18 holes, if he plays only this many, apply in each of them.

First, second and third prizes will be awarded in each contest, the prizes all being sterling silver loving cups. The playing may be done at any time on Sunday. In case of ties in either contest, additional rounds will be played by those who are tied on either Monday or Tuesday of next week. Each participant in the tournament will have the privilege of selecting his own handicap in the Kickers' contest and the winning score will be the lowest between 71 and 76. All scores under or over these amounts will be disqualified. The Medal Play handicap awards will be based on the regular handicaps and resulting net scores of the players.

The following persons have entered the tournament up to the present time:

H. C. May	La Fayette Country Club
Charles A. Schroyer	Westward Ho
H. H. Kerr	Westmoreland
John B. Wright	Edgewood Country Club
C. C. Castle	Rockland Country Club
B. A. Hegeman	Rockland Country Club
N. E. Chilcoat	Edgewood
T. W. Williams	Baltusrol
F. M. Nellis	Belmont Springs
W. K. Krepps	Wykagyl
R. C. Vilas	Glenview
Merrill G. Baker	Unattached
L. F. Deming	Whitemarsh
W. O. Kellogg	Woodbury Country Club
C. A. Raymond	Unattached
B. Pratt	Calumet
B. V. H. Johnson	Glen Echo
George E. Howard	Glen Echo
George T. Cooke	Englewood
J. S. Seeley	Calumet
J. E. Buker	Calumet
C. F. Palmer	Algonquin
Samuel O. Dunn	Westmoreland
Harold N. Scott	Chicago Golf
J. G. Tawse	Calumet
L. R. Dewey	Calumet
Prescott Dudley	Chicago Golf
Edw. E. Silk	Unattached
C. B. Field	Evanston
G. H. Musgrave	Commonwealth
H. M. Perry	Jackson Park
C. J. Olmstead	Unattached
S. G. Downs	Unattached
C. C. Farmer	Unattached
E. Quincy	Salesbury
H. R. Newlean	Jackson Park
L. E. Jones	Belmont
B. P. Flory	Orange Co.
D. R. MacBain	Shaker Heights

Vote of thanks to Ernest Shackelford, manager of the Pier, for the thorough manner in which he has co-operated with the committee in its work. Never before has there been so little difficulty in keeping the public off the Pier, notwithstanding the innovation of excluding outsiders for all five nights instead of only two, as in former years.

Conventionalities

B. W. Mudge is evidently out for blood in the golf tournament. He has wired Junior for his favorite "putter."

W. H. Forsyth, general manager of the Curtain Supply Company, has been detained, but is expected to arrive in Atlantic City on Saturday.

W. H. Wilkinson, of the Pressed Steel Car Company, was feeling pretty glum until he learned that his side partner, Jack Turner, would sure be here on Sunday.

E. L. Grimm, Chief Draftsman, Northern Pacific

The Hunt-Spiller sextette, under the leadership of Walter B. Leach, certainly look good in their holdovers. Wonderful what a little sponging and pressing will do!

H. Rauch, general foreman of the New York Central at Avis, Pa., is leaving Friday night to attend a flag raising at the Avis shops. The celebrated apprentice band will give a concert.

Left to Right—H. E. Passmore, Grip Nut Company, and Willard Kells, Asst. S. M. P., Atlantic Coast Line

Owing to business reasons and sickness some members of the entertainment committee are unable to be here. In consequence the chairman, George R. Carr, is obliged to do an unexpectedly large part of the work. It is another case

tirely equal to the task.

Hugh Montgomery is not with the Bangor & Aroostook as indicated in yesterday's *Daily*, but as his many friends know is superintendent motive power and rolling stock of the Rutland.

Left to Right—J. C. Little, Mechanical Engineer, C. & N. W., and S. A. Boone, General Chairman, Brotherhood of Locomotive Firemen, C. & N. W.

George Thibaut, recently appointed master mechanic of the Erie at Port Jervis, is attending the convention for the first time. He was formerly general foreman at Susquehanna.

Frank Huffsmith, formerly superintendent motive power of the International and Great Northern, sends greetings to his

Left to Right—H. M. Brown, Shop Supt.; J. R. Gould, S. M. P.; and H. C. Gillespie, Master Mechanic (All of the C. & O.)

friends at Atlantic City and says that Palestine (Texas) now has the best of hotel accommodations.

The *Atlantic City Review* says, "A Massachusetts farmer claims to have a horse with a wooden leg. The Greeks once presented the Trojans with a horse which had four of them." He must have hit the sawdust trail and stopped to graze on the way.

A large railroad in the west finding its files cumbered with letters that were long-winded and full of circumlocution issued an order, commanding brevity. The first fruit of this was a

G. W. Lillie, mechanical superintendent, second district, Chicago, Rock Island & Pacific, located at Topeka, Kan., is accompanied by Mrs. Lillie. He reports a bumper wheat crop in his district and believes that if the weather remains favorable it will surpass the excellent crop of last year.

George S. Goodwin, mechanical engineer, Chicago, Rock Island & Pacific, who so clearly established the value of a

F. P. Pfahler, Inspector I. C. C., and His Son Fred

locomotive at the Western Railway Club last winter, is here for the M. M. convention. Mr. Goodwin was elected a member of the executive committee of the club at its last meeting.

Frank H. Harrison, of W. L. Brubaker & Bros., was added to the enrollment committee to take the place of Dick Sawyer who could not attend the convention. The change was made at the last moment, which accounts for Mr. Harrison's name not appearing as a member of the committee in Wednesday's daily.

G. T. Depue, Shop Superintendent, Erie

F. W. Kiesel, Jr., assistant mechanical engineer of the Pennsylvania, says that the Pacific type locomotive, Class K-4-s, which was exhibited at last year's conventions, is in service on the Pittsburgh division and giving excellent results. No more of these locomotives have as yet been built, however, as it has been found that the engines of the Atlan-

are now in service and more are under construction at the Juniata shops.

George M. Basford has had a practical demonstration of the value of the bonus system, which has dispelled any skepticism he may have had on that point. He finds that everything depends on the size of the bonus, but says it

Grant W. Lillie, Mechanical Supt., Rock Island Lines

was really worth a dollar to have Howard Gray dress for dinner in six minutes. Gray says he can beat even this record if there is sufficient incentive.

J. F. De Voy, assistant superintendent motive power, Chicago, Milwaukee & St. Paul, will be greatly missed this year, especially on account of his severe illness. He underwent a major operation some time ago that evidently was not entirely successful, as he was again operated on last week. A. E. Manchester reports, however, that he is getting along very nicely and he fully expects a reasonably early recovery.

getting up at 5 o'clock every morning to let it out, after which he starts to work in his garden. In spite of all measures which he has taken he still continues to be an early riser at Atlantic City.

C. E. Postlethwaite, of the Pressed Steel Car Company, is a graduate of the Altoona (Pa.) High School, class of 1883. On his way to Atlantic City he stopped off at his old home town to attend a reception and entertainment in honor of Miss Linda E. Hooper, who had decided to retire after having taught in the school for 43 years. Interest in the affair was heightened by the fact that it was also a reunion of classes, every class since 1879 having been represented by former pupils.

The quotation "B. A. F. Y. D. F.," used in an advertisement in *The Daily* by his friend Bert Waycott, had been puzzling Harry Frost for some hours when he finally appealed to our copy service department for a translation. Not having written the advertisement; and not being familiar with the language that his friend might use in trying to induce a railway man to buy a Fulcrum, we pleaded ignorance, but suggested that perhaps it was something that needed an injection of formaldehyde.

W. D. Arter, who was supervisor of apprentices of the New York Central & Hudson River, now the New York Central east of Buffalo, has had his jurisdiction extended over the lines west of Buffalo which formerly made up the Lake Shore & Michigan Southern and the Chicago, Indiana & Southern. This adds about 225 apprentices to those under Mr. Arter's jurisdiction, 125 of these being at Collinwood, 75 at Elkhart and 25 at Gibson. This makes the total number of apprentices on the New York Central 510.

William Schlafge, general mechanical superintendent of the Erie, is justly proud of the size of the contingent from that road at the convention this year. Besides Mr. Schlafge, there are included, E. S. Fitzsimmons, mechanical superintendent at New York; C. James, mechanical superintendent at Cleveland; W. C. Hayes, superintendent of locomotive operation, New York; R. B. Watson, engineer of tests, Meadville, Pa.; W. S.

Left to Right—M. W. Hassett, M. M.; J. G. Parsons, Supt. Shops; C. H. Hogan, Asst. S. M. P.; and A. J. Fries, Asst. S. M. P. (all of the N. Y. C.) and Fred Riegler, Machine Foreman, W. & L. E.

Blackburn, apprentice instructor at Dunmore, Pa. All of the division master mechanics but three are at the convention, those present being F. H. Murray, Jersey City; W. H. Snyder, Stroudsburg, Pa.; W. S. Haines, Dunmore, Pa.; G. Thibaut, Port Jervis, N. Y.; H. H. Harrington, Susquehanna, Pa.; L. R. Laizure, Hornell, N. Y.; George Depue, Galion, Ohio; and J. Borden, Cleveland. All of the car shop superintendents will be here next week for the Master Car Builders' convention.

C. H. Andrus, Master Mechanic, Pennsylvania Railroad

Habit and custom play queer tricks on us. The editors of this paper are accustomed to dictating their copy. When working on *The Daily* they write most of it with pen or pencil; and sometimes, in the hurry of work, the untrained and unruly pens and pencils play queer tricks. Yesterday, one of them, while the man holding it was not looking, concluded a sentence regarding the fact that Mrs. Burton W. Mudge and son, Burton, Jr., were not at the conventions this year with the statement, "Mrs. Mudge decided to stay at

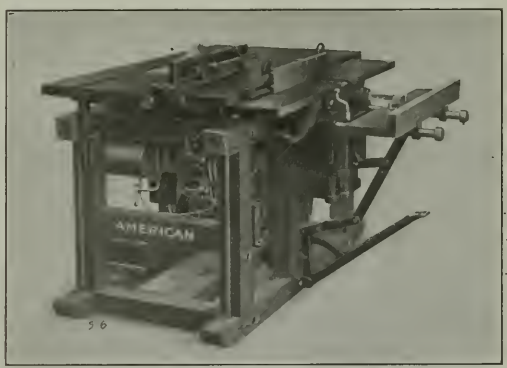
W. T. Kuhn, Supt. Motive Power, T. H. & B.

home with it." Needless to say, we were referring to Burton, Jr., in that sentence, and no one who knows that interesting young gentleman would think of referring to him in such an impolite way. This conventionality also is being written with a pencil. Do you see any "bugs" in it? We don't. If there are any, they are due to bad eyes and an ungovernable pencil. Meantime, we apologize to Burton, Jr.

A self-contained variety wood worker is on exhibition which will meet the requirements of many outlying car repair points where a variety of jobs are occasionally met with but where a completely equipped mill is not justified. The machine is self-contained; the frame being built up of seasoned hardwood, well bolted together, and contains either a complete gasolene engine outfit or an electric motor. It consists of a combined rip and cut-off saw bench with a boring attachment, a hollow chisel mortiser and a jig saw attachment. It also includes a six-inch jointer and dado head.

The top is a 54 in. by 30 in. iron casting accurately planed and strongly hinged to the rear of the frame. It is readily raised and lowered by a hand screw and may be firmly clamped in any position. It is independent of the jointer table, neither interfering with the other. The jointer has a steel cutter head fitted with two six-inch knives and slotted on two sides to receive matcher bits or molding cutters for working a large variety of shapes. The tables are 7½ in. wide by 43 in. long and are adjustable to any desired position. The jointer head is removable to permit the use of a sander drum.

The hollow chisel mortiser will work bits from ⅜ in. to ¾ in. The mortiser table has a vertical adjustment of 3½



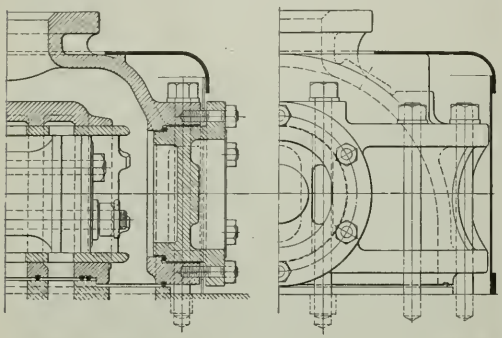
Self-Contained Engine or Motor-Driven Variety Wood Worker

in. and a travel of 4 in. in line with the spindle. It is provided with a foot pedal for feeding the work to the bit and a coil spring for the return motion. By removing the mortising chisel and substituting a regular boring bit the mortiser may also be used as a boring machine.

This wood worker is built by the American Saw Mill Machinery Company, Hackettstown, N. J., and a motor-driven machine may be seen in operation at the booth of this company. The floor space required is 54 in. by 54 in. and the machine has a total height of 36 in. The arbor takes saws with a one-inch hole up to an outside diameter of 16 in. which is the largest that can be used. Without an engine the machine weighs 850 lb., the engine increasing this weight to 1,150 lb.; with a 5-hp. motor the total weight is 1,250 lb.

THE PART OF THE ORLEANS RAILWAY IN PROTECTING PARIS.—The Orleans Company last fall had to undertake the supplying of part of the entrenched camp round Paris. Up to September 30, it carried into the capital and its environs 117,000 tons of various commodities, 66 tons of forage, 107,000 beeves, and 211,000 sheep and pigs, while it had also to carry concurrently the daily supplies of men, horses, food and ammunition to the army and to bring back the wounded and prisoners from the front.

iting a universal valve chest for use in applying piston valves to slide valve cylinders, which has been altered to make possible the removal of the valve without disturbing the valve

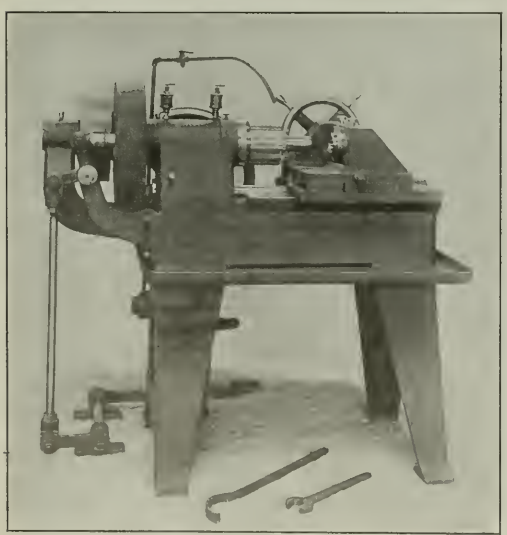


Universal Valve Chest with Front Head for Removing the Valve

chest itself. As originally built the front of the chest was provided with a hole large enough to allow the use of a wrench on the valve stem nut, this being closed with a plug, or a relief valve. The new type has a large opening in the front wall through which the valve may be removed, this being closed by a deep head secured with six studs.

EXPANDING AND BEADING MACHINE FOR INJECTOR PIPE COUPLINGS

From a careful analysis of injector steam pipe failures it has been found that over 50 per cent are due to coupling sleeves failing. Recent reports of the federal bureau of

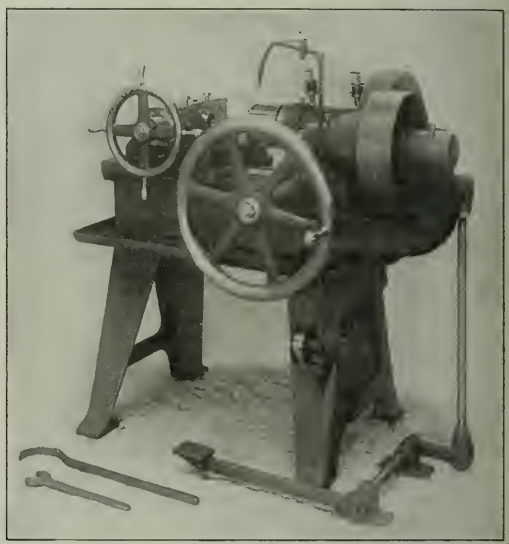


Rear View of the Expanding and Beading Machine

locomotive boiler inspection show that these failures continue to be one of the most frequent causes of serious accident and are the only ones which show an increase during

ures and is being used to some extent. The rolled and beaded joint eliminates the necessity for brazing and the consequent danger of injuring the pipe due to overheating. Defects in workmanship are readily discovered in such a joint, while the condition of a brazed joint is a matter of uncertainty and defective joints are often placed in service.

The expanding and beading machine, illustrated herewith, is similar to the machine described in a paper on Dimensions for Range and Screw Couplings for Injectors, read before the American Railway Master Mechanics' Association last year, by O. M. Foster, master mechanic, New York Central, but differs in the method of control. It is designed for rapid and economical application of coupling sleeves to copper pipe ranging from one inch to three inches in diameter and will handle pipes having short U or S bends. The



Operating Side of the Expanding and Beading Machine

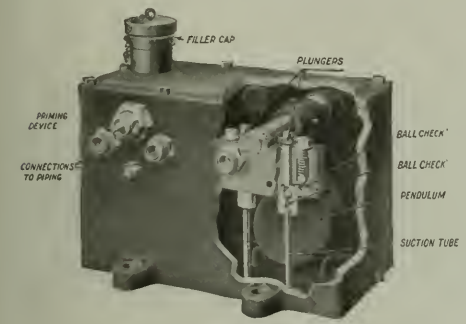
time required to apply a sleeve is claimed to be much less than that required for brazing, with the additional advantage that the finished connection is much safer.

The pipe is clamped in a movable chuck, with its end facing a roller expander attached to the spindle of the machine. After placing the coupling sleeve over the end of the pipe the chuck is moved forward by means of a hand wheel and screw feed until the expander enters the pipe. The rollers are then expanded by means of a conveniently located foot pedal; the end of the pipe is beaded by a further forward movement of the stock. The beading tools are interchangeable for the ball and socket members of the coupling.

As regularly furnished this machine is adapted for either belt or motor drive. The regular equipment includes a countershaft, wrenches and one set of chuck jaws and tools for applying sleeves to one size pipe. Tools for additional sizes are furnished extra. The floor space occupied is 3 ft. by 4 ft. and the machine weighs 1,650 lbs. A metal cutting power saw may be had as an attachment to the expanding and beading machine for cutting off and squaring the ends of the pipe. The expanding and beading machine is being exhibited at the booth of H. G. Hammett, Troy, N. Y.

A flange oiler fed by an automatic pendulum pump has been developed by the Detroit Lubricator Company, Detroit, Michigan. It consists of an oil tank or reservoir and the feed nozzles on the flanges; the tank contains the pumping mechanism and is connected to the feed nozzles by the necessary piping, in which are placed the regulating valves and check valves which control the flow of oil to the flanges.

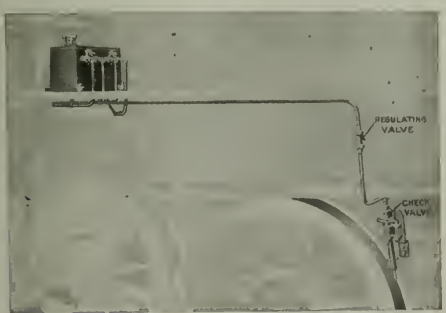
The tank may be placed in any convenient location and is so installed that the pendulums swing in a plane at right angles with the engine frame or boiler. Any swinging motion or rolling on curves, or lateral motion of any kind,



Broken Section of the Oil Tank Showing Details of the Pendulum Pump

causes the pump to operate. The oiler shown has four feeds and the tank contains two pumps, one for each two feed tubes. Each pump is operated by a pendulum which is sensitive to the slightest movement, any lateral motion of the locomotive causing it to swing. The pendulum shaft is pinned to a transverse rod, the ends of which engage the two plungers, and its swinging results in alternate up and down strokes of the plungers in the pumping unit.

On the up-stroke of a plunger oil is drawn up past a ball check; on the down-stroke it closes the passage into the



Force Feed Flange Oiler with Automatic Pendulum Pump

suction tube and oil is forced past another ball check into the pipe leading to the feed nozzle. Another check valve is located in the pipe line just above the feed nozzle. This is held to its seat by a spring which does not release until a predetermined pressure is reached in the pipe line, when it recedes from its seat and permits the oil to flow down the feed nozzle and onto the flange. After the pump is once in operation and as long as there is oil in the tank this pressure between the ball check in the pumps and the check valve above the feed nozzles is constantly maintained, consequently flanges.

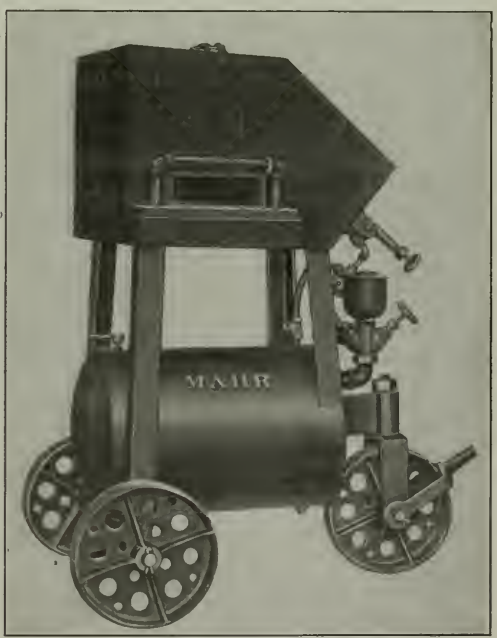
In order that the pump may supply oil to the flanges immediately after being installed a priming device is provided by means of which the pendulum shaft may be oscillated from the outside of the tank. It consists of a small rod extending through the side of the tank on the center line of the shaft. A tongue on the inner end of this rod engages a groove in the end of the shaft, the parts being normally held apart by a coilspring.

The regulating valves are installed in the pipe lines just above the feed nozzles and are within easy reach. Each valve controls the amount of oil that is fed to the flange and is regulated by the operator to meet the particular requirements of each individual installation. This device installed on a working model may be seen in operation at the Detroit Lubricator Company's exhibit.

PORTABLE RIVET FORGE

The portable rivet forge shown in the illustration has recently been added to the line of the Mahr Manufacturing Company, Minneapolis, Minn., and is included in its exhibit on the pier. The furnace is provided with combustion and heating spaces, so arranged that a minimum amount of scaling of the rivets takes place. It is built up of steel and all corners are welded; there is a removable cover on the upper inclined surface. It is lined with standard fire brick, the interior being readily accessible for this work.

The burner is designed to use crude oil, tailings, distillate or kerosene oil and operates on any air pressure from 10 lb. up to 125 lb. per sq. in. The tank which has a capacity

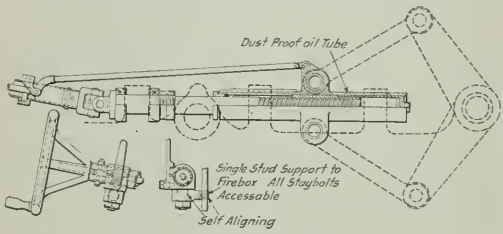


Portable Rivet Forge with Welded Frame

of 18 gal. is provided with a filling funnel and an oil measuring gage. It is welded to the frame by which the furnace is supported and forms a part of the truck frame. The wheels have wide tires to facilitate handling the outfit when using it about repair tracks. A chain is attached to the hood of the forge for use in moving it about the shop with a crane.

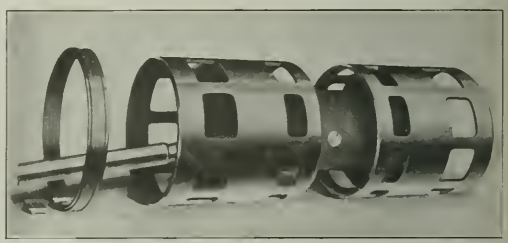
The Pyle-National Electric Headlight Company, Chicago, has in operation at its exhibit a full-sized model of the Young locomotive valve gear, including piston valves of an unusually light design, and a screw reverse gear designed to meet the special requirements of this valve gear. This valve gear was introduced about two years ago,* the most notable feature of the motion produced being the long travel of the valve. Several changes have since been made in the method of transmitting the motion across the engine.

The motion in this gear is derived entirely from the cross-



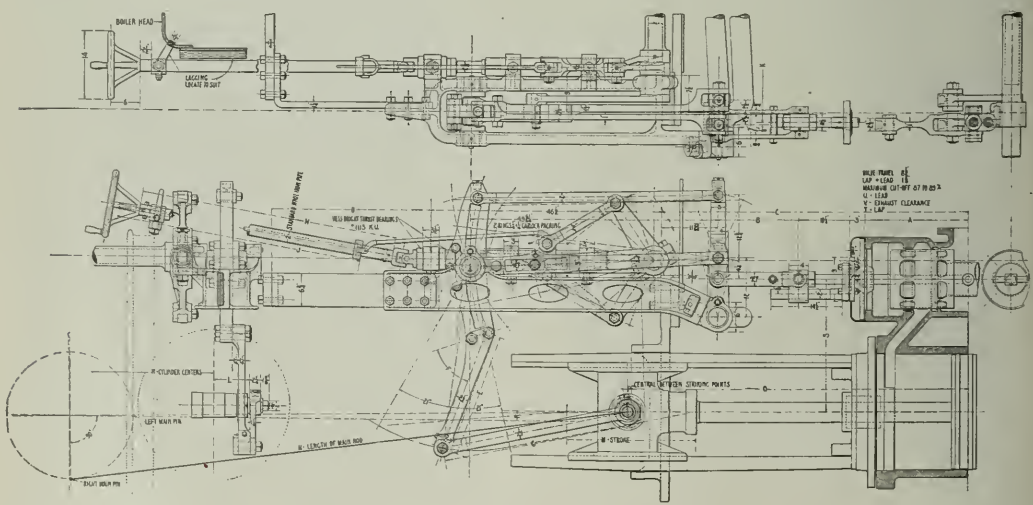
Details of the Screw Reverse Gear

head connections and the 90-deg. movement necessary for the main travel of the valve is obtained by means of a pair of interlacing rockers, concentrically mounted, each with a bearing on the other rocker at one end and in the valve-gear frame at the other end. As shown in the drawing, these rockers transmit the variable component of the motion from the crosshead and link on one side of the engine to the lap and lead lever on the other. Each link thus swings in unison with its own crosshead and the lap and lead, or fixed component of the motion for each valve is taken from the top



Young Piston Valve with Knuckle Joint Stem Connection

tudinally in the supporting block, which is split on one side, and to it is attached a hand-operated lever, by which it may be clamped to secure the rod in any desired position. The cut-off is thus unaffected by the expansion of the boiler. A graduated cab indicator projects through the center of the



Young Valve Gear and Screw Reverse Gear

of the link on its side of the engine. The link block is made with integral trunions, which make possible a reduction in the size of the block as well as in the size and weight of the link.

A maximum valve travel of 8½ in. is obtained with this gear, with a total angle of oscillation for the link of only 42 deg. The entire weight of the gear on both sides of the total, their weight being 1,484 lb.

The reverse gear is of the screw type, and is supported directly on the valve gear frame. The screw is immersed in a dust-proof oil tube, within which the nut is so secured that it may be readily removed for renewal. A packing gland in the end of the tube provides for the movement of the tube on the rod without the loss of oil or the entrance of dust. The operating rod is of pipe, and is universally jointed to the screw. The hand wheel support is a block pivotally secured to a single stud tapped into the side or corner of the firebox. This provides a universal adjustment for readily maintaining the operating rod in perfect alignment, and leaves the staybolts accessible. The rod is free to move longi-

hand wheel, which shows the exact cut-off of the gear in any position.

The piston valves used with this gear reverse the usual packing ring arrangement. The valve is a light cylinder, cast in one piece, and of uniform thickness throughout. The ends are of a hollow, cylindrical form, somewhat resembling the bushings applied to the usual type of valve chamber. The rings are stationary and are recessed into the walls

*For a description of the original gear, see the *Railway Age Gazette, Mechanical Edition*, January, 1914, page 43.

them. The operation is thus similar to that of a plug valve, and the weight of the valve is materially reduced by the elimination of the bull rings and followers necessary with a ring-packed valve.

Another feature of interest in the construction of this valve is the method of making the valve stem connection. The end of the valve stem is provided with a knuckle, which is secured to the center of the valve spool by a fitted pin. It is thus possible for the valve to properly align itself regardless of the alignment of the stem, and a source of much unequal wear to the valve and the packing rings is thus eliminated.

These valves weigh but 100 lb. each. The long travel of the valve obtainable with the Young gear permits the use of a valve of comparatively small diameter without sacrifice of steam admission area. The valves in this case are 12 in. in diameter, which, in itself, effects a reduction, this being still further increased by the construction of the valve.

DEVICE TO PREVENT LADDERS FROM SLIPPING

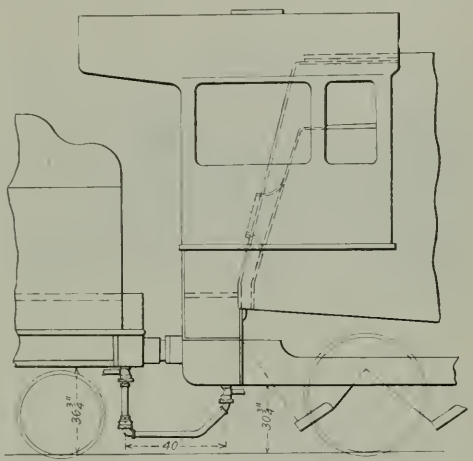
A hinged shoe for application to the bottom of ladder string pieces has been devised by the American Mason Safety Tread Company, New York, to reduce the danger of accidents caused by the slipping of the ladders on the floor. The bottom of the shoe, which comes in contact with the floor, is faced with a coarse carborundum grit which possesses exceptional gripping qualities and is claimed to hold

Ladder Shoes to Prevent Slipping

firmly even to the smoothest of concrete or steel floors. The shoes, it will be noticed, are swiveled to the ends of the ladder string pieces, thus permitting the base of the shoes to lie flat against the floor regardless of the angle at which the ladder is placed. This device is being exhibited at the booth of the manufacturer.

ROLLED STEEL PISTONS.—Included in the exhibit of the Carnegie Steel Company, Pittsburgh, Pa., are a number of rolled steel sections of various kinds manufactured at its Slick works. Among these are two styles of forged and rolled steel pistons for locomotive cylinders, which are of especial interest at the present time because of the increasing tendency toward the reduction in weight of reciprocating parts.

The Barco Brass & Joint Company, Chicago, is exhibiting this year a flexible water connection for use between engine and tender, which was recently redesigned to reduce the number of nipples and pipe fittings required in setting it up. As now designed, it permits a combination of the swivel and angular motion of the ball, and all of the joints are hung in a vertical position, so that the ball tends to maintain a full bearing against the surface on the gaskets by gravity.



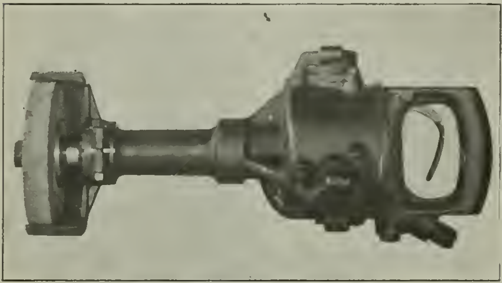
Flexible Water Connection with Vertical Members

The entire connection is suspended by bolts from plates under the engine and tender, to which the joints are attached by means of integral flanges. The long leverage of the horizontal connection prevents any severe thrust or shock being transmitted to the joints due to the vertical motion between the engine and tender. An angle ball is used on the engine end in order that the pipe may not revolve around the axis of its own thread, thus obviating the danger of its coming unscrewed, which would exist if a straight ball were used with an elbow and vertical pipe connection. A patent has been applied for.

LOHMANNIZED BOILER TUBES.—Several specimens of Lohmannized boiler tubes are on exhibit at the booth of the Parkesburg Iron Company, Parksburg, Pa. These tubes have been subjected to a pickling process in a special chemical bath after which they were dipped in a lead and antimony alloy. This process gives to the metal an alloy coating which cannot be physicially separated and experimentally has proven impervious to the action of acid and alkaline solutions; nor has it developed any electrolytical affect which might be detrimental to other parts of the boiler. These tubes are intended for use in feedwater heaters and condensers where excessive corrosion takes place.

WHEEL PRESS AND LOCOMOTIVE GAGES.—General improvements have been made in the devices exhibited by the Ashton Valve Company, Boston, Mass. Among these is a wheel press recording gage, which is furnished with a glass pen of the capillary style. This makes a very fine line and produces a satisfactory record. The gage is also furnished with ruled record charts, which are an improvement over the plain paper records previously used. A steam gage is also being shown which is provided with a white porcelain enamel dial. Each dial is graduated to conform to the individual movement in the gage in order to insure accuracy.

pneumatic grinder, in the design of which simplicity and accessibility of the parts has been carefully considered. In order to eliminate unnecessary parts the valve is made part of the crank shaft and all valve motion parts are thus dispensed with. The handle is secured to the cyclinder casing by six cap screws the removal of which exposes the entire interior for inspection. The motor is designed especially for grinding work and runs in an oil bath. The cylinders



Portable Pneumatic Grinder

are made separate from the casing to facilitate replacement. Ample provision for wear on the exposed corners of the cylinders is provided for by pads and as they become worn the cylinders may be interchanged thus bringing the pads on the opposite sides into use. The exhaust is covered with an adjustable deflector. The grinder is being exhibited by the Ingersoll-Rand Company, New York, and many of the details, including the piston and connecting rod connections, are of the standard type embodied in the line of "Little David" pneumatic tools manufactured by this company.

CARBON-VANADIUM FORGING STEEL

To meet the need of greater strength in material for locomotive axles and forgings, the railroads have turned to heat-treated carbon and heat-treated alloy steels. One obstacle to the adoption of heat-treated forgings, however, is the lack of equipment for heat-treatment in most railroad shops. This operates particularly in repair work where for any reason the forging has to be locally heated, thereby destroying the effect of the heat-treatment.

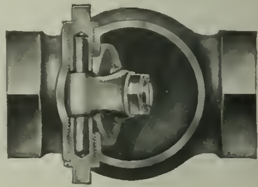
Many motive power men and producers of locomotive forgings believe that it is extremely desirable to obtain a steel of moderate cost that, without heat-treatment other than annealing to toughen and refine the grain, will have physical properties equal to those specified for heat-treated carbon steel forgings. With the reduction in the cost of vanadium that has taken place during the last year the American Vanadium Company resumed the investigation and study of the application of vanadium to simple carbon forging steels, which was dropped about 12 years ago on account of the high price of vanadium. At that time some tests were made on the effect of vanadium in simple carbon steels and a very considerable increase in strength was found to result. The effect of vanadium on alloy steels such as chrome steels was, however, so much greater that development proceeded with these steels rather than the simple carbon steels.

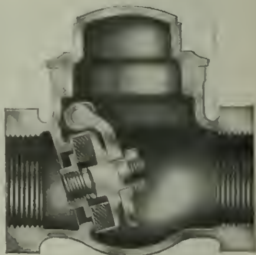
As the result of its latest investigations this company has developed a type of simple carbon-vanadium steel which is said to meet all the requirements specified for heat-treated carbon steel forgings, without heat-treatment other than annealing, these results being obtained from steel of lower carbon content than is generally required to obtain the speci- be heated uniformly to a temperature of 1,425 deg. to 1,475 deg. F. and then removed from the furnace to cool in air, protected from strong drafts and rain or snow.

Still better results can be obtained by annealing, as this material may be subjected to heat-treatment with results which are said to approximate those obtained from more expensive alloy steels. The treatment consists of first heating to a temperature of about 1,600 deg. F. and quenching in oil. The forgings should then be drawn back to about 1,100 deg. or 1,150 deg. F.

SWING CHECK VALVE

A check valve offering a full opening free from obstruction and with practically no pocket at the bottom of the body has been added to the line of Jenkins Bros., New York, and is on exhibit at their booth. This valve is fitted with a renewable disc and is supplied with either a semi-hard composition especially adapted for hot water service in boiler feed lines and returns, or with a soft pliable composition for use with cold water or air.





Swing Check Valve

By referring to the illustration it will be seen that the hanger pin is carried and held in place by two long plugs inserted in the sides of the body, and has a long bearing both in the plugs and in the hanger. By unscrewing the cap and plugs the hanger pin may be removed and the disc and hanger lifted out of the valve. The bodies are made for either screwed or flanged connections in sizes from ¼ in. to 3 in. inclusive and the valves are perfectly adapted for use in either horizontal or vertical positions.

Horizontal Boring, Drilling and Milling Machine.—A new model horizontal boring, drilling and milling machine is being exhibited by the Lucas Machine Tool Company, Cleveland, Ohio. This machine differs from the previous model only in size and capacity. The spindle has been made larger and the total traverse increased from 48 in. to 52 in. The vertical capacity has been increased 6 in. to a total of 30½ in. and the platen has been increased in width. It now has six T-slots instead of four as formerly.

Metallic Packing Material.—The Lubricating Metal Company, 2 Rector Street, New York, is exhibiting a bearing metal and metallic packing, which are being introduced in railroad service after nine years of successful use in rolling mills, cement plants and general bearing and packing work. It is claimed that this material, known as Noheet metal, has an elastic limit of 10,000 lb. per sq. in. as against about 6,500 lb. per sq. in. for genuine babbitt and lower for other metals, and a tensile strength of 13,500 lb. per sq. in. As it contains no antimony, copper or spelter it has a uniform testure and is claimed not to score shafting or rods. It has a low coefficient of friction and, on account of its natural lubricating properties, is said to require less oil than other bearing metals.

The RAILWAY AGE GAZETTE and all other Simmons-Boardman publications are members of the Audit Bureau of Circulations.

The training of enginemen is a serious problem on all railways. If it is to be done properly it requires patience, tact and a knowledge of human nature on the part of the man in charge. Such a man cannot be chosen at random; he must be selected only after a careful appraisal of the qualifications of all likely candidates. The road foreman needs all the qualifications of the successful educator: his duties include the hiring and training of men whose work intrusts them with the care of many human lives, and to satisfactorily perform such duties he must be of the proper temperament, otherwise he may do more harm than good. The right kind of man as road foreman, given absolute charge of the hiring of firemen and the training of both firemen and enginemen, and held responsible for the development of the highest class of men, can produce remarkably gratifying results.

Qualifications of a Road Foreman

The convention of the Master Mechanics' Association which closed yesterday was unusually successful. The reports seem to be more carefully prepared, particularly with a view to conciseness, and there are a number of them which reflect more than ordinary credit on the members of the committees. Three of those deserving of special mention are the reports on Fuel Economy and Locomotive Counterbalancing and Boiler as they might have been, but on the other hand the members seemed, for the most part, to know pretty well what they wished to say, and said it without consuming too much of the convention's time. The individual paper on Variable Exhausts will prove a valuable addition to the proceedings of the association. The topical discussions were selected with evident care and it was unfortunate that there was not time to go into a full discussion of all of them, as they were timely and worthy of very careful attention on the part of the entire membership.

A Successful Convention

Almost any one can prepare an elaborate chart showing a system of organization, but the ability to prepare it does not make the organization effective in practice. To be most effective an organization requires at its head a man who will deal with it as would the father of a family. We recently heard it said that the reason for the success of a certain superintendent of motive power lies mainly in his ability to choose men of reliability, and then let them see by his actions that he is not afraid to place confidence in them. His predecessor was disliked and had not the confidence of his subordinates because he did not place confidence in them, but employed a number of officers who acted practically as spies. No man can expect to build up an effective and efficient organization by such methods. The man who places confidence in those whom he appoints as subordinate officers and shows them that he is interested in their success, can feel sure of their co-operating with him and furthering his efforts at all times.

Treatment of Subordinates

Anyone who travels frequently is familiar with the comment of passengers on the rough handling of some of our passenger trains, especially at starting. With the very long and heavy trains, now so common in fast through service, it is often impossible for an engineman to get under way without taking the slack at least once, so that many of the annoying shocks are almost, if not quite, unavoidable, at least under present conditions. However, there is some of this rough handling that is inexcusable, particularly in the case of the shorter trains. Many enginemen are careless in judging their stops at stations, bringing the train up with a final brake application that is likely to throw passengers off their feet. In a large measure, the correction of this abuse lies in the hands of the road foreman of engines. Carelessness due to lack of supervision is directly responsible in many instances and the road foreman has it in his power to promote a better feeling among the road's patrons by giving closer attention to the instruction of the enginemen under his jurisdiction.

Rough Handling of Passenger Trains

ELECTION OF R. S. M. A. EXECUTIVE MEMBERS

THE Railway Supply Manufacturers' Association is a business organization. Therefore, sound business principles should govern in the choice of its officers. The district meetings will be held today for the election of four members of the executive committee. As a business proposition, the only thing which should be considered in determining the selection of these executive committee men is their fitness to contribute their share toward making the work of the association as efficient as possible. The executive committee appoints the chairmen of the various committees; they, in turn, appoint the members. In order that the work of the association may be kept going properly, the members of the exhibit, entertainment, enrollment and other committees must devote much time and energy to their duties. Therefore, they should be

tions, for election to the executive committee, and should, therefore, be elected to it. Furthermore, if good timber is put on the executive committee, it will follow that this committee will afford the best material from which to select the higher offices of the association.

In other words, good business suggests that, as far as practicable, civil service rules be followed, and that those who render the best service on the subordinate committees be promoted to the committee chairmenships and to membership on the executive committee; and that, in turn, those who give the best service on the executive committee be given the honor, opportunity and responsibility of the vice-presidency and the presidency. There is always danger of politics working in, and over-riding, business considerations in the affairs of the Railway Supply Manufacturers' Association. This always will do harm. When the members cast their votes today for executive members, they should remember that the application of sound business principles will always promote the efficiency of the organization, while the intrusion of politics will always interfere with its efficiency.

LIGHT RECIPROCATING PARTS

THE committee on counterbalancing deserves a great deal of credit for the high character of the report presented at Friday morning's session. The tables which accompanied the report of those which appeared with the series of articles on Reciprocating and Revolving Parts, by H. A. F. Campbell, now appearing in the *Railway Age Gazette, Mechanical Edition*, to which reference was made in the report of the committee, give convincing proof of what is common practice and of what can be done, in the way of reducing the weight of reciprocating parts. The column showing the piston load carried per pound of weight of reciprocating parts is eloquent of the poor practice which has been so commonly employed, but it will be seen from these tables that the desirability of having these parts as light as they could be made was realized by some roads many years ago and consistent efforts made ever since to keep their weight to a minimum in new power. If this report were to accomplish nothing else it should be the means of setting some of our mechanical engineers thinking along the right lines.

The evidence submitted by officers of the Pennsylvania as to the service of the heat treated parts used in their latest locomotive designs disposes in a convincing manner of the idea that lightness and strength cannot be combined, and when we consider the weights now being carried on single driving axles, we cannot but agree with the committee in the statement that the lighter the reciprocating parts can be made the better the results which will be obtained. The racking and disturbing effects of improperly balanced locomotives traveling at high speed were clearly brought out by S. G. Thomson, superintendent of motive power and rolling equipment of the Philadelphia & Reading, and chairman of the committee, in his closing remarks, and we agree thoroughly with him in his reasoning that cost should be left out of consideration in any efforts to obtain the lightest possible parts, at least for locomotives in high speed passenger service, as any extra cost will very soon be absorbed by the decrease in maintenance expenditure. The work of producing improved materials for accomplishing just such purposes is receiving greater impetus every day and there is no reason why the same degree of refinement should not be obtained in locomotive practice as is now the case in automobile construction.

Undoubtedly careful attention must be given to the matter of heat treating when this process is employed for improving the quality of steel, as the very best material is absolutely necessary when reciprocating parts are made as light as those design, construction and operation that are going to require much greater care in the future than they have ever before received. Mr. Thomson's concluding statement of the text of the committee's report is a good one—make the reciprocating parts as light as possible and the undesirable counterbalancing effects will be reduced to a minimum.

COST OF CONDUCTING TRANSPORTATION

MECHANICAL department men are usually keenly alive to the necessity for keeping expenses at the lowest possible point, but they are not always interested as much as they should be in the matter of expenses outside their immediate department. Practices in the motive power department have a direct bearing on the cost of conducting transportation. Motive power that will haul the greatest tonnage with the least amount of expense for fuel and upkeep is, of course, one of the principal factors in reducing transportation expenses. If a careful study is made of the conditions of operation when deciding on new power, it will be found that the after-effects in the way of reduced expenses due to increased tonnage and reduction in the overtime of train crews amply justifies the time and money spent in making such a study. Overtime has become a prominent factor in increasing wage expenditures, and the question of supplying engines that will get maximum tonnage trains over the road within the time limit, ought to be given an important place in considerations pertaining to new locomotives or alterations to old ones.

The time which it is necessary to hold a locomotive out of service at terminals is of vital importance to the operating department and depends to a great extent on the equipment of engine houses, the suitability of their arrangement for the quick and easy movement of locomotives without interfering with one another, and the size of the force employed. One of the worst causes of delays at engine terminals is insufficient coaling and ash-handling facilities, causing locomotives to stand for long periods awaiting their turn for coaling and fire cleaning before entering the engine house so that actual repairs can be begun. Of course, an engine house foreman by the exercise of ingenuity and good judgment can do much to offset inferior equipment and poor location of a roundhouse, but he can use his ingenuity to much better advantage in a properly equipped plant, and the advantage in the movement of trains which results from the speedy return to service of locomotives after they arrive at a terminal, while beyond definite calculation, is very considerable. Careful attention to both back shop and roundhouse repairs has a direct bearing on the cost of conducting transportation. Slipshod methods in general repairs will invariably cause heavy running repairs and the greater the amount of such repairs the longer the locomotive must remain in the engine house between trips. Moreover, unless repairs are given the attention which they should have, engine failures will increase rapidly and the effect of an engine failure in demoralizing train movements is well known. It is difficult to imagine any saving which might be effected by skimping on running repairs, which could be claimed to justify even the most trivial engine failure.

Of course, the greatest portion of the cost of conducting transportation is chargeable to fuel and, while much has been said in these columns on this subject, it should not be amiss to call further attention to the great need of effecting every possible economy in fuel consumption. The kind of training which enginemen receive affects fuel consumption in a very direct way, and a lack of proper training also affects transportation expenses injuriously, because of improper locomotive handling.

Dollar Pier.

9.00 P. M.—Vaudeville Entertainment. Million Dollar Pier.

RAILWAY CLUB SECRETARIES

The annual meeting of the Society of Railway Club Secretaries will be held at 10 o'clock this morning in room 193 of the Blenheim.

DYNAMOMETER CAR

The Southern Railway is exhibiting its new dynamometer car at the track exhibit at Mississippi Avenue, two blocks south of the pier. The car is in working condition and contains a number of new and interesting features.

ATLANTIC CITY ROTARY CLUB

The Rotary Club of Atlantic City will hold its weekly luncheon at the Hotel Schlitz, Tuesday, June 15, at 1 P. M. James S. Murphy, city passenger agent of the Pennsylvania Railroad is chairman of the entertainment committee and will be glad to have any visiting Rotarian attend the luncheon.

TODAY IS R. S. M. A. ELECTION DAY

The annual meeting of the Railway Supply Manufacturers' Association, for the election of officers and the transaction of such other business as may be brought up for attention, will be held at 12 o'clock noon today in Convention Hall, Million Dollar Pier.

The voting for four members of the executive committee will be done in the room at the front of pier adjoining Mr. Conway's office. The polls will be open from 10 a. m. to 12 noon. The vacancies in the committee to be filled are: one from the first district, succeeding Fred. M. Nellis, of Boston; one from the second district, succeeding Oscar F. Ostby, of New York; one from the fourth district, succeeding J. C. Whitridge, of Columbus, Ohio, and one from the seventh district, succeeding S. M. Dolan, of St. Louis.

In both instances each member is entitled to one vote, residence of the voting delegate registered with the secretary will determine the district in which a proxy vote may be cast.

THE CARNIVAL DANCE

The carnival dance held last night proved a great success. A good deal of mystery seemed to be attached to this affair, in that it was a new feature on the program. In consequence, everybody came early so as not to miss anything—and the moment that Leader Richardson raised his baton at 9.30 things broke loose. At 10.30 the entertainment committee distributed 30,000 rolls of serpentine, rubber balloons and novelties and scores of paper hats and caps. Immediately the air was filled with a storm of streamers, formality was swept away and from then on the whole became as one big happy family on a picnic.

Thoughtful as ever of the pleasure of those attending, the dance committee interspersed old dreamy waltzes and lively two-steps with the more modern numbers so everyone could participate. Owing to the sudden illness of W. K. Krepps, chairman of the committee in charge, who was taken with tonsilitis Wednesday, A. B. Wegener took his place and was ably assisted by Langley Ingraham, J. F. A. Comstedt, C. D. Jenks, G. R. Berger, R. J. Faure, C. D. Eaton, C. C. Farmer, A. MacRae.

THE GOLF TOURNAMENT

The following persons have registered for the golf tournament, in addition to those mentioned in yesterday's Daily. Others desiring to enter may leave their names at the *Railway Age Gazette* space today or at the Sea View Club early tomorrow morning.

President Gaines called the meeting to order at 9.40 o'clock a. m.

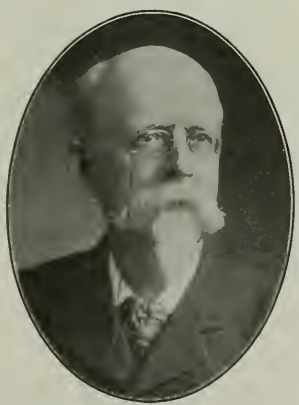
VARIABLE EXHAUSTS

By J. Snowden Bell.

[The author presented an interesting description of the various variable exhausts used from 1803 to the present time. From lack of space we are compelled to omit those invented prior to 1901.—Editor.]

The Olsen variable exhaust consists of two flexible "adjusting plates," the lower ends of which are fixed to a bridge piece in the exhaust nozzle, and which are spread outwardly, to reduce the discharge outlet, by an interposed transverse shaft, which is flattened centrally and operated by a rod. The plates are returned to their normal position, in which the maximum discharge outlet is given, by their own elasticity. This variable exhaust is shown in Fig. 1. In the construction shown, the discharge outlet is variable between a maximum area corresponding to a diameter of 6 in., and a minimum area corresponding to a diameter of 4½ in. This nozzle has been used on the Canadian Pacific and the Duluth & Iron Range but is not now in service.

Wallace & Kellogg Variable Exhaust, 1003.—This design is shown in Fig. 2. The front and rear sides or "doors" of the exhaust nozzle are hinged to it at their lower ends, and are simultaneously moved toward and from each other, to diminish or



J. Snowden Bell
Paper on Variable Exhausts

increase the area of discharge outlet, by a double grooved cam, which is rocked by an arm connected to the reverse lever. The grooves of the cam engage pins on the hinged "doors." This design was applied on the Pere Marquette and Duluth & Iron Range, and W. L. Kellogg reports that it was used for several years with very good results, and that tests with a dynamometer car proved that by its use the efficiency of the engine was increased and material saving in coal effected.

Baker Variable Exhaust, 1012.—Another variation of structure is shown in Fig. 3, from which it will be seen that the design consists of two co-acting "nozzle gates" or valves, which are pivoted to the top of the nozzle and are swung horizontally toward and from each other, with a consequent decrease or increase of discharge outlet area, by a transverse shaft, having right and left hand threads engaging threaded sleeves coupled to the nozzle gates. This variable exhaust was applied and used for about a year and a half on the St. Joseph & Grand Island, with the result which is stated as follows by C. E. Slayton, assistant superintendent:

"The adjustable feature worked well, that is, we were able to keep it in working order without any trouble. They did not effect saving enough to warrant us in applying them to more locomotives."

As was early recognized, and as is familiar to all who have had experience with variable exhausts, the greatest objection that has been developed in their operation is their liability to become gummed up and stuck fast by the action of foreign matter and the heat of the smokebox, unless frequently moved from one adjusted position to another, and if manually adjusted, such movement is liable to be, and generally has been, neglected. To overcome this objection, automatically adjustable appliances have been proposed, the Wallace & Kellogg appliance before described being an instance. This is connected to the reverse lever and is operated when the lever is moved.

While a number of the variable exhaust appliances before noted have been experimented with, and have, in some cases,

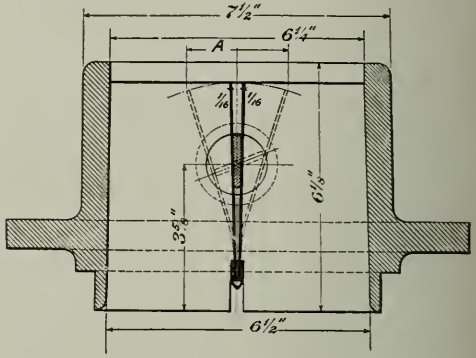


Fig. 1.—Olsen Variable Exhaust

been found to effect an economy in fuel, none of them has been considered to be sufficiently satisfactory or desirable to be retained in use. In Europe the early introduction of the variable exhaust has been followed by its general application, and it is understood by the writer to be standard to-day in the practice of leading French railroad systems, and probably also in other countries of Europe. A description and illustration of the latest type used on the Chemin de Fer du Nord, of France, have been furnished by Geo. Asselin, chief engineer of that road, and is presented as representative of the most approved design of present European practice. The following is quoted from Mr. Asselin's letter:

"The plan view of this device is shown in Fig. 4. The con-

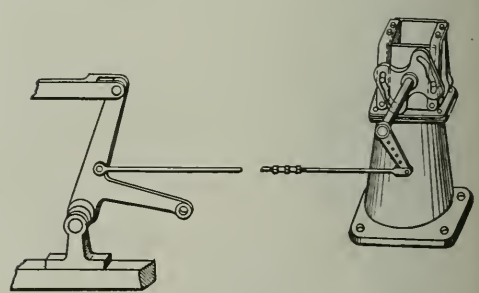

Fig. 2.—Wallace & Kellogg Variable Exhaust

traction of the exhaust is regulated by the height of the interior movable nozzle. The latter is controlled by a forged finger on the exhaust moving shaft, which extends across the smokebox in the ordinary manner. The engineman operates the movement by means of a hand-wheel and a screw; he has in sight a graduated scale which indicates to him the degree of contraction.

"From the point of view of ease of taking down and cleaning of the different parts, and of their perfect centering, this head has given entire satisfaction; but it was necessary to study the

less. It was, therefore, thought that it would be possible to avoid this imperfection by imparting a movement of rotation to the exhaust jet, in order to maintain the same degree of

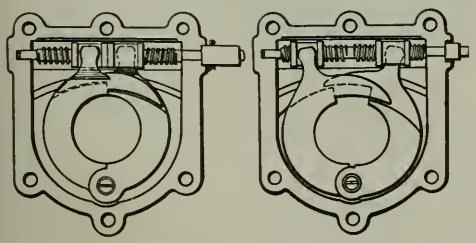

Fig. 3.—Baker Variable Exhaust

efficiency, whatever may be the degree of contraction of the exhaust. This end has been attained by the helicoidal wings.

"As a matter of fact, the exhaust jet expands as much more as the section of the exhaust head is more reduced, and, consequently, as the speed of the steam is greater. It follows that the gaseous column always completely fills the stack. Furthermore, this movement of rotation, due to the wings, augments the intimacy of the mixture of steam and hot gases, and communicates to it a greater quantity of live force. It has also been immediately recognized that, with equal section of passage of

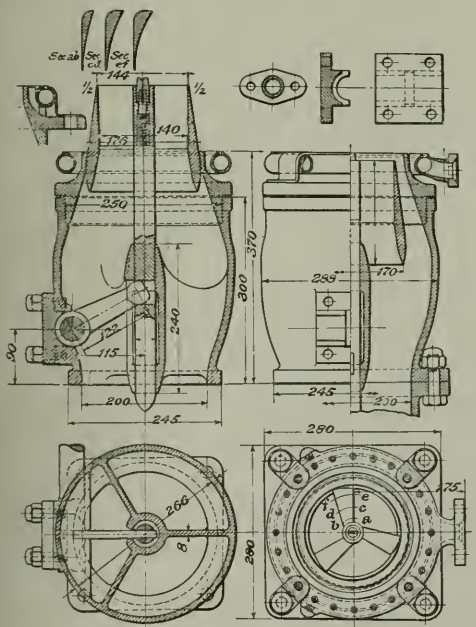

Fig. 4.—Latest Type of Variable Exhaust Used on the Chemin de Fer du Nord

the steam in the exhaust head, the draught was noticeably increased by this last arrangement.

"The character of the steam equally plays an important part in the question of the exhaust, and from the first application of superheating on the 'Atlantic' engines it has been recognized that it was necessary to choke the exhaust much more (nearly 15 per cent) to obtain the same useful effect. This new exhaust, giving at the same time a more intense vaporization and less back pressure, permits us to attain higher speeds by providing more facility for the management of the fire, or to augment the loads hauled by providing a more easy management of the power officers to the writer's inquiries, and the tenor of these replies is that its failure to be generally adopted in railroad service is largely, if not altogether, due to the fact that, under existing conditions, it does not seem possible to ensure it proper attention and protection from misuse on the part of engine crews.

The view of the writer as to the variable exhaust is to the same general effect as those of members of the Association and others who have expressed their ideas to the author, and he has brought this subject before the Association in the hope of sufficiently indicating its importance, to enlist the interest of the members and their consideration of the advisability of its development in their service. If this interest and consideration be given, there is no room for doubt that a variable exhaust can be produced, in which the requirements called for in the replies of the members would be fully complied with—that is to say, it would be "properly constructed," would be "automatically operable," and would be "fool-proof," because independent of the "human factor." Under the present conditions of railroad operation, the claims of this, as of every other appliance which is designed to operate in the direction of economy of fuel, merit a careful consideration on the part of motive power officers, and the standard of intelligence and ability of locomotive engineers at this time is so high that it would be unfair to them to believe that an appliance of such character, if approved by their superiors, would fail to receive fair and unprejudiced treatment in the operation of their locomotives.

DISCUSSION

C. A. Seley: While in the West recently I saw a device which Mr. Bell mentioned as having been developed by Mr. Mertscheimer, and that gentleman is quite enthusiastic over the device, believing, although not having made a scientific test of it, that he will save not pounds, but tons of coal.

D. R. MacBain, (N. Y. C.): I believe that until we get a variable exhaust that will work automatically, and almost humanly, we had better stick to a sure thing and make the nozzle large enough to keep the engine steaming and go along on that basis. The practical way at the present time to insure good locomotive service is to make the locomotive, when it is turned out of the shop, as nearly foolproof as it can be made, because if you depend on any person, other than the men who make the mechanical arrangements for you, you are going to lose on the proposition. My own personal experience has been that the thing to do is to make the nozzle as large as consistent and at the same time so design the nozzle so that the steam column will pass it without raking the sides of the stack in any direction. When you do that you allow space around the circumference of the steam column for the gases to be entrained and carried out. We have found that the exhaust steam left the top of the stack at a pressure of about five pounds. When you come to consider that you have five pounds pressure in a solid column of steam it is rather inconsistent to believe that any quantity of the front end gases are going to crowd themselves into that column of steam and be carried out, so what you have to figure on is a column of steam of great enough circumference to entrain a sufficient amount of gases per minute in order to create the desired draught. On the New York Central, west of Buffalo, out of many thousand locomotives operated our steam failures for the year 1914 were 46, and 146 failures were due to leaking.

W. E. Symons: The exhaust nozzles of locomotives, regardless of whether or not they are saturated steam, compound or superheater engines, is the medium that offers the back pressure to the pistons and therefore controls in a large measure the economical operation of the machine. It is a feature that should have been included in the field of investigation in the work of developing an economical machine. I have known of instances where an engine with but 25,000 lb. tractive power, equipped with a variable exhaust nozzle, could, by adjusting the nozzle, increase its power from 800 to 1,000 h. p. I have seen some statements made by one of the leading railroads of this country where the back pressure on certain engines was as much as 800 h. p.

JOINT MEETINGS

The Committee on Joint Meetings of the two associations presented a tentative program based on the work to be done at the 1915 Convention, to indicate how the two conventions could be held in one week. At the joint session which would be held on Wednesday, several reports which are common to both Associations were scheduled for discussion as follows: Safety Appliances; Revision of Standards and Recommended Practice;

not recommend that it be done, believing that much better results are obtained from these conventions by following the present plan of holding each convention separately.

The report is signed by:—J. F. De Voy, (C., M. & St. P.); C. E. Chambers, (C. of N. J.), and C. F. Giles, (L. & N.), Committee A. R. M. M. Assn., and R. W. Burnett, (C. P. R.); J. S. Lentz, (L. V.), and T. H. Goodnow, (C. & N. W.), Committee M. C. B. Assn.

TRAIN RESISTANCE AND TONNAGE RATING

The committee has, in accordance with instructions, endeavored to get additional information to enable it to submit a final report at this convention. While some information has been available, yet the committee desire additional data as to the comparison of the drawbar pull curve of superheater locomotives, as compared with that of saturated locomotives. Data is also desired as to the resistance of the ninety-ton cars now coming into use. The committee will be able to obtain the information desired and submit a final report to the Association in 1916, and would ask permission to carry over the final report to that time.

P. F. Smith, Jr. (Penn. Lines), chairman; W. E. Dunham (C. & N. W.); J. S. Sheafe (B. & O.); H. C. Manchester (D., L. & W.); C. E. Chambers (C. of N. J.); J. H. Manning (D. & H.), and Frank Zeleny (C., B. & Q.).

COUNTERBALANCING

The following report will consider only the counterbalancing of two-cylinder locomotives, the three and four cylinder locomotives being less of a problem on account of the reciprocating parts more or less balancing each other.

GENERALLY ACCEPTED RULES AND PRINCIPLES.

The reciprocating parts to be considered in counterbalancing are: The piston head, rod and nut; the cross-head, cross-head key, pin and nuts; approximately one-half the total weight of the main rod; arm and link fastened to cross-head for outside valve gear.

Each driving wheel should have sufficient weight added to counterbalance exactly the weight of its revolving parts, which

S. G. Thomson
Chairman, Committee on Locomotive Counterbalancing

are: Crank pin, crank-pin hub, and the proportion of the weight of the side rods attached to the pin. The main driving wheel should have added approximately one-half the total weight of the main rod, plus two-thirds the weight of the eccentric arm, considered acting at crank pin distance, for outside valve gear.

The overbalance which is used to counteract the desired portion of the weight of the reciprocating parts should be distributed as nearly equally as possible among all driving wheels, adding to it the weight of the revolving parts for each wheel.

Centrifugal and reciprocating forces are usually figured at a speed in miles per hour equal to the diameter of the driving its weight, and is at a maximum at the top and bottom position of the crank. This force is added to the static weight, in the lower position of the overbalance, and is opposed to this weight, in the upper position. Approximately one-fortieth of the static weight on a wheel will therefore give the weight of the reciprocating parts which could be balanced without causing the wheel to rise from the track at diameter-speed.

METHODS FOR DETERMINING THE AMOUNT OF OVERBALANCE.

The method most generally used for many years in counterbalancing locomotives has been to balance a portion of the total weight of the reciprocating parts, usually about two-thirds.

A second method, and the one recommended in the 1896-97 reports to the Master Mechanics' Association, is to leave unbalanced, on each side of the locomotive, a portion of the reciprocating parts equal to $\frac{1}{400}$ of the weight of the locomotive.

Neither of the above methods seems to give good results in all cases, and the committee presents another relationship which seems paramount to proper counterbalancing: The ratio of the total weight of the reciprocating parts on each side of the locomotive to the total weight of the locomotive in working order.

To show the necessity for this ratio, and to demonstrate the failure of the former rules when applied to locomotives with heavy reciprocating parts running at high speed, the committee made some tests on the Philadelphia & Reading, as shown in the accompanying table. These tests included a series of high-speed locomotives having very heavy reciprocating parts, equal to $\frac{1}{139}$ of the total weight of the locomotive.

One of this series of locomotives, No. 345, had 69 per cent of the reciprocating parts balanced, and was so rough at high speed that many parts of the locomotive were being continually shaken loose, thus disproving the rule requiring about two-thirds of the weight of the reciprocating parts to be balanced. This locomotive also had $\frac{1}{447}$ of its total weight unbalanced, which also disproves the second method of calculation.

Three more of these locomotives, Nos. 346, 341 and 347, were counterbalanced with 64 per cent, 55 per cent and 48 per cent, respectively, of the weight of their reciprocating parts balanced, which was $\frac{1}{385}$, $\frac{1}{308}$ and $\frac{1}{266}$ part, respectively, of their total weight unbalanced. The best riding of these locomotives was No. 341, with 55 per cent or a little more than half of the weight of its reciprocating parts balanced. But this locomotive had too much fore and aft motion at moderate speed, due to the very heavy reciprocating parts. This fore and aft motion, however, was largely absorbed at the higher speeds, and a considerable vibration, due to the vertical forces of the overbalance, took its place; showing that, with such heavy reciprocating parts, even as low a portion as 55 per cent was too much overbalance for high speed. No. 347, with 48 per cent balanced, was not so bad in its vibrations at high speed, but had an excessive fore and aft motion at the moderate speeds.

The test of No. 345, therefore, with 69 per cent of its heavy reciprocating parts balanced as mentioned above, shows that it is the overbalance which makes a locomotive rough at high speeds, rather than too great an amount of the weight of the reciprocating parts left unbalanced. In other words, the fore and aft or nosing effect of unbalanced reciprocating parts seems to become absorbed, in passing through the moderate speeds, and the overbalance then becomes the disturbing factor at the higher speeds in setting up excessive vibration.

Locomotives 342 and 301, having lighter reciprocating parts and with 72 per cent balanced, seem to be well proportioned to prevent fore and aft movement, but the large percentage of overbalance necessary to accomplish this makes them rough at very high speed.

It will be noted that locomotives 341 and 301, which ride very much the same at high speed, have $\frac{1}{308}$ and $\frac{1}{268}$ part, respectively, of their total weight unbalanced; showing that this method of calculation is not reliable for the higher speeds. It will be noted, also, that the dynamic augment for these two locomotives is about the same.

It would therefore seem, from the above results, that the riding of a locomotive at high speed can be greatly improved

*The dynamic augment varies with the stroke.
If W = overbalance or excess weight at stroke distance.

then	with	18-in.	stroke,	dynamic augment = 29.1 × W	at	diameter-speed.
then	with	20-in.	stroke,	dynamic augment = 32.3 × W	at	diameter-speed.
then	with	22-in.	stroke,	dynamic augment = 35.5 × W	at	diameter-speed.
then	with	24-in.	stroke,	dynamic augment = 38.5 × W	at	diameter-speed.
then	with	26-in.	stroke,	dynamic augment = 41.7 × W	at	diameter-speed.
then	with	28-in.	stroke,	dynamic augment = 44.9 × W	at	diameter-speed.
then	with	30-in.	stroke,	dynamic augment = 48.4 × W	at	diameter-speed.
then	with	32-in.	stroke,	dynamic augment = 51.7 × W	at	diameter-speed.
then	with	34-in.	stroke,	dynamic augment = 54.9 × W	at	diameter-speed.

cating parts can be left unbalanced, the counterbalancing of 345 was changed to 30 per cent balanced and 70 per cent unbalanced, which, for these very heavy reciprocating parts, represented excessive conditions, shown by the fact that as much as $\frac{1}{498}$ of the total weight of the locomotive was unbalanced, instead of $\frac{1}{400}$ as per the former rule. This locomotive had excessive fore and aft movement, too great for service even at low speed, but had no perceptible vibration due to vertical forces at high speed.

A second test was made with the 301, with 50 per cent of the weight of the reciprocating parts balanced, which was equal to $\frac{1}{341}$ part of the weight of the locomotive. This gave better results that any of the tests with locomotive having the heavier reciprocating parts.

We can conclude from the above tests that the lighter the reciprocating parts can be made, the better results will be obtained. We can also conclude, when counterbalancing for very

Therefore: 15,000 lb. dynamic weight is added to the 30,000 lb. static weight, giving a total of 45,000 lb. on the rail.

The dynamic augment may be expressed in percentage of the static weight on one driving wheel. These static weights, dynamic augments and percentage increases in weights are given as illustrations in connection with tests shown, where it will be seen that the percentage increase varies from 32 per cent to 72 per cent. The committee, however, believes that 50 per cent increase in the static weight on the driver at diameter-speed would represent good average practice, while much less than this percentage is greatly to be desired.

The committee concludes, therefore, that the secret of proper counterbalancing for any class of locomotive in any service is to reduce the weight of the reciprocating parts as far as possible.

Great benefit will be obtained if the railroads will determine the maximum load that they can carry on the rails, bridges, etc., and then reduce the weight of the reciprocating parts to a point

high speed, that a larger portion of reciprocating weights can be left unbalanced than has been the practice.

CONCLUSIONS.

A simple counterbalancing rule expressed in general terms, which should give good average results when applied to any class of locomotives in any service, might be stated as follows: Keep the total weight of the reciprocating parts on each side of the locomotive below $\frac{1}{400}$ part of the total weight of the locomotive in working order, and then balance one-half the weight of the reciprocating parts.

The above general rule is based upon diameter-speed, and should keep the dynamic augment well within the limits of good practice. Where the normal speed is regularly considerably below the diameter-speed, it may be desirable to increase the proportion of the reciprocating weights to be balanced, to as much as 60 per cent or 65 per cent.

Another counterbalancing rule is, to set an arbitrary percentage which the dynamic force of the overbalance will be allowed to increase the static weight; for example:

If it is desired that the dynamic force of the overbalance at diameter-speed should not increase the static weight on a wheel more than 50 per cent, calculation could be made as follows:

4-4-2 type locomotive with 26-in. stroke.
Given: Static weight on one wheel = 30,000 lb.
To find: Maximum permissible weight of reciprocating parts to be balanced in one wheel = W.

$$W = \frac{\text{50 per cent static weight on one wheel} \times .312}{\text{Crank radius in inches.}}$$

$$W = \frac{15{,}000 \times .312}{13} = 360 \text{ lb.}$$

Therefore: The total reciprocating weight to be balanced on one side of this locomotive would be 720 lb. And with 50 per cent of the total reciprocating parts balanced on one side, the total weight of these parts must be designed to weigh 1440 lb.

where the dynamic augment of the parts balanced will be only a small proportion of this maximum allowed load.

Special designs of piston heads, cross-heads, hollow piston rods, and the use of high-grade materials, including heat-treated carbon and alloy steel, aluminum, etc., make it possible to construct very light parts, the expense of which will be many times justified by the consequent saving in repairs to equipment and track, as well as the saving due to the increase in tractive power of the locomotives. With a refinement of design along these lines, it is altogether possible to construct reciprocating parts approaching in lightness $\frac{1}{240}$ part of the total weight of the locomotive in working order, instead of $\frac{1}{160}$ part as expressed in the previously mentioned general rule representing a fair average. With an increased tendency toward these very light parts, the percentage of narts balanced or unbalanced becomes less and less a factor. Greater efficiency is thus given to the locomotive, in that more and more of the weight allowable on the rail will be used in starting and pulling the train.

The committee wishes to acknowledge its indebtedness to members of this Association, and others, who have furnished data; to the *Railway Age Gazette*, for the use of data contained in an article published therein by H. A. F. Campbell; and to George R. Henderson, who kindly offered his services to the committee; all of which assisted greatly in the preparation of this report.

The report is signed by:—S. G. Thomson, (P. & R.) Chairman; S. M. Vauclain, (Bald. Loco. Wks.); F. J. Cole, (A. L. Co.); John Purcell, (A. T. & S. F.); W. H. V. Rosing, (S. L. & S. F.); O. C. Cromwell, (B. & O.), and T. W. Heintzleman, (So. Pac.).

DISCUSSION

M. H. Haig, (A. T. & S. F.): Much of the information in the report bears on the reduction of weight of the reciprocating parts. Reference to light parts makes the strength of material a pertinent factor in the discussion of this

same time prevent engine failures requires that the material must be durable. Reference was made to the light parts in the locomotives built in 1914. Some locomotives built in that year have already had some of their parts break, and it would be interesting if we could find out to what extent there have already been breakages of the parts of some of the other engines, no doubt investigated by this committee. Many locomotives delivered by the builders are required to be re-counterbalanced after they have reached the various railroads. I know it to be a fact that some locomotives which have been re-counterbalanced according to the two-thirds method have given much more satisfactory results after having been re-counterbalanced according to that method. Because of my experience along that line it does occur to me that balancing only one-half of the weight of the reciprocating parts is too little.

William Elmer (Penn.): The committee recommends the application of the counterbalance at a point directly opposite the crankpin. It is my understanding that in some quarters it is the practice to slightly advance the counterbalance, so that it is not at a point directly opposite the crankpin.

C. D. Young (Penn.): We have a large number of high speed passenger engines in which the relation of the weight of the locomotive to the weight of the reciprocating parts is 230. In order to obtain as high a figure of the weight of the locomotive to the weight of the reciprocating parts, I believe it is necessary to heat treat the reciprocating parts. On these engines the piston rods are hollow, the pistons are rolled steel, the cross heads are made light by the use of electric cast steel, there is a hollow crankpin, and the lever is attached directly to the crankpin, with the union member attached. These have been in service now almost two years and we have not received in our department a record of any broken parts so far. There is a great deal of lightening accomplished by design, of course, in that hollow rods and pins are used, and a design of crosshead was used which was very light for its bearing area. I believe that the members can very safely lighten up the parts both by design and material, if the material is closely supervised when it is being treated.

J. E. Pilcher (N. & W.): I have in mind an investigation I made some years back of a peculiar knock that occurred on an engine in which the reciprocating parts were very heavy. In making the investigation the curve of the piston load was plotted from indicator cards, a definite speed and a corresponding pressure curve for the reciprocating parts was laid out, and we discovered for the first three inches in the stroke at that particular speed, the crankpin was pulling the reciprocator parts. That is, the curves crossed at 3 in. of travel. That illustrates the effects of the very heavy reciprocating parts and the necessity for reduction. Of course that is an example of how not to do it.

Mr. Thomson: I think any type of locomotive today could be designed without spending very much money in refinements and stick to the 1-180th part of the locomotive for the total weight of the parts, but the committee thought, to be very conservative in that matter, they would simply figure it 1-160th, to represent good average conditions. The figures vary on freight built locomotives, built before 1904, from 203 down to 144, and after 1904 from 199 to 134. Now, anybody building a freight locomotive with the reciprocating parts weighing 1-134th part of the locomotive is going to have trouble regardless of how much they balance it. Those figures will not require exceptionally light parts and the use of very high grade material. When you get up to 1-240 then you do have to use high grade, heat treated material, and have to resort to the very best designs. But I believe it can be done, and done very profitably to the railroads.

I do not think the matter of heat treated parts or the cost should have entered our heads, because it is a matter of a few dollars, and it will pay for itself the first two or three years you bring it into the shop. The contention about our not being able to get results with heat treated steel and the refinement of parts I do not think should be considered. In regard to the knock that some people will find in an engine, this is not always due to the counterbalancing. There are a great many other things that make an engine rough, besides faulty counterbalance. If the weights are less, the engine will be very rough, and the higher the speed the worse it will be. The question of preadmission and cushioning the parts are all very pertinent to the subject, and it resolves itself back again to the point that the important thing is to make your parts light—that seems to be the fundamental text of the report this year.

ary 1, 1913. Summarized, it shows electrification on parts of 14 steam railroads, to the extent of 591.3 route miles, including 1761.65 miles of track.

All of the members of the committee making this report are responsible for the maintenance of electric equipment on steam railroads and four of them acquired their experience in the steam motive power department. In general, the committee considers that experience in maintaining steam equipment is the best possible training for the new responsibilities, about the only additional requirement being an ability to understand and use intelligently the necessary electrical terms. This is not difficult.

A study of the plans of shops designed and built by two steam railroads especially for the maintenance of their electric equipment shows that they are equally well adapted to the repairs of either steam or electric equipment; and of the tools used almost all are necessary for the maintenance of steam equipment alone. This should convince the most skeptical that no master mechanic who is successfully maintaining steam rolling stock need hesitate to undertake the maintenance of electric equipment.

In connection with the experience with electrification, the following list shows the additional tools which were found neces-

C. H. Quereau
Chairman, Committee on Maintenance and Operation of Electrical Equipment

sary for handling the electric equipment at one shop which was originally equipped only for the maintenance of steam equipment:

One 190-ton portable hydraulic press for removing crank pins from discs, and discs from motor shafts.

A hook for lifting the front end of the locomotive.

A lifting beam for motors. It is necessary to have a lifting beam for removing and replacing motors.

A lifting beam for removing and replacing cabs.

A special chuck for boring jack shaft and motor bearings.

A tension device for re-bending armatures. The armatures are all bended on a driving wheel lathe, and this machine is placed conveniently in order to maintain a constant tension on the banding wire, the tension being indicated on a scale in pounds.

An insulation testing transformer consisting of a 3-kw. transformer mounted on a truck with voltmeters for testing from 200 to 6000 volts, and is used for testing armatures and fields for grounds.

A cradle for holding armatures after removing them from the locomotives when it is not necessary to work upon them.

A feature worthy of note in connection with the maintenance of steam and electrical equipment will be found in the comparatively small machine tools and light cranes installed in electric locomotive repair shops. The reason for this is the relative lightness of the individual parts of the electric locomotives. Another feature is that, on the average, the age of the employees in an electric equipment shop is less than in a steam equipment shop. One reason for this is that the maintenance of electric equipment on steam roads is a comparatively new business, and has been in existence too short a time to have employees grow old in the service.

One might easily assume it is essential the workmen have a rather extensive electrical training, and it is true that a mainte-

road repair shops.

There is this characteristic difference between steam and electric equipment. With steam locomotives it takes about five minutes to locate a defect and from a day to a week to make repairs; with electric equipment it takes an hour or two to locate the cause of the trouble and from five minutes to a day to repair the defect.

At the time of introduction of electric operation on any railroad, the usual plan is to qualify the regular steam locomotive engineers and firemen for service on the electric locomotives. A few days' instruction by a qualified traveling engineer and a few trips over the road under his supervision are sufficient. To those without the experience, this statement may appear fanciful, but as a matter of fact it may be accepted without question.

A little consideration will convince even the most skeptical that a knowledge of the Book of Rules, the significance of signals and train orders, experience in handling the air brakes and an intimate knowledge of the territory constitute at least nine-tenths of the qualifications of an efficient engineman. These are

under three headings: "Man Failures," "Electrical and Mechanical." The headings "Electrical" and "Mechanical" are self-explanatory. The other heading "Man Failures" is intended to cover failures of equipment which are due to the men operating it.

The report is signed by:—C. H. Quereau (N. Y. C.), Chairman; G. C. Bishop, (L. I.); G. W. Wildin, (N. Y., N. H. & H.); J. H. Davis, (B. & O.), and R. D. Hawkins, (G. N.).

DISCUSSION

G. W. Wildin (N. Y. N. H. & H.): We think we have about the best electrical repair shop in the United States for electric locomotives. Of course, there is in our shop some very peculiar machinery designed especially for the peculiar equipment we have on that road—I presume we have the most complicated electrical equipment there is in the United States—and for that reason perhaps we do not make as many miles per detention as some of our neighbors, but you must realize that we have both the alternating and direct current equipment to contend with, and we have more trouble in the changing over from

the same for electric and steam operation. The operation of electric equipment is much simpler than for steam locomotives. The motorman does not have his vision blinded or confused by smoke or steam, coal dust or ashes; his attention is not distracted by watching the steam gage or water glass, or instructing his fireman in his duties, nor is he bothered by balking injectors, ash pans or leaky flues. There are, of course, no stops for coal and water and there need be no long wait between trains for cleaning fires or ash pans.

Numerous statistics relating to electrically operated roads have been published, including the cost of labor and material expended in repairs, and to the efficiency of the apparatus and the maintenance methods as shown by the number of delays. Several of these statements use as a basis for judging the efficiency of the equipment and its maintenance the unit "Miles per Detention," and also the unit "Miles per Minute Detention," but the majority of the statements published do not show the former item. For the operating officials the unit "Miles per Minute Detention" is of decided value, but this is not the proper basis on which to judge the efficiency of the apparatus nor of the force that maintains it, because the length of the delay is affected in most cases more by operating conditions than by the nature of the failure originally causing it.

alternating current to direct current than in any other one particular feature of our operation, which would not happen if we had either system pure and simple. For the benefit of the steam men who have not had any more electrical experience than I had when I took hold of the New Haven system eight years ago, when it was just in the infancy of the electrification, I will say that we have seen many bugs picked out of that system, and we have been good missionaries for the rest of the steam lines which have got to come to electrification in some sense or another, and I will say that those men who are going up against electrification in these days are not justified in approaching the subject with that fear and trembling which was common some years ago. There is no reason why a man who is used to putting together two pieces of steel should not be able to put together two pieces of copper and put them back just as he found them before—there is no great complication to it, and it is merely a matter of keeping the apparatus in working order.

We should first define what is going to be a detention. There is no use in saying we shall have so many miles per detention, unless we define whether the detention is to be one minute, two minutes, or five minutes as the period. Mr. Quereau has already, apparently, adopted two minutes as the period. Another man who

The committee feels that the following table expresses the maximum fiber stresses which should be used in heat-treated carbon and alloy steel materials for forgings, and therefore presents it to the Association as information, suggesting that it be submitted as Recommended Practice:

	Heat-Treated Carbon.		Alloy.	
	Tension and Compression.	Bending.	Tension and Compression.	Bending.
Main and parallel rods.....	10 000	14 000	12 000	17 000
Piston rods	11 000	15 000	13 500	18 000
Driving axles	.....	20 000	.....	24 000
Crank pins	.....	17 000	.....	20 000

The committee prepared a specification for alloy steel forgings of the chrome-nickel type. After consideration of the criticisms of this specification, and of the quenched and tempered carbon steel and alloy steel (chrome-vanadium type) specifications, the committee recommends the following:

(a) That the present standard specifications for quenched and tempered carbon steel axles, shafts and other forgings for locomotives and cars, be modified in accordance with the proposed specifications for quenched and tempered carbon steel forgings as submitted in Exhibit *A*. This in order to harmonize this specification with our alloy steel specifications and also include a recommended proof test.

(b) That the present specifications for alloy steel forgings, be modified as submitted in Exhibit *B*. This change consists

C. D. Young
Chairman, Committee on Forging Specifications

in adding to the present alloy steel specifications for chrome-vanadium, a chrome-nickel alloy and also a recommended proof test.

The report is signed by:—C. D. Young (Penn.), Chairman; A. H. Fetters (U. P.); H. B. MacFarland (A., T. & S. F.); J. R. Onderdonk (B. & O.); H. E. Smith (N. Y. C.); J. W. Taylor (Sec.), and Frank Zeleny (C., B. & Q.).

The principal difference between Exhibit *A* of the committee's report and the specifications referred to are in the chemical composition and the proof test. The chemical composition presented by the committee follows:

Chemical Composition.—The steel shall conform to the following requirements as to chemical composition.

Carbon	First class	0.38 —0.52 per cent.
	Second class	0.45 —0.60 per cent.
Manganese		0.40 —0.70 per cent.
Phosphorus		not over 0.05 per cent.
Sulphur		not over 0.05 per cent.

A paragraph was added under proof tests as follows:

(b) A recommended test for axles, shafts and similar forgings is as follows: Place the forging upon supports 3 ft. apart mounted on an M. C. B. drop test machine. The forging should then be struck two blows by a tup weighing either 1640 or 2240 lb. falling from heights proportioned according to the follcenter in inches.

Diameter of Shaft at center, inches.	Height of drop in feet. 1640-lb. tup.	2240-lb. tup.
5	1 ft. 3 in.	0 ft. 11 in.
5½	1 ft. 8 in.	1 ft. 3 in.
6	2 ft. 2 in.	1 ft. 7 in.
6½	2 ft. 9 in.	2 ft. 0 in.
7	3 ft. 5 in.	2 ft. 6 in.
7½	4 ft. 3 in.	3 ft. 1 in.
8	5 ft. 1 in.	3 ft. 9 in.
8½	6 ft. 2 in.	4 ft. 6 in.
9	7 ft. 3 in.	5 ft. 4 in.
9½	8 ft. 7 in.	6 ft. 3 in.
10	10 ft. 0 in.	7 ft. 4 in.
10½	11 ft. 7 in.	8 ft. 5 in.
11	13 ft. 4 in.	9 ft. 9 in.
11½	15 ft. 3 in.	11 ft. 3 in.
12	17 ft. 3 in.	12 ft. 7 in.
12½	19 ft. 5 in.	14 ft. 3 in.
13	22 ft. 0 in.	16 ft. 0 in.
13½	24 ft. 7 in.	18 ft. 0 in.
14	27 ft. 5 in.	20 ft. 0 in.
14½	30 ft. 6 in.	22 ft. 3 in.
15	33 ft. 9 in.	24 ft. 8 in.

NOTE.—The above heights are to the nearest inch.

The changes presented in Exhibit *B* are likewise in the chemical composition and in addition to the proof tests. The chemical composition is as follows:

Chemical Composition.—The steel shall conform to the following requirements as to chemical composition.

	Chrome Nickel.	Chrome Vanadium.
Carbon	0.28—0.42 per cent.	0.28—0.42 per cent.
Manganese	0.40—0.70 per cent.	0.40—0.70 per cent.
Silicon	0.10—0.30 per cent.	.....
Phosphorus, not over.....	0.05 per cent.	0.05 per cent.
Sulphur, not over.....	0.05 per cent.	0.05 per cent.
Chromium	0.60—1.00 per cent.	0.75—1.25 per cent.
Nickel	1.00—1.50 per cent.	.....
Vanadium, not under.....	.....	0.15 per cent.

[The addition to the proof tests is the same as given in Exhibit *A*.—Editor.]

DISCUSSION

C. D. Young: I move that the recommendations of the committee be submitted to letter ballot as recommended practice.

(The motion was carried.)

A. R. Ayers (N. Y. C.): Under Class *A* in the specifications for alloy steel forgings the committee includes piston rods which are subject to requirements of 10,000 lb. per square inch, less than axles, crank pins, etc. My recollection is that that was worded that way in the original alloy steel specifications, and was later corrected, so as to put piston rods in Class *B*, to get the benefit of the heavier requirements. It is not evident why piston rods should not be subject to just as good treatment as axles, and I would ask if there would be any objection to putting piston rods under Class *B*, with axles?

C. D. Young: Class *B* says "and other forgings." It was the thought of the committee, I believe, at the time this was discussed, that it might be well to keep piston rods, especially those which are hollow bored and forged, under Class *A*, and if desired they could be included as "other forgings" under Class *B*. I see no objection in specifically mentioning piston rods in both classes—the classes must take care of themselves by the expression of what they are supposed to cover.

BOILER WASHING

The committee in its endeavor to ascertain the general practice of washing locomotive boilers sent out a letter requesting answers to 20 questions. From 118 letters sent out replies were received from 93, representing 51,294 locomotives. The information received is summarized as follows:

2. Miles Made between Wash-outs.—9760 engines make less than 500 miles. 11,283 engines make over 500 and less than 1000 miles. 8312 engines make over 1000 and less than 1500 miles. 20,472 engines make over 1500 miles. 2467 not replying or unable to furnish information. The passenger locomotives make 30 per cent greater mileage between wash-outs than freight engines.

3. Water Changes.—Only about 5 per cent of the roads in the country practice changing water in the boilers.

4. Blowing Out at Terminals.—About 15 per cent practice some regular system of blowing boilers at terminals. About 35 per cent of the engines are blown out regularly and systematically while on the road to remove mud or sludge that may have accumulated in the boiler, and to prevent foaming.

5. Wash-out Holes in Boilers.—The maximum number of wash-out plugs reported in a boiler was 52, with a minimum of ten, or an average on all modern power of 32.

cold water.

7. Boiler Washing Pressure.—The average boiler washing pressure at the pump or line was 96 lb. and about 72 lb. at the nozzle.

8. Hot Water System for Washing Boilers.—Hot water systems were reported as being used on 54 roads, 13 being the maximum number reported on any one road. Some report using injector to heat washing and filling water.

9. Reduction of Water on Account of Hot Water Plants.—The use of hot water for boiler washing plants shows an average reduction in the amount of water used of 3427 gal. or 36 per cent, some roads reporting as much as 9000 gal.

10. Reduction in Amount of Time on Account of Hot Water Plants.—A reduction in time of 1 hr. and 54 min., or 42 per cent.

11. Saving of Fuel on Account of Hot Water Plants.—A saving in fuel of 897 lb., or 36 per cent.

12. Improvement in Performance of Firebox Sheets, Stays, etc., on Account of Hot Water Plants.—All roads except one report a great reduction in boiler troubles, especially as to cracked sheets, leaky stays, etc., or an average reduction in these troubles of 34 per cent.

13. Water-treating Plants.—Thirty-one roads report using water-softening plants at wayside tanks.

14. Treating Water in Engine Tanks.—Forty-five roads report using chemicals in engine tenders, 19 using soda ash and 26 boiler compound.

15. Treatment to Prevent Incrustation.—Seventy-six roads

John Purcell
Chairman, Committee on Boiler Washing

report using boiler compound, soda ash and other chemicals, to prevent incrustation.

16. Treatment to Prevent Foaming.—Twenty-nine roads report using boiler compound or other chemicals to prevent foaming.

17. Treatment to Prevent Corrosion and Pitting.—Very few roads specifically treat water to prevent corrosion, but water treatment as explained in answers to Questions 13, 14 and 15, often prevents corrosion of sheets, flues, etc.

18. Increased Repairs to Packing, Cylinders, etc., Due to Water Treatment.—Seven roads report water treatment increasing repairs to valves and packing, due principally to boiler foaming. Others report no increase in repairs.

19. Increased Mileage Due to Water Treatment.—All roads using water-softening plants report great increase in mileage between flue setting and boiler repairs, some roads reporting as high as 300 per cent. An average increase in mileage of over 100 per cent is given.

20. Experience in Handling Mechanical Water Purifiers.—None of the roads report using mechanical water purifiers. Some report as having experimented in the past, but not using same at the present time.

Rules.—Sixteen of the roads report having regular rules governing the washing of boilers, and the majority report that they comply simply with the Interstate Commerce Commission's instructions as to washing boilers.

In further explanation of the above answers, washing boilers

In explanation of answer to Question 4 in reference to blowing out, while some roads have regular systematic methods of blowing out boilers at terminals, the majority seem to leave it entirely with the engine crew. It has been demonstrated on two or three roads using water which foams badly that with the intelligent use of anti-foaming boiler compound and a liberal use of blow-off cocks, a locomotive could be run 2000 miles or more without foaming trouble. Better results are obtained if the boiler is blown out while not using steam, or after engine has been standing a while.

As to Question 6, the cost of washing boilers, as stated, this question was evidently misunderstood. With the large modern boilers where engines are thoroughly washed, it is evident from this report that this can not be thoroughly done for less than $3.50, where cold water is used, both for cooling down and washing out, and where scraper is used and loose scale removed.

Question 14. Treatment of water in engine tanks.—This practice is more prevalent on divisions where they have one or two bad water stations, the other water on the division being good. All the roads report a great improvement in boiler maintenance where water softening is practiced, either in wayside tanks or where chemicals are used in the engine tenders.

Owing to the great difference in conditions under which locomotives are operated it is felt that the subject can be successfully treated only in a general way, and the following method of washing boilers is given at this time as being a good general practice:

METHOD OF WASHING BOILERS.

Frequency of Washing.—All locomotives in service must have boilers washed at least once every thirty days, or more frequently if conditions require.

Cooling Boilers.—Boilers should be thoroughly cooled before being washed, except at points where improved hot water washout systems are installed. When boilers are cooled in the natural way without the use of water, the steam should be blown off, but the water must be retained above the top of the crown sheet and the boiler allowed to stand until the temperature of the steel in the firebox is reduced to about 90 deg., or so that it feels cool to the hand; then the water is drawn off and the boiler washed. When the engine can not be spared from service sufficiently long for it to be cooled in this manner before washing, proceed as follows:

Use of Injector for Cooling Boilers.—When there is sufficient steam pressure, start the injector and fill the boiler with water until the steam pressure will no longer work the injector. Then connect water-pressure hose to feed pipe between the engine and tender and fill the boiler full, allowing the remaining steam pressure to blow through the syphon cock or some other outlet at the top of the boiler. Open blow-off cock and allow the water to escape, but not faster than it is forced in through the check, so as to keep the boiler completely filled until the temperature of the steel in the firebox is reduced to about 90 deg.; then remove all plugs and allow the boiler to empty itself.

How to Wash a Boiler.—Remove all wash-out plugs. Begin washing through the holes on the side of the boiler opposite the front end of the crown sheet. Wash the top of the crown sheet at the front end, using Nozzle No. 1 or 2. Then use Nozzles 3 and 4 to wash between the rows of crown bars and bolts at right angles to the nozzle, directing the stream toward the back end of the crown sheet. After washing through the holes near front end of the crown sheet, use the holes in their respective order toward the back of the crown sheet. The object of this method is to work the mud and scale from the crown sheet toward the side and back legs of the boiler and prevent depositing it on the back ends of the flues.

Washing Crown Sheet.—Next wash the crown sheet from the boiler head, using Nozzles 1 and 3 or 6. When Nos. 3 or 6 are employed, the swivel connection with the hose should be used and the nozzle should be inserted to the front end of the crown sheet and slowly drawn back and revolved at the same time, so as to wash the top of the boiler and all the radial stays or bolts as well as the crown sheet.

Washing Flues.—Wash the back end of the flues through the holes in the connection sheet, using Nozzles Nos. 1, 5 and 6, and revolve them by means of a swivel connection when the curved nozzles are used. The same nozzles are to be used and the same system followed when washing any part of the flues or feed-water heater flues.

Washing Back Head Water Spaces.—Wash the water space between the back head and the firebox door sheet through the holes in the back head with Nozzle No. 6, being careful to remove all scale and mud above and below the fire-door hole.

Washing Arch Tubes.—Arch tubes must be washed and scraped

liable to pull out or explode. Therefore a locomotive should not be allowed to leave a terminal with dirty arch tubes, and all concerned are instructed to strictly comply with the rule.

NOTE.—The condition of an arch tube as to scale on the water side can readily be determined by the presence of clinker adhering on the fire side.

Washing Side-sheet Water Spaces.—Now return to the holes on the side of the boiler opposite the crown sheet, using Nozzles 5 and 6, and revolve them so as to thoroughly wash down the side sheets and staybolts, making sure that all spaces on the side of the firebox are clear of mud and scale. Then wash through the holes near the check valves near the front end of the boiler, using Nozzles 1 and 5 or 6, with a swivel connection.

Washing Barrel or Boiler.—Then wash through the hole in the bottom of the barrel of the boiler near the rear end, and wash toward the front end. If the engine has no mud drum, wash toward the throat sheet with Nozzles 5 or 6. Then use the straight nozzle directly against the flues, reaching as great a space as possible in all directions. Then use the bent nozzle through the front hole in the bottom of the barrel, and also the straight nozzle in same manner as above, until certain that the flues and spaces between the flues and the barrel are as clean as it is possible to make them.

Washing Mud Ring.—Then use Nozzles Nos. 5 and 6 in the side and corner holes of the water legs, revolving them thoroughly to clean the side sheets, and finally clean off all scale and mud from the mud ring by means of straight nozzles in the corner holes.

Inspection after Washing.—It must not be assumed that because clear water runs from the holes that the boiler is cleaned, but all spaces must be examined carefully with a rod and light, and, if necessary, use a pick, steel scraper or other tools, to remove accumulated scale.

Filling Boilers.—When cooling and filling boilers, they must be filled through the injector check. The injector steam pipe valve at the fountain must be closed. Filling up boilers through blow-off cocks will not be permitted except at hot water boiler washing plants and when hot water is being used.

Fig. 1 shows the nozzles referred to above. Experience shows that wash-out nozzles should be smooth and constructed so as to throw a solid stream out of a 5/8-in hole with 100 lb. pressure back of it for a distance of 10 or 12 ft., which gives a very effective washing force. The aim is to have 100 lb. pressure at the nozzle, which can usually be had by having 125 lb. at the pump; this varies somewhat according to pipe lines. Fig. 2 shows a scraper and an oil and electric inspection torches.

Fe hot water wash-out plants. Their figures show, with the cold water wash-out system (not including overhead charges), a cost of $4.42 to handle a modern locomotive boiler; this includes cooling from 100 lb. steam pressure, emptying, washing, filling, firing up and raising the steam pressure to 100 lbs., also the cost of water and fuel. It requires not less than 5 hours' time for the operation, while with the hot water system a boiler can be emptied, washed, filled, fired up and steam raised to 100 lb. pressure for $3.01, including the cost of water and fuel. A saving of $1.41, and a reduction in time of about 1½ hours for each engine.

The operation of changing water in a boiler with the cold water plants costs $3.54, with the hot water plants $2.13, a water change being only 88 cents cheaper than a wash-out with either system. The following is a detailed statement of the various items involved:

COST OF BOILER WASHING, COLD WATER WASHING SYSTEM.

A modern boiler, 100 lb. steam; 4 in. of water in glass.

Cooling to 90 deg. F., cooling water 57 deg. F., 9000 gal. at 4 cents per 1000 gal.	$0.36
Time cooling and draining boiler 2 ft. 30 in. at 20 cents per hr., one man	.50
Removing and replacing plugs, two men, 30 min., 40 cents per hr.	.20
Washing boiler, two men, 1 hr., at 40 cents per hr.	.40
Water used washing boiler, 3000 gal. at 4 cents per M. gal.	.12
Water used filling boiler, 4000 gal. at 4 cents per M. gal.	.16
Time filling boiler, 45 min., 1 man at 20 cents per hr.	.15
Laying fire bed, 1000 lb. coal, 10 cents per 100 lb.	1.00
Additional fuel to raise steam to 100 lb. boiler pressure, 1100 lb.	1.10
Time of fire builder, 45 min.	.15
Add 20 per cent. to time of men for changing tools from engine to engine	.28
Total	$4.42

COST OF BOILER WASHING, HOT WATER WASH-OUT SYSTEM.

A modern boiler, 100 lb. steam; 4 in. of water in glass.

Blowing steam and water out of boiler, one man, 1 hr.	$0.20
Removing and replacing plugs, two men, 30 min., 40 cents per hr.	.20
Washing boiler, two men, 1 hr at 40 cents per hr.	.40
Water used washing boiler, 3000 gal., 4 cents per M. gal.	.12
Water used filling boiler, 4000 gal., 4 cents per M. gal.	.16
Time filling boiler, 45 min., one man at 20 cents per hr.	.15
Laying fire bed, 1000 lb. coal, 10 cents per hundred	1.00
Additional fuel to raise steam to 100 lb. boiler pressure, 500 lb. at 10 cents per 100 lb.	.50
Time of fire builder, 30 min., at 20 cents per hr.	.10
Add 20 per cent. to time of men for changing tools from engine to engine	.18
Total	$3.01

The saving in water and fuel of the hot water over the cold water system depends on how well the hot water plant is oper-

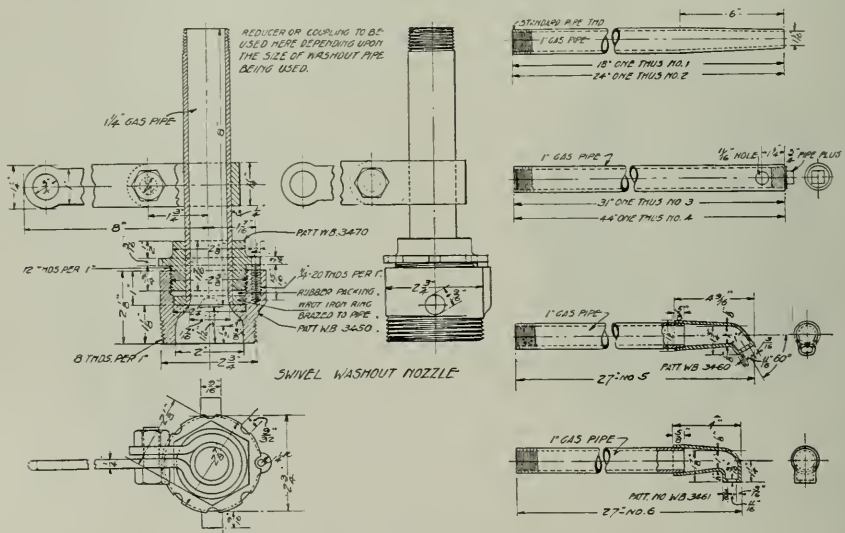

Fig. 1.—Nozzles for Washing Locomotive Boilers

water as much hotter as it can be obtained without the use of live steam. Reservoirs of ample capacity should be provided to conserve heat which may be collected from various sources, other than that blown out by locomotives and which can profitably be applied in heating the washing or filling water for locomotive boilers.

The Central of Georgia reports making some tests on cost saving and time saving on boiler washing with hot water washout systems as compared with cold water. These tests were followed up accurately by the testing engineer, with watch, actual weights on fuel, and actual consumption of water by use of meter. The saving in boiler maintenance and repairs, as well as flue and firebox failures on the line of road, shows a decided improvement when engines are washed with the mechanical hot water system as compared with cold water system. For instance, on this road, with average water conditions, since installing hot water washing outfit the life of the flues has been practically doubled. The life of fireboxes, staybolts and boiler sheets shows a material improvement. Failures on account of leaky flues and fireboxes have been practically eliminated, and, last but not least, the mileage of engines between wash-outs has been doubled. Under these circumstances the saving in boiler and flue repairs is, conservatively, $200 per locomotive per year, with the hot water system as compared with cold water. In the bad water districts these figures would show considerable increase. With the outfit at the Macon engine-house piped to 17 pits, it is necessary to only wash out two engines per day to show an actual money saving on the investment of 5.7 per cent. An outfit for average small enginehouse could be installed for $7500.

ing, min.	25	25½	27
Total number of engines filled	174	222	223
Average temperature of filling water, degrees	210	207¼	211
Average time taken per engine in filling, min.	26	24⅓	24¾
Total number of engines fired up	189	217	218
Average time taken per engine in firing up to 100 lb. steam, min.	46	43	41
Average extra consumption of water per boiler washed out, gal.	No record.	1753⅓	1732⅔

The condition under which these tests were made require that all the blow-off water from the locomotive boilers be utilized again for washing and refilling. This plant has been in service one year and no live steam has ever been used for heating water. The cost of boiler washing with this system is approximately as follows:

AVERAGE COST OF BOILER WASHING—HOT WATER SYSTEM.

Blowing steam and water out of boiler	1 man, 15 min.	@ $0.22	$0.055
Remove and replace plugs	2 men, 30 min.	@ .22	.220
Washing boiler	2 men, ½ hr. ea.	@ .22	.220
Water used washing boilers	1 500 gal.	@ .08	.120
Water used filling boiler	No charge.		
Time filling boiler	1 man, 30 min.	@ .22	.110
Laying fire bed, 1 000 lb. coal (Bit.)		@ 2.00 net	1 000
Additional fuel to raise steam to 100 lb. pressure 500 lb. (Bit.)		@ 2.00 net	.500
Time of fire builder	1 man, 45 min.	@ .175 hr.	.131
			$2.356

This road reports that this plant is very economical and that nothing has been spent for repairs to the plant during the past year. The plant has a total water capacity of 60,000 gal., 30,000

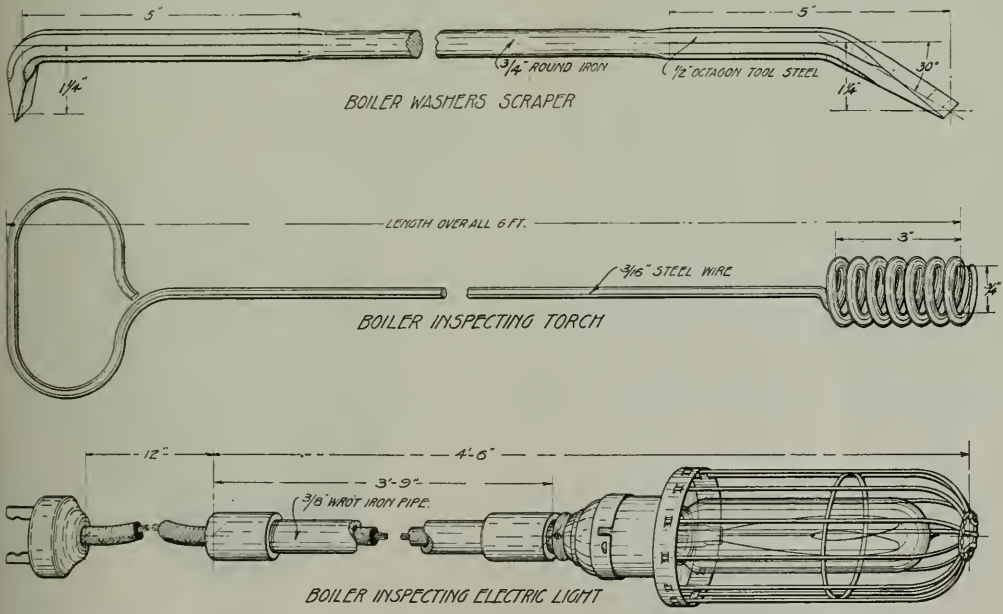

Fig. 2.—Scraper and Inspection Torches for Washing Boilers

There is in operation at the Communipaw roundhouse, of the Central Railroad of New Jersey, at Jersey City, N. J., a Winter's boiler wash-out plant. The plant consists of two standard 3-in. cypress tanks, one submerged within the other. The outside tank forms the hot well in which the locomotives are blown off; the inside tank contains the water for refilling. The following data indicate results of tests made at this plant from September 1, 1914, to November 30, 1914:

	Sept. 1 to 30.	Oct. 1 to 31.	Nov. 1 to 30.
Total number of engines put through plant for any purpose	202	228	226
Total number of engines blown down	179	203	197
Average steam pressure per engine on boiler at time of blowing down, lbs.	103	110	108

gal. of which is in the hot well, 18,000 gal. in the refilling tank, and 12,000 gal. in the cold water storage.

[A copy of the instructions for washing boilers as used by the Pennsylvania Lines was also included.—Editor.]

WATER TREATMENT TO PREVENT INCRUSTATION.

The Santa Fe, which has more water softening plants in operation than any other road, reported: The Santa Fe went into the water treatment in the latter part of 1903, since that time 115 water treating plants have been established. The lowest incrustants before treatment in any water treated is 16.6 gr. per gal. The highest incrustants before treatment is 80.9 gr. per gal. The average cost of water treatment on the Santa Fa is 3¼ cents per 1000 gal. The average amount of incrustants in all waters before

The incrusting matter in boiler waters consists almost entirely of carbonates of lime and magnesia and sulphates of lime and magnesia. The carbonates require treatment with hydrated lime and the sulphates require soda ash. Any system of water softening to be effective must work within certain prescribed limits, such as automatic means of proportioning the correct amount of chemicals to the water should be provided. The water should have not less than four hours' time in which to complete the reaction and settle out the precipitates.

There are two general classes of water softening plants on the market: one known as the "Continuous" and the other as the "Intermittent" system. There are advantages in both systems, but on the whole it is considered that the Continuous system is preferable on account of requiring less floor-space and also less labor and fuel charges for the additional pumping.

There are a number of factors which should be considered when deciding whether or not to build a water softening plant. As a rule little is gained by putting up a single plant here and there over the division. Treatment of only a small fraction of the waters can not possibly result in the preventing of the formation of all scale, and these plants always get the blame for any foaming troubles which arise on that division, whether justly or not.

Soda ash applied in an engine tender has this disadvantage that the water in the engine's tender becomes partly treated and will, with high sulphate, throw down its solids at a reasonably low temperature, and in many cases the temperature of the injector is sufficient to do this and the result is rapid incrustation of injector, injector parts, and connections, and increase of injector troubles. This tender treatment is therefore a very poor substitute for water softening plants, but will to a certain extent relieve the situation on those branch lines where the waters are only moderately hard.

It would be profitable, where much water is used, to treat it when the incrusting solids exceed 12 grains per gallon. This is especially desirable where treated waters may be on both sides of untreated water tanks, for the reason that the incrusting solids in the untreated water, after they are precipitated, greatly add to the sludge and aggravate foaming conditions.

The beneficial results of following water treatment may be approximately shown by the increase in flue mileage between failures on the Santa Fe since the beginning of water treatment in 1903. The mileage between flue failures on the Santa Fe System on account of leaking for the last eight months in 1903 was 17,557 miles. This has shown a steady increase until for the first eight months for 1914 the mileage per flue failure was 168,624 miles.

It is safe to say that water treatment has in many cases increased the life of fireboxes 300 per cent, it being considered that the improvement in the flue performance represents very largely a correspondingly improved performance in firebox sheets.

The report is signed by:—John Purcell (A., T. & S. F.), Chairman; W. H. Fetner (C. of Ga.); J. C. Little (C. & N. W.); W. P. Carroll (N. Y. C.); G. W. Rink (C. of N. J.); E. S. Fitzsimmons (Erie), and G. E. Sisco (Penn. Lines).

DISCUSSION.

W. E. Dunham (C. & N. W.): For those of us who have to deal with particularly bad water conditions, it hardly seems as if it would be necessary to outline a set of rules, as presented here, but that is the fact, and not very long ago we outlined a set of rules very similar to these, and the results obtained from being systematic and thorough in your washing out of boilers, even though you are not equipped with the latest and most expensive requirements of hot water washout plants and all of such details, are all well worth while. I have usually specified that the roundhouse foreman of either the day or night force should inspect the boiler after it was washed out, and by doing that we have been able to eliminate flue failures and fire-box failures where we had them before, and had lots of them. There is only one variation which I found necessary from the plan here outlined, and that is under our local conditions we have found it very necessary to wash from the front of the boiler back through the flues first, and then follow the procedure practically as Mr. Purcell has outlined it here. We have a very heavy accumulation of mud and scale, and we believe it is advisable to get that off of the flues first, and then we finish up with that the last. In other words, we give our flues a double washing, you might say, and we find it pays exceedingly.

D. R. MacBain (N. Y. C.): The importance of good washing out I do not believe would be questioned by any person, excepting it was some superintendent or trainmaster who Association as a text, and I wish to say further that following it in the finest detail outlined you will not be going too far so far as the interest of the company is concerned. I move that the paper be accepted as read, and be submitted to letter ballot as recommended practice

Mr. Dunham: References are made to certain nozzles in the report. If the wording of the outline could be changed so that the nozzles would be designated as a "right angled nozzle" or a "straight nozzle" or something of that kind, it would be of little more general use than the detail shown here. With that change I would second Mr. MacBain's motion.

Mr. MacBain: That is agreeable.

(The motion was carried.)

O. C. Wright (Penna. Lines): I would like to call attention to the boiler inspection electric light. It is shown with a brass socket connected to wrought iron pipe. We have had some experience with a similar inspection light and found that on account of the fact that the lamp was subjected to moisture and mechanical abuse it was almost impossible to keep it free from ground, which makes it a very unpleasant as well as a rather dangerous lamp to handle. We have designed and are using a lamp of very similar construction to this, with a porcelain socket sealed in and attached to a fibre tube. We have gotten very good results from this lamp.

FLANGE AND SCREW COUPLINGS FOR INJECTORS

The committee has endeavored to decide upon standards for flange and screw couplings which can be adopted for locomotive service with the least inconvenience and expense to railroads and manufacturers.

Form and Dimensions of Threads.—Analysis of the statements of the roads which communicated with the committee and co-operation with the injector manufacturers led to the conclusion that a pitch of 10 threads per inch could be adopted as a future common standard with the least expense to all concerned. It was decided that a thread adopted as standard should interchange with either a sharp V-thread or with the U. S. standard thread. A modified form of the U. S. thread will meet this requirement and is suggested as the proposed standard. The form and dimen-

M. H. Haig
Chairman, Committee on Dimensions of Flange and Screw Couplings for Injectors

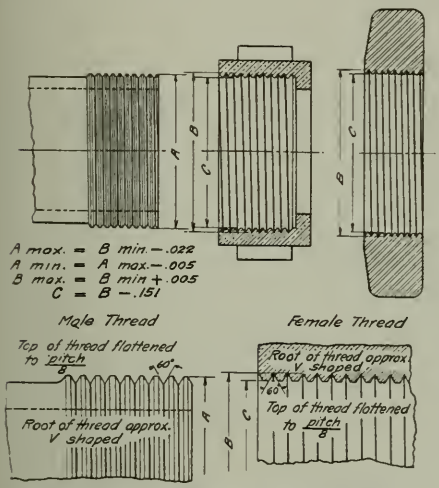
sions of this proposed thread are shown in Fig. 1. These threads are proposed for all injector connections, including the overflow, as well as for all couplings used throughout the injector piping system, whether of the nut or flange type.

Coupling Nuts and Sleeves.—As a result of investigation it is believed that certain sizes of nuts can be selected as standard for certain sizes of iron and copper pipe. On the same principle it is believed that certain sizes of sleeves (collars or tail pieces) can be adopted as standard for use with definite sizes of nuts and pipes. The proposed standard dimensions of these coupling nuts and sleeves are shown in Fig. 2. The proposed standard forms of the nuts and sleeves are shown in Fig. 3.

It is proposed that each manufacturer shall continue the size of

improper handling and to provide against nuts being stretched by tightening or cracked by pounding, the proposed standards include dimensions for greater thickness throughout than found common in past practice. It is proposed that the outside of injector coupling nuts shall be left rough, except in the grooves.

In planning proposed standard dimensions for sleeves, various sizes were considered by which it might be possible to make the sleeves thicker. Making the sleeves thicker than in the past would increase their diameter. This in turn would require a greater diameter of nuts used with given sizes of pipe. Such increases in diameter of nuts would prevent interchangeability with previous equipment where interchangeability between proposed standards and much old equipment would otherwise be possible. With the possible exception of the sleeve for 1½-in. copper pipe it is believed that the sleeves shown for use with copper pipes are of reasonable thickness. Injectors on locomotives in present railroad service are seldom, if ever, equipped with 1½-in. copper pipe. This size, in all probability, will gradually become obsolete. The committee, therefore, does not regard it as of sufficient importance to justify any radical change.



PIPE SIZE INCHES		NOMINAL SIZE OF THREAD INCHES	THDS PER INCH	OUTSIDE DIAMETER OF FLATTENED MALE THD "A"		OUTSIDE DIA OF SHARP "V" IN FEMALE THD "B"	
IRON	COPPER			MAXIMUM INCHES	MINIMUM INCHES	MAXIMUM INCHES	MINIMUM INCHES
1		1 7/8"	10	1.728	1.723	1.755	1.750
1¼	1⅜	2"	10	1.971	1.966	1.998	1.993
1½	1⅝	2 3/8"	10	2.375	2.370	2.402	2.397
1¾	1¾	2 13/16"	10	2.796	2.791	2.823	2.818
2"	2	3	0	3.009	3.004	3.036	3.031
2"	2¼	3	10	3.009	3.004	3.036	3.031
2½	2⅝"	3⅝	10	3.488	3.483	3.515	3.510
3	2⅝, 3⅛	4⅛	10	4.103	4.098	4.130	4.125

Fig. 1.—Proposed Standard Form and Dimensions of Threads for Injector Couplings. Ten Threads per Inch.

Application of Coupling Sleeves.—The committee favors copper pipe extending throughout the full length of the sleeve under all conditions. When the pipe is brazed, its end should be belled out to fill the chamfer shown at upper end of each sleeve for copper pipe in Fig. 1. This application is shown by Fig. 4. Under no circumstances should a sleeve be counterbored for a portion of its length and a copper pipe fitted into this short counterbore and brazed. Another practice to be avoided is that of brazing a short ring on the end of a copper pipe instead of applying a proper sleeve.

A collar 1¼ in. long is considered of ample length with either a mechanical joint or brazing. It is not probable that a longer surface will be thoroughly brazed throughout its entire surface.

The sleeves for use with iron pipes as shown in Fig. 1 are considered of reasonable thickness. It will be observed that the pitch shown in Fig. 2 and the sleeves used with flange couplings

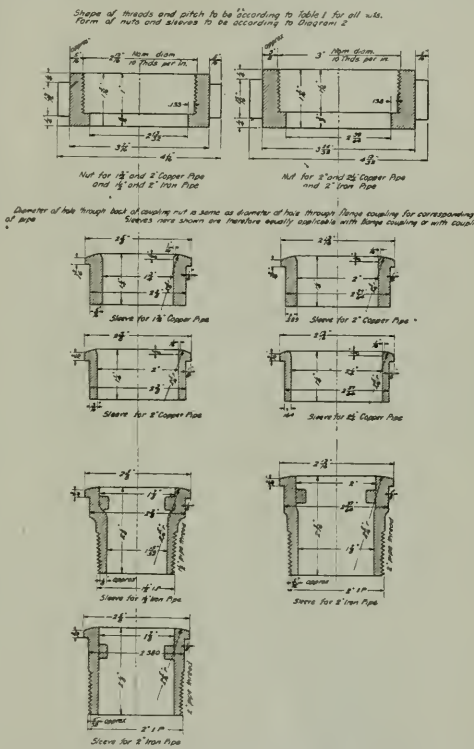


Fig. 2.—Proposed Standard Dimensions of Injector Coupling Nuts and Sleeves

should conform to the dimensions shown in Fig. 1 for the respective sizes of pipe. The dimensions of flange couplings of the different manufacturers have been compared and considered with the dimensions of connections submitted by the various railroads.

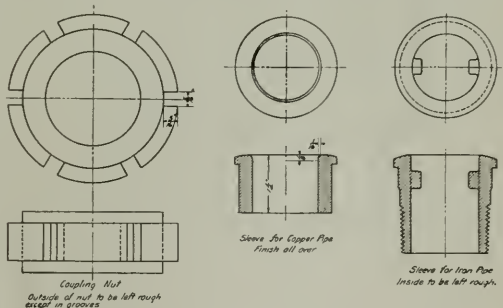

Fig. 3.—Proposed Standard Forms of Coupling Nuts and Sleeves

This investigation has led to the proposed standard form and dimensions of flange couplings shown, Fig. 5. To provide against any possible weakness due to blow holes, porous metal or other defects in cast steel, it is recommended to make the flanges

of forged steel. It is believed that the little additional cost of drop forgings will be justified.

Typical examples were shown of mechanical joints now in service on a few roads to which equipment of dimensions shown in Fig. 5 are applicable with the pipe secured by beading over the end or by brazing. The hole through the flange is of the same diameter as the hole through the coupling nut, and, consequently, fits the same sleeve for a given size of pipe.

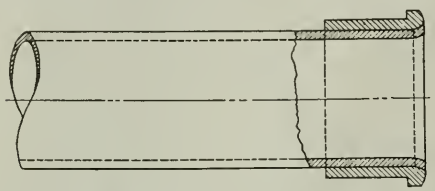

Fig. 4.—Proper Application of Sleeve to Copper Pipe with Brazed Joint

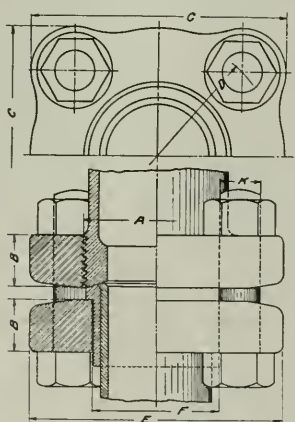
Brazed and Mechanical Joints.—The replies made by the roads to the committee's questions, as well as the prints submitted, indicate a very general use of the brass spanner nut. The most common practice is to braze a brass sleeve to a copper pipe and to screw a brass sleeve to the iron pipe. Of the 36 roads communicating with the committee, 31 report using brazed joints only and 5 report using some joints that are not brazed. Among the 31 are 2 roads which chamfer the end of the sleeve and expand or bell the end of pipe into the chamfer. This supplements the



Material in Flange — Forged Steel

PIPE SIZE INCHES IRON	PIPE SIZE INCHES COPPER	NUMBER OF THREADS PER INCH	NOMINAL DIAMETER OF THREADS INCHES	B INCHES	C INCHES	D INCHES	E INCHES	F INCHES	K INCHES
1¼	1⅜	10	2	3/16	3 5/16	3 5/16	3 5/16	1 3/32	5/8
1½	1⅝	10	2 3/16	1/8	3 5/8	3 5/8	3 5/8	2 5/32	5/8
1 15/16	2 1/16	10	2 7/16	3/16	4 1/4	4	4 1/4	2 23/32	5/8
2	2 1/4	10	3	1/8	4 1/2	4 1/4	4 1/2	2 27/32	5/8

3	2 7/8 3 1/8	10	4 1/8	5/16	5 5/8	5 3/8	5 5/8	3 5/32	3/4

Dimension F of flange coupling is same as diameter of hole through coupling nut for corresponding size of pipe, shown by diagram 1
Sleeves secured by beading over end of pipe are of the same dimensions as those secured by brazing. Equipment of above dimensions are, therefore, applicable with either method of securing pipe.

Fig. 5.—Proposed Standard Form and Dimensions for Injector Flange Couplings

brazing and the roads using it report this practice as quite satisfactory.

The 5 roads which report joints without brazing, extend end of pipe through nipple and bead over the end of pipe so that it forms a ball joint. As to comparison between the brazed and mechanical joints, most of the roads are noncommittal, having had no experience with the mechanical joint. Several of these roads state very definitely that the brazed joints are thoroughly satisfactory and have led to no complaint. With regard to recommending mechanical joints as standard, nine roads definitely vote "no" and two "yes."

Flange Connection as Compared with Spanner Nut.—Twenty-four roads reply definitely "No" to the question as to whether the flange connection is favored in preference to the spanner nut. A road using spanner nuts in connection with lifting injectors and the flange connection with non-lifting injectors, reports both as satisfactory where used. Another comment is worthy of quoting in full: "Have never used flange connection. While it is possible the flange connection would not be as subject to leaks as a coupling nut and nipple, these joints are broken so many times that the ease with which the coupling nut connection can be taken apart we believe outweighs any advantage to be gained with the flange."

Material in Coupling Nuts and Sleeves.—Spanner nuts and sleeves are commonly made of brass. A number of compositions, some more or less alike, were reported by various railroads. The following composition impresses the committee as a satisfactory mixture:

Copper	84 to 86 per cent.
Zinc	4 to 6 per cent.
Tin	4 to 6 per cent.
Lead	4 to 6 per cent.

Spelter.—In brazing, the usual practice of spelter with borax flux is commonly followed. A mixture of fifty per cent copper and fifty per cent zinc seems to be the most commonly used.

Brazing by Oxy-acetylene Process.—A shop of one road reported doing all brazing by the oxy-acetylene process. The reply is quoted, in part, as follows: "Since adopting this practice we have had very good success with it; in fact, have not had one joint leak where it was brazed, and we do not find that it oxidizes the zinc in the brass or causes joint to become porous. We find it saves a great deal of time. In fact, we can braze pipes by this method in five to eight minutes which would otherwise take thirty minutes with charcoal fire. In the eight months that we have been using this process we have not had one failure."

Application of Injector Equipment.—The water feed or suction pipe in particular should be thoroughly clamped. Injectors should be properly bolted to stiff brackets. Steam pipes should be bent with easy curves and the bends should not be abrupt. It is necessary that due allowance be made for expansion and contraction and it is the opinion of the committee that a bend approaching a reverse curve meets requirements most satisfactorily. The bends in the pipe should be on a radius of at least from 10 in. to 14 in.

Lever Starting Valve Support.—It is recommended that the lever starting valve of non-lifting injectors be clamped to the boiler and that the valve body be designed with a lug to facilitate this. To support valves not already provided with such lugs, a rigid clamp should be secured to the steam pipe immediately below the starting valve and one just above the starting valve.

Use of Standards.—If the standards proposed by this committee are to be adopted, the votes deciding this should be cast with the idea of applying future injectors and couplings accordingly. If the question is voted on in the affirmative without intending to use the standards, it will be better to reject them.

The report is signed by:—M. H. Haig (A. T. & S. F.), Chairman; T. F. Barton (D., L. & W.); S. B. Andrews (S. A. L.); W. H. Winterrowd (C. P. R.), and B. F. Kuhn (N. Y. C.).

DISCUSSION.

Mr. Haig (Chairman): The preparation of a set of standards naturally incurs more or less inconvenience and expense. It was therefore the effort of the Committee to decide upon standards which would result in the smallest amount of expense, hardship or inconvenience upon the railroads or the manufacturers. The manufacturers were invited to co-operate with the committee and were urged to be present at all meetings. Representatives of some manufacturers attended all the meetings.

J. Strickland Knease (Wm. Seller & Sons): I acted as chairman of the committee of manufacturers to discuss this subject and it was considered from the same point of view as your committee, with the idea of reducing the number of threads to the minimum, and at the same time obtain the strongest form which would be of service. Certain recommendations which were made by the manufacturers committee were not accepted. The principal one to which I wish to call your attention is the pitch of thread. It further desired to reduce the variety of coupling nut thread and pitches as much as possible, each manufacturer willingly sacrificing his own design if he considered it obselete. I would therefore ask consideration of certain recommendations in Mr. Haig's report with which I do not agree, stating that my opinion is supported by two large manufacturing companies who also have had wide experience along these lines.

In regard to coupling nuts: Your committee advocates a uniform pitch of ten threads per inch. The manufacturers' committee thinks it preferable to increase the pitch with the diameter of the nut within certain limits, on account of the difficulty of properly fitting fine threads with large diameters, and the danger of crossing the threads when the nuts are partially worn. For these reasons the manufacturers' committee recommends and is prepared to supply nuts and branches threaded eight per inch for all diameters, 3 inches and above, in accordance with standard nuts in use on railroads since 1876.

Your committee accepted the recommendation of the manufacturers' committee covering the special shape of thread. The writer brought this form of thread to the attention of the association in the discussion of Mr. Foster's paper last June, which was designed in 1890, and has been used ever since and corresponds almost exactly to the standards. The manufacturers' committee also think that your committee has made the coupling nuts unusually heavy. There is sufficient metal now in the nut if properly designed. If cast with the mixture given in the committee's report, an eight per inch nut for 2½ inch iron pipe will stand a strain of 30,000 to 35,000 lbs. before yielding at the collar. It would be therefore entirely unnecessary to increase the thickness or width of the nut, especially as the increasing cost of copper, tin and zinc would add materially to the expense. Another detail is the radius of the ball joint. I should say without going into detail that the ball joint as designed is rather flatter than the accepted standards, and both standards are proving entirely satisfactory. The general practice of the foreign roads, especially the English, is to use much more conical joints than we do.

As to brazing unions, I would say that the form of brazing ring has been re-designed. Some roads prefer the brazed connection in order to meet the improved form of brazing ring. Your committee recommends a counter bore of the brazing ring itself. The committee of manufacturers made tests of the brazed union which show that the cause of failure was due to lack of penetration of the brazing material between the copper pipe and the ring. For that reason they recommend a counter bore of the rings to a point within its head and the bevelling of the lower face to permit slight flanging of the copper pipe toward the ball joint. This counter bore leaves a space of about 1/64 in. on each side to permit the brazing material to run down to the collar of the brazing ring, adding materially to the strength of the joint. The breaking strength of the joint runs from 17,000 to 22,000 lb.

The Vice-President: Mr. Haig, would your committee like to have another year with the Manufacturers' Association to present something that we could go on as recommended practice?

Mr. Haig: Mr. Knease's presenting his remarks as the representative of the Manufacturers' Committee was somewhat of a surprise to me, for the reason that I do not understand his statements to agree with those of individual representatives who have discussed this matter with me.

I think that the matter which Mr. Knease presented to-day would have been to much better advantage presented at the meetings at which he was urged to be present.

The tables which he presents were thoroughly investigated and discussed by the railroad men, as well as by the representatives of manufacturers, and it was agreed that his old standards would not be as satisfactory as those which the reports from the railroads indicated to be the more common.

S. G. Thomson (P. & R.): It does not seem to me, mechanically, that ten threads is right for a ⅜ in. pipe, if it is right for a 3 in. pipe. Of course you can make the threads heavy enough to prevent trouble, but we have had a great deal of trouble from fine threads on large pipe. It seems to me that there ought to be some division, say ten threads up to 2 inches, and eight threads above. I move that this committee be continued and come together and give us another report next year.

(The motion was carried.)

SUBJECTS

The Committee on Subjects for the 1916 meeting of the Association submits the following report:

That the present standing committees be continued.

That the following subjects be assigned to special committees:

1. Equalization of long locomotives, so as to secure the most effective guiding from the trucks, both leading and trailing.
2. Best practice and type of tender truck for passenger locomotives. Has a swing truck any advantage over a rigid truck?
3. Reciprocating and revolving weights. Committee to report on possibilities of lightening.
4. Transmission of electric power from motors to driving wheels of electric locomotives. Committee to report on the progress in this direction.
5. Use of pyrometers on superheater locomotives.
6. Piston valves, rings and bushings. Best material and sizes, with particular reference to superheated steam.
7. Metal pilot designs.
8. Modernizing existing locomotives, which can then remain in service for ten or fifteen years.

That the following subjects be assigned for topical discussions:

1. Advantages, if any, of compounding superheater locomotives.
2. Side bearings on tenders.
3. Tender derailments: Causes and remedies.
4. Road instruction for enginemen and firemen.
5. Crosshead design.

The report is signed by:—A. W. Gibbs (Penn.), chairman; D. R. MacBain (N. Y. C.), and C. E. Fuller (U. P.).

The report of the committee was received and each subject was referred to the incoming committee.

CONCLUDING EXERCISES

The following officers were elected for the ensuing year: President, E. W. Pratt (C. & N. W.); first vice-president, William Schlafge (Erie); second vice-president, F. H. Clark (B. & O.); third vice-president, W. J. Tollerton (C. R. I. & P.); treasurer, Angus Sinclair. The following executive members were elected: C. H. Hogan, (N. Y. C.); J. F. De Voy, (C. M. & St. P.) and J. T. Wallis, (Penn.).

W. E. Symons, in presenting retiring-president Gaines with a past-president's badge said:

The year which has just closed, the fiscal year of this association, has been a very trying one to all railway companies, by reason of questions of economy, valuation and various other matters with which railway officers have to deal, and placing heavy burdens on the leaders of the motive power departments of our railways and upon officers of associations like this who have to devise ways and means for reaching these economies. Our retiring President, Mr. Gaines, has been no exception to the rule in this respect, and his activities have only reflected honor and credit to himself. It has been customary on past occasions to present the retiring president with a jewel indicating the degree of esteem and affection in which the members of the Association hold him as a man, as an engineer, as an executive officer, and as a citizen, and on this particular occasion the duty of making the presentation of this jewel has fallen upon me.

I take great pleasure, Mr. Gaines, in presenting to you the past president's badge, which you receive as the retiring president of this association, and to say to you that it embodies in part our estimation of you as an executive officer, as an engineer and as a railway man, and our esteem and consideration for you as a citizen. I have also noted with much pain and sympathy your present slight physical indisposition, but we hope, and I feel justified in saying to you, that if the affectionate regard in which you are held by the members of this Association has any curative properties, you will be almost immediately restored to your perfect good health, and that we will have the benefit of your wise counsels in years to come.

SAFETY WATER GLASS COCK

A newly developed water glass cock is being exhibited by the Sargent Company, Chicago, which automatically drains the water from the glass when either or both top and bottom cocks are closed. With the ordinary type of cocks used on water glasses, it is possible to trap water in the glass by inadvertently closing both cocks, the indication of a false water level being thereby made possible. Should either one of the cocks be closed or should they be only partially open a similar dangerous condition is produced.

The new water glass cock is designed to prevent occurrence of these conditions. It contains a double seated valve, one side of which controls the passage from the boiler to the glass, and the other side a passage from the glass to the atmosphere. When the boiler passage is closed the outlet is open, and vice versa. Should either valve be open at the boiler connection while the other is closed the pressure will cause a flow through the glass and thence out through the open cock. When both boiler connections are closed the glass will drain through the lower cock. The arrangement is such that it is necessary to fully open both valves in order to close the passage from the glass to the atmosphere, and it is impossible to operate with cracked valves, as is frequently done when ordinary cocks are used.

COMPARATIVE REGISTRATION FIGURES

In studying the following figures of registration to Friday morning it must be remembered that, so far as railroad men are concerned, the numbers for this year should be compared with those of 1913 and 1911, when M. M. Association met first. Compared with 1913 their is a falling off of 16 in railroad men (members and special guests), but a very considerable falling off—368—in the number of supply men.

W. V. TURNER'S LATEST IMPROVEMENT IN BRAKING EQUIPMENT

Walter V. Turner, chief engineer, Westinghouse Air Brake Company, is attending the conventions this year. His most recent contribution to the art of transportation is the variable load brake and the variable road accelerator for electrically operated cars. The equipment of the New York Municipal Railway Corporation is provided with these features, which, with the electro-pneumatic brake, has permitted obtaining a capacity over four times as great as compared with the ordinary electric trains operated with the perfected air brakes. Mr. Turner has recently been made a fellow of the Royal Society of Arts in England.

MOTOR CARS IN INDIA.—Motor cars are extensively used in India, there being about 2000 in Calcutta and 1000 in Bombay. Values of exports of cars to India in the fiscal year 1913-14 are stated as follows: Motor cars, $3,680,855; motor-cycles, $346,490; motor wagons, $185,165; parts and accessories, $761,257. The United Kingdom leads in these items with the United States second.

Conventionalities

Harry Coddington, engineer of tests of the Norfolk & Western, was delayed two days in reaching the convention, because of the arrival of a little girl at his home.

C. W. Cross is accompanied by his son, who has just finished his special apprenticeship course at the Elkhart, Ind., shops of the New York Central. The trip is in the nature of a reward for the good record he has made.

The new cane sported yesterday by E. W. Kavanagh, of Ryerson & Son, attracted considerable attention. It was supplied at the expense of J. B. Warren, who fell down badly on a little matter of figures.

Frederic Schaefer, who recently organized the Schaefer Equipment Company, is attending the convention in the interests of his new company. Mr. D. Schaefer was formerly connected with the Summers Steel Car Co.

John Carroll (B. & O.) Admiring His Own Work

Henry Gardner, well known because of his work in the development of the modern apprenticeship system and improved shop organization, has Mrs. Gardner and his seven-year-old daughter, Elizabeth, with him this year.

The M. M. and M. C. B. Associations have established a reputation as the star orange juice consumers. The lady at the drinking fountain at the entrance to the Blenheim says her heaviest business of the year is during these conventions.

Mrs. Walter H. Bentley was detained at home this year on account of an operation performed about a month ago. She is convalescing rapidly and desires to be remembered to the many friends she made at the 1914, her first convention.

C. L. Bardo, general manager of the New York, New Haven & Hartford, is one of the convention visitors who are taking much interest in the exhibits. Needless to say, now that he is here, he intends to play in the golf tournament on Sunday.

Jack High is located just across the aisle from Herman Ball. Ed. Walker in passing by spoke to both of them. Contrary to his usual habit, he was quite dignified and used their last names. "My goodness," said an elderly lady who was passing at the time, "I didn't realize that they had 'highballs' on the pier."

Frank J. Barry, M. M., N. Y. O. & W.

George B. McGinty, secretary of the Interstate Commerce Commission, and a party of the locomotive boiler inspectors of the commission are here for the conventions. The party includes, Frank McNanamy, chief inspector; G. P. Robinson and A. Pack, assistant chief inspectors, and Inspector Scudder, Milwaukee; Boltwood, Denver; Adair, St. Louis; McNanamy, Grand Rapids; Wilson, Memphis; Wintersteen, Philadelphia, and Phfaeler, Washington. Next week seven of the commission's safety appliance inspectors will arrive to attend the Master Car Builders' convention. They will be headed, as usual, by

M. K. Barnum, S. M. P., B. & O., Had Put Some "Pep" Into It

Chief Inspector H. W. Belnap. Mr. McGinty is this year accompanied to the conventions for the first time by Mrs. McGinty. He expects to remain at least until Monday. .

It is remarkable how quickly the Lake Shore crowd have become accustomed to the new order of things. Not a single

T. F. Barton, M. M., D. L. & W., and Mrs. Barton

one of them stirred when President Gaines called for some one from the Lake Shore to give certain data as to conditions on that road. When M. D. Franey was singled out he started off in this fashion: "Speaking for the fourth district of the New York Central, etc."

Among those here is E. Borcea, of Roumania. In normal times he is a railway man, being identified with the construction department of the Roumania Government Railways. Recently, however, he was transferred to the War Office and is in this

J. J. Carey, M. M., Texas & Pacific

country with a captain of artillery looking into the possibilities of getting munitions of war. This is Mr. Borcea's second convention, he having attended in 1913.

C. W. Beaver, manager hoist department, Yale & Towne Manufacturing Company, who recently returned from a business trip to Cuba, reports that business there is in a very flourishing condition, the principal contributing cause being the demand for sugar. So long as the European war lasts the beet sugar output of the East will be very small. It is probably this increased demand upon the sugar market of Cuba that has made it necessary for the Havana Central to go into the market for 600 freight cars and 10 cabooses.

George A. Post narrated an incident the other night which he says explains several things. He is to be the orator this year at the commencement exercises of a small academy from which he graduated a greater or less number of years ago. When the announcement was made that he was to speak, the editor

C. S. Adams, Asst. Gen. For., New York Central

of a local paper, who was the editor of it also at the time he graduated, and who is a quite venerable gentleman now, sent Mr. Post a copy of an academy entertainment program in which the latter had a part years ago. In this entertainment several of the students took the part of animals, one being a dog,

C. C. Elmes, Assistant Engineer Motive Power, Philadelphia & Reading, at the end of a drive

another a cat and "Georgie" Post being a goat. "I wrote him in reply," said Mr. Post, "thanking him for recalling this entertainment to me and adding that the fact that I began to take that part so early explained many things in my subsequent career."

Railway Age Gazette

DAILY EDITION

VOLUME 58. JUNE 14, 1915. NUMBER 24

PUBLISHED EVERY FRIDAY AND DAILY EIGHT TIMES IN JUNE BY THE SIMMONS-BOARDMAN PUBLISHING COMPANY
WOOLWORTH BUILDING, NEW YORK

CHICAGO: Transportation Bldg. CLEVELAND: Citizens' Bldg.
LONDON: Queen Anne's Chambers, Westminster.

E. A. SIMMONS, *President*
L. B. SHERMAN, *Vice-President.* HENRY LEE, *Sec'y & Treas.*
The address of the company is the address of the officers.

EDITORS
SAMUEL O. DUNN, *Editor*
ROY V. WRIGHT, *Managing Editor*
W. E. HOOPER, B. B. ADAMS, E. T. HOWSON, H. H. SIMMONS, H. F. LANE, R. E. THAYER, A. C. LOUDON, C. B. PECK, W. S. LACHER, C. W. FOSS, F. W. KRAEGER, J. M. RUTHERFURD, GEORGE MITCHELL

BUSINESS DEPARTMENT REPRESENTATIVES
CECIL R. MILLS, FRANK S. DINSMORE, F. H. THOMPSON, H. H. MARSH, W. M. FORD, A. F. ASHBACKER, W. D. HORTON

Subscriptions, including 52 regular weekly issues and special daily editions published from time to time in New York, or in places other than New York, payable in advance and postage free:

United States and Mexico	$5.00
Canada	6.00
Foreign Countries (excepting daily editions)	8.00
Single Copies	15 cents each

Engineering and Maintenance of Way Edition and four Maintenance of Way Convention Daily issues, North America, $1.00; foreign $2.

Entered at the Post Office at New York, N. Y., as mail matter of the second class.

WE GUARANTEE that of this issue 10,011 copies were printed; that of those 10,011 copies 8,572 were mailed to regular paid subscribers to the Railway Age Gazette and the Railway Age Gazette, Mechanical Edition; 150 were provided for counter and news companies' sales; 189 were mailed to advertisers; 100 were provided for bound volumes, and 1,000 for distribution at Atlantic City.

The RAILWAY AGE GAZETTE and all other Simmons-Boardman publications are members of the Audit Bureau of Circulations.

Car Inspectors

In considering the qualifications of a man for the position of car inspector, it should be borne in mind that the duties of an inspector in a terminal yard differ somewhat from those of one on interchange work. A terminal inspector must be qualified to determine whether or not the cars which he inspects are defective in any way, and what repairs are necessary to place them in such a condition that they will be safe to run. On interchange work, besides these qualifications, an inspector requires a much more detailed and thorough knowledge of the M. C. B. rules of interchange and of the law governing the application of safety appliance details. He must also determine the serviceability of a car which is about to be interchanged and pass upon the matter of car clearances. From a consideration of the foregoing it would seem that the terminal yard inspector is, from his experience, the man best fitted to develop into an interchange inspector.

How Would It Work?

The report of the Committee on Boiler Washing, which was referred to letter ballot for adoption as recommended practice, is deserving of special note and is of such a valuable nature that it will not detract from it to use it as an example of what might be done under the plan of reorganization for all the mechanical associations, suggested by President Gaines in his opening address. In brief, this subject could have been referred by the supreme executive committee to what is now the Master Boilermakers' Association for action on matters of detail. After receiving the thorough attention of this branch of the combined associations, the findings of the committee, as modified in the convention, could be referred to the higher association for action on matters which could not be settled satisfactorily by the previous committee, and for final action in the adoption of standards. As previously stated, we use this merely as an example to point out the possibilities of such a combination as President Gaines suggested.

The 36-Foot Box Car

Why was the American Railway Association box car made 36 ft. long? This is a question that was asked recently and which we have heard repeated on a number of occasions. An example of the difficulty that arises because of the 36-ft. length is afforded by the experience of a road in the southwest which has to haul many cars of this dimension empty in one direction because lumber manufacturers refuse to load them, the reason being that much of the material shipped is in 18-ft. lengths, which run two or three inches over length, the result being that it is impossible to load two lengths in a 36-ft. car. This is true of other commodities besides lumber. Would it not be advisable to adopt 40 ft or possibly 40 ft. 6 in. for the inside length of box cars and eliminate the 36-ft. dimension for the future? There is no question that this would result in an increase in revenue-ton-miles for the freight equipmtnt on a number of roads.

Maintenance of Car Journals

It has been demonstrated that in order to obtain the best results in fuel economy the co-operation of all the departments of a railroad is absolutely necessary. The car department is in a position to very materially aid in this respect. Hot-boxes have always been a live issue and they are now being eliminated to a very large extent. It must not be forgotten, however, that a poorly maintained journal will have a very marked effect on the tonnage an engine can handle, which, of course, means increased fuel consumption per ton-mile. Tests have shown that the power required to haul one car dry or scantily lubricated would be sufficient to haul six or eight cars properly lubricated. Thus it will be seen that if the journals are not in the proper condition it may mean a difference of 10 or 15 cars per train. Journals in this condition will not necessarily cause a hot-box and it is therefore difficult to detect them. The only way in which the problem may be satisfactorily handled is in having adequate inspections and a corps of car inspectors and maintainers that will do their work thoroughly and conscientiously.

Steam Railway Men and Electrical Operation

Electrical engineers have on more than one occasion made the statement that a man, to be successful in the electrical operation of railways, must be trained in the electrical field. The report of the Master Mechanics' Association committee on Maintenance and Operation of Electrical Equipment and the discussion of the report, brought out evidence which distinctly refutes this. G. W. Wildin, mechanical superintendent of the New York, New Haven & Hartford, a road which has gone through all the trials and tribulations of pioneer electrification, is emphatic in his opinion that the best results from electrified steam railways are to be obtained by the employment of men already trained in the operation of a railroad by steam locomotives. There is no great mystery about electrical apparatus and it must be conceded that whether the motive power be steam, gas or electricity, the equipment is all based on mechanical principles. It is probably advisable to have consulting engineers on the mechanical department

staff to deal with matters which are distinctly electrical, but as far as the matters of operation and maintenance in general are concerned they require only the common sense and knowledge of railway conditions, with which any successful mechanical department man is equipped. Such roads as the New Haven, the New York Central and the Pennsylvania, which were among the first to employ electric traction to any extent, have gone through the pioneer stages of electrical operation, and their experience in matters of this kind should be of much more value to the roads now beginning or contemplating electrification than the opinions of electrical engineers who, no matter how competent they may be as electrical engineers, are seldom thoroughly trained as railroad men.

With the Exhibitors

The exhibitors are, of course, anxious to get the attention of the railway men and explain the merits of their devices to them: On the other hand the railroad men are just as desirous of getting in touch with and studying devices which they have reason to believe will help them solve their problems and get better results. It is interesting to note how systematically some of the roads are making use of the opportunity of examining and studying devices and equipment which is on exhibition. In one case the exhibit was first given a general survey by individual members of a delegation and then all of them went together to study those devices which specially appealed to the individual members of the party. In other cases visitors have come with instructions to specially examine and report on certain items or to make a written report on features which they had examined and believe would relieve certain troublesome conditions. Probably at no meeting of the year can so many experts be found together, who are available for consultation and who are only too glad to give advice. Simon-pure railway supply salesmen have in many cases been entirely displaced by sales engineers or engineering experts. Not the least of the advantages of attendance at the convention is the privilege of meeting and consulting with these men.

Variable Load Brakes for Freight Cars

The legal difficulty which the Virginian Railway experienced recently in the handling of long freight trains with the hand brake has once more accentuated the demand for the variable load brake. As stated in an article published in the *Railway Age Gazette* of May 14, page 1018, the United States Circuit Court of Appeals, Fourth District, has held that the use of hand brakes in the operation of trains is contrary to law. This decision is of special importance to those roads operating on heavy grades. Walter V. Turner, chief engineer of the Westinghouse Air Brake Company, in a paper before the Railway Club of Pittsburgh has shown that in order to handle long trains on heavy grades satisfactorily it is necessary to either increase the brake pipe pressure beyond practical limits, to use enough empty cars to furnish the necessary additional braking force, or to reduce the speed, the train tonnage, or the weight and capacity of the cars to a safe minimum. The empty and load brake will make these precautions unnecessary and not only permit of satisfactory operation of all trains on grades, and by giving safety and uniform brake operation, will permit of materially increasing the road capacity both for grade and level work. With the application of this type of brake, a more uniform braking force is obtained throughout the train. For example, assuming an empty car of 54,000 lb. which, when loaded, will weigh 208,000 lb. and braked empty to give 60 per cent nominal braking force, only 15.6 per cent braking force is obtained on the loaded car with the standard brake equipment, whereas with the empty and load brake 40 per cent braking force will be obtained. It will be seen that the difference between the braking force of the loaded and empty cars equipped with the standard brake is much greater than when they are equipped with the empty and load brakes. This greatly reducing the damage to lading and equipment as well as making safe the operation of all trains on all grades. In addition to making it possible to better operate the trains, it will be found possible to materially increase the length of these trains, tests having shown that 7,700 tons can be safely handled.

DEFECTIVE BOX CARS

THERE is a saying to the effect that "success is the result of keeping everlasting at it." We have "kept at" several car department matters for some years in order to point out where improvements can be made, and whether or not our efforts have been of any assistance in accomplishing it, there is no doubt that improvement has been made along these particular lines. Some of these matters, however, are susceptible of still further improvement and some are as yet a long distance from perfection.

The condition of box car roofs, while considerably improved over what it was a few years ago, is still far from satisfactory in many cases. The smallest leak in a roof is likely to let enough water through to cause damage to the lading to an extent that will result in much labor for the claim department and the loss of a considerable sum of money to the company, while there is always the danger of an incensed shipper turning his business over to another road because of such an occurrence. Leaky roofs are taken care of on at least one railway by an inspection system which includes passing the cars under a specially devised sprinkler after the roof has been repaired.

In studying the prevention of damage to and loss of the contents of cars, the side doors naturally come into prominence. Like the roof situation, the box car side door has been greatly improved during the past two or three years, but there is still need of continued effort to place this part in a condition that will decrease the trouble from loss and damage as well as the danger of doors side-swiping passenger trains on double track. Careful attention should be given to bottom door guides and locking facilities; it is still common to see cars fitted with wooden door stops held in place with only two small bolts. In some cases the use of a steel door has been resorted to and, while it has received some very severe criticism, the results obtained from it in the matter of protection to lading are gratifying.

Much more attention could well be given to the inspection of the methods of loading box cars. Not all shippers know that the Master Car Builders' Association has formulated a set of rules for loading all classes of cars, and if the fact that there are such rules were brought to their attention in the right way, there is little doubt that they would endeavor to conform to them for their own sake if not for the railways, and both would benefit thereby. Local freight agents should familiarize themselves with the more important requirements and thus be of assistance to the shipper in getting the shipments properly placed in the cars and effectively blocked in place. A practice that is worthy of mention in this connection is that of a large eastern road which has obtained very satisfactory results from the appointment of a committee consisting of representatives from the traffic department, the operating department and the mechanical department, to confer with the shippers, inspectors and traffic department men in improving loading conditions. The matters to which we have called attention are a few which need constant attention and while, as previously stated, we have referred to them on many occasions before, we feel that too much attention cannot be given to them.

PROGRAM FOR THE WEEK

MASTER CAR BUILDERS' CONVENTION

MONDAY, JUNE 14, 1915

Address by the President	9.30 A. M. to 10.30 A. M.
Reading of the minutes of the 1914 Convention	10.30 A. M. to 10.35 A. M.
Report of secretary and treasurer	10.35 A. M. to 10.50 A. M.
Assessment and announcement of annual dues; appointment of committees on correspondence, resolutions, obituaries, etc.	10.50 A. M. to 11.00 A. M.
Election of auditing committee	11.00 A. M. to 11.05 A. M.
Unfinished business	11.05 A. M. to 11.10 A. M.
New business	11.10 A. M. to 11.20 A. M.
Discussions of reports on:	
Nominations	11.20 A. M. to 11.30 A. M.
Revision of standards and recommended practice	11.30 A. M. to 12.00 M.
Train brake and signal equipment	12.00 M. to 12.30 P. M.
Brake shoe and brake beam equipment	12.30 P. M. to 1.00 P. M.
Car wheels	1.00 P. M. to 1.30 P. M.

AFTERNOON SESSION—3.00 O'CLOCK P. M.

The Executive Committee decided that it would be best to have a session devoted exclusively to a discussion of the revision of the Rules of Interchange and that it form a part of the proceedings.

At this session the following reports of committees will be considered:

1. Arbitration Committee.
2. Revision of prices for labor and material.
3. Settlement prices for reinforced wooden cars.
4. Compensation for car repairs.

ENTERTAINMENT

10.30 A. M.—*Orchestral Band Concert.* Entrance Hall, Million-Dollar Pier.

3.30 P. M.—*Orchestral Band Concert.* Entrance Hall, Million-Dollar Pier.

9.00 P. M.—*Social Gathering and Informal Dance.* Special Feature, Costume Recital, Miss Betty Lee. Ball Room, Million-Dollar Pier. Don Richardson Orchestra.

TUESDAY JUNE 15, 1915

Discussion of reports on:	
Couplers	9.30 A. M. to 10.30 A. M.
Safety appliances	10.30 A. M. to 10.45 A. M.
Rules for loading materials	10.45 A. M. to 11.00 A. M.
Overhead inspection	11.00 A. M. to 11.10 A. M.
Interline inspection	11.10 A. M. to 11.25 A. M.
Car construction	11.25 A. M. to 12.00 M.
Specifications and tests for materials	12.00 M. to 12.30 P. M.
Tank cars	12.30 P. M. to 12.45 P. M.
Individual paper—What is the value of a patent? By Mr. Paul Synnestvedt	12.45 P. M. to 1.30 P. M.

ENTERTAINMENT

10.30 A. M.—*Orchestral Band Concert.* Entrance Hall, Million-Dollar Pier.

3.30 P. M.—*Orchestral Band Concert.* Entrance Hall, Million-Dollar Pier.

9.30 P. M.—*Informal Dance.* Special Feature. Costume Recital, Miss Betty Lee. Ball Room, Million-Dollar Pier. Don Richardson Orchestra.

WEDNESDAY JUNE 16, 1915

Discussion of reports on:	
Train lighting and equipment	9.30 A. M. to 10.00 A. M.
Car trucks	10.00 A. M. to 10.30 A. M.
Draft gear	10.30 A. M. to 10.45 A. M.
Joint meeting with A. R. M. M. Assn.	10.45 A. M. to 11.00 A. M.
Individual paper—Impact between freight cars in switching service. By Prof. L. E. Endsley	11.00 A. M. to 11.30 A. M.
Topical discussion:	
Air brake maintenance	11.30 A. M. to 11.45 A. M.
Unfinished business; Reports of Committees on Correspondence, Resolutions and such other committees as may be named during the convention	11.45 A. M. to 12.00 M.
Election of officers	12.00 M. to 1.30 P. M.

FIRST AID PRECAUTIONS

In case of accident a nurse or interne will be found at a desk in the end of Machinery Hall nearest the Boardwalk. First aid supplies will be available and in case of serious injury arrangements may be made for prompt expert service.

PRESIDENT CRAWFORD HONORED

Few, if any, motive power men have ever been able to boast of having a Doctor's degree. In fact, at the moment, we do not remember a single one. This unusual distinction was conferred on D. F. Crawford, president of the M. C. B. Association, and general superintendent motive power of the Pennsylvania Lines west of Pittsburgh, last week by the State University of Kentucky. He received the degree of Doctor of Engineering and was also initiated into TAU BETA PI, the honorary engineering or scientific society. It was this that prevented his attendance at the Master Mechanics' convention last week.

$6,000,000 RUSSIAN ORDER

The following item dated Philadelphia, June 12, is taken from the New York Times of yesterday:

"The Baldwin Locomotive Works has received a cable order from the Russian Government for 250 locomotives to be built before the close of the year.

"The order, which approximates $6,000,000, is one of the largest ever booked by the Baldwin Company, and means that the concern's big plants in this city and Eddystone, will be worked to capacity for months.

"Alba B. Johnson, president of the Baldwin Company, confirmed the receipt of the order. It was declared that the orders placed with the Baldwin Company by the Allies now foot up to more than $20,000,000."

ANNUAL MEETING OF THE R. S. M. A.

The annual meeting of the Railway Supply Manufacturers' Association was held in the Convention Hall at twelve o'clock Saturday.

President Johnson referred briefly to the work necessary to make the association a success. He regretted that the attendance of the supply men was below that of last year but said that there was enough money in the treasury to meet all obligations. He expressed his appreciation of the support of the executive committee, by whose co-operation and work he had been enabled to practically eliminate all "kicks" this year. The only serious complaint was the lighting in the Exhibition Hall the first two days due to generator trouble, which, of course, could not be foreseen.

Of exhibit space, 70,538 square feet were taken this year as against 82,218 in 1914—a decrease of about 14 per cent.

The following officers were elected for the year 1915-1916: President, Oscar F. Ostby; vice-president, Edmund H. Walker; Members of the Executive Committee: First District, J. G. Platt,

Hunt-Spiller Manufacturing Corporation; Second District, C. D. Eaton, American Car & Foundry Company; Fourth District, John F. Schurch, Damascus Brake Beam Company; Seventh District, C. B. Cass, Westinghouse Air Brake Co.

The new president in expressing his appreciation of the honor conferred upon him, stated that it would be his endeavor to work at all times for the good of the association; that he wanted the support of and suggestions from the members and as their servant would do what was wanted for the best interests of all.

A hearty and unanimous vote of thanks was given to the retiring officers.

CHICAGO & NORTH WESTERN CLUB

A large number of the members of the Chicago & North Western Club, which was formed at the convention last year, held an informal meeting on the porch of the Shelburne on Saturday evening at 8.30 o'clock. There were about 18 members present, presided over by H. T. Bentley. After a short meeting, in which Mr. Bentley spoke to the members and extended the best wishes of Mr. Quayle, who unfortunately could not get to the conventions this year, the members attended the vaudeville show at the Hippodrome. R. B. Moore, superintendent of motive power of the Denver & Rio Grande, was indisposed and could not attend the meeting. John P. Neff was appointed a committee of one to extend the sympathy of the club to him.

REGISTRATION FIGURES

The number of railroad members registered at the conventions, as shown by the third enrollment book, issued on Saturday morning, is only three less than for 1913. While it is 53 less than the number registered for the same period last year, it must be remembered that the Master Car Builders' Association met first last year and that the attendance at that convention is ordinarily larger than for the Master Mechanics' convention, so that as far as railroad men are concerned the record is a most gratifying one. As noted in the comments on the registration for the first two days, the principal falling off as compared with two years ago is in the number of supply men, there being exactly 400 less this year than in 1913.

COMPARATIVE REGISTRATION—THE THIRD ENROLLMENT LIST FOR 1911-12-13-14-15.

	1911	1912	1913	1914	1915
Members M. M. and M. C. B.	612	303	489	539	486
Special Guests	331	365	373	360	299
R. R Ladies	401	256	345	269	264
Supply Ladies	355	208	282	254	208
Supply Men	1572	1408	1516	1349	1116
Totals	3271	2540	3005	2771	2373

RAILWAY CLUB SECRETARIES' ANNUAL MEETING

At the annual meeting of the Society of Railway Club Secretaries, held Saturday morning at the Marlborough-Blenheim, Chairman J. B. Anderson, of the Railway Club of Pittsburgh, presided. Other members present were New York Railroad Club and Central Railway Club, Harry D. Vought; Canadian Railway Club, James Powell, Montreal; Richmond, Va. Club, F. O. Robinson; Southern and Southwestern Club, A. J. Merrill, Atlanta. B. W. Frauenthal of the St. Louis Club wired regrets, being detained by official railroad engagements.

A report was received that the organization of the Society of Technical Associations Secretaries had been completed with Mr. Vought as president and Bradley Stoughton of the Society of Mining Engineers as secretary-treasurer.

The advisability of amalgamating with this new society was discussed and held over for another year, the society to be satisfied with recognition as one of several groups organizations.

Advices were received of new railroad clubs which will be invited to unite with the Society of Club Secretaries.

Since the last meeting more than 7,000 copies of the Index of Subjects published by the society have been distributed to

ENROLLMENT COMMITTEE

Top Row, Left to Right—L. D. Mitchell (Detroit Graphite Co.), F. N. Bard (Barco Brass & Joint Co.), H. G. Thompson (Edison Storage Battery Co.), C. W. Beaver (Yale & Tower Mfg. Co.), and C. H. Gayetty (Quaker City Rubber Co.)

Bottom Row—W. J. Fleming, Jr. (Automatic Ventilator Co.), F. E. Harrison (W. L. Brubaker & Bro.), F. H. Smith (Gold Car Heating & Lighting Co), H. A. Brown, Chairman (Pocket List of Railroad Officials), G. A. Barden (Chicago Pnuematic Tool Co.), T. D. Starr (Wm. C. Robinson & Son Co.), J. A. Stevens (F. W. DeVoe & C. T. Raynolds Co.), and R. F. Moon (Westinghouse Electric & Mfg. Co.).

members of the railway clubs and educational institutions.

Much time was given to the consideration of methods and practices of the various clubs, as a result of which each secretary received advantageous information for future use.

Officers elected for the ensuing year are: Chairman, A. J. Merrill, Atlanta; vice chairman, W. E. Cade, Jr., Boston; secretary-treasurer, Harry D. Vought, New York.

TRACK EXHIBIT

The exhibit on the Philadelphia & Reading tracks near the Boardwalk includes, beside the Philadelphia & Reading 4-4-4 type locomotive, which was described in the *Daily Railway Age Gazette* of June 9, a Gilman-Taylor dump car, a Southern Railway dynamometer car, an Erie Railroad hopper car, and a convertible general service or ballast car.

The Gilman-Taylor car is exhibited by the Goodwin Car Company and is an air dump and air replacing ballast car for either center or side dump. It has a capacity of 100,000 lb. and weighs 53,000 lb. The Southern Railway dynamometer car is one which has recently been added to the testing equipment of that road and is exhibited by the Burr Company, Chicago. The Erie hopper car is fitted with Barber double action trucks. It is 40 ft. 6 in. long, and has a capacity of 2,646 cu. ft., or 140,000 lb., while the weight is 60,700 lb. The convertible general service or ballast car is exhibited by the Enterprise Railway Equipment Company and has a capacity of 100,000 lb. and a weight of 49,800.

W. J. TOLLERTON

W. J. Tollerton, who was elected third vice-president of the Master Mechanics' Association at its closing session last Friday, made a splendid record in testifying in the arbitration proceedings in the Western engineers' and firemen's wage controversy in Chicago last spring. Under the most difficult conditions, he set forth clearly the railroad side of the case and made a most enviable record. The association undoubtedly made a wise selection in honoring him with a position on its official staff.

Mr. Tollerton was born in St. Paul, Minn., in 1870, and was educated in the public and high schools of that city. He entered the service of the St. Paul & Duluth, now part of the Northern Pacific, as a machinist apprentice and subsequently became a fireman on the Chicago, St. Paul, Minneapolis & Omaha. From 1890 to 1896 he was foreman and then general foreman on the Union Pacific; he then became master mechanic on the Utah division of the Oregon Short Line; in 1903 he was made master mechanic of the Idaho, Utah and Montana division of that road, with headquarters at Pocatello, Idaho. From July, 1906, to April, 1907, he was superintendent of motive power of the Chicago, Rock Island & Pacific in charge of the lines west of the Mississippi River, with headquarters at Topeka, Kans. From April, 1907, to May, 1912, he was assistant general superintendent of motive power of the Rock Island Lines, with headquarters at Chicago. For the following eight months he was mechanical superintendent of the Rock Island Lines and on January 1, 1913, was made general mechanical superintendent, which position he now holds.

THE VAUDEVILLE ENTERTAINMENT

There was a goodly crowd out Saturday night to attend the vaudeville entertainment in the Hippodrome. George Carr, chairman of the entertainment committee, and his associates had worked hard in preparing for the event in order to insure an enjoyable evening to all. Everything would have moved like clockwork had it not been for the inexcusable blunder of some of the pier people in handling the moving picture feature. Through the courtesy of D. F. Crawford, general superintendent of motive power, Pennsylvania Lines West, an intensely interesting film was obtained of the moving of the Muskegon River bridge, a detailed description of which appeared in the *Railway Age Gazette* some weeks ago. Henry Ford, head of the Ford Motor Company, supplied a film story of his wonderful plant, which showed graphically every step in making an automobile from the raw material to the finished machine. Arrangements had been made with the pier people to place their regular machine operator at the disposal of the committee. Instead, however, they supplied an old machine, which proved to have a cracked gear and broke down entirely, making a fizzle of this part of the program and unfortunately throwing a damper on things until George Carr came to the rescue and started the vaudeville acts. These were furnished by Francis Rockefeller King direct from the B. F. Keith circuit.

The vaudeville program was opened by Natalie and Ferrari in a whirlwind dancing specialty, followed by Nonette, the gypsy violinist, who was easily the hit of the evening. Her sweet voice and wonderful handling of the instrument won her audience, who would gladly have kept her there all evening, as evidenced by their applause. Claude Golden executed some difficult card tricks and was followed by the inimitable Charlie Case, the man who talks about his father. The closing performance was by Horace Wright and Rene Dietrich, whose happy melange of high-class and popular songs placed a finishing touch to a well-planned program.

Mr. King had sent to New York for the last film of that prince of comedians, Charlie Chaplin, which unfortunately could not be shown on account of the disabled machine. Both the films furnished by Mr. Crawford, of the Pennsylvania, and Mr. Ford will be shown Monday evening in the ballroom on the pier. Don Richardson furnished the music, which, needless to say, was appreciated. The committee in charge was C. W. Floyd Coffin, chairman; W. K. Krepps, J. P. Landreth, R. J. Faure, J. F. Forney, C. D. Eaton, G. E. Ryder.

TENTH ANNUAL CORNELL DINNER

Cornell alumni at the conventions held their tenth annual dinner at Barnay's on Saturday evening. This meeting was particularly enjoyed by the 30 present because of the stereopticon views of the University and the description of the recent changes given by Professor Kimball, who came to Atlantic City for this meeting. He discussed informally the methods and objects of the faculty, particularly that of Sibley College of Engineering, and made clear its real desire for close, active cooperation with the alumni. After the discussion of the newer courses of study now being offered and the expanding practical research work undertaken in the laboratories, views of the present campus were thrown on the screen. These pictures were a revelation to most of the older graduates, and showed them that the university as they knew it ten or fifteen years ago is now but a small section of the whole. The new dormitories now under construction through the energies of Mr. Bolt, and the new athletic field and the armory, which is to be the largest in the country, aroused enthusiasm.

It appears that there are now over 5000 students, of which 500 are women, enrolled in regular four year courses. This excludes all summer and short time students. The growth of the college of agriculture, both in equipment, buildings and students has been remarkable. The college of engineering also has shown a healthy growth when the fact that the entrance requirements are the highest in the country is understood.

A number of the usual regular attendants at these dinners were absent this year because of illness or reunions at Ithaca. F. F. Gaines and J. F. DeVoy were particularly missed. At the suggestion of President C. D. Young, a telegram of regret was dispatched to the latter.

Mr. W. L. Bliss, '90, United States Light and Heating Company, was elected president and Mr. A. S. Lewis, '02,

Chicago-Cleveland Car Roofing Company, was re-elected secretary for next year.

Those present included the following:

E. A. Averill, Standard Stoker Co., Inc.; A. R. Ayres, Principal Assistant Engineer, New York Central; F. N. Bard, Barco Brass and Joint Co.; W. L. Bliss, U. S. Light and Heating Co.; F. T. Connor, Carbon Steel Co.; R. S. Cooper, Independent Pneumatic Tool Co.; A. M. Darlow, Supt. Motive Power, Buffalo and Susquehanna; S. W. Edlund, Greenlaw Mfg. Co.; E. S. Foote, Cutler-Hammer Mfg. Co.; G. S. Goodwin, Mechanical Engineer, Rock Island Lines; M. H. Haig, Mechanical Engineer, Santa Fe; W. O. Kellogg, General Electric Co.; A. S. Lewis, Chicago-Cleveland Car Roofing Co.; C. F. Meyer, Landis Machine Co.; H. G. Macdonald, Standard Steel Car Co.; Ralph McCarty, Alleghany Steel Co.; J. N. Mowery, Keystone Equipment Co.; J. C. Nulsen, American Malleable Casting Assn.; F. H. Philbrick, Midvale Steel Co.; G. A. Post, Jr., Standard Coupler Co.; W. G. Ransom, Bettendorf Co.; W. E. Ricketson, Mechanical Engineer, Big Four; G. W. Ristine, Jr., Pressed Steel Car Co.; H. A. Rodgers, Woven Steel Hose and Rubber Co.; L. H. Snyder, Joseph Dixon Crucible Co.; F. M. Whyte, Hutchins Car Roofing Co.; C. D. Young, Engineer of Tests, Pennsylvania, and Halsted Little, Princeton 1910, Detroit Twist Drill Co., and Mr. John Thomas, of the Standard Paint Co. of New York.

THE GOLF TOURNAMENT

The second annual golf tournament in connection with the conventions took place at the Sea View Golf Club yesterday. The tournament consisted of an 18-hole medal play handicap and an 18-hole kicker's handicap. Three prizes were to have been awarded in each contest, but there were ties in each, and in consequence the awards were not made. The various ties may be played off on Monday or Tuesday, but the entertainment committee would greatly prefer to have them played off Monday afternoon in order that the prizes may be awarded at the informal dance Monday night.

Four players were tied for the low net score in the medal play handicap. These, with their scores, were as follows: George A. Post, Jr., 98-26-72; C. R. Naylor, 103-31-72; Charles Fair, 104-32-72; D. R. MacBain, 108-36-72.

The players tied in the kicker's handicap for first prize are G. L. Bourne and R. H. Weatherly, net 71; for second prize, H. M. Perry, C. H. Williams, B. P. Flory, A. L. McNeill, J. D. Purcell, W. L. Allison, net 74; for third prize, F. L. Connable, W. J. Tollerton, R. C. Vilas, W. L. Conwell, S. W. Sergeant, net 75.

The lowest gross scores of the day were those of J. K. Bole, 80-0-80, and Charles Ripley, 86-10-76. Other low gross scores were made by S. W. Sergeant, 84; D. F. Mallory, 87; E. Quincy, 88; J. R. Prentiss, 89; G. C. Hopkins, 89; R .C. Vilas, 90; G. H. Musgrave, 90.

The weather for the tournament was perfect, except that at about 3:30 o'clock a light rain began to fall. The total number of entries was 124.

The committee in direct charge of the tournament deserves great commendation. It consisted of D. E. Sawyer, chairman; M. G. Baker, B. A. Clements, H. N. Scott, and F. H. Thompson. Chairman George R. Carr of the entertainment committee also worked very hard and effectively to make the affair a success.

The scores of the players in detail were as follows:

Name.	Gross.	Medal Play Handicap.	Net.	Kickers' Handicap.	Net.
T. W. Aishton	104	22	82	26	78

THE PURDUE DINNER

The Purdue graduates in attendance at this year's convention, enjoyed their customary get-together dinner Saturday evening, at the Shelburne. Notwithstanding the fact of its being an "off" year, the Purdue boys are very proud of the representation they have been able to muster by virtue of their connection with railway mechanical affairs. Among those registered to date and otherwise known to be present, are the following:

C. D. Barrett, Pennsylvania R. R., Williamsport, Pa.; B. F. Bilsland, General Electric Co., Chicago; J. T. Carroll, Baltimore & Ohio R. R., Baltimore Md.; E. G. Chenoweth Chicago, Rock Island & Pacific Ry., Chicago; H. W. Coddington, Norfolk & Western Ry., Roanoke, Va.; E. E. Chapman, A. T. & S. F. Ry., Topeka, Kan.; Chas. Ducas, Jacobs-Shupert Locomotive Firebox Co., New York; L. E. Endsley, University of Pittsburgh, Pittsburgh, Pa.; F. B. Ernst, American Steel Foundries, Chicago; E. L. Grimm, Northern Pacific Ry., St. Paul, Minn.; N. E. Gee, Pennsylvania R. R., Altoona, Pa.; E. E. Greist, Pennsylvania Lines West, Ft. Wayne, Ind.; R. J. Himmelwright, American Arch Co., New York; H. A. Hoke, Pennsylvania R. R., Altoona, Pa.; J. M. Henry, Pennsylvania R. R., Pittsburgh, Pa.; Tabor Hamilton, Pennsylvania Lines East, Chambersburg, Pa.; F. T. Huston, Pennsylvania Lines West, Ft. Wayne, Ind.; Fred Hartman, General Electric Co., New York; J. H. Jaschka, National Malleable Castings Co., San Francisco; J. R. Jackson, A. T. & S. F. Ry., Topeka, Kan.; D. M. Knox, American Car & Foundry, Chicago; J. M. Lammedee, *Railway Review* Chicago; "Bud" Leet, Pennsylvania R. R., West Philadelphia, Pa.; Fred Mathews, Standard Railway Equipment Co., Chicago; B. B. Milner, New York Central R. R., New York; R. R. Mitchell, Crocker-Wheeler Co., Ampere, N. J.; J. R. Mitchell, H. W. Miner Co., Chicago; Sam. Morgan, B. M. Jones Co., Inc., Boston, Mass.; J. E. Muhlfeld, Consulting Engineer, New York; H. C. May, Monon Route, La Fayette, Ind.; J. P. Neff, American Arch Co., New York; C. D. Porter, Pennsylvania R. R., Altoona, Pa.; A. K. Reading, The Bettendorf Co., Davenport, Ia.; G. P. Robinson, Interstate Commerce Commission, Washington, D. C.; W. L. Robinson, Baltimore & Ohio R. R., Baltimore, Md.; E. E. Silk, The Bettendorf Co., Chicago; F. A. Schaff, Locomotive Superheater Co., New York; A. G. Vogt, Pennsylvania R. R., Altoona, Pa.; A. O. Van Dervoort, H. G. Hammet Co., Troy, N. Y.; R. B. Watson, Erie R. R., Meadville, Pa.; Prof. L. W. Wallace, Purdue University, La Fayette, Ind.; J. C. Whitridge, Buckeye Steel Castings Co., Columbus, O.; O. C. Wright, Pennsylvania Lines West, Ft. Wayne, Ind.

AS OTHERS SEE US

If the daily newspapers are no more accurate in reporting other things than they are in telling their readers of what happens in Atlantic City during the mechanical conventions we are fearful of the consequences. It has been suggested by some of the officers of one of the associations that it might be advisable to have a press committee to censor the news and prevent the correspondents sending out such misleading and distorted information.

The following, for instance, is taken from the *New York Times* of Saturday morning:

> Failure of the Committee on Resolutions to offer any possible changes in the present system of railroading created no little surprise at the closing session today of the Master Mechanics' Association.
>
> Not even one variation was mentioned, although recommendations were made favoring electrical equipment, as the committee members concede the days of steam railways are numbered.

The first paragraph is absolutely unintelligible to those who are familiar with the work of the Master Mechanics' Association. How the correspondent got his material for the second paragraph from Mr. Quereau's splendid report on electrification is a question.

Apparently the article which was published in the *Atlantic City Review* on the same morning is not intended to be serious, but it throws an interesting side light on some of the phases of the exhibition which have attracted the attention of outsiders. The article which appeared on the first pages is signed Peggy Prattle and is headed, "Car Builders' Convention—Why Exhibits Have Unique Interest for Both Sexes." Near the end of the column we find these words:

> They also had all kinds of novelties such as apple corers, knife sharpeners, siphon corks and table sweepers,—just the things to win a woman's heart and make her happy.
>
> After all, isn't this the main object of the Master Mechanics and Master Car Builders Convention? The nicest girl in the world is usually the inspiration for all the fine things an American man accomplishes.

ADDITIONAL MASTER CAR BUILDERS' REGISTRATION

Acker, Charles L., M. M.; Toledo Terminal; Armstrong.
Alter, William, Shop Supt.; Erie; Pennhurst.
Andrewcetti, Jos. A., Asst. Elec. Engr.; C. & N. W.; Dennis.
Andrews, S. B., M. E.; Seaboard Air Line; Shelburne.
Ayers, A. H., Prin. Asst. Engr.; N. Y. C.; Blenheim.
Barrett, R. W., M. C. B.; N. & S.; Lexington.
Beaghen, Thos., M. C. B.; Union Tank Line; Traymore.
Beaumont, H. A., G. F. C. S.; B. & O.; Dennis.
Boyer, Chas. E., Genl. Car Inspt.; P. R. R.; Runnymede.
Carson, G. E., D. M. C. B.; N. Y. C.; Dennis.

Sinnott, William, M. M.; B. & O.
Smith, R. E., G. S. M. P.; S. C. L.; Chelsea.
Thompson, W. O., M. C. B.; N. Y. C.; Blenheim.
Wall, George L., V. P.; Lima Loco. Corporation; Brighton.
Werst, C. W., Supt. Works; Lima Loco. & Mch. Co.; Blenheim.

ADDITIONAL SPECIAL GUESTS

Baird, B. H., Car Draftsman, So. Pac.; Strand.
Baldwin, C. D., Pur. Agent; Bangor & Aroostook; Traymore.
Barstow, Wm. A., Asst. to Pres.; Union Tank Lines.
Bateman, Frank, Director, Atlantic City Ry.
Baumbush, A. J., General Foreman; N. Y. C.
Berg, J. V., Clerk; N. Y. C.; Pennhurst.
Bigelow, C. H., Chief Mech. Engr., Millville Trac. Co.
Broderick, J. T., Ch. Cl. to V. P.; B. & O.; Brighton.
Brooke, J. C., Gen. For.; B. & O.; Tabor Inn.
Busse, F. W., Chief Clerk to Gen'l S. M. P.; B. & O.; Strand.
Butterworth, J. A., Asst. to Pur. Agt.; So.; Blenheim.
Clark, J. C., For. Boiler Maker; P. & R.
Clark, W. A., Supvr.; P. R. R.; Bathwell.
Craig, J. M., Supt. Elec. Car Lighting; P. R. R.; Shelburne.
Creach, J. B., Havana Rys.; Shelburne.
Danbach, C. O., Supt.; B. & O.; Sterling.
Deyo, Leib, Chief Order Clerk; N. Y. C.; Blenheim.
Donaghue, C. H., Gen. Foreman; N. Y. C.; Pennhurst.
Dunlap, W. J., Storekeeper; B. & O.; Emmett.
Flannagan, Harry, M. C. B. Clerk; Great Northern.
Gainy, J. J., M. C. B.; Q. & C.; Chalfonte.
Geoghegan, T. T., Mech. Engineer; C. N. O. & T. P.; Chalfonte.
Gority, John, Gen. For.; P. R. R.; Traymore.
Gustin, W. M., C. C. I.; Ban. & Aroos.; Haddon Hall.
Hale, Arthur, Chairman Com. on Relations; Brighton.
Hale, Arthur, Genl. Agent; Amer. Ry. Assn.; Brighton.
Hall, John M., Interstate Commerce Com.
Hayes, J. C., M. C. B. Bill Clerk; N. Y. C.; Pennhurst.
Henry, H. B., Asst. to Dir. of Pur.; So. Pac.; Chelsea.
Heyden, Thos. Vander, Draftsman; P. R. R.; Shelburne.
Hutchison, W. M., Vice President; Union Tank Line; Traymore.
Kapp, J. B., Asst. M. M.; P. R. R.; Ardmore.

FOREIGN VESSELS ADMITTED TO AMERICAN REGISTRY.—The total number of foreign-built vessels admitted to American registry under the act of August 18, 1914, up to April 17 was 137 with a gross tonnage of 489,508. The number of sailing, steam and unrigged vessels built in the United States in March was 111, of 24,538 gross tonnage.

Conventionalities

George W. Rink, mechanical engineer of the Central Railroad of New Jersey, has just been honored with an appointment in the Railway Committee of the American Society of Mechanical Engineers.

H. T. Bentley has during the past year joined the ranks of "grandfathers," being automatically appointed through the birth of Margaret Oadams Bentley, the daughter of Mr. and Mrs. Walter H. Bentley.

Daniel Brady is attending his forty-second consecutive convention, the first one he attended being held in New York City in 1875. In those days most of the railroad men brought their families with them.

For a little chap Hiram Hammett, of Troy, is surely holding down some pretty big jobs. A month ago he was elected president of the Chamber of Commerce and Troy is already beginning to loom up larger on the map.

C. F. Quincy (Q. & C. Co.), Keeping His Eye on the Ball

Stanley Bullard, vice president of the Bullard Machine Tool Company, will not be at the conventions this year. He recently underwent a serious operation, from which we can with pleasure report that he is recovering very nicely.

August W. L. Hartbauer, formerly of the railway sales-organization of the McCord Manufacturing Company of Detroit, Mich., has been promoted to the position of superintendent of the automobile radiator, gasket lubricator and railway appliances department.

O. C. Cromwell, mechanical engineer of the Baltimore & Ohio, had quite a serious operation for appendicitis several months ago, from which he has hardly yet fully recovered. He is looking fine, however, and expects shortly to get back on the job.

Mrs. J. W. Fogg, who has been a regular attendent at the conventions will not be here this year on account of the illness of her father, Reverend Dr. Kennedy Marshall. Her many friends hoped to see her here with her 4-year old daughter Elizabeth Mary.

Arthur J. Merrill, Secretary, Southern & Southwestern Railway Club, and Mrs. Merrill

W. L. Robinson, supervisor of fuel consumption of the Baltimore & Ohio, has been attending the conventions for twelve years. This time he was only able to get away long enough to spend Sunday on the Pier, it being necessary to hurry back to attend a monthly meeting of the operating officers.

S. P. Bush, Buckeye Steel Castings Co., at the Top of His Drive

Our friend, Stephen C. Mason, of the McConway & Torley Co., was a little late in getting here, and the cigars have not yet arrived; but he took the time to call at the *Daily* office the first thing Saturday morning and leave a copy of his prescription for eternal youth. It reads, "don't worry!"

Left to Right—Jas. J. Connors, Asst. Supt. Motive Power, C. M. & St. P., and J. W. Fogg

E. L. Chollman, of the Southern Locomotive Valve Gear Company, says that throughout the south and southwest there is an undercurrent of optimism, a feeling that business is on the upclimb, and that the railroads are gradually beginning to feel the impetus of new business and renewed confidence.

D. R. McBain's Club Was Faster than the Camera

Oscar P. Wilkins, master painter, Norfolk & Western, past president of the Master Car & Locomotive Painters' Association is attending the M. C. B. convention. He reports very prosperous times on the N. & W. Since the first of March the Roanoke shops have been operating full force and full time.

Chairman George R. Carr, of the entertainment committee, is sorry because Mrs. Carr is not able to be with him at the conventions, but he is perfectly satisfied with the cause of her absence. That cause is that they have at their home a little daughter who is now only three months old. The young lady, who has been named Katherine, is getting along finely.

S. S. Riegel, mechanical engineer of the Delaware, Lackawanna and Western, reports that dynamometer car tests are being made of the Pacific type locomotive equipped with his water tube firebox. A second engine fitted with one of these fireboxes will be delivered to the road by the American Locomotive Company within the next two or three weeks.

"There is something wrong about this war order business," says W. W. Melcher, of the Mass. Mohair Plush Company. "All other railway equipment companies seem to be so favored as to stand in the very path of many easy orders from Europe, but not the mohair plush trade. Blankets—even corduroy—has been in demand by the armies abroad. The

E. H. Bankard, Purchasing Agent, B. & O., Makes a Practice Stroke!

war order plays about mohair plush like fitful lightning but never hits.

Through the inadvertent (?) burning of Scott's garage in Chicago last week, the mechanical fraternity of the Central West suffered the loss of one of the most famous monuments thus far known to this horseless age; the suffering being the more acute on account of the wide-spread common interest (?) held in this machine. A stick of "Polarized" is said to have short circuited the pilot light. Fortunately there was no insurance.

Word has just been received from William V. Dee, of the G. Drouve Company, Bridgeport, Conn., that he will not be at the convention this year. Will Dee was for so many years identified with these conventions, first in the capacity of a staff member of the *Daily* and later in his present connection, that his friends are many. All regret to learn that his physician has ordered him to take a month's vacation in order to rebuild an overworked system.

L. M. Schechter, chief engineer and commercial manager of the Russia Locomotive & Machine Company, Kharkoff, Russia, is a visitor at the conventions. Mr. Schechter is in the United States for the purpose of studying American rail-

way mechanical conditions and equipment and purchasing machine tools. He says that largely because of the conditions arising from the war in Europe, the trade relationship between Russia and the United States is likely to be much closer in the future than it has been.

The Pittsburgh & Lake Erie men all have their families with them this year. Dave Redding, master mechanic, is accompanied by his wife and his niece, Miss E. G. Leonard. His son Robert is also helping at the enrollment booth. Sam

C. W. Cross and His Son Who Has Just Finished His Special Apprenticeship Course on the N. Y. C. at Elkhart

Lynn, master car builder, has Mrs. Lynn and his daughter with him. W. P. Richardson, mechanical engineer, is accompanied by his wife and seven-year-old daughter, Alice. Mrs. Redding and Mrs. Lynn have attended several conventions, but this is the first one for Mrs. Richardson.

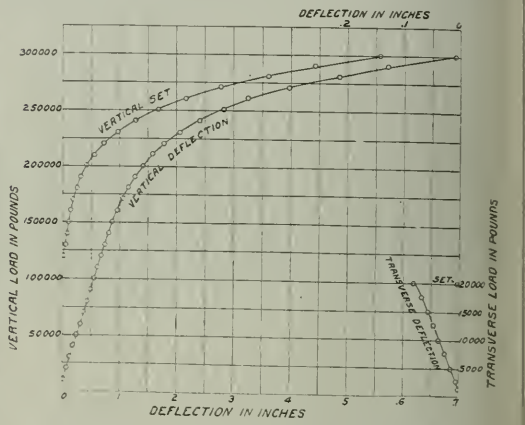
The entertainment committee deserves to be especially commended for the plans it made for the carnival dance on Friday night and the great success with which it carried them

L. A. Richardson, Mech. Supt., First District, C. R. I. & P. and Mrs. Richardson

out. Probably no entertainment feature in connection with the conventions was ever more enjoyed. Furthermore, as economy is the keynote of everything done in the railway and railway supply businesses these days, it is worth while to mention the fact that this function was remarkably inexpensive. The total amount which the committee spent for it did not exceed $75. In spite of this, the scene after the serpentine balloons and paper hats and caps had been distributed was as attractive as the entire party was merry.

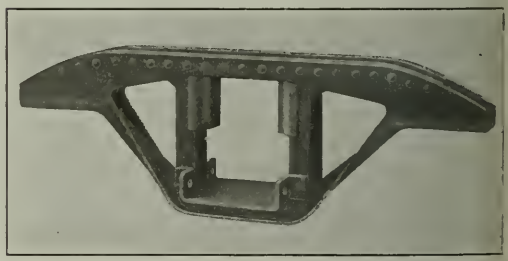
FORGED STEEL TRUCK SIDE FRAME

The Allegheny Steel Company, Pittsburgh, presents this year a new forged steel truck side frame of interesting design. The illustrations give a very clear idea of its construction. It is made up of three pressed steel members riveted together. The compression and tension members are pressed from one piece, and the columns and spring seat support from another. The third piece is a channel stiffener riveted to the top member as indicated in the illustrations. Bolster



Deflection and Set Tests on Forsyth Forged Steel Truck Side Frame

wearing strips are riveted to each column and a spring plank support is riveted to the bottom member of the frame. The weight of the frame is approximately 480 lb. It was designed and patented by W. D. Forsyth to meet the requirements of the high capacity cars. From tests made by Professor L. E. Endsley, of the University of Pittsburgh, it was found that with a vertical load of 68,500 lb. and a transverse load of 9,000 lb. the maximum stress obtained at any one section was 13,500 lb. This occurred at three points in the



Forsyth Forged Steel Truck Side Frame

frame. The deflection and set of the frame was taken in increments of 10,000 lb. up to 320,000 lb., after which the frame was loaded to destruction, the maximum load being 473,000 lb. The results of these tests are shown in the accompanying curve. It will be noted that for a load of 150,000 lb. the deflection was .09 in. and the set .01 in.

FLEXIBLE CONNECTIONS.—In the article describing the flexible connections made by the Barco Brass & Joint Company, published in the *Daily*, of June 11, page 1285, it was indicated that these joints were used exclusively for water lines. Their principal uses are in steam, air and oil lines, the use on water lines being limited.

MALLEABLE IRON EXHIBIT

The National Malleable Castings Association is exhibiting a number of malleable iron castings made from a mixture said to produce a metal which is similar to mild steel in many of its physical characteristics. The association is made up of about 30 manufacturers of malleable castings for the purpose of improving the quality of their product and of conducting an educational campaign as to the possibilities of this material. The mixture exhibited has recently been developed after about two years of research work.

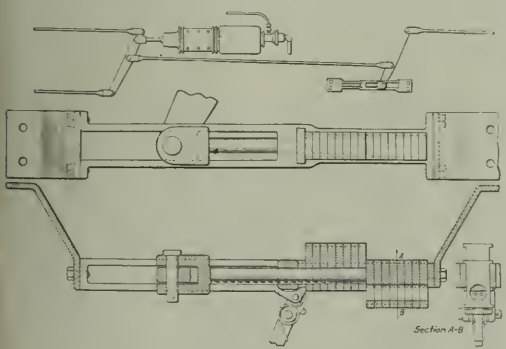
Malleable Iron Wedges Tested Under a Drop Hammer

The illustration shows the result of subjecting wedges of this material to a drop hammer test, indicating its toughness. It is claimed that malleable sections may be produced with a thickness as great as two inches and the material may be machined without detriment to its physical qualities. Micro-photographs are included in the exhibit showing the structure of the metal at all stages of its manufacture.

SLACK ADJUSTER FOR BRAKE EQUIPMENT

To provide a convenient means of manually taking up the slack and adjusting the piston travel on foundation brake gears the device shown in the illustration has been developed and is being exhibited by the H. W. Johns-Manville Company, New York. As shown it is applied to the fixed end of the floating lever but is equally adapted for use on any other part of the brake gear where piston travel may be adjusted from one point.

The frame of the device, which is attached to the car body,



Freight Car Slack Adjuster

has a four-bar section at one end and a two-bar section at the other. The four bars serve as guides for the jaw connection on the end of the thrust rod, to which the end of the floating lever is pinned. Between the two bars, which open vertically, are placed a number of blocks or shims, the lower ends of which are provided with holes for the passage of the thrust rod. These are retained between the bars by means of flanges at the top and bottom but have a considerable amount of vertical play. The thrust rod is fitted with ratchet teeth on its under side, these being engaged by a lever-operated pawl.

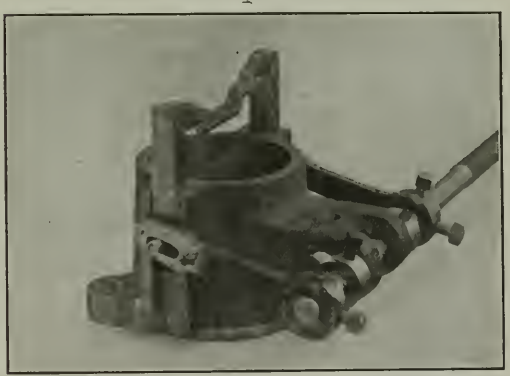
When assembled the thrust rod passes through a guide in the frame and thence through the shims which are raised to their upper position to bring the holes in line. To take up slack it is only necessary to move the thrust rod ahead by means of the lever and ratchet until one or more of the shims is free from the end of the rod, when they will drop down and close the opening for the rod.

This device makes it unnecessary to crawl under the truck and take up the slack by removing the cotter keys and shifting the lever from hole to hole in the brake rod jaw. By providing a means of taking up the slack at one conveniently located point under the car it is expected to result in more uniform attention to proper adjustment of the slack and consequently in more uniform piston travel.

VARIABLE EXHAUST NOZZLE

In discussing J. Snowden Bell's paper on Variable Exhausts, presented during the Friday morning session of the American Railway Master Mechanics' Association convention, C. A. Seley referred to a variable exhaust nozzle developed by F. Mertsheimer, superintendent motive power and car department of the Kansas City, Mexico & Orient. This device is in use on a number of engines, some of which have been equipped since September, 1914.

The nozzle is cast with lugs on one side through which is run a shaft which extends out through the left side of the smokebox. A stepped bridge 7-16 in. wide is guided in vertical slots on the outside of the nozzle. This is con-



Variable Exhaust Nozzle in Use on the Kansas City, Mexico & Orient

nected to the shaft by arms which raise or lower it as the shaft is turned. An arm one the end of the shaft outside of the smokebox is connected to the operating lever in the cab by a reach rod. In its lower position the bridge extends down into the nozzle and it may be raised to a clear height of 1⅜ in. above the top of the nozzle.

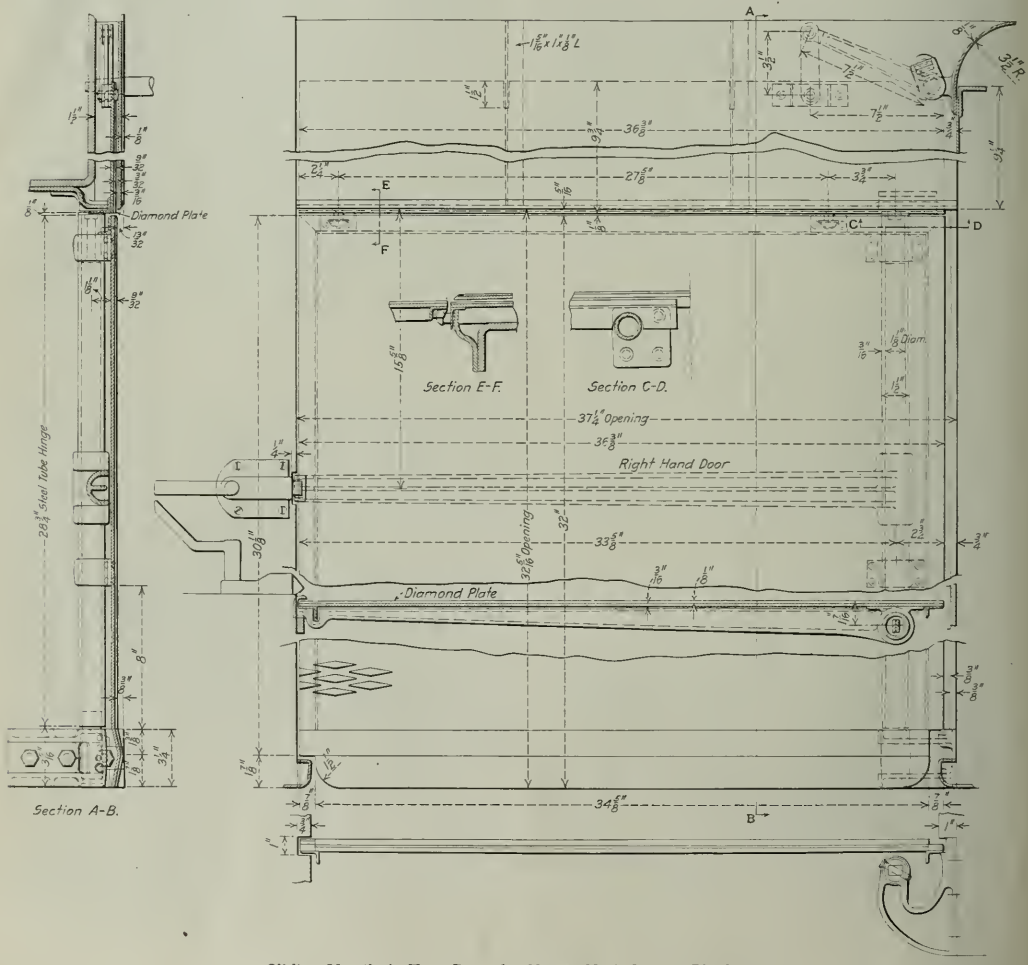
In applying it to nozzles which have been running with round nozzles, unbridged, the new nozzles are made ⅛ in. larger than the old ones. Where the old tips are bridged the new ones are made ⅛ in. smaller than those replaced. This results in a larger opening when the movable bridge is raised in either case. Considerable saving in coal is said to have followed the application of these nozzles and it has eliminated steam failures. Their use has also effected considerable reduction in the amount of fire cleaning required on the road and at terminals. The device has been patented by Mr. Mertsheimer.

SLIDING VESTIBULE TRAP DOOR

The trap door shown in the illustration is designd to slide laterally beyond the side of the car when discharging and taking on passengers at high station platforms. There is usually a dangerous gap between the side of the car and the edge of such platforms and the purpose of this trap is to insure safety at such points.

Aside from the sliding feature the door operates in the usual manner. It is pivoted on a hinged tube which contains the torsional spring bar, and near the center of which is placed a stationary arm of malleable iron. This bar extends entirely across the under side of the door and is turned up at the end to form the latch plate. The door itself is free to slide on the hinge tube and is operated by a mast and handle located near the end door post. The mast is connected by a lever and link to a slide plate located under the car platform and to which the trap door is attached when closed. By turning the operating handle the slide is forced outward and in turn moves the door which slides through slots provided in the vestibule door casing. When it is extended beyond the side of the car the slots in the casing prevent the trap door from being opened.

This device is now in service on a number of cars and is manufactured by the O. M. Edwards Company, Inc., Syracuse, N. Y., in whose exhibit it may be seen.

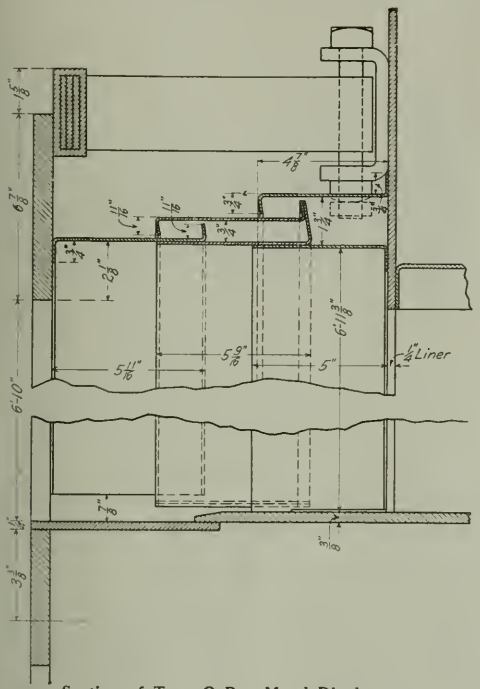


Sliding Vestibule Trap Door for Use at High Station Platforms

LONG TRAVEL FRICTION DRAFT GEAR.—A friction draft gear having a travel of 3¼ in. has been designed by the Gould Coupler Company, New York, and is being exhibited at the booth of this company during the convention. The design is such that the gear will go into the recommended M. C. B. pocket space and the friction elements are the same as in the gear having 2½ in. travel. Owing to the increased travel, however, it was impossible to use coil springs for releasing the friction elements and the release rigging is made up of leaf springs which give the additional travel and also a high release capacity. In order to avoid confusion in taking apart and assembling the gear the release spring elements are assembled before being placed in the gear which is assembled complete in a casing of substantial design. This gear has a capacity of 300,000 lb.

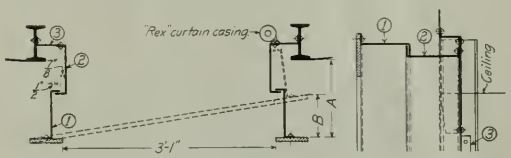
REX METAL DIAPHRAGMS

One of the interesting improvements in passenger train equipment that has just been placed on the market is the Rex metal diaphragms. The Curtain Supply Company, Chicago, has taken over the two-piece diaphragms known as type *L. S.*, and the



Section of Type Q Rex Metal Diaphragm

three-piece diaphragm, known as type *Q*. Both these diaphragms have been in successful operation on the Lake Shore and Chicago, Burlington & Quincy, respectively. By referring to the illustration shown herewith the construction of both types may be readily understood. They perform all the functions of the present diaphragms, being fireproof, waterproof, dustproof, flexible and may be applied to all types of existing equipment presenting no difficulties in being used in connection with equipment provided with the old diaphragms. In addition, their chief characteristic is their substantial construction. There is no question but they will outlive the present duck diaphragms and it is expected that they will last for the life of the car.



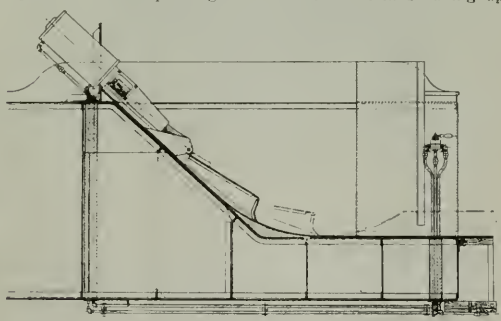
Section of Type L. S. Rex Metal Diaphragm

The *Q* type lends itself particularly to application to existing equipment, as it can be applied with no alteration to the end construction. The *L. S.* type in some cases will require slight alterations in the vestibule end post. On new equipment either may be applied with equal facility. Both types of diaphragms are supported in the customary manner.

Type Q and Type L. S. Rex Metallic Diaphragms

LOCOMOTIVE COAL PUSHER

A coal pusher designed for application to the tenders of existing locomotives with a minimum amount of attention, is being exhibited by the Locomotive Stoker Company, Schenectady, N. Y. The cylinder is mounted on a sheet placed over the back and bottom coal pit sheets and covering the original shovel sheet. Secured to this sheet are two steel bars which form the guides for the crosshead. A shield casting extends down over the piston rod, which is thus entirely covered, an extension on the crosshead moving up into the shield when the pusher is in its upper position. The crosshead extends across the coal pit and is designed to form a pushing shoulder to assist in breaking up



Sectional View of Tender With Coal Pusher and Elevated Shovel Plate

and moving the coal forward. To it is hinged an apron which forms the main pushing member.

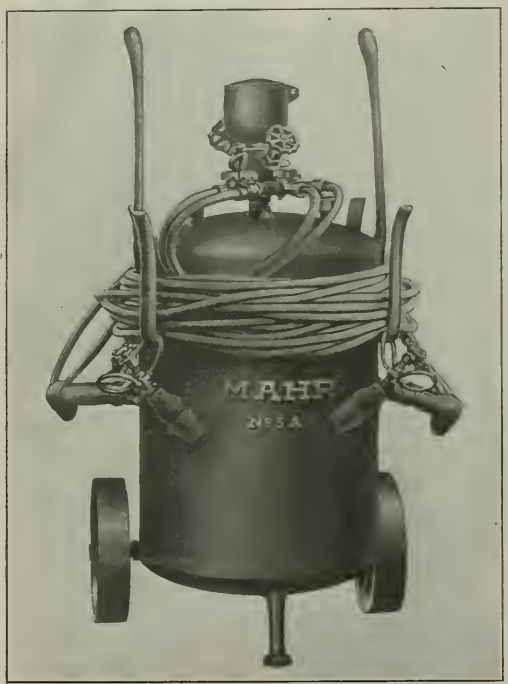
The pusher, being located under the coal pile, tends to break up the entire body of coal should it be frozen, and works it forward to the shovel sheet in condition for handling. As shown in the illustration, the operating valve is located above the tender deck near the coal gates. It may be placed on the cylinder, however, and be operated by a lever and reach rod. The tank sheets are subjected to no additional stresses due to the operation of the coal pusher because the entire equipment is a unit assembled on the sheet covering the bottom and back of the coal pit.

A raised shovel sheet is shown in broken lines on the drawing, the purpose of which is to raise the coal to the level of the fire door.

PAINT BURNER

The paint burning outfit, illustrated herewith, is designed to use kerosene as fuel. The usual method of burning paint is with gasolene and the introduction of the kerosene burning equipment is for the purpose of reducing the danger involved in the use of gasolene as fuel about the paint shop.

The torches of the outfit operate on the atomizing principle and require cleaning less frequently than would torches of the generating type due to the formation of carbon in the generating tubes and small gas outlets. The torches are



Kerosene Paint Burner

light and conveniently arranged for handling and the size of flame may be readily varied by the operator to meet the requirements of the work. The equipment is designed to operate with any air pressure from 10 lb. to 125 lb. per sq. in. An outfit, consisting of two torches and a fuel tank, is on exhibit at the booth of the Mahr Manufacturing Company, Minneapolis, Minn.

LIGHTING FEATURE OF THE BABCOCK WATER GLASS GUARD.—Changes in the design of the Babcock water glass guard have been made during the past year which have considerably increased the serviceability of this device. In general design it consists of two parts—the back, which includes the ends and packing glands and is provided with an outlet at the bottom for steam and broken glass; and the removable front, which contains the sight glasses. The change of greatest importance consists in the redesign of the front casing to include a narrow slot at the apex of the angle between the sight glasses in front of which the gage lamp is placed. The light thus admitted thoroughly illuminates the interior of the guard and clearly indicates the water level in the gage glass. This device is on exhibit at the booth of the American Car and Ship Hardware Manufacturing Company, New Castle, Pa.

CLOSE QUARTER DRILL

A recently designed drill for use in close quarters is shown in the illustration. It is being exhibited by the Ingersoll-Rand Company, New York. The motor is of the three-cylinder type, controlled by a valve of the same design as used in the regular line of "Little David" drills, manufactured by this company. The valve is geared to the crank shaft, which obtains its motion from three rocking levers con-

Drill for Use in Confined Spaces

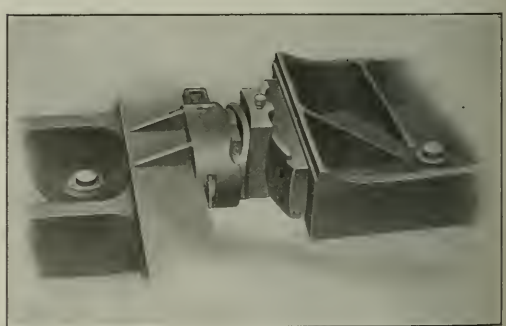
necting the pistons to the drill spindle. As may be seen in the photograph, the throttle is located in the handle.

The design of this drill is simple and rugged and it is adapted to all work in confined spaces. It has few parts, and is therefore easy to overhaul and assemble. The movement of the spindle is steady and the motor is claimed to require one-fifth less air than others of a similar type.

RADIAL BUFFER

A radial buffer is being exhibited by the Economy Devices Corporation, New York, which has been designed to provide for all movement between the engine and tender whether vertical, horizontal or rolling. It is made in two types, one in which the tender buffer is provided with twin springs for taking up the slack and the other in which a wedge is used, the latter being shown in the illustration.

The essential features of this buffing device consist of a chafing plate on the tender, having a vertical cylindrical surface, a spherical chafing plate on the engine and a floating block one side of which is spherically curved to conform to the engine chafing plate and the other radially curved to



Radial Buffer Having Universal Movement

conform to the chafing plate on the tender. Vertical movements are taken care of between the surface of the tender chafing plate and the floating block; horizontal movements by the sliding of both chafing plates on the surfaces of the floating block, and rolling movements between the surfaces of the floating block and the spherical chafing plate. All parts are cast steel with specially treated wearing surfaces.

M. C. B. Rules of Interchange

The suggestion of President Crawford that the Interchange Rules remain in force for at least two years before being materially changed, is one that will be appreciated by every car inspector and car foreman who has to use them. At best, it is difficult to get an interpretation of the rules that will be satisfactory to all. When rules are changed it takes several months for the inspectors throughout the country to become thoroughly familiar with them and interpret them correctly. By allowing them to remain in effect for a longer time, the troubles due to these misunderstandings will be minimized and for a year at least cars should be interchanged with a great deal less difficulty than at the present time. Various car associations have realized this and have refused this year to offer any suggestions to the arbitration committee in the hope that this committee would not make any radical changes in the present rules.

M. C. B. Association and the Minor Organizations

President Crawford, in his address, made a good suggestion regarding an arrangement whereby the Master Car Builders' Association could be kept in closer touch with the minor car organizations. A suggestion has been advanced several times to the effect that a representative of the M. C. B. Association should attend the Chief Interchange Inspectors and Car Foremen's Association Conventions to assist the members of that association in placing correct interpretations on the M. C. B. Rules of Interchange. That association meets for the sole purpose of establishing among its members a uniform understanding of the rules. In numerous cases it has been found that what they conceived to be the right interpretation was not in accordance with what the arbitration committee intended. This makes it necessary to undue a lot of work, as these opinions are spread through the entire country. With a representative of the Arbitration Committee at the meetings the liability to misunderstandings would be greatly reduced.

Scrap Lumber From Box Cars

The opportunity of making use of scrap lumber from dismantled cars and bridges is not always given proper consideration. With the increasing cost of lumber it presents a field of endeavor that can be made very remunerative. The Chicago, Burlington & Quincy has gone into a study of this problem extensively. At a recent meeting of the Western Railway Club, William Queenan, assistant shop superintendent at Aurora, Ill., stated that from 700 dismantled cars about $15,000 worth of lumber, rated at $14. per 1,000 ft., was reclaimed at a total cost of between $11,000 and $12,000. This lumber is used for repairs and as excessive amounts accumulate, the lumber is used in the construction of new stock cars, at a very great saving. They even find it expedient to remove the nails from all good sheathing, finding many uses to which it may be placed. The ingenious car man will be able to find many uses for lumber that is now thrown away. As useless as scrap lumber may superficially appear, the possibilities for its reworking have been demonstrated and those roads that have not investigated the matter will be surprised to find what can be done with it.

Increased Freight Car Mileage

One of the most important points brought out in President Crawford's address is that of the necessity for increasing the mileage of freight cars. This is a matter which does not concern merely the car department, but the entire railway organization, bearing as it does so directly on both earnings and expenses. Operating officers are particularly interested in this subject and, as stated in the address, in order to obtain the greatest practicable mileage per car per year, concerted efforts should be made. The suggestion regarding elimination as quickly as possible of such rules of the various associations as tend to hinder a prompt car movement, is also a good one. It is, of course, not intended to urge the running of cars that are not in an altogether safe condition, but much can be done to facilitate movement and at the same time give proper attention to repairs. This is a point which should be carefully weighed in deciding on new equipment. The officers who object so strenuously to the expenditure of an extra dollar on any special device on or special construction of freight cars, should bear in mind that the cheap, flimsy car is bound to be on the repair tracks more than the car which is substantially built, and that a car undergoing repairs is not earning money for the company.

STEEL PASSENGER CARS

WHEN we published the article on the Steel Passenger Train Car Situation in the *Railway Age Gazette* of November 21, 1913, our records showed that on January 1 of that year that there were 7,271 all-steel passenger cars in service, 3,296 steel underframe cars and 46,926 wooden cars. A statement just issued by the Special Committee on Relations of Railway Operation to Legislation shows that on December 31, 1914, two years later, there were in service 12,900 steel, 5,700 steel underframe and 43,512 wooden passenger train cars. The figures are not strictly comparable because those for January 1, 1913, cover roads owning 57,493 passenger-train cars and operating 227,754 miles, while the more recent figures cover roads having 62,112 passenger equipment vehicles and operating 245,721 miles. During the past six years the percentage of all-steel passenger cars built has increased from 26 to 74.6, while the percentage of steel underframe cars built has changed from 14.8 to 20.9 per cent

The older wooden cars are being retired steadily, so that the percentage of steel and steel underframe cars will increase rapidly within the next few years. Wooden cars to the number of 1,048 were retired during the calendar year 1914. It is estimated that to replace the present wooden cars will cost approximately $560,000,000.

Legislation to require railroads to build nothing but steel or steel underframe cars and to retire the wooden cars within a given period has been advocated for several years, but Congress has never taken any definite action. There would now appear to be no need for such action, as the roads have practically discontinued the building of wooden passenger-train cars and such cars as are now in service will be retired as they become worn out or obsolete. At the rate at which the change is now going on the larger proportion of the roads will have all the steel cars needed in high speed and heavy traffic within a comparatively short time; in fact, many of them are now in this condition.

What our legislators will have to guard against is taking any action which will put the railroads to unnecessary heavy expenditures in changing equipment, when better results can be obtained by using the same money to provide other things which will contribute more effectively to the prevention of accidents and to the safety of the passengers and employees.

IMPROPER CHARGES FOR CAR REPAIRS

"IT is quite possible that some few car owners deliberately charge for repairs not made, possibly not with the consent of the higher officers, but through the over-zealousness of some of the minor officers who are endeavoring to make a record for low cost of maintenance," is a statement made by a prominent car department officer.

This is a very good answer to the insinuations that have been made regarding the charging for fictitious repairs to foreign equipment. Whether the officers know or do not know that there are irregularities practiced by their subordinates in the repairing of foreign equipment something must be done to correct the evil. The trouble probably lies with the "over-zealous" minor officers and while some may follow questionable methods "to make a record for low cost of maintenance," the majority are guilty of malicious negligence. In other words, some find it easier to make "pencil repairs" than to do the actual work.

In order to overcome this, some mechanical officers have suggested that an inspection bureau be formed to operate under the jurisdiction of the M. C. B. Association, the inspectors being sent to different parts of the country to investigate the practices of the various roads. It would appear that a bureau of this kind would be unwieldy, would increase the work of the association and, unless the number of inspectors was very large, the desired results could not be obtained. Another suggestion that appears to have much more merit is that each road establish its own system of inspection. Such a system is already in effect on some few roads with very good success. With inspectors reporting direct to headquarters, the heads of the mechanical departments can be kept fully informed as to the conditions and govern themselves accordingly. The inspectors being continually on the road, jumping from place to place, will be in a position to make what might be termed "surprise inspections." Then those local inspectors who have been in the habit of making "pencil repairs," not knowing when such inspections are to be made, will be more careful to see that the work is done properly and that all the repairs for which bills are to be rendered are actually made. When it is known that their superiors are determined to have the work properly done and that they will not tolerate any irregularities there cannot help but be a marked improvement.

Had this practice been followed in past years, there would have been far less cause for the above noted insinuations. Many disputes would not have arisen and a large amount of ill-feeling now existing between the roads regarding repair bills would not have been engendered. With the present rules requiring that all foreign cars be maintained in the same serviceable condition as home cars, the work on foreign equipment has naturally increased and with it the opportunities for a larger number of irregularities. It, therefore, cannot be too strongly urged that every road institute its own system of inspection with a view of determining whether or not the local inspectors are maliciously billing for repairs to foreign cars not actually made. Where this is found to exist, prompt and drastic measures should be taken.

LOSS AND DAMAGE TO FREIGHT

SIXTEEN dollars paid out for loss and damage to freight for every $1,000 of gross freight revenue is a large percentage, and yet it is not an unusual one and is probably not far from the average for all of the roads in this country. A considerable portion of this loss and damage can be traced directly or indirectly to defective equipment. On two roads where campaigns of education have been waged to reduce loss and damage to a minimum it has been found possible to bring the figure down to $10 for every $1,000 of gross freight revenue. While the campaigns on both of the roads in question were conducted in such a way as to secure the interest and co-operation of every man who could be at all helpful, and this meant pretty nearly every man in the organization, and while the greater part of the saving was not due to improved equipment, yet that item has been a not unimportant factor in securing better results.

In one case the officer in charge of car design is known to have kept closely in touch with the performance of all of the cars in service as regards the protection of the lading against leakage, pilfering and the elements. He spent much time in keeping in intimate touch with the practical men of the car department and therefore knew almost as much as they did as to where the cars were weak and where they could be improved to advantage. On another road the general manager became interested in studying this phase of the problem and the next order of cars contained features which had never before been used on that road. True, they cost more, but after several years' experience the officer in question is certain that this was one of the best investments that he has ever made.

The trouble has been in too many cases that those who were responsible for the design or purchase of the cars, or who were interested in the cost of conducting transportation, did not really know where the trouble was and how to go about remedying it. One road has achieved excellent results by developing a loss and damage prevention movement similar to the safety first campaigns. Division and general committees have been appointed and to these committees every man in the organization feels that he can make suggestions or call attention to abuses, knowing that the information will not be used for purposes of discipline but to improve conditions and remove abuses.

To reduce and eliminate as far as practicable the losses due to damaged and stolen freight the supervising officers must know in detail just what is responsible for causing the damage. It is not right that the car repairman should think only of getting the work done and the cars off his hands and out of the terminal, but he should make sure that the work which he has done will not prove defective and allow freight to be damaged. The operating man, when damage is done, should insist on knowing the exact causes so that steps may be taken to prevent a reoccurrence. The mechanical department officers, and particularly those in the car department, should do everything in their power to have the men understand fully just what they can do to help improve the loss and damage record so far as it concerns defective equipment. As suggested by President Crawford, in his address, much can be also done in this respect by giving more attention to proper loading and the bracing of the loading. In addition to this car department employees are often in a position to notice abuses or wrong practices outside of their immediate department which they should be urged to report, not with the idea of spying on anybody, but of correcting abuses.

TODAY'S PROGRAM

TUESDAY JUNE 15, 1915

Discussion of reports on:

Couplers	9.30 A. M. to 10.30 A. M.
Safety appliances	10.30 A. M. to 10.45 A. M.
Rules for loading materials	10.45 A. M. to 11.00 A. M.
Overhead inspection	11.00 A. M. to 11.10 A. M.
Interline inspection	11.10 A. M. to 11.25 A. M.
Car construction	11.25 A. M. to 12.00 M.
Specifications and tests for materials	12.00 M. to 12.30 P. M.
Tank cars	12.30 P. M. to 12.45 P. M.
Individual paper—What is the value of a patent? By Mr. Paul Synnestvedt	12.45 P. M. to 1.30 P. M.

ENTERTAINMENT

10.30 A. M.—*Orchestral Band Concert.* Entrance Hall. Million-Dollar Pier.

3.30 P. M.—*Orchestral Band Concert.* Entrance Hall. Million-Dollar Pier.

9.30 P. M.—*Informal Dance.* Special Feature. Costume Recital. Miss Betty Lee. Ball Room, Million-Dollar Pier. Don Richardson Orchestra.

LOST

Badges 2722 and 3580 have been lost and if found should be returned to Secretary Conway.

ANOTHER CARNIVAL DANCE TO-NIGHT

The Carnival dance on Friday night proved so spontaneously successful that Chairman Carr of the entertainment committee has decided to repeat this feature to-night. The hall will be strung with twine as before so that the paper streamers when thrown will hang in festoons. While a special order has been placed for a large assortment of rubber novelties, such as balloons which when blown up and thrown burst like a bomb. One of the special features of the evening will be afforded by Miss E. M. Kegel and Frank Caslin who will give an exhibition of all the late dances on roller skates.

Miss Betty Lee will sing several songs and the Don Richardson orchestra will furnish all music. This is sure to be the "big" night, so do not fail to come early prepared to enter whole heartedly in the frolic.

ASSOCIATION OF RAILWAY ELECTRICAL ENGINEERS

The eighth semi-annual meeting of the Association of Railway Electrical Engineers was held at the Hotel Dennis, Atlantic City, June 14. President H. C. Meloy, New York Central Lines, made a brief address welcoming the association to the city. The secretary-treasurer reported a membership of 500, with a cash balance of $418.91 in the treasury. Progress reports of various committees were presented. The committee on Standardization of Cranes, Turntables and Transfer Tables reported that it was taking under consideration the standardization of motors to be used for these purposes.

The Committee on Compressed Air is to make an investigation of the power used for driving compressors and the abuse of the use of compressed air in shops. The Committee on Train Lighting Lamps is working towards a standardization of the various lamps now used with a view to decreasing the number. It is also making an investigation as to the proper method of rating lamps. The Committee on Standards is working with the M. C. B. Committee on Train Lighting. The Committee on Conduit Specifications reported that tests were being made on the Pennsylvania Railroad which would be available for the committee when completed. A number of minor changes have been made in the Specifications of Wires and Cables and the work of the committee is being broadened out to include specifications for wires to carry

TRANSPORTATION COMMITTEE

Top Row, Left to Right—L. S. Hungerford, Jr. (Peerless Rubber Mfg. Co.); R. W. Benson (American Flexible Bolt Co.); T. P. O'Brian (O. M. Edwards Co.); H. Chamberlain (Transportation Utilities Co.); A. L. McNeill (Central Electric Co.); J. T. Anthony (American Arch Co.); J. L. Randolph (Economy Devices Corporation); A. N. Dugan (Bronze Metal Co.); C. C. Schumaker (The Carborundum Co.).

Bottom Row—R. P. Cooley (Chicago Car Heating Co.); W. Anderson (Pantasote Co.); George T. Cooke, Chairman (Chicago Car Heating Co.); D. L. Clement (Pratt & Lambert); A. S. Lewis (Chicago-Cleveland Car Roofing Co.), and E. A. Averill (Standard Stoker Co.).

25,000 volts. The shop practice committee is to report at the annual convention on electricity vs. compressed air for portable tools, electrical furnaces for hardening tools and electro-magnets and magnetic chucks. The Committee on Illumination will report on yard elimination in classification yards.

A BUSY DELEGATION

The ten representatives from the Santa Fe have been making a most profitable and systematic inspection of the exhibits. The delegation is headed by John Purcell, assistant to vice president, the other members being Maham H. Haig, mechanical engineer; Charles T. Ripley, general mechanical inspector; H. B. MacFarland, engineer of tests; J. H. McGoff, mechanical superintendent; J. E. McQuillan, mechanical superintendent; Frank W. Thomas, superintendent of apprentices; Albert McRae, editor of the Stanta Fe Magazine; M. Robinson, master mechanic, and J. E. Symons, master mechanic. These officers were in attendance at all of the sessions of the Master Mechanics' Association, two of them taking an important part in the proceedings in the capacity of committee chairmen, Mr. Purcell being at the head of the Committee on Boiler Washing and Mr. Haig chairman of the Committee on Dimensions of Flange and Screw Couplings for Injectors.

Mr. Purcell had given his lieutenants instructions to do all the scouting among the exhibits necessary to pick out anything in which the Santa Fe might be interested before Saturday, and to make a note of it. On Saturday morning the entire delegation visited all of the exhibits which had been thus reported and held a joint discussion on the merits of the various devices. In this way a decision was reached as to the advisability of making further investigation and more was accomplished in a few hours than could have been done in a considerable period if it had been necessary for the members to study these devices from such information as they might obtain from other sources and advise among themselves by correspondence or discussion when they did not actually have the devices before them.

Mr. Thomas came east in advance of the rest of the party and attended the annual meeting of the National Association of Corporation Schools, which was held at Worcester, Mass. He is delighted with the progress which has been made by this association and says that the convention last week was the best which has yet been held. Several of the railroads have representatives in this association and seem to agree with Mr. Thomas in his estimate of its work.

GOLF ATOP OF THE TRAYMORE

One stunt was pulled off yesterday evening at 6.30 o'clock which was not on the program of the entertainment committee. This was a golf driving contest from the top of the Traymore hotel, the object being to see who could drive a ball farthest out to sea. Those who entered the contest were D. R. MacBain, superintendent of motive power of the New York Central-west of Buffalo; S. P. Bush, president of the Buckeye Steel Castings Company; and Clement F. Street, vice president of the Locomotive Stoker Company. Mr. Bush was the winner of the contest. Each contestant drove four balls, and two of those of Mr. Bush went far out to sea, so far, in fact, that they nearly "beaned" the judges who had gone out in a life saving boat to a distance which was assumed to be safe.

The judges were George R. Carr, Chairman of the Entertainment Committee, and Samuel O. Dunn. They were accompanied to sea by J. Will Johnson, president of the Railway Supply Manufacturers' Association; and the boat was propelled and controlled in its wayward course by two sturdy members of the Atlantic City Life Saving Crew.

The tee on which this novel driving contest was held was a wooden platform which had been improvised on the roof of the Traymore just in front of the front dome. This platform was about 150 feet above the ground, and was so narrow that when the players followed through, their clubs swung out over an aching void reaching clear down to the Boardwalk below. There are some golf courses in this country with tees at the top of pretty high hills, but this is undoubtedly one of the highest tees ever played from.

Mr. Street drove the first, and all his balls sailed out over the Boardwalk, and went pretty far to sea. Mr. MacBain, unfortunately, was not well equipped with a club. He is a "southpaw," and, as his clubs were not at his hotel, it was necessary to borrow one for him. The only thing that could be gotten was a cheap, light brassie, which was obtained from a store on the Boardwalk, and it did not have the right "feel" in his hands. However, he got his balls well away from the tee, considering the difficulties under which he labored.

Mr. Bush drove just as if he had been playing his own course; and that means that his two longest drives would have covered 250 yards on any good course.

While the players were performing on the roof, Mr. Johnson and the judges were having an exciting experience of their own. Mr. Carr took his seat in the bow of the boat and Messrs. Johnson and Dunn sat in the stern. The sea was a little rough, and every time a roller came in it pitched Mr. Carr's end of the boat clear out of the water. In the midst of the proceedings, which means right when the occupants of the boat were most intently watching the doings on the Traymore's roof, a big wave rolled up unexpectedly, deluged Mr. Carr from his hat to his shoes, and then spread itself out neatly and evenly over the rest of the party. The only ones who enjoyed this feature of the game were the life-savers. They had on bathing suits!

The judges picked up the two balls driven out to sea by Mr. Bush, and brought them in to him as souvenirs.

COMPARATIVE REGISTRATION FIGURES

The following table gives the number of persons registered at the conventions at the end of the fourth day for the years 1911-15, inclusive:

	1911	1912	1913	1914	1915
Members, M. C. B. and M. M.	712	445	575	631	592
Special Guests	757	449	495	451	381
Railroad Ladies	699	329	426	352	344
Supply Ladies	399	218	282	272	224
Supply Men	1684	1446	1574	1403	1178
Totals	4251	2887	3352	3109	2719

It will be noted that the number of members of the M. C. B. and M. M. Associations registered this year was greater than up to the same time in either 1912 or 1913. The total number of all persons registered is the smallest in any year in the period, but this is due mainly to the reduction in the number of supply men here. In view of the general conditions prevailing, the registration of railway men shows an encouraging maintenance of their interest in the proceedings of the associations and in related convention matters.

ROCK ISLAND APPOINTMENTS

M. B. McPartland has been appointed master mechanic at Goodland, Kan., vice E. F. Tegtmeyer resigned. Richard Reiter, general foreman at Valley Junction, Iowa, has been appointed general foreman at Chicago. W. Abbington, general foreman at Trenton, Mo., has been transferred to Valley Junction. John Fitzgerald, roundhouse foreman at Chicago, has been appointed general foreman at Trenton, Mo. Wm. Glenn, assistant roundhouse foreman at Chicago, has been promoted to roundhouse foreman, and Frank Maher from Little Rock, Ark., has been promoted to assistant roundhouse foreman at Chicago.

Master Car Builders' Association Proceedings

Reports on Standards, Brake and Signal Equipment, Car Wheels, Revision of Prices and Compensation for Repairs

The first session of the forty-ninth annual convention of the Master Car Builders' Association was held in the Greek Temple on Young's Million-Dollar Pier, Atlantic City, N. J., on Monday, June 14, 1915.

The president, D. F. Crawford, of the Pennsylvania Lines West of Pittsburgh, called the meeting to order at 9.50 A. M. Prayer was offered by Rev. Newton N. Cadwell, of the Olivet Presbyterian Church, of Atlantic City.

PRESIDENT'S ADDRESS

A splendid exhibit of railway appliances, skillfully and tastefully arranged for our inspection, has again been prepared by the members of the Railway Supplymen's Association, and it is suggested in order to acknowledge our appreciation of the time, effort and expense incident to its preparation, that all take advantage of the opportunity to become familiar with the various devices which, while primarily designed for railway use, are ultimately for the public good. For after all it is the public that benefits the most from improvements in the means of transportation and the details of its instruments.

D. F. Crawford
President, M. C. B. Association

The problems involved in the construction, operation, maintenance, interchange and accounting for the use and repairs of cars, seem each year to become more complicated. Notwithstanding the excellent,—yes almost wonderful work accomplished by the Master Car Builders' Association, there remains much to be done, and much that can only be accomplished by more closely co-ordinating the work and rules of the several associations having to deal with the different phases of car construction and operation. We should seek to establish closer relations with the American Railway Association, the Association of Transportation and Car Accounting Officers, and American Railway Accounting Officers' Association, not only for the purpose of a better understanding of the requirements of these bodies, but to avoid duplication of investigations and conflict of rules or regulations. Concerted effort must be made to obtain the largest practicable mileage per car per year, with proper regard for the safety of operation, and to eliminate as rapidly as may seem proper, any rules which unnecessarily hinder the prompt movement and interchange of cars. Any method which would expedite, with efficient safeguards, the movement of freight cars, would be welcomed by those responsible for the financial results of railway operation, as well as by the operating officers. To inaugurate and give impetus to consideration of this subject it might be suggested that this association express formally to these kindred bodies, and all others interested, our desire to confer with them.

Bearing in mind the increasing complexity of the many points included in the construction, maintenance and interchange of cars, it would seem imperative that the members of this association observe more closely the proceedings of such voluntary bodies as the Air Brake Association, Car Foremen's Association, Interchange Inspectors' Association, and similar associations, in which, from time to time, are discussed questions regarding cars and their use, to the end that information promulgated by them may not be regarded as authoritative insofar as it may conflict in any degree with a strict interpretation of the Master Car Builders' rules.

There is in this suggestion no intent to deprecate or criticize the work of these industrious, capable and energetic associations, but it is highly desirable to avoid conflicting views, as well as to conserve the full benefit of the time and labor of these associations for the railways which employ their representatives. Would it not be advisable for one of the existing committees, or a special committee of this association, to review their proceedings and advise if it will not be possible to make their work more co-operative and consequently more valuable to all.

Since the passage of the amended Safety Appliance Acts in 1910 there has been no important Federal legislation regarding railway cars, but in several of the States, in addition to laws regarding the construction of cabin cars, legislation in which cars or car condition is involved has been considered. In some instances, when proposed laws to limit the length of freight trains, either by measurement or number of cars, were under discussion, much prominence was given to isolated cases of air-brake failures, and, as is too often the case, no mention was made of the fact that every day thousands of trains are handled without any semblance of air-brake troubles. Undoubtedly improvement in maintenance of the air-brake apparatus, coupled with more skillful operation of the device, would have reduced the number of so-called failures, and it is thought that this subject is of sufficient importance to warrant its discussion at one of the sessions of this meeting.

Although already referred to by my predecessors, the subject of the proper application and maintenance of safety appliances is of such importance that it seems desirable to again bring it before you, and to urge that all give careful consideration to the establishment of adequate supervision and inspection of these appliances to insure, as far as may be possible, their compliance with the several laws relating thereto.

It is not my intention to refer to the committee reports in detail or to anticipate their presentation by attempting to summarize the conclusions. I do, however, wish to present to you some comments on the subjects assigned to, and the work before some of the committees.

The Arbitration Committee, in addition to the consideration of several cases put before them for decision, bears a heavy burden in the formulation and revision of the Rules of Interchange, and during the past year has devoted much attention to the study of the questions submitted to them regarding the code of rules, and to the preparation of the interpretations which have been promulgated to all of the members. Since the publication of the Code of Interchange Rules, effective October 1, 1914, this committee has prepared answers to about 150 questions.

This means that to cover 113 pages of the rules, we now have before us 50 pages of interpretations which, while intended to conduce to a better understanding of the rules, are likely to cause confusion in the minds of those who, when consulting the code, fail to carefully scan the interpretations. That it is necessary to interpret the rules is apparent from the number of questions that have been addressed to the secretary, but from even a casual inspection of the questions it is apparent that by a little study many almost trivial questions would be avoided, and that in several instances the inquiries covered points which warranted submission of briefs for bona fide arbitration.

Undoubtedly the number of questions will decrease as the information already available gradually clears up any vagueness in the code, but with the realization that members of this committee are busy men, the labor imposed upon them should be reduced, by the members refraining from placing before them items of small importance and of rare occurrence.

In connection with the report of this committee, and the many interpretations already given to you, it would appear to be advisable to arrange to re-codify the Rules of Interchange, embodying as far as possible, the several points of the interpretations.

In view of the large amount of work imposed upon the Arbitration Committee perhaps it would be advisable to appoint a special committee to assist in the suggested re-arrangement of the rules. When it is considered that 60,000 copies of the code are distributed each year, and that the majority of these are placed in the hands of men who, in addition to the enforcement of the rules, must inspect the cars, the desirability of fixed instructions is apparent. I would, therefore, recommend that most serious consideration be given to the idea of having the Interchange Rules remain in force for two years at least, instead of making material changes at each annual convention.

The motto of our Committee on the Revision of Standards should be, and apparently is, "Hasten Slowly," for they have succeeded in keeping the standards and practices in accord with the development of the art, and have met changing conditions without radical departure from principles long established. My hope is that ere long we may see many more of the parts involved in car construction, and indeed the designs for the entire car, turned over to this committee for the same thoughtful consideration that has been given the standards and practices already adopted.

The importance of proper maintenance of air brakes has already been referred to, and it might be well for the Committee on Train Brake and Signal Equipment to give this point some attention, in addition to making a careful study of the brake equipment for passenger cars, a subject well worthy of thorough investigation. Would it be asking too much to have this committee review the proceedings of the Air Brake Association, and include in their report to our convention their recommendations regarding any points brought forward by those who are following the details of air brake operation and maintenance more closely than it is possible for us to undertake?

Failure of the members to adopt as standard the brake beam recommended by the Committee on Brake Shoe and Brake Beam Equipment, should not discourage the committee, but rather spur it to further efforts to present to the association such sufficiently impressive reasons as to cause the adoption of a standard beam at an early date. Think of the economy which could be realized, and the convenience it would be were all brake beams alike.

The achievement of a single standard coupler is drawing closer each year. Your committee having this subject before it is giving the most painstaking care to the development of a coupler which will not only be suitable for service conditions, but one that will assist in obtaining economy in maintenance and operation. The task set for this committee is not simple, and their efforts warrant the cordial support of the association.

The enforcement of the Loading Rules of the association is now quite generally insisted upon, and it has resulted in expedited movement of traffic and decreasing claims for loss

D. R. MacBain
Vice-President, M. C. B. Association

R. W. Burnett
Vice-President, M. C. B. Association

and damage to lading. Opportunity still exists for further development and extension of these rules, as the railways paid in 1914 claims amounting to $32,375,617.55, a material proportion of which might have been saved had the shipment been properly packed and secured.

Unfortunately, there appears to be a tendency on the part of some members of the association to minimize the fact that the contour of car wheels should bear some relation to the limiting dimensions of rails, frogs, cross-overs and switches on which they are used. Wheels not conforming to the standards of this association, or the limits set by the American Railway Association, have been placed in service, without awaiting the results of the investigation now under way by your Car Wheel Committee, working jointly with a committee of the American Railway Engineering Association. While there is no question as to the desirability of taking advantage of every real improvement offered, it would seem to be the part of wisdom to defer the introduction of wheels differing from those approved by the association until such time as they can be adopted by all, their manufacture becoming effective at a given date, as has been done several times in the past. The data regarding wheel breakages and other wheel defects, now being collected by the committee, will surely give accurate information upon which to base recommendations as to whether changes in our standard designs are necessary.

The work of the Committee on Car Construction is of such importance that detail reference to it is desirable. Among other items there is submitted specifications for car doors, which should serve as an excellent guide in designing new doors, and assist in preparing designs for the modification and strengthening of existing doors and their fastenings.

A very complete analysis of the principles involved in the design of draft gear attachments is given, which should prove of value to roads designing new cars, as well as for consideration in the adoption of methods for improving cars now in service.

In submitting to you tentative designs of a standard M. C. B. box car, the committee has performed most commendable work, and with the co-operation of the members, by heeding the request of the committee for complete criticisms by December 1, 1915, it should be possible to have the designs sufficiently complete to submit them to our next convention for adoption as a recommended practice.

That the Master Car Builders' Association should have complete specifications for all materials that enter into the construction of cars, there is no doubt. Therefore, the work of this committee should receive the support of the members, who, by insisting that materials meeting the requirements of the M. C. B. specifications be used to the fullest extent, will assist in evolving correct specifications.

For the present, at least, the adoption of a standard truck for freight cars is really of more moment than the adoption of a standard car, and to that end the labors of this committee should be directed to harmonizing the conflicting points in design, and thus hasten the general use of a single design.

It is to be regretted that the pedestal type of truck has been introduced for freight car service. This type of truck, while it may have many points in its favor, requires a journal box differing from the M. C. B. standard, thus compelling all roads to increase the kind and quantity of stock material carried or to accept the less desirable horn of the dilemma, and delay the movement of the car until non-standard material may be obtained from the car owner.

The Committee on Prices for Labor and Material still has before it many points for consideration, and their burden will be increased should this convention look with favor on the recommendations regarding compensation for car repairs. Apparently it would be of great assistance to the committee to have assigned to it members representing the refrigerator and tank car lines, as the labor and material required for such cars differ materially from those ordinarily used by the railways. I would, therefore, suggest that the Executive Committee give consideration to the appointment of such members to this committee for the coming year.

The salient features of train lighting and equipment seem

C. E. Chambers
Vice-President, M. C. B. Association

J. S. Lentz
Treasurer, M. C. B. Association

to have been fairly well established through the efforts of the committee, and it is desirable to have the benefits of their supervision over the subject, so that future extension may be in line with, instead of contrary to, simplicity in taking care of the cars of various companies at joint terminals and through line connections, where such exist.

When rules regarding the construction and equipment of tank cars were first promulgated by the association, much objection was made to them and their enforcement. I wonder if we all fully realize what the work of this committee has meant in added safety of transportation. Notwithstanding the tremendous increase in the amount of inflammable and explosive liquids transported since the inception of the committee, the number of fires and the effect of such fires, have been much reduced. During 1914, with the remarkable movement of gasolene brought about by the growing use of motor vehicles, but 80 accidents occurred. While perhaps the work already accomplished has lessened the labors of the committee, it is recommended that such a committee be continued, and if advantageous, to have its sphere extended to assisting the Bureau of Explosives in its work.

In giving considertion to the settlement prices for reinforced wooden cars, I might caution you that any prices determined upon apply only to cars destroyed away from the owner's line, and care should be exercised that our rules are not complicated with many technicalities in endeavoring to cover circumstances which, at most, are of but rare occurrence.

The study of draft gear is of the utmost importance, as with couplers of increased strength it is quite likely breakage will occur in other parts of the car unless draft gear of adequate capacity is provided, and the committee should be continued until it has submitted, for adoption, requirements as to dimensions and capacity for both spring and friction draft gear.

The attention of the members is directed to difficulties experienced by your several committees in obtaining replies to their circulars of inquiry. It is expected that every member will reply fully and promptly to every circular received. Without replies from a large majority of the members it is quite possible that the committees may be misled and spend much time in making reports, which will not be acceptable to the convention. The high standard of the work already done by this association should be the incentive to all to contribute prompt and accurate information to the committees.

During our convention of 1909, in a topical discussion on "The Abuse of the M. C. B. Repair Card," the following statement was made:

"The repair card unfortunately makes possible the misuse, which there can be no doubt is often indulged in. Prominent railways quite frequently render bills for defects which seem unreasonable on their face, etc."

Following this discussion resolutions were adopted calling on the members to file with the Executive Committee any evidence tending to show misuse of the repair card. The subject was referred to at the 1910 convention, and again at the 1912 convention. Notwithstanding repetition of the requests of the Executive Committee for evidence, but one definite case was brought to their attention. While six years have elapsed since this subject was first brought to your attention it is apparent, from communications which I have recently received, that the efforts of the Executive Committee have not succeeded in eliminating improper billing. Although I do not believe, for one moment, that the alleged improper practices are at all widespread, or that they are indulged in with the consent or knowledge of the officers of the railways, there is sufficient ground to warrant the association taking cognizance of the conditions.

It has been intimated to me that our rules should be revised to take care of this situation, but I have been unable to determine how any additional legislation would prevent anyone who wanted to do so, from making a bill for repairs not made, especially if the car was too far from the owner's line to admit of checking. There is no doubt that the cause for a large proportion of the improper bills may be traced to the misunderstanding of the rules by the inspectors, repairmen and bill clerks. However, I do not think this association should rest when criticism is even possible; therefore, I would recommend:

1.—That suitable resolutions be approved by the convention and forwarded to each of the adherents to the Rules of Interchange.

2.—That the Executive Committee renew their requests for evidence of improper billing.

3.—That a special committee be appointed or the Arbitration Committee be authorized to confer with the proper committee of the American Railway Accountants' Association, to formulate, if possible, methods which will permit of more accurate accounting for car repairs.

4.—That the American Railway Accounting Officers' Association be requested to give consideration, at the earliest possible date, to adopting a rule requiring that all bills for repairs to cars be rendered within 90 days from the date of making repairs.

5.—That each member of this association will take such steps as will insure those having to do with repairing of cars and billing for such repairs on their lines, being fully instructed as to the meaning and limitations of the rules.

As accounting for the repairs of cars is closely interwoven with the Rules of Interchange, and on nearly all railways one or more men have become quite familiar with the rules of the association, and many times the services of men with such knowledge would be of value on our committees, it is suggested that consideration be given to the revision of the constitution to make chief motive power clerks, motive power accountants and M. C. B. bill clerks, or similar employees, eligible for membership.

At the present time the constitution requires that only such private car lines as may own 1,000 cars or over may have a representative member in the association. In order to have full representation I would suggest that the constitution be so changed as to permit private car lines operating 500 cars or over, to name one representative member.

For the future work of the association three items seem to me to stand out prominently:

1.—Standardization of equipment. Much indeed has been accomplished, but up to the present time attention has been largely devoted to dimensions and details. Of course, each detail decided upon gives promise of ultimately reaching a conclusion on the larger problem, but is not now the time for this association to agree on standard freight car trucks, standard box, stock, refrigerator, hopper, gondola and flat cars? We all remember the letter written by E. P. Ripley, president of the Atchison, Topeka & Santa Fe on this subject, which was read at the convention last year. Can we not, by concerted efforts, adopt standards which will make unnecessary such stimulation?

2.—Simplification of the Rules of Interchange. One has but to read in the report of the Arbitration Committee the suggestions they receive as to changes in the rules, to fully realize how much has already been accomplished in this direction, but I trust they will harden their hearts and make even less changes than they have in the past. The members can assist them very much indeed by confining their recommendations for changes to those items only which are frequently involved.

3.—Co-operation with the American Railway Association in expediting the movement of cars.

The expenses of the Association approximate 9-10 of one cent per car per year, including salaries, rent, printing (which is a large item) and all other items, and when we consider all that is accomplished by this very small expenditure, it is indeed remarkable.

Of course, this amount does not include the amount expended by the railways for experiments made by them, or for the time and expenses of those engaged in M. C. B. work, but even if this were added it would be found that the Master Car Builders' Association has given to the railways and the public a very large return on a small investment.

At times it is desirable for the Association to undertake certain tests, such as those on brake shoes, brake beams, etc., but recently the available funds have not been sufficient to permit such work. To meet this condition it is suggested that when funds for such work are desirable, the question of an assessment for the purpose be submitted to letter ballot of the representative members of the association. An assessment of 1 or 2 cents per car would sufficiently provide for the majority of the work undertaken.

ASSOCIATION BUSINESS

Secretary Taylor presented his report, which showed that the present number of active members is 429, representative members 502, associate members 13, life members 19, making a total of 891 members. During the year 66 additional roads and private car lines have become subscribers to the rules of interchange. The report of the treasurer, showed a balance on hand of $627.91. The reports of the secretary and treasurer were referred to an auditing committee consisting of J. M. Borrowdale, I. C.; W. C. A. Henry, Penn. Lines; and T. J. Burns, M. C.

The Secretary: At a meeting of the executive committee held last evening, it was decided to recommend that the due of active members be fixed at $5 a year, and that of representative members at $7 a year.

(The recommendations of the executive committee were confirmed by the Association.)

The executive committee proposed an amendment to the

constitution intended to make more explicit the voting power of active members. This will lie over till next year before being voted on.

REPORT OF THE COMMITTEE ON NOMINATIONS

The committee suggested the following: For President: D. R. MacBain, S. M. P. & R. S., N. Y. C. Lines West; For First Vice-President: R. W. Burnett; For Second Vice-President: C. E. Chambers, S. M. P., C. R. R. of N. J.; For Third Vice-President: T. W. Demarest, S. M. P., Pa. Lines West—N. W. System; For Treasurer: J. S. Lentz, M. C. B., Lehigh Valley R. R.; For Executive Members: C. E. Fuller, S. M. P., Union Pacific R. R.; F. E. Gaines, S. M. P., Central of Georgia; I. S. Downing, G. M. C. B., C. C. C. & St. L. Ry.

The balloting will take place on Wednesday morning.

REVISION OF STANDARDS AND RECOMMENDED PRACTICE

After due consideration of present Standards and Recommended Practices of the Association, together with replies from members to the Circular of Inquiry, also requests involving Standards presented through the secretary, the committee submits the following report:

[EDITOR'S NOTE:—In abstracting the report we have left out several items referring to corrections on the drawing plates which the committee concurred in and referred to the secretary for action; also several paragraphs referring to suggestions which did not meet with the approval of the Committee or were of minor importance and were referred to other Committees or otherwise disposed of.]

JOURNAL BOX AND DETAILS. (Standard)

Pages 634-637

For Journals, 3¾ by 7 in. Sheet M. C. B. 3.
For Journals, 4¼ by 8 in. Sheet M. C. B. 6.
For Journals, 5 by 9 in. Sheet M. C. B. 9.
For Journals, 5½ by 10 in. Sheet M. C. B. 12
For Journals, 6 by 11 in. Sheet M. C. B. 12-C.

A member suggests that journal box wedges be provided with hole through front flange of wedge for all sizes of journals to facilitate removal of wedge by use of packing hook. The Committee concurs in this recommendation.

T. H. Goodnow
Chairman, Committee on Revision of Standards and Recommended Practice

MARKING OF FREIGHT EQUIPMENT CARS. (Standard)

Page 761. Sheet M. C. B. 26-A

The Committee wishes to renew the recommendations to the 1914 Convention, at which time revised Sheet M. C. B. 26-A

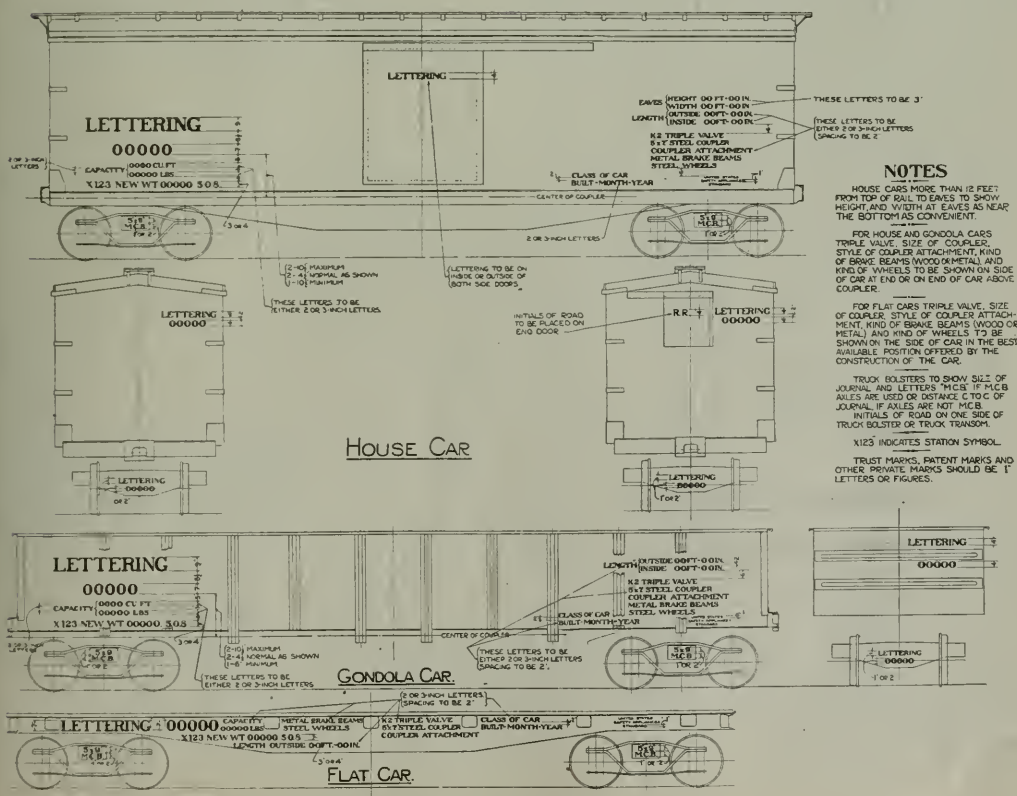

Fig. 1.—M. C. B. Standard Marking of Freight Cars

(see Fig. 1) was presented, and was lost by letter ballot, and again presents same, with the exception of the omission of the stenciling of light weight on end of car.

LINING FOR OUTSIDE-FRAMED CARS. (Recommended Practice)
Page 759. Sheet M. C. B.—F

Through the secretary, communication was received from W. J. McBride, president of the Haskell & Barker Car Company, regarding the desirability of standardizing lining for outside-framed box cars.

Since the adoption of 1¼-in. lining in 1913 as Recommended Practice, the committee believes that it is desirable with future built cars to adopt the additional sizes shown in Fig. 2 as Recommended Practice.

SPRINGS AND SPRING CAPS FOR FREIGHT-CAR TRUCKS. (Recommended Practice)
Page 877. Sheets M. C. B.—H and H-1

The committee recommends that springs and spring caps, as shown on Sheets H and H-1, be advanced to Standard.

STEAM HOSE COUPLINGS. (Recommended Practice)
Page 873. Sheet M. C. B.—Q-1

A member calls attention to the difficulty in interlocking of the different makes of steam heat couplers due to the guard arm not being long enough, or too low, to provide a bearing for some of the types of locks that are being used, and suggests changing of the present M. C. B. design to provide for the guard arm being of sufficient length and height to make all of the coupler locks effective.

The committee concurs, and recommends the appointment of a special committee to go into this matter, taking it up with the coupler manufacturers with a view of adopting a Standard M. C. B. coupler.

PLATFORM SAFETY CHAINS. (Recommended Practice)
Page 758

Several members suggest safety chains as one of the desirable standards for the interchange of passenger equipment. The committee concurs, and in view of the changes in passenger equipment since the adoption of the present Recommended Practice, suggests that this be referred to a special committee for investigation and report, and to include all appurtenances on end of car below platform.

DEFINITIONS AND DESIGNATING LETTERS OF GENERAL SERVICE—FREIGHT EQUIPMENT. (Recommended Practice)
Page 887

Through the secretary, request was received from Arthur Hale, general agent of the American Railway Association, for change in the description of "XI" box car, insulated, as follows: "A box car having walls, floor and roof insulated, not equipped with ice bunkers or ice baskets. This car ordinarily used for transporting vegetables, freight, etc." The committee concurs in this recommendation.

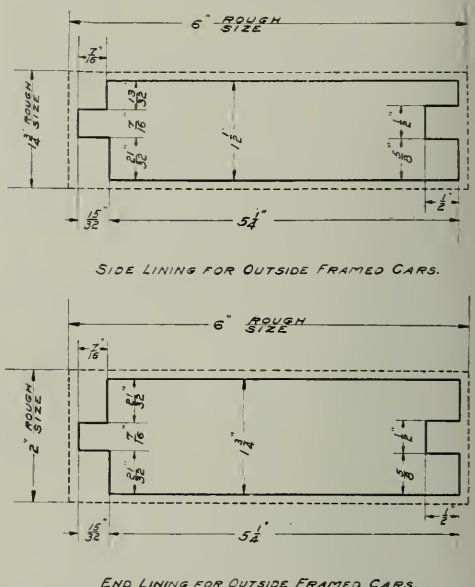

Fig. 2.—Recommended Lining for Outside Framed Box Cars

NEW SUBJECTS

A member suggests that a standard height from rail to top of platform buffer for passenger cars be established, this to be

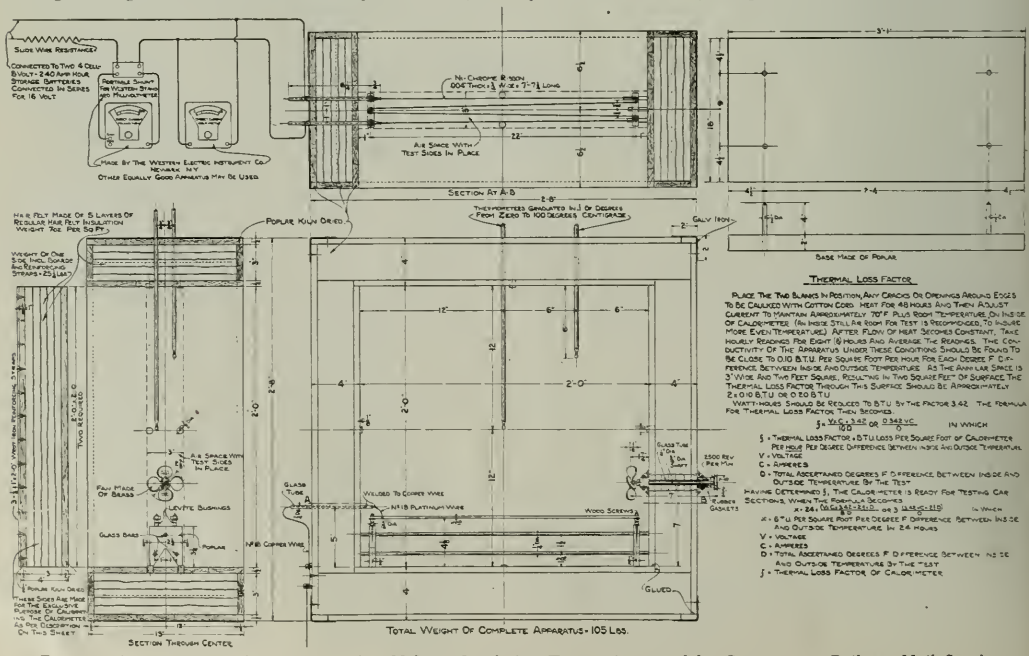

Fig. 3.—Arrangement of Apparatus for Making Insulation Tests—Approved by Government Railway Mail Service

nominally 51 in. The committee concurs in this recommendation.

A member suggests that the method of making insulation tests, together with description of testing machine as approved by the Government Railway Mail Service, be incorporated in the M. C. B. Proceedings as follows:

"SECTION 23.—INSULATION.—(a) The car shall be insulated throughout, including floors, sides, ends and roof (except pier panels), with material of such a nature that it can be securely fastened so as to withstand the vibration incident to railway service. The insulating material must be such that it will not support combustion, will not absorb moisture beyond its own weight, and when wet, will not become corrosive.

"(b) Side and end wall and roof insulating material shall be securely fastened. Where the nature of the material permits, it shall be cemented; and also mechanically clipped if necessary for proper support. Floor insulation shall extend the entire distance between side walls either in one full width or in sections fitted between floor supports and be secured in place.

"(c) The construction of side and end walls and roof of car shall be such as to avoid or reduce to a minimum continuous metal connection from outside to the inside of the car.

"(d) To insure maximum of insulating and sound-deadening efficiency, the construction at the junction of side and end walls and floor shall be such as to prevent the circulation of air through the side and end walls or through the floor or into the car.

"(e) The thermal efficiency of the materials in side and end walls, in roof and in floor, must be such that a test duplicate section through walls, roof or floor (duplicate with the exception of framing members such as posts, braces, carlines or stringers which are to be omitted), will not transmit, when subjected to the test hereinafter described, more than the following amount of heat per square foot of surface in twenty-four (24) hours for each degree Fahr. difference in temperature between the inside and outside walls of the section.

"For side walls, end walls and roof.....8 B. t. u.
"For floor .....7 B. t. u.

"The method of testing shall be as follows:

"A calorimeter, as illustrated in Fig. 3 and described in R. M. S. drawing, Sheet 18, shall be used in all tests. It shall be carefully constructed and of the materials indicated and before used must be standardized for its thermal loss factor. The sections to be tested shall truly represent the materials as used and disposed in the car.

"The heat must be supplied by direct electric current of constant voltage, measured by standardized instruments. The difference between inside and outside temperatures must be held as nearly seventy degrees Fahr. as possible. Readings of temperature and current shall not be recorded until forty-eight hours after heat is turned on and test begins, in order to insure thorough heat saturation of calorimeter and test sections. The duration of actual test shall be eight (8) hours, during which time temperature and electric readings shall be made and recorded each hour or more frequently, if considered necessary. The average of all readings thus recorded shall be taken as the final result. All differences regarding results which may arise between the Postoffice Department and the railroad companies affected shall be referred to the United States Bureau of Standards for decision."

The committee concurs in this recommendation.

The following suggestions were received in answer to the Circular of Inquiry No. 18, but in the opinion of the committee were not directly involved in the interchangeability of passenger cars and are, therefore, mentioned in this report with no further recommendation except to bring them to the attention of the Association in the event that it should be felt that further consideration should be given, and in that case to be referred to special committees: Emergency tool equipment. Retainer valve location. Standard requirements for brake beams similar to requirements for freight cars. Hand brake pawl and shaft and a uniform percentage of braking power and a fixed basis for figuring this. Coupler shanks on passenger cars. Standard dimensions for diaphragm face plates. Uniformity between wood and steel passenger equipment as to the height of the door threshold above the platform. Distance from face of buffer to pulling face of coupler to be not less than 25/8 in.

The report is signed by:—T. H. Goodnow (C. & N. W.), chairman; W. H. V. Rosing (St. L. & S. F.); C. E. Fuller (U. P.); A. R. Ayers (N. Y. C.); O. C. Cromwell (B. & O.); O. J Parks (Penn. Lines), and R. E. Smith (A. C. L.).

In presenting the report the chairman, T. H. Goodnow, C. & N. W., said: That since the report was closed one or two communications had been received which should be mentioned and acted on. One was a letter from Mr. J. T. Wallis, general superintendent motive power, Pennsylvania Railroad, stating that manufacturers of drop forged wedges of the M. C. B. type, have recently called attention to the fact that these wedges could be made at less expense if the arc recess on each side bearing face were omitted. The omission of these recesses gives greater bearing surface, and, therefore, less wear between parts in contact, aside from permitting cheaper manufacture. The letter recommended that the M. C. B. drawings of all journal box wedges and bearings be revised, omitting the arc shaped recesses where the wedges and journal bearings abut against the sides of the journal box.

The other letter was from R. B. Kendig, chief mechanical engineer, New York Central, and requested that a recommendation favoring the location of the uncoupling lever of passenger equipment on the left-hand side facing the car, be submitted to letter ballot.

DISCUSSION

R. L. Kleine (Penna. R. R.): Under Marking of Freight Equipment Cars, the committee recommends the omission of light-weight stencilling on end of cars. The committee on car service rules of the American Railway Association, in their Rule No. 11-A, state all freight cars shall be light weight stencilled, and shall be marked in accordance with M. C. B. rules. Light weight marking is a transportation matter and I believe before this is submitted to letter ballot the committee on standards should have a conference with the proper committee of the American Railway Association to determine what they desire.

T. H. Goodnow: The committee felt that the present standard of the Association was not in accordance with present practice, and that if the standard practice were brought up to date, it would probably accomplish some results and get roads more in line in the stencilling of their equipment.

J. J. Hennessey (C. M. & St. P.): This question was pretty thoroughly discussed before the Convention a year ago. The concensus of opinion was that the lettering on the end of cars was unnecessary. It delayed the weighing of cars. It entailed a great deal of expense that was not really considered necessary, and I believe it is only on rare occasion when the lettering on the end of cars is made use of. It seems to me that the matter in its present form is all right. The customary way of weighing is to push a train of cars over the scale, and stencil them on the side. If you are going to put the weight on the end of the car, you have to hold up the train while you put men in between the cars to do the necessary stencilling. We will not derive from it any benefit commensurate with the expense incurred.

C. E. Chambers (C. of N. J.): Regardless of the expense we will still be required to stencil the light weight on the end of the cars. There are a good many things we would like not to do, but some other department requires that they be done.

T. H. Goodnow: The light weight on the end of the car is optional at the present time. While it was shown in the standards, it was not carried out by many of the railroads. If the recommendation should carry by letter ballot as it stands it would still leave the matter optional with the railroads. Those stencilling would continue to do so, and those who do not now stencil would not do so.

F. H. Brazier (N. Y. C.): The lettering is entirely uncalled for and unnecessary. I do not think that we should ask the men to go between the cars for this purpose as it is an unsafe practice.

(The recommendation regarding the stencilling of light weight on the ends of cars was referred to letter ballot without conference with the American Railway Association.)

The President: Is it your intention to sumbit a supplementary report in regard to stencilling light weight and capacity on tank cars, item No. 160?

T. H. Goodnow: As a result of action since this report was printed that will be necessary. It will come up at the arbitration committee meeting and in sending it to letter ballot, will be changed in accordance with whatever action is taken by the convention at that meeting.

The President: What is your suggestion as to the two communications received?

T. H. Goodnow: Had Mr. Wallis' communication in regard to the journal bearing wedges, been in the hands of the committee at the time the report was considered, it would have embodied it in the report and presented for letter ballot. If the convention will approve, we will include it in our letter ballot, and then it can be acted on by the members. The matter of uncoupling levers has not been discussed by the committee, and the different roads vary in their opinion on that matter. It is a subject which should go to the standards committee for consideration.

F. W. Brazier (N. Y. C.): It seems singular that the Master Car Builders' Association has one location for the uncoupling lever for freight service, and another for pas-

senger service. The New York Central, in the case of its passenger equipment, had all the uncoupling levers changed from right to left. We are having trouble with our lines running west, because in the case of some roads the uncoupling lever remains on the right, and ours is on the left. In some cases we are compelled to put on a double uncoupling arrangement, which is an unnecessary expense.

T. H. Goodnow: The federal regulations regarding uncoupling levers do not require the change as far as passenger equipment is concerned. It is only a question of where a passenger car is handled deadhead in a freight train. Mr. Brazier says he has made the change and the western roads have not. If this was a matter of interchange, and it was brought up by Mr. Brazier on that understanding, I would be willing to agree with him.

F. F. Gaines (C. of Ga.): We have a lot of trouble from having uncoupling levers on the right side. If you have all of them on the left side you can run mixed trains. I think it would be better to make the left side standard.

D. R. MacBain (N. Y. C.): The question is—are we going to have single or double uncoupling levers on our passenger equipment? We have to run passenger equipment cars from New York to San Francisco over the eastern and western roads, and we have all of our equipment left hand so that we may deadhead our equipment at times in freight trains. It is a question of having one standard on the left side, or forcing the railroads to put a standard uncoupling lever for freight cars on the left side, and another one for passenger cars on the right side, which means a double arrangement with all the incidental complications arising therefrom.

G. W. Wildin (N. Y., N. H. & H.): The New Haven has a heavy passenger equipment, and we went to considerable expense to fit all our equipment with uncutting levers on the left side to conform with the federal regulations when deadheading passenger cars in freight trains. I agree that we should have one standard in this respect.

(A motion was made and carried that the committee include a recommendation in favor of adopting the left side as the standard location of passenger car uncoupling levers, to be submitted to letter ballot.)

TRAIN BRAKE AND SIGNAL EQUIPMENT

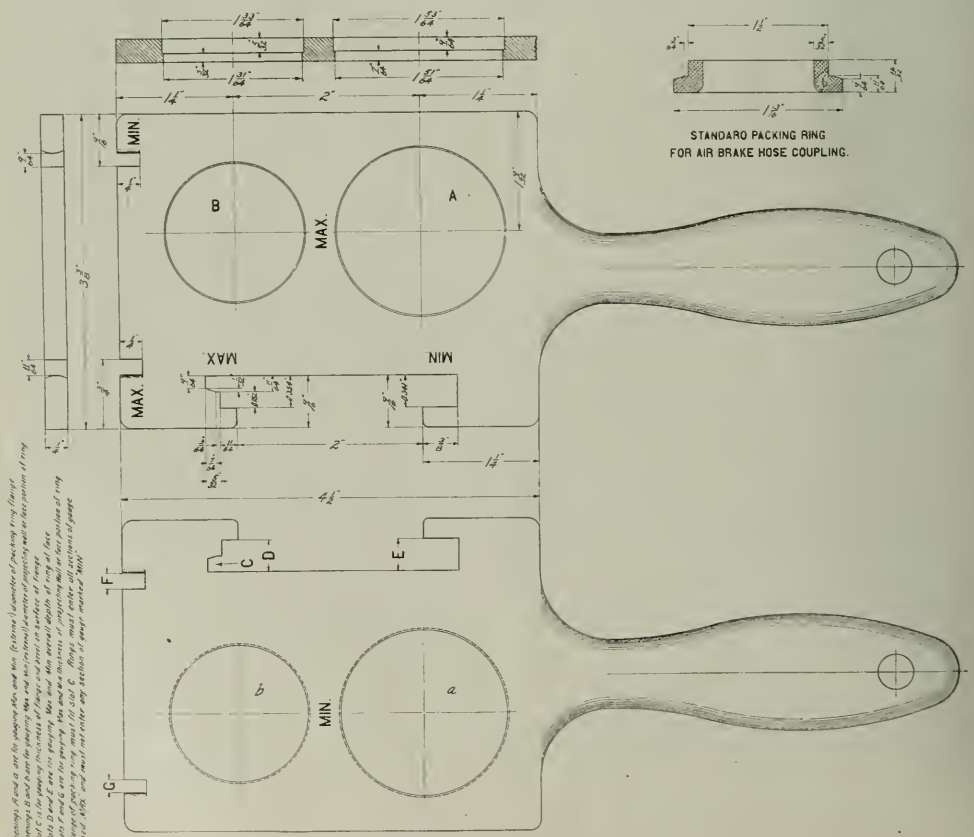
The following subjects have been considered by the committee, and are presented for such action as the Association deems fitting.

SLIDING BRAKE PIPE HANGER

Effort has been made to produce a design of gage for use in determining the end locations of brake and signal pipes to fix them in their proper relations to all other parts of car ends so as to permit of the required lateral and vertical movement, with sliding or swinging hangers, without interference. It has been found, however, almost impossible to construct a gage of this character that would be universally applicable on account of the wide range of varying conditions, and the committee believes that the designs of sliding and swinging hangers already illustrated in the 1913 and 1914 reports supply ideas that will enable any road to apply a satisfactory sliding or swinging device to its cars to allow the required movement of brake and signal pipes, necessary to prevent hose parting on curves, each road to make the necessary modifications in the design of hangers selected to suit its own peculiar conditions.

TYPE OF CONDUCTOR'S VALVE TO EMPLOY

In the 1914 report of this committee the B-3-A type of conductor's valve was recommended for adoption. The recommendation was submitted to letter ballot and was defeated by a



Gage for Air Brake Hose Coupling Packing Ring

very close margin. The committee has decided to bring this matter before the Association for reconsideration.

CLASP TRUCK BRAKE FOR PASSENGER EQUIPMENT CARS.

To date there are in service about 2500 sets of truck clasp brakes in use on modern passenger car equipment on about a dozen leading railroads of the country. So far as your committee has been able to learn this type of rigging is maintaining its claims for reduced brake shoe wear per given number of foot-pounds of brake work done, for reduced number of hot journals in so far as the brake may be responsible for them, for smoother riding of car during time of brake action and for remarkable low cost of maintenance both with respect to the parts of the rigging itself and to the cost of brake shoe renewal, while the stopping efficiency is about 20 per cent greater than the single shoe arrangement. Where the wheel load is approximately 12,000 lb., clasp brakes should be applied.

The committee recommends, therefore, that truck clasp brakes be applied to all four-wheel truck passenger cars weighing 96,000 lb. or over, and to all six-wheel passenger cars weighing 136,000 lb. or over.

HAND BRAKES FOR HEAVY PASSENGER CARS

This subject has engaged the attention of the committee during the past year, but so far no design of hand brake gear examined seems to be entirely satisfactory. What is needed in a hand-brake rigging for heavy cars is one that will take up quickly

R. B. Kendig
Chairman, Committee on Train Brake and Signal Equipment

all slack in the brake chain and bring the shoes in contact with the wheels—this part of the operation can be performed with comparatively low leverage; then when the shoes are in contact with the wheels, means for easily increasing the leverage sufficiently to permit of the average man producing the required brake force, this increased leverage to come into play when the shoe movement is practically little or nothing.

The question of whether it would not be better to divide the hand brake so as to have it operate on a single truck has arisen and in the judgment of the committee there is much to recommend serious consideration of this plan, since it permits of a reduction in the total leverage and enables the operator to apply the brake on the single trucks with an effectiveness in excess of what is obtainable where the brake operates on both trucks, and what is very important, this effectiveness is obtained in much less time.

HOSE COUPLING GASKET GAGE

The committee has examined several designs of hose-coupling gasket gages for use in determining whether gaskets are of proper dimensions or not, with the result that the one illustrated herewith is recommended for general use. This gage has the advantage of being made all in one piece making it convenient for use, and gaskets conforming to its limits will be satisfactory so far as dimensions are concerned, for service.

The report is signed by:—R. B. Kendig (N. Y. C.), chairman; B. P. Flory (N. Y., O. & W.); J. M. Henry (Penn.); R. B. Rasbridge (P. & R.); L. P. Streeter (I. C.); A. J. Cota (C., B. & Q.), and W. J. Hartman (C., R. I. & P.).

(It was noted that the items on the conductor's valve, clasp truck brakes and hose coupling gasket gage be submitted to letter ballot as recommended practice.)

BRAKE SHOE AND BRAKE BEAM EQUIPMENT

The committee has devoted its entire attention this year to the subject of brake beams, the work on brake shoes having been completed for the present at least. The committee, however, submits a resume of the tests so far made on brake shoes for the years 1906 to 1914, inclusive, as showing the data which underlie the specifications of this Association at present in force.

BRAKE SHOES.

During the years 1906 to 1914, a considerable number of brake shoes of different materials and construction have been tested

C. H. Benjamin
Chairman, Committee on Brake Shoe and Brake Beam Equipment

on the Master Car Builders' machine at Purdue University. Determinations have been made of the average coefficient of friction, the rise in the coefficient of friction of the average coefficient of friction, the rise in the coefficient of friction at the

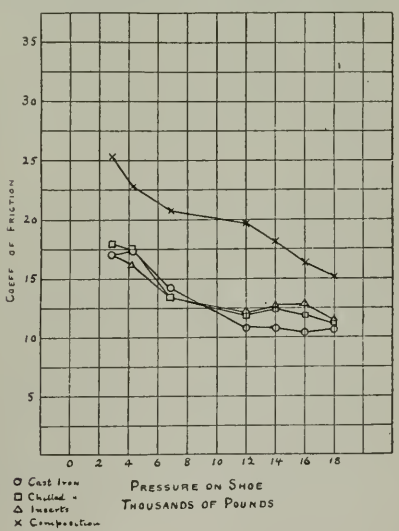


Fig. 1.—Mean Coefficient of Friction (in per cent) of Brake Shoes on Steel Tired Wheels at 65 M. P. H.

end of the run, and the loss of weight of the shoe in comparison with the number of foot-pounds of work done. The shoes have been tested at various speeds ranging from 20 to 80 miles per

hour, and under pressures of application varying from 1080 lb. to 2000 lb.

The materials have been classified as follows:

a. Plain cast iron such as can be easily drilled.

b. Chilled cast iron where the surface has been partially or wholly hardened by chilling.

c. Cast iron shoes with inserts of harder material.

d. Shoes having a cast iron shell filled with a comparatively soft composition as in the Pittsburg shoe.

The readings for each group have been averaged and these averages plotted as shown in the accompanying plates. Figs. 1, 2 and 3 show the variation in mean coefficient of friction while Figs. 4 and 5 show the loss of weight compared with the number of foot-pounds of work done.

Conclusion.—It is apparent from Figs. 1, 2 and 3 that the coefficient of friction diminishes as the pressure on the shoe is increased, but that for pressures from 12,000 to 18,000 lb., inclusive, the difference is slight. It is furthermore apparent that pressures in excess of 18,000 lb. are not economical.

Reference to Fig. 2 shows that the coefficient of friction at high speeds is very much less than at moderate speeds, the average coefficient at 80 m. p. h. being less than 10 per cent. or less than one-half the corresponding average at 40 m. p. h.

The coefficient of friction of filled or composition shoes is in

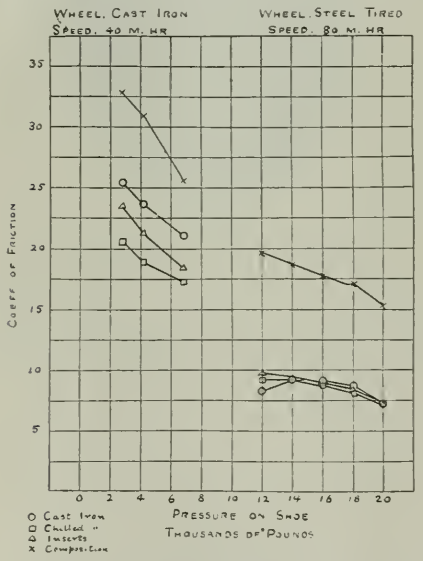

Fig. 2.—Mean Coefficient of Friction (in per cent) of Brake Shoes on Cast Iron and Steel Tired Wheels at 40 and 80 M. P. H., Respectively

all cases considerably greater than the average for the other three groups, being from 50 to 100 per cent. in excess.

It is apparent from Figs. 4 and 5 that general conclusions can not safely be drawn as to the effect of speed and pressure on the loss of weight, except that pressures in excess of 18,000 lb. cause an abnormal loss.

An inspection of the results show marked discrepancies in the loss of weight of two shoes of the same material under similar conditions, and that it can not with certainty be predicted whether the loss of weight will be greater or less as the pressure is increased. The general trend of the lines, however, indicates an increasing loss of weight with increase of pressure and speed. In other words, as these two factors increase, the wear of the shoe compared with the work done in stopping the wheel increases. On the whole, the tests indicated in the tables justify the specifications of the Association as at present in force.

BRAKE BEAMS.

Last year this committee recommended that a new method of procedure for testing No. 2 brake beams should be adopted to take the place of those given in the M. C. B. Proceedings for 1913, page 854. This recommendation was approved by the convention and made the subject of letter ballot. It received a majority of the votes cast but lacked a few votes of the necessary two-thirds. The committee believes that this was due to a misapprehension and desires to state that the proposed test is no more severe than that at present in use but is much more

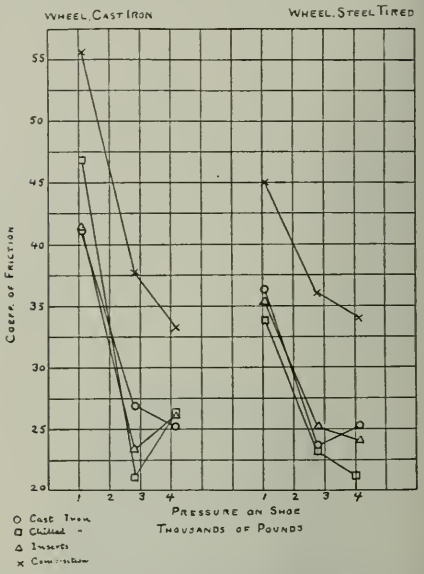

Fig. 3.—Mean Coefficient of Friction (in per cent) of Brake Shoes on Cast Iron and Steel Tired Wheels at 20 M. P. H.

in line with accepted practice in the matter of testing units and structures.

Frequent communications have come to this committee calling

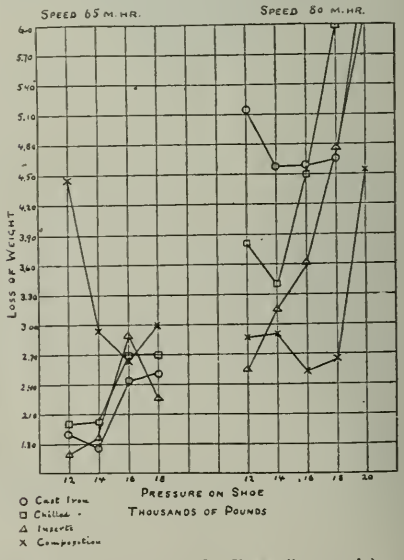

Fig. 4.—Loss of Weight of Brake Shoes (in pounds) on Steel Tired Wheels at 65 and 80 M. P. H., Respectively

attention to the fact that there should be some notation and specifications for beams heavier than the No. 2. After carefully considering these communications and the various weights of

beam in common use, the committee has decided to recommend a classification of beams heavier than No. 2 to be known as No. 3, 4, etc. To properly determine the class in which such beams belong, the committee recommends the following specifications for testing to be substituted for the specifications and tests for Nos. 1 and 2 brake beams as given in the M. C. B. Proceedings for 1913, page 854:

Initial Load.—Apply on initial load corresponding to the number of the beam, as in the second column of the accompanying table, then reduce to zero. Apply a load of 500 lb. and reset the deflection instrument to zero.

Test Load.—Apply a test load corresponding to the number of the beam, as in the second column of the accompanying table, and under this load measure the deflection, which is desired to be 1-16 in. or 0.0625, but should not exceed 0.07 in.

Test for Set Load.—The beam must then be loaded to the load shown in the third column of the table after which the permanent set shall not exceed 0.01 in.

Total Deflection Test.—The brake beam should stand a total motion of the head of the machine of not less than 2 in. without failure at any point.

Number of Beam.	Deflection Load.	Set Load.	Ratio.
1	6 500	14 000	47
2	12 000	24 000	50
3	18 000	30 000	60
4	24 000	36 000	66.7
5	30 000	42 000	71.2
6	36 000	48 000	75

It will be noted that in each case the test load corresponds with the working load of the beam and that these loads, with

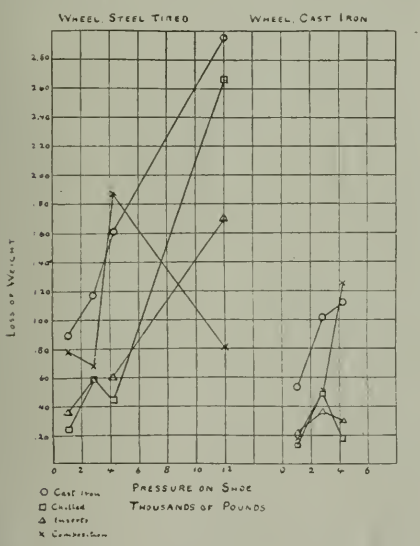

Fig. 5.—Loss of Weight of Brake Shoes (in pounds) on Steel Tired and Cast Iron Wheels at 20 M. P. H.

the exception of the No. 1 beam, vary at intervals of 6000 lb. Further, that the set load will correspond practically to the elastic limit of the material.

The last column of the table shows the ratio existing between the two loads. The proper values of the set load have been determined from experiments made at the testing laboratory of the Pennsylvania Railroad at Altoona by C. D. Young of the committee and are shown in Fig. 6.

Attention was called in the report of the committee last year to the desirability of some further specifications concerning the weight of struts and other elements of the beam. The committee at that time reported that specifying minimum weight would not solve the difficulty but that some specifications detailing the sizes of the heads and struts should be determined. The committee recommends that tests be undertaken by the Association next year and would ask for instructions on this point.

The committee has received some criticism of the 500-lb. initial load in the proposed specifications, it being claimed that in the case of light nonadjustable beams such a load might influence the acceptance or rejection of the beam. To settle this point, C. D. Young of the committee tested several beams of this character, using the 50-lb. initial load and the 500-lb. load. The results of these tests show that this criticism is unfounded.

The committee urges that a load of at least 500 lb. is necessary with the class of machines generally used for testing brake beams in order to take up the lost motion in the machine and in the beam itself and that it is so small compared with the working load of the beam as not to influence the results otherwise. The committee further recommends that in testing beams which

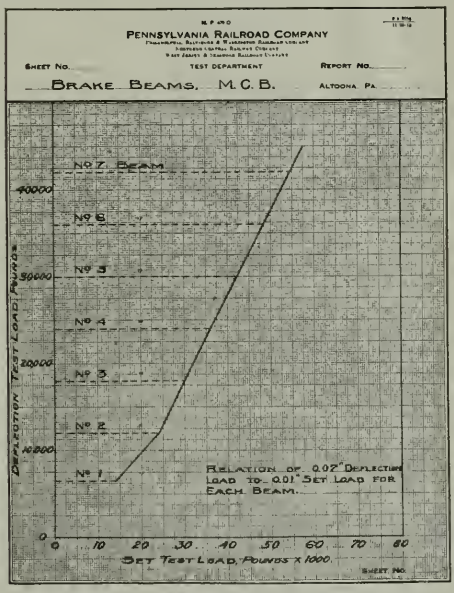

Fig. 6.—Relation of 0.07 in Deflection Load to 0.01 in Set Load for Various Size Brake Beams

have adjustable heads, the heads should be removed before the beam is tested so as to avoid unnecessary lost motion during the test.

The report is signed by:—Prof. C. H. Benjamin (Purdee Univ.), chairman; C. D. Young (Penn.); R. B. Kendig (N. Y. C.); J. F. DeVoy (C. M. & St. P.), and C. B. Young (C. B. & Q.).

DISCUSSION

Prof. C. H. Benjamin (Chairman): I wish to emphasize the desirability at the present time of testing brake beams with the operation of strain gage so as to determine the exact stresses present in different kinds of beams at different loads. Our test at present simply show the strength of the beam as a whole. What we desire to know is what is the strength of the units or elements of which the beam is made up, and that at the present time can be very readily done.

J. J. Tatum (B. & O.): If a minimum weight is not set for a brake beam, how long can we expect a brake beam that gives the test required when new, to maintain the required strength in service? These beams due to deterioration result in a sectional area of metal vastly reducing. The question is: Are we going to have a brake beam in service a justifiable length of time in accordance with its cost, if we do not apply a minimum weight? Just recently I have checked a number of beams and find beams of the same manufacturer, the same style, materially reduced in sectional area. That beam when tested new will give the desired results but after having been in service, due to deterioration we have not gotten the results required by the test. How is that going to be taken care of?

C. D. Young (Penna.): I think that is largely a question of the manufacturer making the beam to meet the test at the time the test is made; when he reduces the section he raises the carbon in the tension member to meet the test. I believe, however, that the committee should have more information than

they have at the present time before they could establish a minimum weight of beam. The committee has through its recommendations, offered to the association at two different times what they consider to be a satisfactory No. 2 beam, and on letter ballot that beam has been rejected by the association, although the committee has not been able to get any definite information from those voting against the beam why they voted unfavorably to it. The beam is probably heavier than the majority of the No. 2 brake beams which are purchased in the market today as No. 2 brake beams. The committee felt that there should be some factor of safety above that required in the test when new. If we were to establish a minimum weight with the information which we now have available, I am afraid that the weight would be so high that the members, in view of what they are purchasing, would not adopt it as recommended practice for the association. If we have a test or an investigation of this kind made we may be able to develop from that data a construction which will permit a beam that will meet specifications during a large portion of its life, and at a weight which is somewhere comparable with the present weight which we are buying in No. 2 brake beams. I believe it was the intention that this investigation cover a No. 2 brake beam only. We would be spending a lot of time on useless work to investigate the No. 1 beam, since so few of those beams are coming into use due to the requirement of the No. 2 beam on a 32,000 lb. light weight car.

J. J. Tatum: I hope every railroad considering this matter will give thorough attention to the required minimum sectional area and weight, so that when we do establish a brake beam we will have one which will stay in service a little while. Further, I would rather see one beam and not two beams. If we are going to have a standard coupler, why not have one standard brake beam so that we can repair anybody's car with the brake beams we have in stock?

D. R. MacBain: I have taken a great deal of interest in the report brought in by the committee on this very important subject, but I feel that the matter is not as well canvassed as it ought to be at the present time for the association to arrive at any definite conclusions as to what ought to constitute a brake beam in its entirety. A few months ago Mr. Chidley and I, being pressed from all official quarters on account of derailments we were having on our line, and other troubles caused by brake beams dropping down, etc., went out and spent a day in one of the important yards and noted incoming trains and outgoing trains. The result of our day's study of the situation was that ninety-five per cent of our brake beam trouble was in the brake shoe and in the brake head and the hanger. The situation seems to me to be more one of brake heads, brake shoes and brake hangers at the present time than anything else. We found that the loop hanger brake head was a very fruitful source of failure. We found that the cast iron brake shoe breaks off, leaving probably half a shoe on, and that on the next application of the brake out on a division the brake head is worn off on the toe. When the train gets in, probably the brake shoe is discovered by the switchman or inspector and replaced. A cast iron shoe put on such a head will usually break and go off altogether, and then the brake head wears down on the center or the loop that the pin goes through. The next time a new shoe is applied it promptly breaks in the middle. The loop hanger brake head is not strong enough. The loop hanger brake head breaks through the back, probably will not be noticed by the car inspector in making the ordinary inspection the car then goes through the yard and out on the division, and finally, under a severe application of the brake, will give way, causing a derailment or some lesser trouble. The next point is the brake shoe itself. This Association should go on record to the management of the railroads for a brake shoe which will not break under any of these slight disadvantages but will yield slightly to resist unequal pressure. Following this investigation, we issued instructions to all the important yards requiring the master car builders to send special men along with the inspectors to examine the trucks in every instance where we could do it without delaying an important train. If there was defective equipment on the brake rigging it was corrected. The result is that we have a miscellaneous assortment of brake heads, brake hangers, pins, etc., amounting to between 60 and 90 tons, taken off at three prominent yards on the New York Central, west of Buffalo. I wish to appeal to the members of this association to do something toward the end that after a while we may get out of service the thousands of defective heads, defective hangers and defective pins that are now causing the real trouble.

Prof. L. E. Endsley: I have tested in the last few years several brake beams with a Berry strain gage, and any beam that will stand the recommended specifications will not have the compression of tension members over-strained. The fact has been that a great many very light heads have been made in order to make the beam stand up under the specifications. Neither the strut nor the head will show any appreciable amount of stress when tested. The stress which comes on the head is due to something else. This association should make a minimum weight of head so that it will not break when a little extra strain is put on it, but as far as the tension and compression member is concerned there are thousands of beams that have plenty of metal in them to stand all the stress if the head remains in its designed position. The strut is another thing which, while not showing stress under the Berry strain gage, is often broken due to hanging the brake wrong or to the stress coming on at an angle rather than in the way it was designed, because of the brake shoe getting worn at one end. A special study of tests for the head of the brake beam is a very important thing for the association to take up.

J. J. Tatum: We have for the last three or four years very materially increased the sizes of our brake hangers and the brake heads have been improved. We find the same condition with reference to the struts and are now attending to the weaknesses that have developed in the tension and compression members.

H. C. Manchester (D. L. & W.): We are having with very undesirable frequency the dropping of brake beams, largely due to the hangers coming out of the recesses in the heads. These cause in many cases quite serious wrecks, and ordinarily more or less interference with the traffic. I come here with an urgent request from the management of the Lackawanna for this body to do everything possible to bring about an improvement in the design of brake hangers. I have written a letter to the Secretary containing recommendations and enclosing a blueprint showing a design of an improved head and hanger to meet this condition, from which we are having a hundred brake beams made. This is the worst small thing that we have to contend with every day in the year.

J. J. Hennessey: If there is one thing that the railroads need more than anything else at the present time it is a standard brake beam. I do not mean just one design, but a brake beam on which the heads and struts can be interchanged, so that you can remove one beam and put on another without changing the length of the brake rods. The difficulties that we are all complaining of arises because we have got too many different styles of hangers, too many different styles of brake beams, too many different styles of connections and fasteners.

Prof. Benjamin: Today we have certain methods of determining whether the brake beam as a whole is strong enough to do the work that is required of it, but we have no means of determining whether the individual elements are properly designed. All that the committee desires is permission to make such tests on beams which are now acceptable to the Association and are in use. No. 2 beams—as shall determine the stresses which come on the various elements of the beam. We will then be able to frame specifications which would meet the points here raised. In regard to the question of brake shoes we have found that those which were cracked sometimes gave better results than those which were whole. If you see fit to adopt a cast iron shoe with reinforced back, you will frequently get better results from your brake shoe after it is broken than before.

H. H. Harvey (C. B. & Q.): Where you have one case of beam trouble you have ten cases of brake hanger or brake hanger pin trouble. You may not believe that, but go out in the field and look it up and you will find that it is true. This Association cannot do any greater work this year than to do something on the whole brake matter.

C. D. Young: I am glad to hear the association talk the way they are this morning. About ten years ago I was on the brake beam committee. We recommended a standard brake beam and when it came before the association it was split up into all its parts. The members went back home and defeated what the committee had done at that time in attempting to make a standard brake beam, and got two or three standards. We have been sleeping at the switch long enough. We go to a great deal of pains to take care of our passenger car brake beams and break heads so they will be safe. These are also the cars that we pay most attention to in the matter of inspection.

When it comes to freight equipment which runs all over the United States and is inspected indifferently wherever it goes, we put on the poorest kind of equipment. The argument presented at the time I refer to was the fact that we had so many cars in service that to go to a standard brake beam would involve a lot of expense. I imagine we have spent more in the matter of wrecks and damages, thousands of times over, than it would have cost us to go a standard

brake beam at that time, and one that would have given us at least less than 15 per cent of the wrecks on our railroads.

F. W. Brazier: On our equipment we put a safety strap under everything, and that safety strap is strong enough so that if our hangers break, it will prevent the beam from going down and coming in contact with the rail.

Prof. Benjamin: The committee is perfectly willing to undertake the consideration of the method of holding the brake beam if the association tells us it is a part of our business, but heretofore we have not held that it was our right to meddle, in that it belonged to another committee.

H. C. Manchester: There are a lot of good brake beams on the market now if there was something to hold them up. That is what we do not have. I do not think we ought to spend any money on something to catch a beam, but the money should be spent on something to hold the beam up.

E. T. Millar (B. & M.): Too little attention is paid to the material that is put in the hanger. If we had some specifications for this material, it would enable us to get a material which would not crack at the corners where it is bent, and where it is practically impossible for the inspectors to see. I know of a number of cases where accidents and serious derailments involving a great deal of expense have occurred, due to a concealed crack in the corner of the loop hanger. There are a number of heads failing at the back part, on the inside, another place where, by ordinary inspection with the limited time that an inspector has to look over the train, it is practically impossible to detect the failure. Why should we not have the specifications for the head and the hanger?

F. F. Gaines: We have been riveting angle irons on the bottom of our shoes. We have not had a single case where they have come down and caused any trouble. It is not expensive; you can pick up old angle irons and T-irons and rivet them on, and they make a good job.

M. K. Barnum: The suggestion that we have one standard brake beam is entitled to very careful consideration. The difference between the two present standard beams is not very great and it is assumed that the requirements for the present standard beam are such as to allow for corrosion and deterioration of strength by natural wear. It may not be necessary to have a standard minimum weight adopted, but in looking over a great many second-hand brake beams I have been very much impressed with the amount of deterioration. I have seen a great many that I am sure were not one-half as strong as they were when new. If there is any doubt on the part of the committee as to their functions I would suggest that they be requested to cover the whole subject of the brake beam and its accessories.

O. D. Buzzell (A. T. & S. F.): I believe that most of our troubles can be eliminated by changing our hangers and enlarging them. Our brake heads in many cases are also weak and should be strengthened. I have occasion to see and examine a great many brake beam failures, and I assure you that trouble is with the hangers and heads, more than with the brake beams.

C. E. Chambers (C. of N. J.): I want to voice my approval of the safety hanger. That is recommended practice, but a great many roads do not pretend to apply them. The Central Railroad of New Jersey is doing so. With a good safety hanger a great many derailments would be averted after the hanger is broken.

C. D. Young: I have listened to this discussion with pleasure because it confirms what the committee has been saying for about five years at each convention. The reason they did not say it so specifically this year is because they have been so generously turned down on the letter ballot. We have proposed a standard brake beam for recommended practice only, and when the question has been presented to letter ballot, if practically any member, who has stood on his feet here and advocated its adoption, had voted for it, it would have resulted in its adoption as recommended practice, the vote was so close.

In last year's committee report we pointed out that about 75 per cent of the defective brake beams found on their roads were removed on account of worn brake heads, indicating that if beams were properly hung and the locations for hanger holes and hanger brackets were standardized a large number of failures could be prevented. Failure of the compression and tension members is further shown to be due largely to poor fits between the heads and struts and the other members. In other words, it is apparent that a more careful standardization of brake beams would result in a much smaller percentage of failures and much less expense to the railway companies. That is practically what has been said this morning. We said this last year, as the final word, coming at the end of the report, and we hoped that when the question went to letter ballot as the No. 2 brake beam was then offered by the committee, as shown on sheet 17-B of the committee's report, there would be enough members who would place in service the beam reported as recommended practice design, so that we could get some experience. However, nothing was done.

A. R. Ayers (N. Y. C.): If the head continually wears on account of the shoe losing off; if the shoe loses off because it is a plain cast iron shoe, it would seem that some action should be taken to discontinue the use of plain cast iron shoes, which will fall off the heads if they crack; and they are pretty sure to crack. If the cast iron shoe gets heated it will warp so that it does not conform to the curvature of the wheel, taking a smaller radius than the curvature of the wheel, so that if pressure is applied to the brake shoe at the center it will crack. On the other hand, it may be that the lugs on the shoe which engage the head, and are keyed there, are twisted out of place; they are not very deep. I have seen among the brake shoes shown on the pier at these conventions shoes where the lug on the shoe, designed to keep the shoe parallel with the head, did not engage it fully. The only thing which kept the shoe on the head was the pressure of the flanges of the wheel. There was 1-16 in. clearance between the toes of the head at each end. The entire design was made with the idea that it shall be an easy matter to take off the old shoe and put on a new one, and it follows that it is a comparatively easy matter for the shoe to work off itself. It would seem that the present brake shoe design is of sufficient age to warrant a little investigation as to the possibility of making improvements.

With respect to the design of head submitted for recommended practice, by simply having the bottom lug on that head so that it stands back a little further, the head can be increased thirty per cent in strength. I believe that the committee should give special attention to the fastening of the shoe to the head and small details which have been standard practice for a number of years and which according to present indications require some revision.

H. C. Manchester (D., L. & W.): I move that the matter of improved brake hangers be made a part of the work of the Brake Beam Committee, or that a special committee be appointed to investigate and report on brake hangers.

The President: The Association has a special committee on car trucks. Is there any objection to having that committee study the brake beam?

H. C. Manchester: No, I just want to have some committee study the design of the brake hanger.

A. R. Ayers: I would like to suggest that the Car Truck Committee can take care of almost any modification of the upper end of the hanger that is desired, but the most difficult end of the hanger to take care of is that at the brake head. I move that the question of a proper brake hanger be referred to the Brake Beam Committee, because it would not be possible to do much with the hanger without encroaching on the work of the Brake Beam Committee.

The President: Would not the Brake Beam Committee be under the same difficulty as regards fixing the top of the hanger? Perhaps it would be well to refer it to those committees jointly.

A. R. Ayers: I believe the two committees would have no difficulty in taking care of anything necessary.

O. C. Cromwell (B. & O.): I believe most of the trouble with the brake beams is the question of suspension, and I suggest that the committee give some attention to the third point of suspension. I think it is important to keep the shoe parallel to the tread of the wheel and to give that proper consideration will, in my opinion, eliminate some of the troubles. We avoided many failures in connection with third suspension, and we also got after the brake beam hanger, particularly with respect to its attachment to the column. We resorted to the use of a threaded bolt with a cotter in addition, and in addition to that we made our hangers ⅞ in. in diameter, and give a good lateral fillet between the horizontal and vertical members of the lug. We have little trouble from cracking in the corners when this arrangement is used. I think the question of the third suspension of the brake hanger is important, so as to keep the shoe parallel with the head.

T. H. Goodnow: I endorse the point Mr. Ayers brought out as to getting a bearing of the lug where it fits into the recess of the head. Some years ago we had considerable trouble on the Lake Shore with broken brake heads in passenger service, and that trouble was cured by changing the lug and filling up the recess, so we did not get any spring in the head when the brakes were applied.

With respect to the inspection of the brake beams to determine whether the proper beam is on the car, most roads feel that the car inspector can do that. I, for one, do not believe he can, considering the way the beams are marked at the present time. The inside hung beam is prac-

tically the common standard now with one or two beams, and if we increase to six beams, as this report would indicate, the car owner is going to protect his car by having his inspectors find out what kind of a beam is on the car; and at night, with an inside hung brake, and with the marking on the fulcrum or strut, it cannot be done. The marking must be on the outside, where it can be seen in the ordinary construction of the car.

D. R. MacBain: I move that this matter be referred to the incoming Executive Committee for consideration and atcion.

F. F. Gaines: I wish to ask a question about having only two beams.

T. H. Goodnow: The committee recommends six beams.

The President: Your idea is also to refer that point to the Executive Committee?

D. R. MacBain: Yes.

The President: Doctor Benjamin, is it your idea that the change on page 16, with regard to specifications, be referred to letter ballot?

Professor Benjamin: Yes.

(The motion made by Mr. MacBain was seconded, put to vote and carried.)

E. W. Pratt: How does the matter stand as to the committee's recommendation regarding the use of strain gage? Is that to be handled by the Executive Committee?

The President: Yes.

CAR WHEELS

This report is largely in the nature of a progress report, as it has been impossible to complete in time for this report various investigations of wheel design that are now under way. A circular of inquiry was sent out by this committee, requesting the members to furnish full information in regard to broken wheels. A total of 33 railroads and one private car line, all members of this Association replied, the companies in question representing an ownership of 1,297,909 cars. While some few replies were received promptly, the majority were so late in coming in as to preclude the possibility of completing an investigation and arriving at joint conclusion with the committee of the American Railway Engineering Association in time for this report.

Three tabulations of the reports received, covering cast-iron

W. C. A. Henry
Chairman, Committee on Car Wheels

wheels having broken and cracked plates, have been prepared, as follows:

Table I.—This tabulation shows the number of wheels having cracked and broken plates, of 625, 675 and 725 lb. weight, respectively, and separated as between refrigerator, box and all other cars.

Table II.—This tabulation shows the number of wheels of each of the three different weights, separated as between refrigerator, box and all other classes of equipment, and grouped by gross weights of car and lading.

These tabulations present one very striking feature, namely, the high percentage of wheels removed from refrigerator cars. By referring to Fig. 1 it will be seen that of 904 625-lb. M. C. B. wheels reported as being cracked and broken in the plate, 575, or 63.6 per cent., were under refrigerator cars. There is no question but that the failure of wheels under this class of equipment is out of all proportion to the number of cars. Attention is called to the large number of 625-lb. wheels that failed under refrigerator cars of a gross weight of 105,000 lb. or more, which weight is considerably in excess of that supposed to be carried by these wheels. It is not believed, however, that this overloading will entirely explain the situation.

According to present M. C. B. practice, cars are braked to 60 per cent. of their light weight, based upon 50 lb. pressure. The result of this condition is that a refrigerator car of 60,000 lb capacity, weighing 44,000 lb., equipped with wheels of 625 lb. weight, will have a braking power, in many instances, equal to

WEIGHT OF WHEEL	NUMBER OF PLATES								TOTAL			
	CRACKED				BROKEN							
	Refr.	Box	All Other	Total.	Refr	Box.	All Other	Total	Refr	Box	All Other	Total.
625	556	236	72	864	19	14	7	40	575	250	79	904
675	33	414	199	646		4	1	5	33	418	200	651
725	3	118	517	638		6	3	9	3	124	520	647

Table I.—Number of Wheels Having Cracked and Broken Plates Reported

or greater than a car of 100,000 lb. capacity weighing 40,000 lb. and equipped with 725-lb. wheels. For example: Take the two cases just cited: the refrigerator car will have a gross weight of 110,000 lb., with a brake pressure of 26,400 lb., which is 60 per cent. of the light weight and 24 per cent. of the loaded weight. The other car will have a brake pressure of 24,000 lb., which is also 60 per cent. of the light weight of the car, and but 16 per cent. of the loaded weight, and which at the same time is 2400 lb. less than the brake pressure of the 60,000 lb. capacity refrigerator car.

If it is true that heating due to the action of the brakes is

Table II.—Tabulation of Wheels Having Cracked and Broken Plates Reported

largely responsible for this trouble, it is only to be expected that under this condition the number of failures of 625-lb. wheels under this class of equipment is going to be large.

Attention of the Association is again called to recommendations made in previous reports, that wheels of the proper size be used, especially under refrigerator-car equipment, as at the present time many cars are running with lighter wheels than are proper, in accordance with the standards of this association.

The report is signed by:—W. C. A. Henry (Penn.), chairman; A. E. Manchester (C., M. & St. P.); R. W. Burnett (C. P. R.); R. L. Ettinger (So. Ry.); O. C. Cromwell (B. & O.), and J. A. Pilcher (N. & W.).

As there was no discussion, the report was received, will be printed, and the secretary will arrange for making the curves as suggested by the committee.

The meeting then adjourned.

REVISION OF THE RULES OF INTERCHANGE

During the last few years there has been quite an undercurrent of feeling that the rules should not be revised so often, that their period of effectiveness should extend over a longer period of time. The St. Louis Ry. Club recommends that no changes be made in the rules, and the Chief Joint Interchange Inspectors at a recent meeting took similar action, and, to a certain extent, the committee coincides with this feeling. While Rule 124 provides that the Arbitration Committee shall ask for suggestions of changes, amendments and additions to these rules prior to each convention, the fact that so many interpretations had been rendered, and the feeling of letting the rules alone for a year or two, led the committee to refrain from asking

for such suggestions this year. Naturally enough, in any set of rules some changes are necessary to conform with changed conditions, and during the year a good many suggestions have been received, which have been incorporated in this report, with the recommendations of the committee. Your committee would recommend that in so far as the interpretations rendered during the year are concerned, they be not incorporated in the body of the rule, but that they be printed on the opposite page in the rule book to the rule itself. It is thought that the rules and the interpretations are now thoroughly understood, and their incorporation into the rules may lead to further misunderstandings, which may be avoided by keeping them separate.

[Following are the more important suggested changes in the rules.—EDITOR.]

Rule 1.—It must be understood that Rule 1, as written to-day, simply calls to the attention of handling companies that the details of repairs to foreign cars on their lines should be maintained in the same general condition as it maintains its own cars, whether the defects are billable against the owner or not.

Rule 2.—To conform to A. R. A. Car Service Rule 15a, the committee would recommend the following:

Rule 2 F.—The following defects must be repaired while car is under load:

1. Defective wheels and axles under all cars
2. All other truck defects on home cars.
3. All other truck defects on foreign cars, except metal bolsters, metal truck sides and metal spring planks; also excepting

J. J. Hennessey
Chairman, Committee on Arbitration

non-M. C. B. standard journal boxes and contained parts in cases where the M. C. B. standard is not a proper substitute.

4. Defective outside wooden end sills on all cars.
5. Defective body center plate or body center-plate bolts, except where such center plate is cast integral on bolster of home cars.
6. Renewal of roof boards of outside wooden roofs, and of inside metal roofs, where such renewal does not exceed 25 per cent. of the roof boards, and where purlines, rafters, ridge pole, side and end plates are in good condition, on all cars.
7. Side doors, where lading is properly loaded as required by the Loading Rules, on all cars.
8. Missing or defective side doors where requiring no protection; end doors, roof doors and hatch covers, on all cars.

F. C. Schultz suggests adding to the last three paragraphs of this rule, after the word "carded," the words "on both sides of car." The committee approved of this suggestion.

Rule 3.—The committee recommends that section (d) be divided into two paragraphs, as follows:

Cars built after October 1, 1915, with axles other than M. C. B. standard, will not be accepted in interchange.

Cars built after October 1, 1916, with journal bearings other than M. C. B. standard, will not be accepted in interchange.

The committee proposes the appointment of a special committee to consider a redesign of the M. C. B. journal bearings and wedges, with the view that the bearings and wedges, as finally redesigned, may be used without conflicting with any patented devices.

The Chicago Car Formen's Assn. suggests advancing the date of effectiveness to October 1, 1916. The committee approves of this suggestion.

Rule 8.—The Central Railway Club and the Railway Club of Pittsburgh suggest that this rule be changed to read:

"Billing repair card shall be made in duplicate, the original to be known as the billing repair card and the duplicate to be known as the record repair card, and to be of the form shown on pages 107, 108, 109 and 110, all items of repairs to be in handwriting.

"Note.—Use of present forms, if not conforming to recommended forms, may be continued until stock is exhausted."

Wording of rule to cover a new form which has been recommended for a wheel and axle billing repair card (copy shown herewith), which form should be shown on pages 109 and 110.

The committee approves of this suggestion.

Rule 21.—The Pittsburgh and Central Railway Clubs suggest adding the following in Section (a), after the word "roof" in last line, changing the period to semicolon:

"or for the cost of applying temporary hand-railings to, or boarding over the opening on, empty well-hole cars."

The committee approves of this suggestion.

Rule 30.—Rule 30 will be revised to correspond with the revision adopted by the Amrican Railway Association.

Rule 33.—The Pittsburgh Railway Club, Central Railway Club and Niagara Frontier Carmen's Association suggest that rule be removed from bracket and changed to read:

"Owners will not be responsible for the expense of repairing or replacing ladders, handholds, sill steps, brake shafts, brake wheels, ratchet wheels, brake pawls, ratchet and pawl plates, upper brake-shaft bracket, brake-step board and brackets, brake-shaft casting where same is used to secure brake shaft to roof of car, brake-chain bolt when in connection with repairs to brake shaft; also, any bolts, rivets, nuts or keys used in securing the above parts, whether or not in connection with other repairs."

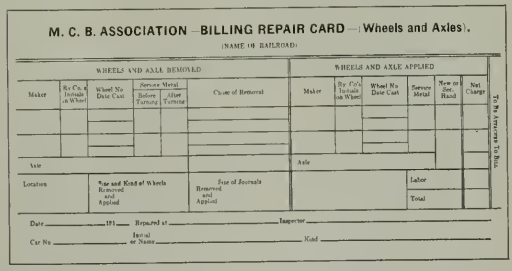
For the reason that the rule has been revised to include all of the detail parts that have been included in the Arbitration Committee's interpretation of this rule in Circular No. 9, and will avoid any future misunderstanding of the rule.

The Arbitration Committee reconsiders its suggestion in Circular No. 9, with reference to the elimination of prices for straightening handholds, sill steps, brake shafts, etc., and would recommend that these items be retained for uniformity in charges in cases of cars damaged at industries located on handling line, cars loaded up and shipped home, or cars damaged on the handling road by the crew of another road.

Rule 40.—The committee recommends the elimination of this rule.

Rule 42.—The committee recommends that the first paragraph of the note following this rule remain as at present; that the second paragraph be eliminated and the following substituted:

"In the case of four or more longitudinal sills requiring renewal or splicing, if the repairs of each of such sills are due



M. C. B. ASSOCIATION—BILLING REPAIR CARD—(Wheels and Axles).

Axle					
				Labor	
				Total	

Date _____ 191__ Repaired at _____ Inspector _____

Car No. _____ Initial or Name _____ Kind _____

New Form for Billing Repairs to Wheels and Axles. A Duplicate to be Used Entitled "Record Repair Card" and to be Retained by Party Making Repairs

to decay or elongated bolt holes, the car shall be held and joint-inspection statement forwarded to owner, who shall promptly authorize repairs at his expense, or destruction of car. In this case, any sill decayed and cracked, or decayed and broken, must be considered as a broken sill."

Rule 52.—The committee suggests the following additional sentence be added: "The use of drive screws is not permissible."

Rule 54.—The committee recommends the removal of this rule from the bracket, and change to read: "Car owners are not responsible for damage to any part of the brake apparatus caused by unfair usage, derailment or accident that requires repairs or renewal."

Rule 60.—The Pittsburgh Railway Club and the Central Rail-

way Club suggest that, following the word "tested" in second line, the addition of "Or dirt collectors not cleaned."

The committee approves this suggestion.

Rule 68.—The committee recommends that the rule read: "Flat sliding; cast iron, cast steel, wrought steel or steel-tired wheels; if the spot is 2½ in. or over in length, or if there are two or more adjoining spots, each 2 in. or over in length, the same responsibility to apply to mate wheel, regardless of length of slid spot.

"A separate defect card to be furnished in the case of wrought-steel or steel-tired wheels."

Rule 88.—F. H. Clark suggests that the repair card be changed so that repairing road will be required to designate on repair card the repairs they have made, and whether any of the repairs made were wrong repairs and whether or not defect card was attached to car for such wrong repairs.

The committee does not approve of the suggestion stating that if the spirit of Rule 88 were following out this matter will be taken care of. There is no more guarantee that the parts repaired will be noted on the repair card than the present rule provides.

Rule 94.—The committee recommends an addition to this rule as follows: "except as follows: In the case of repairs covered by defect card, if the owner changes the original standard of parts so involved, the charge must be no greater than if original design had been followed.

"If owner elects to dismantle the body or trucks, or both, charge may be made for such material as would have been required for the repairs covered by the defect card, but no labor shall be charged in such case, except in so far as labor is already included in M. C. B. prices for material."

Rule 95.—The committee recommends that the paragraph read: "Couplers, including yokes, springs, followers, and friction draft gears complete, when lost with the coupler."

Rule 96.—The Pittsburgh and Central Railway Clubs suggest the following: Eliminate second paragraph of this rule and, also, the form shown on page 109, as this form is not generally used and is not desirable, for the reason that all necessary information in connection with renewal of wheels and axles should be shown on a special billing repair card for wheels and axles, which is recommended and covered by proper reference in proposed revision of Rule 8.

The committee approves of the suggestion.

Rule 99.—The committee recommends an addition to this rule reading:

"When axle is removed on account of owner's defects on wheel, and the journal has increased in length more than 3/8 in., or the collar is worn to less than 5-16 in., or the diameter of the journal is not at least 1/8 in. greater than the limiting diameters given in Rule 86, the axle shall be considered as scrap and credit allowed accordingly."

Rule 108.—The committee recommends the following change in this rule:

"No labor to be charged for the inspection of cars, testing or adjusting of angle cocks or tightening unions.

"No charge to be made for the material or labor of lubrication."

Rule 120.—The committee recommends that the rule be changed to read:

"Where the labor cost of repairs exceeds 10 per cent. of the base price of car body, as given in Rule 116, such car shall be jointly inspected by handling line and a representative of car owner or of a disinterested line (whichever can be most conveniently obtained), and form furnished as shown on page 105, showing all defects found on car and an estimated total cost of the repairs. Upon receipt of this information, owner must either authorize destruction or repairs. In the latter case owner must forward to handling company necessary plans and specifications for such repairs.

"If owner authorizes destruction, handling line shall allow credit for all material at M. C. B. scrap prices, less labor cost of destruction.

"The base price of car body under Rule 116, as referred to above, not to include value of air brakes, or other additions for special items as referred to in Rule 116."

Rule 122.—The Pittsburgh and the Central Railway Clubs suggest the following: Add an additional sentence after the word "line" in the last line, as follows:

"A separate bill, with copy of freight or express bill attached, should be rendered for the freight or express charges, showing reference to bill covering repairs.

The committee approves this suggestion.

PASSENGER CAR RULES

Rule 4.—The Canadian Railway Club suggests a new paragraph reading:

"Billing repair cards shall be furnished in all cases where repairs have been made."

The committee approves of this suggestion.

Rule 10.—The Pittsburgh and the Central Railway Clubs suggest that in paragraph (a), after the word "inches." in third line from bottom, add the words, "or having seamy journals, fillets in back shoulder worn out, the length of journal increased ½ in. over standard length, or collars broken off or worn to ¼ in. or less under fair usage."

The committee approves of this suggestion.

The report is signed by:—Jos. W. Taylor, secretary.

DISCUSSION.

The Secretary: At the meeting of the Arbitration Committee last evening they received a communication from the American Railway Association requesting that the light weight be marked in tank cars. It is therefore recommended that Rule 3 be changed as follows:

Rule 3.—Add a new section, Section O, reading as follows:

"After October 1, 1917, tank cars not stencilled with light weight and capacity in pounds, will not be accepted in interchange."

Rule 86, page 48, first paragraph after the tables: Omit the words "except tank cars." in the first line. Also add at the end of the rule a note reading as follows: "Attention is called to Section O of Rule 3, regarding limit of time for light weights and capacity on tank cars."

Another communication has been received from the American Railway Association in the form of a resolution adopted by the Committee on Relations between Railroads, at its meeting held in Chicago on April 12, which reads as follows:

"Resolved, that the Master Car Builders' Association be advised that the National Railways of Mexico (including the Mexican Central Railway and the Mexican International Railroad) have been suspended from the Per Diem Rules Agreement and that this suspension has resulted in making the delivering road responsible for the per diem accruing on the cars while on the National Railways of Mexico, and that it be suggested that the Master Car Builders' Association investigate the situation and take such action as is necessary to protect the owners of the cars delivered to the National Railways of Mexico."

Recommendation is made that an addition be added to rule 113 as follows:

Rule 113—Add: "When a car owned or controlled by a railway company is damaged or destroyed on the tracks of a road which is not member of the per diem rules agreement of the American Railway Association, the road responsible for the per diem while in possession of the non-subscriber shall be responsible to the owners for the damage or destruction."

John S. Lentz (L. V.): I move that the report of the Arbitration Committee be accepted and their recommendations approved.

M. K. Barnum: I second the motion.

R. L. Kleine, (Penna.): There are discrepancies in the Arbitration Committee's report as compared with the report of the Committee on Prices, and before that motion is put I believe that part ought to be cleared up.

J. J. Hennessey, (Chairman): For the last several years where there was a discrepancy in prices between the Arbitration and the Price Committees, it has always been understood that the recommendation of the Price Committee prevails.

Mr. Kleine: According to one of the decisions, the Arbitration Committee does not prohibit the welding of arch bars on cars in interchange, claiming that they do not have sufficient information as to the accidents involved. I might say that it is absolutely dangerous to weld arch bars. It has been prohibited by nearly all the roads. I would like to see that provision cut out.

Mr. Hennessey: The welding of arch bars has been allowed by the rules for a great many years. We have added onto the rules this year, as you will note, a great deal of repairs that can be made without transfer of loads. While I agree with Mr. Kleine that an arch bar may be poorly welded, I will say that an arch bar properly welded is not dangerous. I believe it would be perfectly safe to allow the rules to remain as they have been for that great number of years, and not tie up cars at isolated points.

Mr. Kleine: Mr. Hennessey is incorrect in the statement that the M. C. B. Rules of Interchange have ever permitted the welding of arch bars. I would refer him to Rule 107. That does not mean the welding of arch bars, Mr. Hennessey. It has never meant that. It means the straightening of arch bars. I say it is an absolutely dangerous practice, and I have a list of cars here that have had arch bars welded and that have caused accidents. I move that that particular reference be omitted.

A. La Mar (Penn.): I second the motion.

Mr. Hennessey: I will have to disagree with Mr. Kleine,

with all due respect to the attention he has paid. The rules have allowed welding of arch bars for I don't know how many years.

F. W. Brazier: If we are going to cut out arch bars, we will have to cut out truss rods, tie rods, and everything else. I think that the rule as it is running is all right, and the Arbitration Committee felt that way and they wanted to help out the old equipment.

Mr. Kleine: We have had wrecks on that account. We have absolutely issued instructions against this practice years back, and so have other railroads, and I do not think it is a parallel case to bring up at this time the welding of a truss rod as compared with an arch bar.

Mr. Hennessey: Don't forget this thing. The traffic department is insistent on the moving of freight, and you are going to put a terrible block in the quick moving of freight at outlying points.

G. W. Wildin (N. Y., N. H. & H.): I agree with Mr. Hennessey that a properly welded arch bar is all right, but if he is doing this in the interest of the little small outlying points, he is going to get a large car welded improperly; and I say Mr. Kleine's contention is all right on the lines of safety.

M. K. Barnum (B. & O.): I would like to ask Mr. Kleine if his record shows that any more arch bars broke, welded, than those that were not welded.

Mr. Kleine: Yes, sir.

Mr. Barnum: What percentage, please?

Mr. Kleine: I have not got the percentage, but the one that caused the serious wrecks and where we had the arch bars examined afterwards, we found it was due to the welded arch bars; and in a number of cases tank cars were involved, involving inflammable liquors.

J. J. O'Brien (Term. of St. L.): In the terminals at St. Louis we handle between 12,000 and 15,000 cars in 24 hours, and I am frank to say that in a number of years I have not heard of an accident being attributed to a welded arch bar.

(Mr. Kleine's motion was put and lost.)

The Chairman: The original motion will now be put before you, the motion to accept the report of the Arbitration Committee.

(The motion was put and carried.)

PRICES FOR LABOR AND MATERIAL

The committee in this year's report has brought the passenger car price rules up to the same standard as the freight car prices. Below is given an abstract of the more important recommendations of the committee, for the changes in price rules, both freight and passenger cars, that will make them conform more nearly to the proper cost for both labor and material:

	Scrap.
One axle, 50 000 lb. or under	$1.65
One axle, 60 000 lb.	2.00
One axle, 80 000 lb.	3.00
One axle, 100 000 lb.	3.70
One axle, 140 000 lb.	4.50

Add the following paragraph on page 53 following the Table of Prices:

The following average scrap credit prices must be allowed for wheels removed from dismantled cars, under the provisions of Rule No. 120:

	Scrap.
One cast iron wheel, 50 000 lb. capacity or under	$2.75
One cast iron wheel, 60 000 lb. capacity	2.90
One cast iron wheel, 80 000 lb. capacity	4.75
One cast iron wheel, 100 000 lb. capacity	4.75

Substitute the following paragraph for the first full paragraph on page 54:

The price for new wrought steel wheels shall be based on the scrap value of $4.50 for metal inside the condemning limit (which is ¼ in. above the limit groove), plus $0.625 for each 1/16-in. of 1½-in. service metal (on radius of tread), in connection with standard full flange contour, also base of limit groove not less than 29½ in. in diameter. In no case shall a charge or credit for service metal be made in excess of 1½ in.

Rule 102—Page 61.—Add an additional paragraph as follows:

In computing charges for lumber, if finished length of the piece in odd inches is under 6 in., the half foot will be allowed for rough length; if 6 in. or over, the even foot will be allowed. Finished thickness, if under 1 in., consider as 1 in. rough; if 1 in. or over, but under 1½ in., consider as 1¾ in. rough; 1½ in. or over, but under 2 in., consider as 2 in. rough; and upward on corresponding scale. The same scale to apply to width, except for matched sheathing, roofing, lining and flooring, which shall be charged according to M. C. B. specifications for rough width. The total amount of each item may be charged in even feet B. M.; if fractional amount is less than ½ ft., it should be dropped.

Rule 116—Page 88.—Change the price of 8-in. air brake, as shown in first paragraph of this rule from $27.50 to $10.

Page 90.—Under head of "Bodies for 8-wheel cars, steel," change Item 1 to read:

Box, wooden body, metal underframe, 30 tons capacity, 36 ft. 6 in. or over, but less than 40 ft. over end sills...$825.

Change Item 2 to read:

Box, wooden body, metal underframe, 30 tons capacity, 36 ft. long or over, but less than 38 ft. 6 in., over end sills .....$740.

Change Item 3 to read:

Box, wooden body, metal underframe, 30 tons capacity and over, 40 ft. long or over, but less than 46 ft., over end sills .....$850.

Change Item 4 to read:

Box, wooden body, metal underframe, 30 tons capacity and over, 36 ft. long, over end sills.....$725.

Change Item 5 to read:

Box, wooden body, metal underframe, 40 tons capacity and over, but less than 50 tons capacity, 36 ft. long and over, but less than 38 ft. long, over end sills.....$730.

Change Item 6 to read:

Box, wooden body, metal, underframe, 40 tons capacity, but less than 50 tons capacity, 38 ft. long but less than 40 ft long, over end sills.....$775.

Change Item 7 to read:

Box, wooden body, metal underframe, 40 tons capacity, but less than 50 tons capacity, 40 ft. long or over, but less than 46 ft. over end sills.....$800.

Eliminate Items Nos. 8, 9, 10 and 11 and substitute the following:

Box, all-steel, any capacity or length.....$0.0325 per lb.

Eliminate Items 12, 13, 14, 15 and 16 and substitute the following:

Flat, wooden floor, metal underframe, any capacity or length .....$0.0325 " "

Eliminate Items 17, 18, 19, 20, 21, 22, 23, 24, 29, 30, 31, 32, 43 and 44 and substitute the following:

Gondola, all steel, any capacity or length, having either solid, drop or hopper bottom or self-clearing by floor dropping on side.....$0.0325 " "

Eliminate Item 33.

Eliminate Items 35, 36, 37, 38, 40, 41 and 42 and substitute the following:

Hopper, all-steel (including coke cars), self-clearing, any capacity or length.....$0.0325 " "

Items 45 and 46 should be made to follow other items covering gondola cars.

Insert the following item after Item 37:

Stock, wooden body, metal underframe, 30 tons capacity, 36 ft. long or over, over end sill.....$775.

Rule 117—Page 94.—Change second paragraph of this rule to read:

In the case of all-steel car bodies or car bodies with steel underframes and steel superstructure frames, the depreciation shall be figured at 5 per cent per annum. Steel superstructure frame car indicates a car having the side and end uprights, braces and plates riveted together.

Change third paragraph to read:

In the case of car bodies with steel underframes and wooden superstructure the depreciation shall be figured at 5½ per cent per annum, with the exception of steel underframe flat cars having wooden floors, which shall be figured at 5 per cent per annum.

Page 95.—Change last paragraph of this rule to read:

The amounts $10 and $35 for air brakes shall not be subject to any depreciation.

Page 135.—Add a new paragraph under the 4th paragraph, reading: On electrical head end lighting system of passenger equipment trains, a charge of 40 cents shall be made for the use of electrical equipment for each 100 miles car is run. The charge does not include cost of coal and attendant. (Expense of attendant may be added if furnished and charged for on mileage basis.)

The report is signed by:—F. H. Clark (B. & O.), chairman; H. H. Harvey (C., B. & Q.); C. E. Carson (N. Y. C.); C. F. Theile (P. C. C. & St. L.); Ira Everett (L. V.); C. C. Swanson (A., T. & S. F.), and Sam'l Lynn (P. & L. E.).

(The report was approved.)

COMPENSATION FOR CAR REPAIRS

The committee on the subject of Compensation for Car Repairs was instructed to give consideration to the following items:

First:—Is it desirable to make an allowance for overhead charges incident to the repairs of cars?

Second:—If so what items should be included therein?

Third:—What ratio should such overhead charges bear to the labor cost?

The conclusions of the committee regarding each of these subdivisions of the subject are:

First:—That it is proper that those making repairs to cars should be fully reimbursed for the actual expense incurred by them, including what are generally referred to as overhead charges.

Second:—That there should be added to the direct labor cost an allowance for the expenditures made for:

DIRECT SUPERVISION.—This item includes the proper proportion of the wages of foremen, assistant foremen, gang foremen, clerks, etc., chargeable to the actual repairing of freight cars. Amounts paid all other men whose time is properly chargeable to freight-car repairs, excepting those engaged in the manufacture of stock material.

SHOP EXPENSES.—The proportion assignable to the actual repairing of freight cars, the expenditures for general employees, power, heating, lighting, shop supplies, and incidental expenses connected with shop operation.

SHOP SWITCHING.—As provided for by the authorized accounting system.

SUPERINTENDENCE.—The proportion properly chargeable to freight-car repairs of the salary and expenses of the general superintendents motive power, mechanical superintendents, master car builders, superintendents motive power, master mechanics, etc.

USE OF FACILITIES.—To include interest on the investment, depreciation, maintenance, insurance and taxes on that part of the plant or plants used for the repairing of freight cars.

Attention is directed to the fact that the allowances mentioned above should be carefully segregated so that the allowances applicable to the repairs of cars, and those applicable to the manufacture of material, should be separate and distinct. As for material, an especially determined allowance, including an adequate amount for storehouse expenses, is required.

Third:—The ratio that such overhead charges should bear to the labor cost.

To determine as accurately as practicable what allowance should be made for the items mentioned above, the committee assigned the task of assembling the necessary data to the subcommittee named below:

W. L. Wilt, chief motive power clerk, Penna. Lines West, chairman.
J. H. Connor, chief motive power clerk, Union Pacific.
Wm. McMunn, general car inspector, N. Y. C.
F. H. Swerengen, M. C. B. Streets Western Stable Car Line.
E. E. Jette, M. C. B., Morris & Company.
W. A. Guy, assistant general car inspector, Penna. Lines West.

The experience of all of these gentlemen is such as to especially qualify them for the work required. After considerable study this subcommittee prepared a list of questions, which, after approval by the committee was submitted to the association, as Circular No. 8.

Owing to the large amount of work required to compile the necessary data, and the short time available to complete the report, it was decided to request the information for the month of November, 1914, only.

Replies were received from 58 railroads, owning 1,618,675 cars, and 11 private car lines, owning 52,102 cars. Summarizing the replies gives the amounts expended as follows:

		Average per Hour.
Direct labor, 8,019,862 hours	$2,226,750.85	27.7c
Direct supervision	303,294.00	
Total	$2,530,044.85	
or the average expenditure per hour of direct labor for labor and direct supervision		31.5c
The proportion of shop expenses, shop switching and superintendence allotted to the repairing of freight cars amounted to $758,182.66, or for each hour of direct labor		9.4c
That is, for 8,019,862 hours direct labor there was expended:		
Direct labor	$2,226,750.85	
Direct supervision	303,294.00	
Shop expense, shop switching and superintendence	758,182.66	
Total	$3,288,227.51	or 41.0c

Consequently, as the average hourly payment for direct labor was 27.7c per hour, and for direct labor and all supervision was 41.0c per hour, an allotment of 48 per cent. must be added to the hourly payment for direct labor to fully reimburse those repairing freight cars, without any allowance for the use of facilities, such as interest on the investment, depreciation, taxes and insurance on, and maintenance of, shops, repair tracks, etc.

While the committee made inquiry as to the proper allowance that should be made for the use of facilities, the wide divergence in the replies received indicates that precise data are not available, and it is therefore deemed desirable to postpone consideration of this point until more correct information may be obtained; perhaps until the valuation of railway properties now in progress indicates a more definite line of procedure.

It is important to note that all of the data given above refers only to what may be called shop repairs; that is, where the use of facilities is involved, as the committee is of the opinion that such light repairs as are ordinarily made in classification yards or on the line may be more satisfactorily covered by fixed prices, as is now the practice in application of air-brake hose, etc.

The committee recommends:

First:—That the prices for individual items of work performed, as now embodied in the Code of Rules of Interchange of Cars, be based on the average time required to perform each operation. That to simplify calculation and accounting a rate of 28 cents per hour be used as representing the average hourly cost for direct labor, adding to this amount 12 cents per hour as meeting the requirements for overhead charges. The reduction in the total hourly charge from 41 cents to 40 cents reduces the overhead rate from 48 per cent to 44.4 per cent, and is felt advisable, due to the fact that the month of November, for which the figures were obtained, might not generally be considered as a representative month.

Second:—That fixed prices, including labor and material, be determined and listed separately for such items as: Application of cotter keys, knuckle pins, knuckles, air hose, safety appliances, brake shoes, and kindred repairs such as are ordinarily done in classification yards. These fixed prices to apply whether the work is performed in the classification yards, shops or repair yards.

Third:—That this report, with the approval of the convention, be referred to the Committee on Prices for Labor and Material, with such instructions as may be necessary to make effective the above recommendations.

This report is signed by: D. F. Crawford, chairman (Penna. Lines); F. F. Gaines (C. of Ga.); M. K. Barnum (B. & O.); C. E. Fuller (U. P.); C. F. Giles (L. & N.); Thomas Beaghan (U. T. L.); H. L. Osman (Morris & Co.), and M. F. Covert (Swift Ref. Trans. Co.).

T. W. Demarest, (Penna. Lines): I move that the recommendation of the Committee be adopted by the Association and the report in turn referred to the Price Committee for their consideration during the coming year.

(The motion was carried.)

SETTLEMENT PRICES FOR REINFORCED WOODEN CARS.

After the committee was constituted its scope was enlarged to include the subject of depreciation in relation to settlements for cars destroyed on foreign roads. The principal question involved is to determine what measure of repairs and the character of additions and betterments which so increase the strength, utility and value of a unit of equipment that fairly justify a complete depreciation cut-off. The committee, therefore, had two distinct problems before it and they are discussed separately.

J. McMullen
Chairman, Committee on Settlement Prices for Reinforced Wooden Cars

Settlement Prices.—To get the proper perspective of this problem it is necessary to keep steadily in view the essential fact that the basic, arbitrary prices now provided in the rules for wooden cars are quite liberal; hence, before it may be adjudged fairly that any particular part of a car or an appliance, even though

obviously an improvement over wooden construction, merits a special price as a betterment, it should be determined whether the basal price does not cover, reasonably, any difference in value that such part or appliance bears over the type of construction upon which the basic prices were determined. Having this fully in mind, the committee is of the opinion that the following items should be added to the present basic prices for car bodies when so equipped.

It is recommended that the wording of the last paragraph of Rule 116, on page 89, and the first paragraph on page 90, be changed to make the language uniform with that of the new matter proposed by the committee, and that the second and third paragraphs of this rule, on page 90, be omitted entirely. Following the second paragraph from the bottom of page 89, the committee submits the following revision and additions to Rule 116:

The prices for car bodies contained in the foregoing schedule are exclusive of the following items, the prices of which may be added when a car is so equipped:

(a) Double-deck stock cars, per car.....$25.

(b) Metal body bolsters; also composite body bolsters in which the metal members are at least 8 in. in depth and have an aggregate minimum sectional area of 16 sq. in., provided car is 60,000 lb. capacity or over and so stenciled, and has trucks with journals 4¼ in. or over when new, per car....$30.

(c) Center sills or continuous metal draft members shall be figured per lineal foot per member, according to depth and weight as follows and including draft lugs riveted on, or cast integral on cast-steel extensions. (Where such cast-steel extensions are used, the metal center sills or continuous metal draft members to which they are attached must be figured full length of car.)

Eight in. in depth and not less than 18 lb. per ft.....	$0.90
Nine or ten in. in depth and not less than 20 lb. per ft....	1.10
Twelve in. in depth and not less than 25 lb. per ft.....	1.30
Fifteen in. or over in depth and not less than 33 lb. per ft..	1.50

(d) Cover plate used on metal center sills or continuous metal draft members, per lineal foot of the sills actually covered, whether plate is applied on top or bottom, or both, or in part on top and in part on bottom.....This price shall not apply to what is commonly known as tie plates, regardless of dimensions ..... .65

(e) Metal draft arms extending 24 in. or more back from center line of body bolster, including draft lugs, whether riveted on or cast integral, per car. 65.

(f) Friction draft gears, per car..... 25.

(g) Metal needle beams, when used in conjunction with metal center sills or continuous metal draft members, per car..... 10.

(h) All-steel ends of the corrugated type, per car..... 40.

(i) Where allowances as above are based upon length, fractional parts of a foot in the aggregate length shall be counted as one foot, if one-half or greater; if less than one-half, they shall be dropped.

NOTE.—Paragraphs (a), (f) and (h) to apply to all cars so equipped.

Depreciation.—On the question of depreciation to be figured on rebuilt cars, the committee, after carefully reviewing the question from various angles, found it was unable to come to any conclusion, or to arrive at any workable basis upon which all could agree It asks that this question, together with the general provisions in Rule 117 limiting depreciation to 60 per cent of value new and covering the rate per cent of depreciation, be carried forward in the work of the ensuing year.

The report is signed by:—J. McMullen (Erie), chairman; H. G. Griffin (C. P. R.); T. J. Burns (M. C.); J. E. Mehan (C., M. & St. P.); H. H. Harvey (C., B. & Q.); C. N. Swanson (A., T. & S. F.); F. F. Gaines (C. of G.).

DISCUSSION

J. J. Tatum (B. & O.): There are some items of cost in this report which would very much affect our road if they are adopted. Reducing the allowance for the metal body bolster from $40 to $30 will result in bringing the cost of the improvements which we have applied to our cars below the figure which they cost us. In place of being an encouragement for the improvement of equipment, it will rather lead us to wear out our cars as they were originally built. We paid between $120 and $130 for a center sill for our equipment with the bolster built integral. The present M. C. B. price is $80, plus $40, which is about what we pay for these articles but these changed figures will very materially reduce it. I move that the matter be referred to letter ballot.

M. K. Barnum (B. & O.): If the report is to be passed on as a whole I would like to second Mr. Tatum's motion.

T. J. Burns (M. C.): As you are probably aware, the committee has had a good deal of work to do. One phase of the work was to look after the settlement price, which had to do with rule 116, and the other phase of the work assigned to the committee was to figure the question of depreciation on rebuilt cars. In the matter of rule 116 I feel we could safely refer that to letter ballot, but on the question of depreciation, I feel that the committee has come back to the convention in a sense empty-handed. I would suggest on that phase of the work, that the committee be continued along this line, and the membership of the committee enlarged. I should suggest a representative committee of about ten be appointed and see if they cannot come back next year with some practical proposition on this matter. In speaking of the underframe, in order to protect the car owner, it occurred to the committee after the paper was written, that possibly there should be included in this report, and submitted with the report to letter ballot, a proposition that would provide for the returning of the underframe to the owner of the car, at his option. That would protect the car owner until such time as we can arrive at some conclusion as to what we shall do with the rebuilt car. The committee's idea of a rebuilt car is a car taken to the shop, and given a new underframe and steel ends and brought up to modern requirements. I think the best way to handle this report would be to submit it to letter ballot as a whole, and add a paragraph, providing it is agreeable, covering the return of the underframe to the owner of the car at his option.

Mr. Tatum: I make an amendment to my motion that each item of the report be submitted to letter ballot separately.

Mr. Barnum: It seems to me that it would be desirable to take the suggestion under the heading "Depreciation," and to have the committee continued and instructed to make further study of that question by itself.

T. H. Goodnow. (C. & N. W.): It would be better for Mr. Tatum, even if he is not getting what he feels is his whole due, to accept what the committee offers for the year, and then get the increase next year. Hundreds of thousands of cars are now being reinforced, and settled for on their original cost, and it is a question if that part of the Committee's report has not been overlooked where they refer to the basic prices under the rules established at the present time.

Mr. Tatum: I do not think we should make a rule unless we make it as near right as we can when we start.

J. J. Hennessey (C. M. & St. P.): In my opinion there is only one class of cars that will be really barred from receiving the benefit that this report today covers, and that is the class of cars that have the steel casting two feet back of the body bolster, extending that distance back. The cars that Mr. Tatum and Mr. Goodnow speak about, that have metal center sills should be settled for, not on the basis of the original cost of the car, but they should be settled for on the basis of the cost of the car as it exists, what is allowed in the rules of the present time for metal center sills only, and then the depreciation will have to be figured from the time the car was originally built, so really the only thing that seems to me to be before the Convention is the question of the cars that are equipped with the cast steel draft arm, not the continuous sills.

Mr. DeGraff (Erie): There is a decided difference of opinion as to what the question involved is. Mr. Hennessey says it is confined to the cast steel extension. The present rules do not provide for a large part of the reinforcing of old equipment that is being done today in this country. We are reinforcing between 6,000 and 7,000 of our cars, and we are doing it in a way that we would not get any return, as the rules stand today. We are reinforcing 1,800 of our cars for which the rules do not provide one additional cent of compensation, and these cars are as good as the average steel underframe car, or all steel construction today. Now the present provision was put into rule 116, without referring it to letter ballot, obviously for the purpose of protecting car owners who were reconstructing their equipment in order to stand modern traffic conditions, the conditions the cars must stand up under today. I agree with Mr. Goodnow that this is not the time to refer this to letter ballot. There is no especial damage done if we pass upon this today. It will not be irreparable. If Mr. Tatum does not get exactly what is coming to him, in the end it will balance itself up. We cannot attempt to amend the rules of interchange on the basis of what the effect will be on one railroad. We have a bigger mission here, Mr. Chairman, and that is to protect the railroad interests of the United States, and I will include Canada and Mexico.

Mr. Hennessey: I want to make a correction to my previous statement, and refer to one thing that is not covered.

and that is the all-steel end. That I should have included in my previous remarks.

H. H. Harvey (C. B. & Q.): I do not think Mr. Tatum figured his car costs up right. He gives $120 as the cost of the reinforcing of the car, $80 for the sills and $40 for the bolsters. He will find he will get a whole lot more in the committee's present recommended prices than he gets under the present prices—those which are now in vogue. The committee did not try to cut down any compensation, but to even up the matter between the railroads. If Mr. Tatum will figure the center sills on the foot price given in the report he will find that he will get more than $80. The price is regulated per foot per member. Under the present rule, a man putting metal draft arms on, he does not get anything for it. If he puts on friction draft gear, he gets nothing for that. If he puts metal ends in, there is nothing for that. In fact, all he gets is for his steel center sills and body bolsters, and I think it will be a mistake to put this thing off for another year.

Mr. Barnum: I suggest before the report is sent out that the items referred to by Mr. Harvey be made to read 18 lb. per foot per member. Otherwise I think it is likely to be misunderstood.

D. R. MacBain, (N. Y. C.): The majority of the equipment in the country today is not up to the standard necessary for safe and successful and economic operation. That is one point we should consider. The next point is to consider the means of getting the equipment to that point of efficiency. If we stop progress by any laws passed by this organization, that is to say, if we legislate against anything that any road is trying to do to bring the equipment up to its proper efficiency, we are doing the wrong thing. The road I am connected with has in the past 6 or 7 years equipped some 35,000 or 40,000 cars with steel center sills, steel ends, and various other improvements which bring the car up to a better state of efficiency than it was the day it was built. If one of these cars of ours is destroyed on a foreign road, it seems to me a matter of equity that it should be considered exactly the same as though a farmer borrowed my thousand dollar wagon and broke it, and the only fair thing for him to do would be to buy me a new wagon in its place.

F. W. Brazier (N. Y. C.): All we ask is that we be paid for our betterments which are put on the car. I see no harm in the report going through. It is not business-like to destroy a car belonging to the New York Central, on which we have spent $400 or $500, and then, in the settlement, carry that car back twelve years to the time when it was originally built.

Mr. Burns: While the committee has provided for a charge to take care of the underframing, as the report stands now, all a man will get who puts the underframe on now will be the depreciated value of the underframe. That is why I suggested it might be possible for the owner to have the underframe returned.

C. F. Thiele (Penn Lines): How will you decide between two roads, where a car is destroyed, which is equipped with the underframe? How is the charge to be arrived at, $10, $12 or $18 per foot?

J. MacMullen (Erie): The committee bases its figures on the weight of the channel used together with the depth.

F. H. Stark (Montour): I move to amend the committee's report making an allowance of $36 instead of $30 for the metal body bolster. If we can compromise on this point, I believe that it is advisable to act now.

Mr. Goodnow: I happen to know something regarding the work of the committee, and believe that the prices they have established are as equitable to all as they can be at this time. It is possible in another year the prices will have to be changed, the same as any other prices are changed.

(The motion to submit the report to letter ballot was withdrawn.)

Mr. Goodnow: I move that the committee's report be approved and that the committee be continued to handle the question of depreciation as they ask.

(The motion was carried.)

AN EGYPTIAN RAILWAY BRIDGE.—A curious fact is reported with reference to a new combined road and railway bridge which was to have been erected at Emambagh in Egypt. The contract was placed with a firm which in turn placed the order for construction with a firm in Northern France. The bridge was constructed in the works, one span was shipped and has since been delivered in Egypt; then the Germans invaded France and captured the remainder of the spans. As they are not likely to give them up, work on the bridge is temporarily abandoned.

FOUND

A ladies' pin was found on the floor of the ball room on the pier last night. The loser can recover it by calling at the booth of the *Daily*.

PRIZE WINNERS IN THE KICKERS' CONTEST

The ties for first and second prizes in the Kickers' contest of the golf tournament were played off yesterday. George L. Bourne defeated R. H. Weatherly for the first prize, and the second prize was won by B. P. Flory, the others tied for it played with him being J. D. Purcell, W. L. Allison, and H. M. Perry.

THE DANCE LAST NIGHT

The opening dance for the Master Car Builders held last evening proved quite as successful as those held on the pier last week. The program was similar to that of last Wednesday night, being entirely informal, with Miss Betty Lee in costume recital and music by the Don Richardson Orchestra. During the day it was very warm, but long before 9.30 P. M., when the dancing commenced, it was evidenced that it would take more than heat to keep the crowd away. Owing to the fact that the entertainment committee did not use the orchestra on the pier Sunday, one hour's more music was provided, and was much more appreciated than would have been the case had the original schedule been followed. The committee in charge were Walter H. Bentley, chairman; W. K. Krepps, Burton W. Mudge, H. W. Scott, C. D. Eaton, A. B. Wegener, J. P. Landreth, J. F. A. Comstedt, W. W. Melcher, C. C. Farmer.

THE NUMBERS USED IN THE KICKERS' HANDICAP

It is not generally understood how the numbers used on Saturday as a basis for determining the results of the kicker's handicap contest in the golf tournament were arrived at. As was announced in advance, the players were allowed to choose any handicaps that they pleased and the winning net scores had to be between 71 and 76. After the players had gone out on the course, slips marked with the numbers from 71 to 76 were placed in a hat. They were then drawn out at random by George R. Carr, chairman of the Entertainment Committee, who picked up numbers 71, 74 and 75. This determined that players coming in with a net of 71 would be in line for the first prize; those coming in with a net of 74 for the second prize, and those with a net of 75 for the third prize. Through an oversight L. A. Cameron, who came in with a net of 71, was not included among those who were mentioned as having tied for the first prize. Mr. Cameron will play off the tie with G. L. Bourne and R. H. Weatherly.

R. S. M. A. COMMITTEE APPOINTMENTS

President-elect Ostby has named the following committees and committee chairmen for the coming year:

Hotel Committee, J. H. Kuhns, Republic Rubber Company, Chicago (chairman); P. J. Mitchell, Philip S. Justice & Company, Philadelphia, Pa.; C. D. Eaton, American Car & Foundry Company, New York.

Finance Committee, J. C. Currie, Nathan Manufacturing Company, New York (chairman); J. F. Schurch, Damascus Brake Beam Company, Cleveland, Ohio; C. E. Postlethwaite, Pressed Steel Car Company, Pittsburgh, Pa.

Badge Committee, Edmund H. Walker, Standard Coupler Company, New York (chairman); C. B. Cass, Westinghouse Air Brake Company, St. Louis, Mo.; J. P. Schurch, Damascus Brake Beam Company, Cleveland, Ohio.

Exhibit Committee, C. B. Yardley, Jr., Lubricating Metal Company, New York (chairman); George H. Porter, Western Electric Company, Chicago; J. G. Platt, Hunt-Spiller Manufacturing Corporation, Boston, Mass. A sub-committee on Lighting

and Power will be appointed to insure plenty of light and power.

By-Laws Committee, C. E. Postlethwaite, Pressed Steel Car Company, Pittsburgh (chairman); F. E. Beal, Magnus Company, Inc., Atlanta, Ga.; C. F. Elliott, American White Lead & Color Works, Detroit, Mich.

Entertainment Committee, Gilbert E. Ryder, Locomotive Superheater Company, New York (chairman).

Enrollment Committee, Charles W. Beaver, Yale & Towne Manufacturing Company, New York (chairman).

Transportation Committee, J. L. Randolph, Economy Devices Corporation, New York (chairman).

John D. Conway has been re-elected secretary and treasurer of the association.

ADDITIONAL MASTER CAR BUILDERS' REGISTRATION

Acker, C. B., General Car Foreman; P. S. & N.; Monticello.
Adams, H. T., G. C. F.; Wabash; Grand Atlantic.
Akans, Geo., M. M.; Southern; Traymore.
Andrus, Chas., Supt. Shops.; Mather Stock Car Co.
Barba, C. E., Asst. Engr.; Chalfonte.

THE McBARMMA GOLF LEAGUE

One of the most interesting organizations ever formed to afford a little recreation in connection with the hard work done by the railway men and railway supply men attending the mechanical conventions is the McBarmma Golf League. The league derives its name, of course, from the initials of the Master Car Builders' Association and the American Railway Master Mechanics' Association. It was organized at Saratoga on June 15, 1906. At that time golf had not become the popular pastime which it is now. It was played in this country by only a few as compared with the large number who now indulge in it. Its virtues as an exercise and a diversion had not become universally appreciated and all those who played it were regarded with some scepticism by the rest of mankind.

For that reason, in the early history of the McBarmma League its members slipped quietly out to the golf course on the Saturday between the conventions and slipped as quietly back again, and the fact that a tournament had raged all day was kept measurably quiet. But within recent years the social and medicinal qualities of golf have become more generally recognized all over the country. Almost everybody is playing it and those who have not begun to do so have begun to regard it with longing rather than suspicion. In consequence, the time has arrived to "expose" the McBarmma Golf League, give some of the facts in its history and for the first time publish the scores made and the prizes won in one of its tournaments.

The charter members of the league number 16. Its usual membership at present is about 30. Every one of its charter members is still living and ten of them took part in the McBarmma tournament last Saturday. These are E. H. Bankard, F. H. Clark, D. F. Mallory, C. F. Quincy, G. H. Sargent, R. F. Carr, F. V. Green, H. A. Gillis, S. P. Bush, and C. F. Street. The charter members who were not here are R. P. C. Sanderson, H. H. Vaughan, O. H. Cutler, T. H. Symington, D. D. Pendleton and F. Conklin.

At the club tournament last Saturday 18 holes were played in the morning and 18 in the afternoon, as usual. The scores made in the morning were as follows:

	Gross.	Handicap.	Net
C. F. Quincy	99	10	89
C. L. Bardo	93	6	87
F. H. Clark	105	14	91
C. F. Street	108	14	94
M. K. Barnum	118	18	100
R. F. Carr	92	12	80
D. R. McBain	105	18	87
J. T. Carroll	102	18	84
W. O. Wood	111	16	95
J. McNaughten	119	18	101
C. C. Elmes	123	24	99
J. L. Replogle	97	10	87
F. V. Green	124	30	94
H. A. Gillis	92	6	86
G. H. Sargent	122	18	104
W. C. Arp	115	14	101
E. O. Warner	92	10	82
D. F. Mallory	79	0	79
N. M. Garland	89	4	85

A. H. Sisson	93	9	84
W. L. Conwell	95	4	91
S. L. Knease	113	10	103
E. H. Bankard	102	14	88
W. D. Robb	114	24	90

The gold medal for the best gross score was won by D. F. Mallory, who shot a 79. The club handicap cup for the lowest net score was won by R. F. Carr, but passed to W. R. Warner because Mr. Carr won another prize during the day and under the rules of the club no player can be awarded two prizes in the same tournament. The handicap cup must be won by a player three times before he can keep it, and S. P. Bush is the only member who has ever succeeded in doing this.

On Saturday afternoon there was a tournament for class A and class B players. The scores in class A were as follows:

	Gross.	Handicap.	Net.
C. L. Bardo	96	4	92
R. F. Carr	90	12	78
D. R. McBain	106	18	88
J. T. Carroll	111	18	93
J. L. Replogle	94	10	84
H. A. Gillis	88	6	82
D. F. Mallory	99	0	99
A. H. Sisson	103	0	94
W. L. Conwell	93	4	89
E. O. Warner	103	10	93

The winner of the first prize was R. F. Carr, and the second went to H. H. Gillis.

The following were the scores in class B:

	Gross.	Handicap.	Net.
C. F. Quincy	109	10	99
F. H. Clark	107	14	93
C. F. Street	107	14	93
M. K. Barnum	107	18	89
W. O. Wood	101	16	85
C. C. Elmes	141	24	117
F. V. Green	124	30	94
G. H. Sargent	119	18	101
E. H. Bankard	118	14	104
W. C. Arp	111	14	97
S. L. Kneass	106	10	96
J. McNaughton	113	18	95
W. D. Robb	122	18	98

The first prize in this class was won by W. O. Wood, and the second by M. K. Barnum. The Carr handicap cup given by R. F. Carr was won by J. L. Replogle. The Sargent luck cup given by G. H. Sargent, was won by C. L. Bardo. This cup must be won three times in order to be retained. The prize in the approaching and putting contest was won by W. L. Conwell. Each member of the club has a goat medal for which they play during the year; and the man who comes in with the largest number of medals gets a prize. The goat prize was awarded to N. M. Garland, who came in with six medals.

The McBarmma Club had its annual dinner Saturday evening and the following officers were elected for the ensuing year: President, S. P. Bush; vice-president, C. L. Bardo; secretary-treasurer, C. F. Street.

At their dinners the members of the club sing various improvised songs appropriate to the occasion, and the following which was sung Saturday night to the tune of "Mr. Dooley," was a tribute to the directing spirits of the club:

Who is it rules with iron hand
McBarmma and its crew?
Who runs the show from soup to nuts?
Who tells us what to do?
We dare not say our soul's our own—
In fact we have no soul:
They swiped it from us when they swiped
The Jobs they now control.

'Tis Charlie Quincy, old Charlie Quincy,
Laying in cahoots with Clement Street:
Old Bill the Geezer and Julius Caesar,
They never saw the day they had them beat.

Conventionalities

F. H. Stark, general superintendent, Montour Railroad, is looking for information as to the desirability of using high or low steam pressure on some new locomotives which are in process of designing.

Stephen C. Mason, of the McConway & Torley Company, made another call at the office of the *Daily*, and left behind material

R. T. Jaynes, M. M., Lehigh & Hudson, and Mrs. Jaynes

evidence of the fact that the cigars got here all right. Many thanks, friend Mason!

The steel back gold dust twins, N. H. and T. C. Davis, made the rounds yesterday. They seemed lost without a brake beam or brake shoe exhibit; but they are thoroughly enjoying their temporary retirement from the railway field.

Jack High on the Left, A. E. Calkins, Assistant to Supt. Rolling Stock, N. Y. C., on the Right

G. W. Denyvan (Denny), of the Parkesburg Iron Company, has the distinction of having won the prize, a beautiful vanity box, at the dancing contest on the pier last Tuesday evening. (His was the lucky number that was drawn from the hat.)

F. C. Pickard, master mechanic of the Delaware, Lackawanna & Western at Buffalo, spent several days before coming to the convention riding the Pacific type locomotive with the Riegel

water tube firebox which is now being tested out with a dynamometer car.

Harry Frost left Sunday evening for Lawrenceville, N. J., to be with his son at the graduating exercises of the school at which the young man has been preparing for Princeton. It seems but yesterday when son Frost, then but a few years old, used to be known at the conventions as a "little freezer."

Albert MacRae, who, besides his other activities, is secretary of the Illinois Athletic Club in Chicago, has found that there are 35 railway and supply men attending the conventions who belong to this organization. Twenty-eight of them got together Monday and had a photograph taken out on the pier.

Through an error in the print shop the word "Miss" was made to read "Mrs." and it would appear from the photograph which was shown in the *Daily* of June 14, page 1318, that L. A. Richardson, mechanical superintendent of the first district, Chicago, Rock Island & Pacific, was accompanied by his wife rather than by his daughter, who is visiting the convention this year.

Of the two men killed on board the Metropolitan Line Steamer Bunker Hill on Sunday night, one, George H. Kendrick, was a supply man and left Atlantic City Sunday afternoon for home. He was the Boston representative of the Anchor Packing Company. This had been his first convention and his first trip to Atlantic City; and he went away determined to return next year and bring Mrs. Kendrick with him.

R. D. Smith, Supt. Motive Power & Rolling Stock, B. & A.

Owing to the demands of business B. A. Clements, of Worth Bros. Co., had to return to Chicago Sunday night. He will be much missed by the other members of the entertainment committee. "Burt" was chief assistant to chairman Sawyer of the golf committee in addition to being chairman in charge of the door at all entertainments and his thoughtful attentions to all and his hustling qualities did much toward insuring the success of the assignments given him.

H. W. Belnap, chief of the Division of Safety of the Interstate Commerce Commission, accompanied by five of the safety appliance inspectors of the commission, arrived yesterday to attend the conventions. The inspectors in the party include T. C. Hays, J. J. Coutts, James A. Lawson, Charles S. Roberts and Harry A. Adams. The government representatives will remain through the Car Builders' convention, and are interested visitors both in the convention hall and in the exhibits on the pier.

F. H. Clark, general superintendent of motive power of the Baltimore & Ohio, and Robert F. Carr, president of the Dearborn Drug & Chemical Company, left Sunday morning for Champaign, Ill. Mr. Clark is an alumnus of the University of Illinois, and goes to attend a reunion of the class in which he graduated. Mr. Carr also is an alumnus and goes to attend a meeting of the board of trustees of the university, of which he was elected a member by the voters of Illinois at the last state election.

The announcement in the New York papers of June 13 of the engagement of Miss Mildred Rhoades Whaley to Joseph Earle Sample is the culmination of a romance which began at the conventions in Atlantic City three years ago. Miss Whaley is a daughter of A. R. Whaley, vice-president of the New York, New Haven & Hartford, and was a visitor at the conventions in 1912. Mr. Sample is with the Hill Publishing Company, of New York, and was here also as a convention visitor. The young people met then for the first time.

Left to Right—J. F. Sheahan, S. M. P., and B. L. Bugg, Assistant General Manager, A. B. & A.

G. F. Laughlin, Gen. Supt., Armour Car Lines, and Mrs. Laughlin

Geo. L. Lord, manager of the railroad department of the West Disinfecting Company, New York, met with a serious accident on the pier while engaged in arranging the exhibit of his company last Tuesday. Owing to the collapse of a step ladder while hanging an electric sign, the latter dropped and struck Mr. Lord, wrenching his left knee and cracking one of the bones below the knee. Mr. Lord remained in attendance at the booth for several

days before the seriousness of his injuries was known. He is now confined to his room in the Chalfonte and H. E. Daniels, the company's western representative, reports that his condition is improving.

Yesterday morning the members of the enrollment committee presented their chairman, Harold A. Brown, with an unusually complete traveling case. Mr. Brown has been one of the loyal workers on that committee for four years, the last two of which he has been chairman. During that period his friends

H. R. Thomson, M. M., Newburg & South Shore

have not only greatly increased in number, but the quality of friendship has been strengthened because of his natural inclination and ability to be both accommodating and fair. The tangible expression of appreciation and respect shown him by his co-workers is something that will serve to remind him of the bright side of a task which, to say the least, has been confining.

Among the interested convention visitors on Saturday and Sunday were Mr. and Mrs. Edward Hungerford and Richard

R. J. Turnbull, Mech. Supt., Missouri Pacific

C. Ellsworth of New York City. Mr. Hungerford's name is doubtless familiar to many of the convention visitors, because he is probably the most widely read and authoritative writer of non-technical railway literature in this country. His articles and stories regarding railway matters have often appeared in the Saturday Evening Post, the Metropolitan Magazine, Munsey's, and other publications of general circulation, and he is the author of a very readable and valuable book entitled "The Modern Railroad." Mr. Hungerford has traveled widely in the United States and one of the results has been the production of a book entitled "The Personality of American Cities," which shows his familiarity with the life and atmosphere of almost every large place in the United States. He is, besides, the author of some short stories and two novels. He was formerly editor of the Erie Railroad Employee's Magazine, was subsequently publicity manager of the Brooklyn Rapid Transit Company, and is now advertising manager of Wells, Fargo & Co. and an editor of the Wells Fargo Messenger, which is a monthly paper published by this company. Mr. Ellsworth is widely known in the newspaper field, being editor of the Brooklyn Times. Mr. Hungerford and Mr. Ellsworth returned to New York Sunday, while Mr. Hungerford left for the West for an extended trip.

The Chicago Railway Equipment Company contingent, including President E. B. Leigh, Vice-Presidents F. T. De Long and C. H. Williams, Jr., and George N. Van Sweringen, arrived on Saturday and Sunday, but came by entirely different routes. Messrs. Lee and Williams came by train, while Messrs. De Long and Van Sweringen drove through from Chicago in the former's automobile. They took the road by way of Cleveland, Buffalo, Erie and New York City, leaving Chicago on Saturday, June 5, and reaching New York on Saturday, June 12.

John McMullen, Mechanical Superintendent, Erie

The maximum mileage in any hour made by them was in one when Mr. Van Sweringen was at the wheel, and was 27 miles. This is not a large maximum mileage, and yet they did not make less than 174 miles in any day, and in one day attained 212 miles. The nearest they came to having real trouble was about 40 miles from Atlantic City on the road from Lakewood. This was on Sunday evening when it was raining hard. Mr. De Long had just improvised a lunch, which they intended to eat whenever the spirit moved them, when he heard a sound like a peanut-stand whistle and felt one of his tires going down. He had his side curtains down and he immediately decided that he did not intend to get out in the rain to fix that tire. He therefore climbed over into the back seat, lighted a lantern, spread the lunch out on his knees, and they proceeded to eat lunch right there. By the time lunch was finished the rain had ceased and it was possible to fix the tire without any discomfort except that of getting out of the mud. There is some difference of opinion between Mr. De Long and Mr. Leigh as to how Mr. De Long's car is going back to Chicago. Mr. De Long expects it to return under its own power, with him as chauffeur, while Mr. Leigh opines that it will go back in a freight car. In any event Mr. De Long says that the trip down was fine.

CEILING FAN

The ceiling fan shown in the illustration is being exhibited by the Safety Car Heating & Lighting Company, New York. While the general features are similar to those embodied in the type of fan exhibited by this company last year, and briefly described on page 1403 of the June 13, *Daily Railway Age Gazette*, it has been redesigned so that the entire unit including the motor may be applied below the ceiling of the car. The previous type necessitated the cutting through the ceiling or roof of the car for its installation.

The parts are so arranged that the entire unit may be released from the ceiling plate and removed for inspection by pushing a button, which releases an automatic lock, and then slightly turning the lower portion of the fan towards the left. Electrical connections are made by a plug connector which may be readily removed or inserted. The brush boxes on the motor are conveniently located so that brushes may be replaced without disturbing any part of the fan.

Removable Ceiling Fan Unit

These fans are hung from the ceiling in the center of the car from 9 ft. to 12 ft. apart and can be had with lighting fixtures included on the frame of the fan, the combination fixtures being made for either one, two or four lights each. The current consumption of the fans when operating at maximum speed is 75 watts and by means of the revolving deflecting plates a well distributed circulation is provided.

MONROE CALCULATING MACHINE.—Among the recent developments for reducing the cost of handling all kinds of accounting work is a calculating machine manufactured by the Monroe Calculating Machine Company, Orange, N. J. One of the notable features is its simplicity; it has a much smaller number of parts than the usual type of adding machine. The operation is simple and may be readily mastered by an unskilled person in a few minutes. It handles percentage, pro-rating, extensions, engineering problems, estimating or any kind of accounting work, every calculation being made by direct methods. The crank is turned forward for addition or multiplication and backward for subtraction or division. The machine is being exhibited during the conventions this year.

IMPROVED REX CURTAIN ROLLERS

The Curtain Supply Company, Chicago, has recently applied to the Rex curtain rollers a sliding pawl to engage the ratchet in the end of the roller when it is desired to remove the roller from its fastenings. The illustration shows this attachment

Sliding Pawl Attachment for Rex Curtain Rollers

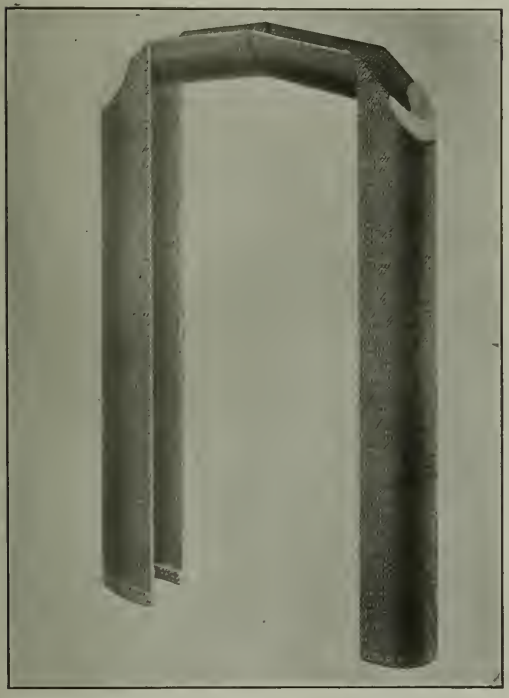
applied to a vestibule curtain roller. The improvement will be well appreciated by those who have had experience with the handling of curtain fixtures in the present day equipment.

NEW DESIGN OF GRATE BAR.—There is being shown at the exhibit space of Joseph T. Ryerson & Son a model of a locomotive grate which is the invention of S. D. Andrews, mechanical engineer of the Seaboard Air Line. The principal feature of this grate is the incorporation of wrought iron bars, which are placed in the mold and are cast in the grate. The purpose of these bars is to hold up the grate in case the cast iron is burned completely away, thus permitting the engine to get into a terminal without a failure. It also provides a grate which has greater strength in relation to the weight, with a consequent increase in the air openings.

FORGED AND ROLLED STEEL SPRING GEAR RIM.—Included in the exhibit of the forged and rolled steel sections manufactured by the Carnegie Steel Company at its slick works, is a gear rim for a recently developed type of spring gear transmission for electric cars. This transmission is in use on the Long Island and Pennsylvania Railroads, and also under consideration for use on the locomotives for the Chicago, Milwaukee & Puget Sound electrification. Its purpose is to provide a shock-absorbing medium between the motor and axle. This is accomplished by making the gear in two parts so arranged that the torque on the rim is transmitted to the hub through a system of coil springs secured to the hub. The entire transmission is thus relieved of the shocks due to lost motion between the pinion and gear teeth.

REVERSE UNIFOLD DIAPHRAGM

The Acme Supply Company, Chicago, is exhibiting a unifold diaphragm of a design which permits the use of one piece of belting in its manufacture without cutting or shaping at the corners. The top is of the usual U-shape, while the sides are of the reverse of this shape, the change in section being made by the reverse folds at the upper corners. The belting is reinforced at the corners where the turn is made with specially prepared chrome tan leather and the feet are turned up and stitched securely. Owing to the fact that the sides fold out instead of in any width of belting may be used



Unifold Diaphragm With Reverse Folds at the Corners

without encroaching on the passageway between the vestibules, and this design prevents the fold of the diaphragm chafing the vestibule curtains, and the construction is such that a large amount of expansion is permitted without straining the material.

The diaphragm is made of dyed or water-proofed and fireproofed belting and may be provided with an auxiliary asbestos woven belting fire-proof hood if desired. It is on exhibit at the booth of the Acme Supply Company.

SANITARY TOILET

The West Disinfecting Company, New York, is exhibiting a model of a sanitary toilet for use where sewer connections are not available. This toilet, known as the Sanitor, is of metal construction and consists of a case within which is a tank containing a chemical manufactured especially for this use. It is a powerful germicide and disintegrator. A vent pipe is carried from the toilet through the roof of the building. The model shows an application suitable for small railway stations and includes a baffle tank placed underground outside of the building.

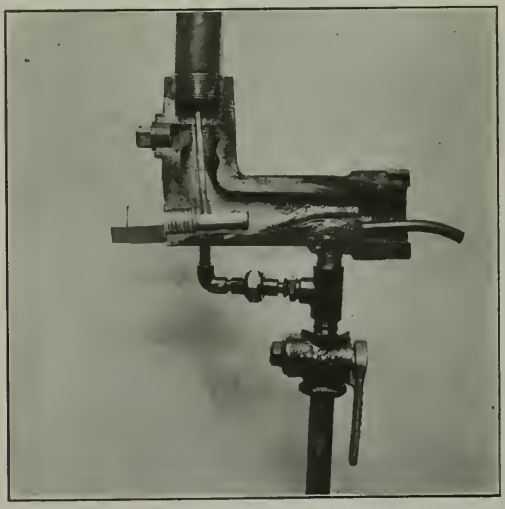
All organic matter is thoroughly treated with the chemical disintegrator and automatically flows from the toilet into the baffle tank. The overflow from this tank is said to be entirely sterile and odorless.

An application of the same principle is now being developed for use on passenger coaches.

LOCOMOTIVE SANDER

The White American Locomotive Sander Company, Inc., Roanoke, Va., is exhibiting a locomotive sanding device, which includes a means of clearing clogged sand pipes both above and below the points of its application. The device is shown in section, in the illustration, and is simple in construction.

The trap consists of an elbow casting through the wall of which the air nozzle is inserted. It is located at any convenient point in the sand pipe and the air nozzle may be adjusted to deliver any predetermined amount of sand. Another air connection is made to the trap from which lead two lines of small brass pipe, one extending up through the sand pipe to the dome and the other down into the delivery pipe below the trap. The end of the upper pipe is closed and a number of small holes are drilled through the walls at various points, at an angle which delivers the air downward. The other pipe is open at the end. Should the sand pipe be clogged below the trap, the admission of air to the auxiliary connection provides a strong downward blast which clears it without the necessity of leaving the



Self Cleaning Locomotive Sander

cab. Should the pipe be clogged above the trap, the upper branch of this connection will break up the body of wet sand and carry it down to the trap.

This device is being tested in service on three railroads. It is said to be giving good service, and to require practically no attention.

Malleable Iron Exhibit.—In an article in the June 14 issue of the *Daily Railway Age Gazette* describing an exhibit of malleable iron castings made from a recently developed mixture, the name of the exhibitor was given as the National Malleable Castings Association. This is incorrect, the name being the American Malleable Castings Association, with headquarters in the Penton Building, Cleveland, Ohio.

M. C. B. BILL MACHINE

Included in the exhibit of the Burroughs Adding Machine Company, Detroit, Mich., is a machine recently developed especially to print and add the items of M. C. B. bills which are made up from the billing repair cards. The machine has a 17-column keyboard which can be split into separate adding sections so as to handle the different items required for this kind of work with the greatest dispatch. It has special keys for fractions and is equipped with automatic cross tabulating, counter-control, and has injector and ejector devices for inserting and removing forms quickly and evenly. It is electrically operated.

With this machine the operator is said to be able to register 55 cars to the sheet, whereas by hand but 37 can usually be included on one sheet. The bill is footed automatically as the items are listed. On the Michigan Central, where this machine is in service, the following comparison of the daily output by hand and by machine was established:

By hand .....1200 cars per day of 8 hrs.
By machine .....1875 cars per day of 8 hrs.

On this basis one man with the M. C. B. billing machine will bill 14,852 more cars in 22 full working days of 8 hrs. each than one man can handle by hand, which is equivalent to a saving of 12 days per month for one man. On a salary basis of $75 per month this is equivalent to an average saving of $30 per month or $360 per year for one man working with the bill machine.

FLUSH BOX CAR DOOR

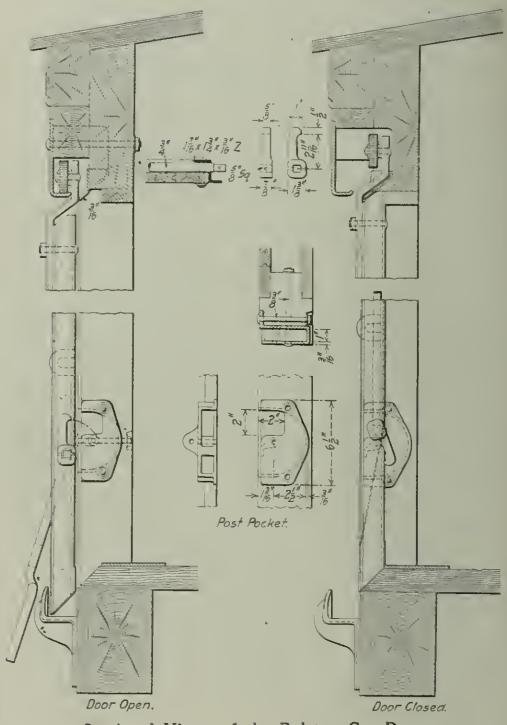
The box car door shown herewith has been designed to meet the requirements which, within the last two or three years, have come to be considered essential for satisfactory service. To adequately protect the lading the door must be storm, spark and burglar proof and to best meet these conditions a flush door is necessary.

The way in which the door is operated will be understood

Ohio Flush Car Door

by referring to the drawing showing sections of the door in the open and closed positions. The track on which the hangers operate is attached to the outside of a filler or water table which is bolted to the side plate and is so formed as to protect itself from the weather. In closing the door the top is first drawn inward and upward and is guided into the closed position by means of an oblique angle plate which enters between the diagonal portion of the door hanger and the top of the door.

The closing mechanism consists of a horizontal shaft inside the door, to each end of which a pawl is attached, these being located at either side of the door. The shaft is operated by means of a lever placed in a pocket near the center of the door. Malleable iron pockets are set into the door posts in line with the pawls, and in these are shoulders which serve as fulcrums against which the pawls operate in lifting and closing the door. The edges of the door are faced with Z-bars so placed that when the door



Sectional Views of the Ralston Car Door

is closed the outside edges of the Z-bars fit into rabbetted pockets in the door posts and completely cover the pawls and the malleable iron pockets which hold the door in position. The operating lever is locked by means of a staple and latch pin and when properly sealed it is impossible to open the door without first breaking the seal.

The door is claimed to work freely and smoothly and may be opened by simply removing the latch pin from the staple, which allows the door to drop down away from the car onto the track. It is known as the Ohio flush side door and is being exhibited at the booth of the Ralston Steel Car Company, Columbus, Ohio.

YOUNG VALVE GEAR.—In an article published in the June 11 issue of the *Railway Age Gazette, Daily Edition*, entitled Young Valve Gear, Reverse Gear and Valve, the following statement was made: "This valve gear was introduced about two years ago, the most notable feature of the motion produced being the long travel of the valve." While the principle underlying the design of both gears is the same, the above statement is misleading in that the two gears are not the same, being of entirely different construction and covered by separate patents.

United States and Mexico.....$5.00
Canada 6.00
Foreign Countries (excepting daily editions)..... 8.00
Single Copies .....15 cents each

Engineering and Maintenance of Way Edition and four Maintenance of Way Convention Daily issues, North America, $1.00; foreign $2.

Entered at the Post Office at New York, N. Y., as mail matter of the second class.

WE GUARANTEE that of this issue 10,011 copies were printed; that of those 10,011 copies 8,572 were mailed to regular paid subscribers to the Railway Age Gazette and the Railway Age Gazette, Mechanical Edition; 150 were provided for counter and news companies' sales; 189 were mailed to advertisers; 100 were provided for bound volumes, and 1,000 for distribution at Atlantic City.

The RAILWAY AGE GAZETTE and all other Simmons-Boardman publications are members of the Audit Bureau of Circulations.

Car Wheel Failures

The report of the Committee on Car Wheels brought out the fact that of 904 625-lb. M. C. B. wheels reported as cracked and broken in the plate, 63.6 per cent were under refrigerator cars. A great many wheels of this size are used under cars which have a gross weight of over 100,000 lb. and, as pointed out by the committee, the overloading, combined with the high braking force, is probably the cause of so many failures under these cars. While the overloading is not entirely to blame, it probably has a good share in causing the failures, and the recommendation of the committee that wheels of the proper size should be used under refrigerator car equipment by all railways and private car companies, should be acted on. The interests of safety demand the employment of wheels of the proper dimensions under all freight cars.

Specifications and Tests of Materials

In presenting the report of the Committee on Specifications and Tests of Materials at Tuesday's session, C. D. Young, the chairman, called attention to the fact that should these specifications be adopted as recommended practice their later advancement to standard practice would depend entirely on the information derived from their actual use by the members. The point raised cannot be emphasized too strongly. There is too often a laxity on the part of the individual members of the association in putting into practice the recommendations which are adopted by the association. This is not only discouraging to the committees making the recommendations, but tends to burden the recommended practices of the association with what is dead matter judged by its practical effect. The preparation of the report of this committee has entailed a large amount of detailed investigation in an endeavor to provide the association with complete specifications for practically all material used in car construction, and it is especially worthy of the support of the members. The effectiveness of the work of the association depends on the use made of its committee reports.

Car Department and Increased Earnings

In a paper presented before the Car Foreman's Association of Chicago in May, 1913, C. J. Wymer, general car foreman of the Chicago & Western Indiana, urged the members to do what they could to get the car department on an equal footing with other departments of no greater importance. We have before pointed out that much of the very efficient work which has been done in the car department has been in spite of the discouraging treatment received from railway officers, rather than because of their encouragement. The car department is not always looked upon in the right light; in the majority of cases it is considered rather a necessary evil, but do the higher officers realize that by giving the car department a fair show it can produce wonderful results, not only in the way of reduced maintenance charges, but of increased earnings? The car department can do very much to facilitate car movement and increase the miles run per car per year.

The Report of the Coupler Committee

The vote of thanks to the Coupler Committee, which was adopted at Tuesday morning's session, is particularly appropriate. The work which this committee has done has been of the highest order throughout and the amount of labor involved must have been enormous. W. L. Kleine, the chairman of the committee, deserves special thanks, and the various manufacturers have been of great assistance to the committee by their hearty co-operation. There has seemed some fear on the part of a few railway men that the experimental couplers are too heavy, but it must be remembered that the strength of a coupler depends largely on the amount of metal in it and the committee has used every means of reducing the weight to the safe minimum, consistent with ample strength. Members should also bear in mind the requests and suggestions of the committee regarding the use of the experimental couplers. The committee believes that with proper co-operation it will be able to recommend a final standard coupler at the 1916 convention, and every member should take cognizance of the remarkable work of the coupler committee and make every effort to help it bring this about.

Box Car Doors

Considering the importance of the subject, the lack of discussion following the presentation of the report of the Committee on Car Construction is somewhat surprising. The subject is one which is growing in importance; in fact some of its phases are of immediate vital importance. The failure to discuss the section devoted to the design of a standard M. C. B. box car may be understood, since the details of the design presented can undoubtedly be better handled by the written discussion recommended by the committee. The lack of discussion on the section devoted to car doors and fastenings, however, is not so readily understood. The committee has now presented reports on this subject at two conventions, requesting a thorough discussion of its recommendations. Neither last year nor this year did the matter receive the attention which its importance would seem to warrant. The protection of

lading both from the weather and against theft depends on the effectiveness of the car door and its fastenings, and the endeavor of the committee to formulate specifications to meet the requirements ought to be of general interest.

Maintenance of Air Brakes

The expression, 100 per cent operative brakes, is in some ways misleading, as was pointed out in the committee report on this subject presented by George H. Wood, of the Santa Fe, before the Air Brake Association last month. While a train may be operated with 100 per cent operative brakes, the efficiency of these brakes may be very low. The only way in which it will be possible to maintain the air brakes in the proper condition will be to give them thorough inspection and insist on their proper maintenance. Many times cars will be found cut-out in trains for apparently no reason. All the train crews should be instructed to report every car cut-out and the reason therefor; these reports to be given to terminal repairmen as soon as the train arrives at its destination. Another method of keeping the brakes in good condition and thus preventing air brake failures is to establish dead lines at various points on the road. This has proved satisfactory on the Santa Fe. At certain points all cars with inoperative brakes are held and the brakes are put in first-class condition before they are allowed to proceed. The practice of testing the brakes on incoming trains cannot be emphasized too strongly. It is evident that if this is done the defective brakes can be found and repaired with less amount of dead time to the cars and their lading than when the inspections are made on the outgoing tracks. Careful supervision and inspection is absolutely necessary and in order that all repaired triple valves may be in first-class condition when placed on the cars, it has been strongly recommended that the testing of them be done by a competent inspector rather than by the man who cleans them, many cases having been found where stenciled triples have become inoperative before their limit of service had expired.

THE CONSOLIDATION PROBLEM

PRESIDENT GAINES, of the Master Mechanics' Association, in his presidential address, strongly advocated the consolidation of all of the railway mechanical associations to the extent at least of having a governing body direct and supervise the work of all of them to prevent duplication and useless expenditure of energy, to insure the adoption of uniform standards, and to bring their work to as high a practical efficiency as possible.

A study of the programs of the two conventions at Atlantic City this year throws an interesting side light on such a movement so far as it concerns the work of the Master Mechanics' and Master Car Builders' Associations. Of the sixty items on the two programs, ten are identical although, except for safety appliances and the question of holding joint meetings, these items are largely matters of routine business. Of the 60 items, however, 38, or 63 per cent, are matters which could well be considered in joint session, while there are only 22—15 on the Master Mechanics' Association program and 8 on that of the Master Car Builders' Association—which are not suitable for joint discussion.

Whether a governing body directs the work of the associations, or a general mechanical association is formed with different sections meeting together or separately as the conditions at the time may warrant, or the two major associations continue on as they are but hold their meetings in the same week with a joint session during the middle of the week, is a matter for discussion. There can be no question, however, as to the desirability or even necessity of taking some measure immediately to secure greater co-operation on the part of all of the railway mechanical organizations. This has been realized for a long time, and we have consistently advocated it in our columns. The minor mechanical associations are doing excellent work, and yet in the majority of cases they feel the need of more recognition from the larger associations and would undoubtedly be glad to work with them with the idea of going thoroughly into the details of those questions with which they are most familiar and making definite recommendations to the major associations for approval and adoption as recommended practice or standards.

The time is now ripe for action. The question has been debated pro and con for a number of years and there should be very little trouble in securing some definite action. It only needs the right man or men to get behind the move and bring it to fruition. Will this be done?

TWO SUCCESSFUL CONVENTIONS

SEVERAL reports of more than ordinary importance were presented at both of the conventions this year. If the discussions were not as long or as extensive as might have been expected in some cases, this was apparently due to the fact that the committees had done their work particularly well, rather than because of any lack of interest. The committee reports were also especially well presented by the chairman who, practically without exception, used good judgment in placing the vital points before the members and using the time allotted to them to the best advantage. The new meeting room made a big difference, allowing the members to be seated to better advantage than in the old hall, and providing a seating capacity sufficient to easily take care of all of the members in attendance at any one meeting. The acoustic properties are better than those of the long narrow room which was used last year.

While the exhibitions were fewer in number than last year, over 70,000 square feet of space was used. It is doubtful if any exhibit has shown more new or improved devices, and from an educational viewpoint it could hardly be surpassed. It would appear that the railway men appreciated this and made good use of the opportunity of studying those devices which seemed to give promise of helping them to solve their special problems. We have heard many comments about the thorough way in which certain individuals and groups examined the exhibits with this in view.

The entertainment features were delightful. Simplicity and informality governed and in a quiet way the members seemed to thoroughly enjoy themselves. The weather man helped the entertainment committee out, we have had a little fog, a bit of rain on Sunday, but generally speaking the days were clear and warm.

It has been said that the pier was a little quiet, with less rush and bustle than in previous years. It is true that the total attendance has fallen off some, due in large part to the business depression, but the falling off in the registration of railroad men is small. It must be remembered, too, that the tone of the associations has been gradually changing in recent years. The problems up for consideration have steadily grown bigger and bigger, and have demanded more searching and technical examination and study. The effect of this is noticeable and undoubtedly the added responsibility has had some effect on the meetings as a whole.

As in recent years the attendance of government representatives was large. The presence of George B. McGinty, secretary of the Interstate Commerce Commission; H. W. Belnap, chief of the division of safety, and Messrs. McManamy, Robinson and Pack of the department of locomotive boiler inspection, with a large number of inspectors from both the safety appliance and boiler departments cannot help but develop a closer co-operation and better understanding between the representatives of the government and the railways.

Taken all in all those who were in charge of the planning of and carrying out of the meetings can well afford to be proud of the outcome.

TODAY'S PROGRAM

WEDNESDAY JUNE 16, 1915

Discussion of reports on:	
Train lighting and equipment.....	9.30 A. M. to 10.00 A. M.
Car trucks	10.00 A. M. to 10.30 A. M.
Draft gear	10.30 A. M. to 10.45 A. M.
Joint meeting with A. R. M. M. Assn.	10.45 A. M. to 11.00 A. M.
Individual paper—Impact between freight cars in switching service. By Prof. L. E. Endsley	11.00 A. M. to 11.30 A. M.
Topical discussion:	
Air brake maintenance	11.30 A. M. to 11.45 A. M.
Unfinished business; Reports of Committees on Correspondence, Resolutions and such other committees as may be named during the convention	11.45 A. M. to 12.00 M.
Election of officers	12.00 M. to 1.30 P. M.

LOST

Badge 3584 has been lost. Finder will kindly return to Secretary Conway.

OBITUARIES

President Crawford has appointed committees to draw up obituaries for the following members who died during the past year. Active Members: P. P. Mirtz, Lake Shore & Michigan Southern; C. J. McMasters, Rutland Railroad; H. R. Payne, Union Tank Line; F. W. Chaffee, New York Central & Hudson River; H. C. Bossinger, Chesapeake & Ohio Representative Members. T. E. Adams, St. Louis Southwestern; A. Stewart, Southern Railway; E. C. Hawkins, Copper River Railway; S. D. Freshman, Sierra Railway of California; E. A. Miller, New York, Chicago & St. Louis; H. C. Millis, Western Live Stock Express. Life Members: J. P. Levan, Pennsylvania Railroad; B. Welsh, Southern Pacific, and C. Wicks, Cumberland Valley.

A HANDSOME PRESENT FOR CHAIRMAN CARR

On Monday evening, just before the informal dance on the Pier began, Chairman George R. Carr, of the entertainment committee, was lured to the porch of the booth of the Dearborn Chemical Company, of which he is vice-president. When he arrived he found the members of the entertainment committee assembled, and in a short address expressing the committee's pleasure in having worked with him, and its appreciation of the efficiency of his efforts, Gilbert E. Ryder, on behalf of the committee, presented Mr. Carr with a gold pocket knife with a gold and platinum chain. On one side of the knife is engraved Mr. Carr's name and on the other the words "Entertainment Committee M. M. and M. C. B. 1915." The present is a handsome one and is highly appreciated by its recipient.

PAST PRESIDENT'S BADGE FOR J. WILL JOHNSON

At the noon meeting yesterday of the executive committee of the Railway Supply Manufacturers' Association, C. B. Yardley, Jr., chairman of the badge committee, in a happy speech, presented on behalf of the committee to J. Will Johnson, the retiring president of the association, a past president's badge. This is the sixteenth past president's badge which has been presented on behalf of the association. Mr. Yardley paid high tribute to the hard and efficient work in various capacities which Mr. Johnson has done over a long period of years to

ENTERTAINMENT COMMITTEE

Top Row, Left to Right—Langley Ingraham (Yarnall Paint Co.); W. H. Bentley (Curtain Supply Co.); Wm. W. Melcher (Mass. Mohair Plush Co.); R. J. Faure (Commercial Acetylene Railway Light & Signal Co.); F. H. Thompson (Railway Age Gazette); G. E. Ryder (Locomotive Superheater Co.).

Second Row—C. C. Farmer (Westinghouse Air Brake Co.); D. E. Sawyer (Illinois Steel Co.); M. G. Baker (American Vanadium Co.); Albert MacRae (MacRae's Blue Book); J. F. Forney (Ralston Steel Car Co.).

Third Row—C. W. F. Coffin (Franklin Railway Supply Co.); W. K. Krepps (Crucible Steel Co.); G. R. Berger (Gould Coupler Co.); J. P. Landreth (Garlock Packing Co.).

Fourth Row—H. N. Scott (Griffin Wheel Co.); J. F. A. Comstedt (Atlas Automatic Jack Corporation); George R. Carr, Chairman (Dearborn Chemical Co.); A. B. Wegener (Camel Co.), and Burton W. Mudge (Burton W. Mudge & Co.).

make the undertakings of the Supply Association successful. He said in part:

"Your training in the way of the railroad man, having yourself gone through the life that knows no hours, whose requirements are sincerity, loyalty, perseverance and unfeeling devotion to duty, a willingness to surmount each difficulty with but one thought in view, has indeed fitted you for the duties you have so conscientiously and happily fulfilled. We trust that you will keep this badge as an emblem without price that represents the personality, friendship and good will of the association. I bespeak for this organization and for this committee the continuance of that interest in our welfare which has been so marked in the past, that often we may greet you and always count you as our friend."

FIFTH DAY'S REGISTRATION FIGURES

The registration figures up to Monday evening, the first day of the M. C. B. convention, and the fifth of the meetings of the two associations, make a very satisfactory showing regarding the attendance of railway men. The statistics, compared with those covering the same period of the immediately preceding four years, are as follows:

	1911	1912	1913	1914	1915
Members M. C. B. & M. M.	719	644	678	730	713
Special Guests	832	583	680	554	505
Railroad Ladies	705	437	505	433	403
Supply Ladies	385	223	308	287	232
Supply Men	1662	1516	1666	1484	1248
Total	4303	3404	3837	3488	3103

It will be seen that the registration of railway men has been only slightly smaller than in 1911 and 1914, and has been substantially larger than in 1912 or 1913. There has been a heavy decline in the registration of special guests since 1911, but this probably is almost entirely due to a reduction in the liberality with which these badges are handed out. Comparing with 1914, the reductions in the registration are as follows: Railway men, 17; special guests, 49; railroad ladies, 30; supply ladies, 55; supply men, 176; total reduction, 385.

The reduction in the registration of supply men is much smaller now than it was on the first day of the Master Mechanics' convention, owing to the fact that many concerns which are interested chiefly in the M. C. B. Convention did not have their representatives come until this week.

THE ASSOCIATIONS INDORSE PRESIDENT WILSON'S POLICY

The Master Car Builders' Association and the Railway Supply Manufacturers' Association yesterday took action indorsing President Wilson's policy in dealing with the Imperial German Government.

D. R. MacBain introduced at the meeting of the M. C. B. Association the following resolutions, which were adopted unanimously in a storm of applause, and ordered telegraphed to the president at Washington:

"The Master Car Builders' Association of America, comprising the mechanical officials of the railways of the United States, in session at Atlantic City, New Jersey, send you assurance of its enthusiastic approval of the notes despatched by you to the Imperial German Government, calling for the maintenance inviolate of all rights of American citizens on the high seas.

"Regardless of the political affiliations of its members, the Association, as one man, applauds the patriotism of your course and the wisdom of your utterances during this critical period of the progress of the dreadful European war.

"We profoundly sympathize with you in the heavy burden of responsibility you are bearing for your fellow-countrymen at this juncture so devotedly and courageously. At this time every American should stand heart and soul with our President."

When the executive committee of the Railway Supply Manufacturers' Association heard of the action taken, it drew up and sent to the M. C. B. Assocation the following communication:

Atlantic City, N. J., June 15th, 1915.

Mr. D. F. Crawford, President,
Master Car Builders' Association,
Atlantic City, New Jersey.

Dear Sir:

The Executive Committee of the Railway Supply Manufacturers' Association indorses with the same enthusiasm the resolution adopted by your association to be sent to the President of the United States, in reference to his notes to the Imperial German Government, and begs to have its indorsement included in your resolution.

Respectfully submitted,

J. WILL JOHNSON, *President,*
C. E. POSTLEWAITE,
F. M. NELLIS,
For the Executive Committee.

This communication was received and included in its minutes by the M. C. B. Association.

THE TRACTION STRIKE IN CHICAGO

The convention visitors from Chicago have been reading with interest the newspaper accounts of the strike of employees of all the elevated railways and surface street railway lines which has been declared in that city. The extremely large area which Chicago is spread out over and other conditions make such a strike there especially serious. It appears from the newspaper reports that on Monday, the first day of the strike, not a wheel turned on the surface lines and only a few trains ran on the elevated lines. One result was an enormous increase in the traffic handled by the steam suburban lines. The Illinois Central ordinarily handles 40,000 suburban passengers a day. The newspapers state that on Monday it handled 280,000. It is evident that while the strike lasts the steam railways will profit by it, but on the other hand the increase in the difficulties under which they operate will be something enormous because of the immense increase in the service which they will have to render without any proportionate increase in their facilities.

THE MUSIC THIS YEAR

The music on the Million Dollar Pier during the mornings and afternoons and for the informal dances in the evenings has excited considerable favorable comment and is probably the best ever had at the conventions. The orchestra is not as large as some of those employed in previous years, but this is not apparent in the volume or effect because of the ability of the individual players and the skillful way in which they are directed. The orchestra is known in New York City, where it has been playing for three years, as the Don Richardson Society Orchestra and makes a specialty of playing at private and club affairs only, probably doing more of this than any other orchestra.

Those who have enjoyed some of the Indian compositions will be interested in knowing that after leaving the University of North Carolina, Mr. Richardson traveled in the Far West and Mexico and spent considerable time at Yuma, where his uncle was stationed as the United States collector of customs. This gave him the opportunity of studying the customs and habits of the Yuma Indians, and his knowledge of their sacred sun dances, snake dances, rain dances, etc., undoubtedly inspired his Papoose Dance, Intermezzo, Cradle Songs and Indian Overture.

Mr. Richardson was the first to adapt the two well-known songs "A Perfect Day" and "Mighty Lak' a Rose" as hesitations in September, 1914. He has also published the Athene Waltz and the Zum one-step, both of which are extensively used throughout the country.

Master Car Builders' Association Proceedings

Reports on Couplers, Rules for Loading Materials, Car Construction, and Specifications and Tests for Materials

President Crawford called the Tuesday morning to order at 9.45. The report of the Auditing Committee was received and approved.

COUPLERS

The course of the committee during the past year was as follows:

A. Road Tests; continuation of the road-service tests on "Present" and "Experimental" types of couplers begun since the inception of this work.

B. Road Tests; results of the recommended road-service tests or trials of the *A* and *B* couplers by the members of the Association.

C. Dynamic and Static Tests.

D. Service Machine.

E. Angling and Coupling.

F. Jiggling or Lock-creeping.

ROAD TESTS

The road-service tests on "Present" (couplers in general use) and "Experimental" types of couplers inaugurated during the early investigation and development stage of the committee work were continued. Each coupler was given a letter designation, to represent the name or type of the coupler tested, as well as the manufacturer. Couplers Ta,

R. L. Kleine
Chairman, Committee on Couplers

Ua, Wa, Xa, Ya and Yc represent couplers of the present types in general service, such as Pitt, Sharon, Major, Simplex, Latrobe and Gould "Z," irrespectively, and couplers Tb, Xe, Yb, Yd, Yda and Ydb represent couplers of increased weight and strength in the development stage, termed "Experimental," a number of each of which were placed in service experimentally.

These road-service tests were conducted with couplers of "Present" type on freight cars, and with couplers of both present and the experimental design on freight locomotive tenders on the Pennsylvania Railroad. The freight car couplers were applied to 100,000-lb. capacity steel hopper cars in the coal trade between the bituminous mines in Western Pennsylvania and tidewater, a service comprising grade and flat country as well as hump-yard classification. The tender couplers were applied to 7000-gal. steel tenders in general heavy freight service on the Western Pennsylvania Division, between Altoona and Pittsburgh, which includes heavy-grade service.

These couplers were measured once every month, to determine their operation and ability to withstand service, and thus draw comparisons between the static and dynamic tests with road-service tests.

The road test of couplers on tenders in freight service develops in the shortest space of time the defects as well as the relative life of couplers. From the test results it was surprising to note the short life, before repairs are required, of couplers of the "present" type in this service, as well as the relatively longer life that is being obtained from the "experimental" couplers. The following couplers were tested:

Freight Tender Couplers:

3 Xa couplers (present type), applied July, 1912.
2 Xa couplers (present type), applied 3-26-13 and 4-3-13, respectively, to replace above Xa couplers removed.
3 Ya couplers (present type), applied July, 1912.
12 Tb couplers (experimental type), applied July, 1912.
6 Yb couplers (experimental type), applied August, 1912.
6 Yb couplers (experimental type), applied November, 1912.
6 Yd couplers (experimental type), applied August, 1912.
6 Yda couplers (experimental type), applied June, 1913.
6 Ydb couplers (experimental type), applied June, 1913.
1 Xe coupler (experimental type), applied February 21, 1913.

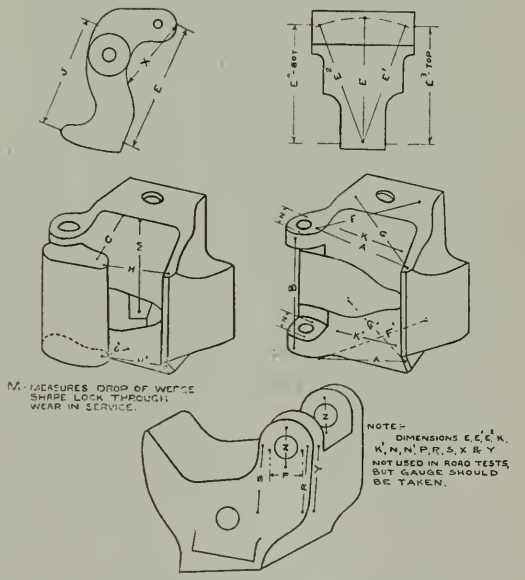

Fig. 1.—Tramming Points on M. C. B. Test Couplers

Freight Car Couplers:

2 Ta couplers (present type), applied July 28, 1912.
2 Ua couplers (present type), applied July 28, 1912.
2 Wa couplers (present type), applied July 28, 1912.
2 Xa couplers (present type), applied July 28, 1912.
2 Ya couplers (present type), applied July 28, 1912.
2 Yc couplers (present type), applied July 28, 1912.

The following table gives the "set" found at *C*, *H*, and *E* of various couplers in service on locomotive tenders:

Class	Type	Date Installed	Date of Last Test	C	C¹	H	H¹	E³	E⁴	Top Gage	Bottom Gage
Tb	Experimental	7-1-12	4-13-15	+ 24	+ 14	+ 24	+ 23	— 08	— 04	$51\frac{1}{32}$	$51\frac{3}{32}$
Yd	Experimental	8-1-12	3-14-15	— 04	+ 07	+ 04	— 09	— 06	— 06	$41\frac{29}{32}$	$49\frac{7}{16}$
Yda	Experimental	6-13-13	3-25-15	+ 15	+ 23	+ 30	+ 19	— 03	— 01	$47\frac{5}{8}$	$42\frac{7}{32}$
Ydb	Experimental	6-12-13	4-6-15	— 05	— 04	— 04	— 02	— 05	— 04	$45\frac{5}{8}$	$45\frac{5}{8}$
Ya	Present	7-8-12	4-16-15	+ 12	+ 11	+ 12	+ 15	+ 19	+ 10	5	$51\frac{1}{16}$

ROAD TESTS—*A* AND *B* COUPLERS

The road tests which are being conducted to develop the operation of the couplers in service as well as the breakages of

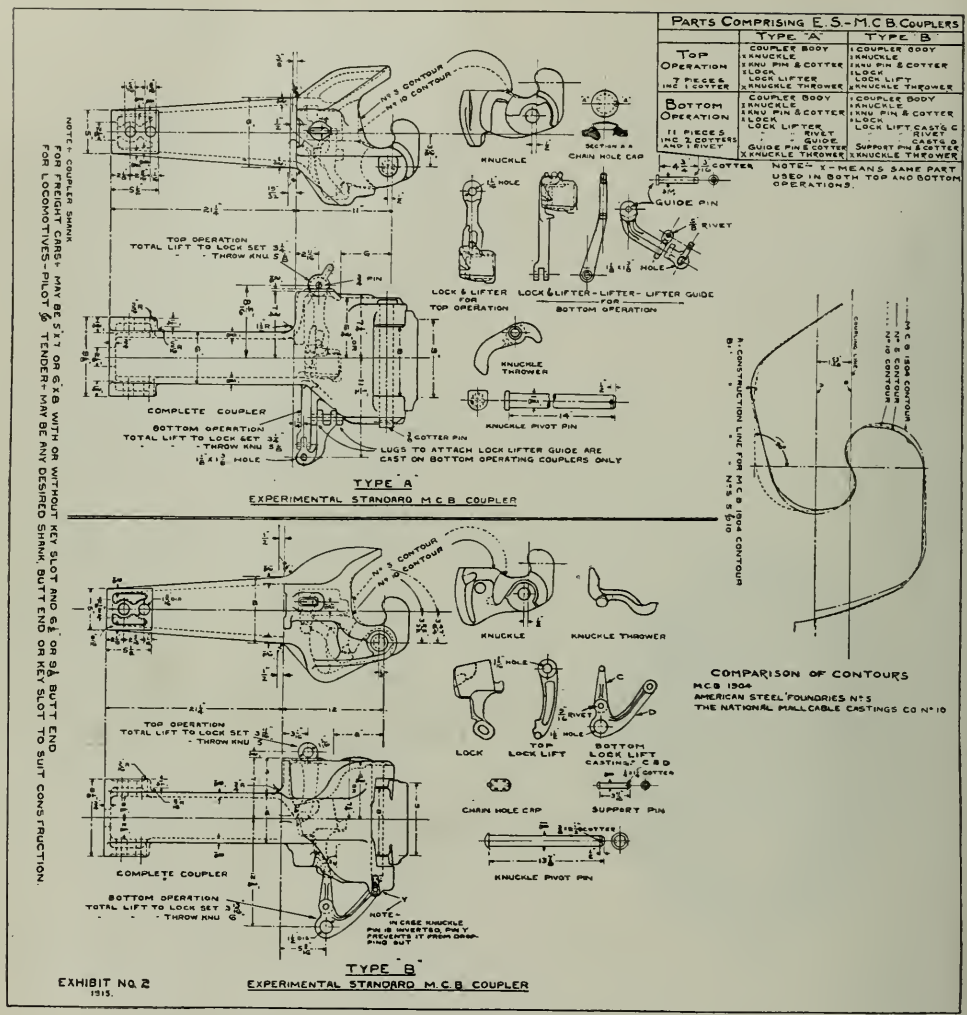

Fig. 2.—General Dimensions of M. C. B. Experimental Couplers, Types A and B

The following is a Summary of measurements, showing the permanent set at *C*, *H* and *E*, of 12 freight car couplers of the "present" type. They were applied July 28, 1912. Nine of the twelve couplers are still in service.

Coupler	Date	Time in Service	Set—Plus or Minus Inches—From Original Dimension						Gage

Average		30 Mo. 11 Da.	+.272	+.280	+.153	+.251			4 31/32	4 31/32
			+.276		+.202				4 31/32	

couplers and parts, are of equal, if not greater, importance than the static and dynamic tests. Many of the existing couplers operated perfectly when first designed or placed in service, and will continue to do so until affected by wear and distortion of parts, and it has required in the past from two to three years' service to develop these conditions. The committee, therefore, can not impress too strongly upon the members of this Association the absolute necessity of not only placing a sufficient number of these experimental standard couplers in service from which to draw proper conclusion, but to follow up particularly

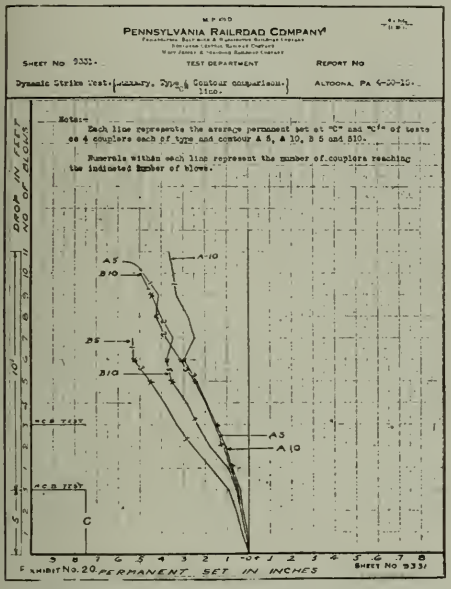

Fig. 3.—Set of *C* Line in Dynamic Strike Test

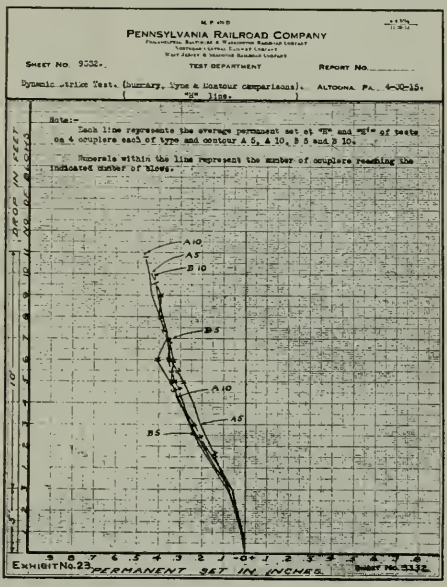

Fig. 4.—Set of *H* Line in Dynamic Strike Tests

the operation and what takes place under the conditions of wear and distortion.

Thus far the couplers have not been in service a sufficient length of time to determine all the weak points or the seriousness of the defects that have developed. This is also the consensus of opinion expressed in preliminary reports received from 32 railroads having these couplers in service.

There are now 3,713 experimental couplers in service as follows: 933 type A, contour No. 5; 793 type A, contour No. 10; 138 type A pilot couplers; 704 type B, contour No. 5; 1,001 type B, contour No. 10, and 144 type B pilot couplers.

The Pennsylvania Railroad placed 30 each of the Type A and B Experimental Standard M. C. B. couplers in road locomotive tender service during the early summer of 1914. These couplers had a 5 in. by 7 in. special shank and were applied to 7000-gal. capacity steel tenders, attached to Consolidation type freight locomotives of 46,290 lb. tractive effort, in general freight service on the Eastern and Western Pennsylvania Grand Division, between Philadelphia and Pittsburgh, which includes ordinary as well as heavy grade service. One coupler of each type and contour (total, 4) was applied to steel tenders attached to latest type passenger locomotives. Six couplers of each type and contour (total, 24) were laid off as per Fig. 1, the bar plates labeled and all parts plainly stenciled. Four of these couplers in each type and contour (total, 16), which had been laid off, were inspected and measured once every month. The remaining couplers (44) had all parts stenciled and were also inspected every month. Below is given the last measurement only of the couplers in the groups of A-5, A-10, B-5 and B-10 couplers, being measured regularly:

The following table gives a report in condensed form of the operation of the *A* and *B* couplers in locomotive service on the Pennsylvania Railroad up to May 1, 1915:

Item.	Coupler and Contour			
	A-5	A-10	B-5	B-10
.... Total number in service.....	57	57	57	13
.... Total number closely examined.....	39	38	38	13
1 Operate good	11	12	27	1
2 Operate fair	6	3	9	7
3 Operate fair, but do not throw satisfactorily	..	..	2	..
4 Operate fair, but throws knuckle poorly....	4	8	..	3
5 Operate poorly	..	..	..	2
6 Operate poorly; does not throw knuckle satisfactorily and lock jams knuckle.....	2	..	..	..
7 Operate poorly; does not throw knuckle satisfactorily and lock sticks between lock-set and full open position but disturbs when knuckle is pulled open.....	13	13	..	..
8 Operate poorly; does not throw knuckle satisfactorily and lock sticks between lock-set and full open position, from which the lock disturbs only occasionally	1	1	..	..
9 Throws knuckle poorly; knuckle thrower interferes with top wall of coupler head..	1	..	..	..
10 Lock sticks above lock-set position but disturbs, lock also jambs knuckle when closing	..	1	..	..
11 Operate poorly due to being tight between coupler ears	1	..	..	..

The defects on the P. R. R. on the type *A* couplers were more varied and numerous than were found on the *A* couplers

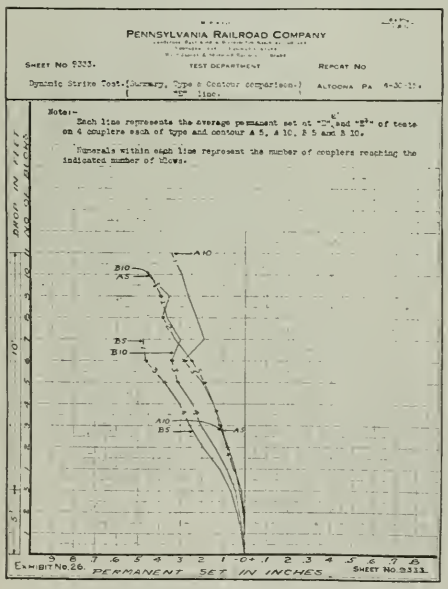

Fig. 5.—Set of *E* Line in Dynamic Strike Test

on the Norfolk & Western during the joint inspection, week of March 8, 1915.

At a joint inspection meeting of the Type *A* and *B* couplers in service on the Norfolk & Western by the committee and the coupler manufacturers H. W. Coddington of the N. & W. stated that road had the Types *A* and *B* couplers on the 750 60-ton steel gondola cars, as well as on the electric locomotives, and that the service being obtained from the couplers was very satisfactory. Mr. Coddington read a statement of couplers and separate knuckles removed to date from service, giving record of particulars in each case of the 33 couplers, 12 knuckles, 1 lock and lifter, and 1 knuckle thrower removed, as well as defects in some couplers still in service which do not yet warrant their removal. The N. & W. test department has examined one or more times the couplers on 607 of the 750 cars, and are very well satisfied with the service being obtained from them. Operation defects as yet minor in character have been found in both Types *A* and *B* couplers, but no trouble in operation has been reported by the transportation department.

It was found that practically all the couplers examined threw the knuckle open good. The principal defects found were as follows: Type *A* couplers, locks would stick in head above lock-set position in all but one examined; Type *B* couplers, lock fulcrum boss interferes with the front face in lifting lock, and the lock sticks in head above full open position. The interference of the fulcrum boss on the front of

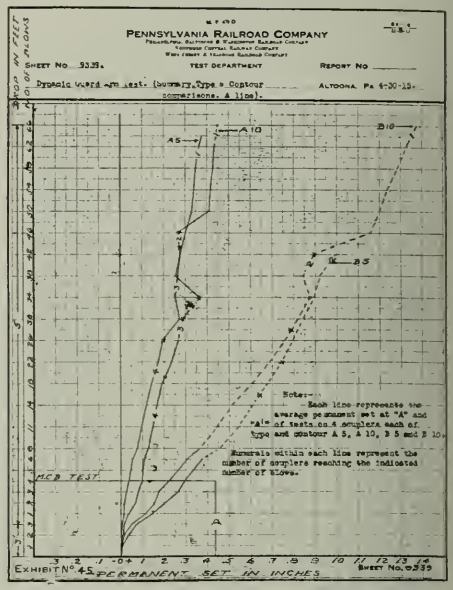

Fig. 6.—Set of *A* Line in Dynamic Guard Arm Test

the Type *B* lock with its pocket in front face of bar, when lifting lock, was only noticed on the couplers with the No. 5 contour. The cause of this is in part due to lack of clearance

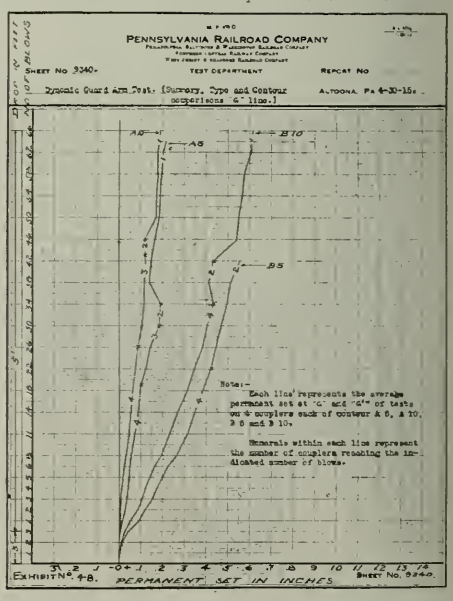

Fig. 7.—Set of *G* Line in Dynamic Guard Arm Test

and to the fact that the front face of bar over the pocket for the lock fulcrum on couplers of No. 5 contour is being dented inward somewhat, reducing the available clearance.

The sticking of the Type *B* lock above the locked position on couplers, with both the No. 5 and No. 10 contour lines, was brought about, in a few cases, by a quick jerk of the lever (the same as in service) in throwing the knuckle com-

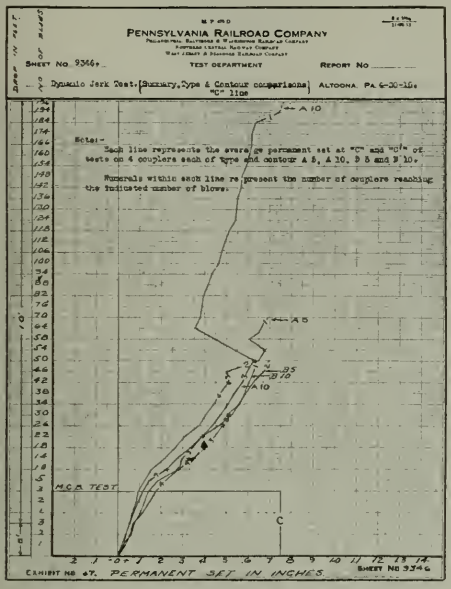

Fig. 8.—Set of *C* Line in Dynamic Jerk Test

pletely open; whereas, in the other cases where this was noted, it required repeated jerks of the uncoupling lever after the knuckle had been thrown to the full open position, and

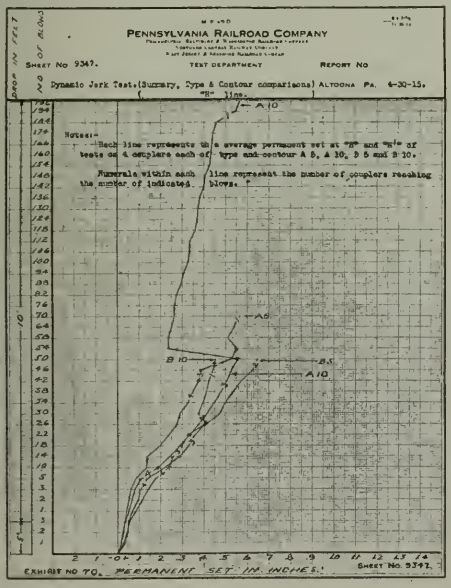

Fig. 9.—Set of *H* Line in Dynamic Jerk Test

bringing the uncoupling lever slowly to rest position, for if the lever was allowed to drop naturally, the lock would generally drop to the proper full open position. The cause of this sticking, as far as it was possible to determine, is due to insufficient clearances.

The following are some of the causes for removal of the experimental couplers on the Norfolk & Western: Type B-5—The knuckle was apparently bent inward about ½ in. and top of guard arm bent ⅜ in. Coupler inoperative on account of binding between lugs. No damage to car except striking plate bent inward ⅜ in. Conditions unknown.

Type B-5—Guard arm broken off at Lambert's Point. Conditions unknown. Guard arm broken off in making coupling at Lambert's Point. End sill plate bent ¾ in., carrier iron renewed and center sill bent out on knuckle side. Guard arm broken off at Lambert's Point. Reported no signs of rough handling.

Type A-10—Removed at Roanoke Shops account of hard blow on top of knuckle face and top lug causing binding between coupler lugs. Guard arm bent out ½ in. at top. Head crushed causing kicker to bind on trunnions making coupler inoperative. Shank bent 1¾ in. Vertical lock guide, knuckle side, broken. This occurred at Lambert's Point 5-23-14 in run-away with car 100069, but was reapplied to the car in error.

Type B-10—Bottom lug pulled from head. This occurred at Bluefield with report as apoeared to be due to rough handling.

Type B-5—Broke both lugs, breaking through mouth of

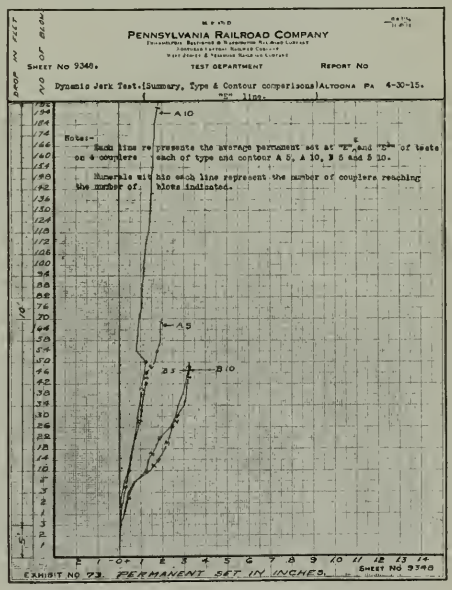

Fig. 10.—Set of *E* Line in Dynamic Jerk Test

bar; lugs and knuckle lost. Occurred west of Bluefield. Conditions unknown.

Type A-5—Burst head. Top wall cracked open forward of lifter hole and down inside of front top face. Marks as would be made by mating coupler guard arm on front face. Removed at Bluefield, car shows no signs of rough handling.

Type A-5—Top of head mashed in so the lock could not go up higher and let the knuckle throw. Also head cracked on inside from mouth of bar to top of head. Coupler does not seem to have had any unusually hard service.

Type B-10—Knuckle broke through pin hole on first car in train. Caused by 90 car west-bound train parting thirty cars back of locomotive and air went on in emergency at Walton, Va. Front half of knuckle lost. Knuckle broke through pin hole at Bluefield. Reported rough handling.

Reports were also received from other roads that are using the experimental couplers—[Editor].

In connection with the question of slack in the *A* and *B* couplers, of both Nos. 5 and 10 contour, an investigation was made on these couplers on an empty train of fifty Norfolk & Western 90-ton capacity steel gondola cars. The cars were all coupled and the train was coupled to a long train

of steel hopper cars loaded with coal, and brakes set on a number of the latter. The train of 50 N. & W. cars upon which the investigation was being conducted was then thoroughly stretched with a locomotive and brakes set on locomotive and several cars next to it, to insure the stretching. Each coupler was centrally punched on top of the head just back of the face and on the longitudinal center line of coupler and the distance trammed. The train was then bunched and the distance between the center-punched marks of each coupling above referred to was again trammed, the difference between this distance and the original distance as laid off with cars stretched being the slack per coupling. These cars and couplers had an average service of a little over nine months at time of these measurements.

The cars were equipped with the Sessions Friction Draft Gear (Type *K*), with the coupler horn originally set 1⅞ in. from the striking plate. The total slack in train consisting of 49 couplings, including couplers and drafts between buffed and stretched positions, was 26 ft. 10½ in., of which 4 ft. 8$^{9}/_{32}$ in. were in the couplers themselves. The following table is a summary of the results:

Number.	Couplings. Type Couplers and Contours Coupled.	Slack per Coupling. Minimum.	Average.	Maximum.
5	A-5 with A-5.....	1.062	1.156	1.281
2	B-5 with B-5.....	.969	.969	.969

DYNAMIC AND STATIC TESTS

The tests mentioned in report of last year as necessary to be made upon the Types *A* and *B* Experimental Standard M. C. B. couplers of both sizes of shank—5 in. by 7 in. and 6 in. by 8 in.—and both contours—Nos. 5 and 10—have been completed recently, and the results are shown in plotted form in Figs. 3 to 16 inclusive. The couplers were laid off the same as in previous tests, as per Fig. 1 and measured after each drop or increment of load. These tests were conducted by the Pennsylvania Railroad Company at Altoona, under the direct supervision of C. D. Young, Engineer of Tests, and the chairman of this committee.

SERVICE TESTING MACHINE—FINAL TESTS

As a result of the tests on the Types *A* and *B* couplers in the service test machine conducted during January and February, 1914, at the works of the American Steel Foundries at

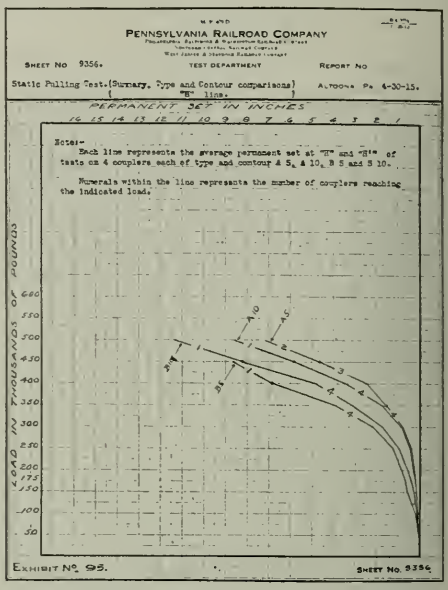

Fig. 12.—Set of *H* Line in Static Pulling Test

Alliance, Ohio, certain slight modifications in the details of the couplers were found desirable. The changes on the couplers were made by the respective manufacturers, and

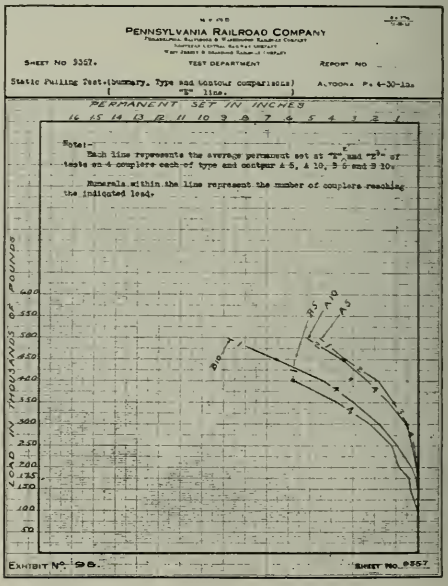

Fig. 13.—Set of *E* Line in Static Pulling Test

couplers embodying the modifications were tested on the same machine. Both types of couplers with the No. 5 contour lines were separately subjected to 30,000 cycles of the

machine, every cycle representing one each of the following operations, namely: Coupling, lock-setting, uncoupling, closing knuckle and throwing knuckle open. After completion of

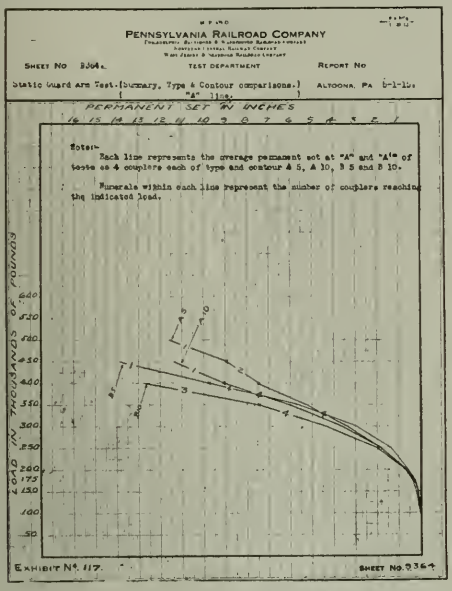

Fig. 14.—Set of *A* Line in Static Guard Arm Test

tests both types of couplers were in good operating condition, and, while during the test some minor defects of operation were noted, it was clearly established that the modifica-

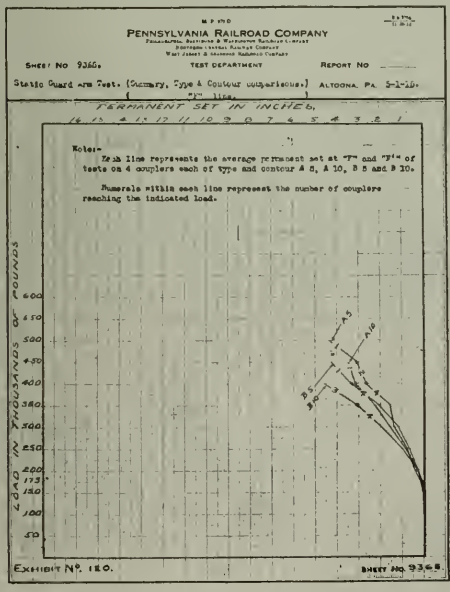

Fig. 15.—Set of *F* Line in Static Guard Arm Test

tions which had been made, as the results of the former tests, were beneficial to the extent of correcting most of the trouble previously experienced.

WEIGHT OF TYPES "A" AND "B" COUPLERS

The opinion has been voiced, although no specific objection has been made, that the weight of the Experimental Standard M. C. B. couplers is too great; and this subject has been seriously considered by the committee, as well as jointly between the committee and the coupler manufacturers, and from what can be learned, the objections that have been raised are commercial, based on the increased cost due to the increased weight, rather than any definite mechanical objection to the increased strength or weight. The breakage in the Experimental Standard M. C. B. couplers in service demonstrates conclusively that the strength of the coupler is not abnormal, and the tests prove that there is a maximum strength per pound of weight employed in the designs.

NEW EQUIPMENT TO BE DESIGNED TO ACCOMMODATE THE STANDARD COUPLER

The committee deems it advisable to call to the attention of the members the desirability of designing any new equipment—locomotives or cars—to accommodate the standard coupler. It has been found that a 6 in. by 8 in. shank is essential on the standard coupler, and, therefore, provision should be made for the same in all new or redesigned equipment, so that the standard coupler can be applied in repairs when finally adopted. In so far as locomotives and tenders

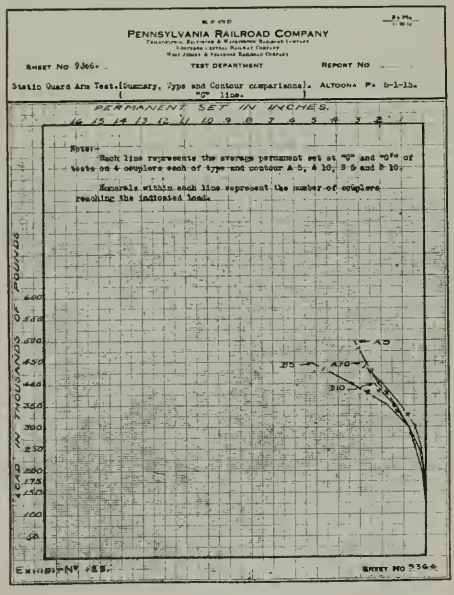

Fig. 16.—Set of *G* Line in Static Guard Arm Test

are concerned, it is economical to immediately apply the present Experimental Standard M. C. B. couplers, inasmuch as they are not interchanged, and obtain the saving resulting from the increased life of these couplers.

The report is signed by:—R. L. Kleine (Penna.), chairman; G. W. Wildin (N. Y., N. H. & H.); F. W. Brazier (N. Y. C.); F. H. Stark (Montour); J. F. De Voy (C., M. & St. P.); B. Julien (U. P.), and J. W. Small (S. A. L.).

DISCUSSION

F. W. Brazier (N. Y. C.): I cannot let this opportunity go by, although I am a member of the committee, without telling you gentlemen of the immense amount of work which has been done in getting up this report through the efforts of Mr. Wallis and Mr. Kleine, and the debt we owe to the Pennsylvania Railroad Company for the work it has undertaken in this direction. It is sometimes asked why the coupler should weigh approximately 400 lb. The committee would like to get it down to 100 lb. but in order to get strength you must have weight. Although these couplers will cost more, with the heavy engines now in use, and with the increased weight of equipment generally, it is necessary we should plan to put in new couplers, and I

hope to live long enough to see the railroads of this country agree on one standard form of coupler.

D. R. MacBain (N. Y. C.): I move that the convention extend to Mr. Kleine and his committee the thanks of the Association.

(The motion was carried.)

R. L. Kleine (Chairman): I thank you, gentlemen. I might say that the coupler manufacturers have worked equally hard with this committee in endeavoring to bring about one standard coupler.

The President: The privilege of the floor is extended to such representatives of the coupler manufacturers who may desire to speak.

R. E. Janney (Am. Steel Fdries): I would like to say that the coupler manufacturers have as much to thank your committee for, and probably more, than they have to thank us for.

S. P. Bush (Buckeye Steel Castings Co.): The coupler manufacturers are very much interested in this question. We are particularly interested in seeing the best coupler that can possibly be devised adopted as a standard. The question of weight is a very important consideration. In coming in contact with railroad representatives in different parts of the country we find that certain railroads feel that they do not need such a heavy coupler, and doubtless for their own local conditions that may be true. But a coupler has got to be considered in the light of the interchange service, and the future certainly must be considered in the matter. It is not unlikely that the average service of the next ten years is going to be increased in severity, so that if there are any objections to a coupler of the weight that has been suggested it would seem that the reasons ought to be fully set forth. From a manufacturer's standpoint we feel that as long as the association undertakes to adopt a standard it would be decidedly advantageous to have a single standard.

S. L. Smith (Nat'l Mall. Castings Co.): The committee seems to be very unanimous in its opinions, and I think they have found that the coupler manufacturers were willing to go along with them. When you get a standard coupler, it will be the result of the joint efforts of the Coupler Committee, and the majority at least, of the coupler manufacturers.

E. M. Grove (McConway & Torley): A number of years ago when the 100,000 lb. cars were first advocated, the small coupler was the standard all over the country. They were placed on these cars and in an air-brake test they went to pieces. Today the same conditions prevail with the larger cars, the larger locomotives, and the larger trains. We have got to meet the marked progress. You cannot buy 400 lb. of material at the same price that you can buy 300 lb. of material. I believe that in getting the additional strength, the additional weight, that the railways will be well repaid by the increased amount of service that they will get out of the couplers.

G. W. Wildin (N. Y., N. H. & H.): I move that it is the sense of this convention that the strength of the coupler and its resultant weight as presented by the Coupler Committee is necessary to provide for the proper strength and service in interchange.

M. K. Barnum (B. & O.): I second Mr. Wildin's motion. The B. & O. finds that the present coupler is not equal to requirements.

A. R. Ayers (N. Y. C.): In case of the heavy couplers being unsatisfactory to apply to existing cars, and in case the large coupler is adopted, what provision could be made in the way of adopting a shank on the proposed coupler that would fix existing cars, and in case you do use a small shank will it be an overbalanced coupler.

Mr. Kleine: The committee has recommended two shanks, the 5 in. by 7 in. shank for existing cars and the 6 in. by 8 in. shank for new cars. The 5 in. by 7 in. shank is just a little too weak for the head, but it is giving us very satisfactory service. We have asked, in new cars and in re-designing the present equipment, that room be left in the end sill for the 6 in. by 8 in. shank.

William Schlafge (Erie): We have equipped 200 cars with the couplers recommended by the Association. It was necessary to use the 5 in. by 7 in. shank, and so far we have not experienced any trouble whatever.

Mr. Janney: In regard to the weight, there is a limit beyond which the coupler cannot go, limiting dimensions having been placed upon the size of the head. It is not such a great increase, when you consider after this you have reached the limit. (Mr. Wildin's motion was put and carried.)

The discussion was closed.

D. R. MacBain, (N. Y. C.): I move that the incoming Executive Committee shall take as a text for its work during the next year the address of the president to this convention. I am sure that we have never had anything more directly in line with the cause we are pursuing than President Crawford's address delivered at the opening of this convention, and if this association, through its Executive Committee, will profit by the suggestions made by President Crawford, I feel that a great deal of good will result.

(The motion was seconded and carried.)

SAFETY APPLIANCES

The President: The next business is the report of the Committee on Safety Appliances. As chairman of the committee I beg to report to you that during the year which has elapsed nothing has come up which has warranted the holding of a meeting of the committee, and I therefore have nothing to report on this subject.

The report was accepted.

LOADING RULES

The committee calls special attention to the suggested addition to Rule 120, covering the loading of large blocks of stone. It spent considerable time with the stone shippers, in an endeavor to determine the best method of securing such stone containing 100 cu. ft. and upward, known as "mill block." A number of tests were made by dropping cars loaded with such stone against a draft of cars, the speed of the impact ranging from 3 to 6 m. p. h. It was shown that at a speed of about 4 m. p. h. the stone actually moved, although protected by standard end stakes. The committee, with the railroad representives present, have been convinced that the value of the present form of stake under such condition is limited.

In order to prove the value of cleating against side creeping, Mr. May, superintendent motive power of the Chicago, Indianapolis & Louisville, with representives from the stone quarries, made some observations in train service between Bloomington and Lafayette, Ind. Seventeen cars loaded with mill block were selected and accurate measurements were taken en route. It was conclusively shown that the stone did creep, both side and end wise. The committee is not unanimous in its approval of the suggested paragraph, there being one dissenting vote.

The committee recommends the following changes in the present M. C. B. Loading Rules:

Rule 12-*C*.—After the word "pockets," in the third line, change the rule to read, "by driving wedges in from the top of the pocket and securely nailing them to the stake."

Rule 15-*A*.—Has been changed to read as follows: "For loads carried on one bearing piece per car (with or without sliding pieces), located at or near center of car, the weight of lading must not exceed two-thirds the capacity of car carried on flat or low-side gondola cars of all-steel or steel underframe construction, or on flat or low-side gondola cars of wooden construction having more than two truss rods. On steel flat and steel drop-end gondola cars, constructed with fish-belly girders, the weight of the lading must not exceed three-quarters of the capacity of car."

Rule 15-*B*.—Has been changed to read as follows: "For loads carried on one bearing piece per car (with or without sliding pieces), located about equal distance from center of car and center of truck, the weight of lading must not exceed three-quarters of the capacity when carried on cars of all-steel or steel underframe construction, or on flat or low-side gondola cars of wooden construction having more than two truss rods."

Rule 15-*F*.—Omit.

Fig. 5.—Eliminate note reading as follows: "For logs, piling, props and telegraph poles, use 10 strands or 5 wrappings, Rule 57."

Rule 93.—After the word "iron" in sixth line insert "¼ in. by 6 in. for loads of 40,000 lb. or less, and ½ in. by 6 in. for loads over 40,000 lb."

Rule 98.—The last sentence should be changed to read as follows: "Rolling freight must be loaded longitudinally with car, and must be substantially chocked with side blocking in height equal to one-seventh (1/7) the diameter of rolls, provided that blocking of more than ten (10) in. in height will not be required. End blocking to be not less than four (4) in. in height."

Rule 98-*B*.—The committee would recommend the incorporation of a new rule 98-B, as follows: "Loose wheels and tires should preferably be loaded in gondola cars that do not have drop doors. Such material should not be loaded in gondola cars having drop doors in steel floors larger than the lading. When such material is loaded in gondola cars having doors in wooden floors larger than the lading, the entire door opening must be properly protected with boards of sufficient strength, securely nailed to the floor of the car to prevent shifting."

Rule 117-*C*., *Fig.* 61-*E*.—Should be inserted in the Code, also

added to Rule 117-C. This cut shows another manner of loading mining cars. (See Fig. 1).

Rule 120.—As a second paragraph of Rule 120 add the following:

"Mill block containing as much as 100 cu. ft., resting on channel or gabled surface not less than 25 sq. ft. or proportional for increased sizes must be so loaded that the weight of total lading will be uniformly distributed over the floor of the car, resting on a layer of sand, cinders or crushed stone, covering the entire bearing surface of the stone.

"Gondola cars are preferable for such shipments, but if flat cars are used, the lading must be placed at least 18 in. back of the end of the car. Each block of stone loaded lengthwise,

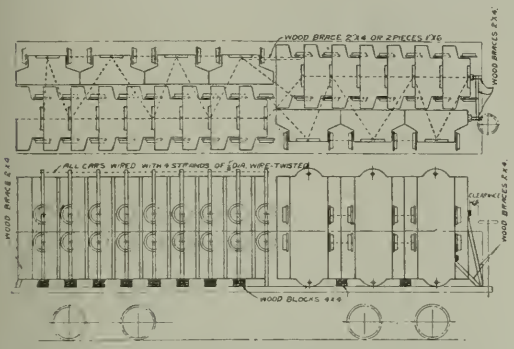

Fig. 1.—Manner of Loading Mining Cars in Gondola Cars

crosswise or obliquely must be protected against creeping by side and end cleats, securely nailed to the floor of the car with forty-penny nails. (When two blocks of stone are loaded parallel and close to each other, or wedged apart, they will be considered as one stone as to cleating.)

"If stone is placed lengthwise of the car and is 4 in. or closer to the side of the car, two standard side stakes 6 in. in height must be placed opposite such stone in lieu of cleats, on that side of the stone. Stone must not be loaded obliquely when it is possible to load it lengthwise or crosswise of the car.

"Cleats must consist of not less than 2 in. by 4 in. sound, straight-grained lumber, and extend at least three-quarters of the length or width of stone.

"If the 2-in. cleat does not have a full 1-in. vertical bearing

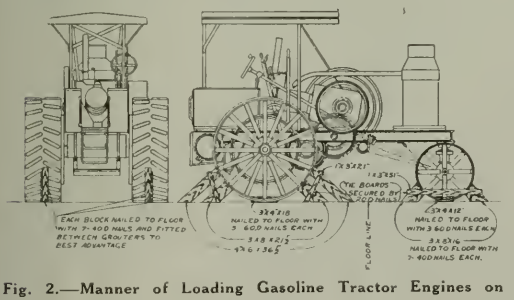

Fig. 2.—Manner of Loading Gasoline Tractor Engines on Flat Cars

for its full length against the edge of the stone, cleats may be built up to the requisite height, retaining the specific width."

Rule 121-*B*.—Add a new sentence to the end of the rule reading as follows: "Shipments of gasoline traction engines should be secured as per Fig. 64-G or 64-H." (See Fig. 2.)

Rule 124.—Should be changed to read as follows:

"Lading must be secured in closed cars so that it will not come in contact with side doors or roll or shift in transit, and must be so placed in car that there will not be more weight on one side of the car than the other.

"Lading of a character requiring protection to prevent it falling or rolling out at doorway, or coming in contact with door while in transit, must have the prescribed stripping across the door opening.

"Door strips must be nailed to the inside of door posts (never on the outside), and must not be less than 1 in. thick by 5 in. wide, straight-grained sound lumber, or their equivalent; or slab wood not less than 1½ in. thick at center; spaced sufficiently close to floor of car and to each other to prevent the lading from falling or rolling out of car or coming in contact with the door.

"When necessary to nail cleats or braces to lining of box cars having steel superstructure without exterior siding, the nails must not be driven entirely through the lining."

Rule 124-*A*.—Change to read: "Brick 15 in. or less in length loaded crosswise at doorway do not require door protection if built up as per Fig. 68-B, (See Fig. 3) and packed tight to prevent motion between bricks. Brick of any length loaded lengthwise at doorway must have door protection as per Fig. 68-C. Such brick should also be packed tight to prevent motion between each other."

Rule 126.—Should be changed to read as follows: "Barrel staves, fence posts, wooden billets, lath, tan bark and similar short wood should be loaded in accordance with Figs. 68 or 68-A. If the pieces are tapered, they must be loaded with tops and butts alternating. The material must be loaded longitudinally with car, except at door openings, where it must be placed crosswise. If loaded in accordance with Fig. 68, the doorway must be protected with strips extending across door opening, securely nailed on the inside of door posts. For the size of strips and manner of stripping doorway see Rule 124.

"If loaded in accordance with Fig. 68-A, the outer ends of staves or similar short material, whatever it may be, but of a length permitting two piles to be loaded end to end in doorway and still be at least 10 in. inside or door line, must rest on pieces

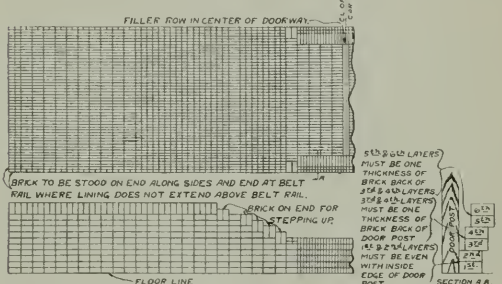

Fig. 3.—Manner of Loading Brick 15 inches or Less in Length Without Door Protection

not less than 4 in. thick and lengthwise of door openings, in order to make the pile incline toward center of car. This method makes the stripping of door opening unnecessary."

Rule 130.—Omit.

The report is signed by:—A. Kearney (N. & W.), chairman; L. H. Turner (P. & L. E.); J. M. Barrowdale (I. C.); G. H. Gilman (N. P.); Chas. N. Swanson (A. T. & S. F.); A. B. Corinth (A. C. L.), and R. L. Kleine (Penn.).

DISCUSSION

F. W. Brazier (N. Y. C.): Regarding the recommendation made with reference to changing Rule 124. We all know that we have a great deal of trouble with freight coming in contact with the doors under load. There is no way that any inspector can know or see what the condition of the lading is in a car that is sealed up. It is a traffic matter, and when we get home we should go to our managers and to our agents and see that they know the cars are loaded right. The thing is this: Will they live up to the rules? The rules are all right. It is a matter that the traffic department should be severely censured on. Under Rule 120 it says: "Cleats must consist of not less than 2 in. by 4 in." I hope there will not be any microscopic inspectors who will hold up a car because the cleats are 1⅞ in. by 3⅞ in. I would say that it should read "about 2 in. by 4 in." The doors on the equipment throughout the country are much improved, but there is still a good chance for those who are maintaining equipment to pay more attention to the door brackets, fastenings and to the hangers.

(It was voted that the recommendations of the committee be submitted to letter ballot.)

OVERHEAD INSPECTION OF BOX CARS

The committee explained in its last report that the result of its work had been turned over to the Committee on Relations between Railroads of the American Railway Association, with the advice that it was ready and desired to assist in any way their committee thought the work might be further pursued.

Few additional roads have done very much toward even trying out the proposed certificate of inspection card, although it was recommended by the American Railway Association. Those that are experimenting have found difficulty, it is reported, and quite naturally, on account of so few roads having taken up the proposed inspection. It may be unfortunate it has not received wider attention, if for nothing else than to ascertain its value or determine what, if any, alterations and modifications might be effected to make it more suitable, and possibly better accomplish the desired end, or possibly permit the working out of some entirely different direction for higher general efficiency. The Committee on Relations between Railroads of the American Railway Association will again urge that the card be given a trial.

The report is signed by:—A. Kearney (N. & W.), chairman; L. H. Turner (P. & L. E.); C. N. Swanson (A. T. & S. F.); J. M. Barrowdale (I. C.); G. H. Gilman (N. P.); A. B. Corinth (A. C. L.), and R. L. Kleine (Penn.).

DISCUSSION

C. N. Swanson (A., T. & S. F.): This is one of the most important subjects to come before this convention. You heard yesterday of the millions of dollars being paid out for loss and damage to freight. I believe that more attention should be paid to our house cars, on the initial loading line. We are in hopes that some action will be taken by the organizations higher up, insisting that more money be spent on our box cars to stop this unnecessary draining of our treasury.

INTERLINE LOADING.

As this subject reached this association through the Conference Committee of the American Railway Association, it has been concluded, after consultation with the latter committee, that doubtless the energies of the M. C. B. committee might be best utilized by assisting the committee of the American Railway Association. It was considered such a course would be most profitable, besides would be helpful toward a better understanding of the M. C. B. loading rules requirements, which have for their principle mainly the safe carriage of shipments; secondly, it should tend to harmonize related rules reached by the Classification Committee in the formulation of their schedules.

The report is signed by:—A. Kearney (N. & W.), chairman; L. H. Turner (P. & L. E.); C. N. Swanson (A. T. & S. F.); J. M. Barrowdale (I. C.); G. H. Gilman (N. P.); A. B. Corinth (A. C. L.), and R. L. Kleine (Penn.).

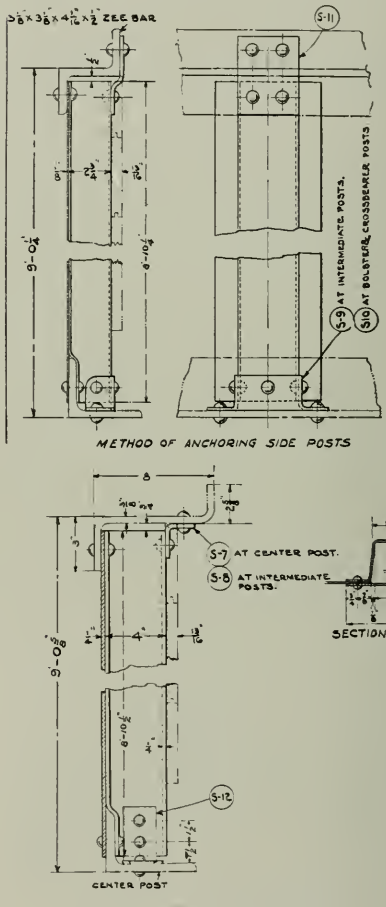
CAR CONSTRUCTION

During the past year the committee has given careful consideration to the various types of existing freight car designs, and has investigated current troubles and analyzed causes for such troubles. A large number of failures can be traced directly to weak center-sill construction and incorrect analyses of draft gear effect on center-sill construction. The committee

W. F. Kiesel, Jr.
Chairman, Committee on Car Construction

has, therefore, elaborated more than at first intended on the subject of draft attachments. In the following and in previous reports simple formulæ have been incorporated. The use of engineering formulæ to define fundamental requirements, without restricting types of design, is unavoidable. It must be understood that instructions governing specific designs or constructions may be based on these general formulæ by the engineering department of any road, without direct use of these formulæ, and which will be readily understood by those handling the interchange of cars.

At the 1914 convention your committee submitted a specification for box-car doors and fastenings, including a specification for reinforcing existing doors, a specification for complete new doors for existing cars, for new construction, and a revision of Sheet M. C. B. 30 embodying various improvements. The specification for complete new doors was referred to letter ballot and lost. The committee submits herewith another specification for box car doors, which is limited to new equipment



Method of Anchoring End and Side Posts

and which permits the use of top or bottom rollers, and which it is thought represents the minimum requirements that should be accepted for box car doors on new cars.

SPECIFICATION FOR BOX CAR OUTSIDE HUNG SIDE DOORS FOR NEW CARS

Doors may be either of wood or steel construction. If of wood construction, the wood frame and sheathing must be contained within a steel frame, riveted together at the corners and having at least one additional horizontal steel stiffener securely fastened at the ends to side members of steel frame.

Means must be provided for continuous weatherproofing and fireproofing around the top, bottom, front and back edges of the door when closed. The top of the door must be continuously supported against outward pressure, and this support must also form the weatherproofing.

Closed door stop must be of metal, preferably continuous from top to bottom of the door. If the continuous door stop does not support the door against outward pressure, such support must be provided by not less than two brackets with lips, equivalent to brackets shown on Sheet M. C. B. 30, and located as shown thereon.

Metal open door stops are recommended, one or more in number, equivalent in strength to the design shown on Revised Sheet M. C. B. 30, securely bolted to the belt rails or framing of the car with at least two ½-in. bolts or their equivalent. If wood open door stop is used, it should extend the entire height of the door and be reinforced by clip washers, or through bolts to prevent splitting.

The bottom of the door must be supported against outward pressure at not less than two points for any position of the door. If individual bottom door guides, fastened to the car body, are used, they must be as least four in number, one located adjacent to each door post, one in the middle of the doorway, and one between the back door post and the open door stop, approximately as shown on Revised Sheet M. C. B. 30, and similar in design, with particular reference to the height of the lip, which should be not less than 1¾ in.

If door hangers are fastened to the door with bolts, the design of the door fastenings must be such that with hangers broken or removed the door can not be removed from the car, except by removal of either the track, door guides, or door stops. When substantial hangers are riveted to steel doors, or to steel frames of wooden doors, with not less than four ⅞-in. rivets or their equivalent, this provision need not apply.

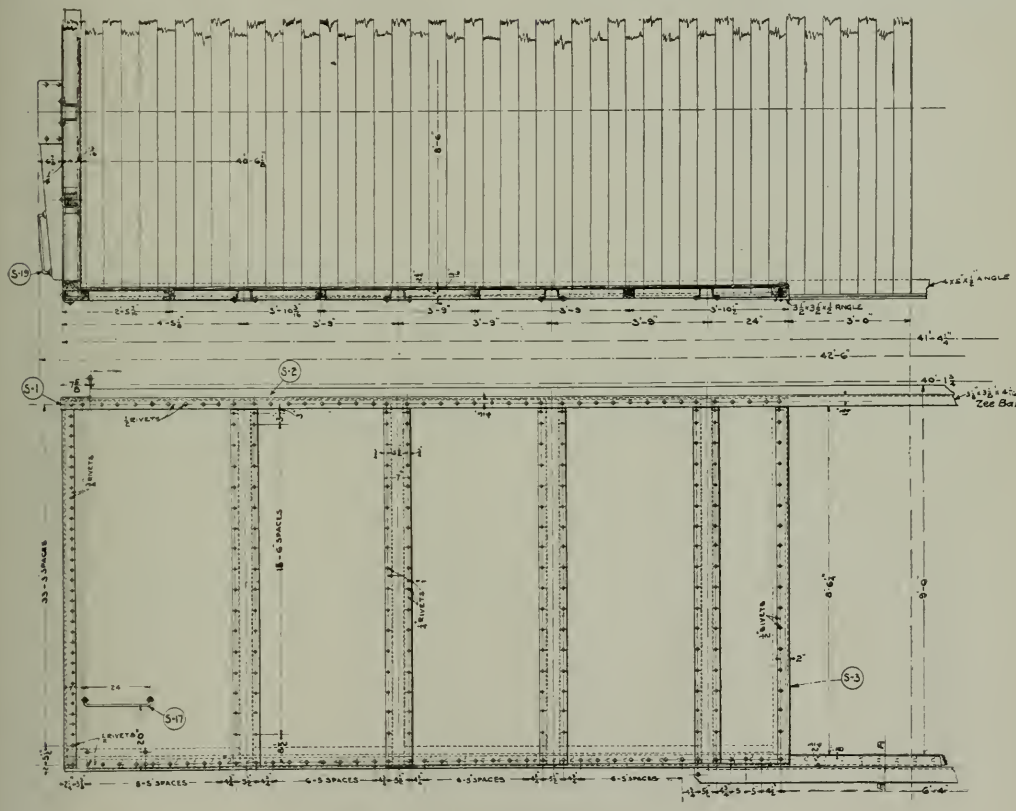
When hangers or rollers are fastened directly to the sheathing of wooden doors, bolts must be not less than ¾ in. in diameter, at least four in number for each hanger, and spaced not less than 4 in. apart horizontally and 5 in. vertically, hangers to be preferably located so the bolts will pass through two or more boards.

The door track may be located either above or below the door opening and the door supported so that under any service conditions there will be no binding of the door from vertical interference with the door guides or track. The upper door track, if used, must be continuous in one piece, strong enough so that it will not sag, and securely fastened to the car; proper flashing, if necessary, to be provided over the door track. If the door is supported at the bottom, means for keeping the supports in alignment must be provided.

For wooden doors, the door-hasp fastener must be at least 24 in. long, fastened with not less than five ⅞-in. bolts, with nuts on the inside of the door. The door-hasp fastener must be of such design that the hasp can not be removed without removing the bolts from the fastener. The door-hasp fastener must be secured to the steel frame of the door by at least one bolt or rivet. For steel doors, the door-hasp fastener must be riveted to the door.

Proper clearance must be provided so that ⅜ in. bulging of the side of the car will not interfere with the free movement of the door. Door mechanism must be so designed that in a closed position the door is drawn reasonably tight against the side of the car. It should be possible for one man to open or close the door readily from the ground without tools.

All of the above recommendations apply particularly to cars with 6 ft. door openings and single outside hung side doors, and in all cases where a particular construction is described, or specific dimensions are given, their equivalent will be acceptable.



Arrangement of Side and End Sheets, M. C. B. Standard Car

DRAFT GEAR

The report submitted in 1914 was rejected, and criticisms from various sources indicated that the restrictions recommended were considered insufficient to eliminate undesirable draft gears and to sufficiently reduce the excessive repairs now required for old equipment. In this report it has, therefore, been the object of the committee to formulate rules based on fundamental prin-

ciples and comparable with the strength of other parts of the car. This naturally involves reference to the center-sill construction. Many roads are at present modifying wooden cars, which make it desirable to have a guide for minimum strength requirements for reinforcement of existing wooden cars to fit them for some years further service. For such cars the following rules are submitted:

The draft attachments, including draft arms—if used, must be of metal, of either integral or riveted construction.

The strength value of the draft attachments and center-sill construction must be equivalent to at least 10 sq. in. of steel in tension and compression, 6¼ sq. in. of rivet-bearing area, and 12½ sq. in. in shear. The ratio of unit stress to end load must not exceed 0.15.

Metal draft arms applied to wooden center sills must extend at least 30 in. beyond the center line of the bolster, toward the center of the car, must be securely fastened to the bolster and the center sills, and where possible should butt against the compression members placed between the draft arms and needle beams and also between the needle beams. Hardwood or yellow pine center sills may be considered equivalent to steel in center-sill construction between bolsters if they have four times the specified unit values, namely, 40 sq. in. tension and compression area, and a ratio of unit stress to end load not exceeding 0.0375. Where wooden members are reinforced with metal (composite construction) either the steel or the wood must alone meet the strength requirements. Where the horn of the coupler is allowed to come in contact with the end sill, the latter must be provided with a striking plate of sufficient strength to resist its proportionate load without deformation.

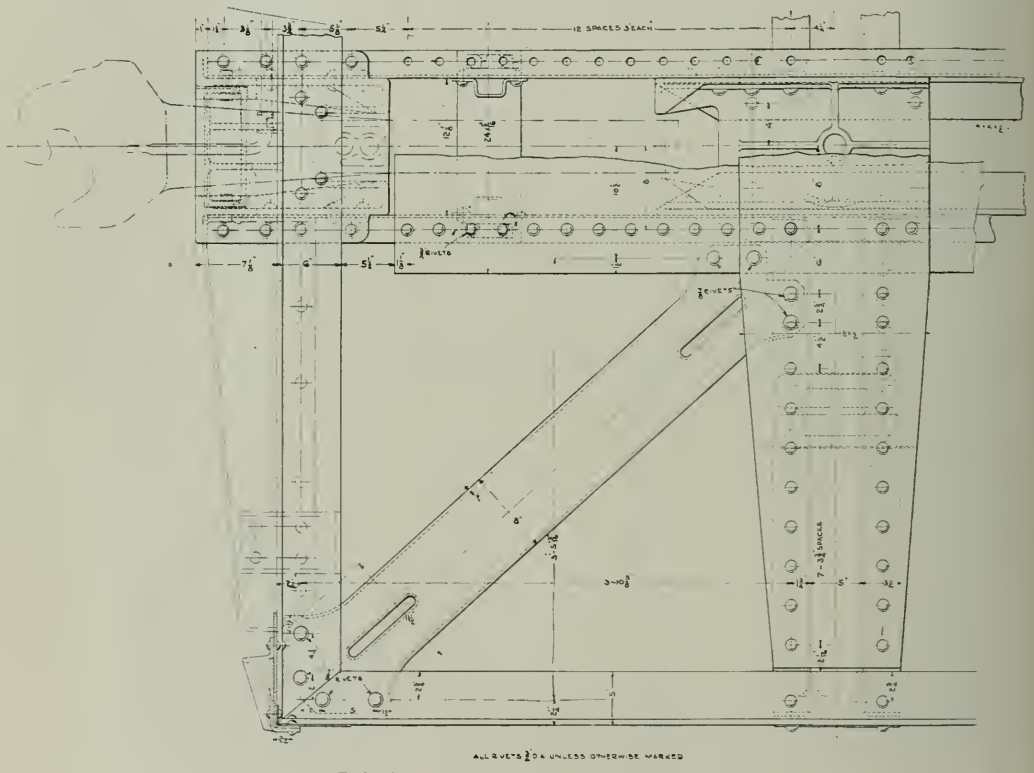
The intensity of end force is assured to be equivalent to 250,000 lb. static, which may be concentrated on the center line of the draft gear or distributed between the draft gear and end sill. The point of contact between the horn of the coupler and the striking plate is assumed to be 2 in. above the top of the coupler shank. For a shank 5 in. deep the distance from the center line of the draft gear to the assumed point of contact of the coupler horn is 4½ in. The proportion of end force acting on the striking plate is assumed to be 250,000 lb. less R, which is the resistance of the draft gear when the horn of the coupler touches the striking plate. Hence, when the coupler shank is 5 in. deep, and the horn of the coupler is allowed to touch the striking plate before the draft gear is solid, the end force of 250,000 lb. is effective on a line located a distance Y above the center line of draft gear,

$$Y = 4.5\left(1 - \frac{R}{250{,}000}\right)$$

It should be clearly understood that these rules are not intended to modify the recommendations made by this committee under heading "1a" for minimum strength of existing steel and steel underframe cars, and which were referred to the Arbitration Committee in 1914. Many existing wooden cars can be reinforced to come within "1a" requirements at little more expense than that necessary under the rules given above.

DESIGN OF A STANDARD M. C. B. BOX CAR

The committee submits a tentative design of a box car with the request that each member interested study it and send to the committee, before December 1, 1915, a letter—accompanied by sketches or drawings where necessary—giving recommendations for modifications; also expressions of preference of other details that can be used, or approval of materials and details shown in this design. The reason for the last request is to indicate to the committee whether the majority prefer the tentative design, or some change.



End Sill and Bolster; M. C. B. Standard Car

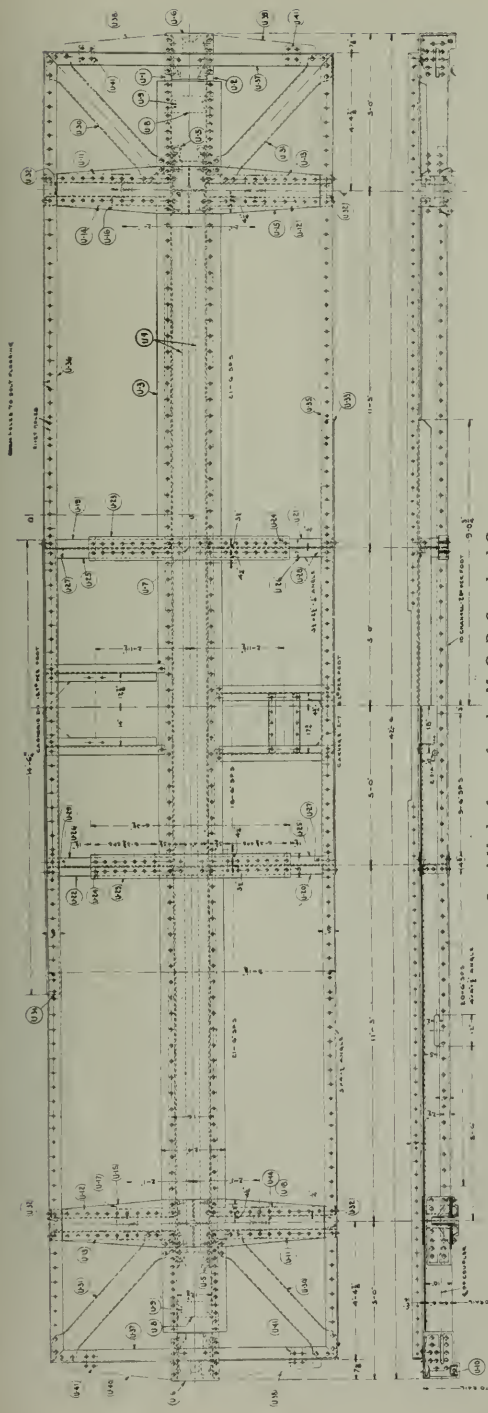
This tentative design is intended to cover the following:

Strength.—A small amount above the minimum requirements.

Weight and Cost.—The least that can be obtained per unit of strength.

Flexibility of Design.—To permit substitution of stronger parts or patented details interchangeable with those shown.

Type.—The committee selected the steel-sheathed type box car because it avoids loss of lading on account of shrinkage or damage to single courses of wood, because the smooth exterior



Steel Underframe for the M. C. B. Standard Car

reduces wind resistance, and because it permits the elimination of diagonal braces.

Underframe.—All parts thought to be unnecessary have been eliminated. As the side and end angles are a part of the side and end frames, the underframe consists of the center sill construction, two bolsters and two cross-bearers The cross-bearers transfer the load from the center sills to side frame. The bolster cover plate must be not less than ⅜ in. thick for 30-ton cars; 7/16 in. thick for 40-ton cars; and ½ in. thick for 50-ton cars. Rule 1B, adopted as Recommended Practice in 1914, requires that the center-sill construction shall have at least 24 sq in. section area, that the ratio of stress to end load shall not exceed 0.26, and that the length of the center and of the draft sill members between the braces shall not exceed 20d.

An analysis of the ends of center-sill construction follows:

The design is for the use of gears which do not permit the horn of the coupler to strike the end casting, and concentrate all end compression force on rear followers, but other gears are also applicable.

AREA:

Cover plate	24 in. by 5/16 in.	= 7.5	sq. in.
Two channels	2 in. by 5.88 in.	= 11.76	sq. in.
Two angles	2 in. by 3.75 in.	= 7.5	sq. in.
Total		26.76	sq. in.
Allowance for rivet holes in bending		1.3	
Net area for bending		25.46	sq. in.

NEUTRAL AXIS OF SECTION:

In this calculation the moments of areas are taken with reference to top line of cover plate.

Cover plate	7.5 sq. in. by	in.	= 1.17
Two channels	11.76 sq. in. by 5	in.	= 62.5
Two angles	7.5 sq. in. by 9.13	in.	= 68.47
Total Moments			132.14

$$\frac{\text{Total Moments}}{\text{Total Area}} = \frac{132.14}{26.76} = 4.938$$

which is the distance from top of cover plate to neutral axis.

MOMENT OF INERTIA OF SECTION:

Top cover plate	$(bh^3 \div 12)$	= .06
Top cover plate	(Ah^2)	= 160.43
Two channels	(I)	= 157.4
Two channels	(Ah^2)	= 1.65
Two angles	(I)	= 11.12
Two angles	(Ah^2)	= 131.74
Total		462.40

SECTION MODULUS (SM):

$$\text{For top fibers} \quad SM = \frac{462.4}{4.94} = 93.6$$

$$\text{For bottom fibers} \quad SM = \frac{462.4}{5.375} = 86.03$$

These calculations determine that

A = 26.76 sq. in.
X = 1.375 in.
SM at top fibers = 93.6
SM at bottom fibers = 86.03

Substituting these values in the formula $\frac{1}{A} + \frac{X}{SM}$, the ratio of stress to end load, when all of the end load is concentrated on the center line of coupler, is 0.05335, or less than .06. Similar calculations show that to meet the requirements the resultant line of the end force must not be less than 3 7/16 in. from the bottom line of the channels, and not less than 2½ in. from top line of channels. The center line of draft gear, which is the lowest possible line of end force, is 4 in. above bottom line of center-sill channels, and, therefore, well within the limits.

The end force through the horn of the coupler striking end casting may be assumed to act on a line 2 in. above the top line of the coupler shank, or for a shank 5 in. deep, 4½ in. above the center line of the coupler, which, in this case, is 1½ in. below the top line of the center-sill channels. The committee bases calculations on a total end force of 250,000 lb. From limitations determined above, this whole force may act on a line 3½ in. above the coupler center line, which determines that for this design the draft gear resistance, when the horn strikes the end sill, must be at least 19,500 lb., leaving 230,500 lb. acting on end casting. This in turn requires an effective area of center-sill construction of 22 sq. in. between the end sill and the rear follower. The tentative design has an effective area of only 11.76 sq. in. in compression, and 10.56 sq. in. in tension, requiring a draft gear resistance of at least 122,500 lb. when horn of coupler strikes the end casting. If this resistance is less, the ends of the channels must be reinforced accordingly.

The distance between the rear followers is 35 ft. 3¾ in., or less than twenty times the width of cover plate, which is 40 ft. The greatest length of bottom center-sill flanges, between anchors, is 125¼ in., or less than 20 in. by 6.74 in. = 138.8 in. The bottom

side angles are held in line by the floor boards, and the top side Z-bars are held in line by the roof. The minimum effective area of the center sills in tension is 10.56 sq. in., or 5.6 per cent. more than required by Rule No. 6. The draft attachments shown are of the type commonly used. Other attachments suitable for tandem or other gears can be readily substituted.

The flooring has been made 2⅜ in. thick, to avoid the use of intermediate sills. It is tongued and grooved, bolted to the center-sill cover plate and side angles, and all crevices, especially those between floor boards and side and end angles, are to be filled with melted bitumen, or other compound.

The brake arrangement shown differs from that now representing M. C. B. practice. This type has been selected because it does not vary the brake effect when cars pass around curves, and because the cylinder pressure acting on the live lever is counteracted by the strain on the dead lever, thus eliminating strain in the underframe braces. The old type brake can be readily substituted.

Side and End Framing.—The side sheets are ⅜ in. thick, and the side posts are U-shaped, uniform in section, except where offset for bottom angle, and do not necessarily require dies for their manufacture. The bottom angles and top Z-bars, forming lower and upper flanges, must be at least ⅜ in. thick for 30 tons, 7/16 in. for 40 ton, and ½ in. thick for 50 ton cars. The combined section modulus of all posts, on one side except corner posts, is 20.7.

The end sheets are ¼ in. thick, and the end posts are also U-shaped. The total section modulus of the end posts, not including corner posts, is 15.75. This covers requirements of rule in No. 2. The Z-shape of side and end plates permits ready application of any type of roof. If loose plate roofs are applied, the carlins should be a design that will brace the side plates both transversely and diagonally. Any type of carlin is satisfactory when solidly riveted roof is used.

Although the lining is shown for the full height of car, this may be partly or entirely eliminated. If the lining is entirely omitted the end posts should all have flangs riveted to the end sheet. The base of the door opening is flush and raised away from the side sheets of the car a distance of ⅜ in for 30 ton, 7/16 in. for 40 ton, and ½ in. for 50-ton cars.

General Remarks.—The tentative box-car design submitted has the following general dimensions:

Length of frame over striking casting	42 ft.	6 in.
Width over sheathing	9 ft.	1¾ in.
Length, inside	40 ft.	6⅛ in.
Width, inside	8 ft.	6 in.
Height, inside	9 ft.	
Height, from rail to bottom of bolster	2 ft.	6 in.
Height, from rail to floor	3 ft.	8½ in.
Height, from rail to top of running board	13 ft.	4½ in.
Height, from rail to top of brake staff	13 ft.	2 in.
Width, at eaves	9 ft.	2⅛ in.
Height, at eaves	12 ft.	5¾ in.
Side door opening		
Width	6 ft.	0 in.
Height	8 ft.	6½ in.
Cubic volume under carlins	3096 cubic feet.	

The examples of box cars now passing over the roads in America illustrate that it will be of inestimable advantage, at least to the smaller railroads, who do not design their own cars, to have an M. C. B. design representing a standard of minimum strength required. Manufacturers of roofs, doors, draft gear and other specialties can reduce cost of manufacture, and can make more real progress in quality, if their various types of roofs, doors, etc., are interchangeable.

It will be noted that the end-sill design is such that it can be omitted, if desired, without affecting the integrity of the car. The permissible variations due to capacity are few. The bolster plates, side angles, Z-bars, and facing angles for door posts, may be ⅜ in. thick for 30-ton cars, 7/16 in. thick for 40-ton cars, and ½ in. thick for 50-ton cars. All other parts of the car body are governed by conditions which admit of no reduction in area or weight, for cars of less than 50-ton capacity.

SHEARING VALUES OF STRUCTURAL, RIVET AND MILD STEEL

Many experiments to determine the shearing values of steel have been made, and values of the ratio of shearing strength to tensile strength, varying between 65 per cent. and 85 per cent. have been recorded. Woehler's researches led him to establish a ratio of 80 per cent. This figure was later confirmed by Baushinger, for shearing strength, provided the shear is in a plane perpendicular to the direction of rolling. This figure has been generally adopted, and the committee recommends that, in all calculations for strength of parts, the following rule shall govern:

The allowable stress per square inch, for iron or steel subject to shear in a plane perpendicular to the direction of rolling, shall not exceed 80 per cent. of the allowable stress per sq. in. for tension, in the direction of rolling.

The report is signed by:—W. F. Keisel, Jr. (Penn.), chairman; A. R. Ayers (N. Y. C.); S. G. Thompson (P. & R.); C. E Fuller (U. P.); E. G. Chenowith (C. R. I. & P.); J. C. Fritts, (D. L. & W.); T. M. Ramsdell (O-W. & Nav. Co.), and C. L. Meister (A. C. L.).

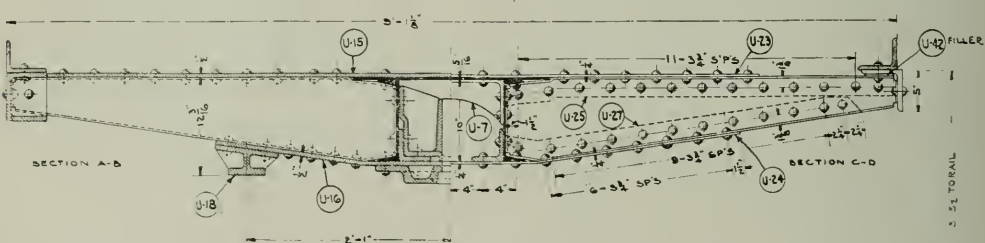
DISCUSSION

W. F. Keisel, Jr. (chairman): This week two communications were received which I think it would be well to read to the association. The committee has not taken action thereon, as we received one yesterday and one today.

[Both communications were received from the International Association of Railway Special Agents and Police—the following are abstracts from them.—Editor.]

The first communication contained the following:

"It has been established by a number of actual tests made by this association on cars of 30 different railroads, which



Cross Section of Steel Underframe for the M. C. B. Standard Car

had been in service from 2 to 8 years, and by experience gained in the investigation of a large number of claims and car robberies, that over 50 per cent of the box cars used in daily merchandise traffic can easily be entered without tampering with the seals, and without leaving any trace to indicate where or how robbery was committed.

"It was demonstrated that this condition is due to two faults in the construction of the car door. First the use of door brackets or guides 2 in. or less in height, which permit lifting the door over the rear bracket or guide with the aid of a small lever or brake shoe key so it can be pulled out sufficiently to allow the removal of packages of large dimensions. Second, the use of square head bolts in applying brackets, guides, rails and fastenings, on the outside of the door or car, and the failure to rivet bolts over the nuts or washers permits the removal of the brackets, guides or fastenings and the entering of the car without tampering with the seals and the replacing of these parts in such a way as to escape detection by ordinary examination.

"We find the first condition can be overcome by the use of a bracket or guide 2½ in. or more in height, which would be sufficient to allow for shrinkage in wood, the loss in rigidity and loosening of the hanger track, and still be high enough to prevent car being entered by the means above described.

"The second condition can be remedied by the use of round head bolts, riveted over nuts or washers on the inside of the door or sill which will prevent removal of the brackets, guides or fastenings by ordinary means."

The second communication stated, in part, as follows:

"A resolution was adopted by the International Association of Railway Special Agents and Police, based on many years experience and a report made by their committee on seals and fastenings to the effect that inasmuch as train crews and yard or seal clerks very seldom take a record of seals on

or note the condition of end doors on merchandise cars, which violation of the rules is supported to a considerable extent by the principle of 'Safety First' it is the sense of this Association that all end doors on cars now in use which require sealing be fastened permanently by means of a bolt ⅜ in. or more in thickness which should pass through end or side of the door about midway just above the fastenings and then through the car and be fastened on the inside by means of a nut which can be removed and replaced in case the car is to be loaded with a commodity necessitating the opening of the end door. This will obviate the necessity of sealing the end door as well as the taking a record of such seals.

"It is also suggested that in building new cars that end doors be eliminated when possible, and that when it is necessary to install them, that the fastenings be placed on the inside, and that they be so constructed as to cause the end door to lock automatically when it is closed, which will obviate the necessity for sealing.

"Quite a number of robberies are committed daily through the end openings, and, because of the failure of employes concerned to take a record of end door seals, it is practically impossible to determine point of robbery, which makes such thieves immune from capture."

The M. C. B. committee will go into the matter further with this Association.

A. B. Appler, (D. & H.): I would ask what the committee had in mind when applying the diagonal brace from center sill and bolster to the side sill and end sill, instead of applying it from the bolster and side sill toward the end sill and center sill. Just what is the minimum strength provided for in that arrangement.

Mr. Keisel: The reason for putting the diagonal brace that way was to concentrate any end shock on the center sill.

Mr. Appler: The thought in my mind was it might be more advantageous to brace the center sill than it would be to provide for the corner of the cars.

Mr. Keisel: The center sill is supposed to be strong enough to take any reasonable end shock the car receives. It has been found that by putting the brace on the car in that way, it saves a great deal of expense on repairs.

R. E. Smith, (A. C. L.): Has the committee considered the suitability of a steel sheathed car for warm climates and lines handling perishable products, vegetables and other shipments, that require ventilation and as cool a temperature as possible. Another thought is, what will be the effect on the life of the steel sheathed cars when such cars are devoted to the handling largely of commercial fertilizers which give off fumes of sulphuric acid which, combined with condensation on the steel sheathing, will subject them to rapid corrosion, due to the formation of dilute sulphuric acid.

Mr. Keisel: The committee did consider the question of such cars running in warm climates. For warm climates it is essential to line the car with wood, and it is also essential to ventilate it. If the car stands in the open sun the steel will absorb the heat from the rays of the sun, and though the outside temperature may be 90 deg., the steel may be 110, or 115 deg. Even though the car is merely a steel frame car, and not a steel sheathed car, the same thing obtains. Therefore, in order to keep down the temperature we will have to build an entirely wooden car. In regard to the sulphuric acid, we have the same conditions in coal cars. In the hopper bottom car it will be a matter of protecting it with paints, more or less impervious, and they should be impervious, if possible, to the action of the sulphuric acid.

G. F. Laughlin (Armour & Co.): I would ask the committee why it recommended that metal draft arms applied to wooden center sills extend 30 in. beyond the center line of the bolster. There are some types with 24 in. and 26 in., which give sufficient protection.

Mr. Keisel: The 30 in. referred to is an arbitrary figure. The support of the draught arm should be well beyond the center line of the bolster. Cars that have had 24 in. stood up quite well, but from what we saw of cars which had 30 in. beyond the center line of the bolster, the improvement was so great that we thought we ought to make that a minimum figure.

S. G. Thomson (P. & R.): Before this report is submitted to letter ballot, I want to call attention to several features regarding the draft gearing. The specification will show some radical departures from present practice, so that some members in reading it might think that if they voted for it they would have to immediately put it into effect. Take for instance 6a, which reads: "The draft attachments, including draft arms—if used, must be of metal, of either integral or riveted construction." That was put in to get rid of the old wooden draft arms which are giving us all of the trouble in the draft gear problem to-day. The committee thought seriously at one time in their conference, of including in the report a requirement that these specifications be compulsory for all cars in interchange after a certain number of years. However, there is no feature that brings out the actual time in which this method, if adopted by letter ballot as recommended practice, was to be put into effect; but the fact that the specification was approved would give everybody a chance to start, and possibly next year the committee would be in a position to say on what date the railroads of the country should agree for putting such a specification into use.

(It was voted to refer the specifications for box car outside hung side doors for new cars, the rules under draft gear, and recommendations concerning malleable cast iron and shearing values of structural, rivet and mild steel to letter ballot.)

SPECIFICATIONS AND TESTS FOR MATERIALS

The committee sent out for criticism Circular No. 14, containing the following proposed specifications, with the exception of those for Journal Bearings for Passenger and Freight Equipment Cars, which have been rewritten in line with criticisms received during the past year:

Structural Steel, Steel Plate and Steel Sheets for Passenger Equipment Cars.

Structural Steel, Steel Plate and Steel Sheets for Freight Equipment Cars.

Malleable-iron Castings for Passenger and Freight Equipment Cars.

Miscellaneous Steel Castings for Passenger and Freight Equipment Cars.

Journal Bearings for Passenger and Freight Equipment Cars.

Mild-steel Bars for Passenger and Freight Equipment Cars.

Rivet Steel and Rivets for Passenger and Freight Equipment Cars.

Galvanized Sheets for Passenger and Freight Equipment Cars.

All the criticisms, 22 roads replying, were considered by the committee, resulting in numerous changes and modifications in these specifications. The committee, therefore, recommends:

First: That these specifications (shown in Appendix B) be submitted to letter ballot as Recommended Practice.

Second: That the Specifications for Chain for Passenger and Freight Equipment Cars, Recommended Practice, be modified to include electric-welded chains. (These modifications are made with the idea of harmonizing the present chain specifications with the Iron and Steel Chain Specifications of the American Society for Testing Materials).

Third: That the following section be added under the subhead of "Physical Properties and Tests," in the present Specifications for Steam-heat Hose for Passenger Equipment Cars, Recommended Practice:

"*Digester Test.*—The digester shall consist of a cylinder containing dry saturated steam at a pressure of 45 lb. per sq. in. The hose shall be put into this digester and will remain there for 48 hours continuously. An examination of this section, after being submitted to the heat of the steam, should not disclose any blistering of the inner tube or any loosening of the tube from the fabric. Examination and test after heating, prescribed in the specifications, will be made as soon as possible after the specimen has cooled for 24 hours. The test will be made at a temperature of not less than 60 deg. F."

Fourth: That the label under Section 5 of the Specifications for Steam-heat Hose for Passenger Equipment Cars have added thereto, after the word "Road" the word "Steam," and after the date of manufacture, the Cars.

Fifth: That the changes shown in Appendix A be made in the Standard Specifications for Air-brake Hose for Passenger and Freight Equipment.

The changes in the air-brake hose specifications were made with the following objects in view:

(a) That the title of the present standard specifications include signal hose.

(b) Combining the Specifications and Tests for Woven and Combination Woven and Wrapped Air-brake Hose into the present Standard Specifications for Air-brake Hose.

(c) Eliminating Section 6, covering "Tensile Strength of Duck," which has proven unsatisfactory due to the difficulty in testing, and substituting therefor an addition to the requirements under "Bursting Test."

(d) Specifying the manner in which the thickness of the test specimen shall be measured and the instrument with which it shall be measured. This standardizes the practice of this Association with the Manufacturers' Association, United States Navy Department, and the Underwriters' Laboratories.

(e) Omit present Figure 1, page 672, 1914 Proceedings.

(f) A permissible variation as to location of label has been provided.

(g) The requirement of making tests within 90 days of date of shipment of material in the old specifications has been reduced to 60 days, as it is well to reduce this time as much as possible.

A test was conducted by the Canadian Pacific to determine if the present standard specifications amply protected the purchaser

against stiff hose under freezing conditions. This test has developed the fact that our present specifications, covering the tensile strength of the material in the tube is satisfactory, in so far as stiffness is concerned and, therefore, no changes are needed in the specifications to take care of this condition.

In addition to this work, the committee, with the Manufacturers' Association, still have in view the problem of a uniform test specimen, and although a large amount of work has been done upon this subject, progress only can be reported.

Prior to writing the present standard specifications an elaborate series of tests was started on various pieces of air-brake hose made in accordance with the ideas of the different manufacturers. This test is progressing and information is being accumulated.

It has been discovered that certain manufacturers' hose purchased under our standard specifications is showing rapid checking of the rubber in the cover after exposure to the weather. This matter is being made a subject of special investigation by the committee with the hope that something may be presented at the next meeting upon this subject.

The committee contemplates next year, in addition to the above, the following:

(a) Harmonizing of drop test for all sizes of axles under one weight of tup with the specification requirements of the American Society for Testing Materials.

(b) Taking under consideration and endeavoring to formulate Specifications for Recommended Practice, covering the following materials: Bolts and nuts, oxide of iron pigment, linseed oil, drier, paint vehicle, stencil paint.

(c) The committee is working with the manufacturers of insulating materials to the end that a standard method of testing this grade of material can be prescribed. Until this work can be completed it will be impossible to prepare a specification covering this grade of material.

The committee has received a communication from the chairman of the Coupler Committee, in which they recommend that the number of couplers required for test purposes on each lot of 1000 be reduced from a total of 13 to 8, by submitting but 5 instead of 10 couplers to the strike test. The committee, therefore, recommends that the specifications be reworded to incorporate this change.

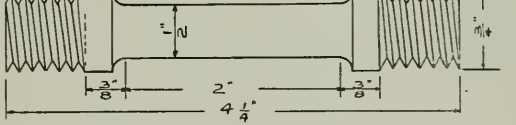


Fig. 1.—Test Specimen for Structural Steel, Steel Plate, and Miscellaneous Steel Castings

The report is signed by: C. D. Young (Penn.), chairman; J. J. Burch (N. & W.); A. Copony (G. T.); I. S. Downing (C. C. C. & St. L.); A. H. Fetters (U P.); H. B. MacFarland (A. T. & S. F.); J. R. Onderdonk (B. & O.); J. W. Taylor (Sec.); E. B. Tilt (C. P. R.), and Frank Zeleny (C. B. & Q.).

APPENDIX A

SPECIFICATIONS FOR AIR-BRAKE AND SIGNAL HOSE

1. Scope: These specifications supersede all previous specifications for Air-brake and Signal Hose, including that for "Woven and Combination Woven and Wrapped Air-brake Hose." Air-brake hose of the Woven and Combination Woven and Wrapped type shall meet all tests of these specifications, except that of friction, Section 4, on those constructions where friction can not be made.

Present Sections, 1, 2, 3, and 4 changed to Sections 2, 3, 4 and 5. Present Section 6 to be omitted. Present Figure 1 to be omitted.

8. Bursting Tests: Add to this paragraph the following: "After which the hydraulic pressure shall be increased to a minimum of 700 lb. per sq. in. without bursting, at the rate of not less than 100 or more than 200 lb. per five seconds."

9. Test Specimen: Add paragraph as follows: (b) "In measuring the thickness of the test specimen shown in Fig. 1 to determine the strength per square inch, a micrometer graduated to 0.001 in. having a shoe 0.24 to 0.26 in. in diameter, exerting a pressure of from 8 to 10 oz. on the test specimen shall be used."

Fig. 2 to be changed to Fig. 1.

14. Label: Change last sentence to read as follows: "This label shall be applied around the hose at a point 6 in. from the end, a variation of ½ in. either way will be permitted, and with the top of the lettering toward the center of the hose."

16. Rejection: Material which subsequently to above tests at the mills or elsewhere, and its acceptance or prior to being placed in service, develops weak spots or imperfections, or fails to pass any one of the tests herein required within sixty days from date of shipment, will be rejected and shall be replaced by the manufacturer at his own expense.

APPENDIX B

SPECIFICATIONS FOR STRUCTURAL STEEL, STEEL PLATE AND STEEL SHEETS FOR PASSENGER-EQUIPMENT CARS

I. MANUFACTURE

2. Process.—The steel shall be made by the open-hearth process.

II. CHEMICAL PROPERTIES AND TESTS

3. Chemical Composition.—The steel shall conform to the following requirements as to chemical composition:

Carbon, not over	0.25 per cent.
Manganese	Optional per cent.
Phosphorus, not over	0.05 per cent.
Sulphur, not over	0.05 per cent.

III. PHYSICAL PROPERTIES AND TESTS

6. Tension Tests.—(a) The material shall conform to the following requirements as to tensile properties:

	Structural Steel	Plates for Cold Flanging
Tensile strength, lb. per sq. in.	50 000—65 000	48 000—58 000
Yield point, min. lb. per sq. in.	0.5 tens. str.	0.5 tens. str.
Elongation in 8 in. min. per cent.	1 500 000	1 500 000
	Tens. str.	Tens. str.

(b) The yield point shall be determined by the drop of the beam of the testing machine.

7. Modification in Elongation.—(a) For material over ¾ in. in thickness, a deduction of 1 from the percentage of elongation specified in Section 6 (a) shall be made for each increase of ⅛ in. in thickness above ¾ in., to a minimum of 18 per cent.

(b) For material under 5-16 in. in thickness, a deduction of 2.5 from the percentage of elongation in 8 in., specified in Section 6 (a), shall be made for each decrease of 1-16 in. in thickness below 5-16 in.

8. Bend Test.—(a) The test specimen for structural steel shall bend cold through 180 deg. without cracking on the outside of the bent portion, as follows: For material ¾ in. or under in thickness, flat on itself; for material over ¾ in. to and including 1¼ in. in thickness, around a pin the diameter of which is equal to the thickness of the specimen; and for material over 1¼ in. in thickness, around a pin the diameter of which is equal to twice the thickness of the specimen.

(b) The test specimen for plates for cold flanging shall bend cold through 180 deg. flat on itself without cracking on the outside of the bent portion.

9. Test Specimens.—(a) Tension and bend test specimens shall be taken from the rolled material.

(b) Tension and bend test specimens, except as specified in Paragraph (c), shall be of the full thickness of material as rolled; and may be machined to the form and dimensions shown in Fig. 1, or with both edges parallel.

(c) Tension and bend test specimen for plates and bars over 1½ in. in thickness or diameter may be machined to a thickness or diameter of at least ¾ in. for a length of at least 9 in.

10. Number of Tests.—(a) One tension and one bend test shall be made from each melt; except that if material from one melt differs ⅜ in. or more in thickness, one tension and one bend test shall be made from both the thickest and the thinnest material rolled. Shapes less than 1 sq. in. in section need not be subjected to a tension test.

(b) If any test specimen shows defective machining or develops flaws, it may be discarded and another specimen substituted.

(c) If the percentage of elongation of any tension-test specimen is less than that specified in Section 6 (a), and any part of the fracture is outside the middle third of the gage length, as indicated by scribe scratches marked on the specimen before testing, a retest shall be allowed.

IV. PERMISSIBLE VARIATIONS IN WEIGHT AND GAGE

11. Perimssible Variations.—The cross section or weight of each piece of steel shall not vary more than 2.5 per cent. from that specified; except in the case of sheared plates, which shall be covered by the following permissible variations to apply to single plates:

(a) *When Ordered to Weight.*—For plates 12½ lb. per sq. ft. or over:

Under 100 in. in width, 2.5 per cent. above or below the specified weight; 100 in. or over in width, 5 per cent. above or below the specified weight.

For plates under 12½ lb. per sq. ft.:

Under 75 in. in width, 2.5 per cent. above or below the specified weight.

75 to 99 in., inclusive, in width, 5 per cent. above or 3 per cent. below the specified weight.

100 in. in width or over, 10 per cent. above or 3 per cent. below the specified weight.

(b) *When Ordered to Gage.*—The thickness of each plate shall not vary more than 0.01 in. under that ordered.

An excess over the nominal weight corresponding to the dimensions on the order shall be allowed for each plate, if not more than that shown in the following table, 1 cu. in. of rolled steel being assumed to weigh 0.2833 lb.

Thickness Ordered, In.	Nominal Weight, Lb. per Sq. Ft.	Allowable Excess (Expressed as Percentage of Nominal Weight), for Width of Plates, as Follows:						
		Under 50 in.	50 in. to 70 in. excl.	70 in. or over.	Under 75 in.	75 in. to 100 in. excl.	100 in. to 115 in. excl.	115 in. or over.
1/4 to 5/16	5.10 to 6.37	10	15	20	. . .	. . .	. . .	. . .
5/16 to 3/8	6.37 to 7.65	8 5	12 5	17	. . .	. . .	. . .	. . .
3/8 to 1/2	7.65 to 10.20	7	10	15	. . .	. . .	. . .	. . .
1/2 . . .	10.20	.	.	.	10	14	18	. . .
5/8 . .	12.75	.	.	.	8	12	16	. . .
3/4 . . .	15.30	.	.	.	7	10	13	17
7/8 . . .	17.85	.	.	.	6	8	10	13
1 . . .	20.40	.	.	.	5	7	9	12
1 1/8 . .	22.95	.	.	.	4 5	6 5	8 5	11
1 1/4 . .	25.50	.	.	.	4	6	8	10
Over 1 1/4	. .	.	.	.	3 5	5	6 5	9

(c) A variation from the length ordered of ⅛ in. either way will be permitted for lengths 12 ft. and under and ¼ in. either way will be permitted for lengths over 12 ft.

[NOTE:—Only the more important paragraphs of these specifications are printed here.—EDITOR.]

SPECIFICATIONS FOR STRUCTURAL STEEL, STEEL PLATE AND STEEL SHEETS FOR FREIGHT-EQUIPMENT CARS

These specifications are the same as those for passenger equipment cars with the exception of the section on physical properties and tests, which is as follows:—[EDITOR].

III. PHYSICAL PROPERTIES AND TESTS

6. Bend Tests.—(a) The test specimen for structural steel shall bend cold through 180 deg. without fracture on the outside of the bent portion as follows: For material ¾ in. in thickness and under, flat on itself; for material over ¾ in. to and including 1¼ in. in thickness, around a pin the diameter of which is equal to the thickness of the specimen; and for thicknesses over 1¼ in. around a pin the diameter of which is equal to twice the thickness of the specimen.

(b) Angles ¾ in. or under in thickness shall open flat, and angles ½ in. or under in thickness shall bend shut, cold, without fracture.

NOTE.—The above tests may be made either by pressure or by blows.

(c) Bend test specimens shall be 1½ in. or over in width by the thickness of the material, with planed or milled edges.

7. Number of Tests.—At least one bend test for structural steel shall be made for each thickness from each melt, and shall be taken from the finished product.

SPECIFICATIONS FOR MALLEABLE-IRON CASTINGS FOR PASSENGER AND FREIGHT EQUIPMENT CARS

I. MANUFACTURE

1. Process.—Malleable-iron castings may be made by either the open-hearth, air furnace or electric furnace process.

2. Annealing.—Malleable castings shall be neither over nor under annealed.

II. PHYSICAL PROPERTIES AND TESTS

3. Tensile Test.—The tensile strength of the standard test bar shall not be less than 38,000 lb. per sq. in. with an elongation, measured in 2 in., of not less than five per cent.

4. Transverse Test.—The standard transverse test bar, tested cope side up and on supports 12 in. apart, with the load applied at the center shall show the following deflection:

900 lb. with 1.25 in. deflection in ½ in. specimen
1400 lb. with 1.00 in. deflection in ⅝ in. specimen
2000 lb. with 0.75 in. deflection in ¾ in. specimen

NOTE.—The test specimen shall be 14 in. long, 1 in. wide and either ½, ⅝ or ¾ in. thick, these thicknesses to be proportional to the thickness of the material which they represent.

7. Standard Test Bars.—All test bars shall be cast without chills, and with the ends left perfectly free in the molds, using heavy risers of sufficient height at each end to insure sound bars. Of the bars selected, two tensile and two transverse test bars shall be cast in one mold. Where the full heat goes into castings which are subject to specifications, two molds shall be poured within five minutes after tapping into the first ladle and two from the last iron of the melt. Molds shall be suitably stamped to insure identification of the bars, the bars being annealed with the castings. Where only a partial melt is required for work in hand, two molds shall be cast from the first ladle used and two after the required iron has been tapped.

(a) *Tensile Test Bars.*—The test bar as cast shown in Fig. 2 shall be used for all tensile tests.

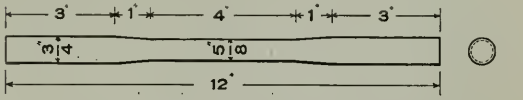

Fig. 2.—Test Specimen for Malleable Iron Castings

(b) *Transverse Test Bars.*—The purchaser and the manufacturer may agree upon a transverse test bar, as cast, the width of which shall be 1 in., the thickness ½ in., ⅝ in. or ¾ in., depending upon the thickness of the castings represented, and the length to be 14 in.

8. Number of Tests.—Of the test bars required for each melt, two shall be tested for tensile strength and elongation and two for transverse deflection; these bars shall be taken from the hottest and coldest parts of the annealing furnace.

[NOTE:—Only the more important paragraphs of these specifications are printed here.—EDITOR].

SPECIFICATIONS FOR MISCELLANEOUS STEEL CASTINGS FOR PASSENGER AND FREIGHT-EQUIPMENT CARS

I. MANUFACTURE

1. Process.—The steel may be made by the open-hearth, crucible or any other process approved by the purchaser.

2. Heat Treatment.—Castings shall be allowed to become cold, they shall then be uniformly reheated to the proper temperature to refine the grain (a group thus reheated being known as an annealing charge), and allowed to cool uniformly and slowly. If, in the opinion of the purchaser or his representative, a casting is not properly annealed, he may at his option require the casting to be reannealed.

II. CHEMICAL PROPERTIES AND TESTS

8. Chemical Composition.—The steel shall conform to the following requirements as to chemical composition:

Carbon	Optional per cent.
Manganese	Optional per cent.
Phosphorus, not over	0.05 per cent.
Sulphur, not over	0.05 per cent.

III. PHYSICAL PROPERTIES AND TESTS

6. Tension Tests.—The steel shall conform to the following minimum requirements as to tensile properties:

Tensile strength, lb. per sq. in.	60 000
*Elongation in 2 in., per cent.	1 400 000/tensile strength
Reduction of area, per cent,	30.

*Not under 22 per cent.

7. Alternative Tests to Destruction.—In the case of small or unimportant castings, a test to destruction on three castings from a lot may be substituted for the tension tests.

8. Test Specimens.—(a) Sufficient test bars, from which the test specimens required in Section 9 may be selected, shall be attached to castings weighing 500 lb. or over, when the design of the castings will permit. If the castings weigh less than 500 lb., or are of such a design that test bars cannot be attached, two test bars shall be cast to represent each melt; or the quality of the casting shall be determined by tests to destruction as specified in Section 7. All test bars shall be annealed with the castings they represent.

9. Number of Tests.—One tension test shall be made from each melt.

[NOTE:—Only the more important paragraphs of these specifications are printed here.—EDITOR.]

SPECIFICATIONS FOR JOURNAL BEARINGS FOR PASSENGER AND FREIGHT-EQUIPMENT CARS

1. Classification.—This specification will cover two grades of bearings and will be known as *A* and *B*.

I. CHEMICAL PROPERTIES AND TESTS

2. Composition of Shell.—The shell shall conform to the following requirements as to chemical composition:

SHELL	A.	B.
Lead	24.0 to 30.0 per cent.	8.0 to 16.0 per cent.
Tin, not less than	4.0 per cent.	7.0 per cent.
Zinc and other impurities, not over	3.0 per cent.	3.0 per cent.
Copper, not less than	65.0 per cent.	Not over 82.0 per cent.

3. Composition of Lining.—The lining metal shall conform to the following requirements as to chemical composition:

LINING	Up to ⅛ In.	⅛ In. and Over.
Lead	94.0 to 96.0 per cent.	Not over 88.0 per cent.
Antimony and Tin	3.0 to 5.0 per cent.	17.0 per cent.
Tin	0.50 to 1.5 per cent.	
Other impurities, not over	0.5 per cent.	0.75 per cent.

4. Analysis.—The sample for chemical analysis shall be taken from the shell and lining at three points along the fractured surface, described in Section 5, either by drilling or by using cuttings thus obtained, well mixed.

II. PHYSICAL PROPERTIES AND TESTS

5. Tests.—The finished bearing representing a lot for acceptance shall be broken along the center line of the bearing, without nicking, in order to ascertain the uniformity of the grain of the metal. When this fracture shows distinct signs of imperfect mixing, such as separation of component parts and dross or dirt spots, the lot shall be rejected.

6. Number of Tests.—Bearings shall be divided into lots of three hundred or less and one bearing shall be taken for test and chemical analysis from each lot.

III. PERMISSIBLE VARIATIONS IN GAGINGS

7. Gaging.—All bearings shall conform to gages and dimensions shown on drawings, and when linings are required they shall conform to the gages and dimensions for linings as shown on drawings.

IV. MARKING

8. Marking.—Each lot of three hundred or less shall bear a serial number, commencing with one at the beginning of the year and continuing consecutively until the end of the year, the year when cast, and the pattern number, legibly cast, by depressing the letters, on the sloping surface of the shoulder of the brass, and on the opposite sloping shoulder the railroad company's initials, M. C. B., and either "A" or "B," depending on the composition of the metal, and the figures to show the size of the journal bearing, and on the collar the manufacturer's name or trade-mark. All letters to be ¾ in. high, except the manufacturer's name or trade-mark which should be the width of the shoulder or collar. The above marking shall be in accordance with Fig. 3.

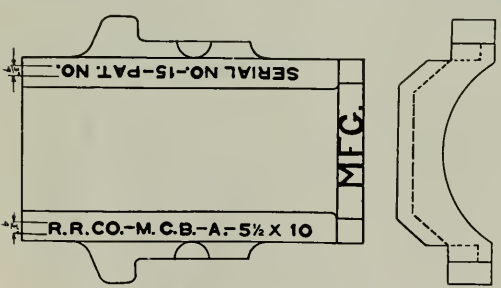

Fig. 3.—Marking for Journal Bearings

[NOTE:—Only the more important paragraphs of these specifications are printed here.—EDITOR.]

SPECIFICATIONS FOR MILD STEEL BARS FOR PASSENGER AND FREIGHT-EQUIPMENT CARS

I. MANUFACTURE

2. Process.—The steel shall be made by the open-hearth process.

II. CHEMICAL PROPERTIES AND TESTS

3. Chemical Composition.—The steel shall conform to the following requirements as to chemical composition:

Carbon .....Optional per cent.
Manganese .....Optional per cent.
Phosphorus, not over.....0.05 per cent.
Sulphur, not over.....0.05 per cent.

*This material may be used when so desired for rivet steel.

III. PHYSICAL PROPERTIES AND TESTS

6. Tension Tests.—The steel shall conform to the following requirements as to tensile properties:

Tensile strength, lb. per sq. in....50 000-65 000 for sizes smaller than 1 in flats and 2 in rounds.
Tensile strength, lb. per sq. in....50 000-60 000 for larger sizes.
Elongation in 8 in., per cent.....1 500 001 tensile strength.

7. Yield Point.—The yield point as determined by the drop of the beam of the testing machine shall be one-half the ultimate tensile strength.

8. Bend Test.—The test specimen for rounds, squares and hexagon bars shall bend cold through 180 deg. without cracking on the outside of the bent portion, as follows: For material ¾ in. or under in thickness, flat on itself; for material over ¾ in. to and including 1¼ in. in thickness, around a pin the diameter of which is equal to the thickness of the specimen; and for material over 1¼ in. in thickness, around a pin the diameter of which is equal to twice the thickness of the specimen.

9. Test Specimen.—Tension and bend-test specimens shall be of the full section of material as rolled, if possible; otherwise the specimen shall be machined from the material as rolled. The axis of the specimen shall be located at any point one-half the distance from the center to the surface of round bars, or from the center to the edge of flat bars, and shall be parallel to the axis of the bar.

10. Number of Tests.—(a) All bars of one size shall be piled separately. One bar from each 200 or less shall be selected at random and tested as specified.

IV. PERMISSIBLE VARIATIONS IN GAGE

11. Permissible Variations.—(a) *Round Bars.*—Round bars shall conform to the limits as given in Table No. 1.

TABLE No. 1

NOMINAL DIAMETER OF STEEL IN.	Large Size End, In.	Small Size End, In.	Total Variation, In.
¼	0.2550	0.2450	0.010
5/16	0.3180	0.3070	0.011
⅜	0.3810	0.3690	0.012
7/16	0.4440	0.4310	0.013
½	0.5070	0.4930	0.014
9/16	0.5700	0.5550	0.015
⅝	0.6330	0.6170	0.016
¾	0.7585	0.7415	0.017
⅞	0.8840	0.8660	0.018
1	1.0095	0.9905	0.019
1⅛	1.1350	1.1150	0.020
1¼	1.2605	1.2395	0.021
1⅜	1.3860	1.3640	0.022
1½	1.5115	1.4885	0.023
1⅝	1.6370	1.6130	0.024
1¾	1.7625	1.7375	0.025
1⅞	1.8880	1.8620	0.026

Round steel 2 in. and over in diameter shall not be under size or more than 1/32 in. greater in diameter.

(b) *Flat Bars.*—Thickness shall not vary more than corresponding diameter for rounds; thus, 1 in. thick could vary from 0.9905 to 1.0095 in.

(1) Sizes under 3 in. wide shall not be more than 1/32 in. under or over size in width.

(2) Sizes 3 in. and over shall not be under size or more than 1/16 in. wider than ordered.

[NOTE.—Only the more important paragraphs of these specifications are printed here.—EDITOR.]

SPECIFICATIONS FOR RIVET STEEL AND RIVETS FOR PASSENGER AND FREIGHT-EQUIPMENT CARS

I. MANUFACTURE

1. Process.—The steel shall be made by the open-hearth process.

II. CHEMICAL PROPERTIES AND TESTS

2. Chemical Composition.—The steel shall conform to the following requirements as to chemical composition:

Carbon .....Optional per cent.
Manganese .....Optional per cent.
Phosphorus, not over.....0.05 per cent.
Sulphur, not over.....0.05 per cent.

5. Number of Samples for Chemical Analysis.—One bar from every 200 bars or less of each different size of section shall be taken, and a piece 2 ft. long shall be cut off and given the purchaser or his representative, or 10 rivets from every 100 kegs. These samples shall be used for check analysis by the purchaser.

III. PHYSICAL PROPERTIES AND TESTS

6. Tension Tests.—The bars shall conform to the following requirements as to tensile properties:

Tensile strength, lb. per sq. in.....45 000-60 000
Elongation in 8 in., per cent.....1 500 000/tensile strength

7. Bend Tests.—The test specimen shall bend cold through 180 deg. flat on itself without cracking on the outside of the bent portion.

8. Test Specimens.—Tension and bend-test specimens shall be of the full-size section of bars as rolled.

9. Number of Tests.—(a) All bars of one size shall be piled separately. One bar from each 200 or less shall be selected at random and tested as specified.

[Permissible variations are the same as those given in the specifications for mild-steel bars.—EDITOR.]

16. Bend Tests.—The rivet shank shall bend cold through 180 deg. flat on itself, without cracking on the outside of the bent portion.

17. Flattening Test.—Rivet heads shall be flattened down cold to a thickness of one-third, and when hot to a thickness of one-fourth, of the original diameter of the shank at the working heat when driving without splitting.

18. Number of Tests.—One of each of the above tests shall be made for each 100 kegs for each different size of rivets.

19. Size of Heads.—Standard rivet heads shall conform to the following:

Size Diameter, In.	Head.		Countersunk.	
	Height, In.	Diameter, In.	Depth, In.	Diameter, In.
1/2	3/4	7/8	1/4	2 3/32
5/8	29/64	1 1/16	5/16	1
3/4	17/32	1 1/4	3/8	1 3/16
7/8	39/64	1 7/16	7/16	1 3/8
1	11/16	1 5/8	1/2	1 9/16
1 1/8	49/64	1 13/16	9/16	1 3/4
1 1/4	27/32	2	5/8	1 15/16

[NOTE:—Only the more important paragraphs of these specifications are printed here.—EDITOR.]

SPECIFICATIONS FOR GALVANIZED SHEETS FOR PASSENGER AND FREIGHT EQUIPMENT CARS

I. MANUFACTURE

1. Process.—The sheet material manufactured under this specification may be either a mild steel or iron made from puddled bars made wholly from pig iron, and shall be thoroughly cleaned before being coated.

II. PHYSICAL PROPERTIES AND TESTS

2. Bend Test.—Test specimen as described in Section 3 shall be subjected to the following tests:

(a) Test specimen shall bend double on itself around two thicknesses of the material tested and straightened, without showing any cracking or flaking of the galvanizing on either side of the test specimen.

(b) Test specimen of the base material shall bend twice in the same direction, first around a mandrel the diameter of which is equal to 15 gages of the material tested and straightened, and then bent flat on itself and straightened, without cracking of the specimen.

(c) Gages 26 and lighter shall double-lock seam without cracking of the sheet or galvanizing.

3. Test Specimen.—(a) Strips about 8 in. long and 2 in. wide shall be cut from the center of a sheet selected at random from each lot of 1000 sheets or less, and the average thickness or weight of the coating across this width shall be used.

(b) Corrugated sheets shall be flattened with a wooden maul before making the required tests.

IV. PERMISSIBLE VARIATIONS

6. Permissible Variations.—(a) The inspector shall weigh and check the measurements of one sheet in each 200 sheets in each order or shipment.

(b) A variation in weight of the finished sheet of 2½ per cent either way from that shown in the following table will be allowed.

*Gage No.	Thickness of Sheets, In.	Weight of Sheets per Sq. Ft., Oz.	Minimum Weight of Coating per Sq. Ft., Oz.	*Gage No.	Thickness of Sheets In.	Weight of Sheets per Sq. Ft., Oz.	Minimum Weight of Coating per Sq. Ft., Oz.
16	.0625	42.50	2.00	25	.021875	16.50	1.45
18	.0500	34.50	1.90	26	.01875	14.50	1.40
20	.03750	26.50	1.80	27	.017187	13.50	1.35

*The above gage is of the finished sheet.

[NOTE:—Only the more important paragraphs of these specifications are printed here.—EDITOR.]

(The report will be submitted to the association by letter ballot for adoption as recommended practice.)

TANK CARS

The report was submitted by A. W. Gibbs, (Penna.) who said: As chairman of the Tank Car Committee, I have taken the responsibility of making no recommendations affecting the tank car specifications this year. This is not for the reason that the committee does not feel that certain changes should be made in the Specifications. After the meeting of the committee, however, complaint with respect to the 60 lb. test pressure required for cars carrying inflammables was made before the Interstate Commerce Commission by the National Petroleum Association and others, against the Pennsylvania Railroad and the Atchison, Topeka and Santa Fé directly, but, really, as stated in the complaint, against "railroads generally throughout the United States, too numerous to be made defendants." The complainants ask the commission to restrain the railroads from enforcing the requirements of the specification, and to find and put into effect such pressure test as it may find to be just and reasonable. If the complaint is sustained, it is probable that other requirements of the specifications may be attacked, and it may be necessary to change the whole specification. It is therefore felt that it would be unwise to make any change in the present specifications until it is known by the decision of the commission in this case whether they are to be reversed or modified by the commission.

A number of questions of tank car owners are now before the committee.

As regards the recommendation of the Arbitration Committee that the Tank Car Committee name a date after which tank cars not strictly complying with the M. C. B. Tank Car Specifications shall not be received in interchange, the committee recommends that this question be held in abeyance for one year, for the reasons already given for not taking any action concerning tank cars at this time.

THE LAMENT OF THE FOREIGN BAD-ORDER EMPTY CAR

At the opening of the afternoon session yesterday, when the rules of interchange were under consideration, Secretary Taylor read the following amusing anonymous poem with the above caption:

No one seems to care
How many moves I make;
No one seems to worry
At the circuitous routes I take.
No one sees me moving
From Maine to Californ—
And I get so tired and weary
I wish I never was born.
No one wants to fix me,
No one will spend a cent
To put me in good condition,
So I can earn the rent.
My owner will pay the money,
As soon as the work is done,
As soon as I'm fixed and ready
To go out on the road and run.

But it's always the same old story,
As I wander from road to road,
In search of a friendly fellow,
Who'll fix me up for a load.
"There's nothing allowed to repair you."
Is all they say at each place,
"We need all the money allowed us,
To keep our own cars in the race."
And so I just wander and wander,
O'er the face of the whole country wide,
With a "Bad Order—Return When Empty"
Carding upon my side.
Somebody ought to fix me,
I don't *want* to roam,
So if you can't spare the money,
Please, sir, *please* send me home.

THE DRIVING CONTEST IN PICTURES

The Daily published yesterday an account of the golf driving contest from the roof of the Hotel Traymore over the Boardwalk into the ocean which was participated in by D. R. MacBain, C. F. Street and S. P. Bush. While the driving was going on a photographer was stationed on the dome just back of the tee, but the pictures taken were not finished in time to be reproduced in yesterday's *Daily*. They are given herewith, and they probably illustrate the highest golf driving

George Carr and Will Johnson Just Before They Went to Sea

contest ever held in the history of the great Scotch game. The publicity agent of the hotel confides to us that the roof of the Traymore is the most elevated point on the Atlantic Coast south of the Statue of Liberty, and in the absence of evidence to the contrary we take his word for it.

The players can be very distinctly seen in the photographs. The judges are less fortunate. Even in the picture of them going to sea the familiar features of Will Johnson and George Carr cannot be recognized. In the other pictures the boat

The Judges Going to Sea

and its occupants are shown as a mere blur because when the camera was snapped the boat was doing gymnastic stunts as energetic as the army setting-up exercises.

We present a photograph taken of Messrs. Carr and Johnson just before they went aboard. We regret not to be able to present one of them just after they came ashore, for the contrast between Mr. Carr's clothes before and after a large

C. F. Street Showed Excellent Form

roller from mid-ocean had swamped him was striking. Everybody who has seen the picture of C. F. Street admires the

D. R. MacBain Driving—The Judges' Boat in the Distance To the Left of the Cross

excellent golf form he showed even though he did not get the distance attained by S. P. Bush.

S. P. Bush Winning the Driving Contest on the Traymore's Roof

THE WINNERS IN THE GOLF TOURNAMENT

The tie for the prizes in the medal handicap of the golf tournament was played off yesterday by D. R. MacBain, C. R. Naylor, and George A. Post, Jr. Mr. MacBain won the first prize with a score of 108-36-72; Mr. Naylor won the second with 108-31-77, and Mr. Post was third with 104-26-78.

The tie for the third prize in the kickers' handicap also was played off, the winner being W. J. Tollerton.

M. C. B. CARNIVAL DANCE

The M. C. B. Carnival Dance last night was in point of its success as well as in many other respects, a repetition of the carnival dance of last week. One of the features of the program was a skating act by Miss E. M. Kegel and Harry Walls. Miss Betty Lee also sang some of the best songs from her repertoire. The music was furnished by the Don Richardson orchestra.

The committee in charge of the dance included Langley Ingraham, chairman; Burton W. Mudge, J. F. Forney, H. W. Hegeman, G. R. Berger, D. E. Sawyer, W. H. Bentley and C. W. F. Coffin. The crowd was large and everybody seemed to have a very merry time.

LITTLE INTERVIEWS

Co-operation between the Interstate Commerce Commission and the railways was the keynote of an interview given yesterday by George B. McGinty, secretary of the commission, regarding the legislation recently enacted by Congress extending the regulatory authority of the commission over the entire locomotive. "It will be necessary," said Mr. McGinty, "to draw up rules and regulations for the application and administration of this legislation. We recognize the fact that this will not be an easy task and that if it is to be done satisfactorily it will be necessary for the representatives of the commission and of the railways to co-operate frankly and fully. The commission usually has received the close co-operation of the representatives of the carriers in the administration of the boiler inspection law, and I am sure that we will receive it in the application of broader provisions of the new law. The better the understanding reached and carried out, the more satisfactory the results would be for all concerned."

WILLIAM S. MORRIS DEAD

Word was received from Mrs. W. S. Morris, of Fort Wayne, that Mr. Morris died at 4 o'clock Tuesday morning. Mr. Morris is well known because of the interest that he took in the work of both the Master Car Builders' and Master Mechanics' Association; he was president of the latter in 1900-01. He was born March 4, 1857, at Chicago, and was educated in the public schools of that place and at the Cook County Normal School. He entered railway service in 1874 as a machinist apprentice on the Housatonic and at the completion of his apprenticeship worked as a journeyman machinist on that road and on the Wabash. In 1879 he became a locomotive fireman, later being advanced to the position of engineer and then becoming master mechanic of the Fort Wayne, Cincinnati & Louisville. In 1884 he went with the Missouri Pacific as master mechanic, but in 1886 returned to the Wabash as master mechanic of the eastern division. In 1889 he was made superintendent of motive power and rolling stock of the Chicago & West Michigan; Detroit, Lansing & Northern; and Saginaw Valley & St. Louis roads. From April, 1893, to June, 1902, he was superintendent of motive power of the Chesapeake & Ohio, leaving to take the position of mechanical superintendent on the Erie in June, 1902, and remaining in that position until April, 1904. For a short time he was in the supply business and then returned to the Chesapeake & Ohio remaining in the transportation department of that road for two or three years, after which he retired and has since been living in Fort Wayne, Ind.

Conventionalities

Amos Turner, master mechanic of the Lehigh Valley, who is attending the conventions, has been in the service of that road over 50 years. He is commonly known as the "Grand Old Man."

R. W. Burnett, vice-president of the M. C. B. Association, who until recently was with the Canadian Pacific, will not be at the convention. He is making an extensive western trip which will include a visit to the Panama Exposition.

Wm. Schlafge, Gen. Supt. of Motive Power, Erie Railway

Frank A. Barbey, of good old Boston town won't have as good an opportunity to distribute his American flags this year on June 17, Bunker Hill Day, as the conventions come earlier than usual. However, he wants us all to remember that that is the day Boston should be sacredly remembered.

Among the missing faces are those of O. C. Gayley, vice-president of the Pressed Steel Car Company, and J. F. MacEnulty, general manager of sales of the same concern. Mr. Gayley is of a retiring disposition and makes little noise, while Mr. MacEnulty is the reverse. By the law of averages, therefore, the hole in this year's din, made by their absence, is sufficiently large to be noticeable.

F. C. Pickard, master mechanic of the Lackawanna at Buffalo, brings word from his general foreman, W. W. Scott, who is president of the International Railway General Foremen's Association, that all of the reports for the annual meeting of that association are in hand and will shortly be issued in printed form so that the members will have plenty of time to study them over in advance of the meeting next July.

THE ARBITRATION COMMITTEE

Top Row, Left to Right—James Coleman, Supt. Car Dept., Grand Trunk; T. H. Goodnow, Asst. Supt. Car Dept., C. & N. W., and T. W. Demarest, Supt. Motive Power, Penna. Lines.

Bottom Row—J. J. Hennessey, M. C. B., C. M. & St. P., and F. W. Brazier, Supt. Rolling Stock, N. Y. C.

TWO PITTSBURGH & LAKE ERIE FAMILIES

Master Car Builder Sam Lynn, with Mrs. Lynn and Daughter on the Left, and Mechanical Engineer W. P. Richardson, with Wife and Daughter Alice on the Right

Charles A. Lindstrom, assistant to president of the Pressed Steel Car Company, is a grandfather, a little daughter having been born to Mr. and Mrs. Frank Cairns, of Toronto, on Sunday, June 6. Mrs. Cairns used to attend these conventions as Miss Charlotta Lindstrom, and was married last spring. Mr. Lindstrom's daughter Jean, also a regular conventionite, was married on June 8 to John Clark, of Clarksburg, Va. Mr. and Mrs. Clark wil live in Pittsburgh.

Some of the Thirty-Five Members of the Illinois Athletic Club Who Are in Attendance at the Convention

Top Row—W. H. Bentley, Will Miller, F. L. Barber. W. L. Allison, C. W. Floyd Coffin, C. J. Olmstead, L. D. Mitchell, C. J. Blatchford.

Second Row—William Anderson, C. C. Farmer, B. W. Mudge, B. Pratt, R. W. Benson, Frank O'Brian.

Third Row—Joe Brown, George H. Porter, W. J. Walsh, Albert MacRae, Claude Baker, John P. Landreth.

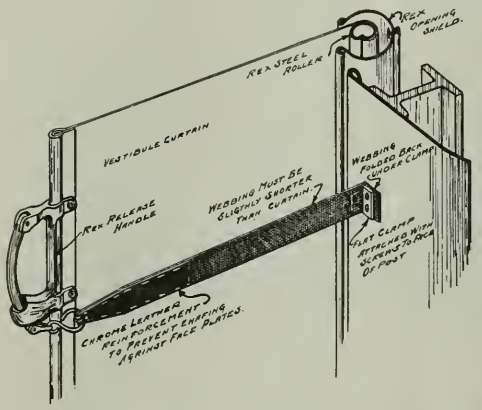
A GROUP OF CHIEF CAR INTERCHANGE INSPECTORS

Top Row, Left to Right—M. W. Halbert, W. J. Stoll, T. J. O'Donnell, B. M. Waldo.

Bottom Row—J. W. Hogsett, F. W. Tapnell, H. Boutet, W. R. McMunn.

IMPROVEMENTS TO REX DIAPHRAGM CURTAINS

The Curtain Supply Company, Chicago, is now arranging its vestibule curtains so that the webbing connected to the releasing handle is attached to the face of the post instead of to the roller, as has been formerly customary. This is done for the purpose of reducing the wear of the curtain due to webbing rubbing against it. The manner in which the releasing handle is connected to it is clearly shown in the illustration. The



Improved Arrangement for Tripping the Rex Releasing Handle

webbing is reinforced with chrome leather at the end where it rubs against the face plates. It has been found that most satisfactory results are obtained with this arrangement and that the life of the curtain is lengthened.

SOLID FORGED BRAKE BEAM FULCRUM

The illustration shows a forged brake beam fulcrum of a type which was originally developed by the Damascus Brake Beam Company, Cleveland, Ohio, for application to this company's own beams. This design is applicable to beams of channel

Forged Brake Beam Fulcrum for Channel Section Beams

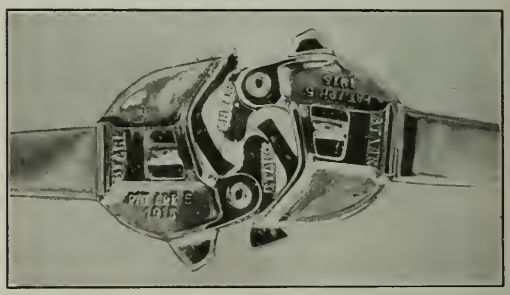
section and is clamped to the beam without the necessity of drilling holes through the latter. It is held in position by a single bolt which clamps the sides of the fulcrum against the outside of the channel. This and other types of solid forged fulcrums are on exhibit at the booth of the Damascus Brake Beam Company.

NEW RAILWAY LINES IN RUSSIA.—In connection with the proposed direct international railway communication, the Russian tariff committee proposes to construct direct lines connecting Archangel with Vologda, Petrograd, Moscow, Kief, Warsaw, Saratof, Kharkof, Odessa, Ekaterinoslav, Omsk, Riga and Reval, and through Archangel connecting with the ports of New York, Halifax, Liverpool and Glasgow.

AUTOMATIC COUPLER WITH MOVABLE GUARD ARM

A coupler designed to be automatic in its action under all conditions is being exhibited by the Stark Car Coupler Corporation, Washington, D. C. Present standard couplers will not couple when both knuckles are closed, and under certain conditions when only one knuckle is open. It is often necessary to run the risk of injury in adjusting the position of the couplers on moving cars to insure that the coupling will "make." The Stark coupler is provided with a movable guard arm which is free to open except when coupled. This provides sufficient opening between the side of the knuckle and the guard arm to permit closed knuckles to pass each other, thus insuring automatic action under all conditions.

The movable guard arm is pivoted against a shoulder in the coupler head. It is provided with a tail piece which conforms to the contour of the head when closed. When open this swings out from the face of the head and on coupling is forced back to the contour line by the knuckle of the adjoining coupler, by which it is held in the closed position.



Couplers with Movable Guard Arms Open

The design of this coupler offers several advantages aside from its automatic action. The most notable of these is the ability to renew all wearing parts. The guard arm is as readily replaced as the knuckle and the life of the head is thus greatly increased.

TURRET LATHE OPERATION.—The Warner & Swasey Co. have been demonstrating some interesting possibilities of the turret lathe at their exhibit. One example was on aeroplane motor cylinders which are being finished in 2½ hours as compared to 37 hours, the former time.

KELLEY COUPLER.—The Kelley Railway Appliance Company, Gradyville, Ga., is exhibiting a coupler which is arranged to permit unlocking when under load. The knuckle tail and the lock block have diagonal surfaces which eliminate the friction which must be overcome in lifting the lock. When locked the knuckle lock is prevented from working up by an additional locking device of small area which swings over the top of the main lock. The knuckle and head are designed to relieve the knuckle pin of strain when the coupler is closed.

FRICTION BUFFER—The Gould Coupler Company, New York, is exhibiting this year a recently developed friction buffer for heavy steel passenger equipment which has a total travel of 5 in. When free the buffer extends beyond the coupling line 2½ in., which is sufficient to insure that the buffers will not separate when the cars are coupled. A further travel of 2½ in. brings into action the friction draft gear which has a capacity ranging from 100,000 lb. to 150,000 lb. as may be desired. The friction elements are contained in a housing, making a complete unit, the principle of construction being the same as in all Gould draft gear. Two release springs are used to insure the release of the friction elements.

The RAILWAY AGE GAZETTE and all other Simmons-Boardman publications are members of the Audit Bureau of Circulations.

Provide Good Car Repair Facilities

A great many of the engine houses on American railways were, up to a few years ago, poorly built, poorly equipped, and in general, places calculated to make the effective repairing of locomotives as difficult as possible. There has been a great improvement in these conditions within recent years, but there has not been a corresponding improvement in car repair yards. The old idea that the worst place in the yard will do for the "rip" tracks still holds in many places. We have in mind one case in particular in which the terminal has a new and modernly equipped engine house, while the car repair tracks are in a most inconvenient location, with the space between them not leveled off or planked, and the material stores a full half mile away. Such conditions as these prevent the prompt repairing of cars, cause friction between the mechanical and the operating departments, and increase expenses.

Impact Between Freight Cars

The individual paper on Impact Between Freight Cars in Switching Service, by Prof. L. E. Endsley, proved of very considerable interest to the convention and brought out a lively discussion. There seems, however, to be quite a little difference of opinion concerning the amount of such shocks, and judging from this and the curves presented in the paper, it would seem desirable to go further into the matter. It hardly seems possible that the enormous shocks indicated could be absorbed by present-day car construction; in fact, if such shocks were very frequent in service it would seem that there must be a great increase in the number of disabled cars. The investigation, however, is of extreme interest, and bearing so directly on the matter of efficient draft gear, the association acted wisely in referring the matter to a committee for further investigation.

Joint Car Repair Shops

The proposition of providing a joint car repair shop at large terminals for the purpose of making repairs to foreign equipment coming into these terminals, is a question of importance. The General Superintendent's Association, of Chicago, is now seriously considering a proposition of this kind. The establishment of a joint shop in the switching district of Chicago, located at the Stock Yards, is the plan it has in mind. By this means it will be possible to take defective cars coming into this district and repair them, making them available for loads. The switching of defective cars to the lines from which they were received will be eliminated, with the corresponding expense and a reduction in congestion of the switching lines. It has been estimated that 250 cars per day would need such repairs at the joint shops in Chicago, these to include both light and heavy repairs. Such shops would also increase the available car supply in the congested districts, thereby saving considerable money both in intermediate charges and per diem which accumulates while such cars are being moved back and forth.

The M. C. B. No. 2 Brake Beam

The M. C. B. Committee on Brake Shoe and Brake Beam Equipment has twice submitted to the association a recommendation for a standard No. 2 brake beam which it considered satisfactory for adoption as recommended practice. On both occasions the association refused to adopt the committee's recommendations, but, as stated on the floor of the convention on Monday, the committee was unable to obtain from those who objected to the beam any specific reasons for their action or any definite information which would help them in deciding on a design which would meet with general approval. Whatever the reasons for such action, it can scarcely be termed creditable to the association. If the members were not in agreement with the action of the committee they should have at least stated their reasons, giving the committee something to go on in continuing its work. As no specific information was obtainable after the recommendations had beeen rejected, there was, of course, nothing left for the committee to do but drop the matter; but this year the discussion in the convention brought out clearly that the brake beam as recommended previously by the committee is desirable.

Wooden Draft Arms

In the report of the Committee on Car Construction it was recommended that the draft attachments, including the draft arms, if used, must be of metal, of either integral or riveted construction S. G. Thomson, in explaining this, said that it was placed in the report to get rid of the old wooden draft arms which are causing so much of the trouble with the draft gear. The committee has considered the advisability of requiring the removal of all wooden draft arms from cars in interchange service by a certain date. It was decided, however, not to take any definite step at present, but the members would do well to carry out Mr. Thomson's suggestion. Wooden draft arms are a source of great trouble; the sooner they are dispensed with the better. Railways should take it upon themselves to remove them just as quickly as possible so

that if a date is finally set in which cars so equipped will not be received in interchange service, the number of cars left to be changed will not be so large that a remote date will be necessary. The members of the association have here an opportunity to be of great service to the railways in general without the compelling force of any association requirement.

Developing Car Foremen

Because of the large amount of work that is done piecework in the car department, and the employment in such work of unskilled and illiterate laborers, this department has suffered beyond some of the other branches of railway work. It is a trying problem under such conditions to obtain the right class of men for development into inspectors and foremen. The requirements of interchange make it necessary that car department officers be of a studious nature and capable of handling the large number of reports and statements which originate in such work. This requires men of more than ordinary intelligence and it is seldom that they can be procured or developed from the class of labor that is commonly employed in making car repairs. The position of car inspector is the most natural one from which to select a man to advance to the position of foreman, as an inspector must be thoroughly familiar with car repairs. It will, therefore, be necessary to develop some means of training men along these lines for later promotion to the minor official positions. An efficient apprenticeship system would seem to be the most logical means of accomplishing this and great care should then be taken in selecting the men for promotion to see that those chosen show promise of the proper qualifications.

SCIENTIFIC SELECTION OF MEN

WE commented in *The Daily* of June 9th on Professor Herman Schneider's paper before the National Association of Corporation Schools on the selection of men for given jobs. Long study, based on practical observations of an exceptional nature, has forced Professor Schneider to the conclusion that the only way of successfully selecting a man is by actual practical trial on the job. If the man fails, the reasons for the failure should make it possible to transfer him with some degree of assurance to a class of work for which he is better fitted. Assume for a moment, however, that Professor Schneider is wrong and that it is possible scientifically to select men by other means that require a less tedious and shorter examination or observation. What good would it do if the organization was such as not to make scientific use of the men after they were selected? How many organizations are now operated on such a basis that the officers know with any degree of accuracy whether they are getting the best efficiency from the men as individuals, or the organization as a whole? How many railway officers really know whether they are getting 50, 75 or 90 per cent efficiency from the department under their direction, whether it be a repair shop, a car repair yard, an engine terminal, or an office?

Instances are not by any means unusual where investigation has developed the fact that a department was working at 50 or 60 per cent efficiency. Better supervision, improved facilities, etc., may have been introduced which brought it up to 90 or 95 per cent efficiency. The point which we wish to make is that employers are not by any means making the best use of the men that they have, and until this is better understood there is little or no use of going to extremes in trying scientifically to select men. It is true that there may be certain highly specialized jobs which require men of a special type, but such jobs are comparatively few. On average jobs the average men available will do about as well in one class of work as another, within reasonable limits.

Our friends in certain of the European railway shops, realizing the necessity of trying the men out in a practical way, are handling this matter in a way which we can well afford to study with a view to improving our own practices. They study the apprentices while they are in training and find out just what classes of work they make the best records on and seem best adapted to. At the end of their apprenticeship they are assigned to certain departments on the basis of this data, which is a matter of record. For instance, if they are of what may be designated the mental type, there is little use of assigning them to manual work. A man with a highly nervous disposition will make a success of certain classes of work in the machine or erecting shop, but will have an extremely low efficiency on work which requires a steady plodder. Certain types of work require initiative; others do not call for this characteristic and can be filled by men who are good on routine work but helpless when it comes to developing new plans or methods.

It would seem that under present conditions we are not warranted in going much farther into the scientific selection and assignment of men than is done on these foreign roads. There is a field, however, which offers great possibilities, but which thus far has not been worked to any great extent by either our railroad or industrial managers; this is, that of more critical and logical study of the performance and possibilities of the men already in the service, and this study should extend from the very top to the bottom of the organization. No man should ever be promoted in a haphazard manner. Records should be available, and these can be easily kept and at a very low expense, showing in a rough but fairly accurate manner whether a man is good or bad in respect to those traits which affect his work and fit or unfit him for executive positions. When the time comes for promotion, it is not safe to look a man over and promote him on the basis of the impressions of the moment as to his fitness for the job, but simple records should be available as to his work and personality which will check this decision. These records should be revised from time to time so that the supervising officer will know whether a man is improving or not, and whether his immediate superior officer is developing him along proper lines. Such a system has been tried out with good practical results, and was fully described in the *American Engineer* of November, 1908.

If you do not have such records, why not? It is a comparatively easy and simple matter to install and maintain them, and the expense is practically negligible. The trouble is not so much to know how to do the thing as to get people to realize the necessity of so doing, or in other words, to wake them up to a matter of vital importance which is not now as generally appreciated as it should be. Until those in charge make every effort to study and analyze their men in this way, in order to get the maximum individual and collective efficiency from them, there is little use in wasting time in going to extremes in selecting the raw material which is taken into the organization at the bottom; and, moreover, if Professor Schneider's conclusion is correct, and the data which he presents leaves very little question as to its correctness, it is folly to try to find a shorter and less tedious method of selecting men than that of trying them out under actual working conditions. The essential thing is to first establish a management sufficiently scientific to make the best use of scientifically selected men, and this applies to shopmen or car repairmen selected for the greatest output; car inspectors selected for their ability and speed in doing their work, or engineers selected for reliability.

In addition, the railroads can well afford to establish employment bureaus to select the men along broad lines, looking into their records and making such examinations or inquiries as to insure the selection of clean, strong, capable men. Such a bureau should also look into the conditions of employment and questions connected therewith, but little more than this can be done under present conditions so far as the scientific selection is concerned.

Master Car Builders' Association Proceedings

Reports on Train Lighting; Car Trucks, and Draft Gear; Papers on Value of a Patent and Impact of Cars in Switching

President Crawford called the meeting to order Wednesday morning at 10 o'clock.

[The following individual paper was presented at the Tuesday meeting, but was not included in the yesterday's *Daily*.—EDITOR.]

WHAT IS THE VALUE OF A PATENT?

BY PAUL SYNNESTVEDT

That the value of a patent is often the subject of a wide divergence of opinion may be well illustrated by an incident which came to my notice a short while ago. In the case in question—which related to a refrigerator car structure—there had been an accounting ordered, after a finding of infringement, and the master appointed to take testimony on the accounting had handed in a report recommending a recovery totaling $663,000. This recommendation had come up for action before one of the district judges in the United States Court, who had come to the conclusion that, under the law as announced in the authorities, the right to recovery had not been established, and that, therefore, he could award only what is called "nominal damage," the amount being fixed at 6 cents.

When it is taken into account that in connection with the incident just related the master was acting on his understanding of facts formally made of record, and the widely variant conclusion of the judge was rendered by one of our most highly respected authorities on the same facts, it is clear that to fix the value of any given patent in an exact amount of dollars and cents is a very difficult thing to do. On the other hand, it can, I think, be fully maintained that there are elements bearing upon such a question which as to the principle involved may be clearly established.

VALUE OF A PATENT TO THE GENERAL PUBLIC

A patent is a benefit to the public because it is a reward peculiarly adapted to the nature of the service rendered, and adjusts itself with great nicety, so far as concerns the value of the reward or the patent itself, to the value of the service which the inventor has conferred. It is clear that if the invention is a new thing—and this is a necessary part of the assumption of the validity of the patent—then the grant to the inventor of the exclusive use of that new thing for a limited term has not taken from the public anything which it before possessed, but, in consideration of the limited monopoly, it has given to the public the benefit and knowledge of the invention, which is made of record and open to all to use after the expiration of the patent. Thus the right to secure an injunction under a patent becomes of value just in proportion exactly as the invention is of value. The difficulty that arises in estimating the value of any patent always comes in connection with a determination of the amount of damage recoverable for infringement which has taken place before the issue of injunction.

VALUE OF A PATENT TO THE PATENTEE CONSIDERED IN ITS COMMERCIAL ASPECTS

This value is really commensurate with the value to the general public; that is to say, the measure of value is the measure of utility of the invention itself; and it is largely from a failure to fully recognize this important point that the court decisions present such widely varying extremes in fixing the matter of damages. There are certain cases in which it has been made clear by the testimony that the entire value of the device sold was due to the fact that as a commercial article it included the patented invention; that is to say, that the article sold in accordance with the patent would have been entirely worthless without the invention. Such a situation obviously renders the patent of great value, as it then becomes the basis of the entire business. In other cases there may be but slight value attached, but sufficient to cause the patented article to sell at a slightly better price than other things available in the market of similar kind.

To the patentee himself a patent often has another value of a secondary character somewhat analogous to the commercial value of a trade-mark protection, because it may serve the purpose of helping a manufacturer to preserve some distinctive peculiarity in the appearance or character of his product.

Perhaps the most difficult situation under which to fix the distinct value of a patent arises where the invention defined in the patent, or the novel feature contributed to the art by such invention, constitutes but a part of some general structure embodying possibly a number of other inventions, all commonly sold in the trade as a whole article of commerce. Something of this situation existed in the refrigerator car case referred to. In that particular case the special features of invention had reference primarily to the use of a certain form of partition wall adjoining the ice chamber of the refrigerator car, and, of course, the car itself was made up of roof, sides, floor, doors, bolsters, trucks and brakes, all of which were included in the article as placed upon the market as a whole.

It is interesting to note that since the second decision was rendered the Court of Appeals for the Third Circuit, which heard the argument on this case some time ago, has rendered a decision in which it has taken ground intermediate between the master's recommendation of $663,000 and the lower court's award of 6 cents, and have calculated that the patentee is entitled to a recovery which apparently comes to a total of $41,000, this conclusion being based upon certain percentage calculations.

It appears from the Court of Appeals' decision that the car cost $914.38, without trucks, and that the profit thereon, after deducting material and labor and other manufacturing expense, was $171.74, which gave a proportion on the car which, expressed decimally, is 18.78 per cent., as a basis of calculating a profit assignable to any particular part of the cost of the car.

On some of the cars, amounting to several thousand, the testimony of one of the witnesses showed an average cost of the particular slotted partitions, which the court treats as constituting the special essence of the improvement, of $45. In the case of nearly 12,000 cars, it seems that the purchasers themselves furnished the partitions and the defendants in the suit had installed them when they built the cars. The view of this taken by the court seems to be that, while it is true that on these partitions defendants could not have made any profit, there was expended upon them a certain cost of labor in installing them, and on such cost of labor there should be calculated a proportional profit. It was calculated that such installation did not cost less for ordinary wages than $3 for each of the infringing partitions, and figuring from this, with the percentage basis of 18.78, there was derived a profit of something over 56 cents upon such labor of installing the partitions, and this on the cars on which such installation was made was calculated to produce a total of $6724.17. In view of all of which, taken from the report of the master in that part of his figures which were apparently approved by the Court of Appeals, it was found that the proper basis of recovery was the sum of the profits on the partitions made by the infringer and sold with the cars, such profit amounting to $34,623.74, and the profit on the labor involved in the installation of the other partitions, amounting to $6724.17, giving a total award against the infringer of $41,347.91.

By way of further explanation, it should perhaps be added that in determining the question of recoverable profits in any such accounting case, the figures are generally obtained by deducting from the net selling price the actual items of cost, including not only the labor and material involved in the construction, but also a certain percentage of overhead charges and selling expense, in some instances, and various other items entering into what is normally known as legitimate manufacturing cost.

On the other hand, because of certain peculiar rules which have become established in connection with accountings in patent suits, the profits which are found by the court to be the amount of recoverable judgment do not altogether correspond with the profits as they would be calculated in ordinary commercial usage. Thus, for example, while it is customary, in estimating the profits in these court proceedings, to deduct from the amount actually received for goods sold certain allowances for cost of material and actual labor expended, and certain other items, such as interest actually disbursed on money borrowed to carry on the infringing business, rental of buildings necessarily used in the manufacture, and certain salaries of parties who are paid employes, it has been held in many cases that no allowance will be made for the time and services of the infringing defend-

ant, or of either of the defendants, if the infringement is by a firm, even although legitimate salary has been paid. There are other cases in which the courts have refused to allow credit to the infringer for interest on capital invested in the general business, or the item of *insurance* even although this be upon the property actually employed in the infringement. Just what the reasoning may be which has justified some of the courts in allowing certain interest charges in some cases and refusing similar charges in others, and in altogether rejecting insurance expense, it is difficult to understand.

Another rule which it is important to bear in mind in this connection is that in most of the authorities the courts refuse to offset losses incurred in part of the infringing manufacture against profits on other infringing operations; that is to say, if for a certain period the infringing business was unprofitable, the loss can not be offset against profits made at another time. Thus, if the infringement extends through a series of years, the rule of most of the cases is that if losses be incurred in any one or more years, such losses can not be offset against profits made in other years.

Users of Infringed Patents.—Another feature that must be considered, in determining the commercial value of a patent to the patentee, is the hold which the patent gives him upon the infringing users after the validity of the patent has been sustained in court. It has been settled in various decisions, including cases in the U. S. Supreme Court, that the liability of an infringing *user* of a patented device is separate from the liability of the one who *made* and *sold* the device, and judgment against the maker or seller does not, in the absence of express stipulation, release the user of the infringing mechanism, and it is optional with the patentee, if he chooses to make settlement with the manufacturer without releasing the user and enforce his right to an injunction prohibiting any further use of the infringing apparatus by the purchaser. This is a matter of great importance to the railroad, because there is always present a danger that the issue of injunction against infringing apparatus may tie up their equipment; and it is on this account largely that, in cases where question arises, it is thought wise by many roads to insist upon the requirements of a bond to indemnify the road against damage in case of any interference with apparatus which is alleged to infringe outstanding patents.

Among the most interesting cases along this line which have come to my notice may be mentioned the case of the Westinghouse Air Brake Company vs. The Great Northern Railway, about fifteen or sixteen years ago, in which one of the judges of the U. S. Circuit Court, in an order which was afterward affirmed by the Court of Appeals in New York, issued a decree requiring the removal of air-brake triple valves which had been found to infringe the Westinghouse quick-action patents, from some thousands of cars, the order being modified slightly, however, to allow limited time to make the change because of the great inconvenience to the general public which would have been incurred had the equipment all been taken out of service at once.

In affirming this decision the Court of Appeals called special attention to the fact that, the railroad having had notice of infringement, it became a deliberate user of a large number of infringing triple valves, and had preferred to run the risk of an injunction rather than to change its equipment. In rendering the decision on appeal, the Court of Appeals referred back to an earlier case along similar lines, in which the Court said: "I can not in the decree do less than give the plaintiff his full right, and I can not bargain for him what he may choose or may not choose to do.' It does not lie with the infringer to say that the owner of the patent will be fully compensated by a money recovery, and ought to be satisfied thereby. It is for the latter to say whether he prefers an injunction or a money recovery, or both; and, at his option, he is at liberty, at final hearing, to waive an account and insist upon his injunction."

It is very interesting to observe the great changes which have taken place within a period of, say, about ten years in the matter of recovery of damages in patent cases. A few years ago, the question was brought up to the U. S. Supreme Court, in a suit known as Westinghouse vs. Wagner Electric Co. They held that where the patentee had shown there was commercial value in his patent, but that he was unable to segregate or separate that value from other values in the device of the infringer, that then the infringer, being the party in the wrong, should assume the burden of producing figures intended to show a basis for determining the question of recovery.

At the present time the tendency of the decisions in most of the courts seems to be to try and find a middle ground and apply more reasonable and moderate rules, and to base results somewhat upon what may be called the calculation and estimate method, supported, if necessary, by expert evidence as to values not deducible in actual dollars and cents in certain phases of the figures. Without expressing any opinion one way or the other as to the accuracy or correctness of the conclusion finally reached by the Court of Appeals in the Third Circuit, in the decision on the refrigerator-car case referred to, it is thought that the effort therein made by the court to find a reasonable ground upon which to stand and to avoid a position which would be too extreme one way or the other, is very strongly deserving of commendation.

It is clear that the award of excessive and confiscatory recoveries in cases of infringement would tend rather to decidedly discourage the progress of science and the useful arts by imposing penalties so heavy as to drive capital and enterprising managers out of the manufacturing industries.

VALUE OF A PATENT AS BETWEEN EMPLOYER AND EMPLOYE

Taking up for consideration next the question as to how to fix a value upon patented inventions of employes where they are made use of by the employer, and where generally developed by the employes in connection with their employment and in the regular course of duty, it is to be observed that the law herein establishes certain fundamentals, the first of which is that the making of a new invention under such circumstances does *not*, in the absence of special agreement, give the employer a right to entire ownership of such patent. It does, however, recognize in some cases what is called an implied license or shop right, giving the employer the privilege of *using* the invention within certain limitations dependent upon the facts of the particular case.

In order to avoid confusion and controversy, and to protect the rights and interests of both parties, some of the railroads in this country have considered the advisability of arranging definite written service agreements with employes such as are engaged in that class of work which would probably lead to the development of new improvements; and it is undoubtedly to the interest of both the railroad and the employe that such agreements be made upon a just and equitable basis, which reason dictates should leave the ownership of the patent within the hands of the employe, limted only by a license right in the road to use the invention upon its own lines and in its own service.

One advantage to the railroads in having new devices invented by their employes covered by letters patent under some such service agreement is that the taking out of such letters patent, which involves the making of record in the Patent Office at Washington a full disclosure of the invention itself in the specifications and drawings, is one of the surest and best means for protecting the railroads against claims that may be advanced by other inventors, who may secure patents either fraudulently or otherwise on such improvements.

Of course, the above analysis of the law and principles applicable to this matter of fixing a value upon letters patent might be extended indefinitely, but that is beyond the scope of a paper of this general character.

TRAIN LIGHTING

One of the most important items that the committee has under consideration in this year's report is the standardization of armature pulleys. The committee held a joint meeting with the committee on standards of the Association of Railway Electrical Engineers and with the representatives of the various axle dynamo manufacturing companies.

The committee recommends the following changes and additions to the present Recommended Practice:

That paragraph 12, under the caption, "Control and Protection of Parts," page 943, 1914 Proceedings, be changed so as to apply to wooden cars. Paragraph to read as follows: 'That on wooden cars, where axle dynamos are used, negative, positive and field shall be fused as close as possible to the dynamo and prior to the said leads either entering the conduits or being secured to the bottom of the car. The above fuses to be used for emergency service only, and to be at least 100 per cent above the capacity of the fuses on the switchboard protecting the same leads."

That a paragraph be added following paragraph 19, under the caption of "Batteries," page 944, 1914 Proceedings, to read as follows: "Battery boxes shall have the following minimum dimensions: Height in clear, 21½ in.; depth front to back, 2 ft. 1 in. Length of compartment to hold two standard double-compartment trays, 22⅝ in. Length of compartment to hold four standard double-compartment trays, 3 ft. 9¼ in."

That a paragraph be added following paragraph 28, under the caption "Axle Dynamos," page 945, 1914 Proceedings, reading as follows: "On all new and remodeled axle dynamos provided with ball or roller bearings, armature pulleys shall be in accordance with dimensions as shown in Fig. 1." This provides for either an 8 in. or 11 in. pulley.

That after this paragraph the following paragraph be added: "In all new or remodeled ball or roller bearing axle dynamos the details of the pulley end of the armature shaft shall be in accordance with the dimensions as shown in Fig. 2."

That following the paragraph recommended above an additional paragraph should be added, reading as follows: "On all sleeve-bearing generators having armature shaft less than 1⅝ in. in diameter at the inside end of the pulley fit, it is

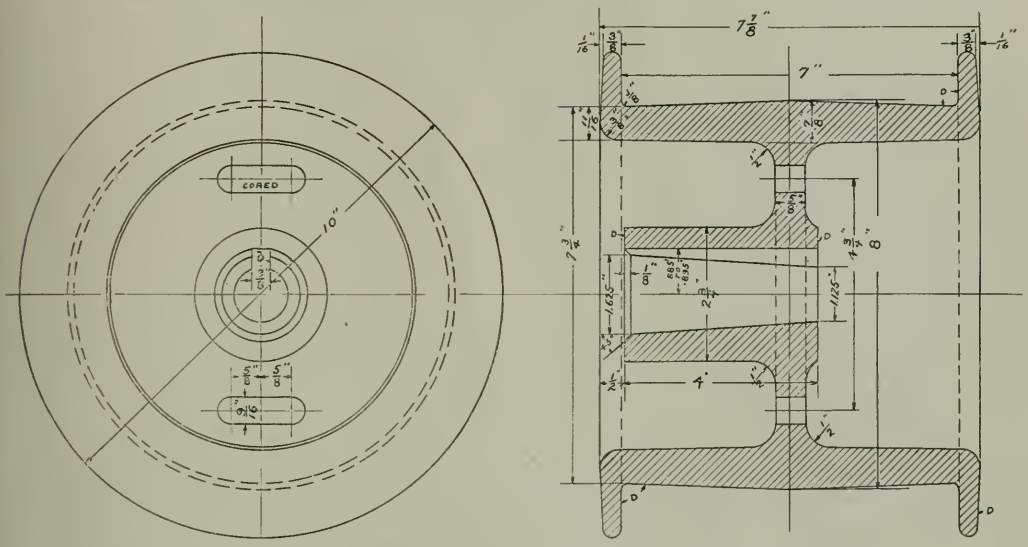

Fig. 1.—Armature Pulleys for Axle Lighting Systems

recommended that taper fit of ¾ in. in 12 in. be used; the inside dimension of the taper fit being 1½ in., with a length of 2½ in., measured on the axis of the shaft." The committee makes the foregoing recommendations in order to assist in the standardization of the armature pulleys on existing machines, it being necessary to establish a standard with smaller dimensions than the proposed standard for ball and roller bearing machines on account of the size of the shaft.

That following the above recommendation a paragraph should be added reading as follows: "On all future and remodeled ball and roller bearing axle dynamos, the roller or ball bearing in annular ball-bearing size used shall be that known as No. 412."

That paragraph 4, page 940, 1914 Proceedings, be changed to read as follows: "That in wiring cars for electric lighting, all the wire shall be run in conduits, and the conduit shall be so installed that the wires can be pulled in and pulled out of the conduit after the car is completed." The committee feels that the above recommendation is desirable in view of the present state of the art.

That paragraph 20, page 944, under the caption of "Axle Dynamos," the last sentence in this paragraph to be rewritten, omitting the word "perforated," paragraph then reading as follows: "The generator pulley should be flanged and crowned, and have a 7-in. face. The diameter of axle pulleys should preferably be 17 in. or 21 in.; the diameter of the generator pulley should preferably be 8 in. or 11 in."

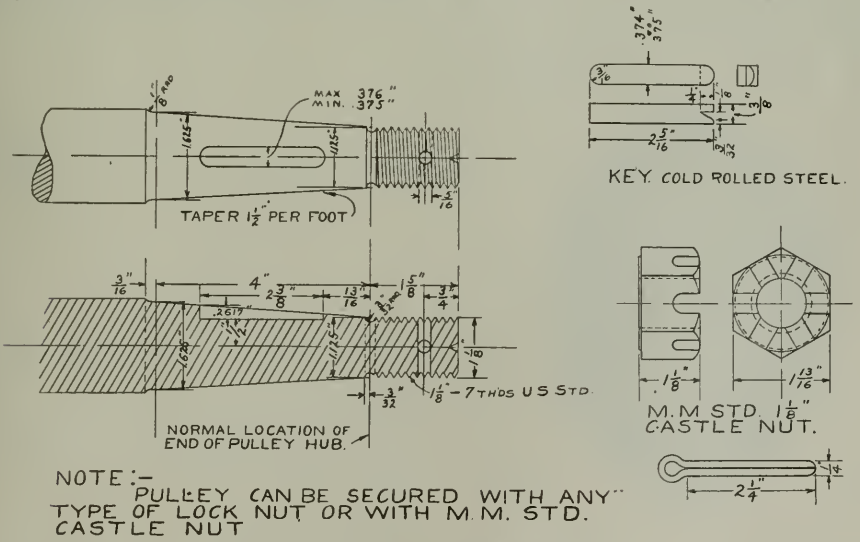

Fig. 2.—Pulley End of Armature Shaft

The committee recommends that the foregoing items be submitted to letter ballot separately.

The report is signed by:—T. R. Cook (Penn.), chairman; H. C. Meloy (N. Y. C.); Ward Barnum (L. & N.); D. J. Cartwright (L. V.); E. W. Jansen (I. C.); J. H. Davis (B. & O.), and C. H. Quinn (N. & W.).

(In the absence of the chairman the report was presented by H. C. Meloy, N. Y. C.)

DISCUSSION.

C. H. Quinn (N. & W.): As a member of the minority section of this committee, I would like to call your attention to the fact that in recommending 1½ in. taper in 12, statistics will show that at present there are more machines in service with a ¾ in. taper than with a 1½ in. taper. As a mechanical proposition it would be much easier to turn down 1½ in. taper to ¾ in. taper, than to increase from ¾ in. to 1½ in. I think the mechanical practice, as usually carried on in our machine shops for drill center and lathe center, more nearly fits the ¾ in. taper in 12. In a mechanical proposition of this kind I would be governed by the practice of tool builders and other men who have made a particular study of the item rather than to arbitrarily accept 1½ in. in 12. As I take the report it is a question of whether we shall vote on accepting the 1½ in. taper or nothing. I do not see any reference to the opportunity of accepting ¾ in. and it is not standard at the present time. There is now no standard.

G. W. Wildin (N. Y., N. H. & H.): I would like to ask if, in stipulating a minimum diameter of 8 in. for the armature shaft pulley, we are not cutting out certain manufacturers of high speed machines?

H. C. Meloy: The committee understood in talking with the various manufacturers that they would furnish any taper desired, or any pulley diameter desired, and the question of body suspension was not up at the time of the meeting. This only refers to truck suspension.

C. H. Quinn: Probably there will have to be taken under consideration in the next year's report, if this committee is continued, the diameter of pulley covering the body suspended machine. There seems to be a tendency for the standardization of dynamos in reference to speed and temperature. If we can bring about such a standard that will more or less settle the recommended practice for a body suspended machine. (It was voted to refer the report to letter ballot.)

CAR TRUCKS

At the last convention the recommendations of the committee were received and submitted to letter ballot.

The majority of the items which were rejected were defeated by a very small number of votes, and, in order to ascertain the objections of the members who voted in the negative, a communication was addressed to them to ascertain their specific

J. T. Wallis
Chairman, Committee on Car Trucks

objections, with a view of reconciling the differences as far as may be practicable. The replies received were given careful consideration, and as a result of this investigation, as well as further tests made and conferences with the manufacturers of cast-steel truck sides and bolsters, the committee presents the changes it recommends, under the respective headings.

SPECIFICATIONS AND TESTS OF CAST-STEEL SIDES

The committee modified the clause providing for a proof load test on each truck side to requiring a minimum of one frame from each melt, and not less than 2 per cent. of the total frames furnished to be subject to the proof test, resubmitting it as follows:

Under Article III, Physical Properties and Tests, after Section 10, Physical Properties, add new section for Proof Test, as follows:

Proof Test.—A minimum of one frame from each heat and not less than 2 per cent. of the total frames furnished shall be tested in a suitable machine to the loads shown in the table for different capacity car trucks.

Car Capacity.	Initial Load.	Load.	Maximum Deflection.	Maximum Set.
Lb.	Lb.	Lb.	In.	In.
80 000	20 000	110 000	0.15	0.01
100 000	25 000	135 000	0.15	0.01
140 000	35 000	175 000	0.15	0.01

After applying initial load, reduce load to 5000 lb. and set deflection instrument at zero; apply the requisite proof load and

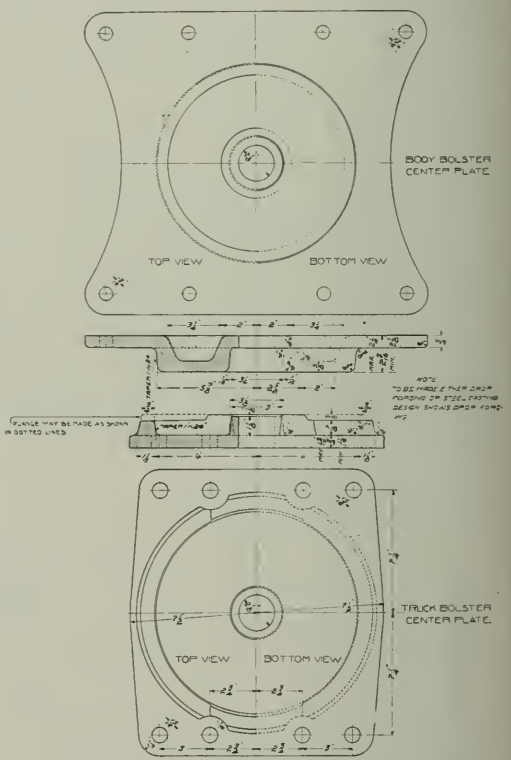

Fig. 2.—M. C. B. Standard Center Plates for 80,000, 100,000 and 140,000 Lbs. Capacity Freight Cars

measure deflection; reduce load to 5000 lb. and measure the set. Truck sides may be supported at each end, directly beneath the center line corresponding to center line of axle when side frame is in the truck and loaded at center of bolster opening midway between supports, or they may be supported in the center and loaded at the ends. The deflection and set shall be measured at the center line of spring seat.

The committee carefully reviewed the weights recommended last year, and had a large number of side frames for 100,000-lb. and 140,000-lb. capacity cars weighed and checked, and found the weights recommended last year practically correct. The same opportunity was not afforded on the side frames for 80,000-lb. capacity cars, and it is believed, therefore, that the limiting weights on the latter should be held in abeyance until the actual weights can be positively determined. For side frames for the 100,000-lb. and 140,000-lb. capacity cars the com-

mittee recommends that under Article IV, Weights, Section 13, Variation in Weights (new number 14), change to read as follows:

Limiting Weights.—Truck sides shall conform to the weights given in table. In case the castings have met all requirements except that of overweight, they may be accepted at the maximum allowable weight here specified:

Car Capacity. Lb.	Weights, Lb. Minimum.	Normal.	Maximum.
100 000	485	500	515
140 000	640	660	680

The present recommended practice covering rejection should be changed to conform with the change recommended in the proof test, and the committee therefore suggests the following modification:

Rejection.—In case the test pieces do not meet the specifications, all castings from the entire melt shall be rejected. If the side frame selected to represent a melt does not meet the proof test, then all the frames from that melt shall be subjected to the proof test, and any such frames failing to meet the test shall be rejected.

DESIGN OF CAST-STEEL BOLSTERS FOR 80,000, 100,000 AND 140,000 LB. CAPACITY CARS

The design of each of the above bolsters failed to be adopted by 117 votes. The main objection of the members who voted in the negative is that the detachable center-plate adds weight and that the trouble experienced with center-plate cast integral is not sufficient to warrant the added expense of the independent center-plate. As this feature does not in any way affect the interchangeability, the committee, upon further consideration, feels that this matter should be left optional with the car owner. This involves two designs of bolsters, slightly different in detail but both conforming to the limiting dimensions, and, therefore, interchangeable. [The committee presented drawings of both designs for adoption.—EDITOR.]

The question was also raised in regard to having insufficient support under the center-plate. This had been tested out, and no failures occurred with the design as presented.

Under Article III, Weights, change Section 13 to read as follows:

Limiting Weights.—Bolsters shall conform to the weights given in table which cover the bolster casting, either with center-plate cast integral or separate center-plate, and does not include side bearings, fulcrum castings, or other attachments. In case the castings have met all requirements except that of overweight, they may be accepted at the maximum allowable weight specified.

Car Capacity. Lb.	Weights, Lb. Minimum.	Normal.	Maximum.
80 000	600	710	730
100 000	750	775	800
140 000	970	1 000	1 030

(The above weights are tentative. Several bolsters have been ordered which will be carefully weighed and two tables will be substituted. One covering bolsters with separate center plates and the other covering center plates cast integral.)

PRESSED-STEEL TRUCK BOLSTERS FOR 80,000, 100,000 AND 140,000 LB. CAPACITY CARS. ALTERNATE STANDARD

The replies to the circular letter asking for specific objections to the pressed-steel bolsters presented by the committee to the last convention indicated that the members voting in the negative on the pressed-steel bolsters did so for the reason that they did not approve of certain details on the cast-steel bolsters. The committee suggests that the pressed-steel bolsters should be treated and considered as a separate problem. If a cast-steel bolster is preferred by a car owner, it should not affect the status of the pressed-steel bolster, and vice versa. The two proposed standards are interchangeable, but it is not to be assumed, nor is it the intention, to permit the substitution of one for the other in repairs; the idea in establishing the two standards is to give to car owners the choice of either a cast-steel or pressed-steel bolster of approved design. The committee tested four bolsters of each capacity, which met the tests in every respect. From these bolsters the average weight was computed. It was, therefore, recommended to submit to letter ballot the following:

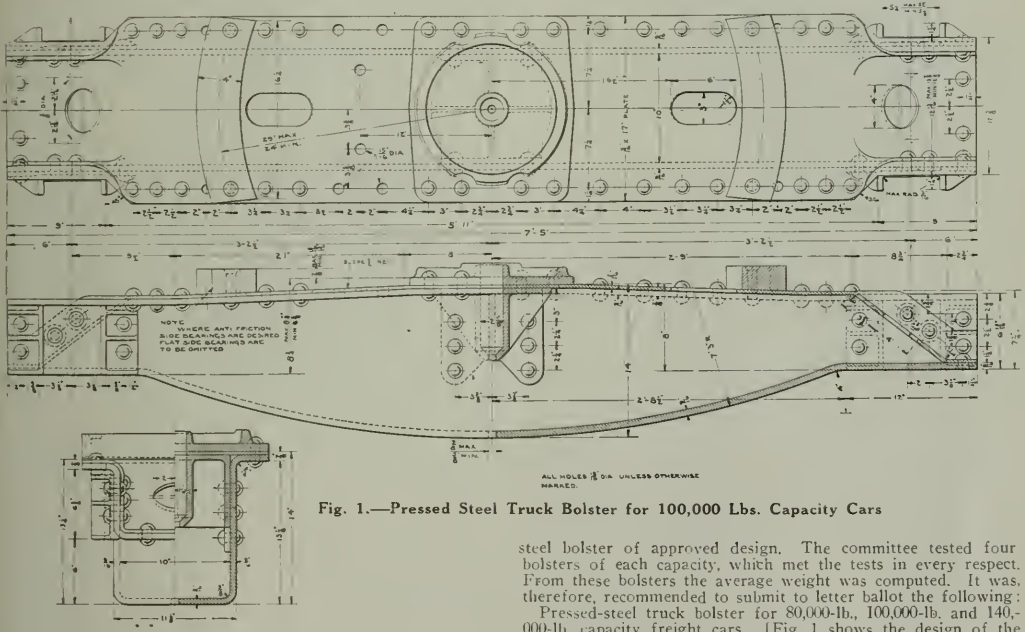

Fig. 1.—Pressed Steel Truck Bolster for 100,000 Lbs. Capacity Cars

Pressed-steel truck bolster for 80,000-lb., 100,000-lb. and 140,000-lb. capacity freight cars. [Fig. 1 shows the design of the bolster for 100,000-lb. capacity freight cars.—EDITOR.]

Specifications and Tests.—The steel should conform to the requirements of the M. C. B. specifications and tests for structural steel for freight cars.

Limiting Weights.—Bolsters, including center-plate and side bearings, shall conform to the weights given in table. In case the bolsters have met all requirements except that of overweight, they may be accepted at the maximum allowable weight here specified.

Car Capacity. Lb.	Weights, Lb. Minimum.	Normal.	Maximum.
80 000	775	795	815
100 000	840	865	890
140 000	1 110	1 140	1 170

SPREAD OF SIDE BEARINGS

It is customary and proper to assume that the height of center of gravity of a loaded car may reach 6 ft. above top of rail. It has also been determined from actual test that the height of center of gravity above top of rail occasionally reaches 7 ft. Following customary practice, based on height of center of grav-

ity of 6 ft., and making proper deduction for truck weight to determine height of center of gravity of loaded body alone above the level of the side bearings, it has been determined that the radial distance from center-plate to side bearing must be at least 24 in. (or 48 in. center to center of side bearings), in order to avoid overturning of body on side bearings before the whole car tends to overturn on the rail, the spread or gage of the rails being the accepted limiting feature. It is, therefore, recommended to submit to letter ballot the following: "That the side-bearing spacing, center to center of side bearing, be within the limits of 48 in. to 58 in., both inclusive, on the M. C. B. design of bolsters."

CENTER-PLATES AND GAGES FOR 80,000, 100,000 AND 140,000 LB. CAPACITY CARS

The change in center-plates failed to receive the necessary two-thirds vote by 118 votes. The main objections of those voting "no" are the height of ring on the outside of center-plate being too low and insufficient radial clearance between the male and female center-plates. The design has been changed, providing for a uniform height of flange of 1¼ in. on the outer ring of the female center-plates and the radial diameters changed so as to provide a total clearance of ¼ in. instead of ⅛ in., as at present, and preserving interchangeability with present M. C. B. standard center-plate. The center-plate shown in Fig. 2 was recommended for adoption as standard.

TRUCK SIDES WITH FEDESTAL TYPE JAW

It has been brought to the attention of your committee that there are in use a large number of cast-steel truck sides designed with a pedestal jaw, to keep the journal box in place, and doing away with the regular journal-box bolts, and a request has been made that the committee outline limiting dimensions for the pedestal jaw as an alternate for the present limiting dimensions of side frame adjacent to the journal box; also limiting dimensions for journal boxes used in connection with side frames having pedestal jaw.

The committee has made some preliminary investigations among the manufacturers and finds that the interchangeability of boxes presents a difficult problem. Before going into the question further the committee desires to ascertain by a letter-ballot vote whether, in the opinion of the members of the Association, the benefits to be derived from the pedestal-jaw design of side frame is sufficient to warrant establishing the additional standards, which involve carrying in stock the additional material necessary to make repairs to this type of side frames. Three of the four manufacturers advise that up to the present time 243,261 pedestal side frames have been placed in service.

In order to prepare for the adoption of limiting dimensions of pedestal opening and width of box, also for the width of pedestal jaw and corresponding width between pedestal slide on journal box, your committee has canvassed the situation and finds that the various manufacturers of cast steel truck sides with pedestal type jaw are at the present time turning out frames in which the dimensions above referred to for the various capacity cars are practically uniform. It is very desirable that these dimensions be maintained and would, therefore, suggest to the members who are now using the pedestal type of cast steel frame and those who may purchase any in the future that the limiting dimensions shown in the following table be specified.

CAPACITY OF TRUCK	TRUCK FRAME				JOURNAL BOX			
	Jaw Opening		Width of Pedestal		Jaw Opening		Width of Pedestal	
	Max. Ins.	Min. Ins.	Max. Ins.	Min. Ins.	Max. Ins.	Min. Ins.	Max. Ins.	Min. Ins.
40 Ton ...	$9\frac{5}{16}$	$9\frac{1}{16}$	$3\frac{5}{8}$	$3\frac{5}{16}$	9	$8\frac{15}{16}$	$3\frac{7}{8}$	$3\frac{13}{16}$
50 Ton ...	$9\frac{5}{16}$	$9\frac{1}{16}$	$3\frac{5}{8}$	$3\frac{5}{16}$	9	$8\frac{15}{16}$	$3\frac{7}{8}$	$3\frac{13}{16}$
70 Ton	$10\frac{1}{16}$	$10\frac{1}{16}$	$4\frac{1}{2}$	$4\frac{7}{16}$	$10\frac{1}{2}$	$10\frac{7}{16}$	$4\frac{1}{2}$	$4\frac{7}{16}$

The report is signed by:—J. T. Wallis (Penn.), chairman; E. W. Pratt (C. & N. W.); Jas. Coleman (G. T.); J. J. Tatum (B. & O.); Prof. E. C. Schmidt (Univ. of Ill.); L. C. Ord (C. P. R.); J. McMullin (Erie); A. R. Ayers (N. Y. C.), and E. G. Chenoweth (C., R. I. & P.).

The report was presented by A. R. Ayers, N. Y. C. Referring to the limiting weights of cast steel bolsters, he said: After the sample bolsters were received it was evident that it would be better to have two tables, one for integral center plate and another for bolsters with separate center plate, because the design with the integral center plate will be somewhat lighter. The committee will undertake to draw up two tables and include them in the report. Several bolsters of each design have been ordered, so that the weight can be checked carefully

DISCUSSION

C. F. Giles (L. & N.): What consideration has been given to the cast steel side frame with the box cast integral, and what bearing will the report have on that type of frame, if any?

A. R. Ayers: I do not think the conditions are such that we could incorporate that design if this should become standard. That is a special construction, it is only made by one manufacturer.

C. F. Giles: We have many thousands of cast steel truck bolsters in service throughout the country, and I do not know of a single case where they have a separate center casting. I am at a loss to know why the committee recommends such a design. We have had a wide experience with the bolster with the center cast integral, and it is entirely satisfactory. If a bolster with separate center casting is adopted it will complicate the situation in asking for bids, in the purchase of new equipment. We will have to add to the bolster with the separate center plate the difference between the cost of the integral bolster and that of a bolster with a separate center plate, which would add at least $5 or $6 to the cost of the car.

F. W. Brazier (N. Y. C.): My experience has been in favor of the bearing cast integral. With this type, however, you are bound to have wear, and in time there will be no way of replacing the center plate. Where the center plate is lipped over the side of the body bolster, and properly bolted, you will have a chance, if it wears out, to replace it.

R. L. Kleine: The report of the truck committee was lost in the letter ballot last year because some of the members preferred cast steel truck bolsters with the center plates integral. For that reason the committee give the members three options; the pressed steel bolster, the cast steel bolster with the center plate detachable, and the cast steel bolster with the center plate cast integral. They are interchangeable, in so far as dimensions go.

A. R. Ayers: The pedestal and truck is on the market, and there are several hundred thousands of them in service at the present time. The width of jaw and the width of the face of the jaw has been made uniform by all the manufacturers of this form of truck, although the box fastenings are different. There are apparently certain advantages for that form of truck in doing away with the journal box bolts. If they prove to be real advantages, this type of truck will find its place whether or not it is an M. C. B. standard. If the dimensions which are at the present time uniform can be maintained, the problem of adopting a single fastening for a box will be very much simplified and will be an entire possibility in the near future if the association desires to have such a single standard adopted, in which case it would only introduce an additional standard for each size of box.

C. F. Giles: We are using a pedestal style of truck very largely. The principal object was to do away with the journal box bolts which results in the bolts being battered up and having to be renewed. As far as the journal box fastening is concerned it is absolutely unnecessary except in case of a derailment.

(The report was referred to letter ballot.)

DRAFT EQUIPMENT

The accompanying table is made up from replies received to twenty questions sent out in a circular of inquiry for the purpose of finding out general practices and the general weaknesses of the present draft gear appliances.

Sixty per cent. of the total number of cars are of steel center sill construction and are equipped with friction draft gear from a minimum of 100,000 lb. to a maximum of 260,000 lb. capacity. The capacity of these cars varies from 80,000 to 120,000 lb. The question is involved whether the construction of a car is taken into consideration when a decision is being reached as to the capacity of the gear to be applied. It is evident that a draft gear of low capacity necessitates a better construction of car in order to take care of the shocks, which are meant to be absorbed by the gear.

Eighty per cent. of the total replies show preference for a friction draw gear on new equipment. Thirty-six per cent. of the replies express a preference for more coupler travel than the present standard of 2¾ in. between coupler horn and striking plate.

The matter of keeping up nuts on drawbar carry-iron bolts is a great source of trouble. Almost all who advise no trouble in that respect are using nut locks, while some of the largest roads are overcoming this trouble by placing these bolts in shear instead of in tension as has been the general practice.

The following is an abstract of the replies to the twenty questions sent out:

Number of freight cars involved (all types)	956,879
All steel center sills	340,862
All wood center sills	169,915
Wood sills and metal arms	68,111
Friction draft gear	453,725
Spring draft gear	497,874
Wooden cars equipped with higher capacity draft gears or reinforcement	741,018
Failures of drawbar yokes with semi-circular backs	Yes—290,924 / No —179,300
Failures of drawbar yokes with square backs and liner	Yes—618,409 / No —208,201
Drawbar yoke 1¼ in. rivets failing, high capacity gears	Yes—718,124 / No —155,887
Trouble with keys in place of rivets in yokes	Yes— 59,951 / No —320,276
Trouble with draft gears depending on rivets instead of yokes	Yes—182,139 / No —328,044
Friction draft gear preferred on new cars	772,219
Spring draft gears preferred on new cars	22,579
Number of recommendations for coupler travel on high capacity friction draft gears of over 2¾ in.	2 in. to 3 in.—19,983 2¼ in. to 3 in.—23,757 2½ in. to 3¾ in.— 4,159 2¾ in. to 3½ in.—18,387 3 in. to 3½ in.—31,669 3 in. to 3¾ in.—67,452
Difficulty in keeping up nuts on carry-iron bolts	Yes—672,272 / No —271,239
Speed limit on engines in switching service or cars in hump yards	Yes—241,928 / No —680,518

The report is signed by:—J. F. DeVoy (C. M. & St. P.), chairman; W. E. Dunham (C. & N. W.); E. A. Gilbert (So. Pac.); J. R. Onderdonk (B. & O.); A. R. Kipp (M. St. P. & S. S. M.); G. W. Rink (C. of N. J.), and P. F. Smith, Jr. (Penn. Lines).

J. F. De Voy
Chairman, Committee on Draft Gear

(In the absence of the chairman the report was presented by W. E. Dunham, who called attention to the apparent lack of information indicated by the replies to several of the questions in the committee's circular of inquiry and requested that the members make some detailed investigations for its benefit should it be continued for another year. (The recommendation of the committee that it be continued was referred to the executive committee.)

JOINT MEETINGS

[This report is a duplicate of that presented at the M. M. Association—see *Daily Railway Age Gazette* of June 12, 1915. —Ed.]

DISCUSSION.

M. K. Barnum (B. & O.): The committee has done considerable work that is very interesting, but it seems to me that it is possible to go a little further with the result of saving some duplication of work and some time for the convention, and I believe it is a subject worthy of further consideration. I move that the committee be continued and enlarged and requested to report at the next convention.

T. H. Goodnow: The committee was simply appointed to work up a program for the two associations, so in view of what Mr. Barnum says he might wish to enlarge the scope of the committee.

M. K. Barnum: I suggest that the committee be instructed to consider the subject in its broader aspect and make a report on such lines as it shall see fit.

(The motion was carried.)

IMPACT BETWEEN FREIGHT CARS IN SWITHCHING SERVICE

By Louis C. Endsley

Professor of Railway Mechanical Engineering University of Pittsburgh

The purpose of these experiments was to determine this force of impact by obtaining the acceleration of the car during the impact blow. The instrument used to obtain the acceleration of the car during the impact consists of a cylinder mounted on two supports. These supports also carry a rest upon which a slide moved. This slide had mounted in it a lead pencil. The slide was so constructed that it could be connected to the car by

Copyright 1914 Moffett, Chicago

L. E. Endsley
Paper on Impact between Freight Cars in Switching Service

means of a rod. The cylinder could be driven at almost any desired speed by a motor, which received its current from a six-volt storage battery. The speed selected for these tests was 45 revolutions of the cylinder per minute. As the cylinder was 20 in. in circumference, this gave a speed for the paper of approximately 15 in. per second.

The tests were made with a string of eight or ten cars placed

on a track that had just sufficient grade to keep a car in motion after it had been started and not enough to accelerate the car. The brakes on the last two cars on the down-grade end were set and a locomotive was coupled on the up-grade end and the slack was pushed in until just the draft-gear movement was left between each car. The end car was then disconnected and pulled up the track some distance, the chronograph having been

connected to the end car of those standing, the motor was then started and the drum allowed to revolve. The car that the engine had pulled up the track was pushed down the track with the engine disconnected. The car was then allowed to drift into the string of stationary cars. The speed of the moving car was determined by stop-watches, the time of the movement of the last 30 ft. being noted by two stop-watches. The velocity and acceleration of the first standing car was obtained from the record made on the cylinder of the chronograph. The above tests were made on Norfolk & Western 90-ton cars and Pennsylvania 55-ton cars, both kind of cars being tested light and loaded. The tests on the Norfolk & Western cars were made

at Roanoke, Va., and the test on the Pennsylvania cars was made at Conway, Pa.

For the purpose of distinguishing the different cars referred to in the paper, the moving car will be called *A*, the first car of those standing, *B*, the second standing car, *C*, the third standing car, *D*, etc.

The instrument was connected to car *B*, which was the first car in the cut of standing cars. It is a well-known law in physics that if you know the weight of a body and its acceleration, you can determine the force acting on the body. In each

Fig. 3—Table of Results on the Loaded Pennsylvania Cars

case the weight of the car and load was known, and the acceleration was determined from the curve drawn on the drum. The speed of the drum being 15 in. per second, the velocity of the car was determined for each .01 of a second lapse of time and the difference in velocity for each .01 of a second would give the acceleration per hundredth of a second. As this was a very short space of time, the acceleration for each .01 of a second was assumed to be constant. This acceleration, as obtained from the drum, was reduced to feet per second per second and the following formula applied:

$$F = \frac{W}{g} a$$

in which F equals the force in pounds on the car, W equals the total weight of the car, g equals gravity taken as 32.2, a equals the acceleration in feet per second per second as taken from the curve drawn on the drum. There might be some question as to whether the trucks should be included in the weight of the car, but as in most cases the maximum force occurred after the car had moved approximately ¾ of an inch, it would seem that the trucks would be in motion by the time the car body had moved ¾ of an inch, so that the weight of the trucks was included in all results.

Results Obtained.—Figs. 1 and 2 give the results obtained on the light cars of the Pennsylvania and Norfolk & Western, respectively. Figs. 3 and 4 give the results obtained on the loaded cars. Column 1 of these tables gives the speed in feet per second as obtained by a stop-watch for the last 30 ft. of movement. Column 2 gives the calculated speed in miles per hour computed from the values in Column 1. Column 3 gives the maximum speed in feet per second obtained by car *B*, during the impact, this car being the first in the string of standing cars. Column 4 gives the maximum speed in miles per hour of car *B*. Column 5 gives the kinetic energy in foot-pounds of car *A* at the moment of impact. Column 6 gives the maximum

Fig. 4—Table of Results on the Loaded Norfolk & Western Cars

kinetic energy in car *B* during the impact. This last value is obtained from the velocity curves recorded on the chronograph. Column 7 gives the maximum force in pounds as obtained from the maximum acceleration of car *B* during the impact. Fig. 5 shows the maximum force between the cars plotted against the speed in miles per hour of the moving car at the time of impact. That is, the results shown in Column 7 are plotted against those shown in Column 2 of each table. Fig. 6 shows the relation between the weight of the car and the maximum force in impact for speed of two, three and four miles per hour. The values here plotted were taken from the curve in Fig. 5. That is, the pressure at two miles per hour was taken off for each curve in Fig. 5 and likewise for speeds of three and four miles. By an examination of Fig. 5 it is apparent that the maximum force of impact is not directly proportional to the speed, as the curves that represent the average relation in all cases curve up as the speed of the moving car is increased. This, no doubt, is due to the fact that the kinetic energy of the moving car varies with the square of the velocity, and the force of impact would, no doubt, be also proportional to the square of the velocity if the end of each car was of sufficient strength to withstand the force without destroying it partly.

but as the force increases, some of the kinetic energy is used up in the destruction of the coupler, draft-gear connection and end-sill connection, from the horn of the coupler coming in contact with the end sills and other giving of the part. Of course, the draft gear absorbs some at each impact, but this is a constant after the draft gear once goes solid. The loss in each impact is well shown by a comparison of Columns 5 and 6, Column 5 giving the kinetic energy in the moving car and Column 6 the maximum kinetic energy in the first car. That is, the value in Column 6 would also represent the energy retained by the moving car, *A*, and by double the values in Column 6, and subtracting them from Column 5 the loss of kinetic energy for any impact can

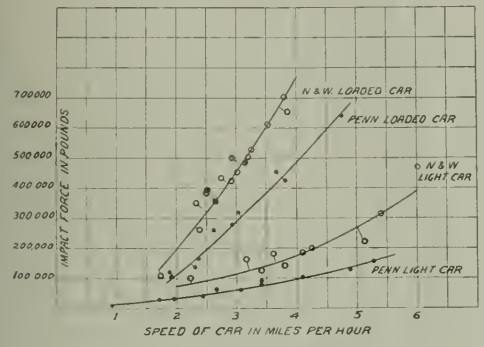

Fig. 5.—Values of Impact for Different Speeds

be determined. This loss in some cases amounts to as much as 70,000 foot-pounds of energy in one test on N. & W. cars. This can only be accounted for by the destruction of some part of the car. During the testing on the N. & W. cars a few impacts were made with the loaded cars that had bumper blocks on the ends of the car. The results are given at the bottom of Fig. 4. It will be seen that a larger per cent of the kinetic energy is transmitted to car *B* when the bumper blocks are on, and also the force between the cars is usually somewhat greater. The five points with a cross in the circle in Fig. 5 show the results on the N. & W. loaded cars equipped with bumper blocks. It will be seen that, with the exception of one point, all fall

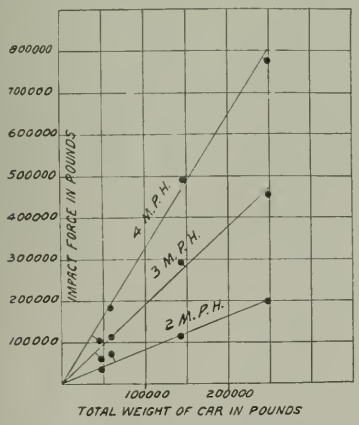

Fig. 6.—Relation of Weight of Car to Impact Force at 2, 3, and 4 M. P. H.

above the average curve. This is, no doubt, accounted for by the fact that the load is distributed over three points and thus a greater force was produced with less destruction than when the couplers and draft-gear connection received all the load. From a study of the value shown in Fig. 6, it will be seen that the maximum force of impact for any given speed is almost directly proportional to the weight of the cars in impact.

An interesting thing, which was plainly shown from the curves made on the chronograph, was the fact that the maximum force on car *B* occurred always before it had moved 1 in. Car *B* usually moved from 4 to 12 in. That is, the maximum force on car *B* occurred before any appreciable force was exerted between cars *B* and *C*, and the speed of car *B* was very slow before cars *C* and *D* had any pressure between them and car *B* was always stopped before the impact between cars *D* and *E* occurred. That is, the largest per cent of kinetic energy is taken out of the moving car in the impact between cars *A* and *B*, and the greatest damage would be done at this point. So as this force occurred before car *B* had moved 1 in., the damage to the end of the car would be just as great if only one car was standing as if a dozen were backing it up, provided there was at least 1 in. slack between the first and second cars of the standing ones. Of course, so far as the damage to the center sills at the center of the car, no doubt this damage would be greater if the cars were backed up by other cars. But these results given in this paper seem to indicate that there would be just as great a force between the cars if one car struck another car or struck a string of cars.

I wish to express my appreciation for the coöperation and assistance rendered in this work by the following men: Messrs. D. F. Crawford and T. R. Cook, of the Pennsylvania Lines West; W. H. Lewis, J. A. Pilcher and H. W. Coddington, of the Norfolk & Western R. R., and W. E. Larsen and C. O. Henry, senior students of the University of Pittsburgh.

DISCUSSION.

W. E. Symons: I would suggest the advisability of a more extended work of this character by Prof. Endsley and others who may be incorporated with him, and that the scope of the work not only be extended, but that such persons co-operate with the draft gear committee. It has been stated on excellent authority that 58 per cent to 60 per cent of our expenses of repairs to freight cars are due to buffing shocks which the draft gear did not absorb. This emphasizes the necessity of work in the direction of improving draft gear or minimizing the effect of the buffing shocks. It might also be emphasized that our freight equipment as a whole, representing an investment of possibly $1,800,000,000, is only in revenue earning service, or it only covers a productive period of about 25 per cent of its time, and possibly less, there being an unproductive period of at least 75 per cent. This fact also emphasizes the necessity of further research work and should be brought to the attention of the management of our railways to impress them with the importance of co-operating with the mechanical officers.

S. G. Thomson (P. & R.): We made a very interesting test that verifies Prof. Endsley's conclusions in regard to the standing car. We took two loaded coal cars, one with a through steel center sill, and the draught arms riveted solidly to the sill; the other one with a steel draft arm lipped tight over the bolster, making a very solid connection with the bolster. We took one car up the incline and left the other standing by itself. Both of them were wooden cars, loaded to about 60,000 lb. There was at least 2½ in. or 3 in. movement of the sills under the car. The through center sill construction gave a very perceptible movement. After the test was over we found it had cut practically every piece of flooring straight through the car. If you are going to the through sill in reinforcing cars, it is very important to tie that through sill to your bolster. If you do not do so you will probably do more damage to your car than if you had no reinforcement at all. Another conclusion that we rather drew from those tests is that, the weaker the draft gear, the less damage to the car. That sounds rather funny, but the weaker gear causes the whole car to absorb the shock and you don't get any tearing action. I think that the draft gear committee and the car construction committee ought to be given more study to the relation between the draft gear and the car construction.

C. E. Fuller: May I ask Mr. Thomson if this car had wooden end sills. You have just said the two center sills were reinforced. Were the two center sills fastened in any other way than than bolted to the wooden center sills?

S. G. Thomson: It was a through girder beam put between wooden center sills, and the draft members came right up solidly and were bolted to the cross bolster, making a fairly solid construction with the bolster, but the fact was that it was not lipped over the bolster. You could not make that construction quite solid enough without lipping over the bolster, which was a metal bolster.

Mr. Fuller: Was it riveted to the bolster?

Mr. Thomson: Yes, sir. The first shock sheared the rivets off and punched the bolts off. These were two 60,000 lb. cars, and the speed I think ranged between 8, 14 and 20 m. p. h. I think we took the cars each way and turned them around, and tried the other ends of the cars, and by the time we were through we had entirely practically

wrecked both cars, but we had gotten a great deal of information from it.

T. H. Goodnow: I would like to ask Professor Endsley if in slack tests, the cars were specially prepared for it? That is, was everything tightened up so that you would only have such slack as would exist in new construction. Taking cars as they ordinarily run, in 75 and 80 car trains, taking two engines, and bunching them, and stretching them, and then going through the same procedure again, we found that there was an average slack per car of 7 in. to 10 in. In the second test, if I remember right, of the 80 car train it ran anywhere from ten to twelve feet more than on the first test. With a train of cars that had just come from the shops that had had steel underframes applied to them, the average was only 2¾ in. to the car, or less than the total travel of both of your draft gears.

Prof. Endsley: I would say that the Norfolk & Western cars were under a year old, had been in service, and had shown that they had done some service, but everything was in good shape on the cars. The cars were pushed in so that any extra slack was not present. The Pennsylvania cars were also new cars, under two years old, but had seen some service, and had a travel of the draft gear before the horn struck of 2⅛ in. on one car and 2⅜ in. on the other. These were both solidly constructed cars, they were not wooden cars, and any comparison you make with the wooden car will be entirely different. On the Pennsylvania this work was done on cars of over 100,000 lb. capacity, weighing 48,800 lb. and having pressed center sills running entirely through. The N. & W. also had a continuous sill running through the car. They were pretty solidly constructed cars. Some of the couplers on the N. & W. cars have shanks that have been shortened up an inch in service. Now, it takes 800,000 lb. in a static machine to shorten the shank on the coupler one inch, this load to be applied in 35 seconds, running from 600,000 up, and back again.

Also some men have said to me here at this Convention that we could not take 800,000 lb. on these couplers. I had a 1,000,000 lb. on a static machine on four different couplers, that after releasing the load, you can open the knuckles with your hand, and take out the locks. These couplers will stand 1,00,000 lb. a good many times under impact. It will take some 50 blows of 800,000 lb. to shorten the shank up an inch

J. J. Tatum (B. & O.): When our presidents ask us "Why do you build cars that are so heavy? Why do you need this standard coupler you are speaking of, that is going to increase the cars in weight and cost? Why does the Committee on standard cars build the underframe so heavy? Why is it that our frictional draft gear does not hold up, that you recommend it would do better than the spring gear?" We can give them the answer to all of these questions right from this paper.

J. J. Hennessey (C. M. & St. P.): Regarding this shortening of one inch in the length of the coupler—did it take place in the horn of the coupler, or at the extreme end of the shank?

Prof. Endsley: In the shank from the head to the end of the coupler, without bending.

D. F. Crawford (Penn. Lines): In 1903 or 1904 we made some tests by dropping a car and a dynamometer car down grade of about 3 per cent against a string of standing cars. The speed was regulated by the distance that we allowed the cars to run down grade, and at that time it was found that the shock recorded by the dynamometer car was about 100,000 lb. per mile per hour up to 6 m. p. h., when the entire capacity of the dynamometer car, which was some 615,000 lb., was absorbed. Since making that experiment we have assumed that our cars must be prepared to stand an end shock of at least 250,000 lb. with comparatively small stresses. The cars that Prof. Endsley used on the Pennsylvania, and I know also on the N. & W., are cars of complete steel construction. It is not a question of underframes at all, but the entire car was of steel.

C. D. Young (Penn.): We have had in our department a large amount of experience in the recording of shocks of trains in service, and basing my views on what I have seen recorded as shocks and the resultant damage, it would seem to indicate to me that the impact force in pounds shown here is much higher than the true impact force that the material receives. Judging from these figures, it seems to me that they must be taken with some reserve. Of course, if you figure the fibre stress of center sill construction, figure the strength of the coupler in buffing under the drop or the pulling test of the coupler, and noting that the cars are struck very frequently at such a speed as 45 m. p. h. you would expect a much higher renewal rate than we actually get with these cars in service. It is possible, however, that there are some combinations of the service strains, as compared with the recorded data here, that do not make the figures comparable. It is interesting to note that the trend of the lines of the loaded cars toward a low speed of ⅛ m. p. h. or ¼ m. p. h. are not in the same direction—apparently they are crossing each other, and the loaded car at the low speed of one mile an hour receives less shock than an empty car at the same speed. That would hardly seem to be true, because the shock must be in some proportion to the mass.

Mr. Hennessey: I would ask Professor Endsley at what load the shank of the coupler commenced to compress or shorten up.

L. E. Endsley: The way the test was made, if you stop several times, you will get the coupler shortened by probably two inches. It took its first big move at about 450,000 lb.

Mr. Hennessey: Was that permanent?

Prof. Endsley: It would be permanent. In the case of the shank of the coupler to which we applied 800,000 lb., the coupler would go back .11 of an inch, that being the limit of elasticity in the metal due to its length.

R. L. Kleine (Penn. Lines): The tests which Prof. Endsley made were tests of distortion, leading to destruction. When you shorten a coupler up two inches, the coupler is destroyed. As previously stated in the coupler report, we are working within an elastic limit of material, not only in a compressive stress, but also in the pulling stress, as well as in shock.

Prof. Endsley: Of course, the time of applying the load will affect the total movement or total amount of distortion. It will take some 40 or 50 blows, instantaneous blows, of a drop hammer, of a duration of 1/300 of a second, to equal the same distortion you would get in a static machine in 35 seconds, but the total distortions, the distortions between a static load and a drop test load would be comparable if you could keep the load on any static a given time, and keep the drop test on a given equivalent time. As regards what Mr. Young says, do not imagine you get this load very often in service, because if you do, you are repairing cars. I was in a Pennsylvania yard and I was never able to measure over 3.5 to 4 miles an hour with their light cars, and many cars are switched at less than 2 miles an hour.

Mr. Kleine: Has Prof. Endsley made any tests to find out when permanent set first took place? I have taken the test figures Prof. Endsley furnished on the drop test, and also the figures that he obtained on the pulling test machine, and I might say that the permanent set is not comparable. The *C* dimension, for example, on the pulling test machine ran .02 of an inch at a load of 580,000 lb., and on the drop machine it ran .015 of an inch. There is a wide variation there.

Prof. Endsley: In answer to Mr. Kleine's statement regardings the *C* dimension I will explain that is the measurement from the nose of the knuckle to the head of the coupler. That dimension depends on a great many things, and I would not want it to be said that that was less than 0.1 in. every time, because that is a relation between the set of the knuckle, and not a distortion of metal. If it is pulling the nose out, your lock may be in one position one time and in another position another time. The comparison Mr. Kleine just made is not comparable. I grant in any individual test that the *C* dimension from the nose to the back of the coupler will vary in one direction or the other. If you will look at the report of the Coupler Committee, you will find that the line jumped back and forward, and is not comparable. In service it is an important dimension, but it is not indicated in the report as to whether it could stand overstrain or not, it merely tells us where the lock is, or how much dirt is behind the knuckle.

S. G. Thomson (P. & R.): I think the bug in the whole thing is the way you hold the object you are going to hit. Mr. Young's remarks that we ought to take with some reserve the strains we are getting in the draft gear, are pretty well taken. If we put the coupler up against a block of granite and then deliver such a blow as that, it would smash it all to pieces the first time. That is what we tried to develop in the test I spoke of before. The coupler and the draft gear and the sills themselves are all very flexible. I doubt very much whether you can deliver a blow to a coupler or more than 500,000 lb. on a car. I do not think you can hold it solidly enough to do it. The coupler will take part of the blow. It all depends on the way it is rigged up. If the rigging is so arranged that the butt of the coupler hits the bolster at the same time the horn hits the end sill, that is one condition in the coupler; if the rigging is arranged so you have a rigid and stiff draft gear that takes all the force, and the end sill does not get any of it, you will get another condition, but if the rigging is very light and weak, the less damage to the car and the horn takes all the force, and the steel car or wooden car takes the bumps. Mr. Crawford said his tests showed 100,000 lb. per mile. If that holds out in the test we made, running the car down a hill at 20 m. p. h., there is a force of 2,000,000 lb. This

test did not do much damage. But you can see if it was not a flexible and yielding attachment, that it would be like running up against a block of granite, and it would smash everything to pieces the first crack.

Prof. Endsley: The point made by Mr. Thomson is true, that the efficiency on the start is going to determine the final pressure you have, which will control the measurements. There is no doubt about that, but what I was talking about is a solidly constructed steel car, the car we are eventually going to use. Any comparisons made some years ago of different kinds of cars would not be comparable with these.

Prof. Endsley: As I stated in my paper there was lost in some impacts 70,000 ft lb. of work. We have draft gears on the market that will absorb 14,000 lb. In one impact on the N. & W., to show what damage can be done at 6.6 m. p. h. with a car light, nine journal boxes were broken, 5 on the standing car and 4 on the moving car.

James Coleman: Regarding the cars with which the experiments were made on the N. & W. and on the Pennsylvania, were they equipped with spring tension draft rigging, or friction draft rigging?

Prof. Endsley: On the Pennsylvania cars they were equipped with the Westinghouse gears and on the N. & W. they were equipped with the Session gears.

Mr. Barnum: I would like to amend my motion and add to it that a committee be appointed, with Prof. Endsley as Chairman, to pursue this investigation further.

Mr. Thomson: I believe the force of inertia is sufficient to do a great deal toward this permanent set, and as I said before, the blow that you can strike in holding a car loosely and the most rigid steel car that we can build, is not sufficient to strain the metal in the coupler possibly beyond 400,000 or 500,000 lb., as you cannot hold it solidly enough. I would like the Committee to determine how large a part inertia plays in this matter.

The President: I wish to make one statement—Mr. Thomson quoted my reference to 100,000 lb. per mile per hour. My knowledge of the subject quits at 6 miles per hour, and I cannot say whether he is correct in going above that figure.

(Mr. Barnum's motion as amended was carried.)

AIR BRAKE MAINTENANCE

F. W. Brazier (N. Y. C.): The maintenance of air brakes in first class serviceable condition has always been considered necessary in both passenger and freight service, but investigations of existing freight brake conditions show that they are far from satisfactory. On a 100-car freight train where a brake pipe leakage in excess of 2 lb. per minute exists, it will be found difficult to maintain through the whole brake pipe the uniform pressure necessary to produce uniform rate of deceleration for each car in the train during a brake application; yet such uniform rate of deceleration is required to control properly the motion of the train; hence, in the interest of safe and satisfactory train handling, and in the interest of economy both in time and in the quantity of air used, brake pipe leakage should be reduced to a minimum. The saving in fuel to be effected, as will appear from what follows, and to some extent the saving in wear in air brake hose, and on air compressors and locomotive boilers, should urge us to eliminate this leakage to the fullest extent possible.

Modern freight trains have become so long and the cars composing them so heavy that only the largest compressors are capable of supplying the air required to charge the brake apparatus in reasonable time. From numerous tests it has been shown that the most efficient air brake compressors consume approximately one pound of coal and require 7 lb. of steam for each 35 cu. ft. of free air compressed. The total volume to be charged for a 100 car freight train, all 10 in. brake equipment, is close to 180 cu. ft. A leakage of 4 lb. per minute from this volume—not an unusual amount met with at present in general service—means a loss of 48 cu. ft. of free air each minute, or 2880 cu. ft. each hour. Putting this in terms of coal and water it means an hourly waste of 82 lb. of coal and of 574 lb. of water, but added to this should be the wear on the locomotive boiler in producing the additional steam, and other air brake appurtenances. While 4 lb. leakage per minute has been used above for illustration, in a great many cases it will be found to be 5 or 6 lb., and in some cases it is so high that to apply the brakes all that is necessary is to lap the handle of the brake valve. The loss in coal will of course be directly proportional to the leakage in pounds. A conservative estimate of the coal consumed by the air compressor in supplying air for the average leakage in a 100 car train for 10 hours is from 860 to 1720 lb. It is worthy of note that on many freight trains about as much air is pumped through the system to supply leakage every five minutes as is required to make a full service application of the brakes.

From the foregoing it may be seen that it will cost us no more, if as much, to maintain our freight air brake apparatus practically tight, than it does to allow it to run in the present leaking condition. The cost of allowing the defects in the air system is probably not less than $1.50 for each 10 hours a 100 car train is in operation. In many cases it is much more. Other things, however, as well as a tight brake system require attention in order that the brake condition may be entirely satisfactory, and it will be necessary only to mention them, for the evil effects of continuing them in service and the remedies required to remove the objectionable features are obvious. They are: Excessive piston travel; safety chains missing; brake beam hangers and brake beams worn too thin; holes in brake levers worn oblong; interference of brake pistons with car timbers and beams; corroded brake pipes; angle cocks at improper angles, and handles missing; broken and leaky pressure retaining pipes; missing bolts and cotter keys; missing brake shoes, etc.

In connection with this subject it may be well to suggest that if the standard location of the angle cock back of the pulling face of the coupler was made 10 in. instead of 13 in., heavy strain on and pulling apart of those couplings in many cases would be avoided and also heavy leakage in those couplings. Once the freight air brake conditions are made satisfactory they can be maintained that way with very little additional labor over what is being expended at present in freight brake maintenance; while the economy effected, the improved brake operation resulting, and the freedom from accidents chargeable to air brakes that will follow the realization of the improved conditions leaves no reasonable excuse for the railroads of this country not acting as a unit to bring it about.

D. R. MacBain (N. Y. C.): It is a fact that we are having a great deal of trouble around the country on account of defective air brake equipment. One of the biggest troubles we are having is the air pipe matter.

W. O. Moody (Ill. Cent.): The elimination of leakage is largely the result of facilities at hand to discover the leaks before the engine is put on the train, and we have spent a considerable sum of money the past year in providing air plants so that we can determine the condition of the brakes before the road engine is put on; and wherever such installation has been made, very gratifying results have followed. A great many good roads are laboring under antique methods of testing triple valves; they have no improved facilities; time and money is spent to make tests that really do not amount to anything, and I think the matter of having proper facilities for testing triple valves is something which also should have attention. Various roads have air brake defect cards and have made efforts to put them in service. I should say on the whole the success of the efforts have been rather indifferent. If we could get train men to card the defects when they are observed, the inspectors would know what the trouble is and go right to that car and apply the necessary repairs, but it seems almost impossible to get that card in proper use.

J. J. Tatum (B. & O.): When the cars come on the shop track the levers should be checked to know that the proper lever is maintained on the truck as required by the braking power allowed the car.

ELECTION OF OFFICERS

The following officers were elected: President, D. R. MacBain, superintendent motive power and rolling stock, New York Central Lines West of Buffalo; first vice-president, R. W. Burnett; second vice-president, C. E. Chambers, superintendent motive power, Central Railroad of New Jersey; third vice-president, J. W. Demarest, superintendent motive power, Pennsylvania Lines West of Pittsburgh, Northwest System; treasurer, J. S. Lentz, master car builder, Lehigh Valley.

The following were elected members of the executive committee: C. E. Fuller, superintendent motive power and machinery, Union Pacific; F. F. Gaines, superintendent motive power, Central of Georgia; I. S. Downing, general master car builder, Cleveland, Chicago, Cincinnati & St. Louis.

The election of members for the nominating committee resulted in the selection of F. W. Brazier, superintendent rolling stock, New York Central Lines; J. J. Hennessey, master car builder, Chicago, Milwaukee & St. Paul; F. H. Clark, general superintendent motive power, Baltimore & Ohio; F. F. Gaines, superintendent motive power, Central of Georgia; and A. W. Gibbs, chief mechanical engineer, Pennsylvania Railroad.

W. M. Garstang, T. H. Orchard, J. E. Buker, E. W. Grieves and S. A. Crone were elected life members. Prof. L. W. Wallace was elected an associate member.

LOST

Lady's handbag containing watch with the initials L. K. D. and small amount of money. Please report or return to *Railway Age Gazette* office if found.

SIXTH DAY'S REGISTRATION FIGURES

The registration figures from the sixth enrollment book for the last four conventions are given in the following table. The figures for 1911 are not available, because there were only five enrollment books issued during that convention:

	1912	1913	1914	1915
Members M. C. B. and M. M.	668	700	758	731
Special Guests	684	724	612	541
Railroad Ladies	471	521	467	421
Supply Ladies	223	312	288	235
Supply Men	1523	1680	1497	1254
Total	3569	3937	3622	3182

A. B. APPLER—AN APPRECIATION

Evidently A. B. Appler, mechanical engineer of the Delaware & Hudson, occasionally finds it necessary to discuss matters of design with the Schenectady boys. At least we infer this from the following poem which was picked up on the Boardwalk:

Little Benny Appler is an energetic man,
He comes up to Schenectady just every time he can,
He talks each subject over from every point of view,
It's up to us to cover same in "notes of interview."

There are encyclopedias on which there are no flies,
And Noah Webster's Unabridged is quite a decent size,
But all these pond'rous volumes their "rep." for size would lose,
Should some syndicate but publish these "notes of interviews."

THE NEW VICE-PRESIDENT

At the closing session of the convention yesterday Thomas W. Demarest, superintendent of motive power of the Northwest System of the Pennsylvania Lines west of Pittsburgh, was elected a vice-president of the association. Mr. Demarest was born at Englewood, N. J., March 18, 1868, and was graduated from Stevens Institute of Technology in 1888. He entered railway service as a special apprentice in the shops of the Pittsburgh, Cincinnati & St. Louis at Columbus, Ohio, in 1889. On August 1, 1891, he was made assistant to the superintendent of motive power of that road, and for one year, 1896, was assistant to the master mechanic in charge of shops at Indianapolis, Ind. For the next two years he was general foreman of the locomotive department at that place, and in 1899 was made master mechanic at Logansport, Ind. From January 1, 1900, to July 1, 1903, he was superintendent of motive power of the same road. He was appointed to his present position in July, 1903.

PRESENTATION TO MR. CRAWFORD

At the closing session of the Master Car Builders' Association George A. Post presented the past president's badge to the retiring president, D. F. Crawford. He said in part:

"I come from the Court of Appreciation over which no crowned potentate bears sway, creating favorites without rhyme or reason to gratify caprice, or stripping of honors those who fall under the shadow of a fitful frown. My credentials are from a world power (habitat in the hearts of men) which sits in judgment upon the activities, motives and achievements of struggling mortals, eager to pay tribute to those who prove themselves worthy of reward.

"Young as I am, Mr. Crawford, I have witnessed your novitiate in engineering science; your masterful strides toward the goal of distinction in your chosen field of strenuous endeavor during the intervening years, and today I count myself singularly fortunate that I have been designated to call out publicly the station at which you have arrived *en-tour* where you are stopping only long enough for this appropriate decoration."

Conventionalities

J. F. Walsh, formerly superintendent of motive power of the Chesapeake & Ohio, Mrs. Walsh and daughter arrived Sunday and are stopping as usual at the Chalfonte Hotel. Mr. Walsh has recently recovered from a rather serious illness.

A visit from the "stork" necessitated W. H. Coyle, vice-president of the Franklin Railway Supply Company, remaining home for the early part of the conventions. He arrived today reporting the addition of a bouncing boy to his family. This is the second boy.

William St. John, of the Safety Car Heating and Lighting Company, was unable to attend this year's convention

President-Elect S. W. Pratt, of the M. C. B. Association, and Mrs. Pratt

because of illness. His many friends have missed him; and we join with them in wishing him many happy returns of his birthday, June 18.

J. Leonard Replogle, who left for New York yesterday afternoon, was made vice-president and general manager of sales of the American Vanadium Company on March 1 last and represented that concern instead of the Cambria Steel Company of which he had been vice-president and general manager of

sales and with which he had been identified for more than 26 years.

Charlie Storrs, manager of the railroad department of the Storrs Mica Company, was late in getting here. His tardiness is explained by the fact that he stopped off at Ithaca to attend

Left to Right—S. W. Mullinix, Supt. Shops, C. R. I. & P.; Fred W. Venton (Crane & Co.); J. C. Campbell (Chicago Pneumatic Tool Co.), and L. A. Richardson, Mech. Supt., C. R. I. & P.

his class reunion—something that he has been compelled to miss for several years past because it occurred simultaneously with the conventions.

Among those whom all enjoyed seeing at the conventions in years past, but who are not here this year, is H. J. Small, formerly superintendent of motive power of the Southern Pacific, who has retired, and is now interesting himself chiefly in the progress of his sons in business. T. W. Heintzelman, general superintendent of motive power of the Southern Pacific, expected to come to attend the conventions, but owing to important matters has found it impossible to come. J. F. Graham, superintendent of motive power of the Oregon-Washington Railway & Navigation Co., has not sufficiently recovered from his recent serious illness to make the trip, but his many friends will be glad to learn that he is improving and hopes to be in evidence next year. R. W. Burnett, who recently resigned as master car builder of the Canadian Pacific, has gone to San Francisco for a long

John A. Pilcher, Mechanical Engineer, Norfolk & Western, Wife and Son, William

needed rest, and more particularly with the hope that Mrs. Burnett's health will be improved.

The neat little pencils used at all the dances in connection with the conventions, except the Friday Carnival, were presented to the entertainment committee by the Joseph Dixon Crucible Company, who furnished about twenty-five gross of them. Inasmuch as the committee did not have a large fund to draw upon the gift was much appreciated.

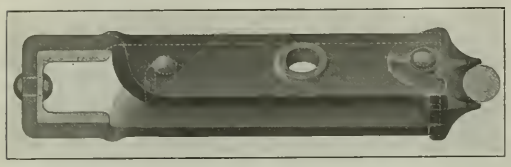
LARGELY SANTA FE OR EX-SANTA FE MEN

Top Row, Left to Right—P. M. Ripley (formerly on Santa Fe), Assistant to Vice-President, El Paso & Southwestern; Albert MacRae, Editor, Santa Fe Employees' Magazine; John P. Landreth, Garlock Packing Company, Chicago; Frank W. Thomas, Supervisor Apprentices, A. T. & S. F.; C. T. Ripley, General Mechanical Inspector, A. T. & S. F.

Bottom Row—M. H. Haig, Mechanical Engineer, A. T. & S. F.; J. H. McGoff, Mechanical Superintendent, A. T. & S. F.; W. L. Allison (Formerly Mechanical Engineer, A. T. & S. F.), Vice-President, American Arch Company; John Purcell, Assistant to Vice-President, A. T. & S. F.; J. E. McQuillen, Mechanical Superintendent, G. C. & S. F.

FORGED STEEL BRAKE BEAM STRUT

A recently developed forged steel strut for truss type brake beams is being exhibited by the Buffalo Brake Beam Company, 30 Pine Street, New York. The strut is a one-piece forging, terminating at the truss rod end in a pocketed steel casting, to the flanges of which it is securely riveted. It



Forged Strut for Brake Beams

is designed to secure greater reliability and strength than is usually possible with a casting and, as shown in the illustration, is simple of design and easy of application.

ALL-STEEL BOX CAR

At the space of the Bettendorf Company, of Bettendorf, Iowa, an all-steel box car is on exhibition which embodies a number of features of interest. The underframe and trucks are of the standard Bettendorf type of construction, all the principal dimensions being in accordance with the recommendations of the M. C. B. committee on car design.

The construction of the superstructure is generally similar to that of the Union Pacific automobile cars described in the *Railway Age Gazette, Mechanical Edition*, for February, 1915, page 73, and in the February 5 issue of the *Railway Age Gazette*. The side sheets are applied to the outside of the frame, however, while those of the Union Pacific cars were applied inside. These sheets are of $\frac{1}{8}$ in. steel cut in panels with the vertical edges flanged at right angles to the body of the sheets. The flanges of the adjoining sheets are riveted to the web of a Z-bar post from the inside of the car, thus producing an extremely smooth exterior.

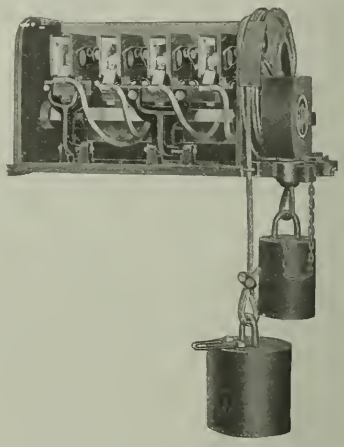
The whole car is wood lined throughout so that severe climatic conditions will not cause precipitation of moisture. The principal data and dimensions of the car are:

Capacity	100,000 lb.
Length inside	40 ft. 6 in.
Width inside	8 ft. 6 in.
Height inside	9 ft. 0 in.
Width of side door opening	6 ft 0 in.
Weight complete with lining	45,900 lb.
Weight of trucks complete	15,000 lb.

SAFETY LIMIT STOP FOR ELECTRIC CRANES

A device designed to automatically prevent over travel of crane hooks is shown in the illustration. It is being exhibited by the Electric Controller & Manufacturing Company, Cleveland, Ohio, and consists of a cast iron frame within which is a set of cam operated electric contacts which control the hoisting motor circuit. The frame is mounted on the top of the crane trolley, where it is accessible for inspection. The contacts are operated by a sheave and steel cable to the ends of which are attached weights of cast iron.

The operation is controlled by a shoulder attached to the crane hook. As the point of highest travel consistent with safety is approached this shoulder raises the lower weight,



Safety Limit Stop for Crane Hooks

and causes the sheave to rotate. The motor circuit is thus opened and a dynamic breaking circuit closed which brings the motor to rest within a hook travel of two inches, regardless of the load or the speed at which it is being hoisted. Lowering the hook permits the moving parts of the automatic stop to return to normal position without attention. The contacts are opened under the influence of a magnetic blow-out, and are protected by a sheet iron cover which may be readily removed for inspection.

Contents

MAINTENANCE OF WAY SECTION

*Illustrated.

It seems that the measure which has been pending in the Illinois legislature to limit the length of freight trains finally has been killed. It originally prohibited the railways from running trains of more than fifty cars. The roads conducted a vigorous campaign against this provision, both at Springfield and in the newspapers of the state. When the labor lobby saw the fifty-car bill could not be passed it substituted a measure limiting the length of trains to seventy-five cars. This at one time received 78 votes in the House, and it looked as if it might be passed; but when it came up for third reading it was defeated, 61 to 7. The labor lobby has introduced train-limit bills in nineteen states this year; and up to date it has been defeated in every state. The hardest fight for legislation of this kind was made in Illinois, and the final complete defeat of it there is a strong indication that it will never be possible to get it passed in another state.

Train Limit Bill Defeated

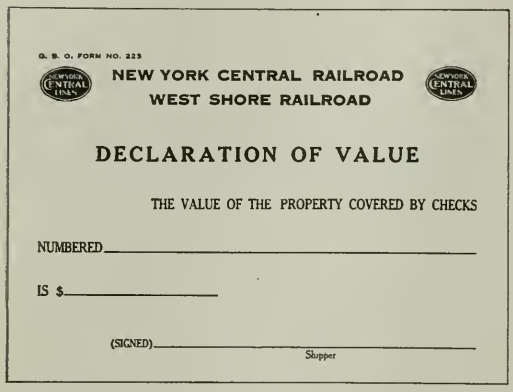
Station baggage men say that the "kickers" against declaring the value of their trunks are very few—as might, perhaps, be expected, when one considers that, after all, this declaration is only a reasonable application of the common law, long settled. If the passenger is well enough informed about the value of the property in his trunk to be able to make a reasonable estimate without stopping to calculate, he need be delayed not more than a minute. It is the railroad, rather than the passenger, who has cause for complaint; for at large stations, where, at best, many passengers will be slow, the checkers have had to be provided with considerable clerical assistance. The Interstate Commerce Commission's declaration about the crime of misstating value appears to have been the cause of a good deal of unnecessary comment. Indeed, the Washington correspondent of the New York World says that he has already been told, at the office of the commission, that a passenger is not bound to declare the full value of his property. As in any other form of insurance, he has a right to insure for less than full value. Jewelry salesmen say that their trunks, often worth several thousand dollars, are regularly insured by policies covering all risks, not only on the cars but at hotels and all places except the owner's store. It is not likely that the commission or the courts would compel double insurance. Making the value low, as a basis for insurance against loss, is a different thing from misstating it for the purpose of securing a reduced rate for transportation. The misdemeanor clause in the commission's report had in view, no doubt, such cases as declaring silk to be no more valuable than cotton, so as to secure a low freight rate. Freight rates are made higher on valuable goods, on the theory that the transportation is worth more to the owner; but in the baggage car the railroad is willing to carry the rich passenger's trunk and the poor passenger's at the same rate. If the owner of a trunk containing diamonds desires to have the carrier assume the large risk of the loss of that trunk, he is rightfully required to pay insurance; and if he prefers to bear a part of the risk himself, it is only reasonable to allow him to do so.

Insurance of Baggage

To write down the value of a piece of baggage and affix a signature to the statement need not take over half a minute; and not over a minute, even if one of the modern six-figure check numbers be added. But besides brevity there is a marked advantage in simplicity; and there are degrees of simplicity. The blank used by the New York Central is reproduced below, two-thirds actual height and width. The only things that detract from its simplicity are the printer's reference line and the two oval trade-marks; and if the advertising agent should claim that the trade-marks do not at all affect the passenger's eye or nerves, or mind, it would be difficult to dispute him. Examining the blanks of two other prominent roads, it will be found that they

Baggage Declaration Blanks

contain 11 and 17 lines, respectively, while yet they provide for no more information than is provided for here. It is natural enough to call a matter of this kind a trifle, hardly worth attention; but it is to be remembered that in transactions which are consummated in a few seconds, apparent trifles often count.



G. B. O. FORM NO. 223

NEW YORK CENTRAL RAILROAD
WEST SHORE RAILROAD

DECLARATION OF VALUE

THE VALUE OF THE PROPERTY COVERED BY CHECKS

NUMBERED_____

IS $_____

(SIGNED)_____
Shipper

Moreover, this declaration is a part of a contract. The passenger cannot afford to treat it as a trifle; and if time is to be saved it is worth while to keep out of sight everything that would tend, unnecessarily, to make him hesitate a second in signing the declaration.

Morris & Essex and the Lackawanna

The Morris & Essex forms the eastern end of the Delaware, Lackawanna & Western, running from Hoboken on the Hudson to Phillipsburg, N. J., and from Denville to West End Tunnel, 118 miles. It was chartered in 1835, and 50 odd miles of road opened in 1854, and completed to Phillipsburg in 1866. There is $15,000,000 stock outstanding, and the property was leased to the Delaware, Lackawanna & Western in 1868, in perpetuity. The lease provides that 7 per cent shall be paid on the stock by the Lackawanna, and that an additional 1 per cent, making 8 per cent in all, shall be paid when the gross earnings of the Morris & Essex have reached a certain figure. The Delaware, Lackawanna & Western owns comparatively little of the outstanding stock, most of it being owned by individuals, trust companies and estates. The Lackawanna has never paid more than 7 per cent to Morris & Essex stockholders. A committee has now been formed with the president of the Metropolitan Trust Company as chairman, which has brought suit against the Lackawanna, claiming that 8 per cent should have been paid for a number of years back. This committee is also asking proxies from stockholders, with the purpose of electing a board of directors not identified with the Delaware, Lackawanna & Western. As to whether or not the accounting should have shown gross earnings sufficient to compel the Lackawanna to pay 8 per cent is a question which will be decided when the trial takes place. The propriety, however, of an independent board of directors which will represent Morris & Essex stockholders' interests and not Delaware, Lackawanna & Western stockholders' interests appears to be hardly a matter that can be questioned. In this case the Morris & Essex stockholders' interests are directly opposite to those of the Lackawanna's. The Morris & Essex stockholders want as large a rental as possible, the Lackawanna as small a rental as possible. There is no question apparently of the management of the property which belongs to the Lackawanna in any case under the terms of the lease. It is one of those things where it would appear to be better practice for the leasor to have a wholly independent board of directors, than to have its own directors or officers acting in dual capacity where there is a possibility of diametrically opposed interests presenting questions for settlement. The trouble in this case is that there is no provision in the lease for paying the directors or for maintaining a separate office and bookkeeping force. This probably has been a fact which Lackawanna directors have used to justify to themselves their action. It will be particularly interesting to follow the attempt of the new committee to arouse stockholders to the situation and the success or lack of success which is met with will be illuminating as to the possibility of getting railroad stockholders to take a more active interest in the affairs of their company.

THE HANDLING OF L. C. L. FREIGHT

WHILE less-than-carload freight forms only about 4.3 per cent of the total tonnage handled, the revenue derived therefrom is a very considerable part of the total income of the railways. This business is, therefore, attractive from the standpoint of the traffic solicitors, although the operating department finds it expensive to handle. In consequence, many operating officers are giving a great deal of attention to means of reducing the cost of handling l. c. l traffic. Houses for the receipt and delivery of less-than-carload freight must be located close to the centers of business in cities and therefore on high-priced land. In most cases those now in existence were built years ago and are receiving more freight than can be handled economically, while the high price of adjoining property makes enlargement difficult and frequently impracticable.

E. H. Lee, vice-president of the Chicago & Western Indiana, has estimated (*Railway Age Gazette*, April 3, 1914) that the fixed charges alone amount in some instances to as much as $1.50 per ton of freight handled. This condition is prompting careful and extensive studies of the design of freight houses to secure the maximum capacity, and thus keep down overhead charges, while at the same time securing economical operation. The increasing use of motor trucks and other mechanical appliances is also beginning to be reflected in the design of freight houses.

The less-than-carload freight gives rise to far more than its proportion of claims for loss and damage. This arises largely from improper packing and marking of the individual packages, from rough handling to and from the cars and from improper loading in the cars, all of which the roads are endeavoring to eliminate.

Another important phase of this subject is the consolidation of less-than-carload freight shipments to secure the maximum practicable car loading. From the nature of the traffic it cannot be expected that its loading will ever approach that of carload freight. At the same time investigations on several roads have shown that it can be materially increased. By an aggressive campaign one road raised the average tonnage of l. c. l. freight per car for all stations from 4.6 tons in 1909 to 6.8 tons in 1914, and estimates that for the first nine months of the present fiscal year it has saved over 14,000 car movements as compared with the same period in the previous year.

One of the most direct opportunities for improvement lies in the reduction of the labor cost of handling at the freight house. In a report just made to the City Council of Chicago, John F. Wallace states that the labor cost of handling l. c. l. freight at 19 houses in Chicago varies from $0.29 to $0.66, with an average of about $0.475. The bonus system and other means for improving the efficiency of the labor employed have been adopted at a number of stations, while the installation and economical use of motor trucks and similar equipment also effects a reduction in the labor required.

The above examples illustrate the importance of this subject. To stimulate discussion of the subject we announce a contest on The Handling of L. C. L. Freight, to include all phases of this problem, from the time the freight is received

at the door of the freight house until it is delivered to the consignee at destination. While general discussions are solicited, descriptions of improvements in operation actually made and detailed statements of the results secured will receive special attention. Prizes of $50 and $35 will be paid for the two best papers received, the award being based on the completeness of the discussion and the practicability of the ideas presented. All other papers accepted and published will be paid for at our regular space rates. Contributions should be sent to the Editor of the *Railway Age Gazette*, 608 South Dearborn street, Chicago, and must be received before August 1, to be considered by the judges.

CREDIT—A NECESSARY ASSET

RIGHTLY understood the question and answer from the Wall Street Journal, reprinted elsewhere in this issue, throws light on one phase of the railroad problem which is probably less understood by the majority of legislators, and even by the Interstate Commerce Commissioners, than any other. The holder of Missouri, Kansas & Texas preferred stock who writes to the Wall Street Journal states substantially correctly the present very good showing which is being made in the operation of that property and winds up with the query: "With all these rugged facts, will the 'Board' dare to pass a dividend on the preferred stock this year?"

The Wall Street Journal points out the reasons why there is very small chance that the Katy will pay any dividends this year on its preferred. The company's credit must be restored, and this is as necessary as was the increase in its earning power. Credit is not only intangible, but of such a volatile nature that to discuss it even may destroy it. Yet credit is an asset just as vitally necessary to the operation and development of a railroad as the rolling stock or the roadway.

The Missouri, Kansas & Texas case is different in particulars from that of other roads of course. The present showing as compared with a year ago is better than the majority of roads are making. There are peculiar difficulties in the way of getting a specific vehicle for long term financing. There is illustrated, however, in this case the principle, the understanding of which is so necessary to an intelligent discussion of American railroad problems.

In a great majority of rate cases decided by the Interstate Commerce Commission, railroad credit never enters into the consideration of the case, and yet in the aggregate the Interstate Commerce Commission rate decisions vitally affect railroad credit. In the 1914 rate case one of the commissioners touched in a somewhat curious way on one of the points that is brought out in the Missouri, Kansas & Texas situation when he asked a railroad president whether he would tell a banker from whom he was going to try to borrow money how bad the earnings of the railroad were. In other words, what he wanted to know was whether a railroad president would make the same exhibit in trying to borrow money as was being made to the Interstate Commerce Commission in asking for higher rates. Pretty surely there were railroad managers who could have put before the Interstate Commerce Commission facts more convincing than any of the generalizations which were introduced as evidence, had it been possible to do so without at the same time injuring the credit of his road or of other roads.

As a railroad executive said recently, probably no one of the Interstate Commerce Commissioners ever raised $100,000 for business purposes in his life. The first plan for the reorganization of the Chicago, Rock Island & Pacific without receivership proceedings fell through, because when President Mudge and some of his operating officers appeared before the bankers who were to underwrite the plan, they could not truthfully say that in their opinion the road would earn the amount necessary to make reasonably sure of a preferred stock dividend. That was not a case of credit, but a case of earning power, and is just the converse of the Missouri, Kansas & Texas case. On the other hand, the present Rock Island situation is one in which credit plays a very important part. The Missouri Pacific is another instance.

Eastern roads especially are beginning to show material improvement in gross earnings. Many roads which had not shown a favorable comparison with the corresponding period of a year before for more than 15 months, showed a gain in May, 1915, as compared with May, 1914. Forces of train men as well as enginering and mechanical forces have been cut to the very minimum. As gross increases, expenditures for maintenance and renewals will be made on a more liberal scale than was possible last year. The Pennsylvania recent rail order is a case in point. The train crew and other forces in the transportation department will necessarily have to be increased and a considerable part of the gains which appear probable in gross will be absorbed in expenses, but not all it is to be hoped. Many roads ought to begin to show a larger net operating income. But beside the showing of earning power to pay interest charges on an issue of new securities for capital expenditures, there must also be a willingness on the part of the bankers to buy these securities. This is a point that is so hard apparently for legislators and theoretical students of railroad affairs to understand. There must be that indefinable something which supplies the incentive for the investment of money in railroads, and broadly that incentive has to be either a hope of very considerable profits or an assurance of a fair return and a reasonable guarantee against the discontinuance of this return. It is one thing to argue that bankers ought to have been glad to finance the Rock Island and quite another to put the deal through. Neither commissioners nor legislators can change a static force into a dynamic force; that is, they cannot make investors actually put their money into some particular enterprise; but what they can do and should do is to recognize that certain conditions are conducive of this change and certain other conditions are unfavorable to it.

PROGRESS OF THE BLOCK SYSTEM

NO less than 76 railroads report to the Interstate Commerce Commission that all of their passenger trains are run under the space-interval system, as will be seen by the abstract of the commission's latest bulletin, printed on another page. That is to say, 76 roads report that all of their passenger tracks excepting, in a few cases, lines on which only one engine is in service—are operated by the block system. In addition to these there are 20 others which report 90 per cent or over, thus operated, making a total of 96 roads reporting 90 to 100 per cent.

This is a gratifying exhibit. Progress in this field until recently has been slow, but at last it seems to be sure. The totals of the government tables are approaching the 100,000-miles mark and evidently the time is not far distant when passenger traffic on the important lines everywhere throughout the country will have the benefit of this system. That the principle of the space interval is well appreciated is evident from the fact that block signals are used on two or three hundred miles of road devoted exclusively to freight traffic; and that the good results on all sorts of lines are substantial is evidenced by the statistics of collisions for the last few years, showing a striking reduction in the losses from this cause. Some of these statistics were given in the *Railway Age Gazette* for May 21 last, page 1036. Another significant item, though it fills only an inch, is that printed in this issue, to the effect that on a very busy division of the Baltimore & Ohio the derrick and tool cars recently had a complete rest for 45 days. This record could be matched on other roads, no doubt. When the "A B C" block system was in use on the Northern Pacific, it was credibly reported that on one division the wrecking car was left standing unused for so long a time that it developed flat wheels!

The number of 100-per cent items in the table published today is about 20 per cent greater than the total in the table issued one year ago. Those in that report numbered only 50,

and the 90-and-above only 16. The increase, however, is not quite so large as it appears, for the Grand Trunk this year is divided into 13 items, while last year the total for the system was consolidated in one item. There are a few other similar cases, making the net increase in 100-per cent items, as stated above, about 20 per cent. Again, it is to be borne in mind that this year there are many new names in the table, including some electric roads; and that on these, while the statistics are new, it may be that the signaling is not. But, making all allowances, there still remains a gratifying increase in the number of roads which believe in the space interval through thick and thin; and this gratification has a substantial basis, notwithstanding the further allowance that must be made, namely, that on some of these 100-per cent. roads the space interval is not much used except for the protection of passenger trains. The use of the space interval in any degree, at any time, is ground for satisfaction, for it has a constant educational effect; and sooner or later this leads to the further introduction and the perfection of the system. The government statistics (Table No. 4, manual block signal practice) afford further gratification in the column headed "permissive signaling forbidden," in which there are 32 items, aggregating 5051 miles of road.

This great improvement costs money, of course. The difficulty of raising money under the present almost impossible conditions is the reason why a greater extension of the best signaling cannot be reported at the present time. It will be noted that the figures of two roads, the Southern Pacific and the New York, New Haven & Hartford, account for 87 per cent of all the increased mileage shown, in the smaller table, under the head of non-automatic signaling. On both these roads this extension has been mostly made on lines not classed as important parts of the system. In other words, the officers have improved their service, not because of losses by wrecks, temporarily stirring the directors' feelings, but from a clear understanding of the permanent principle; the principle that the space interval is fundamentally rational while the time interval can never be other than patch-work. If these officers had shortsightedly drawn a balance between the cost of maintaining safe methods and the cost of wrecks under the old methods they might have decided not to make the improvement. By shutting one's eyes to the future this is often possible. On the New Haven road the change added to the current expenses about $1,000 a month, and that road just now has no thousand-dollar bills to throw away; but, as has been said, the officers evidently decided to do what was best for the service, not what would be best temporarily to sustain the cash balance.

NEW BOOKS

The Panama Canal. By Reuben E. Bakenhus, civil engineer, United States navy; Harry S. Knapp, captain, United States navy, and Emory R. Johnson, professor of transportation and commerce, University of Pennsylvania. Size 6 in. by 9 in., 257 pages, with maps and illustrations. Bound in cloth. Published by John Wiley & Sons, Inc., New York City. Price $2.50.

This book includes under one cover five papers originally published in the Proceedings of the United States Naval Institute. In their preparation the authors have endeavored to present a comprehensive view of the canal, its history, the manner in which it was built, and its place in commercial and international activities. One-half of the book is devoted to the construction of the canal, including discussions of the reasons prompting the adoption of the present location and the lock rather than the sea level type. The chapter on the standing of the canal in international law, including copies of the various treaties concerning it, and the discussion of its commercial importance and its effect on lines of travel, will also be of interest to railway men. In an appendix is given the President's proclamation of last year, assuring the neutrality of the Canal Zone. The book is accompanied by six maps, showing the features of the canal in detail.

Letters to the Editor

STATE AND FEDERAL ACCIDENT-REPORT REQUIREMENTS

New York City.

To the Editor of the Railway Age Gazette:

Your correspondent "R. R. N. Y." in a letter published May 28, under the caption "The Government Accident Records," presumes that the railroads "are using their influence with the Washington authorities, through the committee of which Mr. Kruttschnitt is chairman"; and asks "Why should they not also use their influence with the state commissions?"

The American Railway Association Special Committee on Accident Statistics, in conference with W. J. Meyers, statistician of the Interstate Commerce Commission, arranged for a meeting with the representatives of the railway labor organizations, the National Association of Railway Commissioners, and representatives of the public service commissions of New York and Pennsylvania, at which the proposed accident forms and rules were fully discussed and conclusions were reached acceptable to all interests represented. It was obviously impossible to take up the preliminary steps with the commissions of 45 states, and our committee thought that with the approval and endorsement by the representatives of the National Association of Railway Commissioners, and of the public service commissions of two of the most important states in the Union, of what had been done, that they were making a very fair start, and that after a tentative conclusion had been reached, would be the proper time to submit the forms and rules, etc., to the railway commissions of all of the states that had commissions. The statistician of the Interstate Commerce Commission mailed copies of the revised draft of the rules and the proposed forms to all of the state railroad commissions, to public service commissions, and to all others interested, on May 17, with a request for further criticisms and suggestions.

It is therefore evident, from the above, that the co-operation of the state railroad commissions has been invited, and our committee hopes that the general adoption of the Interstate Commerce Commission's blanks for reporting accidents will result therefrom. J. Kruttschnitt.

SIMPLE TRAIN AND ENGINE NUMBERS

Little Rock, Ark.

To the Editor of the Railway Age Gazette:

Is there any benefit to be derived from trains and engines carrying large numbers? I am sure it is not apparent from a despatcher's standpoint. The car service office and the general transportation clerk may secure a little advantage in being able to know off-hand just where a certain train runs, without having to consult the time cards, but it is doubtful if they rely on that to any degree now. Some tables show individual train and engine numbers as high as four figures; and when a despatcher in writing and sending an order has to spell out the train numbers two or three times, and add the long engine numbers, there is quite a little loss of time. How much easier and simpler to say and write train No. 1, engine 5, than train No. 1326, engine 7702.

Some local trains are run from, say A to B under No. 52, B to C as No. 54 and so on. What is there to prevent No. 52 being carried over the entire line? C. H. A.

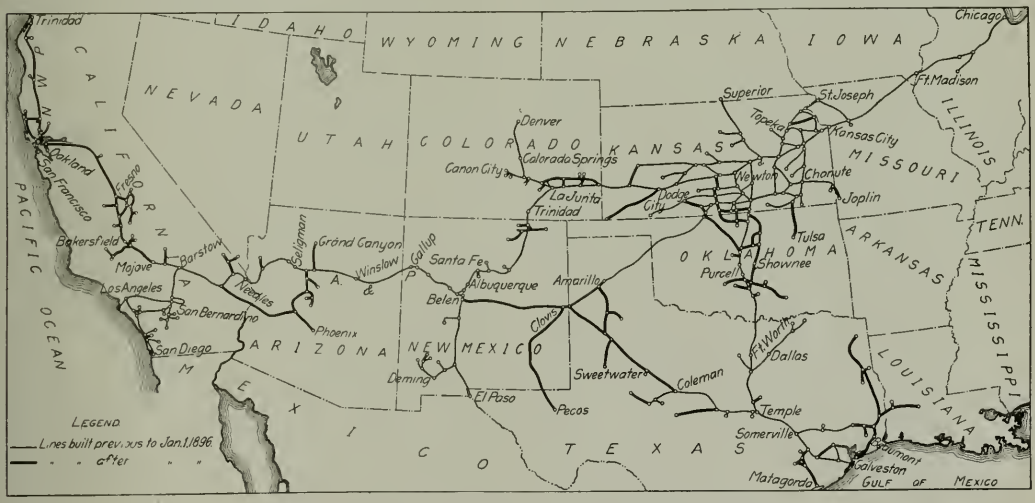
An Argentine Railway Record.—The Central Argentine recently made a record non-stop run. A special train of six cars, a total of 34 axles and 258 tons in weight, made the journey over the Rosario line of the Central Argentine, between Rosario and Retiro, Buenos Ayres, a distance of 189 miles. The run was made without a stop in three hours and 40 minutes, an average of 51 miles an hour.

Nineteen Years' Development Work on the Santa Fe*

Part 1—Outline of Methods by Which Property Has Been Developed and Physical Condition Improved

On January 1, 1896, the Atchison, Topeka & Santa Fe emerged from a receivership of two years' duration with 6,435 miles of line and with gross earnings for the preceding fiscal year of $28,851,841, resulting in a net deficit for the year of $4,433,380, after the payment of fixed charges. On January 1, 1915, nineteen years later, this road was recognized as one of the strongest in the United States, having over 11,000 miles of line, while its gross earnings for the fiscal year ending June 30, 1914, were $111,109,770, and its corporate income available for dividends and surplus was $20,183,965. Its record is made the more interesting by the fact that the gross operating revenues for the first nine months of the present fiscal year show an increase of $4,797,176, while its net corporate income shows an increase of $3,434,626 as compared with the same period last year, at a time when almost every other railroad is showing large decreases in both gross and net revenues.

The means by which this property has been developed from its earlier condition of weakness to its present position of strength, during a period when some of its closest competitors have become involved in difficulties of one kind or another, form a most interesting and instructive example of constructive and efficient American railroading. It will be the endeavor in this article to point out the more important policies underlying this development and the manner in which they have been applied to secure these results.



The Development of the Santa Fe Lines Since the Receivership

CONDITIONS LEADING TO THE RECEIVERSHIP

To understand fully the development which has taken place since the reorganization of the Santa Fe, it is necessary to review briefly some of the conditions leading to the receivership. The road was chartered in Kansas in 1859, but construction was not begun until nearly 10 years later. By 1873 the main line had been built from Atchison, Kan., west 471 miles to the western line of the state, and 38 miles of branches had also been constructed. In 1877, when William B. Strong was placed in charge of the property it had increased to 786 miles, nearly all of which was in Kansas. Mr. Strong was a man of wide vision, and he saw the opportunity for a system extending from the Great Lakes to the Gulf of Mexico and the Pacific coast, not only to reach these important sources of traffic, but to secure a widely diversified traffic. He, therefore, inaugurated at once a policy of active expansion. The main line reached La Junta, Col., in 1878; Albuquerque in 1879, and El Paso, Tex., and Deming, N. Mex., in 1881. The intention at that time was to extend to southern California over the general route now followed by the Southern Pacific, but this was blocked by the Southern Pacific interests building a line east from southern California. The Atlantic & Pacific was then acquired by the Santa Fe and the St. Louis & San Francisco jointly and construction started westward from Albuquerque, reaching the Colorado river at Needles, Cal., in 1883, where it met another Southern Pacific line built south from Bakersfield. An agreement was soon reached whereby this line of the Southern Pacific, from Needles to Mojave, Cal., was leased with an option to purchase. After the reorganization of the Santa Fe this line was secured in exchange for the Sonora line which the Santa Fe had built south from Benson, Ariz., to Guaymas, Mex.

During this time the Gulf, Colorado & Santa Fe was being built north from Galveston by local interests, reaching Fort Worth in 1881 and Dallas in 1882. In 1886 the Santa Fe secured control of this property and extended it north to a connection with its own line at Purcell, Okla., the following year. However, it was from 1885 to 1887 that there was the greatest activity in construction. In 1886 almost 1,700 miles of line were completed, 1,000 miles of branch line being built in Kansas alone. The extension from Pueblo to Denver was completed that year, while the line to Chicago was finished the following year.

This period was characterized by widespread construction work throughout the entire West. It was at this time that the Burlington and Rock Island extended to Colorado, the Southern Pacific

*This, the first of two articles, describes the causes leading to the receivership, the condition of the property at the time of the reorganization and the policies governing the building of extensions and the maintenance of the roadway and equipment. The second article will appear in next week's issue and will describe the means by which the traffic has been developed, the methods of operation and the resulting increase in earnings.

reached New Orleans, and the Northern Pacific, the Great Northern and the Canadian Pacific were pushing westward. All of these and other roads were also building correspondingly large mileages of branch lines. As a result there was over-extension, the country did not develop as fast as the roads, and the net earnings of the Santa Fe, in common with those of other roads, began to decrease rapidly. As a result of accumulated troubles Mr. Strong resigned in 1889 and the management was changed.

The succeeding management at once endeavored to recoup its earnings by engaging in a war of rate cutting. At the same time it secured control of the St. Louis & San Francisco and the Colorado Midland. These developments greatly complicated the already serious problem, and led to the receivership on December 23, 1893. This lasted for two years, during which time numerous improvements were made to the property, and the Colorado Midland was sold. The capitalization was readjusted and on January 1, 1896, the receivership came to an end and the property was placed in charged of the present management.

CONDITIONS OF THE PROPERTY IN 1896

At the time it came out of the receivership the property consisted of 6,435 miles of line extending from Chicago to Galveston, Denver, Albuquerque and El Paso, in addition to a joint interest with the St. Louis & San Francisco in the Atlantic & Pacific, then in receivers hands. Its condition has been well described by Charles S. Gleed, a director, in a booklet entitled, "The Rehabilitation of the Santa Fe Railway System" as follows:

"When the new directors and officers took charge the line from Chicago to Kansas City, which recently had been constructed in very great haste, was in bad condition and required extraordinary expenditures. The line extending from St. Louis toward Kansas City for about 70 miles had to be extended or sold. Many new lines in Kansas needed heavy improvement. The Atlantic & Pacific had to be bought and then rebuilt. The line from Needles to Mojave was a wretched piece of track.

"The new lines in Indian Territory and Texas were in the poor condition usual to new lines in the west. The equipment was inadequate and the buildings were nearly all of the temporary style characteristic of new lines. The Sonora and some other lines were operating at a loss. The St. Louis & San Francisco lines were in most primitive condition. The old main line from Kansas City to Denver and El Paso was the only line in good condition for the service which had hitherto been required of it. Practically all of these lines had been well built and greatly improved, considering the standards of that day and the requirements of the traffic, but they were in no condition to accommodate the high speed and the heavy traffic of the time at hand."

This was the condition of the property when the new management assumed control. President E. P. Ripley and his associates have been in direct and continuous charge since that time, which must be borne in mind, for it is of primary importance in a study of the reconstruction of the property. Too often managements have been changed in the midst of the difficulties following a receivership before they have had an opportunity to demonstrate their ability or the wisdom of their plans. Mr. Ripley and his associates have been given full and uninterrupted opportunity for the working out of the policies outlined by them at the outset.

THE BUILDING OF EXTENSIONS

One of the fixed policies of the present management has been the concentration of its entire attention on the development of the Santa Fe proper. One of its first acts was to dispose of its interest in the St. Louis & San Francisco and other properties not essential to the operation of the Santa Fe itself. The broadness of this attitude and the determination behind it are revealed by the early sale of the St. Louis, Kansas City & Colorado, a short line extending west from St. Louis about 70 miles. At the time the Chicago extension was built this line was bought with the idea of incorporating it into a line from Kansas City to St. Louis to give the Santa Fe an entrance to the latter city, but no work had been done upon the construction of the intermediate link. As there were already several other lines between these two cities, its construction would only serve to further divide the traffic moving between those points and create an economic waste of capital. For this reason the line was sold in preference to building the connecting link. While by this act the Santa Fe gave up its opportunity to secure an entrance into St. Louis with its large traffic, which has been regarded by some as a mistake, it prevented the diversion of interchange traffic to its competitors. On the other hand, the Atlantic & Pacific, owned jointly by the Santa Fe and the St. Louis & San Francisco previous to its receivership and operated as a separate property, was essential to the Santa Fe, and it was taken over by it directly on July 1, 1897.

The same strict policy of conservation of capital has been followed in making expenditures for extensions and for increased facilities. No attempt has been made to engage in competitive building with other lines or to invade territory already provided with transportation facilities, unless the entrance to San Francisco be so regarded, and this was secured by the purchase of a line already built and in operation. Rather, construction activities have been confined to the large area in the southwest without adequate transportation facilities. Even here, a very conservative attitude has been maintained and extensions have been built only to reach sources of traffic definitely known to exist or which gave promise of developing within a very few years. As a result, the mileage of unremunerative branch lines today is limited. In the same way short lines of proven traffic value have been purchased from time to time.

While the attitude regarding extensions has been conservative, the mileage has grown from 6,435 in 1896 to 11,092 on January 1, 1915, located in 13 different states, in addition to 594 miles owned jointly with other companies and 225 miles controlled through lease or the ownership of stock. It is instructive to note that the extensions built by the present management have followed very closely the lines laid down by Mr. Strong. Also, practically all of the lines built during the earlier administration have since proved their value from the traffic and strategic standpoints, evidencing the foresight displayed at that time. As a result the system now comprises main trunk lines extending from Chicago to Colorado, the Pacific coast and Texas, as well as from Texas to the Pacific coast, about which branch line feeders may be built as the country develops as has been done in Kansas, where the Santa Fe now has 2,817 miles of line and enters 74 of the 104 counties.

The policy of avoiding waste of capital by competitive building has also been avoided in numerous instances by joining with other roads in the construction and use of joint facilities essential to both. The most important recent instance of this nature is the co-operation with the Southern Pacific in the construction of the Northwestern Pacific along the coast north of San Francisco for nearly 300 miles. Rather than build another line, the Santa Fe uses the tracks of the Southern Pacific over the Tehachapi mountains for 67 miles, while it shares its tracks with the Salt Lake line for 90 miles over the San Bernardino mountains. Likewise when building second track between Chicago and Kansas City a few years ago, arrangements were made to combine the single tracks of the Alton and the Santa Fe into a double track for 20 miles near Joliet, Ill., while a similar arrangement was made with the Wabash for the joint use of 30 miles of tracks near Carrollton, Mo., so that each road secured the advantage of double track with practically no increased expenditure.

IMPROVING THE PROPERTY

As stated above, while in general the lines had been built well according to the standards prevailing at the time of their construction and the traffic then in sight, heavy grades were common and the facilities were inadequate in many ways when the new management took hold. Practically the only exception to this was the Chicago extension which had been built only a few years before with a maximum grade of 0.8 per cent to handle the relatively large amount of business collected by the network of lines west of Kansas City. Furthermore, the property had been allowed to run down during the years immediately preceding the receivership. Therefore, in addition to constructing extensions to reach new traffic, the new management had to reconstruct the existing property to enable it to handle a greater traffic more economically and to bring it up to the proper standards of maintenance.

Some of the most extensive improvement work has been connected with the reduction of grades. The main line to the Pacific coast crossed four ranges of mountains with ruling grades ranging from 1.8 per cent to 3.5 per cent. The most serious operating problems were presented on that portion of the line between Trinidad, Colo., and Albuquerque, N. Mex. When the line was first projected beyond Dodge City in 1878 it was planned to build directly southwest to Albuquerque, avoiding the Raton mountains. However, local Pueblo interests started building a line east from Pueblo along the Arkansas river, and the Santa Fe location was deflected to meet it at La Junta. The western extension was then continued south from this point, passing over Raton mountain with a 3.5 per cent grade on the north and a 3.3 per cent grade on the south slopes and a tunnel at the summit. Aside from making operations very expensive, these conditions led to very serious congestion and blockades which the construction of a second track only partially relieved, and for a number of years this portion of the line was regarded as limiting the capacity of the entire system. A similar, although less serious condition existed at Glorietta summit, 175 miles further south, while the grade line was badly broken with numerous 1.4 per cent grades all the way to Albuquerque.

To relieve these conditions a new low grade line was built from Belen, 30 miles south of Albuquerque on the El Paso line, east 345 miles to Amarillo on the Pecos Valley line, and the latter line was rebuilt into Wellington, Kans. With the exception of a 1.2 per cent. grade just out of Belen, on which helper engines are operated, the maximum grade on this line is 0.6 per cent each way to Kansas City, a distance of 928 miles. The immediate advantage of this cut-off and alternate main line which was placed in service in 1906, was an increase in the tonnage rating from 900 to 1,000 tons on the old line with considerable helper service, to 2,600 tons on the new. The congestion was also removed, while a considerable saving in the time of trains was also effected. In addition, because of its more southerly location, the new line escapes a large portion of the snow troubles of western Kansas and Colorado. All freight traffic between points east of Newton, Kans., and west of Belen, now moves over this new line, while in conjunction with the line completed last year across west Texas a 0.6 per cent grade is also secured from Belen to a connection with the Gulf lines at Coleman, Tex., and all traffic interchanged between the Gulf and Coast lines is sent over this cut-off, instead of moving through southern Kansas, as was formerly necessary.

Similar extensive improvement work has also been done west of Albuquerque. For the first 158 miles to Gallup, the original ruling grade of 1 per cent has been reduced to 0.6 per cent. Between Winslow and Needles the line was built originally with ruling grades of 2.6 per cent over the summits and 1.8 per cent elsewhere. These grades have now been reduced to 1.8 per cent and 1.4 per cent, respectively. In most instances this has been accomplished by the construction of a single track line on the lower grade for ascending traffic, leaving the old track on the heavier grade for descending trains. However, in one place east of Seligman, where a second track was required and the existing line was already on the desired grade, the unusual practice was adopted of building the new track on a 3 per cent grade for descending trains, thereby effecting a saving of over two miles in distance and a material reduction in the cost of the second track.

In the same way the grades southbound on the line from Newton, Kans., to Texas have been reduced to a maximum of 0.6 per cent to the crossing of the Red river, a distance of 330 miles. From this point to Temple, Tex., the original 1.25 per cent ruling grade still remains.

While not on so large a scale, similar improvements have been made over the entire system according to a carefully prepared program. When work has once been undertaken on one line it has been followed to completion. Only such work has been undertaken as time and the funds available permitted, and when only a limited amount of money has been available it has been devoted to completing the work on a certain mileage rather than distributing it in lesser amounts over a greater area and not completing the work anywhere. By concentrating attention in this way numerous improvements have been made in the way of minor grade reductions, etc., and the main and important branch lines have been improved materially with relatively small expenditures.

INCREASING THE FACILITIES

In this interval of 19 years large additions have also been made to the facilities. At the time of the reorganization only 16 miles of second track was in service. Today there is 975 miles. The line has been double tracked all the way from Chicago to Newton, Kans., 655 miles, while 300 miles of second track has been built west of Albuquerque. Counting the low grade line from Newton to Belen as second track, all but 475 miles, or 22 per cent of the line between Chicago and Barstow, Cal., where the Los Angeles and San Francisco lines separate, is double track. Terminals have also been enlarged. With two exceptions, the road owns its own terminals and it is not dependent on facilities leased from other roads.

While most of the terminals were secured by the earlier administrations the present management has made relatively large expenditures to secure adequate facilities at San Francisco and Kansas City. When the San Francisco & San Joaquin Valley railroad was taken over in 1900 it had limited terminal facilities which have been supplemented since that time at considerable expense.

The water problem is a serious one on all southwestern roads. During the winter of 1897, 43 per cent of the traffic across the desert east of Barstow, Cal., consisted of water and company coal. Relatively large expenditures have been made to develop reservoir and other water supplies, and while it is still necessary to haul water for several stations at isolated points the total amount has been very materially reduced, while the substitution of oil for fuel on locomotives as far east as Winslow, Ariz., has reduced the amount of fuel required on the Coast lines east of Barstow to an average of 14 cars daily.

MAINTENANCE OF WAY AND STRUCTURES

Intimately connected with the policy governing the construction of extensions and additional facilities has been that relating to the standards of maintenance. At the time of the reorganization large parts of the property were badly run down, while at the present time it is one of the best maintained properties in the country. This has been brought about primarily by the expenditure of liberal sums for maintenance regularly from year to year. This is shown most clearly by the fact that for the 19 years since the reorganization an average of 15.2 per cent of the gross operating revenues has been returned to the property in expenditures for maintenance of way. The liberality of this expenditure is indicated by a comparison with that of 52 other leading roads for the past 10 years. During this period these roads spent an average of 13.3 per cent of their gross revenues for this purpose as compared with 15.5 per cent for the Santa Fe. Making another comparison, the average annual expenditure per mile of line on the Santa Fe for the last five years has been $1,589, while on the Burlington it has been $1,458, and on the Southern Pacific $1,529, these latter two roads being recognized as unusually well maintained and as fairly comparable in climatic and other conditions. The activity with which this policy has been followed since the first year of control is shown by a statement in the third annual report for the fiscal year ending June 30, 1898, that "nearly every building on the right of way between Chicago and El Paso, all buildings on the Southern California (those lines in southern California southwest of the connection with the Atlantic & Pacific-Southern Pacific line at Barstow), and a large number of buildings on the Gulf, Colorado & Santa Fe have been painted."

The standards of maintenance are high and a progressive policy has been followed in authorizing increased expenditures

to reduce ultimate maintenance charges as the following illustrations will show. At the present time all main and many branch lines are tie plated continuously, over 50,000,000 tie plates being in service. The Santa Fe has been a pioneer in the use of treated ties, having started treating them on an extensive scale at Las Vegas, N. Mex., in 1885. It now operates treating plants at Somerville, Tex., and Albuquerque, N. Mex., with a combined annual capacity of 3,600,000 ties or practically its entire annual requirements. Over 65 per cent. of all the ties now in the track are treated, and as result the tie requirements for replacement purposes are showing a marked decrease, amounting to over 600,000 ties for each of the past two years, while the average number of ties inserted per mile for the last five years shows a decrease of 9 per cent as compared with the preceding five years.

The Santa Fe has also been a pioneer in the use of screw spikes, installing the first section in 1905 and having over 120 miles of screw spike main track in service on January 1, 1912. Since that time their use has been extended gradually. On the Western lines it is now the standard practice to insert screw spikes in 8 ties per rail length when laying new 90-lb. rail to secure a more rigid track construction. Another interesting maintenance practice which has been followed, particularly on the Western and Coast lines, has been that of laying all curves up to 10 deg. to exact gage without any allowance for curvature, which practice has been found to result in a greatly reduced rail wear.

The Santa Fe has also been a pioneer in the use of ballasted deck bridges. Starting with this form of construction about 1898, over 160,000 lin. ft. of ballasted deck structures are now in service. This construction is general on the main lines, obtaining even on structures as large as the new bridge over the Missouri river at Sibley, Mo., with spans 396 ft. long, and it is being extended gradually to the more important branch lines. By this means, in addition to securing the other advantages of this form of bridge deck, the cost of maintenance is reduced at least one-half. These and numerous other expenditures are already paying excellent returns in the form of reductions in maintenance of way expenditures so that the relative comparisons are even more favorable to the Santa Fe than shown above.

MECHANICAL DEVELOPMENTS

At the time of the reorganization the road owned 962 locomotives while in 1904 this number had increased to 1,433 and at the present time it is 2,150. The number of passenger cars owned has increased from 641 in 1896, to 861 in 1904, and 1,653 in 1914, while the number of freight cars has risen from 27,719 in 1896, to 39,072 in 1904, and 69,366 in 1914. From this it will be seen that the increase in equipment has been particularly rapid during the last decade.

As would be expected, the increase in the weight and tractive power of the locomotives has been considerably greater than in the number of locomotives themselves, for a great deal of attention has been devoted to the development of heavy engines for use especially, on the mountain divisions, and this road has led in the development of certain types of engines. With widely differing conditions as regards grades on different portions of the system, the aim has been as far as possible to so adjust and distribute the motive power with reference to the grades as to require the minimum breaking up of trains at intermediate terminals. Thus, at present, trains are made up at Kansas City for delivery to the Coast lines at Belen and to the Gulf lines at Purcell without breakup, and it is expected that with the readjustment of motive power and of grades now contemplated between Kansas City and Chicago it will be possible within the next two or three years to despatch trains from Chicago to Belen and Purcell without changing tonnage. The average tractive power of locomotives has risen from 25,578 lb. in 1904 to 33,290 lb. in 1914, an increase of 30 per cent in 10 years. This compares with an average tractive power for the locomotives of the entire country for June 30, 1913 (the last figures available) of 29,702 lb. as reported by the Interstate Commerce Commission. West of Belen and Albuquerque the combined improvement in grades and motive power has increased the tonnage rating on the mountain divisions from 416 tons in 1897 to 1,300 tons today.

Because of the large proportion of the traffic which is time freight it has been necessary for the mechanical department to consider the question of speed as well as tonnage in designing the freight locomotives for use on many of the divisions, for it is necessary that they be capable of running at relatively high speed. One of the most successful recent types of locomotives placed in service on this line is the Prairie Mallet, which is hauling trains of 2,250 tons across the Belen cut-off at speeds up to 45 miles an hour.

The efficiency of the motive power and the economy of operation have also been greatly increased by the substitution of fuel oil for coal on all lines west of Winslow, Ariz. To insure a sufficient supply of oil the Santa Fe has acquired large areas of oil land in California which are operated by a subsidiary company. Considerable oil is also purchased from other producers for the purpose of conserving the road's own supply for future years.

Reference was made above to the liberal expenditures for maintenance of way. Those for the maintenance of equipment have been equally liberal. For the entire period under the present management these expenditures have averaged 14.5 per cent of the gross operating revenues, while for the past five years they have averaged 15.9 per cent, rising to 17.2 per cent in 1914. Combining the expenditure for the maintenance of equipment with that for the maintenance of way and structures, it will be seen that an average of 30.4 per cent of all of the gross revenues has been devoted to the upkeep of the property for the entire period the present management has been in control.

Two or three instances will be cited as indicative of the methods by which the equipment is maintained. To insure that the proper repairs will be made on each of the four grand divisions a car repair pool is maintained, and all charges for the system are distributed according to an arbitrary basis. In this way there is no incentive for one grand division to send bad order cars to another. Last fall floating car repair gangs were sent over the lines in the wheat belt of Kansas and Oklahoma to repair the surplus equipment stored along the road in order to insure that every car was in proper condition before loading. In the same way all refrigerator cars are thoroughly inspected and all necessary repairs made at the last terminal before distribution for loading. In this way not only is the equipment kept in good condition, but the damage claims have been materially reduced.

United States Navy Specifications.—The new specifications of the United States Navy indicate a changed opinion as to the extent to which sulphur is detrimental in steel castings. Former specifications allowed a maximum of 0.05 per cent sulphur in all carbon castings of grades A, B and C and 0.04 per cent in nickel-steel castings designated as "special grade." In the new specifications grades A and B are subdivided into two classes—A and D, the high carbon, and B and E, the medium carbon relatively. A and B maintain the old limit of 0.05 per cent sulphur and D and E permit castings to go as high as 0.07 per cent sulphur. The two subclasses include castings of less importance than the others. For castings in grade C the limit is changed from 0.05 per cent sulphur to 0.07 per cent. The nickel-steel or special grade castings now have 0.05 per cent instead of 0.04 per cent sulphur as the limit. The requirements for tensile strength are reduced from a minimum of 90,000 lb. per sq. in. in nickel-steel to 85,000 lb. The elastic-limit stipulation is 45 per cent of the tensile strength in carbon castings, instead of a definite limit in pounds. The elongation requirements are advanced from 20 to 22 per cent in the special, or nickel-steel, grade, and the bending bar required is 120 deg. instead of 90 deg.—*American Machinist.*

Locomotives Recently Built for Foreign Countries

Baldwin Works Completed Engines for France, Russia, East Africa and New Zealand in the Past Few Months

During the past few months, several notable orders for export have been filled by the Baldwin Locomotive Works. These are of special interest, not only because of the types of locomotives built, but because of the quick delivery effected. With comparatively little domestic work in hand, there were unusually good opportunities for the builders to concentrate on the foreign orders.

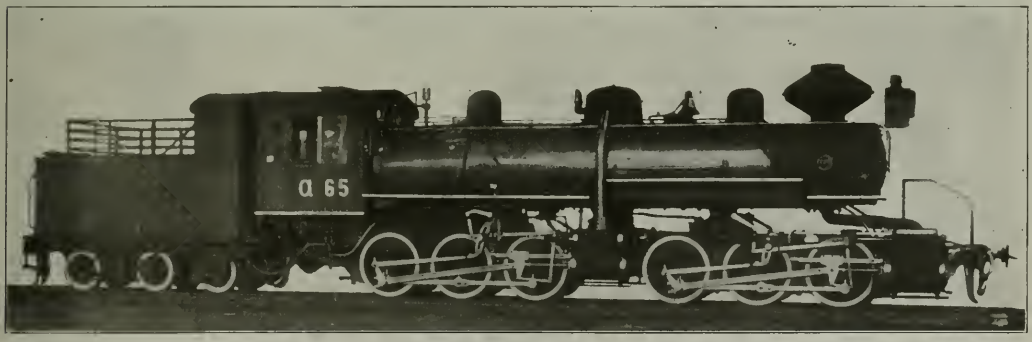
An order for ten Pacific type locomotives for the New Zealand government railways was received November 18, 1914, and the last engine was completed January 7, 1915. These locomotives are suitable for either passenger or freight service; the weight limit specified was 12 tons (of 2,240 lb.) per axle, or 1½ tons per foot of total length. With these limitations, and a track gage of 3 ft. 6 in., a most effective design of locomotive has been produced. The tractive effort exerted is 22,900 lb., which is unusually high in proportion to the weight on the driving wheels, which is 76,000 lb. The driving wheels are 49 in. in diameter, the cylinders 18 in. by 24 in., and the working steam pressure 170 lb.

2-10-2 Type Locomotive for Portuguese East Africa

In construction, these locomotives follow American practice closely. The boiler is of the straight top type, with a wide firebox, a Schmidt superheater and Security sectional arch. The steam distribution is controlled by 9½ in. piston valves, which are driven by Walschaert motion. The cylinders are cast separate from the saddle, and live steam is received through outside steam pipes. Other features of interest include the Hodges design of trailing truck, English Westinghouse brakes, and acetylene headlight and cab lights. The tender is carried on two four-wheel trucks. All the wheels under the locomotive and tender have cast steel centers, and are steel tired.

The 2-10-2 type locomotive illustrated is one of two built for the Lourenco Marques Railway, in Portuguese East Africa. This engine is of rather unusual size and capacity for a gage of 3 ft. 6 in., as it develops a tractive effort of 33,400 lb., with a ratio of adhesion of 4.3. The line is laid with 80-lb. rails, and has curves of 300 meters (984 ft.) radius and maximum grades of 1½ per cent. Under these circumstances, the use of a locomotive having a long rigid wheelbase is not prohibitive. Flange oilers are applied to the first pair of driving wheels, and the wheels of the third pair have plain tires.

These locomotives, apart from their dimensions, are similar in design to the 2-10-2 type locomotives operated in the United States. The special equipment includes a Baldwin steam brake on the driving wheels, and the English automatic vacuum brake on the tender, with train connections. A boiler feed pump is applied, and is driven from the right hand crosshead. The boiler is of the straight top, wide firebox type, equipped with Schmidt superheater and Security sectional arch. The weight on drivers is 144,000 lb., while the total engine weight is 179,100 lb. The cylinders are 21½ in. by 24 in., the driving wheels 48



Wood-Burning Mallet Compound for the Archangel Railway, Russia

in. in diameter and the working pressure 170 lb. The Mallet locomotive illustrated is one of 30 which were built for the Archangel section of the Russian government railways.

The order for these locomotives was received November 10, 1914; the first engine was completed on December 21, and the last on January 6, 1915. The design was new throughout, and special care was necessary on account of the weight limitations imposed. The engines were built for a gage of 3 ft. 6 in., but the design is such that they can be subsequently changed to meter gage if desired.

The boiler is of the straight top type, with a long firebox placed above the frames. The inside box is of copper, and the tubes are of iron with copper ends. Wood fuel is used, and the grate consists of plain bars. The stack is of the Radley and Hunter type, with top and bottom sections of pressed steel, each made in one piece and formed in the same dies.

These locomotives use saturated steam, which is distributed to the high pressure cylinders by 8-in. piston valves and to the low pressure cylinders by balanced slide valves. The Walschaert motion is applied, and the gears are controlled by the Baldwin pneumatic screw reverse mechanism. The machinery is as light as possible, consistent with the required strength. Cast steel is used for the driving wheel centers, driving boxes, pistons, crossheads, and many of the structural parts. The weight on drivers, which is also the total weight, is 105,800 lb.; the cylinders are 13 in. and 18 in. by 22 in.; the driving wheels are 44 in. in diameter, and the boiler pressure is 180 lb.

The tender has a capacity of 2,640 gal. of water and 3½ cords of wood. It is carried on six wheels, the first axle being held in rigid pedestals, and the second and third in a truck of the arch bar pattern. The tender frame is composed of steel channels, and the tank is wedge shaped. The forward end of the tank is covered with a hood, and the locomotive cab is entered through side doors, the arrangement being such as to thoroughly protect the engine crew from cold and stormy weather.

Three orders for locomotives have been received from the French government, and have been filled with unusual despatch. The first order called for 20 tank locomotives of the 0-6-0 type. This order was received on Tuesday afternoon, November 3, 1914, and it was specified that the engines be finished at the earliest date possible. The first boiler was completed November 10, at 11 a. m.; and one of the locomotives was entirely finished on November 13. At 11:35 a. m., November 21, the last engine, completely boxed, left the erecting shop, the 20 locomotives having thus been completed in 16 working days.

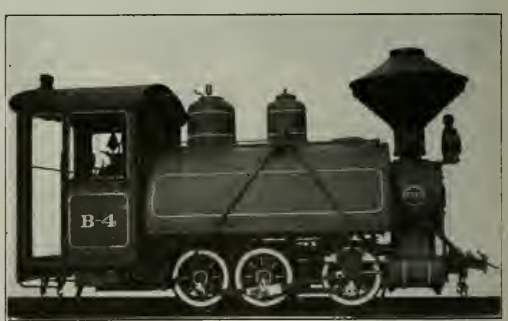
These locomotives have a track gage of 60 cm. (1 ft. 11⅝ in.), and are designed to traverse curves of 45 ft. radius and to operate on rails weighing 9½ kg. per meter (a little more than 15 lb. per yd.). They are equipped for burning wood, and have smoke stacks of the Radley and Hunter pattern. The water supply is carried in a saddle tank. The steam distribution is controlled by plain slide valves, driven by the Stephenson link motion. The cab is of steel, and both side windows and also the front window on the left side have drop sashes of steel, 3/16 in. thick. A steam brake, with auxiliary hand gear, is applied to the driving wheels. The weight of the engine is 29,000 lb., the cylinders being 9 in. by 12 in., while the driving wheels are 26 in. in diameter. These locomotives were each shipped complete in one case, ready to be fired up and operated immediately upon arrival at destination.

The second order from the French government called for six locomotives for service in Morocco. These are tank engines of the 4-6-0 type, built for the same gage as the 0-6-0 type locomotives previously referred to. They were designed to meet a limiting weight of four metric tons per axle. The water supply is carried in side tanks, and the fuel, which is soft coal, in a box back of the cab. The boiler is of the straight top type, with a copper firebox and brass tubes. The firebox rivets and water space stays are of copper. Walschaert valve motion is used, and the steam is distributed by plain slide valves.

Restricted space on these locomotives necessitates an unusual design of engine truck. Each side frame is cast in one piece with its adjacent boxes, and the castings are tied together at their ends by transverse tie rods. The transom is a steel casting which is pinned to the side frames, and supports a swing bolster through two links placed on the center line of the locomotive. The weight is transferred to the bolster through a coil spring, which serves the purpose of a center pin as well as providing the necessary elasticity. These locomotives were each shipped in one piece, completely assembled, except the stack and a few minor fittings.

The third order from the French government was for 100 locomotives of the Pechot type, with 0-4-4-0 wheel arrangement, somewhat similar to the well-known Fairlie type. Fairlie locomotives have been used in this country to only a very limited extent, attempts to introduce them having proved unsuccessful. Their use abroad has been confined to roads where curves are frequent and sharp, necessitating locomotives of unusual flexibility. The Fairlie type differs from the Mallet type in that it is carried on two steam trucks or "bogies," and is provided with a boiler having two barrels, or cylindrical sections, and two fireboxes. The latter are placed in a single outside shell, which is located between the bogies. This provides an exceedingly flexible locomotive, but introduces certain complicated features which have always been considered undesirable in American practice.

The locomotives now referred to have a gage of 1 ft. 11⅝ in. They were built throughout to metric measurements, and



Six Wheel Tank Locomotive for the French Government

represent a design introduced in 1888, and which has several times been duplicated since that date. Although these locomotives are very small, they are of unusual interest in view of the many special features incorporated in their construction.

The boiler has a steel shell, with copper fireboxes and brass tubes. The fireboxes are separated by a water space 50 mm. (about 2 in.) wide. Each communicates with a separate set of tubes, and there is a smokebox and stack at each end of the boiler. A high steam dome is placed above the fireboxes. The boiler barrels are supported on saddles placed above the bogie center pins, and the firebox is supported in a cradle, consisting of two plate frames which are riveted to the saddles. The boiler shell rests on the saddles, but is not fastened to them in any way. This construction supports the boiler firmly, permits expansion and contraction of the shell, and also maintains the correct distance between the bogie centers.

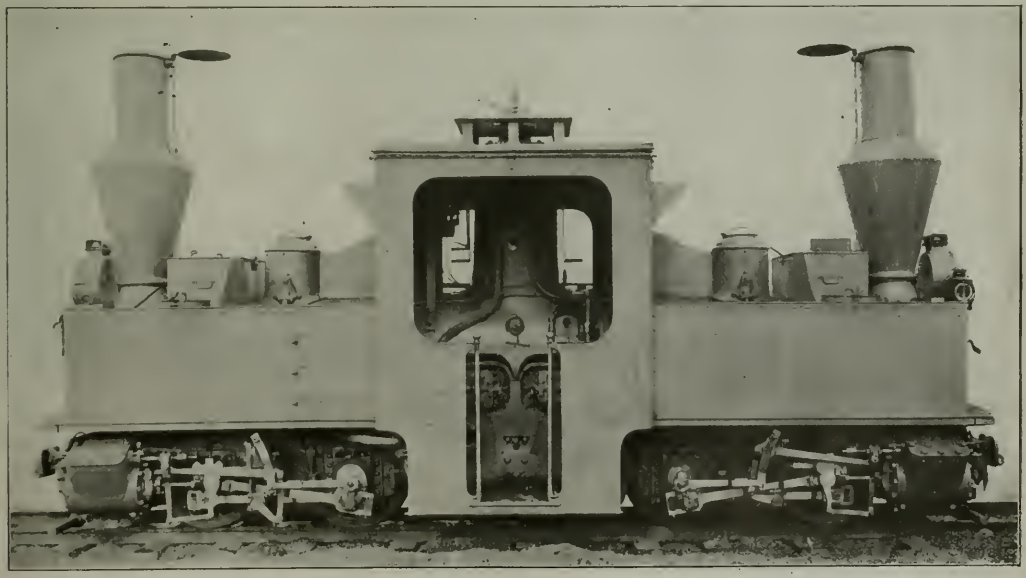
The bogie frames are of steel plate, placed outside the wheels, while the driving boxes are of wrought iron, case hardened and tempered. The wheel loads of each bogie are equalized. The steam distribution to all the cylinders is controlled by balanced slide valves which are circular in plan, and are driven by Walschaert motion. The four gears are controlled simultaneously by means of a hand lever. An interesting detail is the arrangement of the live steam pipes, which leave the boiler through

openings in the bottom and pass down through the bogie center pins. The ball joint in the pipe can thus be arranged to coincide with the center on which the bogie swivels. Each pair of cylinders is located under its respective smokebox, so that a comparatively simple arrangement of exhaust piping can be used. The exhaust pipe has a ball joint at its lower end.

The locomotives weigh, in working order, 12,790 kg., or 28,100 lb. The cylinders are 175 mm. by 240 mm., or 6.88 in. by 9.44 in., and the driving wheel diameter is 650 mm., or 25.5 in.

The water supply is carried in four side tanks, one of which is placed on each side of the two boiler barrels. All four tanks are connected by equalizing pipes. The cab is located between the tanks, in the center of the locomotive. The two tanks on the fireman's side are shorter than the others, thus providing space adjacent to the cab for coal bunkers. Each firebox has a side door. Such an arrangement would be inconvenient on a heavy locomotive consuming large quantities of fuel, but on these small engines firing is a simple matter. However, it is

Running Gears of the Pechot Type Locomotives in the Philadelphia Erecting Shop; They Were Shipped to the Eddystone Plant in Automobile Trucks



Fireman's Side of One of the Pechot Type Locomotives Built for the French Government

necessary to have two operators, as the boiler runs through the cab and it is impossible to step from one side to the other.

The locomotives are equipped with a hand screw brake, which can be applied from either side of the cab. The brake shoes are of poplar. The drawbars are of the radial type rotating about pins whose centers are located as close as possible to the bogie centers. These pins are seated in transverse steel castings, which are riveted to the side frames.

The steam dome contains two sliding throttles, each connected to a pipe leading to one of the bogies. In the cab are three throttle levers; two of these operate both throttles and are so located that one of them can be easily reached from any part of the cab. The third throttle lever controls the admission of steam to the cylinders of one bogie only. Normally this lever is latched with the others, so that all four cylinders receive steam simultaneously. If it is desired to run the engine with one-half of its power, the third throttle lever can be unlatched and steam used in only one pair of cylinders.

Special provision has been made to insure easy riding qualities. The weight is transferred to the bogie center pins through heavy rubber washers, which absorb vibration. The bogie side bearings are also of rubber. The bogie frames are connected to the frames supporting the boiler by links fitted with specially designed springs. These act as a centering device, and aid in restoring the alinement of the bogies after traversing curves.

The American-made equipment used in these engines includes injectors, whistle, safety valves, lubricator, steam gages, headlights, and cab and signal lamps. The steam gages are graduated to indicate the pressure in kilograms per square centimeter.

These locomotives were built to exceedingly rigid specifications, which covered not only the quality of the materials, but also the methods of manufacturing the various details and of erecting and testing. It was specified that each locomotive should be run under its own steam for approximately half a day. The engines were erected at the Eddystone plant, and a special track was built for testing purposes. During part of its run, each locomotive was required to draw a train of four small cars, which were loaded to a total weight of 30 tons. The locomotives rode admirably; there was practically no jar or vibration in the cab and very little lurching when traversing curves and passing over uneven track.

The engines were each shipped complete in one case. The stacks and a few small fittings were removed, but were boxed with the locomotive; so that very little erecting work was necessary on arrival at destination. Considering the unusual design and the rigid specifications, these locomotives were built in a remarkably short space of time. The order was received on February 1, 1915; 40 engines were shipped on March 31, and the last one left the works on April 24.

Germany's Strategic Railways.—Although a multitude of writers have enormously exaggerated the extent of the network of strategic railways in the German Empire, it is a fact that no other country has built anything like such a large railway mileage mainly or entirely with a view to its utilization for offensive purposes. If any country is in the future allowed to build such railways unchecked, it will represent a constant menace to the peace of the world. It is true that Germany's defeat will mean that a large proportion of these strategic railways will pass into other hands, the unification of Poland and the restoration of Alsace-Lorraine to France, meaning, incidentally, the loss to the German Empire of strategic railways. But these territorial changes will not in themselves prevent Germany from laying down a network of strategic railways to convenient points on the new frontiers. If the allies are determined to smash Prussian militarism, they will have to take account of this matter, as well as of armaments and the like. Alone among the great powers, Germany has for years past built railways with the definite and deliberate purpose of aggression. It should be the task of the allies to see to it that the terms of peace contain provisos that will at least check this kind of preparation for war in the near future.—*Railway Gazette.*

MISSOURI, KANSAS & TEXAS

[Reprinted by permission from the Wall Street Journal]

Can you tell me, who, or what, is to blame for the low price of M. K. & T. stock? I am the owner of some of it, and that is why I inquire. Considering all things, of course, it should be low priced now, in common with all other railroad shares, but it does seem to me this stock is unreasonably and unrighteously low, under even present conditions. This company in the ten months of this fiscal year ending April 30, 1915, earned more in gross than in any other like ten months in its history, and nearly a million more than same period last year. It earned the largest net in its history in April, 1915, and the largest net in ten months in its history. Also it earned in that period the largest surplus in its history and the dividend on its preferred stock more than three times over. It has paid its dividend on preferred stock for more than ten successive years, except last year, and has earned an average, at least, of 1½ per cent on its common stock for more than ten successive years, but has paid its common stockholders nothing. It will, at the end of fiscal year ending June 30, 1915, at present operations, have earned more gross and more surplus than any like period of its history. The territory served by the road has grown more rapidly in wealth and population in the past three years than any territory of like extent in this country and every factor that makes for growth, development and wealth is at the present time wonderfully promising. Have gross, net and surplus earnings, and rapid development, nothing to do with values? Compare this road with others of like, or even greater mileage, and M. K. & T. loses nothing by the comparison. If all the above do not create "a marketable and mortgageable equity," what does constitute such things? With all these rugged facts will the "Board" dare to pass the dividend on the preferred stock this year?—C. C. B.

Answer.—This year the earnings of the M. K. & T. have nothing to do with the market price of its shares. M. K. & T. stocks have been low, because of the road's financial position. On May 1, $19,000,000 5 per cent notes fell due, and as no satisfactory arrangements could be made with bankers as to paying them off, holders were asked to consent to an extension of the notes for a year. Interest rate on the notes was increased to 6 per cent. Approximately 95 per cent of the note holders agreed to the extension, leaving about $1,000,000 of the notes still undeposited. Last week, a holder of $10,000 of the notes secured an attachment in the New York Supreme Court against the road for the amount of his holdings. In the meantime, a special committee of directors is working on a financial readjustment plan, which has for its primary object the paying off of the notes, or their permanent funding. This plan has been somewhat delayed by the international situation, but the management hopes to have it completed, and underwritten in the not distant future. Naturally, if such a plan can be underwritten, the company's serious difficulties are at an end, for with the notes paid off or otherwise taken care of, the question of pressing financial obligations would be disposed of satisfactorily. The above situation as outlined explains the weakness of the stock.

To date there has been no acute danger that a reorganization of the road would be sought through the courts. For the fiscal year ending June 30, M. K. & T.'s surplus after charges will be $1,500,000, but there is no question of paying any dividend on the preferred stock. All surplus will be put back into property improvements, or used to clear from the books some of the temporary loans. It is understood that the road has short time bank loans of about $2,000,000. The company officials regard the present traffic outlook as very satisfactory.

Water in Coal Mines.—For every ton of coal raised from one of the anthracite mines, the operators of that field are obliged to pump to the surface about 11 tons of water. It is estimated that in the anthracite mines there are 900 pumps in use at the present time. The capacity of these pumps is approximately 1,000,000 gal. a minute.—*American Machinist.*

The Ticket Offices of Large Passenger Terminals

Factors of Design and Operation Influencing the Efficiency of the Ticket Offices in Such Stations

The ticket office is usually the first place where the passenger comes in contact with the railway, through its representative, the ticket clerk. A passenger's opinion of the line on which he travels is formed very largely by his treatment by the railroad employees. Since first impressions count most it is easy to see wherein lies the real work of the ticket office. It must sell tickets, but it must also do its part to encourage good will towards the railroads. To be efficient the ticket office must be such that its clerks can work in pleasant surroundings under pleasant conditions, for these are conducive to courtesy and careful performance of duty.

The function of selling tickets is so important that the location, layout and organization of the ticket office should receive most careful attention. The existence of so many stations, some of them new ones, in which the ticket offices have been entirely subordinated to architectural exigencies shows that this problem has not always received deserved attention. Every effort should be made, therefore, to ascertain what has already proved best. Presumably those best informed are the ticket agent and his assistants. They know how the traffic runs, they know its peculiarities and they alone know how well or ill their office does its work. The agent usually has some practical ideas of improvement, and whenever he proposes or disapproves his argument should be given weight accordingly. It is often worth while to call on other agents at stations in the same city. Every city has its peculiar idiosyncrasies and other offices may have some good ways of meeting them. Designers often seem reticent to call on the experience of other cities; the idea deserves greater consideration. It is not advisable to introduce new departures in design without careful study. One of the greatest faults in modern passenger terminal design is this striving for the original or the spectacular. The most successful features of proper ticket office or terminal design are the well established ones.

LOCATION

The ticket office should be so placed relatively to the station's other facilities that a person entering the station may buy his ticket, check his baggage and proceed to his train without retracing steps. The office should, if possible, be in plain view. Usually, if it is well placed no signs are necessary to indicate where it is. If it is not so placed there should be signs to make up for the delinquency. Whether the ticket office be in the waiting room, on the concourse or in a special so-called ticket lobby depends entirely on the station. Preferably there should be a ticket lobby through which passengers who have to buy tickets may proceed without molesting persons in the waiting room. If the waiting room is that part of the station around which all the other facilities center, the ticket office, being the most important, should be among them. At stations where there is a large proportion of suburban traffic it is not advisable to make the waiting room a general entrance or passageway. The commuters should preferably enter the concourse directly from the street, and the ticket office and the other station facilities should face or lead from the concourse. This makes the concourse the passageway it is intended to be and leaves the waiting room a place to wait and rest. The tendency of passengers after buying their tickets is to move towards the platform gates. To avoid congestion about the ticket windows, the office should be across the waiting room or concourse from the train shed.

A SINGLE TICKET OFFICE PREFERABLE

It is usually inadvisable to have more than one set of ticket windows. There are some stations used by two or three roads in which each line prefers to have its own ticket office, but unless each office does sufficient business to make it an economic unit, it is usually better to confine the work to one office. The organization is more flexible, and since there is no duplication the work can usually be done by fewer clerks. Patrons find two or more offices an inconvenience, because they are continually going to the wrong window. There is also better opportunity for supervision if the work is confined to one office. In many stations, however, there are special physical conditions which make necessary a division of ticket office facilities, as for example at the Grand Central or the Pennsylvania terminals in New York, where there are two separate levels.

It is impossible to define any rules relative to the size of a ticket office. A passenger station usually lasts at least 20 years. The ticket agent's domain should be designed with that in view, or so laid out that it can be enlarged without unnecessary rearrangement of other facilities or reconstruction of the station. There is absolutely no justification for cramped quarters for the ticket selling force in any new large passenger terminal.

LET THERE BE LIGHT

It is to some extent unfortunate that ticket office designers do not more often consider how easy it is to secure outside light. The problem in many cases is not so much to place the office where it can get natural light but to see that outside light is not shut off. If the office is in a large light waiting room, for example, the proper thing is to get all the light possible from the big area. Instead of placing a solid roof over the office and shutting off the light from the top it would be better to use a grating or a glass roof which can be opened if necessary for ventilation. In the same way, care should be taken to have windows or skylights wherever possible, and, if there are such already, not to block them. The natural light is free; it is far better for the eyes and if there is plenty of it the open and bright effect will have a most salutary effect on the clerks and their relations towards the public. Precisely the same considerations apply to ventilation. A poorly ventilated ticket office is as stuffy as a prison cell and not the least conducive to courtesy and accurate work. Care must be taken, on the other hand, not to have a draughty office; illness will not promote courtesy.

COUNTER ARRANGEMENT

The height of the counter is quite important, especially in a busy office, because if the counter is a few inches too high it hinders rapid work, and if too low the clerk may acquire a stoop. Careful tests have shown that about 3 ft. 8 in. is the best height.

The size of the counter deserves considerable attention. Its width should be sufficient on the inside so that the clerk can easily place the ticket and money on the counter, but not so wide that he has to reach unnecessarily to push them out to the purchaser. It is usually not best to use the inside counter as a desk for writing coupon tickets; it is better to use a special desk set to one side of the window or a few feet in the rear of it for this purpose. This desk is usually like a short bookkeeper's desk. It is the right height for writing; and the clerk while fixing a long coupon ticket can have all the room he wants without being bothered by well intended, but unnecessary remarks about the weather and business.

The tendency is to make the counter too wide on the outside of the grill. The shelf should be wide enough so that the passenger can easily open his pocketbook on it. It should not be so wide that he must lean over it to make himself heard, or to tempt him to put his baggage on it.

The front of the office, outside, is not complete without a baggage shelf about knee high below the counters. Passengers find it a great convenience to rest their bags on this shelf and since the bags are nearer than if they were on the floor feel

more at ease. The shelf should be about 8 or 10 in. wide. It is usually made of some material, such for example as ornamental brass pipe, which harmonizes with the surroundings.

Ticket counters in modern ticket offices are not often of wood. Much better results are obtained by using glass, marble or a similar material. Wood is not fireproof and it has a tendency to absorb moisture on damp days whereupon the difficulty of sliding tickets over it is liable to wear on the seller's nerves. But the worst thing about a wooden counter is that it is so nearly the same color as the money passed over it, that the passengers are much more likely to leave change on it than on glass or marble. The counter should be of a material which does not reflect too much light. Marble is very satisfactory, bright brass or similar material impossible. Thick plate glass firmly imbedded and painted black on the under side or placed on a dark green mat is also satisfactory. The counter should not be so thick that passengers can not take their change without fear of dropping some of it.

If the ideal ticket office were in an ideal community its windows would have no grills. The average ticket buyer goes to a ticket office so seldom that he is easily inconvenienced by having to talk through a grill. Nevertheless it is necessary to protect the tickets and money. Without it the latter would have to be moved so far back from the counter as to interfere with rapid selling. The grill used in railway ticket offices is preferable to the glass front of the average theater ticket office. It should be of simple design and constructed of vertical rods with a dull finish. A grill of complicated design collects dust, is hard to clean and almost serves as a barrier between clerk and patron. One of bright finish reflects too much light.

It has been stated above that the properly located ticket office needs no signs to indicate its position. It is always necessary, however, to have a sign over the office to indicate that it is the ticket office and usually a sign is needed over each window to indicate the kind of tickets sold at that window. The system used at the Grand Central Terminal deserves mention. Over each window is a lighting fixture with a triangular globe on which is painted the word Through, Local or Pullman. There is a light in the globe only when the window is open, and the passenger can see at a glance to what window he must go to get his ticket.

OFFICE EQUIPMENT

Ticket office equipment has become so well standardized that but little need be said concerning it. Although some recent installations of wooden equipment have been made, present tendencies are towards the use of steel cases almost exclusively. Steel is slightly more expensive than wood, but it has advantages that make it peculiarly adapted for ticket offices. It is fireproof, and there are few places where that quality is more valuable than in a ticket office. Tickets are more than "scraps of paper," and if a station's stock of them is destroyed it is a tremendous task, as well as a costly one, to replace them with sufficient quickness to prevent delay to business. Steel cases are more compact and a clerk working at a steel local ticket case has more of his tickets within arm's reach whereby he is saved many extra movements and can work at greater speed. There is also considerable saving in the stock room where the available space is almost always limited. It is well known that steel cases are cleaner than wooden cases and that vermin and rodents, even if they succeed in securing access to them, do not breed in them. The steel cases are less susceptible to weather variations, a considerable convenience in damp climates.

The ticket stock cases in many offices are adjacent to the selling cases. In some offices, however, the reserve stock is so great as to require a separate stock room. Usually the stock for a particular window, or, to be more exact, any particular stock, is kept compactly in a particular section of the storage cases. If a window is assigned and one clerk alone handles the tickets for it the clerk is given responsibility for the section of the cases containing his stock. He has a private key and only he and the ticket agent can have access to the tickets. It is even more essential that the ticket storage cases be fireproof than that the cases in the ticket office proper be so, and for that reason the use of steel cases is most advisable. The stock room should be in close proximity to the ticket office. In some stations the stock cases are on a mezzanine floor in the ticket office. The idea is good from some points of view, but the office is often given a crowded effect and the outside light is sometimes cut off considerably.

The desks for the cashier and the accountants are usually in or near the stock room, for therein is usually the most available space. The idea is good provided the room is light and well ventilated, because it helps to keep the various departments of the office compact. The ticket agent's desk is usually in a convenient nook in the ticket office proper, although in some stations the agent is considered important enough to have an office of his own. In the latter case the agent and his assistants will be saved many steps if this office is adjacent to the ticket office, the stock room and the accounting desks. If these facilities are separated private telephone connection between the various departments is necessary.

Every ticket office should be supplied with lockers in which the clerks may keep their wearing apparel. Steel lockers are to be preferred because they are fireproof. It is also advisable for the office to have its own toilets, as the latter will save many steps and considerable time.

SELLING TICKETS

Hardly two ticket offices have the same method of selling tickets. The chief difference is that in some stations a ticket for any destination may be obtained at any window, whereas in others there is a sharp distinction between local and interline business. Each system has its advantages and its advocates, but the determination of the method to be used at any particular station seems to rest entirely on the character of the traffic. For some reasons it would always be preferable to sell both local and interline tickets from any window. Passengers always have a tendency to go to the first open window they see and resent being sent from one window to another. Many of them either do not see the signs indicating whether the clerk has local or through tickets, or do not understand what the words mean if they do read them.

At many stations, however, it is impossible to sell both local and through tickets at the same window. Reference to conditions at the South station in Boston or the New York Central ticket office in the Grand Central Terminal in New York will explain. At either of these offices, and particularly at the former, a very large proportion of the tickets sold are card locals, while at the same time there is also a large percentage of interline tickets which must be handled in an entirely different way. The card local tickets are almost always purchased in haste; for the clerk to sell one requires but few seconds. The number of interline forms is so great, on the other hand, that the tickets cannot be within arm's reach; to obtain a through ticket, to write up a complicated one, in particular, and to sell it is frequently a matter of two or three minutes. It would check rapid work and try the patience of purchasers of local tickets if the locals were not sold at one window and the interline tickets at another. Except in cases like these, where there are peculiar conditions, it would seem advisable to sell both local and through tickets from one window.

It is next in order to treat of the methods of operation inside the office. As far as the traveler is concerned it would be preferable to have a separate stock of both local and interline tickets for each window. It has been seen that there are some cases where a separation of suburban business must be made. There are other offices where it is manifestly impossible, because of the great number of forms, to have the desired separate stocks of interline tickets. In the New Haven ticket office at the Grand Central Terminal, where there are 10 windows on the upper level selling both local and interline tickets, a through or suburban ticket may be obtained at any window. The interline tickets are, on the whole, comparatively simple and the

number of forms is not large. This is the best system provided conditions permit of its use, because a patron can get his ticket at any window, and because every ticket that may be called for is almost within arm's reach.

The Pennsylvania Railroad follows the same method at its New York terminal. The interline tickets sold at the latter are somewhat more complicated and the number of forms is greater, but the number of local tickets is not as large, since most of the suburban business is handled at the Long Island ticket office on the lower level. The ticket office of the Boston & Albany at Worcester, Mass., sells local and through tickets over three roads. There are five ticket windows and the number of interline ticket forms is so great that the interline ticket case extends the full length of the office. There is a separate stock of local tickets for each window. For each window also there is a supply of the most lively interline tickets, but there is only one stock of the other interline tickets for the entire office. This seems to be the best possible scheme for use at offices where there is a fair local business and where provision must be made for a large supply of interline forms.

At the South station in Boston, there is an absolute division of through and local business. Each local window has a separate stock of local tickets and a supply of some of the more important interline tickets. There is but one stock of the ordinary interline forms for the several windows selling through tickets, but at each through window there is also a supply of some of the livelier long-distance local forms.

It is usual in ticket offices having a sufficient number of windows for the purpose to assign each window to a particular clerk and to permit him and the ticket agent only to have access to his cases. The clerk is thereby given an undivided responsibility for the appearance of his ticket cases and for his tickets, as well as for his cash. The window can only be used when he is on duty and his account for both tickets and cash is entirely distinct from that of any other clerk. Of course if three or four clerks are selling from a single interline ticket case the idea must be modified to suit; in principle, however, it remains the same. In this scheme no tour system is necessary. The clerk going off duty simply closes his window and can check cash and tickets without unnecessary haste and without interference by the clerk who, with a tour system, would follow him at the same window. The clerk coming on duty finds things just as he left them the night before and knows exactly where he stands without having to see that the clerk on duty before him has left matters just as they should be. It is another advantage that if one clerk is to relieve another there is absolutely no delay. It is a disadvantage that there must be a separate stock of tickets for each window, but in most offices a separate stock of local tickets must be supplied for each window anyway. In a busy office, in addition, it should be no hindrance, for the turnover of tickets will be sufficiently rapid for them to be sold before they have become too old. It would seem as though the advantages of assigning windows in a station busy enough to warrant that procedure outweighed to some extent the disadvantages.

Windows cannot be assigned according to the above method unless there is a sufficient number of them or unless a few cages that can be moved on rollers are used. The latter are so bulky and require so much extra room when they are not in use that they do not often meet with favor.

PULLMAN TICKETS

If, in the city served, the railroad maintains a number of city ticket offices, it is a problem to take care of the Pullman reservations. It is usual either for each office to be assigned a certain portion of the chairs and berths, or for one of the offices to be given entire charge, reservations at the other offices being made only on its authority as given by telephone conversation. For obvious reasons the office handling the reservations must be connected with all the rest by private wires. In many cases it has been found best for the one of the city offices to handle reservations. The entire list is kept at that office, entries being made to suit the reservations, until about one-half hour before train time, when the diagrams are sent to the ticket office at the terminal, sales being made there until a few minutes before the train leaves, when the statement is sent out to the train. In some cases the reservations are telephoned to the station office and there are a few instances in which they are telegraphed.

One solution of the problem that deserves more than passing mention is that worked out at one of the terminals in New York City. The ticket office is a large one. There are often four clerks selling Pullman tickets, and in addition it handles reservations for all the city offices. Behind the clerks at the windows is a large rack, holding all the cards for several days ahead. The rack is so arranged that cards may be taken from either side of it. On the opposite side is a table at which sit the clerks who handle the reservations asked for by telephone, the rack being so devised that the clerks on one side of it can obtain the diagrams without interfering in any way with those on the other side.

It is impossible here to treat of the methods of accounting which form an important part of the work of the ticket office.

"COURTESY ALWAYS"

It has been stated that each clerk should be provided with a locker. He should also be assigned a private drawer or compartment for his money in the office safe. Each of these compartments should have an individual lock, a combination perhaps being preferable, and the clerk, himself, and possibly the ticket agent in charge of the office should be the only ones to have access to the contents.

If ever the safety-first movement is succeeded or supplemented by a campaign of "Courtesy—Always," as is beginning to seem possible, ticket agents in charge of terminal ticket offices will have first claim to appointments as "Courtesy-Always" agents. The ticket agent has peculiar qualifications for the job. He knows how to pick men, how to train them in ways of courtesy towards the public, how to supervise them in the results of their training, and presumably he has been through the mill himself. It is possibly somewhat strange to speak almost as though courtesy were the first requirement for proper ticket selling. Courtesy is not the first requirement; it is subordinate to honesty and perhaps to accuracy, but it is the thing that needs most emphasis.

The ticket agent at the large station is usually given entire responsibility for the proper conduct of the work of his office, subject to the approval of the station master or some similar officer. He is, therefore, allowed to choose his own men. Each agent has his own ideas as to the best methods of picking assistants. Some find it best to take men from smaller stations on the line, and others to take them from other service in the terminal, as for example, from the information bureau. In almost every case an effort is made to secure men who have had service with the company. Such men already have a fair knowledge of the road's passenger service and are usually well versed concerning fares and connections. They only need to learn how to sell tickets under the arduous conditions of busy terminal ticket office service. It is now considered bad practice to take men from ticket offices of other roads, for it is the general opinion that positions in the ticket office should be looked upon as rewards for good work in other departments of the service.

The difficult task for the ticket agent is not to find men who are accurate and honest, but to find men who are sufficiently courteous. Courtesy, if it is not born in a man, can be acquired only by long training. It is hard to learn, because it is intangible and because it often seems as if to be courteous to some people were but a step to being servile; and to be servile hurts. The results of courtesy, so far as the ticket clerk is concerned are the impressions made on the minds of the purchaser. The ticket seller, therefore, must be something of a student of human nature. If he is fitted for his work, he should acquire a faculty of telling a person's character and frame of mind almost by his appearance, his actions and the sound of his voice. There are some people, however, who are tough nuts to crack.

The ticket clerk is paid to serve such people right. He will derive the most satisfaction from his work if he can take pride in solving the idiosyncrasies of people. He should feel that he has accomplished something when he has pleased a grouch, when he has convinced a crank that there is something intelligible about the timetables and tickets after all, or when he has conveyed a complicated bit of information to a foreigner who speaks almost no English. It has been suggested that he should put himself in the place of the person outside the window. The idea is a good one. Every person who asks a question usually has good reasons for the query, and if the clerk will think a moment he can usually frame an intelligent answer no matter how foolish the question. There are few snobs in this world, but there are enough and they are the hardest kind of people with whom the ticket clerk has to deal. He should, nevertheless, try to follow his rule of putting himself in their places. When they have gone he can find solace for any ill-treatment in thanking Heaven that the state is figurative, not normal.

It is usual in most large offices for the junior clerk to be put on local tickets first and then for him to work up gradually to one of the windows selling complicated interline forms. In one large office each clerk is strongly encouraged to understudy the next higher man. Each clerk is thus always improving himself for his next higher position, and if the older clerk is out his place is easily filled. Schedules and rates are changed so often that even an experienced clerk must learn new things about his work continually. The ticket agent can never be too careful that the orders and instructions are properly understood and remembered. At the office mentioned above the agent has a check on this in the form of periodical written tests. It is something of a job to compile the various questions, and even more difficult to correct the papers, but the office always knows where it stands. The agent is sure that orders are being understood and he has a check on every man. The same agent also holds monthly or bi-monthly staff meetings. Here he has a chance to emphasize the need of courtesy and every man has an opportunity to offer and discuss all kinds of suggestions for the good of the office. It is a waste of words to say that the staff of this office and its management are unexcelled.

TRAIN ACCIDENTS IN MAY[1]

The following is a list of the most notable train accidents that occurred on railways of the United States in the month of May, 1915:

Collisions

Date.	Road.	Place.	Kind of Accident.	Kind of train.	Kil'd.	Inj'd.
5.	St. Louis, I. M. & S.	Grassy Lake.	bc	P. & F.	1	29
15.	N. Y. Central	Scarborough.	rc	F. & P.	0	6

Derailments

Date.	Road.	Place.	Cause of Derailm't.	Kind of train.	Kil'd.	Inj'd.
3.	Norfolk & W.	Boyce.	unx	F.	1	3
3.	Southern	Marion.	d. track	P.	0	3
14.	Balt. & Ohio	Belmont.	d. drawbar	F.	8	0
15.	Chicago, M. & St. P.	Yankton.	b. flange	P.	0	20
15.	Southern	Toccoa.	unx	F.	0	0
*17.	Missouri Pac.	Nebraska City.	b. wheel	F.	5	0
22.	Northern Pac.	Honeyford.	unx	P.	0	20

The trains in collision near Grassy Lake, Ark., on the night of the fifth were eastbound passenger No. 20 and an engine without train, westbound. Twenty-eight passengers and five employees were slightly injured and a trespasser was killed. The light engine, in charge of a conductor, an engineman and a fireman, had encroached on the road right of the passenger train.

The trains in collision at Scarborough, N. Y., on the 15th were a northbound local passenger train and an electric locomotive without train, the locomotive running into the rear of the passenger train and damaging itself and the rear passenger car. Four passengers and two employees were injured. The electric engine had run past a distant and a home signal set against it.

The train derailed near Boyce, Va., on the third was a northbound freight and 21 cars left the rails. One trespasser was killed and 3 were injured. The cause of the derailment was not determined.

The train derailed near Marion, N. C., on the third was westbound passenger No. 1. One sleeping car was ditched and three passengers were injured. The derailment was due to distortion of the rails by excessive heat, at a place where new ties were being put in.

The train derailed at Belmont, Ohio, on the 14th was a westbound freight, and 14 steel cars were wrecked. Riding on the cars were a number of trespassers, of whom eight are said to have been killed. The derailment was due to the failure of a drawbar which was pulled out and fell to the roadbed.

The train derailed near Yankton, S. D., on the 15th was an eastbound passenger and the three rear cars were overturned. Eighteen passengers and two trainmen were injured, none seriously. The cause of the derailment was the breaking of the flange of a wheel of a freight car.

On the Southern Railway near Toccoa, Ga., on the 15th there was a derailment in which several freight cars were wrecked which ordinarily would not appear in this list, but which became prominent by reason of the fact that the next morning, while the wrecking crew were picking up the last car, six men, including the supervisor, the section foreman, and four laborers, were killed, and nine other employees were injured, by the fall of a car which was being lifted by derricks. A chain slipped and the car dropped suddenly on the men, who were beneath it.

The train derailed near Nebraska City, Neb., on the 17th was a westbound freight, and seventeen cars were wrecked. Oil or gasolene in one of ten tank cars took fire and the wreck was burnt up, including two carloads of silver bullion, the metal in which was melted. Five trespassers riding on the train were burned to death. The cause of the derailment was a broken wheel.

The train derailed near Honeyford, N. D., on the 22nd was southbound passenger No. 14. The train was running about 25 miles an hour. Eighteen passengers and two trainmen were slightly injured. The cause of the derailment was not determined.

[1]Abbreviations and marks used in Accident List:
rc, Rear collision——bc, Butting collision——xc, Other collisions——b, Broken——d, Defective——unf, Unforeseen obstruction——unx, Unexplained——derail, Open derailing switch——ms, Misplaced switch——acc. obst., Accidental obstruction——malice, Malicious obstruction of track, etc. ——boiler, Explosion of locomotive on road——fire, Cars burned while running——P. or Pass., Passenger train——F. or Ft., Freight train (including empty engines, work trains, etc.)——Asterisk, Wreck wholly or partly destroyed by fire——Dagger, One or more passengers killed.

RULES FOR TRACK WALKING.—The first and most important rule is akin to an Irish bull: Don't walk on the track if you can possibly find any other road, path or field to walk on. But if you must walk on the track, then be sure to look behind you frequently, especially if the wind is blowing in the opposite direction as you are walking. On the approach of a train look around and let the engineer know that you see him. Don't wait until he is almost upon you, don't leave him in doubt. Don't compel him to whistle for you. Your danger grates on his nerves and the unnecessary whistling grates still more on the nerves of the peaceful dwellers along the tracks. If on a double track railroad, walk on the track on which trains come towards you, but don't neglect to look behind you often, for trains sometimes run on one track in both directions. . . . Never "hop" a moving car or engine; it is always dangerous; always gets your hands (and often your clothes) dirty, and very rarely brings a reward. Finally, the famous advice of Punch, about telling jokes applies with sledge hammer force to walking on tracks: DON'T.—*Alton (Ill.) Evening Telegraph.*

Necessity for Additional Revenues on Western Railways

Brief Submitted by C. C. Wright in Western Rate Advance Case Discusses Condition of Carriers Since 1901

The attorneys representing the western railways have filed their briefs with the Interstate Commerce Commission in the western freight rate advance case, and oral arguments are to be heard before the commission at Washington beginning on June 22. Separate briefs were filed by the committee of six attorneys representing all of the lines for the different commodities involved in the case. The brief on the necessity for additional freight revenues was prepared by C. C. Wright, general solicitor of the Chicago & North Western and chairman of the attorneys' committee. Some extracts from this brief are as follows:

The question naturally divides itself into three interrogatories, viz.:

(1) What is the revenue of the carriers and what return are they receiving upon their property?

(2) What is the cause of the low returns?

(3) What ought the carriers to earn?

REVENUES

We submit that the showing as to the 41 roads, which has been presented by the carriers, is the fairest way possible in which to determine the actual revenues of the roads in the territory, throughout which the advance in rates is proposed. It is true that there are some small lines which are omitted and that there has not been included in this group some which are known as transcontinental lines, and which will receive an incidental, small advantage by the advance. It is true, some of the lines extend into territory outside of that involved, but sub-groupings make it plain that the 41 roads reflect the condition in the territory.

Attention is particularly directed to the exhibit in relation to the net operating income of the various years. It is shown that the operating revenues for the period 1908-1914 increased $1,348.42 per mile of road, as compared with 1901-1907, but at the same time, the operating expenses, hire of equipment and joint facilities increased $1,407.34 per mile of operated road. The taxes in the second period, over those in the first, increased $115.17 a mile, while the rental and net lease of road decreased $20.95. As a result, the net operating income of these roads, on an average for the last seven years, has been $153.14 less than the average of the seven years immediately preceding. If the last six years are taken, as against the six years prior to that period, the results will not be materially different.

It will be noted that in only four of the years in the last seven, has the net operating income per mile operated, equaled the lowest net operating income during the prior period of seven years. In no year in the last seven has it equaled the highest yield in the prior seven years. The average for the second period was $2,045.34, as against $2,198.48 for the first.

It will be noted also that in 1909 and 1910 the return was much greater than in 1914. In three of the last seven years, the net operating income per mile has been less than $2,000, while it was less than $2,000 in only one year in the first period, which was the year 1904, when all business was paralyzed. If one compares the year 1913, one of large volume of business, with the year 1907, it is readily seen that the operating income per mile for 1907 was $260 in excess of that most prosperous year in the latter period.

If a comparison is made of the last five years, that is, 1910 to 1914, inclusive, with the five years immediately preceding, it will be seen the decrease is even greater than in the preceding seven-year period, so that any grouping of the years which may be selected indicates a declining net operating income per mile of road. Comparing the lowest year in the latter period with the lowest year in the first, shows a decline of $159.93. Comparing the highest year in the second period with the highest year in the first period, shows a decline of $285.63. A like comparison might be made by taking the two and three lowest in each period, or the two and three highest in each period.

The same story is told by Exhibit 10, in a comparison of ratios of operating expenses to revenue. In no year in the last period has the operating ratio been as low as in the former period.

The study of the variations of operating ratios, as made by the commission in connection with this case, is both interesting and illuminating. As stated in the resume presented by A. M. Bean, one of the examiners of the commission, it discloses that while exceptional conditions on individual roads may in part account for unusual variations in the operating ratio, there are certain general conditions which operate alike upon the different roads, which would have the tendency to increase the operating ratio. Among those are included the increase in wages; increase in price of fuel; increase in cost of ties; larger expenditures required to properly maintain road and equipment; increase in taxes; more numerous requirements by state and interstate commissions; decreasing revenue due to reductions in rates, and to the introduction of depreciation charges. These are all general in their character, and there is nothing in the record to indicate that there will be any change which would counteract such increased expenses. The only one of the general reasons why the operating ratio has increased which may be reasonably expected to be remedied is the one mentioned as the decreased revenue due to reduction in rates. That seems to be the only one in which this almost steady increase in operating ratio may be checked without serious detriment to the public service.

It would seem that these exhibits lead irresistibly to the conclusion that the net operating income per mile of road of the carriers is declining. It is shown that in 1914 it was only $1,963.36 per mile of road and that for the average of the last seven years it was only $2,045.34.

If the road and equipment cost, as shown in the exhibits and from the books of the carriers, represents the value of the property, it will be seen that the earnings for the last seven years yielded a net return of 4.19 per cent. In the year 1914, the earnings returned only 3.81 per cent. A comparison of different years in the same period demonstrates the decreasing rate of return, as well as the insufficiency of the revenues. The highest year in the first period was 1907, when it was 5.64 per cent, and the highest year in the second period was 1909, when the return was 4.61 per cent. During the first period, in no year did the return fall below 4.55 per cent. In only one year in the last period did it reach that figure; that is, there is only one year in the last period when the rate of return was as high as the lowest year in the first period. If comparison is made with the earnings in 1914 and the year immediately preceding, it will be seen that the returns had fallen from 4.44 to 3.81. The reports of the fiscal year 1915, so far as yet received, would indicate that 1915 was no better than 1914. The last five years of this period may be compared with any other five years that may be selected, but still the rate of return is less in the last five years. Even the panic year of 1904 was better than any year since 1909.

This showing of the carriers is not met by any counter evidence, because it cannot be. By grouping of strong roads protestants were able to show an earning above 6 per cent on the group selected, but they were not able to show a return of 7 per cent, even after making deductions from road and equipment of amounts which they had pointed out as, in their opinion improperly included, and without adding anything for working cap-

ital, during any of the periods. Even under the showing of selected groups by the protestants, the same downward trend was apparent.

THE CAUSES OF DECLINE

It is proper to discuss the causes of this declining net operating income from rail activities, and determine whether it is due to the fault of the carriers, or to causes beyond their control.

Attention is here directed to the fact that the carriers have been steadily investing more money in the property, amounting in the last seven years to more than a hundred million dollars a year for additions and betterments to the existing roads. They have been steadily improving the character of their railroads and equipment out of the money so expended. The evidence, we believe, fairly demonstrates that the roads in question in this case have been meeting the public demand and improving their service from year to year; they have increased their efficiency by all known means within their power. The density of traffic per mile has increased, and yet, notwithstanding all of these things, which make for efficiency and lower costs, the cost per unit of service has increased.

It is true that the operating revenues of the lines in question have increased, but it is also true that the operating expenses and the taxes have increased at a faster ratio. The revenues per mile of road increased in the last period over the first, on a yearly average of $1,348.42, but the operating expenses, exclusive of taxes, rental, etc., increased $1,407.34; the increase in taxes was $115.17 per mile and the decrease in rentals $20.95 per mile, which results in a net decrease on the average for the last seven years, as compared to the seven years prior thereto, of $153.14 per mile. It thus is apparent that the carriers have not been able by the means employed to meet the increasing costs out of increasing revenues.

It is difficult to determine accurately the extent to which each of the different causes has contributed to this result, but there are some things that can be pointed to as potent factors.

By exhibit 12 it will be seen that the ton-miles per mile of road had increased from an average of 613,059 tons in the first period, to 709,889 tons in the second period. It appears, however, that the increase in the first period was much more rapid than in the second. The average of the second period over the first was approximately 13.5 per cent. The average of the tons per train mile in the first period was 266.78, and in the second, 316.54, which was approximately 18.5 per cent. It will be noted, however, that the greatest increase was in the last period.

Notwithstanding the increased capacity and weight of the freight cars, it will be seen that the increase in the tons per mile, has been less than 10 per cent; and exhibit 14 shows that there has been very little increase in the revenue tons per car mile since 1907. This is partly accounted for by the fact of the low minimums which are enforced by various state commissions, and partly by the fact that with the diversified character of traffic and the necessity of special equipment, the empty car mileage has increased.

That the labor costs have been a material element in the increased expenses of the carriers is not only apparent from the special study of operating ratios, which was made by the commission, but appears conclusively from exhibit 15. This exhibit shows the increase in wages paid, year by year, on account of the increase in rate of pay. The exhibit was prepared to include general officers and also excluding general officers. It will be noted that the increase has been greater when the general officers are excluded than when they have been included. That is particularly noticeable in the last seven years. The increase in labor costs has not been uniform. From 1902 to 1903 there was a very large increase, being a little over six and one-half million. The increase for 1903 to 1904 was over four and one-half million. There was a material increase from 1907 to 1908, being nearly six million, but in 1909 there was a decrease of nearly two and one-half million over 1908. In 1910 the increase was over fourteen million, and in 1911 over twelve million. It will be noted that this increase came at about the time of the decision of the commission in 1910.

This exhibit shows that the increase in expenses, due to increase in the rate of pay for employees, was in the year 1914 over 1900, $85,167,085.95.

On exhibit 17 is shown the increase in taxes and the increase due to the advance in the rate of taxation. It shows that taxes in 1914 were $17,628,142.61 more than they would have been, if computed on the rate of taxation in 1901, or $179.06 per mile of road operated.

The increased labor costs, due to the increase in rate of pay, was $865.11 more per mile of road operated in 1914 than it would have been under the 1900 wage scale. This makes a total increased operating expense per mile of road operated, due to increases in the rate of pay for employees and the rate of taxation by states and municipalities of $1,044.17 per mile, which would be equivalent to a return of 2.02 per cent upon the cost of road and equipment. In other words, if the same wage scale and the same rate of taxation had been applied in 1914 as in 1900 and 1901, the carriers would have been able to have earned a return of 5.83 per cent upon the cost of road and equipment, instead of 3.81 per cent. This very definitely locates a large element of the increased cost.

Exhibit 18 shows in detail the increase in cost of material and other items. Attention is directed to the fact that since 1909 the cost per mile of road for material and other items has increased more than $400.

A study was made to determine as far as possible the relation of the maintenance costs. It was a recognized fact that maintenance costs, particularly of equipment, has increased in the last few years.

The ratio of maintenance of way and structures to the revenue has decreased in the last seven years over what it was in the preceding seven years and there is only a small increase in the ratio of maintenance of way and structures expenses to the cost of road and equipment. On the other hand, maintenance of equipment shows that it has increased faster than the revenue and faster than the cost of road and equipment. For the first period the total maintenance costs were 26.69 per cent of the revenue, and in the second period 29.24 per cent of the revenue. In the first period the maintenance expenses averaged 4½ per cent of the value of road and equipment, and in the second 5.29 per cent.

An examination of this exhibit, however, will disclose a rather uniform advance. It does not indicate an abrupt advance, due to change in accounting methods, in 1908. The increase, 1901 to 1907, in maintenance of equipment, amounted on these roads, to approximately $54,000,000. From 1908 to 1914 the increase was approximately $52,000,000. The gradual increase of this cost of maintenance of equipment would indicate that it was not due to the latter period to the depreciation account, but was the result of far-reaching causes.

Maintenance of equipment shows a much more radical increase. It will be observed, however, that maintenance of equipment per mile of road shows a steady advance. There was no sudden advance from 1907 to 1908. In 1906 maintenance of equipment per mile of all tracks operated was $809.22, in 1907 $894.01, in 1908 $849.08 and in 1909 $887.10.

NEEDS FOR THE FUTURE

In Wettling's Exhibit 29 the carriers assembled the amount of maturing obligations for the next seven years. This was for the purpose of indicating that the carriers involved in this case must renew a large amount of obligations or place new securities beyond the amount necessary for additions and betterments each year. It is true that the building of new roads in this territory has almost entirely ceased. It is not believed that the public is going to be satisfied unless additional lines are constructed. Every indication is that it will require as much for additions and betterments annually in the future as it has for the last seven years, therefore these various carriers must raise at least $100,000,000 a year from

some source, in addition to the amount necessary to refund or refinance their maturing obligations. For 1915 they would require over $155,000,000 for additions and betterments and to take care of maturing obligations.

A noticeable fact in this connection is that the increase in capital liability has been largely made by the increase of interest-bearing obligations, rather than by the increase of stock. Exhibit 28 shows that in 1910 the capital liabilities represented by stocks were 46.33 per cent, by bonds 53.77 per cent. In 1914 this had changed so that the ratio of stock to total capital liabilities was only 37.74 per cent and the ratio of bonds and funded debts had risen to 62.26 per cent.

The facts disclosed cannot help having an unfavorable effect on the borrowing ability of these carriers. We care not whether you call it credit, or not. They will not be able to borrow additional capital on as favorable terms as they would if their proportion of property represented by the bonds and outstanding interest-bearing securities was less. When we speak of the impaired credit of the railroads, we do not refer to the interest rate on underlying securities, which represent less than 50 per cent of the value of the property. What we mean, however, is that for new money and for money which is needed for additions and betterments and the development of the property, the carriers are not now able to borrow on as advantageous terms as formerly; that they have about reached the limit of their borrowing capacity on top of their present debt; and that they are not able to float their stocks, because of insufficient revenues to guarantee dividends commensurate with the risk.

Statisticians may make exhibits without end, but they can never overcome the fact that any company, be it a railroad, an industrial or a public utility company, can not have as good credit with a mortgage covering 65 per cent of the value of its property as it would have if its mortgage covered only 50 per cent of its property, and the increasing per cent of the interest-bearing debt must obviously affect its credit. This fact is aggravated by the large amount of short time obligations entering into the aggregate of its interest-bearing obligations.

While we have not laid any great stress in this case upon impaired credit, we do insist that the evidence shows that the ability of the carriers to borrow new or additional money and the ability of the carriers to raise money by the sale of stocks is greatly curtailed; that higher rates must be paid and that it is increasingly difficult to secure money from any of these sources. This, we believe, to be largely due to the fact of a declining net revenue.

TO WHAT RETURN ARE THE CARRIERS ENTITLED?

The only authoritative statement of the rate of return to which a carrier is entitled is found in the decisions of the courts in cases where the court has been asked to enjoin the enforcement of legislative acts or the orders of commissions, reducing rates or curtailing the revenues of the carrier. These cases must, of course, be based upon individual conditions, *i. e.*, the court can consider only the rate of return to be received by the particular line asking the injunction.

The question before the Commission, in considering an application of this kind, is, of course, much broader. This undoubtedly has been recognized by the commission, but we desire to suggest, in this connection, that when they are considering the reasonableness of rates, the rate of return upon a single line, or upon two or three lines, operating in a territory, can form no criterion as to whether or not the rates are reasonable. This is apparent from the fact that one line, under the same rates, may earn 8, 10 or 12 per cent. upon the value of its property, while another line may earn only 4 or 5 per cent upon the value of its property. It is in recognition of this fact that we have presented the matter as though all the lines in the territory were operated as one line. This must rest upon the assumption that the maintenance of these lines is all necessary and proper.

The carriers in this case have based their contention upon the right to earn at least 7 per cent upon the value of their property. In the Minnesota Rate Case, the circuit court held that the carriers in question in that case were entitled to earn at least 7 per cent upon the value of their property. While the case was reversed by the Supreme Court of the United States, the position of the circuit court as to the rate of return to which the companies were entitled was not reversed nor criticized. In a case, not yet reported, which has been decided, pending this present hearing, by the district court of Arkansas, it was held that the carriers in that section had the right to earn not less than 7½ per cent upon the value of their property. These and other cases indicate very clearly that the carriers in the territory in question, as a minimum, are entitled to 7 per cent upon the value of their property.

The advances in this case were expected to increase the revenues of the carriers by about $10,000,000 per year, as stated in the opening. The evidence and a more careful analysis of it discloses the fact that the estimate was too large. If the increase were $10,000,000 a year, it would make the full net operating income of these roads only $203,286,463.22, and would increase the rate of return by only a small fraction of one per cent. In round figures, the rate of return in 1914, if the proposed rates had been applied, would have been 4 per cent and such rate of return must be considered to be below anything that even the most radical could claim to be reasonable. It would not pay the interest on the bonds, assuming that 100 per cent value of the property could be bonded at the rate of interest accruing on the underlying mortgages.

In this connection, and to meet what appears to be the opinion of the Supreme Court in recent cases, the carriers have attempted to separate the costs of the freight and passenger business and ascertain the rate of return upon each class of business. There being no authoritative method for the separation of expenses the carriers used various methods and any or all of them are only approximate. We believe them to be such reasonable approximations that they may justly and rightly be used as the foundation for an opinion.

Under these bases, as shown by Exhibit 30, the ratio of expenses, including taxes, hire of equipment, etc., to revenue on the freight business, runs from 75.14 to 76.98, and the rate of return under these different bases, on the freight business, varies from 4.23 to 4.68 per cent, so that on any of the bases used there is such a margin of insufficiency of return as to render negligible any possible errors in the bases used.

HOW MAY THE REVENUES OF THE CARRIERS BE INCREASED

From this evidence, it seems that but one conclusion can be drawn, and that is, the increase in rates for the purpose of increase in revenues has been justified. If this conclusion is correct, it remains only to determine in what place and upon what commodities the advance shall be applied. It would be impracticable to make the advance of rates in either of the sections of the territory involved upon such commodities as grain, live stock and packinghouse products, without making a corresponding advance in the other portions of the territory

As to the selection of commodities, there will always be difference of opinion. The striking thing about this hearing has been that each protestant has been vigorous in asserting that the advance ought to be made on "the other fellow's commodity." The carriers in this case have exercised the best judgment they had, having in view the raising of additional revenue and the distribution of the additional charge to the public. The traffic managers familiar with their territory, know very well that there are certain commodities and classes of commodities that cannot stand an advance. If, therefore, there are certain rates which from competitive or commercial reasons, cannot be advanced so as to afford the same ratio of profit to the carriers as the other rates, it constitutes no reason for denying the advances on other commodities. Neither does this necessarily mean unjust discrimination.

The attempt in this case has been to select those commodities which will produce the needed revenue, with the least hardship, and to so distribute the advances that they may be borne by the

public generally, rather than by any separate class. It has not been thought practicable at the present time to advance the class rates in the western territory. They have been, many of them, fixed by orders of the commission, which would prevent an advance, and beyond that, the class rates in the western territory have not been so carefully and uniformly adjusted as in the east.

We beg leave to suggest that the act of Congress in relation to regulation of commerce fully contemplates that the carriers themselves shall retain the initiative in the matter of fixing rates, and the power of the commission is intended to be regulatory only, for the purposes of seeing that excessive or extortionate charges are not made by the carriers, and preventing undue or unjust discriminations. The law does not authorize the commission to fix rates. If, therefore, the initiative in fixing rates is to be left to the carriers, they must be allowed some discretion and must be expected to exercise that discretion within reasonable limits. It would seem that the duty of the commission in passing upon an application of this kind, somewhat general in its character, should be limited to the determination of whether the carriers have exercised a reasonable discretion.

A RECENT DEVELOPMENT IN RAILROAD FINANCE

By George A. Clark

The development of rail transportation in the United States can be conveniently studied from at least three points of view. There may be others, but certainly the problems of this industry fall into three natural groups; these are the physical and engineering problems arising from the construction and operation of the plant, the organization of the employees, and the development of the financial structure of the individual corporation. The latter is primarily of interest at this time because of the significance of a recent development to which as yet little attention has been given.

Capital has entered into the transportation industry in two forms, through the purchase of investors of either a share interest in the undertaking, having a more or less well-defined speculative value, or through the purchase of a fixed obligation (bonds), which generally has a rather well-defined investment value. It has not been feasible to develop a single important railroad system in the United States through the sale of capital stock alone. In every instance from one-third to two-thirds of the capital which has been required for the development of a given property, has been secured through the sale of bonds. Considering the needs of the industry and the resources of the country, it is a tribute to the financial genius of the early railroad promoters that such a large proportion of capital has entered the industry through sale of capital stock.

The sale of bonds for the purpose of inducing capital to enter the industry introduces a consideration of the various elements that have entered into this form of finance. During this period every conceivable modification and variety of obligation has been created to meet real or fancied needs. During the past three years, however, a definite form of obligation securing bond issues has been developed. An instrument has now been devised which meets the more exacting requirements of the state banking and insurance investment laws, and which appears to be adequate for the future needs of the industry. The "blanket mortgage" has at last reached a point where it appears reasonable to expect that there will be no further changes of consequence in the character of obligations of this kind.

Although the more recent "blanket mortgages" are in many ways an advance over the Great Northern first refunding mortgage securing the 4¼s of 1951, it can be said that the precedent in this line, as in many others, was established by James J. Hill when he asked his stockholders to authorize an issue of $600,000,000 bonds. Within the past year the Pennsylvania, the New York Central, the Chicago, Milwaukee & St. Paul, the Northern Pacific and the Erie have secured the approval of their stockholders, authorizing the creation of "blanket mortgages." The New Haven, the Baltimore & Ohio and the Southern legal and financial officers are now working on similar mortgages.

In a very significant sense, this new type of obligation appears to mark the end of the period of construction, consolidation and system building in the railroad development of the United States. A bond has been issued, secured by a mortgage, which appears to incorporate all of the essential features of the divisional, consolidated, refunding, convertible and debenture issued with few of the disadvantages inherent in all of them. In a very real sense of the character of the obligation created by the railroads during their development closely corresponds to the physical development of the business. Out of the great variety of obligations which have been created for the purpose of raising capital, the following may be considered as typical of the period and purpose served.

The first of these is the divisional mortgage of which there still remain a great number. As various pieces of track were projected, the most natural method of raising a part of the capital for the undertaking was to place a mortgage upon the specific piece of track under construction. As detached mileage was welded into through line, the equities in earnings and property values grew rapidly. Many obligations of this type are a favorite with the most conservative investment institutions. There are a few companies which still employ them, notably the Chicago & North Western, which within the past two years created two important mortgages of this kind, the Milwaukee, Sparta & North Western first 4s of 1947 and the St. Louis, Peoria & North Western first 5s of 1948. Both of these issues have since been assumed by the Chicago & North Western. As a type, however, with the refunding of the existing divisional mortgages they will disappear from railroad finance.

The welding of local operating units into through lines brought about the consolidated and unifying mortgage. This type of obligation allowed somewhat greater freedom in the development and expansion of the property than was possible with divisional mortgages. It could be used for refunding such issues, for construction or acquisition of new mileage, for the development of existing mileage and for the purpose of uniting independent properties into a single system. The Louisville & Nashville unified 4s of 1940 is an illustration of this type of bond issue. The consolidated mortgage afforded a method of bringing about one of the most important developments in the industry, namely, the consolidation of local units into through lines.

Closely parallel to the consolidated mortgage but following it as the demand for a more flexible financial instrument arose with the further development of the country, is the general refunding mortgage. This perhaps has been the most conspicuously successful of the various instruments employed to date. A number of well-known issues of this type have served the purpose for which they were created most admirably. Of these, some of the better known are the Chicago, Burlington & Quincy general 4s of 1958, the Chicago & North Western general 4s of 1987 and the Delaware & Hudson first and refunding 4s of 1943.

This type of issue has not been without certain marked disadvantages. The most noticeable of these has been the fixed interest rate common to most of them, the fixed authorized amount and burdensome restrictions as to issuance of bonds for other than refunding purposes. The fixed interest rate has frequently made it impossible for the company to sell bonds except at a prohibitive discount. The general lien 3s of 2047 of the Northern Pacific, and the Atlantic Coast Line unified 4s of 1959 are two instances in point. The general refunding mortgage bonds have been commonly limited as to the total authorized issue by some more or less arbitrarily fixed amount. In no important instance has the amount fixed been adequate.

The third occasion of difficulty in the use of these refunding issues has arisen from what have proven to be unnecessary and burdensome restrictions as to the issue of additional bonds and the absence of liberal provisions as to redemption, con-

vertibility, etc., all of which serve to adapt the issue to the period in which it must be sold. An instance illustrating the importance of this feature is found in the Chicago, Rock Island & Pacific first refunding 4s of 1934 where the amount issuable for additions and improvements to existing lines is limited to $2,500,000 per calendar year. This provision has had the effect of depriving the operating company of the Rock Island system of necessary capital for development of the plant. It has been an important but little recognized factor in bringing the system to the point where a drastic reorganization is necessary.

A number of additional types of obligations have been very extensively used, such as the debenture bond common to New England railroads, the convertible bond common to many of the stronger companies, the equipment trust note and the collateral trust bond.

The debenture has been used by a number of companies of good credit with conspicuous success. Notable among these, in addition to the New England roads, are the New York Central group, the Chicago, Milwaukee & St. Paul, and the Baltimore & Ohio.

The convertible bond has been an effective method of securing new capital without permanently increasing fixed charges. but with the coming of the "blanket mortgage" in the case of the railroads with the better credit at least, it seems probable that they will gradually fall into disuse.

The last step in this process is the "blanket mortgage" variously known as general and refunding, improvement and refunding, etc. The more important characteristics of this type of mortgage are as follows:

The limit to the authorized issue with the exception of the Pennsylvania and the Erie, has been placed at three times the outstanding capital stock. In the case of the Pennsylvania, it is fixed at an amount equal to the capital stock; in the case of the Erie, it has been limited to $600,000,000. The bonds issuable under the mortgage are secured by a direct lien, with minor exceptions, upon the entire property of the company now owned or hereafter acquired. Bonds may be issued in series, the interest rate in no case to exceed 5 or 6 per cent. After the refunding of all existing issues and the use of from $200,000,000 to $300,000,000 additional further bonds can only be issued to pay for new work at from 75 to 80 per cent of its cost, and upon approval of stockholders for each issue or series.

The following comparative table illustrates clearly the remarkable uniformity in the leading provisions of these issues:

Comparison of Salient Provisions in Latest Type of Railroad "Blanket Mortgage" Bonds

	Company			
Provision	Pennsylvania	N. Y. C. & H.	C. M. & St. P.	N. P.
Maturity	100 years from date.	100 years from date.	100 years from date.	133 years from date.
Interest rate	Provision not announced.	To be fixed by company for each series.	To be fixed by company for each series, but cannot exceed 6 per cent.	To be fixed by company for each series, but cannot exceed 6 per cent.
Issuable in Series	Upon vote of stockholders approving each issue.	After $500,000,000 have been issued no additional bonds may be issued except for refunding purposes, unless authorized by stockholders.	Without restrictions.	After $500,000,000 have been issued no additional bonds may be issued except for refunding purposes, unless authorized by stockholders.
Authorized Issue	Limited to an amount *equal* to outstanding capital stock.	Limited to *three* times outstanding capital stock.	Limited to *three* times outstanding capital stock.	Limited to *three* times outstanding capital stock.
Smallest denomination issuable under terms of indenture	Not announced.	$500	$100	$100
Redeemable	Not announced.	Any series may be redeemed as a whole on terms to be stated on each bond.	Any series may be redeemable upon terms stated on the bond.	Any series may be redeemable as a whole upon terms stated on bond.
Convertible	Not announced.	Any series may be made convertible into capital stock.	Any series may be made convertible into capital stock.	No provision.
Further Provision	Not announced.	After $500,000,000 bonds have been issued, not including refunding, bonds can only be issued for new construction on property acquired at 80 per cent of cost.	After $226,961,600 bonds have been issued, not including refunding, bonds can only be issued for new construction on property acquired at 75 per cent of cost.	After $500,000,000 bonds have been issued, including bonds for refunding purposes, additional bonds can only be issued for 80 per cent of cost of new construction on property acquired.
Nature of lien	Direct lien on all property of company with minor exceptions.	Direct lien on all property of company with minor exceptions.	Direct lien on all property of company with minor exceptions.	Direct lien on all property of the company with minor exceptions.
Bonds issued to date	None	$40,000,000	$30,000,000	$20,000,000

The Southern Pacific, the Norfolk & Western and the Atchison, Topeka & Santa Fe have used issues of this type to advantage. This is particularly true of the latter company, which since 1905 has only increased its funded debt from $275,000,000 to $319,146,000, or approximately 16 per cent. In the same period its outstanding capital stock has increased from $102,000,000 to $160,836,500, or more than 87 per cent.

The equipment trust notes has been quite generally used by all classes of companies. It is interesting to note in this connection that the western roads form a notable exception to this general practice. The Great Northern, the Northern Pacific, the St. Paul, the Union Pacific, Atchison and Southern Pacific have not used this form of obligation in recent years. As an investment security it has had a most fortunate record from the point of view of the investor.

The collateral trust bond has been primarily an instrument which has been used in the process of system building. Now that the conditions of the transportation industry have become practically stabilized, it will not be used in the future.

Each of the above obligations has served an important part in the development of the financial structures of the railroads,

Comparing this type of mortgage instrument with the various mortgages which have been drawn in the past, it appears to have successfully overcome the most obviously difficult of those indentures from the point of view of the railroad company at least. All of the issues under consideration run for 100 years or more. In no case is a fixed interest rate provided, thus insuring a degree of flexibility to cope with the problem of shifting investment conditions. The ratio of debt to capital stock has been fixed upon most liberal terms rather than limiting the issue to a fixed authorized amount. The principle of a fixed ratio to capital stock or share interest has been adopted rather than fixing a definite amount. Provisions as to redemption, convertibility, etc., have been satisfactorily provided.

From the point of view of the corporation, the blanket mortgage provides complete freedom for future development.

From the point of view of the investor but one serious criticism can be directed against this type of finance. Too great latitude has been allowed in the creation of debt in ratio to capital stock. Undoubtedly the Pennsylvania has taken the wisest position on this point. The tendency, however, is to take advantage of the widest latitude allowed by the investment

laws of New York, Massachusetts and Connecticut. The reception which investors have accorded the obligations which have been offered during the past year would not indicate any serious disapproval of this feature, however.

With characteristic foresight the Pennsylvania was one of the first to secure approval of stockholders for an issue of this character, although as yet no bonds have been offered under it.

The New York Central & Hudson River in April, 1914, made the first public offering, with a total of $40,000,000 refunding and improvement 4½s of 2014 on a 4.70 per cent basis. The issue was well taken, according to the report of bankers.

The Chicago, Milwaukee & St. Paul followed in June of last year with an issue of $30,000,000 general and refunding 4½s of 2014. In this instance the bankers acted as an agent for the company. No commitment was made, the bankers receiving a commission of ½ point for all bonds sold. In spite of the unusual circumstances surrounding the offering, the issue appeared to go well on a 4.68 per cent basis. In January of this year $30,000,000 additional were offered to stockholders on a 5 per cent basis. This issue was made convertible. In July, 1914, $20,000,000 Northern Pacific refunding and improvement 4½s of 2047 on a 4.64 per cent basis were taken in an unusually short time.

It is of interest to consider this type of financing with reference to the industry as a whole. These instruments represent the last word in the effort of those responsible for the financial well-being of our railroads to provide a dependable and attractive bond serviceable alike to both the company and the investor.

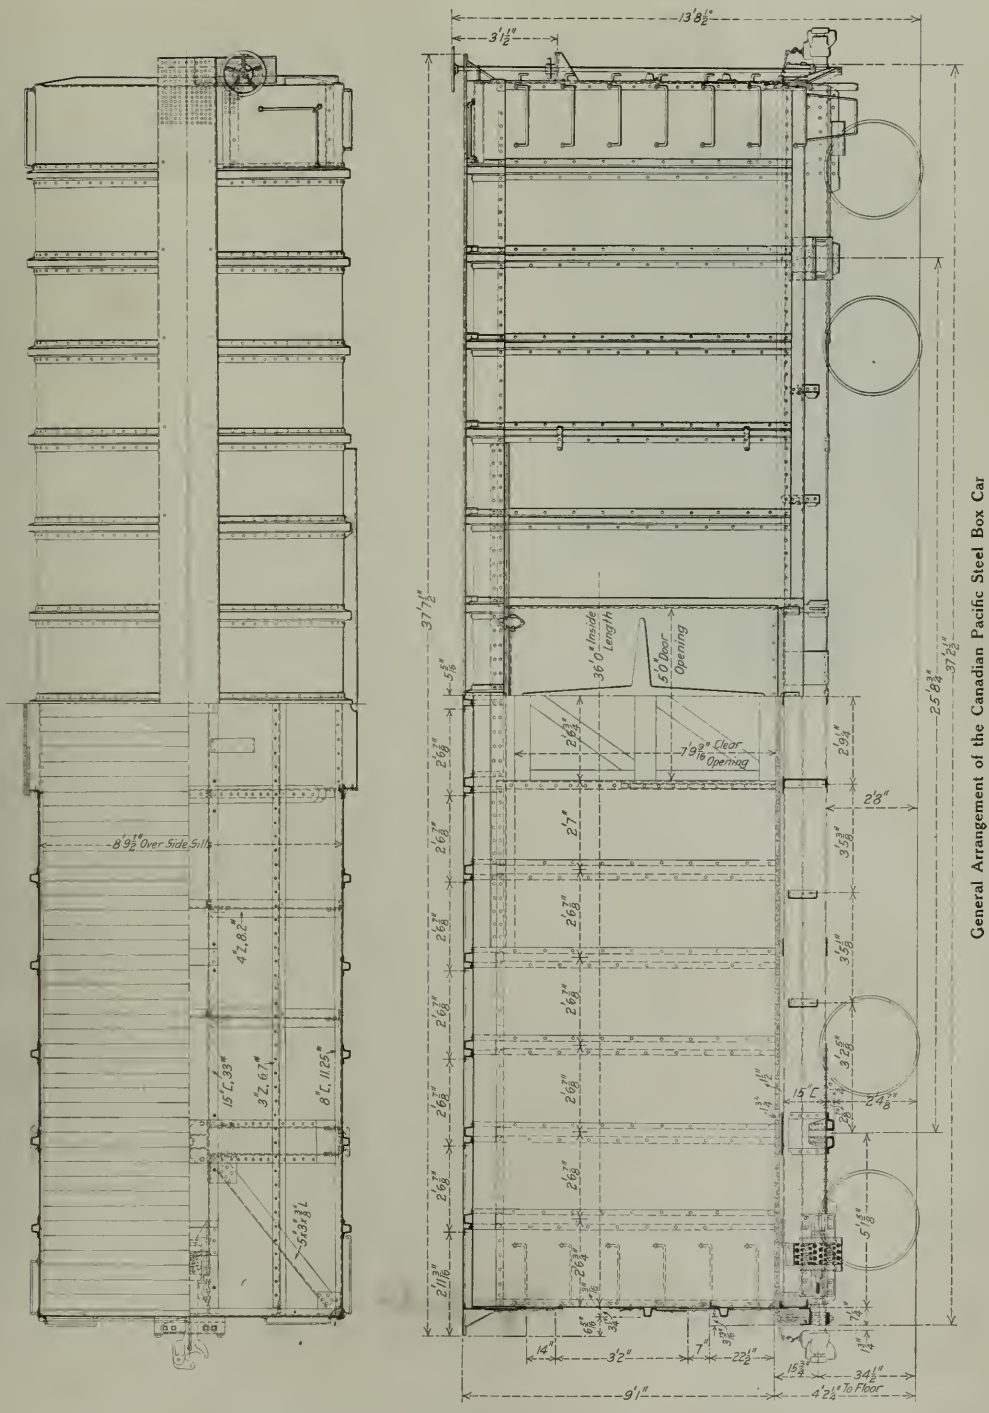
Ultimately the mortgage debt of American railroads, assuming that private ownership of these properties is to continue, will be greatly simplified. The size of the issues should make a better market for this type of bond than is possible with many comparatively small issues outstanding. The provision allowing for the issue of such bonds in denomination of $100 adequately provides for the development of the small investor, one of the most important factors with reference to the future.

STEEL BOX CAR FOR THE CANADIAN PACIFIC

An all-steel box car recently designed and built by the Canadian Car & Foundry Company, Montreal, Que., and now in service on the Canadian Pacific, is shown in the accompanying engravings. The car weighs 37,000 lb., and has an inside length of 36 ft., with a clear inside width of 8 ft. 8 in.

The construction of the car body is such that the interior surface is smooth, there being no braces employed in the side and end frames. The side posts are formed by pressing one vertical edge of each side sheet into a U section and are spaced 2 ft. 6⅞ in. between centers. The portion of the side sheets forming these posts is also offset to lap over the flat edge of the adjoining plate. A similar construction is employed in forming the roof members, the pressed U section in the roof sheets being made to correspond and to lap over the side sheets, thus practically forming a continuous post from side sill to side sill. As shown in the illustrations, these combined posts and carlines are on the exterior of the car, leaving a smooth interior which helps increase the loading space and makes the car easy to clean. The side plates are 3/16 in. thick and the roof plates are ⅛ in. thick, while the end plates are 3/16 in. thick and are reinforced by horizontal stiffeners of U-shaped section. Two sliding doors are provided in one end of the car to facilitate the loading of lumber

All-Steel Box Car Recently Built for the Canadian Pacific



General Arrangement of the Canadian Pacific Steel Box Car

and other long material. The running board is supported on angles riveted to the roof sheet.

The car is 37 ft. 2½ in. long over the buffer blocks on the end

End View of the Steel Box Car

sills and the distance between center plates is 25 ft. 8¾ in. The center sills are 15-in., 33-lb. channels, which are connected by channel-section distance pieces, spaced at 3 ft. 5⅛ in. intervals, and by plates at various points throughout the length of the car, there being no cover plates employed except on the under side for a short distance at the body bolsters. The body bolsters are built up of ¼-in. pressed steel webs or fillers with ½-in. top cover plates and ½-in. bottom cover plates. There are two cross-bearers placed 2 ft. 9¼ in. on either side of the center line of the car and built up of ¼ in. pressed fillers with ½-in. top cover plates and ½-in. bottom cover plates. The side sills are 8-in. 11.25-lb. channels and there are 5-in. by 3-in. by ⅜-in. diagonal bracing angles at the ends of the car, between the junction of the side and end sills at the corner of the car and the junction of the body bolster and the center sills. The center and the side sills are connected by 4-in., 8.2-lb. Z-bars and these support a 3-in., 6.7-lb. Z-bar placed about midway between the side and the center sills on both sides of the car, which acts as a floor stringer. The end sills are built up of steel plates and angles.

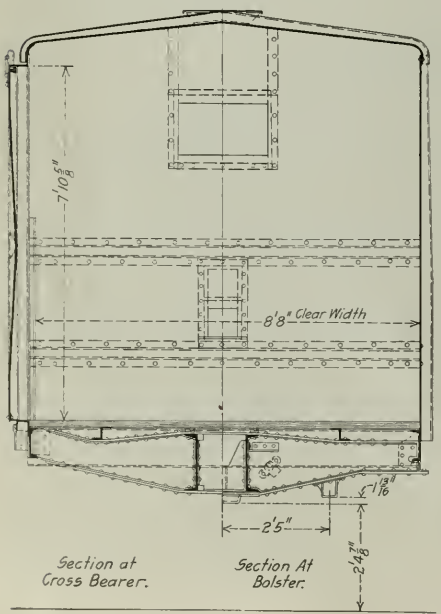
The drawings show provision for a steel door, but a wooden door was used on the car as shown in the photograph. The capacity of the car is 80,000 lb.

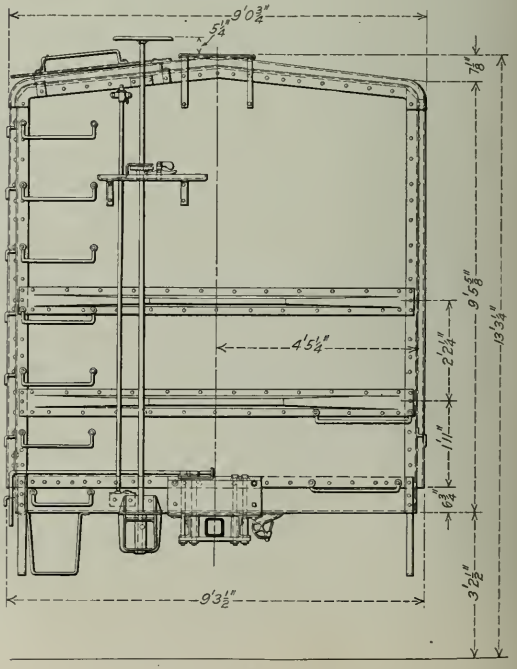
THE FRENCH RAILWAYS IN WAR TIME

The following account taken from an article on the subject in the *Journal des Transports* shows how the French railways are managed in time of war and indicates the efforts made to have them in readiness at the required moment.

Article 54 of the *Cahier des Charges* (specifications) under which the French railways operate, provides that if the government has to transport troops and supplies to any place served by a railway, the companies must immediately place all their facilities at the service of the state. This obligation has existed for over 40 years, so that before the war, a permanent military organization had been created whose duties were to prepare the railways for service in time of war.

Each of the large railways has attached to it a committee, the *commission de réseau*, composed of a technical member, usually





Cross Sections and End Elevation of Canadian Pacific Steel Box Car

the general manager, and a military member, a high officer of the general staff, nominated by the minister of war. The duties of this committee are to investigate in all its bearings, and with a view to strategic requirements, the manner in which the tracks and rolling stock and such special details as military platforms, stopping places for meals, etc., can be utilized in conformity with the needs of the war office.

Besides these individual *commissions de réseau*, there is a superior military railways committee. This body, which was created by a ministerial decree of 1898, is presided over by the chief of the general staff, and is composed of six generals or other officers of high rank, three representatives of the ministry of public works and the members of the above-described *commissions*. Its functions are advisory; it records its opinions concerning any measures proposed by the *commissions de réseau*, as well as on all questions relative to military transport.

On the declaration of war, there are special regulations affecting railway employees. These provide that if a railway man is called to the colors, he is mobilized as a railway man and on a territorial system whereby men employed by the same company are grouped together into regimental units. All these arrangements are worked out in time of peace. They were tested during the railway strike of 1910, when the men were called out under martial law, and for the time being became in effect soldiers whose duties were confined to railway work.

On the first day of mobilization, after having been duly notified by the minister of war, the railways must place at the disposal of the military authorities every available facility on certain divisions, or on the whole system, as the case may be. The railway system of the country is then divided into two "zones," under different authorities. Both are under military control. The "interior zone" comes under the ministry of war; the minister and the general staff regulating conditions of traffic. Under the authority of the minister, the *commission de réseau* of each line handles executive functions and each of the two members retains his individual responsibilities, one being entrusted with military measures, while the technical member sees to it that all requirements for the provision of rolling stock and other matters connected with actual operation are met. They are aided by subcommittees, each of which is also composed of a military and a technical member.

The "army zone" is under the control of the commander-in-chief of the armies in the field, assisted by an officer whose status is that of manager of the army railways. This zone is naturally sub-divided, a distinction being made between sections of line without and within the actual scene of military operations. The lines within the former zone are manned by the employees of the company concerned, organized under the territorial scheme referred to above. Within the zone of actual field operations the service is carried on by military units corresponding more or less with army engineers.

Precedence is naturally given to military requirements, but provision must be made for transporting foodstuffs and general commercial merchandise. Within the "army zone" ordinary traffic is suspended altogether, save for such exceptions as may be authorized by the commander-in-chief. In the "interior zone," such traffic is conducted exclusively according to the conditions prescribed by the ministry of war, which is empowered, after mobilization and concentration are completed, and on the request of the *commissions de réseau*, to authorize the partial or complete resumption of ordinary passenger and freight traffic. Throughout the duration of war, the railways must insure the conveyance of all military traffic under the best possible conditions.

FEMALE BOOKING CLERKS ON THE METROPOLITAN RAILWAY OF ENGLAND.—In common with many other companies, the Metropolitan Railway has now female booking clerks at several of its stations and is rapidly increasing the number in order to relieve men for other duties and to enable them to join the forces.

ANNUAL GOVERNMENT SIGNAL BULLETIN

On following pages we reprint Table No. 1 from the annual statistical report of block and interlocking signals on the railroads of the United States issued by the Interstate Commerce Commission, giving the mileage of road equipped, with other data, as of January 1, 1915.

The changes in total length of road signaled, as compared with January 1, 1914, are as follows:

Miles of Railroad on Which the Block System Is in Use

	Jan. 1, 1915	Jan. 1, 1914	Jan. 1, 1913
Automatic	29,600.0†	26,569.3	22,218.8
Manual	66,679.1†	60,167.6	61,731.0
Total	96,279.1†	86,736.9	83,949.8
Changes*—			
Automatic	I. 3,030.7	I. 4,350.5	
Manual	I. 6,511.5	D. 1,563.4	

The increase in mileage of road equipped with automatic block signals, as shown in the table, 3,030 miles, is less than the actual increase, because the total as given for the preceding year has not been corrected by deducting the duplicated items. The more important increases both in automatic and manual signaling are set forth in a separate table in the bulletin, which is reprinted below. The two largest items in the increase in manual signaling, the Southern Pacific and the New York, New Haven & Hartford, did not appear in the reports received by the *Railway Age Gazette*, and therefore were not counted in the totals published by us on January 1. The New Haven statement was corrected in a subsequent issue; but the ex-

tensive adoption of the manual block system on the Southern Pacific, as here noted, is now published for the first time.

It will be noted that the number of roads reporting block signal mileage for the first time is quite large; and in addition to those which appear in this table, the larger table shows also the following: Eastern of Kentucky; Huntingdon & Broad Top Mountain; Kansas City Terminal; Mineral Range; Nevada Northern; Pittsburgh, Shawmut & Northern, and a number of electric roads.

The cases of the New Haven and the Southern Pacific, just mentioned, are not the only ones in which there is a discrepancy between the data given to the *Railway Age Gazette* and that given to the government. As in former years, the time which elapsed between the sending of reports to the *Railway Age Gazette*, about December 1, and that when the statistics were sent to the government, about January 15, seems to have produced both increases and decreases. The following six roads reported a mileage to the government smaller than to us by the differences shown, the *Gazette* figures being shown first and the government figures following. Central New England, 264—71; Central of Georgia, 73—55; Chicago & North Western, 3,725—3,598; Ft. Dodge, Des Moines & Southern, 120—16; Michigan Central, 1,306—1,163; Southern, 2,378—2,057.

The following three, in addition to the two named above, show increases: Chesapeake & Ohio, 2,008—2,083; Chicago, Milwaukee & St. Paul, 4,386—4,717; St. Louis & San Francisco subsidiaries, 0—625. Many smaller roads show slight differences. The following roads, reported by us, do not appear in the government table: Florence & Cripple Creek, five miles; Rock Island Southern, 80 miles; South Dakota Central, 103 miles.

In the reproduction of Table No. 1, a number of explanatory notes have been omitted, the information contained in them being mainly a repetition of what has been published in former years.

No less than 686 miles of road operated by the manual block system is reported as equipped also with automatic signals, which are not reported in the table of automatic mileage. The roads reporting this apparent duplication are the Atchison, Topeka & Santa Fe; Baltimore & Ohio; Louisville & Nashville; Pittsburgh, Cincinnati, Chicago & St. Louis; Southern Pacific; Wabash.

Table No. 2 shows a decrease in the miles of road equipped with exposed disk signals of 53 miles; and of 68 miles in enclosed disks. On the Reading there is an increase in the item of enclosed disks, of about 38 miles of road, but on the two other roads which make extensive use of these signals—the Chicago & North Western and the Lehigh Valley—there are considerable decreases. The total of miles of road equipped with electro gas signals is 891, an increase of 372 miles which, however, appears to be due to errors in last year's statement. The Delaware & Hudson reports 318 miles of road using these signals, and the Atchison, Topeka & Santa Fe 78 miles.

The mileage of automatic block signals not classified is 353 miles. This represents mostly electric railways.

Tables 3, 4 and 5 give further details concerning methods and apparatus used with the manual block system, styles of automatic signals, data concerning alternating current, etc., and colors of night indications, all tabulated in the same shape as in the last preceding bulletin. Telephones are used in manual block signaling on 28,364 miles of road, or 2,122 miles more than on January 1, 1914.

Tables 6 and 7 give the number, types and characteristics of interlocking plants, with a variety of information concerning details of design and of practice. As heretofore, these tables appear without totals for the whole country, for the reason that a considerable number of interlocking plants are reported each by two or more different roads.

Telephones are used for the transmission of train orders on 93,467 miles of road, or 16,175 miles more than on January 1, 1914.

Russian Railway Affairs.—The Ministry of Ways of Communication has agreed to the need for widening the Archangel Railway next autumn to full gage.

Maintenance of Way Section

The Wage Differential

Officers in the maintenance of way department are familiar with the marked change in the personnel of their employees and also in the attitude of the men towards the companies during recent years. The primary reason for this, the continually increasing difference between the wages of organized and unorganized employees, is pointed out in another column. This problem is a difficult one for the railway managers to solve. Every one will admit that the present practice of increasing wages only where the companies are unable to resist the demands of the employees is a short-sighted one, but no manager has yet had the temerity to raise the wages of unorganized employees to the same basis as those for organized labor in the face of decreasing net revenues. Under present conditions the maintenance of way department employees, who are unorganized, suffer in comparison with those of the mechanical and transportation departments, who are very largely organized. This condition cannot continue indefinitely, and its results are distinctly evident today in the rapidly decreasing efficiency of the men in the former department and in the absence of the loyalty so marked among trackmen a couple of decades ago. It will take courage to meet this issue fairly, but it must be met in the near future, and temporizing with it only increases its difficulty.

The Selection of a Ballast Supply

The ballast best adapted to the needs of a particular railway may be of one material, while that most economical may be of an entirely different character. In other words, the kind of ballast it may be most practical to use depends upon the traffic, topographic and climatic conditions of the track to be ballasted, and also on the kind of material available. There is some particular kind and source of ballast most economical for any particular location. One sees material hauled long distances because of its excellent quality, the long haul making it unduly expensive by the time it is placed in the track. On the other hand, one also sees inferior ballast placed in the track when a better quality can be secured with a slightly longer haul. He also sees one road covering stone ballast with gravel and other placing stone on top of gravel. Between these extremes there is a mean. This prompts the suggestion that on a system of any magnitude a careful survey of ballast conditions can well be made, showing all the available sources of supply, and the relative merits of the different kinds for local purposes. From such a survey the most economical sources of supply can be determined, as well as the limits between which the material from any particular source should be secured. A survey will show the extent to which present practice based on general estimates is sound or unsound. Of course, in some localities there is little choice as to the material to be used, but on most roads this is not the case.

The Merits of Cinders as Ballast

The merits of engine cinders as ballast material are not sufficiently realized on many roads. With the exception of those burning oil in the southwestern and western states, almost every railroad produces large quantities of cinders. Too often they are considered a cause of necessary expense and are wasted or used only for filling. While their quality varies with the character of the fuel burned, in most cases they make excellent ballast for branch lines, or even for freight lines of relatively heavy traffic. They provide excellent drainage and are easily worked, while in many parts of the country they have relatively long life. Because of their relative cheapness, they can frequently be used to improve the condition of branch lines where heavy expenditures might not be justified. Their use should be more seriously considered in connection with other ballast materials.

Motion Study in Track Work

A roadmaster in a northern state was overheard taking a section foreman to task because one of the track laborers was observed to rest his elbow on his knee in lifting his tamping pick. The roadmaster closed his remarks by stating that no man who followed that practice could work on his district. If he should travel through the South he would see many colored track gangs at work, not one, but all of whose members would be observed to be doing the same thing. It is not our intention to discuss the merits of this or any other method of handling a tamping pick, but simply to call attention to the fact that motion study has never been seriously undertaken in connection with track work. Surely there could be no more simple or practical matter to which such study could be applied. References to the proportion of railway revenues expended for track labor have been made too often in these columns to require repetition. A proper study of this subject would involve a relatively insignificant outlay. The objection that the class of track laborers now available is not sufficiently good to offer an inviting field for such study, is answered by the fact that some of the earliest and most successful experiments in motion study related to the very simple tasks of lifting and carrying pig iron. Observations of track work in various parts of the country disclose wide differences in the methods used in doing the same tasks. While it is impossible to say that the method used at one place is correct, and that used at another wrong, there are certain to be material differences found in the efficiency of the several methods investigated. An effort to determine which is the best deserves serious consideration.

Standards of Maintenance

In the conference on valuation held in Washington a few weeks ago, Director Prouty of the department of valuation of the Interstate Commerce Commission asked how deferred maintenance could be determined and whether, comparing one road with a high standard of maintenance and another with a low standard, the one with the low standard should be considered to have deferred maintenance. For instance, one road may paint its stations at intervals of four years and another every six years. Would a union station at a junction point be maintained to the proper standard if it had not been painted for five years? This at once raises the question of how a standard of maintenance is determined. Every road must decide on the standards to which it will keep up its property. A road with a large proportion of heavy freight traffic is not justified in maintaining its tracks to as high standards as one with an equal traffic consisting largely of fast passenger trains. Likewise, track which will ride well at 40 miles an hour may not ride so well at 60 miles an hour. Maintenance of way expenditures are of two kinds, those which make for ultimate economy, such as the use of treated ties, and those necessary for the normal upkeep of the property. It is with the latter class that we are most directly concerned here. It is unfortunately, but necessarily, true that the basic factor governing the standards of maintenance on many roads is the amount of money they can afford to spend. However, on the average

road and during average years money is available for necessary and prudent expenditures. To make these expenditures most economically, those in charge must necessarily determine the standards justified by the traffic not only for the system as a whole but for each subdivision separately. The economy attending this distribution will depend upon the closeness of this determination. From this it can be seen that the answer to Director Prouty's question depends entirely upon local conditions and can only be answered in the light of a definite statement of facts for each particular location.

The Problems of the Supervisor of Bridges

The problems confronting the master carpenter or supervisor of bridges and buildings on the average road differ widely from those contronting the supervisor of track. The duties to be performed are of greater variety, and the difficulty of adequately supervising the gangs is greater. On most roads the bridge supervisor is responsible first for the maintenance and repair of the bridges on his territory. He must give his personal attention to their inspection at regular intervals and direct the work of the bridge carpenters, concrete gangs, pile driver crews and other forces engaged in the renewal or replacement of all but the larger structures. The supervisor of bridges and buildings is also in charge of building repairs, including stations, shops, coal chutes and other buildings on his territory. He has charge of their painting at regular intervals, as well as the painting of bridges, roadway signs, etc. Another important branch of his work is the water service. Usually he is not only in charge of the installation and maintenance of water stations, including the pumps, pipe lines and tanks, but of their operation as well, and the pumpers are carried on his time roll. In short, he is usually in charge of all maintenance other than that of track and signals. The supervisor of bridges usually has a considerably greater mileage than the supervisor of track, his territory frequently coinciding with that of the division superintendent. His gangs are scattered over the division, handling the various specialized problems and frequently moving rapidly from one small job to another, so that under the most favorable conditions a large portion of the time of the employees of this department is necessarily lost in traveling from one place to another. The wide variety of work, requiring men of different experience and skill, and provided with different kinds of tools, combined with the large mileage of line covered, make the securing of economical results in this department very difficult. Furthermore, this scattering of forces makes adequate supervision almost impossible. On some of the more intensively developed roads in the east these conditions have been greatly improved by subdividing the work and reducing the units of supervision. It is entirely possible that this plan can be followed to good advantage on the more important divisions on other roads, subdividing the work either by territorial lines or concentrating certain classes of work over the entire division, as, for instance, water service, with certain gangs. The most practical means of securing more satisfactory results under existing conditions is receiving serious attention on a number of roads.

THE LABOR PROBLEM

SINCE the beginning of railway operation maintenance of way work has been done almost entirely by company forces paid at a flat rate. This is strong circumstantial evidence that such a practice is the best. It is not, however, conclusive. Changed conditions require revised methods in all industries. No one will disagree with the statement that the character of the labor employed in the maintenance of way department has deteriorated within recent years, and the end does not appear to have yet been reached.

The experiment of the Michigan Central in placing ballast under its main tracks by contract, is one attempt to deal with present unfavorable labor conditions. Such a practice would be pronounced impracticable by many if it had not been worked out successfully on this road during the past six years. While contract work in a way, this plan of the Michigan Central in its mode of application is essentially a piecework system. The railroad furnishes the ballast unloaded along the track and the contractor places it at certain fixed unit prices. The company, therefore, provides the material and the contractor assumes the responsibility for the organization and handling of the labor. The incentive of personal gain is one of the strongest that influences mankind. In a large organization, such as that of a railroad, the feeling of personal responsibility for results is not developed as fully as in smaller organizations and many men become mere cogs in a machine. Under the Michigan Central plan the contractor secures directly for himself the benefit of the savings made by any increase in the efficiency of his men. He therefore has a personal interest in accomplishing the maximum amount of work and will put forth greater efforts than the average section or floating gang foreman. He will not only try to secure greater results from his men on the work, but he will naturally select his forces with more care and with more consideration of their qualifications for the work in hand.

He is also free from many of the regulations about rates of pay, etc., governing railway work. By securing reasonably low unit prices in the contract the railroad shares with the contractor in his savings, while the standards of work are maintained by proper inspection. Such a plan is not necessarily limited to ballast work, but is equally applicable to much of the other work commonly done. As with any experiment, great care must be exercised in the selection of the contractor and his foremen to get men who are familiar with the work and who will exercise the necessary precautions for the safe conduct of traffic. In this instance, former employees of the road who were known to be capable were given the contracts.

The method used by the Michigan Central is but one of many that may be employed to create an increased interest and sense of responsibility among track employees. Another road has given careful consideration to a plan whereby certain section foremen will be given definite allowances for labor from month to month and then be permitted to hire their own men and to conduct their work as they believe best, subject to suitable supervision. Any savings made out of their allowances go to the foreman, the idea being to cultivate in these men a sense of proprietorship in their sections whereby they will exercise the same care in the expenditure of the company's money as they would exercise in the spending of their own.

Another eastern road made careful time studies from which it determined the present and possible average unit costs of various items of track work. Standards were then placed before the laborers as well as the foremen and the company divided the savings resulting from the increased output with the men. Although this plan was only in effect a few months, the unit performances increased steadily.

We have given much space in these columns to these and similar developments of methods of increasing the efficiency of the labor in the maintenance of way department, as we believe that herein lies the greatest opportunity for economy in this department. Almost 60 per cent of all expenditures for maintenance of way and structures are for labor, as compared with 40 per cent for materials, in which, from their very nature, only relatively small savings can be made. The expenditures for labor offer a very promising field for careful study. All of the developments to which we have referred may be considered to still be in the experimental stage, and while perhaps the methods used may not be practicable for universal or even wide application in their present form, they may be capable of modification to meet varying conditions. The results to be secured warrant sympathetic and careful study.

NEW BOOKS

Proceedings of the American Wood Preservers' Association. Size 6 in. by 9 in., 527 pages, illustrated. Bound in cloth. Published by the American Wood Preservers' Association, F. J. Angier, secretary-treasurer, Mount Royal Station, Baltimore, Md. Price: cloth, $3.50; paper, $2.50.

The eleventh annual convention of the American Wood Preservers' Association was held in Chicago, January 19-21, 1915. This volume contains the complete proceedings of that convention, which was one of the best in the history of the association. A valuable feature of this book is the statistical information relative to the quantity of wood preservatives consumed and the amount of wood treated in the United States in 1914 and a list of the timber treating plants in operation with data concerning each. There is also published a list of almost 400 United States patents relating to wood preservation.

The Railroad Taper. By Lee Perkins, formerly assistant engineer, Southern Pacific Lines in Arizona and Mexico. Size 4 in. by 6¾ in., 355 pages, 41 figures, 42 tables. Published by John Wiley & Sons, Incorporated, New York City. Price $2.50.

This handbook contains an extension and elaboration of a transition curve devised a number of years ago by William Hood, chief engineer, Southern Pacific, and used extensively on those lines. This transition curve is theoretically a series of compound curves with 30 ft. chords and the tables are prepared so that it may be run with one setting of a transit. All the functions for both field and office work are given for 11 different easements of increasing increment, although three will meet almost all ordinary demands except in mountainous country. The spiraling of old curves is treated separately from that on new work. The discussion of the theory underlying this spiral is followed by the usual complete series of tables.

American Railway Engineering Association Proceedings. Size 6 in. by 9 in., 1,562 pages, illustrated. Published by the American Railway Engineering Association, E. H. Fritch, secretary, 900 S. Michigan avenue, Chicago. Price: paper, $6; cloth, $6.50; half morocco, $7.

This volume contains the complete reports presented before the sixteenth annual convention held in Chicago, March 16-18, 1915, with discussions. It also contains 11 monographs previously published in bulletin form during the year by the association. These proceedings are so well known among railway men that little description is necessary. They form a valuable and necessary part of the library of every railway officer concerned with construction and maintenance of way problems. The book is the same size as that of last year and is printed on thin paper in order that it may be bound in one volume.

Tunneling. By Eugene Lauchli. Size 6 in. by 9 in., 238 pages, 197 illustrations. Bound in cloth. Published by the McGraw-Hill Book Company, New York City. Price $3.

The very rapid and important development that has taken place in tunneling methods and machinery in recent years is in itself a sufficient justification for a new treatment of this subject, and the author has kept in mind the needs of the engineer in discussing these improvements. The book avoids long detailed descriptions of individual tunnel projects and arranges the discussions under the natural divisions of the work of driving and lining a tunnel. In developing the theoretical portions and in the discussion of current practice, however, frequent references to individual tunnels are included. The size of the book precludes a detailed treatment of numerous allied subjects, such as drilling machinery, compressor and ventilating plants and explosives, but ordinarily data on these subjects is readily available elsewhere. Of course, however, in discussing new methods of driving tunnels and of lining them, it is necessary to refer to and to some extent to describe the new types of machinery which have made the new methods of work possible.

Letters to the Editor

THE RISING WAGE DIFFERENTIAL AND THE CURE

CHICAGO, ILL.

TO THE EDITOR OF THE RAILWAY AGE GAZETTE:

As a preface to what follows in this article the writer desires to state that he is not opposed to high wages, nor does he attack as a principle the right of employees to organize in just efforts for their protection and the improvement of conditions. Organization of a few branches of the service, however, has militated against the best interests of those departments which have not organized and which will not or are not in a position to identify themselves with protective affiliations.

In the early days of railroading and other industries in this country there was present a keener sense of loyalty and respect than prevails today, and this fact can be explained by an inspection of the relative treatment accorded to the organized and unorganized branches of the service. As in the case of an individual, no group or large body of men will have either respect or loyal feelings for an employer from whom they extract increases in pay or improved conditions as a result of concerted action of their own whether it be by political influence or sheer force of numbers. This explains the attitude of that group included in the large brotherhoods of this country and an appreciation of this fact will clear the way for an understanding of the reason why the unorganized branches are beginning to lose the old-fashioned sense of loyalty for the respective managements under which they labor.

The enforced recognition of the brotherhoods has worked untold harm on the unorganized branches in that the wages of the former have been boosted so high that the amount or relative importance of the work done is not a factor in determining the rates paid. Thus has come a strange and unnatural relation which may be termed the rising differential.

As successive and successful demands for increases have been made by the brotherhoods, the ratio representing the wages paid to them and to the unorganized branches has steadily risen and the difficulty of securing and retaining the right sort of men has proportionately increased. Loyalty thrives on only one thing —just treatment for all hands. This slogan has been absent from railroad wage adjustments for many years.

The railroads of this country have been very short-sighted in their method of handling wage matters. By ignoring costs of living and by deferring normal increases in pay until forced to make unjust distribution to a few favored departments, they have automatically placed a premium on organization and almost entirely killed that great feeling of loyalty that once existed. Though "almost" killed, there is still left of loyalty a small spark and it can be nourished and warmed into something substantial if steps are taken in time. In the writer's opinion the only cure lies in the establishment of a fixed policy on the part of the railroad managements to the effect that no increases will in future be made to any branch or department individually.

In other words, every increase must be a flat per cent increase on the wages paid to each and every one in the service. Such a policy as this would give to the railroads the greatest bulwark they could possibly secure, as it would make for ultimate peace. If the organized branches were to attack this principle, they would at once forfeit the sustaining power of public opinion, as the utter selfishness of such action would stand forth unmasked. The rising differential is a fact and is a monstrosity born of cupidity and cowardice: cupidity on the part of the organized branches through their clearly defined policy of looking only to their own interests, and cowardice on the part of the railroad managements which should have fought the issue years ago. The fight must be fought some day and the longer deferred, the harder will the contest be.

DIVISION ENGINEER.

The Stripping of Gravel Pits by Hydraulic Methods

An Outline of the Conditions Under Which this Practice is Economical and the Manner of Handling the Work

By W. H. Wilms

Manager, Universal Sand and Gravel Company, Brooklyn, Ind.

During the past ten years there has been a rapid increase in the use of the hydraulic method of earth removal. Engineers are just beginning to appreciate the possibilities of this method of excavation, and the next decade will undoubtedly witness a still greater development and growth in hydraulic excavation. The filling of trestles on the Northern Pacific and the Canadian Pacific at a cost of from 4 to 13 cents per cubic yard; the removal of 34,000,000 yd. of material in the regrading of Seattle, Wash.; the hydraulic construction of large embankments on the Pacific coast extension of the Chicago, Milwaukee and St. Paul; and the more recent construction of the Fernando dam of the Los Angeles acqueduct, where about 2,000,000 yd. of earth were sluiced at a total cost of 7 cents per yard are recent examples. The remarkable results obtained in these cases seem to be little realized or appreciated by many engineers unacquainted with this class of work.

A comparatively large field for this method of earth excavation is in stripping the overburden of gravel ballast pits and stone quarries. Conditions about a gravel pit are quite often favorable to the hydraulic method of stripping. The soil is generally a loam or soft clay that can be handled very effectively with water. A great many gravel deposits are either very close to a stream or river or underlaid with water, an ample supply of water thus being assured. The sluiced material can also be dumped in many cases into the abandoned or worked-out portions of the pit. Where this is possible, ample dumping grounds and sufficient grades for the flumes are generally assured.

Very little if any information of value on the hydraulicking of earth exists in published form. What has been printed is generally of a very meager nature and incomplete in its details. What information of value does exist, relates to the hydraulicking of auriferous gravel which requires much greater quantities of water proportionately than loam or soft clay. The Seattle regrade work and the Chicago, Milwaukee and Puget Sound embankment work, previously mentioned, were gravel or glacial drift; in the former case the material consisted of about 65 per cent gravel and 35 per cent very hard clay, the clay being so hard that it was necessary to use powder to effect its removal by the water; in the latter case the sand and gravel content was equally high. The results of these undertakings, therefore, afford us no criterion as to what can be accomplished in the hydraulicking of ordinary earth, such as loam or soft clay.

The conditions necessary for hydraulicking are an abundant water supply; a material that can be effectively sluiced with water; a dumping ground for the sluiced material; and ample flume grades to the dump. Where all of these conditions are favorable, hydraulicking becomes the most efficient and economical method of earth removal known. However, if any one of these conditions is lacking or decidedly unfavorable, hydraulicking is almost sure to prove a failure. In considering an hydraulic installation, therefore, it is necessary to investigate thoroughly and completely, and to analyze the above conditions before deciding on this method of excavation. The depth of the overburden is also to be considered. If the stripping is shallow, not exceeding 3 ft. in depth, and a large daily output or yardage is desired, the hydraulic method should be adopted with a great deal of caution.

DUTY OF THE WATER AND SIZE OF INSTALLATION

The amount of water necessary to move one cubic yard of material depends upon the grade of the flumes, the character of the material and to a more or less extent upon the pressure of water available. The quantity of water is of more importance than the pressure. Comparatively light grades can be used for the flumes if a sufficient quantity of water is present to effect complete suspension. Clay requires more water, greater pressure and greater flume grades to handle than ordinary loam or dirt. The amount and size of rocks, if any, also effects appreciably the duty or carrying capacity of the water. It may be said, however, that as a minimum, with ordinary loam or soft clay and flume grades of 7 to 9 per cent, 10 cu. yd. of water are required to move 1 cu. yd. of material. As a basis for an estimate, however, it is generally not advisable to depend upon a greater percentage of spoil than 15 per cent for loam or dirt with the usual flume grades of 7 to 9 per cent. For soft clay and heavy, sticky loam, 10 to 12 per cent can be considered a safe estimate where 7 to 9 per cent grades can be obtained. The above duties are based upon a flow of 1,000 gal. per min., which is considered by the writer as the minimum discharge advisable for hydraulicking.

In stripping gravel deposits a considerable amount of water is lost by flowing down into the gravel, which must often be considered in estimating the necessary water supply. If the top strata of the gravel deposit is a sand or compact gravel this loss is generally insignificant, amounting to only 2 or 3 per cent. If, however, the top strata is a coarse, loose gravel, the loss from this source may be as high as 10 per cent.

A pressure of from 40 to 60 lb. per sq. in. at the nozzle is usually sufficient for the sluicing of loam or dirt. For soft clay and some heavy loams, 60 to 80 lb. pressure is usually required. A pump having a capacity less than 1,000 gal. per min. should not be installed. A 1,500-gal. discharge would be more efficient, and for the ordinary installation is to be preferred. With such a discharge, using two nozzles, and with favorable grades, it should be possible to sluice from 450 to 700 cu. yd. of material per day of 10 hours. A crew would ordinarily be required for such an installation consisting of one pumper or engineer; two pipemen; one assistant to the pipemen; three laborers and a foreman tearing down and erecting flumes; and one laborer on the dump.

FLUMES

The water supply, the character of the overburden and the fall available to the dump determine the grades of the flumes. In the stripping of gravel pits where the excavated space is used as a dumping ground, ample grades for the flumes are generally assured. Full advantage, however, should be taken of all the fall available, a difference of only 1 per cent in the grade of the flume effecting a great difference in the carrying capacity or duty of the water. Where the available fall makes necessary the use of low flume grades much larger quantities of water are required to effect complete suspension of the material. For stripping service grades lower than 6 per cent should not be used. Where 3 per cent and 4 per cent are the maximum that can be used, the quantity of water necessary for the operation of such low grades is so great that hydraulicking fails to show any great economy over other methods. While it is true that grades as low as 3 and 4 per cent are often used in large hydraulic mining operations, it should be remembered that in such operations the flume grades must be kept comparatively low, so that the velocity of the water will not be so great as to prevent the gold from settling in the riffles in the bottom of the flume. The object here is to use sufficient water to transport the gold bearing gravel and flume grades that will not cause excessive velocities. It is because of this fact that the carrying capacity of water in hydraulic mining is very low, the

material excavated amounting to only about 2 to 6 per cent of the water used.

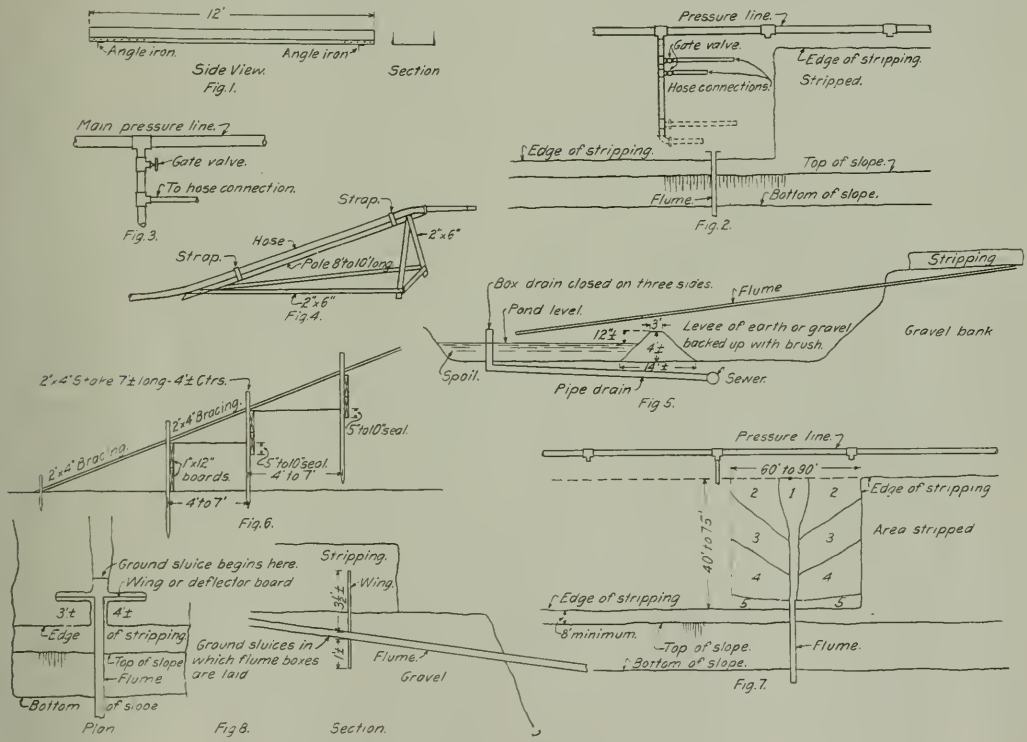
Where conditions will permit, the flume grade should be at least 7 per cent; 8 to 10 per cent grades with an abundant supply of water are considered very satisfactory grades, and are usually obtainable in stripping operations where the material is sluiced into the workedout portions of the pit. These remarks apply only to box flumes. Where ground sluices are used considerably heavier grades must be used, as they are very likely to become clogged up from roots, gravel, sticks and pieces of sod. In such cases the writer prefers to use flume boxes in these open sluices as shown in Fig. 8. The time required to place them will be but a fraction of that lost in continually cleaning out the open ditch.

Flume grades should be made as uniform as possible. A slight break in the grade will often cause clogging, especially if a sandy loam is being handled. Abrupt changes in the alinement of the flumes are best made by making a break or drop in the flume grade.

Sand requires heavy grades and shallow sluices. Wide, shallow sluices should be used where the grades are light. If the overburden contains many stones and boulders deep, narrow sluices should be used. In this case, the depth of the water in the flume should be equal to the width of the flume. The width and depth of flumes depends largely upon the character of the material as well as the water supply.

The rectangular section for flumes is generally to be preferred to the semi-circular or elliptical section. A large amount of the material carried by the water travels or rolls on the bottom of the flume. Where the circular section has been used the wear on the flume has been confined to a relatively small area in the lowest part of the section. Where stones or gritty material are present in the overburden this wear becomes excessive, the metal wearing through and becoming full of holes in a very short time. With the square or rectangular section, however, the wear is quite evenly distributed over the bottom, resulting in a much longer life of the flume.

In order that the flumes may be easily and quickly erected and taken down they should be built in sections or boxes from 10 to 12 ft. long. Both wooden and metal flumes are used. Wooden flume boxes have proven very unsatisfactory for stripping service, as they quickly become water soaked and heavy, and when dried out, check and split badly. Moreover, in the constant rehandling of the flume boxes, they go to pieces very soon. In stripping, flumes are changed many times and a flume box should be built that will not only stand the excessive wear and abrasion of the material being carried, but the rough and constant handling as well. For this service the metal flume is probably the best suited. Fig. 1 is a sketch of a steel box flume that has given very good service. This flume is constructed of No. 14 gage steel, and is made in sections 12 ft. long.



Flume Construction for the Stripping of Gravel Pits

It sometimes becomes necessary to carry the sluiceway or flume through an intervening ridge to obtain a dumping ground for the sluiced material. If the tunnel has a heavy grade, vitrified sewer pipe will prove satisfactory. If the grade is light, however, any slight settlement of the pipe joints is liable to cause clogging. Under such conditions riveted steel pipe in lengths of 20 ft. or more has given very satisfactory results. Pipe of No. 16 to No. 14 gage steel has been used for this purpose.

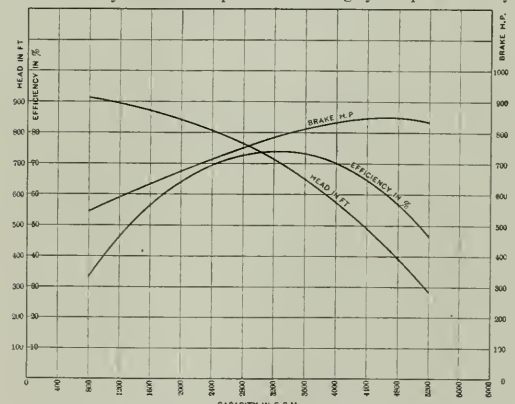
PIPE LINE

For diameters up to and including 10 in. standard lap welded

steel pipe is recommended for the pressure line, there being very little difference in the cost of this pipe and spiral riveted pressure pipe. Above 10 in., however, there is a decided difference in cost between the lap-welded and spiral pipe in favor of the latter. However, if the pipe is to be subject to frequent changes and rehandling, a very heavy grade of steel is necessary in spiral riveted pipe which may entirely wipe out this difference in cost. Owing to frequent rehandling, the asphaltic or tar covering of the spiral pipe, also suffers. Longitudinal riveted steel pipe is not usually obtainable in the sizes ordinarily required for hydraulic operations of moderate size, 20 in. being about the minimum diameter obtainable.

On account of the frequent shifting and changing of pipe a large number of flanged joints in the pressure line are desirable. Standard companion flanges and not flange unions are preferable.

All abrupt angles and changes in the pipe line should be securely anchored, as the water hammer and expansion stresses are extremely severe. Expansion can largely be prevented by



Curves Showing Characteristic of Worthington Turbine Pump

providing one or two gate valves and keeping the line full of water at all times. If the pipe line is particularly long and entirely exposed it may be necessary to provide a heavy expansion joint in the line. Leaky joints and broken flanges are generally the result of failure to provide for this expansion. Where the pipe line is to be permanent, it is advisable to bury it under at least 12 in. of ground.

While local conditions more or less determine the method of arrangement of pipes, Fig. 2, shows an arrangement that has proved very effective. After the overburden for one complete shovel cut has been removed, the main pressure line is uncoupled at the flanges and the pipe rolled back in sections and coupled up again preparatory to another cut. A gate valve is provided in each of the two leads from the main line, making it possible for the pipemen to change their positions without having to shut down the pump. Fig. 3 shows the method of accomplishing this where one nozzle only is being used. For handling from 500 to 700 gal. of water per minute at pressures ranging from 40 to 80 lb., the maximum amount of water at such pressures which it is advisable for one man to handle under conditions of comparatively shallow work, 3½ and 4 in. diameter 6-ply rubber hose has proven the most effective and economical. For ordinary stripping operations 50 to 75 ft. of this hose is usually sufficient. The writer has used 4 and 5-ply rubber hose for this service, but such hose quickly goes to pieces under this constant, hard and severe service. The writer has also used small monitors or giants with 4-in. pipe connections. With the ordinary depth of stripping of from 4 to 8 ft., however, monitors are not to be recommended, as too much time is lost in making and changing pipe connections.

Short play-pipes choke down the water too suddenly, causing a very irregular stream. Play-pipes at least 30 in. in length with a uniform taper, and provided with a small and a large screw tip or nozzle, should be used. A smooth, plain bore and not a ring nozzle should be used. A very convenient and practical device for supporting the hose and play-pipe is shown in the sketch of Fig. 4.

PUMPS

The reciprocating pump has an advantage over the centrifugal turbine pump in the great variation in pressure at constant discharge that it is possible to secure. Its disadvantages are its high first cost in the larger units, such as are necessary for hydraulic operations, and its low efficiency.

The turbine centrifugal pump is now almost universally accepted for all services where it is desired to deliver large quantities of water against high heads. It must not be inferred from this statement that the turbine pump is always to be recommended in preference to the reciprocating pump, as this is not the case. There is a limit to its application, but this limit is being continually widened by improvements in design, and at the present time the turbine pump is successfully employed for service where the reciprocating pump has been used exclusively heretofore.

The two principle factors which have assisted in the development of the turbine pump are the high speed motor and the steam turbine. The high speeds thus obtained make it possible to design a pump with comparatively few stages and with impellers of small diameter. This not only increases the efficiency of the pump, but also considerably reduces the cost. Turbine pumps are now built having efficiencies closely approaching 80 per cent.

Fig. 9 shows an average characteristic curve for a Worthington turbine pump operating at constant speed. It is shown that an increase in the head pumped against causes a reduction in the capacity and the horsepower required, and likewise, a reduction in the head increases the capacity and horsepower. If the total head is greater than that for which the pump was designed, the quantity of water discharged will be less than the full capacity, and may be even nothing at all if the head is sufficiently great. The power will also be less than the power required for the head for which the pump was designed. If the total head is less than the head for which the pump is designed, the amount of water will be greater than the normal capacity of the pump, and the power consumed will be greater.

This illustrates the difference which exists between the turbine and a pump of the displacement type. With a turbine pump the speed at which the impeller operates bears a fixed relation to the total head pumped against, and in order to increase the head it is necessary to increase the speed or reduce the capacity. Theoretically, the head varies as the square of the speed, and the capacity directly as the speed. With a displacement pump, however, the discharge also varies directly with the speed, but the pressure remains constant. With this in mind, it is shown that data regarding the conditions of operation should be verified carefully, in order to get results with turbine pumps. This is particularly necessary when constant speed induction motors are used.

The turbine pump has a distinct advantage over the reciprocating pump in that it is impossible to subject the pump and piping to a dangerous pressure, due to sudden closing of the discharge. The only effect is a slight increase in pressure, and the load on the motor is considerably reduced. Furthermore, air chambers and relief valves are not necessary, as the pressure will never build up to a dangerous point, even though the discharge valve be entirely closed.

With ordinary turbine pumps the horse-power required when operating at heads considerably below that for which the pump was designed, causes a dangerous overload on the motor. By selecting an impeller of suitable characteristic, however, it is possible to confine the overload to less than 25 per cent, which is the rated overload for all standard motors.

Pumps for hydraulic service are generally arranged for direct-connected motor drive, but those of the belted type and also direct-connected steam turbine-driven pumps can be used to advantage. It is common practice in the larger installations to arrange the pumps in pairs, piped so that they can be operated either in parallel or series. This makes it possible to double the pressure by operating in series when a hard strata is encountered. For removing the softer material, the pumps are operated in parallel, and doubling the capacity increases in proportion the amount of material removed.

DEPOSITION OF THE OVERBURDEN

Where it is possible to sluice the material in the worked-out portions of the pit it will be necessary to construct a levee or dike to retain the material and prevent it from spreading over the entire bottom of the pit. Small levees can be built of gravel and backed up with brush, to retain the material and prevent overflowing. Sewer pipe or box drains are placed in the center of the pond thus formed, their tops brought up and kept flush with the pond level (Fig. 5). In many respects a better method of retaining the material is by means of sheerboards. This method, known as sheerboard construction, is largely used in the building of dams and fills by hydraulicking. Under many conditions it is cheaper and more effective than the construction of earth or gravel levees. In this method the material is retained by two or more small bulkheads or sheerboards made of two 1 in. by 12-in. boards, nailed to 2 in. by 4-in. stakes about 7 ft. long. The 2 in. by 4's are pointed at one end and driven into the ground on about 4-ft. centers. (See Fig. 6.)

After the material is carried up to the top of the first row of sheerboards, a second row is built from 4 to 7 ft. back of the first. The bottom of this top sheerboard is placed from 5 to 10 in. below the top of the lower bulkhead to prevent the material from bulging and flowing out between the two bulkheads. The amount of seal necessary depends upon the nature of the material being sluiced. In ordinary loam 6 in. has proven effective, while in fine clay or sandy loam 10 in. is often necessary. As many sheerboards are built in the above manner as are necessary to take care of the stripping over a given area. In this method the water is taken off the top through spillways, which lead to a pipe drain or to a reservoir where the water is again used for sluicing.

If the pit has no natural drainage for the waste water, it is often possible to install an auxiliary pump and use this water again for sluicing. It would be necessary, of course, to excavate or provide a basin or reservoir of moderate capacity in the bottom of the pit sufficiently low to take the drainage or overflow from the spoil bank.

If the flume grades are heavy, however, it is often possible to drive the material as it is broken down directly to the flume, thus greatly increasing the duty of the water. Such conditions are the exception, however, and ordinarily the material must be broken up and put more or less in complete suspension before the flume will carry it. In such cases the water should be so directed as to remain with the material as long as possible.

As an example of what has been accomplished, an overburden 6 ft. deep, composed of a heavy loam, has been sluiced off in strips 90 ft. long and 50 ft. wide. The top of the gravel was practically level, the ground sluice having a fall of 3 ft. in 50. With one setting of the flumes and pipe connections, therefore, it was possible to sluice something like 1,000 cu. yd. of material.

METHOD OF DEVELOPMENT

The overburden being comparatively shallow, the main purpose here is to sluice as large an area as possible with one set of the flumes and pipe connections. In most cases it will be possible to strip a width equal only to one shovel cut, which is from 30 to 50 ft. See Fig. 8. If the top of the gravel deposit has a slope towards the flume, however, a much greater width is possible, depending, of course, on the degree of the slope. In the other direction the distance it is possible to go is also limited by the available fall to the ground sluice. In beginning to strip a given area, a trench is dug by hand down through the overburden and into the gravel a sufficient depth to obtain the necessary fall or grade of the ground sluice, and back a distance of about 3 ft. from the face of the stripping to provide a shoulder. Two short trenches are then dug at right angles to the main trench to provide room for the wings or deflector boards at the head of the first flume box. Bents are then erected, the flume sections put in place and sluicing begun. A comparatively narrow trench is first sluiced out from the head of the flume back as far as the stripping is to be extended. The upper end of this trench is then widened out to permit the pipemen to get their hose down on top of the gravel where the streams can be more effectively used. The material is then sluiced off in the manner shown in Fig. 7.

After the shoulders (5) and (5) (see Fig. 7) have been decreased to a width of from 3 to 5 ft., to prevent sluicing a part of the material over the face of the gravel bank, the streams are directed against the opposite side of these shoulders and the material sluiced backwards in a diagonal direction to the ground sluice. To provide room for the pipemen in removing these shoulders and to prevent the edge of the stripping from caving in and falling down the face of the gravel bank, it is necessary to strip the first "cut" sufficiently wide to provide a berm or shoulder of at least 8 ft.

If the stripping is deep and it is not possible, owing to the limited fall, to get the ground sluice deep enough, it is often advisable to obtain the necessary fall by leaving a portion of the stripping on the gravel until the greater portion is removed, when this wedge-shaped section can be sluiced off by driving it to the flume. This method is used in stripping stone quarries where the former method of lowering the flumes in the gravel is impossible. Where this drive is long and the material hard to handle, such as soft clay, it is often advisable to effect only a partial "clean up" with the water, the remainder being more economically taken off with teams and scrapers.

The direction of the stream on the material will depend entirely upon the amount of water, the character of the material and the grade of the flumes. Ordinarily the material must be put more or less in suspension before the flumes will carry it. In such cases the stream is directed against the bank in a direction opposite to the flow in the ground sluice and flume.

ECONOMY METHODS IN TRACK WORK

By W. C. NISBET

It may be questioned whether progress toward better methods in maintenance of way has kept pace with that in the maintenance of equipment. While naturally favoring the former department on account of long association, the writer, after casting up all the new processes or devices along economy lines generally adopted in the past ten years, ventures the answer that our progress in this line has been slight. Full credit is given for the patient technical labor toward improvements of rail and joint design and for the attempts to increase safety of track while working under reduced appropriation; however, in this paper we are not concerned with design or directly with operation.

Motor section cars are typical of modern improved devices, and it is true that there has been a large increase in their use, though by no means as large as the economy derived from their use warrants. No doubt when hand cars were being introduced there were those who deprecated their use as uneconomical and unsafe and who continued to walk their men to work. Rail handling and ditching machines are also reasonably common, but for regular track maintenance the pick, shovel and spike maul continue to be universally used in spite of the available power for tamping, drilling rail and placing spikes which the gasoline engine of the motor section car furnishes. In this, we might with advantage adapt the power tamping machines of the French railways to our conditions. While much of our American track cannot be tamped economically in this way, even on our dense

traffic divisions little advancement in method has been made if the experimental air tampers on the New York Central and the Long Island are excepted.

One feature retained in the track department, but now largely abandoned in machine and car shops, is payment by an hourly rate instead of in proportion to output. Throughout all modern industrial fields, some form of incentive payment is in use wherever possible, ranging from plain piece work to standard time with premium. There is no doubt but that every man works harder and uses more thought as to his work if he is paid in proportion to what he produces. This results in lower cost per unit.

In track work it would generally be necessary to figure the gang payments collectively, but similar methods are used in certain operations in car shops and in many instances in other industries. This apparent difficulty has a corresponding advantage in the incentive given the foremen to have all the men in the gang competent. This is exactly what is desired by the management, but under the ordinary plan the condition is often quite different.

It has been stated that, on account of differences in topography, climate and traffic, track work does not allow payment by piece work; yet we know that some operations in the car shops, for example, putting in wheels, trucks and drawbars paid for regularly at piece rates, uniform over a whole system of railroad, are frequently done under different circumstances, weather conditions and in varying locations where the conditions of work differ widely. The reason why this arrangement is satisfactory is because the variations average each other in the long run.

Without attempting to give further arguments as to the possibility of payment according to performance in track work, it is sufficient to say that one of the trunk lines has been using this method on three of its most important divisions under varying conditions for two years. The hourly rate is used plus a bonus which increases in proportion as the standard is approached for all jobs on which standard times have been set. The proportion of time covered by the standards varies from 50 to 90 per cent, depending mostly on the time of year. During the tie renewal season the higher figure is reached. The bonus is a per cent of the wages of both men and foremen. Quality of workmanship is controlled the same way as in the many shops where the pay is in proportion to production, that is by inspection and restriction of bonus payments to proper workmanship.

Another broad field awaiting more intensive cultivation is the development of simpler manual processes for the many operations which must continue to be done by hand, a definite campaign to find the best way and a still more definite campaign to instruct the foremen in these methods and to see that they are followed. Long since nearly all railways have had standards for most of their structures and the system is accepted as satisfactory and distinctly advantageous. In the same way there should be standard methods for surfacing track, renewing ties, raising track, etc.

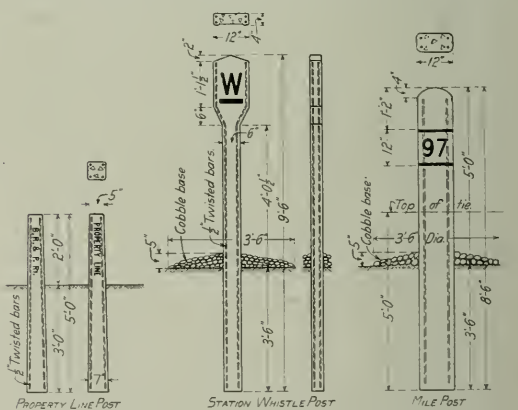
It may be quite generally supposed that in track work there can be but one method to follow in each operation or that if difference exists the result would show slight variation. The writer has looked into this subject on different railways during the last six months and the diversity of method found has been wide; in frequent cases there was great variation even on different sections of the same roadmaster's sub-division. An example of this was respacing ties in gravel ballast where one foreman was respacing 50 per cent more ties per man per day than any other foreman on the sub-division. The workmanship was excellent. The laborers were Americans, as was common in this locality. In this connection it is interesting to note that the second best production observed was made by a mixed gang of foreign laborers, rated as being indifferent workmen.

Some foremen are skilful and quick to find the easiest way to do any given piece of work; others, from inexperience or less ability, need careful teaching. Something more far-reaching than the usual roadmaster's supervision is needed, for, no matter how competent or alert the latter may be, he cannot leave the rest of the sub-division to itself while he teaches a green foreman for two or three days. The roadmasters as a class surely need no defense, as they constitute one of the finest types among railroad men in intelligence, loyalty and keen appreciation of responsibility, but they need assistance if the ideas advanced above are carried out.

Different opinions prevail as to the best method of furnishing such assistance. One way is to reduce the mileage of the sub-divisions. This is a simple plan, but it has defects. The writer favors the appointment of assistants who might be promoted from the foremen, members of the engineering corps or others who might be found to combine experience with the ability to impart knowledge and tact to follow up and check workmanship. These men should work under the roadmaster except as to standards which should be those set by the division engineers, just as the division engineer in the divisional organization takes orders from the superintendent except on engineering matters, in which he reports to the chief engineer or engineer maintenance of way.

B. R. & P. CONCRETE SIGN AND POST PLANT

The Buffalo, Rochester & Pittsburgh has adopted concrete posts and signs for a variety of uses and operates a plant at East Salamanca, N. Y., for the manufacture of these articles. Concrete fence posts are used universally, except in swamps and in places where there is a liability of slides, and since their adoption with the necessary concrete corner posts and braces they have proved very satisfactory. The company plant has manufactured about 15,000 of these posts, 500 concrete mile posts,



Details of Concrete Sign Posts

600 concrete property line posts and 100 concrete whistle posts. In addition, concrete signal foundations, concrete telephone booths and concrete pipe of various sizes are made at this plant.

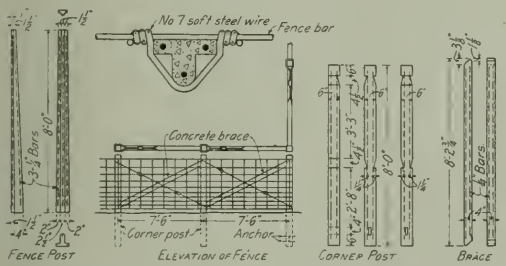
The post and sign plant is housed in a one-story building 90 ft. long and 19 ft. wide with an available floor space of 1,496 sq. ft. Coils of steam pipe are located under the concrete floor and along the sides of the building for heating, and a stationary boiler is provided in one corner to furnish the necessary steam. The cement to be used is stored in one end of the building, securely partitioned off to keep it perfectly dry. The balance of the building is used for the manufacture and curing of the posts and signs, which are stored here until required for use. No special equipment is required in this work other than ordinary concrete mixing tools, as the concrete is mixed by hand except in a few instances when a large amount is to be placed, requiring the use of a mixer to keep a supply on hand. The building is served by tracks along each side, allowing material

to be unloaded and the manufactured articles to be loaded with ease.

The designs of the principal signs and posts are illustrated in the accompanying drawings. The right of way fence posts are of the tapered T-section type 8 ft. long. The flange is 6½ in. wide and 1½ in. thick at the bottom and 4½ in. wide and 1 in. thick at the top, while the stem is 6½ in. deep and 2½ in. thick at the base tapering to 2½ in. deep and 1½ in. thick at the top. The reinforcement consists of three pieces of ¼-in. round bars 7 ft. 6 in. long, one bar being placed in each corner of the post. The line wire is attached to these posts by No. 7 soft steel tie wires, wrapped three times around the line wire on each side of the flange of the post. These wires are pulled tight to bite into the corners of the posts, thus preventing slipping.

The corner posts are 6 in. square and 8 ft. long. Notches 1¼ in. deep are cast 6 in. from the top and 3 ft. 6 in. from the bottom of these posts in which the diagonal corner post braces are set, and a slot 2 in. by 4 in. is provided through the post 6 in. from the bottom, into which short anchor bars can be placed at right angles to the fence line. All corners on these posts are rounded off to a ¼-in. radius. The reinforcement consists of four ¼-in. round bars 7 ft. 6 in. long. Five of these posts are placed at each corner on 7 ft. 6 in. centers, thoroughly braced and tied. The braces used with these corner posts are 8 ft. 2¾ in. long and 4 in. square, with mitered ends to fit into the notches provided in the corner posts. These braces are also reinforced with four ¼-in. round bars 7 ft. 6 in. long, and all corners are rounded to a ¼-in. radius.

The property line posts, which are set on all property corners,



Details of Line and Corner Fence Posts and Braces

opposite the beginning and the end of all curves and at 1,000-ft. intervals on tangents, are 5 in. square at the top and 7 in. square at the bottom with a length of 5 ft. They are set in the ground 3 ft. On one side of the post are moulded the letters "B. R. & P. Ry.," and on the opposite side are the letters "PROPERTY LINE." These letters are 2 in. high. The side of the post with the latter lettering is placed toward the main track whenever possible. The post is reinforced with four pieces of ½-in. twisted steel bars 4 ft. 6 in. long. The corners of the post are rounded to a 1-in. radius.

The concrete whistle posts, which are set on the engineer's side of the track 1,320 ft. from highway crossings and 7 ft. 6 in. from the near side of the post to gage side of the near rail, are 9 ft. 6 in. long, 6 in. wide and 4 in. thick at the bottom and 12 in. wide and 4 in. thick at the top. The latter width is only maintained for a length of 15½ in. to provide room for the letter "W." These posts are set in the ground 3 ft. 6 in. The letter is 7½ in. high, ¾ in. deep and 1¼ in. wide and is placed only on one side of the post, the other side being left blank. This post is reinforced with four pieces of ½-in. twisted steel bars, 8 ft. 2 in. long and the corners are rounded to a ¾-in. radius. Station whistle posts are identical with those described except that a line 8 in. long is cast under the letter "W." These signs are placed ½ mi. from stations.

The concrete mile posts are made in two widths, one for one or two figures, and one for three figures. The former are 6 in. thick and 12 in. wide and the latter 6 in. thick and 14 in. wide. All are 8 ft. 6 in. long with the upper 4 in. rounded off from the edges to the center. The figures, which are 6 in. high, are set into the posts between two horizontal lines ½ in. wide placed 14 in. and 26 in., respectively, from the top of the post. Both sides of the post are made the same. The reinforcement consists of four pieces of ½-in. twisted steel bars 8 ft. long and the corners are rounded to a 1-in. radius. These posts are set 3 ft. 6 in. in the ground, and are placed 10 ft. from the center of the post to the gage side of the near rail on the right hand side of the track going south from Buffalo and Rochester. They are used both on the main line and branches.

A mixture of 1 part cement and 3 parts fine gravel is used in the fence posts, corner posts, and corner post braces, while a 1:2:4 concrete mixture is used in the other cases. The fence posts are cast in gang moulds of 30 each, mounted on trucks. Three of these batteries are used, giving a capacity of 90 posts at one pouring. The other posts and signs described are moulded in wooden forms made of 2-in. surfaced yellow pine, the parts of the moulds being fastened together by hinges and hasps in all cases, except the mile post form, which is clamped in position. In all cases the forms are constructed so that they can be readily removed from the posts after the concrete has set sufficiently, which is about 48 hours. After removing the posts from the forms they are placed on end along timber racks outside of the building for one week to cure properly. During this time they are sprinkled once a day, or as often as necessary, and covered to protect them from the action of the weather. At the end of the week, or when they are strong enough to permit them to be removed, they are corded up in a pile ready for shipment. During the winter they are treated in much the same manner with the exception that they are not taken out of the building until thoroughly cured. The building is kept at an even temperature of 60 deg. After the posts are removed from the forms, the latter are thoroughly cleaned and sparingly coated over with fuel oil to prevent the concrete from sticking to the form when being removed. In the case of the property line post and the whistle post the surface of the concrete is rubbed down to a true, even, uniform surface as soon as the form is removed, using a small briquette and clean water. This briquette is made of 1 part of cement and 2 parts of sand mixed with clean water.

The letters used on these posts are V-shaped and indented into the concrete, the indentation being painted black in the case of the whistle and mile posts. An advantage of this type of letter is that it eliminates the necessity for restenciling the posts from time to time. In the case of the whistle post the letter "W" and the line, when it is used, are fastened to the bottom of the forms and the post made face down. The figures and the cross lines on one side of the mile posts are secured to the forms, while the corresponding depressions for the other side of the posts are moulded into the concrete from the exposed surface while it is in the form. The weights and detailed cost of manufacture of these various posts and signs are shown on the accompanying table.

We are indebted to G. H. Stewart, master mason, for the foregoing information.

		Cost									
		Material									
		Cement			Aggregate		Reinforcement			Total	
	Weight, lb.	Amount sacks	Labor	Cost	Amount cu. ft.	Cost	Amount lin. ft.	Cost		matl. cost	Total cost

Recent Important Developments in Ballast Practice

The Merits of Contracting This Work and of Cleaning Rather Than Renewing Material on Two Large Roads

STONE BALLASTING BY CONTRACT

By John Evans

Division Engineer, Michigan Central, Detroit, Mich.

On the greater part of the stone ballasting on maintenance work done by the Michigan Central since the opening of the working season in 1909, the labor of putting the stone under the track has been handled by contract. A total of approximately 90 miles of double track has been ballasted in this way, distributed over the seasons of 1909, 1910, 1911 and 1913. No stone ballasting was done in 1912 or 1914.

There has been practically no change in the method of procedure since the practice of doing this work by contract was introduced. The contract provides unit prices per foot of track for skeletoning out the old ballast to the bottom of the ties; lifting the track to the grade stakes, and surfacing, lining and trimming. All work not covered by the contract prices, such as unloading the stone, putting in and spacing ties, making a preliminary lift on gravel or cinders, widening banks, etc., is done either by the railroad forces or by the contractor on force account. In either case the unloading of the stone is done under the railroad company's supervision, and the contractor is allowed extra compensation when, on account of shortage or surplus in the distribution, he has to move stone more than 300 ft. to complete the finished ballast section. The railroad company provides bunk cars at its own expense for the contractor's men and supplies all tools and equipment needed in the work. It also furnishes free transportation for the men over its own lines.

The track is given a minimum lift of 6 in. on stone. The contractor makes lifts up to and including 8 in. at the contract price for lifting and for lifts over 8 in. an extra allowance per foot of track for each additional inch of lift is made. In cases where the stakes as set by the engineer show a lift of more than 6 in. for any considerable length of track, the lift to within 6 in. of the top of the stakes is made with gravel or cinders. The contractor is allowed extra compensation on a force account basis where the throw in lining track to the center stakes exceeds 1 in.

The railroad company places an experienced track man on the work as inspector. This man looks over the track after it has been surfaced, lined and trimmed, and either accepts it or notifies the contractor to do such additional work on it as may be necessary to make it acceptable. After the track has been accepted by the inspector, the railroad company is responsible for its maintenance.

The work turned out under the above arrangement has been entirely satisfactory. The track has ridden well when finished and has retained its line and surface fully as well as it has in the best work done by our own forces. We are doing no stone ballast work at the present time, owing to financial conditions, but it is practically certain that our future work of this kind will be handled by contract. As a matter of fact, the contract system of doing track maintenance work is expanding with us and we are extending its application from time to time to new items with satisfactory results.

The men employed on the work are Italians and the contractor is an Italian with wide experience in business dealings of all kinds with his countrymen. He keeps in close touch with the labor situation throughout the country, and his knowledge and experience results in the finding of a better class of men and in getting more and better work out of them. Since starting in this work he has developed several good Italian track foremen.

The contractor, being financially concerned with the amount of work done, has a more effective interest in increasing the output than our own foremen have, regardless of how capable or conscientious they may be. Under this system small concessions can be made to the men in the way of increased pay, whereas wage rates paid by the railroad company are not adjustable. For this reason local shortages in the labor market do not affect the size of the contractor's gangs as seriously as they do the railroad company's. Furthermore, a small increase in pay is usually more than offset by the additional effort which it results in.

Doing ballasting by contract relieves our roadmasters and assistant roadmasters of the greater part of the supervision of this work at the time of the year when their attention is badly needed for other branches of maintenance.

A possible improvement in our method from the railroad company's standpoint would be to have the contractor supervise the unloading of the stone and be responsible for its proper distribution. In this way the clause providing for an extra allowance in case stone has to be moved more than 300 ft. could be done away with. This should work no hardship on the contractor, because it is our experience that very little stone has had to be moved more than the specified distance. There have been several occasions where the contractor has made claims on account of the alleged improper distribution of the stone. In most cases these claims were not allowed, because they did not appear to be justified by the terms of the contract, or to be based on sound argument. If the contractor were unloading the stone, all opportunity for argument from this source would be done away with.

The proportion of the work done under contract could be increased and possibly the cost of the work reduced by having the contractor put in what ties are needed at the time of ballasting at a unit price per tie. I think it not improbable that this will be tried out in some of our future work.

The ballasting done during the season of 1913 included 12 miles of double track on the East division of the main line about 55 miles west of Detroit. On this particular job the total number of men, including force account and contract work, varied from 110 to 140. The skeletoning gang numbered about 15 men, and the lifting gang 50. The remainder of the men were in a gang which worked between the skeletoning and lifting gangs, putting in and spacing ties, widening banks, etc.

The lifting gang did all the track raising, both on gravel and stone. It also surfaced, lined and trimmed the track. The lifting on stone was done in stretches of single track one mile long; that is, no lifting was done until stone was distributed ahead for one mile of track. The lifting of this mile was ordinarily one day's work for the lifting gang. After being raised, the track was allowed to stand for not less than three days before surfacing, lining and trimming was started. Between the time the track was lifted and the time it was finished a speed limit of 30 miles per hour was in effect. After the mile of track had been surfaced, lined and trimmed it was looked over by the inspector, and, if accepted, the speed restriction was removed.

CLEANING STONE BALLAST WITH SCREENS

By H. M. Church

Division Engineer, Baltimore & Ohio, Baltimore, Md.

Previous discussions of the performance of ballast screens and the methods employed for cleaning stone ballast have shown in detail the great saving in both labor and material that can be effected by their use. On the Philadelphia and Baltimore divisions of the Baltimore & Ohio, where traffic is heavy and where considerable ballast has been cleaned, the

results have been quite gratifying and have led to the conclusion that the cleaning of stone ballasted tracks is justified where only one cubic yard of stone may be conserved in a distance of 8.1 lineal feet of double track; that is, one cubic yard of material saved in this distance justifies the employment of the necessary labor to screen it out. In the cleaning of several miles of freight tracks formerly ballasted with stone, it has been amazing to see the amount of stone so saved. Tracks that had deteriorated by the presence of dirt and cinders in the voids of the stone ballast were restored to a condition that had formerly been obtained only by the wholesale removal of the material from the tie cribs; loading and taking it away as waste, an extravagance that has been overcome by the use of screens.

The employment of ballast screens has been found economical in the "out of face" cleaning of single tracks and multiple track and in yards; also in combining the cleaning with tie renewals. As an example of the saving effected, an organization consisting of 12 men, one foreman and one water boy cleaned 200 lineal feet of standard ballasted double tracks per 10-hour day where tracks were 12 ft. centers, using 3 screens, one on either side and one in the center between tracks. The ballast was cleaned 12 in. below the bottom of the tie on the berme, 6 in. below the bottom of the tie in the center ditch and level with the bottom of the tie in the cribs. It amounted to the handling of 104 cu. yd. of stone in the 200 ft. stretch per day. The unit costs of this progress were arrived at as follows:

Length of double track cleaned per day, lin. ft.	200
Cubic yards stone cleaned per day	104
1 foreman at $77 per month.	
1 water boy at 15c. per hour.	
12 laborers at 15c. per hour.	
Total cost per day	$22.46
Total cost per lin. ft. double track	0.112
Total cost per cu. yd. ballast	0.216

The ballast yielded 400 wheelbarrow loads of dirt per 100 lin. ft. of track, representing approximately 50 per cent of the volume of the stone. The voids in the stone amounted to 40 per cent, so that the loss of volume in cleaning amounted to 10 per cent. To determine the extent to which the material conserved justifies cleaning ballast we have the following:

Cu. yd. dirty ballast handled	Percentage of total volume		Total cost cleaning	Cost per cu. yd. stone saved	Cost per cu. yd. new stone unloaded on track
	Stone	Dirt			
104	100	40	$22.46	0.216	1.00
104	90	50	22.46	0.24	1.00
104	80	60	22.46	0.27	1.00
104	70	70	22.46	0.31	1.00
104	60	80	22.46	0.36	1.00
104	50	90	22.46	0.43	1.00
104	40	100	22.46	0.54	1.00
104	30	110	22.46	0.72	1.00
104	21.5	118.5	22.46	1.00	1.00
104	20	120	22.46	1.08	1.00

When only 21.5 per cent of the total volume of material handled passes over the screen and is saved for re-use, the screening operation becomes as expensive as the application of new stone. In other words, 21.5 per cent of the volume per lineal foot of double track represents the amount of stone which must be saved in order that screening be economical, which is equivalent to the conservation of only 1 cu. yd. in 8.1 lin. ft. of double track.

Aside from this very important economy, the practice of screening ballast instead of putting the track up on new ballast admits of maintaining surface without disturbing the roadbed under the ties, a factor of vital importance in ideal track maintenance. It has the advantage of being quicker and more thorough than the fork method; laborers do not tire as quickly under it, and with the screens arranged as described the invariable tendency is for the men to compete with each other for speed.

CHARACTERISTICS OF SLAG AND CHAT BALLAST

By P. H. HAMILTON

Roadmaster, St. Louis & San Francisco, Memphis, Tenn.

All trackmen agree that crushed limestone makes the best ballast under any traffic, or in any locality. However, a large per cent of the railroads in the United States are not so situated that they can secure limestone ballast, or are not financially able to purchase or to produce it. Consequently they are forced to use the best natural ballast available and the refuse, or by-products, from other industries are often utilized.

Cleaning Stone Ballast with Screens

Slag is used extensively by roads entering the great iron and steel producing centers, some of them transporting it hundreds of miles. Slag is the residue stone from blast furnaces, and pig iron smelters produce the best slag. There are many classes and varieties, ranging from snow white to dark brown in color, some are chalky in substance and others hard as flint rock.

When the slag comes from the furnace it amalgamates, and it is necessary to blast it loose before loading. That used for ballast is seldom classified or screened, most roads or contractors loading it directly onto ballast cars with steam shovels. Consequently there is great variation in the size of the particles. The larger per cent runs from ½ in. to 2 in. in diameter; but in a car of fine slag we find many pieces larger than a water bucket, which often cause trouble in unloading. Sometimes they block the opening in the bottom of the car. When a drag tie is being used for leveling the ballast these pieces frequently catch on the track and derail the car being unloaded. Where the ties have been properly spaced previous

to unloading slag these larger pieces often drag on the ties, bunching them and making respacing necessary. These larger pieces may be broken up by hand, but it is more often necessary to discard them when applying the ballast.

The darker slag, called glassy slag, breaks into small particles of prismic form, ranging from ½ in. to 2 in. in diameter, and is considered the best slag for ballast. The white, or grey slag, is lighter in weight. Some of it resembles limestone, and sometimes it resembles coral and breaks up very easily when being tamped. That which resembles limestone makes good ballast, but it is not uniform in size and generally contains a large percentage from 2 to 6 in. in diameter. Sometimes these larger pieces can be broken with spike mauls or tamping picks, but more often it is necessary to lay them to one side and finally to move them to some place where they can be used for bank protection.

While it is not the general practice to classify slag for ballast, I believe that it should be done as it is loaded, and all pieces too large for the purpose should be run through a crusher, or discarded at the pit.

Slag ballasted track can be worked at any time of the year. It drains well and it is practically dustless. It will keep down the growth of vegetation, but it should be cleaned as often as limestone ballast. This is especially necessary on heavy grades where there is an accumulation of engine sand and front-end cinders. Where the embankments are sodded with Bermuda grass the only way to keep this grass out of the ballast is to clean it every two years. Slag has been objected to on account of being chemically injurious to the rails and ties, but this effect is not noticeable. When unloading slag a faint gaseous odor is noticeable, and the dust causes a smarting of the eyelids. However, exposure to the air soon eliminates this chemical property. Like crushed stone, slag is hard to work, and the insertion of ties is more expensive in slag. It is applied and the track is maintained practically in the same manner as with crushed stone.

Chat ballast is used for ballast by all of the roads entering the mining districts of Missouri, Kansas, Oklahoma and Arkansas and is transported hundreds of miles. Chat is flint or ore bearing rock, broken into small angular pieces averaging ¼ in. to ½ in. in diameter. It is the refuse from the jigs at the lead and zinc mines after the mineral has been separated from the stone. It is crushed very fine to get all of the mineral out of it, and is known as tailings at the mines after it has gone over the jigs and all of the lead or zinc ore has been taken from it.

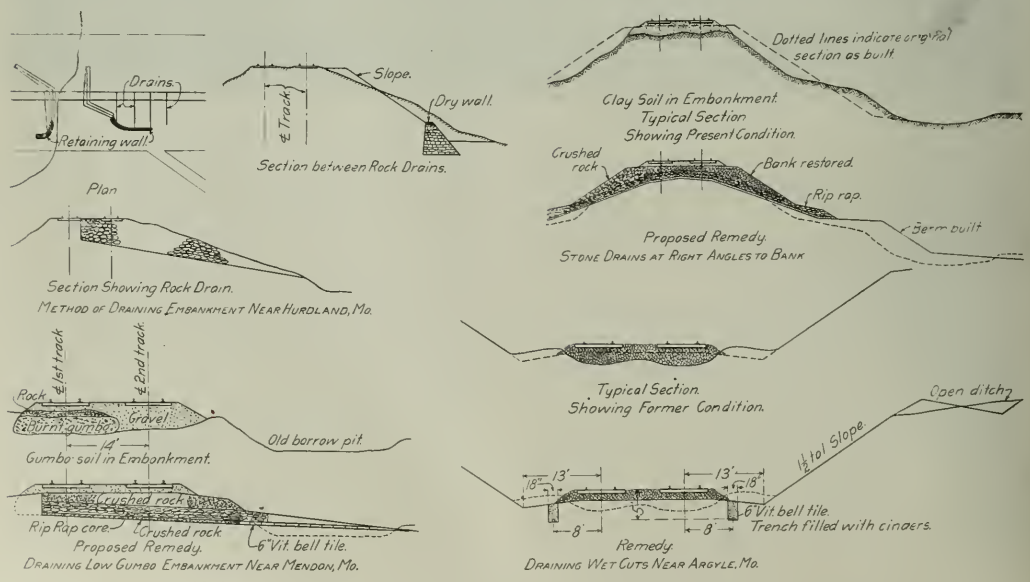
The chat is carried away from the jigs in a stream of water through a trough emptying on to a tailing pile. Sometimes the tailing trough empties into a ballast car, but more often the chat is loaded from abandoned tailing piles with steam shovels. The former method is cheap, but the stream of dirty water passing through the car is injurious to it. It also packs the ballast in the car and makes it hard to unload.

Hand jigged chat is larger than that which goes through the mills, and makes better ballast, but the quantities are limited. Chat has a good weight and is hard. It does not crumble or wear out quickly. It sheds water well, but it is necessary to have a heavy shoulder to hold the track in line, and to keep it from becoming center bound. It is easily worked, all of the tamping being done with shovels or tamping bars. Sometimes "end tampers" are used. Vegetation will not grow in it. At one time the mine owners or mill men were willing to give chats to anyone who would remove them, but now nearly all of the chat piles are controlled by contractors who lease a pile to a railroad, or furnish chat loaded on cars. It costs from 10 cents to 15 cents per cu. yd. loaded on cars.

DRAINING EMBANKMENTS IN MISSOURI

Because of the nature of the soil the railroads in northern Missouri have great difficulty in securing adequate drainage of embankments as well as of cuts. In common with other roads, the Santa Fe has given a great deal of attention to the solution of this problem, and has placed rock drains in embankments at a number of points with satisfactory results.

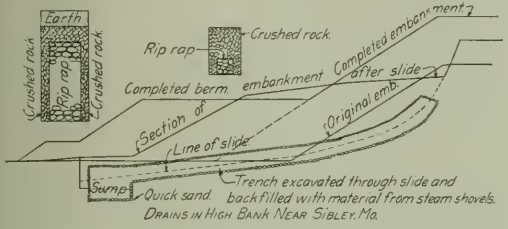
At one point 1½ miles west of Hurdland, Mo., water formerly collected under the ballast, causing slides in the embankment that interfered with traffic not only on the railroad but on an adjacent highway. This condition was overcome by the construction of five rock drains in the embankment extending from the



Methods of Draining Wet Cuts and Fills on the Missouri Division of the Santa Fe

toe of slope of the eastbound track to the inside end of the tie under the westbound track, trapping the water pocket under the latter track. These trenches were excavated to a depth of seven feet under the track and filled with crushed stone and riprap. A dry retaining wall was also built out from the wings of the abutments for a short distance, connecting with these drains as shown in the drawing and the accompanying photograph. Following the constructoin of this system of drains no further difficulty has been experienced in maintaining the track and trains have operated over it at the regular scheduled speeds.

At another point near Mendon where the track was on a low gumbo embankment several barrels of water ran out when a trench was cut into it during the very dry season last year. To



Trenches Built in a High Fill at Sibley, Mo.

drain this place permanently it is planned to dig trenches, filling them with crushed rock with a 6-in. vitrified drain tile in the bottom leading to a drainage ditch parallel with the tracks beyond the toe of slope. At other points difficulty has been encountered with water collecting under the ballast, causing the shoulder to slough off. The drawing shows the manner in which this has been overcome by the construction of stone drains at right angles to the track. In general these drains are built of crushed stone with a core of riprap to facilitate the flow of the water.

In the vicinity of Argyle considerable difficulty was experienced in maintaining the track through clay cuts where the ballast had become compacted into pockets under the tracks somewhat as shown in the accompanying drawing. As the bottom of these pockets was below the side ditches there was no outlet for the

View of the Rock Drains Near Hurdland, Mo.

water. This condition has been overcome by correcting the subgrade conditions, leveling up the ballast and constructing trenches 18 in. wide and extending 5 ft. below the base of the rail, 8 ft. out from the center of the adjacent track. A 6-in. vitrified tile drain was also laid in the bottom of each trench, after which it was filled with cinders above the tile. Since the intsallation of these drains slow orders have been removed permanently while the tracks have been maintained in better condition and at less cost.

In rebuilding the bridge across the Missouri river at Sibley, Mo., it was necessary to raise the grade of the embankment for 10,000 feet on the east approach and to widen it for second track, requiring the addition of 1,750,000 cu. yd. of material. As this material was placed in slabs, and as it consisted of clay, considerable difficulty was encountered with the shoulder sliding off from time to time. To remedy this a trench approximately 16 ft. wide was excavated outside of the toe of the slope and parallel with it to a depth of about 8 ft., which brought it below the level of the strata on which the superimposed material was moving. Sumps were excavated to quicksand at intervals along this trench as the slide was too deep to drain into the surface ditches along the right of way line. Eighty trenches were then excavated into the embankment along the line of the slide and filled with riprap and crushed rock. The large trench was backfilled with material brought in by train from a distance rather than refilling it with the gumbo originally taken out. The berme was constructed over it by work trains. This work was done early last year and it has proven entirely satisfactory so far, while there is no indication that it will not continue so.

SOME OF THE MORE IMPORTANT ELEMENTS IN THE MAINTENANCE OF TRACK

By W. F. Rench
Supervisor, Pennsylvania Railroad, Perryville, Md.

There are certain basic requirements for substantial track which may not be slighted. They are, generally speaking, three in number: Drainage, which has for its two principal adjuncts roadway design and ballast cleaning; adequate crosstie replacement, and proper force and methods for maintaining line and surface. There are other important items such as the organization of the working forces, rail repairs, special equipment, etc.; but those first named are of primary importance.

ROADWAY DESIGN

The standard plans of the road exhibit the ideal cross-section, but most maintenance rules wisely permit a deviation from the plan when necessary to meet local conditions. The essential requirement from the maintenance standpoint is that transverse drainage be afforded not only to the track, but to the sub-bed also and that proper longitudinal drainage be secured either through the surface ditches or by submerged pipes.

The question of draining wet cuts has been a favorite topic for discussion in recent times and it generally appears that the solution found is one of strictly local application. It may not be amiss, however, to refer briefly to three recent developments along this line. The use of a wooden box drain between tracks with its bottom 4 ft. below the base of rail and containing numerous peforations to allow the water to percolate freely has rendered possible the maintenance of high speed service through very bad quick-sand cuts in several instances. The raising of troublesome stretches of road sufficiently to provide a blanket of cinders from 12 in. to 24 in. thick between the ballast and the wet soil has furnished present relief and invariably gives expectation of permanent results. One of the main-line divisions of the Pennsylvania has introduced a rather extensive system of longitudinal underdrainage for wet cuts and the advantage obtained has been quite remarkable. The drain is of 12-in. glazed terra cotta pipe laid upon a floor of boards 5 ft. below the base of rail and 5 ft. from the gage line in both ditches. In order that the water may have free access to the drain the joints are left open. To exclude the soil these have hay packed about them. The entire trench in which the pipe is laid is then back filled with ballast or coarse pebbles. To secure the very best results the sides of the trench and the top of the ballast filling are likewise protected from the entrance of soil by a layer of hay.

BALLAST CLEANING

No drainage system is of complete benefit unless the ballast is kept clean. The depth to which this cleaning should go is a variable one, but it should generally be to the bottom of the ties in the inter-tie spaces and several inches below the bottom of the tie in the ditches. It is desirable to carry the cleaning of the ditches somewhat below the bottom of the

ties as a labor saving item, because when the sub-grade is reached work with the ballast forks is greatly facilitated.

Cleaning the ditches is a slow and expensive process, but it may be rendered less so by the use of a device for loosening up the ballast which has been tried with good success. It is known as a ballast plow and consists of a fish-tail spud about 6 in. long and 4 in. across which is rigidly attached to an arm which can be moved out or in. The arm is attached to a flat car which is heavily weighted to give it stability and to prevent derailment while the car is moving with the plow plunged into the roadbed. All movements of the plow and arm are made by the use of compressed air.

The car moves at a rate of five miles per hour and can thus be used to loosen up a considerable stretch of center ditch in a day. This device saves the labor of many men with picks and the loosening of the ditch in itself supplies improved drainage, which is thus effective somewhat in advance of the actual cleaning. The average accomplishment of one man cleaning a center ditch after it has been loosened by the plow is 100 ft. in one day. It will be found that this dirt with the stone forked out makes an excellent border for the stone ballast on fills as its nearly dead black color contrasts pleasingly with the lighter stone and it is the best material known for retarding the growth of grass and weeds.

The cleaning of track is not of the maximum benefit until a raise is made and a clean bed of ballast applied beneath the ties. If there is a good sub-bed the raising may be made in lieu of the cleaning of the tie spaces, or similarly if the tie spaces are cleaned the raising may be omited, although track never suffers from a light surface raise. Indeed, periodical raising, particularly on lines of heavy tonnage, is the life of main track. The raise should generally be about 2 in., which can be made without flagging. The periods between successive raises are variable for different kinds of roadbed and for different classes of traffic. Generally, for a well-maintained track mostly under passenger traffic, raising once in four years is sufficient, while under a traffic with heavy freight movement predominating, once in two years is none too much and there are places where the service is extreme and the roadbed bad that require this treatment every year.

Its necessity is determined by the appearance of a center-bound condition of the track which fails to give comfortable riding even when the line and surface are perfect to all appearances. The condition as is well known arises from the track having settled into the bed until the unyielding part of the tie support is at the middle of the tie. It is to postpone this condition that maintenance rules prescribe that the tamping should not be carried more than 15 in. inside the rail.

When the roadbed is very hard raising the track in advance of tie respacing or tie renewal effects a large saving in labor. But when the ballast is fairly clean it will generally be found preferable in either work to follow the respacing or the renewal with a light surface raise so that a uniform bed may be secured.

CROSSTIE REPLACEMENT

There has been at times in the past great activity on the part of maintenance officers to effect a stringent restriction in the use of crossties. The thought doubtless is that such restriction is a maintenance economy. But it is a temporary saving, the direct result of which will be a measurable increase in the labor of maintenance later on. There is a stage in the life of a crosstie when no matter what its appearance may be its usefullness in main track is ended. When continued respiking through the absence of tie plates has resulted in the condition best described by the expression, "spiked to death;" when through repeated tamping the bottom of the tie has become rounded and has no base or an insufficient one for adequate bearing upon the bed; when through decay the function of preserving the gage or the surface are lost, then the continuation of the tie in a main track becomes a separate item of expense. Every main line supervisor knows that the track which has a large percentage of inferior ties is the one where most of the sub-division labor is spent.

Appreciating the importance of good tie support the supervisor should carefully ascertain the normal renewals for his sub-division and it should be zealously sought to apply the indicated number of ties year by year. The total number of ties in the main tracks of the main line, divided by 7, in the branch main tracks, divided by 8, and in the sidings divided by 9 will supply the average yearly requirement, where untreated ties largely predominate or where past use of tie plates has not been plentiful. It is assumed that the mileage will be corrected for new tracks that require no renewals and for the distance through switch connections and over bridges. Unless the indicated number of ties is used year after year, the excellence of the track will diminish. Maintenance of good timber on bridges and through switch connections, is of no less importance. The utility of tie plates in prolonging the life of ties and in preserving the gage is so fully recognized that all roads are committed to some definite plan for ultimately equipping all ties both on curves and tangents with this necessary accessory.

LINE AND SURFACE

The maintenance of a good railroad basically requires that the drainage shall be well taken care of and that the ties shall be kept in good condition, but there is also necessary the periodical repair of the track as regards line and surface. This repair should be made on a regular program to be of maximum benefit. The year on the Pennsylvania line is punctuated every seven weeks by the trip of the Track Inspection committee which determines by observation and by the records of certain instruments the relative merits of the different supervisors' sub-divisions by which prizes of considerable value are awarded at the close of the working year. These seven weeks' periods serve to divide the year into convenient intervals for restoring the detail line and surface.

Immediately upon the passing of the inspection party a period of four weeks of steady prosecution of tie renewals, ballast cleaning, rail replacement and track raising is entered upon. At the end of this period three weeks are given over to lining and surfacing the main tracks, so that seven times during the year the riding features of the road are brought to the highest state attainable and naturally through the remainder of the year they do not fall very much below this standard. As far as possible during the four weeks' period of applying material the road is cleaned of scrap, old rails, old ties and dirt. But on busy lines it is not practicable to keep a work train cleaning up with the progress of renewals, and the remaining three weeks, while active renewals are suspended, furnishes the needed time for completion of the cleaning, so that upon the inspection dates the road is likewise fully policed.

As floating gangs are proverbially inefficient in the finer surfacing their labor is mainly devoted to rail renewal and ballast cleaning. With such work lifted from the sub-division forces it has been found that very good results in maintenance have been secured by an allotment of laborers 50 per cent greater than the miles of main track, those sub-divisions having interlocking or other special burdens being allotted additional force.

On busy lines it is important to utilize every advantage that makes for decreased surfacing and to this end joints are eliminated from road crossings by the use of 60 ft. rails; the ties under road crossings are maintained in the best condition possible; the ballast is cleaned below the ties at such points each year late in the season to diminish the trouble from heaving; anti-creeping devises are generously used to modify the trouble from rail running which causes distortion both of the line and the gage; and prompt correction of defective ash pans is made to save burning good ties in the track and to avoid imposing additional burden of dirt upon the roadbed.

Using Bulk Cement on Railway Construction Work

A Discussion of the Advantages of This Practice Including a Reduction in Cost, Methods of Handling, Etc.

By Mac Rae D. Campbell

Although bulk cement is still more or less of an innovation, the idea has a number of strong points to commend it and has won considerable endorsement from several railway systems. Among these are the Chicago, Milwaukee & St. Paul; the Chicago & Alton; the Chicago & North Western; the Duluth, Missabe & Northern; the Bessemer & Lake Erie; the Union Railway; the Pennsylvania, and the Baltimore & Ohio. One cement company reports that bulk shipments from its mills have increased from 15,485 bbl. in 1912 to 180,258 bbl. in 1914.

The economy resulting from using cement in bulk is made up of a number of items. First, there is a saving of 2 cents a barrel in the price made by the manufacturer through eliminating the labor and expense of sacking. Probably no user of cement has escaped the trouble and annoyance consequent upon handling empty sacks preliminary to their return to and redemption by the cement manufacturer. Cement in bulk eliminates sack troubles. Experience has shown that mixing crews of the average size may be reduced by two men, each of whom probably receives $2 per day, which has been estimated as an additional saving of from 2 to 3 ct. per cubic yard of concrete in a daily

Runway for Unloading Bulk Cement from a Box Car Hung by Brackets from the Roof

output of 150 cu. yd. Another saving comes from the elimination of the customary charge made against the job to cover damage or loss of sacks, 2 ct. a barrel being a conservative estimate of the amount that must be so charged off. Collectively the tangible items show a saving of not less than 6, and in some instances perhaps as much as 10 ct. a barrel.

The Chicago, Milwaukee & St. Paul is using bulk cement on the Evanston division track elevation work which has already involved somewhat over 4½ miles of retaining walls. On the Council Bluffs division over two miles of retaining walls were constructed with bulk cement. It was also used by the Chicago & Alton in track elevation work and in connection with shop and other construction work at Bloomington, Ill.

On many roads that are employing concrete construction to an increasing extent, the construction equipment might include a concreting work train outfit planned for using bulk cement. It is probably safe to say that once equipped with an outfit of this kind the engineering department would find employment for it not fewer than eight months a year in most sections of the country, while in the South it would have even a longer period of usefulness. Various types of mixers and associated equipment have been used on railroad construction work where bulk cement has been a feature. Usually it is necessary to modify minor details of the method for handling materials for each particular piece of work. Nevertheless, equipment of this kind can be more or less standardized so that it will serve repeatedly for the usual construction jobs.

Among the ways for devising runways is one shown by one

Wooden Bracket on Roof of Car Supporting a Runway

of the accompanying views which suggests that equipment for this purpose may be made standard and will serve for repeated use. The work train may be made up so that gravel and sand can be handled in a similar manner, thus avoiding the necessity of unloading and rehandling. With an outfit such as suggested, all expense of unloading, housing, and reloading to move to the next job, is eliminated. If more than one car of cement is required it simply becomes necessary to handle two, three, four or more cars in bulk in the train. As soon as the cars are empty they can be returned to regular traffic. The writer's experience in railway

A Work Train, Including Mixer and Material Cars Equipped for Handling Bulk Cement

engineering work convinces him that careful estimates would show that the usual accredited expense of keeping a car out of regular service and using it to house the cement during the period of time necessary to use a carload would be less than the cost of performing repeated loading, and reloading with the consequent loss of sacks and material unavoidable with sack shipments. This presumes, of course, that the job is one that will require at least a carload. Shelters provided on the job to protect cement must be taken down so that the lumber may be

moved and perhaps re-erected elsewhere for a similar purpose. In all of these operations some material is unavoidably destroyed which increases the expense, and each time the labor of erection and wrecking is a total loss.

Loading bulk cement at the mill is performed in a simple manner. A tight car such as would be used for grain, and fitted with grain doors, is required. In loading, a spout is set in place through one of the car door openings. The cement is measured by weighing with a device called a "weightometer," as it passes along the belt conveyor to the spout. This weighing is not the accepted weight under which the car is billed, as it is afterward

Unloading Material to Wheelbarrows Handled Over Double Gangways to Mixer Providing Runway in Each Direction

weighed over track scales, but until the "weighometer" was devised, it was necessary to shift the car several times to track scales in order to determine how nearly the desired loading had been attained.

Experience seems to have proved that bulk cement shipments are more likely to reach their destinations in good shape than sacked shipments. One would naturally expect the opposite to be the case, but the jolting of the car in transit causes the cement to settle down so that at destination the surface of the cement is smooth and level, and the material so compacted that a man can walk over it without sinking in above the soles of his shoes. The total shipments made in bulk by one large cement company dur-

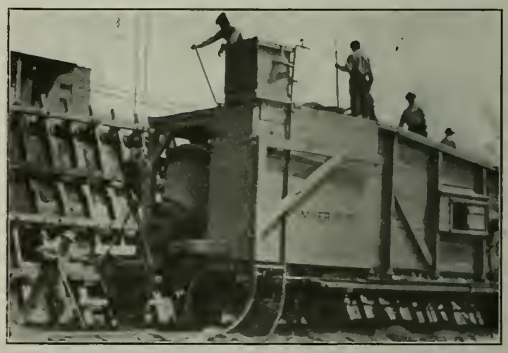
Dumping Bulk Cement Into a Hopper Over the Mixer Showing Absence of Dust

ing three years have involved only one damage claim and this was less than $5.

Several cases have been noted where cars with leaky roofs and loaded with bulk cement have passed through rainstorms with only trifling damage to the contents. Below the hole in the roof there is formed as a result of a leak a small lump of cement about the shape and size of a soup plate. When this has been removed the remainder of the cement is clean and ready for use. If sacked cement is exposed to leaks in the same manner, the rain will run over the surface of the sacks, flow down through spaces between them, possibly to the car floor, and damage a large quantity. One of the commonest causes of trouble with sacked shipments is from nails that work loose in the car floor or sides. It is absolutely impossible to prevent these nails from tearing sacks, so that frequently they are refused for redemption. There is also a considerable loss of cement from the torn sacks.

At first thought one would be inclined to think that the unloading and other handling of bulk cement would raise an objectionable amount of dust. As a matter of fact, there seems to be less dust than results from handling sacked cement. This may perhaps be explained by considering the porous nature of the cloth sack and realizing that there is a continual sifting of contents through it so that more dust results from dropping sacks on a truck than by allowing a shovelful of closely compacted bulk cement to slide into a wheelbarrow.

Two methods of unloading bulk cement that have proved entirely satisfactory are being used: First, shovels and wheelbarrows; and second, a power scoop such as is used for unloading grain. In most cases the shovel and wheelbarrow method will be found the simpler and more economical, although on jobs which are large enough to warrant the expense of additional equipment, the power scoop has shown remarkable efficiency. On one large job it was found that one man with the aid



The Mixer in a Bulk Cement Plant Discharging Into Placing Buckets, One Mix Every 45 Seconds or 220 Yards per 10 Hour Day

of a power scoop, could unload a carload of bulk cement in less than two hours. In this particular case the bulk cement was conveyed to an overhead bin by means of a bucket elevator, so that this man's work represented the entire labor cost of unloading and housing the cement.

Cement when compacted will stand up at an angle of about 90 deg., so that it is advisable that storage bin bottoms and chutes should have a pitch of 45 deg. On a great many construction jobs it will be found unnecessary to provide storage facilities for bulk cement, as it will be both practicable and convenient to use the cement out of the car as needed. When bulk cement must be stored, the ideal arrangement is the overhead bin from which the contents may be discharged by gravity. Where the overhead bin is not practicable, one may be constructed on the same level with the mixer from which the cement may be shoveled or drawn by means of a conveyor into the mixer hopper. Bin walls should be made strong enough to resist considerable side thrust. A safe way to figure the side thrust of loose cement is to estimate 20 lb. to the square foot for each foot of depth; in other words, if the cement is to be placed in a bin 3 ft. deep, the lowest side plank should be strong enough to withstand a pressure of 60 lb. per sq. ft.

Another objection which would naturally be advanced

against the use of bulk cement is the difficulty of measuring it, but those experienced in using it say they have not had any more difficulty in this regard, than in measuring sand, gravel or stone. It is very conservative to figure an average package loss and expense of 5 cents per barrel where cement is used in cloth sacks, or 10 cents per barrel where it is used in paper bags. People fail to realize that they are paying from 5 to 10 cents per barrel to have the cement measured for them.

There seems no reason why bulk cement should not be measured in wheelbarrows or boxes in exactly the same manner that sand, gravel and stone are measured. In the case of a 1:2:4 mix, for instance, measured in this way, any factor of error that may exist is likely to be constant in the case of all the materials, whereas if the cement is measured in sacks, the factor of error will be multiplied by two in the case of the sand and by four in the case of the stone. If greater refinement of measurement is desired, measuring boxes of different types may be used, or if exact measurements are wanted, the cement may be weighed.

Various methods of measuring that have been used on a number of the large jobs have proved that remarkable accuracy may be attained. On one job which the writer has in mind, concrete was mixed for a 1:3:6 mixture in two-bag packages. One man operating the wheelbarrow merely had to bring the wheelbarrow to the measuring box, dump the box and return to the mixer. The efficiency of the measuring device was shown by records made and kept by the foreman on the job. These were checked against the bill of lading and showed a discrepancy of only seven sacks per car, corresponding to an error of only 0.6 per cent.

Concrete products manufacturers, especially those engaged in the manufacture of block, tile, sewer pipe and fence posts, have found it decidedly advantageous to buy and handle their cement to and from storage bins in bulk. This suggests other possibilities for those railroads which are manufacturing fence posts in large quantities, who would, no doubt, find it a distinct economy to install storage bins and other necessary equipment to handle bulk cement at post manufacturing plants. One large machinery concern has devoted considerable attention to designing various equipment for handling bulk cement, but requirements are usually simple and anyone with the average knowledge of conveyor systems can no doubt devise means suited to his individual requirements.

MAKING RECORDS WITH LOADING MACHINES

By F. N. LOUGHNAN
Division Engineer, Lehigh Valley, Wilkesbarre, Pa.

A work train made up of a locomotive and nine loading machines, each manned by an operator, a fireman and four laborers, loaded 115,817 ft. of 90-lb. relaying rail, or almost 11 track miles, on the main line of the Wyoming division of the Lehigh Valley on April 5, 1915. The rails were in a continuous stretch, were numbered consecutively, and were loaded into 37 cars, as they came out of the track in such a manner as to permit of their being unloaded and relaid in track in the same order.

All details of careful organization are attended to every time a work train is used on this road, and, at the same time, arrangements are made to prevent the slightest delay to traffic. Although in the case mentioned the day was Monday when there is no decrease in the usual number of trains operated over the division, there was not the slightest delay or interruption to traffic. The equipment, which included all sorts of loading machines, from a regular rail loader and a locomotive crane to a ditcher equipped for the purpose, started the work of loading at 6:30 in the morning and the last rail was placed on a car at 3:55 in the afternoon. The rails were shipped the same afternoon to the western end of the system, where they will be placed in use again.

The cost of loading and unloading track materials such as rails, switches, frogs, etc., has been greatly reduced by the substitution of mechanical power for manual labor. A work train on the Lehigh Valley ordinarily unloads from 70 to 128 cars of crossties daily while at work on the main line. In unloading and distributing new rail along its main line, picking up rail or unloading ashes, the results are just as interesting. Remarkable results have been obtained through the employment of as many rail loaders and other hoisting machines in one train as are available. The charges for train service are conspicuously reduced because with these machines and one engine as much material is handled in one day as could be done with a single machine in six or seven days.

The use of the work trains is under constant scrutiny. The burden is on the supervisor to show he has need for a work train and then he has the co-operation of all to get his work done as quickly and effectively as possible. The high wages paid engine and train crews have so considerably increased the cost of all work train service that every effort has been directed towards reducing the number of work trains employed and to the substitution of mechanical for manual labor wherever possible.

The largest number of new rails unloaded and distributed along the main line with one work train in a single day was 67,126 ft. of 100-lb. rail. Six machines were used in this case and 22 gondola cars were unloaded. By using two more machines it would have been possible to distribute and unload over 100,000 ft. of new rail in one day with the same work train service. In the work of unloading crossties and distributing them along the main line, 128 cars containing 28,094 ties have been unloaded in a single day. These ties were distributed along a supervisor's subdivision, ready to be used in renewals, and it is now contended that it will be possible to unload 150 cars of ties in a day under similar circumstances. With regard to unloading ashes, the contents of 125 coal cars

A Work Train on the Lehigh Valley with Six Rail Loading Machines

were unloaded on April 6, 1915, with one work train. Regarding the rail loading record mentioned at the beginning, it is believed it will be possible either to pick up or unload the rail for 15 miles of track in one day with one train when organization is further perfected and a few additional machines are available.

THE COMPARATIVE COST OF HANDLING EARTH ON FLAT AND AIR DUMP CARS

In excavating for the new passenger terminal and belt line at Kansas City it was necessary to remove over 2,000,000 cu. yd. of earth and rock. This material was handled on flat cars and on 12-yd. Western air dump cars. For two months, the cost of handling material with these two types of equipment was carefully compiled, and this data has recently become available for publication. During these two months the conditions under which the two kinds of equipment were employed were very similar, the material in each case consisting of at least 75 per cent solid rock. If conditions favored either type of equipment, the advantage was with the flat cars as the interference with traffic was greater at the dump when the air dump cars were used.

The following tabulation gives the relative cost of operation for the two months:

	Flats	Dumps
First Month		
Car repairs	$0.0706	$0.0011
Engines	.0821	.0235
Lidgerwood and airmen	.0052	.0067
Labor on cars	.0274	.0087
Labor on track	.0838	.0658
Eng. and super.	.0043	.0043
Miscellaneous	.0102	.0031
Total per cu. yd.	$0.2836	$0.1132
Second Month		
Car repairs	$0.0698	$0.0070
Engine service	.0748	.0243
Lidgerwood and airmen	.0044	.0080
Labor on cars	.0337	.0077
Labor on track	.0926	.0570
Eng. and super.	.0036	.0050
Miscellaneous	.0063	.0043
Total per cu. yd.	$0.2852	$0.1133

It will be noticed from the above that there was considerable difference in the cost of car repairs. In justice to the flat cars it should be said that the repairs shown for these two months exceeded the average cost up to that time by approximately 1½ ct. per cu. yd. The flat cars were of wooden construction with capacities of 60,000 lb. and 80,000 lb., and had been in constant service for 18 months at the time this information was collected. The dump cars were of steel frame construction, of 80,000-lb. capacity and had been in service five months.

The cost of engine service includes the rental of the engines and the pay of the crews from the time of their arrival to the time of the departure of the trains at the dump. A sufficient track force was always maintained to assure no delays to the trains waiting for the dump tracks to be put into condition. During the two months under consideration the unloading was done in yards exclusively, and for this reason the cost of engine service was not as great as later when the material was unloaded on the main tracks, which carried a traffic of approximately 150 trains per day in addition to many switching movements. Very little unloading was done on the main tracks by means of a Lidgerwood engine and plow because of the danger of delays both to the construction trains and to traffic. On the other hand trains of dump cars were frequently sent out to unload a few minutes ahead of passenger trains with only slight danger of delaying them.

The third item of cost, that for Lidgerwood and airmen, arose from the fact that it was found desirable to have a mechanic operate the Lidgerwood to reduce delays and for the same reason to have a mechanic with the air dump cars. In addition to taking care of the air valves and pipes, this man also made light repairs on the cars. The expense for labor on the cars was much greater on flat than on dump cars, especially during the winter months, as would be expected because of the difficulty of keeping the car floors and aprons clean to prevent the dirt from accumulating and freezing.

The cost of track labor was dependent more on the height of the fill and other conditions than on the type of equipment used. Where it was practicable to use only one track a saving in track labor was effected by the use of the dump cars as they could be unloaded more quickly and thereby cause less delay to the track laborers. Where two dumping tracks were available this difference did not exist.

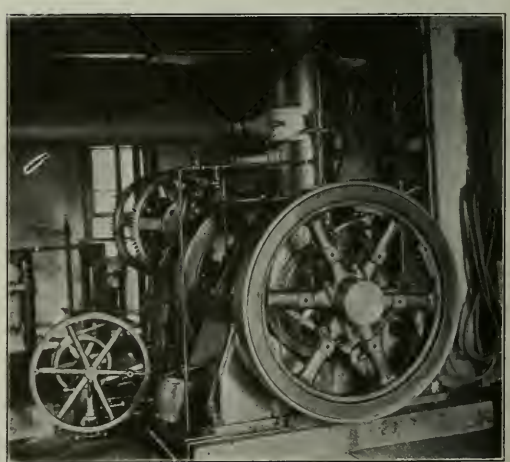
While the last two items in the tabulation do not depend on the type of equipment used, it was found that more emergencies arose from the use of flat cars with Lidgerwood unloaders and plows than from the use of dump cars. Also, it was found possible to unload at the end of a spur track on a fill successfully with dump cars, while this could not be done with flat cars and plows since the plow at the end of the train occupied a space of at least 20 ft.

This work was handled under the direction of, and the data compiled by E. P. Weatherly, formerly engineer maintenance of way, of the Kansas City Terminal Railway, under the general supervision of J. V. Hanna, chief engineer.

SERVICE OF A FUEL OIL ENGINE IN A RAIL WAY PUMPING STATION

About 5,000,000 gal. of water per month is being pumped at the Nevada, Mo., pumping station of the Missouri Pacific at a cost of 1.73 cents per thousand gallons. This service, which is being performed by a fuel oil engine, is considered very satisfactory in comparison with the average rate at steam plants under similar conditions on this and other roads.

In order to obtain a reliable and satisfactory supply of water



The Fuel Oil Engine in the Missouri Pacific Pumping Station at Nevada, Mo.

for roundhouse purposes and for about 1,175 engines per month at this division point, which is the most important terminal on the Joplin division, it was necessary to locate the pumping station about four miles west of the engine house on the Marmaton river, and the abandoned pump house and grounds of the Nevada Water Company were acquired at a very reasonable cost. The plant consists of a 42 ft. by 48 ft. brick pump house, a three-room frame pumper's dwelling, 18,000 ft. of 8-in. discharge line, about 150 ft. of 10-in. suction line, a steel standpipe 24 ft. in diameter and 45 ft. high and two pumping units, each of approximately

400 gal. per min. capacity. A low storage dam has also been provided in the river. The total cost of these facilities was approximately $31,500.

The main pumping unit for regular use consists of a 40-hp. vertical single cylinder Crescent oil engine direct connected to a Deming single action triplex pump having cylinders 9 in. in diameter and a stroke of 10 in. The engine is equipped with a compressed air starting device. The water cylinders of the pump are located in a pit with their base 18 ft. 6 in. below the base of the power head or main floor level of the pump house. The discharge head from the center line of the suction pipe to the top of the steel tank is 164.4 ft. An auxiliary steam unit consisting of a 45-hp. vertical boiler and a 12 in. by 7 in. by 12 in. duplex pump was installed for emergency use.

The fuel oil used in the Crescent engine is low grade engine distillate of 32 deg. to 34 deg. Baume specific gravity. A storage tank 8 ft. in diameter and 28 ft. long is located underground outside of the pump house which provides a storage capacity for approximately 18 months' supply of oil at the present rate of consumption. A test of this fuel oil showed a consumption of 3.23 gal. per hour when the engine was making 300 r. p. m. against a pressure of 96 lb.

The operating expenses of this plant for six months were as follows:

3,250 gal. of fuel oil at 3c. a gal.	$97.50
144 gal. of lubricating oil at 17c. a gal.	24.48
110 gal. of coal oil at 3½c. a gal.	3.98
Labor maintaining	51.00
Minor repair parts	20.00
Salary of pumper	300.00
Total for six months	$496.96

During this time 28,680,000 gal. of water was pumped against a head of about 225 ft., including friction and suction, at the average rate per thousand gallons of 1.73 cents.

The operating cost of a steam plant at this point for the same six months is estimated as follows:

152 tons of coal at $2	$304.00
Hauling coal five miles at $1 per ton	152.00
Oil, waste and supplies	50.00
Repairs	100.00
Pumper's salary	300.00
Total for six months	$906.00

For the total quantity of water mentioned above, this would mean an average cost of 3.09 cents per thousand gallons. The comparative cost of installation of the fuel oil engine and the steam plant is estimated as follows:

40-hp. oil engine	$2,000.00	Boiler in place	$1,200.00
Pumps	600.00	Steam pump	600.00
Foundation	100.00	Foundation	200.00
Pipe and connections	200.00	Pipe and fittings	200.00
Labor	125.00	Labor	200.00
		Boiler feed	150.00
Total	$3,025.00	Heater	200.00
		Total	$2,750.00

ABSTRACT OF ENGINEERING ARTICLES

The following articles of special interest to engineers and maintenance of way men to which readers of this section may wish to refer have appeared in the *Railway Age Gazette* since May 21, 1915:

Preparing for the Federal Valuation of the Railways.—A description of the methods adopted by seven representative roads in preparing their information for the federal valuation parties now working on their lines was published in the issue of May 28, page 1107.

A Modern Concrete and Brick Roundhouse at DuBois, Pa.—The Buffalo, Rochester & Pittsburgh has recently completed a 16-stall roundhouse at DuBois, Pa., involving a number of interesting details of reinforced concrete construction. This building was described and illustrated in the issue of May 28, page 1110.

Fundamental Problems Involved in Railway Valuation.—A detailed report of the conference held in Washington attended by Director Prouty of the federal valuation board and his staff, and over 200 representatives of the railways and state commissions was published in our issue of June 4, page 1146.

Norfolk & Western Elkhorn Grade Electrification.—The Norfolk & Western is now completing the electrification of 30 miles of its main line between Bluefield, W. Va., and Vivian. This installation was described in detail in an illustrated article in the issue of June 4, page 1152. Additional details regarding traffic and operating conditions were discussed editorially in the issue of June 11, page 1230.

Report of the Chicago Railway Terminal Commission.—The recommendations made to the Chicago City Council Committee on Railway Terminals by the Chicago Railway Terminal Commission in a recent report were published in the issue of June 4, page 1163.

Lateral Stresses in Rails on Straight Track.—An extensive series of experiments carried on recently in the main track of a prominent road to determine the lateral stresses in rails on straight track under different conditions of line and surface, and with various types of locomotives running at different speeds, was described by George L. Fowler in an extensive illustrated article in the issue of June 11, page 1231.

Overhead Charges in Valuation.—In an article in the issue of June 11, page 1242, Richard Hoadley Tingley discussed the lack of agreement regarding the allowances generally made in valuation work and urged careful investigation to determine actual charges to this account.

BUFFALO ROCHESTER & PITTSBURGH STANDARD OUTFIT CARS

The Buffalo, Rochester & Pittsburgh provides unusually complete outfit cars for its bridge and building, mason, signal and water service gangs. The equipment for a small gang consists of a foreman's car and a combination dining and sleeping car, while that for larger gangs consists of a foreman's car, a combination kitchen and dining car and as many sleeping cars as are necessary to accommodate the gang. The interior of all cars except the tool and material room in the foreman's car is sealed on the sides and top with ⅞-in. T. & G. seasoned yellow pine over a layer of waterproof building paper. The regular car floor is covered with a 1¼-in. maple flooring laid on a layer of waterproof building paper. Par-

Exterior View of a Camp Outfit

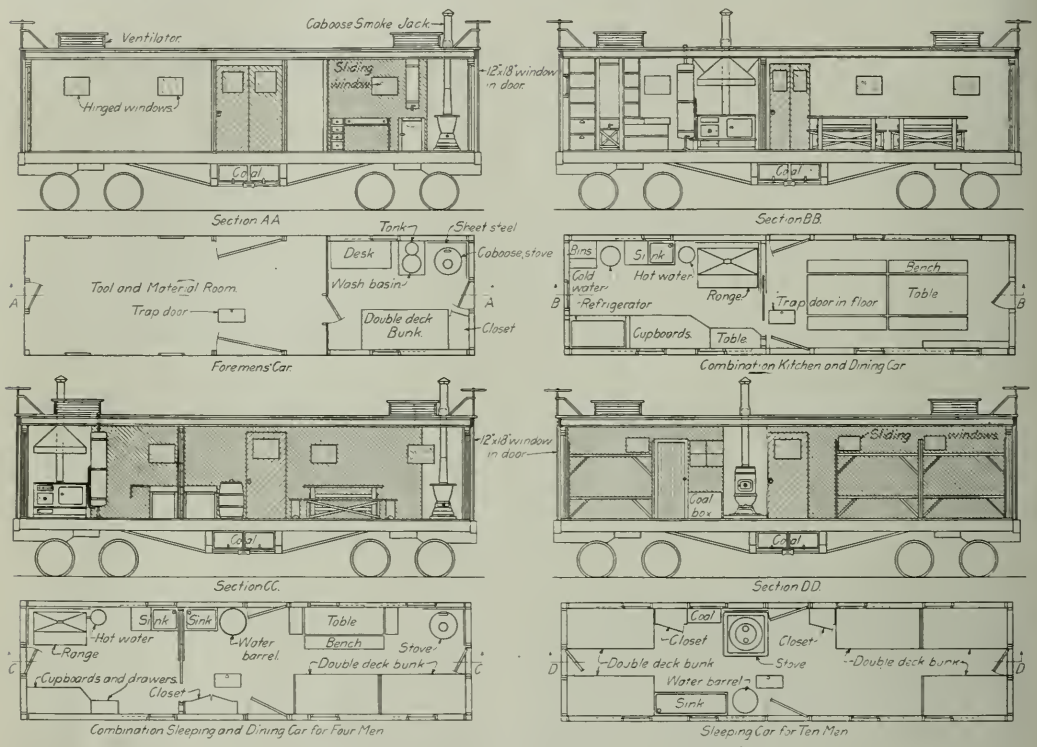
ticular care is taken to secure tight joints and to properly flash around the ventilators and smoke jacks.

The standard foreman's car is divided into two compartments, the larger being used for the storage of material. Partitioned off at one end is the foreman's quarters, provided with a desk, a washstand and a double deck steel bunk. It is heated with an ordinary caboose stove placed in one corner.

The combination kitchen and dining car is divided into two compartments. The smaller one is devoted to the kitchen and contains a stove with a hood, a hot water tank, sink, cold water tank, refrigerator and various storage bins. The stove is placed on a concrete base and thoroughly secured to the floor. All walls and ceilings adjacent to these stoves are protected by sheet steel furred out from the wall and the ceiling. The opposite end of the car is provided with the customary benches and a dining table.

The combination sleeping and dining car is provided with a kitchen at one end and two double deck steel bunks along one wall and a 6-ft. table along the opposite wall in the other end. The standard sleeping car provides for five double deck steel bunks in the ends of the cars and a stove along one wall opposite the door in the center of the car.

A color board is placed on the outside at the upper right hand corner on each side of each car indicating the branch of the engineering department to which the car belongs. The organization of the B. R. & P. is departmental and all mainte-



Standard Outfit Cars of the Buffalo, Rochester & Pittsburgh

Interior Views of the Cars

nance of way work is under the charge of the engineering department. Each branch of this department is assigned a standard color—the bridge and building yellow, mason black, track green, signal gray, water service blue, etc. All hand and push cars, feeders, tool boxes, tools, etc., are also painted with these distinctive colors to distinguish them and indicate their ownership.

STAFF MEETINGS FOR MAINTENANCE OF WAY EMPLOYEES

By J. T. Bowser

Maintenance of Way Department, Queen & Crescent Route, Danville, Ky.

Why should not the practice of holding staff meetings be extended to the maintenance of way department? Meetings attended by section and extra gang foremen and supervisors, presided over by the road master or division engineer cannot fail to be of considerable benefit to the department as a whole. It should not be a difficult matter to arrange for such meetings at stations centrally located, and the managements of many railroads would undoubtedly authorize an arrangement by which the expenses of men who have to be away from home would be paid by the company.

The division officer who is to preside at the meeting should prepare notes beforehand on subjects which he desires to discuss or explain. Such occasions offer excellent opportunities for outlining and explaining new practices, thus insuring their more intelligent application. When these matters have been disposed of the meeting can be thrown open to the men for the general discussion of any questions on which they may desire information. They should be encouraged to describe their methods and to comment on those described. New men should be encouraged to ask questions, and all complaints should be freely discussed and investigated.

The men should be encouraged to make note of conditions involving the safety of employees or others, or in any matter in which the company's interests are involved. Any recommendation should be acknowledged and discussed and if not adopted, the reasons should be explained.

Such meetings, held three or four times a year, will wonderfully improve the spirit and personnel of the organization. The men will become acquainted with each other, with their supervisors and with the division officials. Their interest in their work and in all matters involving the company's interests will be greatly increased, while a general rise in the tone of the organization will be readily noticed. Men who have been in the rut of old methods for years will pick up ideas of improved methods, while the "hard headed" foreman, who cannot be taught or instructed in the usual manner, will assimilate ideas that he might never get otherwise.

A NEW TYPE OF WALL BOARD

The "Certain-teed" wall board recently placed on the market by the General Roofing Manufacturing Co., St. Louis, Mo., is made by cementing together four sheets of clean wood fibre material and is designed to secure great strength and resistance to moisture and dampness. Experiments were carried on for about four years in an endeavor to secure these qualities to the greatest possible extent, with the result that this material is shown by tests to have a strength of 424 lb. per sq. in., and that its absorption of water in a one-hour test is 70 per cent, and in a four-hour test, 98 per cent. While this material has been used satisfactorily for interior finish in many buildings, the object of the manufacturers has been to secure the best service rather than a beautiful finish.

This material is particularly adapted to railway buildings in which there is a considerable amount of vibration, where plaster is cracked and broken. In factories, shops and offices where revolving machinery or passing trains cause such vibration, the wall board can be satisfactorily used and in passenger stations it is more attractive and also more economical than some of the common methods of finishing the interior walls. The further advantages are claimed for it that it is a non-conductor of heat, therefore saving fuel in cold weather and keeping the building cooler in summer, and that it is clean, durable and sanitary. It can be calcimined, varnished

Bundles of "Certainteed" Wall Board Ready for Shipment

or painted with oil or water color paint, and can be applied more quickly and easily than laths and plaster.

This material is made in widths of 32 and 48 in., and in lengths varying from 6 to 16 ft. It weighs approximately 650 lb. per 1,000 sq. ft. It is packed in bundles containing 10 pieces each and protected by container board covering held in place by steel bands, enabling it to be handled readily.

WOOD PRESERVATION STATISTICS

The American Wood Preservers' Association in co-operation with the Forest Service, United States Department of Agriculture, has compiled and published statistics showing the quantities of wood preservatives consumed and the amount of wood treated in the United States in 1914. The following information is abstracted from this report:

In 1914 the Forest Service records showed 122 plants of all types, 100 of which were of the pressure-cylinder type. In Table 1 the consumption of wood preservatives used by the treating plants is shown by years, kinds of preservatives and quantities. For 1910, 1911 and 1912 the increase in the use of creosote oil was approximately 10,000,000 gal. annually. The greatest consumption of preservatives was recorded in 1913. In 1914 the total quantity of creosote oil reported dropped approximately 29,000,000 gal. This was due primarily to the facts, that the supply of creosote from England and Germany during 1914 decreased, and that for years prior to 1914 paving oil was included in the creosote statistics. In this report paving oil, reported as 9,429,444 gal., is listed separately.

Table I—Consumption of Wood-Preservatives by the Treating Plants in the United States, 1909-1914

Year	Number of Plants	Creosote, Gallons	Zinc chloride, Pounds	Other preservatives, Gallons*
1909.....	64	51,431,212	16,215,107	.....
1910.....	71	63,266,271	16,802,532	2,333,707
1911.....	80	73,027,335	16,359,797	1,000,000
1912.....	84	83,666,490	20,751,711	3,072,462
1913.....	93	108,373,359	26,466,803	2,885,738
1914.....	94	79,334,606	27,212,259	{ 9,429,444† / { 2,486,637

*Includes crude oil, coke oven-tar, refined coal-tar, and carbolineum oils.
†"Paving oil."

The total consumption of zinc chloride in 1914 exceeded the 1913 figures by approximately 750,000 lb.

Some firms have experienced considerable difficulty in obtaining foreign oil, very largely due to inability to obtain tank steamers for its transportation. Some of the larger manufacturers of creosote oil in the United States estimate that the production of the American oil has been increased by 25 per cent, owing to the installation of new coke ovens. However, many of the coke ovens which manufacture the crude coal-tar have not been operating; consequently this increased production has not been felt materially to date. The difference in the totals of creosote oil consumed for 1913 and 1914 was nearly equally distributed between the foreign manufacturers and the American producers of this commodity.

Table II—Relative Quantities of Domestic and Imported Creosote Used in the United States, 1909-1914

Year.	Total creosote used, Gallons	Domestic creosote, Gallons	Per cent of total	Imported creosote, Gallons	Per cent of total
1909.....	51,426,212	13,862,171	27	37,569,041	73
1910.....	63,266,271	18,184,355	29	45,081,916	71
1911.....	73,027,335	21,510,629	29	51,516,706	71
1912.....	83,666,490	31,135,195	37	52,531,295	63
1913.....	108,373,359	41,700,167	38	66,673,192	62
1914.....	79,334,606	28,026,870	35	51,307,736	65

The price of domestic creosote in 1914 averaged in the neighborhood of 8 cents to 8½ cents per gallon, f. o. b. plant. Very few quotations for creosote are being given for 1915 delivery, but, owing to the scarcity of oil, prices for 1915 probably will be somewhat higher. Much the same condition exists in the production of zinc chloride, owing to the inability to obtain spelter. However, some firms are buying their supplies of this preservative at very slight increase over the figures current in 1914.

Increased amounts of creosote oil may have to be produced in the United States in the future owing to the perfection in Europe of engines using such oil as a fuel. Also in European countries increasing amounts of tar are being used for road making, and as tar is distilled for commercial creosote the tendency is to reduce the quantity of creosote oil manufactured in Europe for preservation purposes. Considerable progress has been made in this country on some plants located in the Middle West, which when completed, will add 10,000,000 or more gallons annually to the supply of domestic creosote.

The number of ties treated in 1914 exceeded the total in 1913 by 3,577,571. The hewed ties treated comprised about 70 per cent of the total or 30,222,183, while 13,624,804 were sawed. A few companies treated more hewed ties in 1914 than in 1913, owing to the fact that more tie cutters were available during 1914 than in the preceding year. Nevertheless, the increase in the total number of cross ties treated is reflected chiefly in sawed ties. Oak ties lead in the number treated. Over 39,000,000 ties were treated by creosote and zinc chloride, approximately one-half of the total being reported under each class. Over 50 per cent of the ties treated with zinc chloride were oak. The most common treatment of pine was made with creosote, and 1,159,929 ties of the total of 1,956,278 treated with zinc and creosote emulsion were oak. Zinc creosote emulsion was used for treating 1,956,278 cross ties; 2,625,681 ties were impregnated with miscellaneous preservatives, including crude oil, paving oil, refined coal-tar and oils reported as carbolineum. The treatment varied from dipping in open tanks, as practiced by some tracTable III—Number of Cross Ties Treated, by Kinds of Wood and Kinds of Preservatives, in 1914

Preservative	Oak	Yellow Pine	Douglas Fir	Western Pine	Beech	Gum	Tamarack	Maple	Birch	Elm	Other species	Total

Converting Factors

To obtain the number of cross ties, divide figures shown by 3.

To obtain the number of lineal feet of piling, divide the figures shown by .6763.

To obtain the number of lineal feet of poles, divide the figures shown by .5868.

To obtain the number of square yards of paving blocks, divide the figures shown by 2.625.

To obtain the number of board feet of construction timbers, divide the figures shown by .0833.

To obtain the number of cross-arms, divide the figures shown by .6198.

To obtain the number of board feet of lumber and miscellaneous material, divide the figures shown by .0833.

CORRUGATION OF RAILS IN ELECTRIC RAILWAY SERVICE

In a paper delivered before the Institution of Civil Engineers of England by William Willox, on Rail Steels for Electric Railways, there appeared considerable information on the corrugation of rails in electrified steam railway tracks. The electrification of existing railways in England was begun in 1903, and the running of electric trains commenced in 1905. Apparently it was not foreseen that this would have other than the usual effect on the running rails, but it is now evident that electric trains, more especially, perhaps, in London, have reduced the life of the rails in a marked degree. This is due not so much to the fact that the trains are driven electrically as to the design of the motors used. The motors are therefore placed under the floors of the cars, except where electric locomotives are used to haul ordinary equipment. In the former case great difficulty has been encountered in carrying the motors on springs, and they are slung on the axles and so become a dead load, or nearly so. Besides this, the wheels are of small diameter, the trucks are short, the drive is near the extremities of the axles, and after a short period of service where there are curves, the wheels are in many cases of unequal diameter. The result on the road is very marked, the life of the rails being reduced by years. On part of the Metropolitan Railway where electric traction is in use the life of the rails in the open is only about 8 years and in the tunnel section barely 3 years. As the traffic increases, even this life cannot be maintained unless more durable rails than those ordinarily used are substituted. The 3 years' life for the tunnel section is the average, and on curves the life is much shorter.

The first trouble met with under electric traction was side wear, which was excessive on curves and occurred not only there but also on tangents, owing no doubt to the nosing of the motor cars. In order to prevent this on sharp curves inside guard rails were provided. These guard rails lasted only 3 to 6 months and it was necessary to keep a gang at work on renewals continuously. The difficulty has been entirely overcome on the Metropolitan Railway by the use of a special hard guard rail of such a shape as to prevent it from being put into the running rails by mistake.

The second, and a much worse trouble, is the grinding of the running surface of the running rail into hollows, called locally "battering," which is not corrugation but something much more than that. It occurs chiefly on curves. The hollows are nearly always just at the sides of the chairs towards approaching trains, the portion of the rail between consecutive chairs being hardly affected. It would thus seem that where the rail has spring the grinding is much less. The battering is apparently caused by the hammering action of the unspring-borne load of the motors on the rails; by skidding action along the rail, arising from the direct drive on the axle and by skidding action across the rail, arising from the rebound of the rail when it has reached its limit of side spring, caused by the pushing of the wheels as they go round the curve. Ordinary corrugation, such as occurs in street car rails, exists in all sorts of places near stations and between stations, but it has no serious effect, except probably to increase the noise of trains. It is this battering that so seriously lessens the life of the rails, especially on curves.

Because of this experience of the English railways, inquiry was made of Dr. P. H. Dudley, consulting engineer, New York Central Lines, regarding the extent to which this same effect had been noticed on the electrified portions of his lines. We quote from his reply as follows:

"I do not know of any corrugation in our rails, either on the Hudson or Harlem branch operated by electric traction. The rails used for electric traction on the New York Central are either our 6 in. 100-lb. or 105-lb. sections. The breadth of the head at its extreme width is 3 in., with sides inclined 1/16 in. per inch of height, and with 5/16 in. radii for the upper corners. The top radius of the rail is 14 in. This is a broad flat top rail, quite different from the T or doubleheaded section used in England, and I have not noticed any corrugations whatever on rails which have been put in service the last 3 or 4 years. When electric traction was installed with electric motors to draw the former steam cars, it was noticed in one or two places that there was a slight evidence of a sway and a small increase of wear at recurring positions on a few rails, but this has practically disappeared on more recent rails.

"There are two types of corrugations—long and short waves, which must be discussed in electric traction. The first I have partially described, and it no longer appears on our recent rails, while I have never noticed the short waves upon our stiff, broad, flat-topped rails.

"So far as I have observed in this country and in England the method of blooming the ingots is quite different in the ragging of the rolls. We use ragging with one sharp angle, but the other is inclined, while in England the ragging or cogging, as they term it, is done by square projections on the rolls. That type of ragging seems to effect the metal in the passes to an extent by its irregular pressure which is not completely overcome in the final rolling. The heads of the T or doubleheaded section have a smaller top radius with greater corner radii, consequently the actual bearing surface between the rail head and the wheel tread is smaller than in our practice, and corrugations can more readily occur.

"The long waves are due to a repeated oscillation of the equipment over the rails. The short waves produce shorter corrugations, and are noticeable for practically every inch or two in the rail top. I have never observed the latter type on our own rails, but I have seen this type to a slight extent upon rails of a different section of shorter top radius and greater corner radii."

DIFFICULTIES IN INCREASING THE SCOPE OF THE SECTION FOREMAN'S DUTIES

By J. P. Costello

Roadmaster, Atchison, Topeka & Santa Fe, Pueblo, Col.

In a recent issue an article appeared setting forth the economic value of increasing the duties of section foremen to take care of light repairs to bridges, buildings, signals, etc., the main objects being to make repairs quickly and to save the expense of the time lost by workmen moving on trains to and from the scene of the work. I grant that it is unfortunate that, under present arrangements, men cannot be on the ground to make these needed repairs, but the question arises, can the section forces do this work and if they can, will they, by so doing, increase the efficiency of the maintenance of way organization?

In order to save time, special tools and materials for these additional jobs would have to be kept on hand at all times on each section even though some of them would probably only be used on comparatively rare occasions. Although the allotments of tools and materials were small and restricted, their summation would certainly exceed the requirements of one or two special gangs at some central point. There would also be a greater chance of lost, misplaced, or misused tools and materials.

A man accustomed to the use of a claw bar, spike maul, or wrench cannot turn his hand to the use of carpenters' tools with any more readiness than a carpenter can turn from his own tools to those in use by the track department. Neither can a track foreman apply his mind to carpentry or signal work with the precision which he applies to his own class of work. Certain jobs might not present themselves as often as once in a year on an ordinary section. No man can do a piece of work with finished skill the first time it presents itself nor can he do it with real skill if it presents itself only after long intervals of time. The efficiency of a laborer depends upon his skill and skill is the result of experience—practice.

I have seen a statement that railway maintenance forces were less than 40 per cent efficient. I will not argue that this statement is inaccurate and I do not deny that the track forces contribute their share, at least, to this inefficiency. The discussion of increased duties for section foremen is no doubt the result of an attempt to overcome this inefficiency, but why should we expect to increase the efficiency of the whole department of maintenance by requiring more diversified work of one branch of that department? A study of some of our highly efficient factory organizations would indicate that the fundamental idea is to keep certain men engaged at one definite class of work.

Of course, in an organization like that of railway maintenance, where rather small units of the organization are maintained not directly under the eye of a supervising official, the attempt to make the work too machine-like would be a failure. A study of work which is essentially manual in character cannot be considered in the light of an exact science because we have the human element, interest, to deal with. Track work properly conducted and in a state of *evident progress* is interesting, otherwise we would not be able to secure men to handle it and at the same time accept with a degree of cheerfulness the rigors of the occupation.

I am convinced that the duties of section men are far too diversified now—too much energy dissipated in discontinuing one task to take up another. Their duties extend from menial tasks to important ones chargeable to other branches of the service. I agree that many of these things, under present conditions, must be performed by section men for the simple reason that no other provision is made to take care of them.

I have in mind a district which terminated at the end of a bridge over which only a restricted car tonnage was permissible, causing many heavily loaded cars either to be transferred or lightened. At another point were several mines at which cars were frequently damaged and had to be repaired —many times after they had been loaded. At another, a junction point, there was some sort of an agreement or arrangement about interchange of l. c. l. shipments whereby much unloading and concentrating of freight was necessary. The three sections whose headquarters were at these points were very unsatisfactory to handle, because at irregular intervals the heavy work of freight handling was thrown upon the section men and, of course, had to be done regardless of track work. It was impossible to get any systematic "line up" on the work or to arrange any definite program. These sections were always short of men and I am satisfied that this outside work had a greater influence on this shortage than the smallness of the wages which they received. Men engaged in any class of constructive or repair work, no matter what their nationality, intelligence, or education, must be able to see consistent progress in their essential work or they will not be interested. I believe everyone agrees that the *essential work* of section men is track work.

Engineers in charge of maintenance have usually figured that, by increasing the size of a gang at a point where outside work interfered, the same results in track work could be secured as by using a proportionately smaller gang engaged solely in track work. This idea is absolutely wrong. Work accumulates a certain momentum as it progresses. Every interruption or change of work dissipates this momentum—hence, loss of efficiency.

I have observed a couple of roads where the section men were required to wash the windows, scrub the floors and clean the outhouses of local stations. I have observed another road where this was not the rule. I have noticed, in the latter case, that the agent took a little personal pride in keeping his windows clean; that he discouraged the loafers and tobacco spitters, and that he kept his outside toilets locked. With the exception of a very few cases, I have never seen it to fail where section men could be called in to do odd jobs that they were imposed upon.

This new scheme of increased efficiency in maintenance is as much in error as many others for the reason that the idea is to accomplish the same results as formerly by the expenditure of less money. Present conditions require better track and the future will require still better and better track conditions. Why not aid the section foreman to increased efficiency and then encourage him by allowing him to see the results of his efforts?

Although seasonal in character, section work submits to a fairly definite program and by arranging such a schedule better results can be secured as to quantity and quality of work obtained. Increased efficiency will be the result of a definite program, while diversified duties interfere with the carrying out of a definite program of work.

As to the smaller repair jobs, aside from track work, which might be assigned to the section men, these could be better taken care of by special branches of the maintenance department if a definite program of repairs were carried out and I have noticed that, where such a program obtains, the small apparent defects vary inversely as the perfection of the program. The "window-pane" illustration is not a fair one because it refers to a fragile material and a condition of failure which is sudden and not of a progressive nature. Certainly no one would expect a local station to get along with a broken window for several months until the regular time in the program arrived to take care of it. In the proposed scheme, the idea would be to take care of such things as the loose hinge on the station door; the few decayed planks in the freight house platform; the loose shingles on the roof of the pump house; the corroded or broken bond wires at some street crossing; a water accumulation in the pipe lines of the crossing gates; or the thousand and one things which go wrong but which do not arise in a second. The stitch in time idea is all right, but we should not allow our faith in it to degenerate into the belief that repairs should be made in the barest scratch of time necessary to avoid the failure of a device.

Among men who have not handled track work directly the idea seems to prevail that the scheme of section work is for the foreman to find or to have pointed out to him something which needs attention and fix it, then go to some other point and do the same thing and so on. If this idea continues prevalent among the men who influence track work, section work will never be done with efficiency. Section work properly conducted aims at the general prevailing condition. I am satisfied that the present day inefficiency is not due entirely to the class of labor employed.

The position of section foreman is different from most other minor railway positions for the reason that when a man is made foreman in charge of a piece of track, his relationship to that piece of track borders on ownership. He may, at times, work for days or even weeks without conversing with his superior. Unlike other men he is free from intimate directions or regulations. If he is the right kind of a man and if he is not overwhelmed with a multitude of duties he takes a certain pride in the upkeep of the property turned over to him. On the other hand, if he has more duties than he can attend to properly, his attitude becomes that of a property-poor landlord.

To increase efficiency in the maintenance of way department the various branches of the department should be improved. If we condense the section work into the most essential things to be obtained, if we "programize" the work to take care of these essentials at the proper time, if the section men are allowed to carry out each part of their program with a minimum of outside interruptions and if the work be conducted so that the foreman and his men can see actual, positive progress, the increased efficiency of the section gangs will prove that they do not need additional duties. Such a policy should have the support of the highest officials who influence maintenance work.

General News Department

The Pennsylvania Railroad has received word from the Panama-Pacific International Exposition at San Francisco that the company has been awarded the grand prize, the highest honor which could be conferred upon any railroad exhibiting.

Southern Pacific passenger train No. 22, running from San Francisco to Los Angeles, was held up late on the night of June 11, near Chatsworth, Cal., by two masked men who went through the last four cars and robbed a number of passengers. The robbers then stopped the train and escaped.

Miss Irma Pratt, a member of the graduating class of the St. Clairsville (Ohio) high school, who lives at Barton, and has traveled back and forth on the Baltimore & Ohio, 6 miles each day, reports that she did this for five years without ever missing a day or a fractional part of a day of school, and without being tardy.

The Magnolia cut-off of the Baltimore & Ohio, which was opened for traffic last December, has effected an average reduction of 2 hours and 5 minutes in the time of train crews over the east end of the Cumberland division. The Magnolia cut-off, shortening the main line about 6 miles and giving more favorable grades, was described in the *Railway Age Gazette* of April 30, 1915.

The railroad department of the Young Men's Christian Association is establishing a railroad school in its recently completed college for the training of secretaries at Chicago. This course will be under the direction of leading railroad Y. M. C. A. secretaries, with W. N. Northcott, executive secretary of the railroad associations of Chicago, as dean. The purpose of the course is to train men to become efficient secretaries of railroad branches. This department of the school will begin its work next October.

For forty-five days the wreck train assigned to the east end of the Cumberland division of the Baltimore & Ohio was not called out in the territory between Cumberland and Brunswick, which embraces a distance of 102 miles of three-track and four-track railroad for a greater part of its length, and includes the Magnolia cut-off. This section of the Baltimore & Ohio is one of the busiest railroads in the United States.

Railway Sanitation

This is the title of a pamphlet which has been printed by the Baltimore & Ohio for circulation among employees in all departments of the service for the general benefit. It consists of five articles on the subject by Dr. E. M. Parlett, re-printed from the Baltimore & Ohio Employees' Magazine. Dr Parlett is a member of the General Safety Committee of the road. These essays include one dealing in detail with the sanitation of construction camps, and another on typhoid fever and its conquest.

Results of Safety-First Work on Norfolk & Western

C. H. Blakemore, chairman of the safety commission of the Norfolk & Western, has issued a bulletin showing the decrease in injuries to employees during the 20 months ending December 31, 1914, since the safety movement was inaugurated on this road. The improvement with relation to the number of employees is shown on a chart on which is plotted a line showing the number of injuries and a line showing the fluctuations in the pay roll. The total pay roll and the total number of injuries as of May, 1913, is taken as a base line for making comparisons, and with relation to this line from August, 1913 (the high point, with 463 accidents), to December, 1914, with 172 accidents, there was a decline of 70 per cent. From May, 1913, the lines showing pay roll and injuries gradually diverge and at the end of 1913 the pay roll had declined 7 per cent, while accidents had gone down 25 per cent. At the end of 1914 the pay roll had declined to 17 per cent below the base line, while accidents had gone down 58 per cent, a further gain in accident reduction of 41 per cent. When the safety movement was inaugurated one employee on the line was being injured for each $3,600 of pay roll. For December, 1914, one employee was injured for each $7,000 of pay roll.

Economy in Distribution of Time-Tables

[From New York Central Bulletin]

It has probably never occurred to many agents how easy it is to throw away the company's money in handfuls by a wasteful distribution of time-tables.

An agent in an up-state village sent in a requisition for 300 copies form 1001, our General Folder, and 500 form 110, our Adirondack Division folder. We consulted our records and found that this station used about 5 form 1001 and 15 form 110 per month. As the first form costs about 1 cent a copy and the latter ½ cent, this agent would have received $5.50 worth of time-tables, when 25 cents worth would have answered his purpose until the summer schedule becomes effective two months hence. At a larger station, 2,000 copies of form 1001 were ordered. We found that this agent had used but 500 of this form in the past seven months. Bearing in mind the summer change in time 150 copies were ample to meet this requirement and that quantity was sent. If the full quantity requested had been shipped, he would have thrown away $18.50.

You are probably saying that these cases are exceptional. Nothing of the kind. They are every-day occurrences.

Stop and consider that the New York Central is supplying over 2,000 stations monthly with 25 different forms of time-tables, costing from 1 mill to 1 cent each in quantities ranging from 5 to 5,000 copies.

Order enough folders for one month only.

Street Railway Strike in Chicago

The 14,000 motormen and conductors employed on the Chicago surface and elevated lines went on strike at midnight on Sunday last, after the management of the companies had refused their demands for increases in pay and changes in working conditions. The three-year contract between the companies and the Amalgamated Association of Street and Electric Railway Employees of America expired on May 31, and negotiations on the new demands of the men have been in progress for some time. The employees for a long time refused to consider arbitration, and after the mayor of Chicago had held conferences with the officers of the union and of the companies in the effort to bring about an agreement, they proposed a plan of arbitration providing for a guarantee in advance of certain changes in working conditions which the companies declared would amount to an increase in pay of over $1,000,000 a year, while other questions were to be submitted to a board of arbitration composed of one man selected by the union, one by the companies and a third to be selected from a list of five names proposed by the union. The companies declined to agree to this kind of an arbitration and proposed that each side should select an arbitrator and that the two thus selected should choose the third. The company agreed to ask for no reductions in pay. This proposition was declined by the union leaders.

The surface lines made no attempt to run cars on Monday or Tuesday. The elevated lines ran a few trains on Monday without attempting to carry passengers, but on Tuesday attempted to give some service. As a result the steam railroads which normally bring in only a small percentage of the daily current of commuters, were confronted on Monday with an unusual traffic problem, with only a few hours to prepare for it. The railroads that ordinarily operate suburban service put every available car into that service, lengthening the regular trains and putting on as many additional trains as they could handle; and railroads that do not ordinarily run suburban trains put on extras and carried as many people as they could. The Illinois Central, the Chicago & North Western and the Chicago, Rock Island & Pacific, which carry the bulk of the suburban passengers into and out of Chicago, were taxed to the limit of their capacity on Monday, but on Tuesday

had organized the service so that it was handled with less confusion. The ticket selling facilities proved entirely inadequate, and it was found necessary to install many emergency ticket booths; and the cars were so crowded that the conductors missed a large percentage of the fares. On some roads the schedules were practically abandoned and trains were run one after the other as fast as they could be made up, in many instances with passengers hanging onto the engines and the roofs of cars. Emergency stations were established at various points where trains ordinarily do not stop. While there was a great deal of crowding and delay the inconveniences were generally accepted by the public good naturedly.

Many of the large stores and other business houses organized automobile or wagon service for their employees, and every available vehicle of any character was pressed into service to handle the crowds.

On Wednesday morning the officers of the companies and the representatives of the strikers agreed to arbitration, the third arbitrator to be Mayor Thompson.

MEETINGS AND CONVENTIONS

The following list gives the names of secretaries, dates of next or regular meetings, and places of meeting of those associations which will meet during the next three months. The full list of meetings and conventions is published only in the first issue of the Railway Age Gazette for each month.

AMERICAN ASSOCIATION OF DEMURRAGE OFFICERS.—F. A. Pontious, 455 Grand Central Station, Chicago. Next meeting, July 21, 1915, Milwaukee, Wis.

AMERICAN ASSOCIATION OF RAILROAD SUPERINTENDENTS.—E. H. Harman, Room 101, Union Station, St. Louis, Mo. Next meeting, August 19-20, 1915, San Francisco, Cal.

AMERICAN RAILROAD MASTER TINNERS, COPPERSMITHS AND PIPEFITTERS' ASSOCIATION.—W. E. Jones, C. & N. W., 3814 Fulton St., Chicago. Annual meeting, July 13-16, 1915, Hotel Sherman, Chicago.

AMERICAN RAILWAY TOOL FOREMEN'S ASSOCIATION.—Owen D. Kinsey, Illinois Central, Chicago. Annual meeting, July 19-21, 1915, Hotel Sherman, Chicago.

AMERICAN SOCIETY FOR TESTING MATERIALS.—Prof. E. Marburg, University of Pennsylvania, Philadelphia, Pa. Annual meeting, June 22-26, 1915, Hotel Traymore, Atlantic City, N. J.

AMERICAN SOCIETY OF CIVIL ENGINEERS.—Chas. Warren Hunt, 220 W. 57th St., New York. Regular meetings, 1st and 3d Wednesday in month, except July and August, 220 W. 57th St., New York.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS.—Calvin W. Rice, 29 W. 39th St., New York. Next spring meeting, June 22-25, 1915, Buffalo, N. Y. Annual meeting, December 7-10, 1915, New York.

ASSOCIATION OF RAILWAY ELECTRICAL ENGINEERS.—Jos. A. Andreucetti, C. & N. W., Room 411, C. & N. W. Sta., Chicago. Semi-annual meeting with Master Car Builders' and Master Mechanics' Associations. Annual meeting, October, 1915.

ASSOCIATION OF RAILWAY TELEGRAPH SUPERINTENDENTS.—P. W. Drew, Soo Line, 112 West Adams St., Chicago. Annual meeting, June 22-25, 1915, Rochester, N. Y.

ASSOCIATION OF TRANSPORTATION AND CAR ACCOUNTING OFFICERS.—G. P. Conard, 75 Church St., New York. Next meeting, June 22-23, Niagara Falls, N. Y.

ENGINEERS' SOCIETY OF WESTERN PENNSYLVANIA.—Elmer K. Hiles, 2511 Oliver Bldg., Pittsburgh, Pa. Regular meetings, 1st and 3d Tuesday of each month, Pittsburgh.

FREIGHT CLAIM ASSOCIATION.—Warren P. Taylor, Traffic Manager, R. F. & P., Richmond, Va. Annual meeting, June 16, 1915, Chicago.

GENERAL SUPERINTENDENTS' ASSOCIATION OF CHICAGO.—A. M. Hunter, 321 Grand Central Station, Chicago. Regular meetings, Wednesday, preceding 3d Thursday in month, Room 1856, Transportation Bldg., Chicago.

INTERNATIONAL RAILWAY GENERAL FOREMEN'S ASSOCIATION.—Wm. Hall, 1126 W. Broadway, Winona, Minn. Next convention, July 13-16, 1915, Sherman House, Chicago.

INTERNATIONAL RAILROAD MASTER BLACKSMITHS' ASSOCIATION.—A. L. Woodworth, C. H. & D., Lima, Ohio. Annual meeting, August 17, 1915, Philadelphia, Pa.

NIAGARA FRONTIER CAR MEN'S ASSOCIATION.—E. N. Frankenberger, 623 Brisbane Bldg., Buffalo, N. Y. Meetings, 3d Wednesday in month, New York Telephone Bldg., Buffalo, N. Y.

PEORIA ASSOCIATION OF RAILROAD OFFICERS.—M. W. Rotchford, 410 Masonic Temple Bldg., Peoria, Ill. Regular meetings, 3d Thursday in month, Jefferson Hotel, Peoria.

RAILROAD CLUB OF KANSAS CITY.—Claude Manlove, 1008 Walnut St., Kansas City, Mo. Regular meetings, 3d Saturday in month, Kansas City.

RAILWAY TELEGRAPH AND TELEPHONE APPLIANCE ASSOCIATION.—G. A. Nelson, 50 Church St., New York. Meetings with Association of Railway Telegraph Superintendents.

SALT LAKE TRANSPORTATION CLUB.—R. E. Rowland, David Keith Bldg., Salt Lake City, Utah. Regular meetings, 1st Saturday of each month, Salt Lake City.

SOUTHERN ASSOCIATION OF CAR SERVICE OFFICERS.—E. W. Sandwich, A. & W. P. R. R., Atlanta, Ga. Next meeting, July 15, 1915, Atlanta. Annual meeting, January, 1916.

SOUTHERN & SOUTHWESTERN RAILWAY CLUB.—A. J. Merrill, Grant Bldg., Atlanta, Ga. Regular meetings, 3d Thursday, January, March, May, July, September, November, 10 A. M., Piedmont Hotel, Atlanta.

TOLEDO TRANSPORTATION CLUB.—Harry S. Fox, Toledo, Ohio. Regular meetings, 1st Saturday in month, Boody House, Toledo.

TRAFFIC CLUB OF CHICAGO.—W. H. Wharton, La Salle Hotel, Chicago.

TRAFFIC CLUB OF PITTSBURGH.—D. L. Wells, Genl. Agt., Erie R. R., 1924 Oliver Bldg., Pittsburgh, Pa. Meetings bi-monthly, Pittsburgh. Annual meeting, 2d Monday in June.

TRAIN DISPATCHERS' ASSOCIATION OF AMERICA.—J. F. Mackie, 7122 Stewart Ave., Chicago. Annual meeting, June 15, 1915, Minneapolis, Minn.

TRANSPORTATION CLUB OF DETROIT.—W. R. Hurley, Superintendent's office, N. Y. C. R. R., Detroit, Mich. Meetings monthly, Normandie Hotel, Detroit.

UTAH SOCIETY OF ENGINEERS.—Frank W. Moore, 1111 Newhouse Bldg., Salt Lake City, Utah. Regular meetings, 3d Friday in month, except July and August, Salt Lake City.

Traffic News

William A. Colston, general solicitor of the Louisville & Nashville, addressed the Transportation Club of Louisville on June 8, advocating life terms and high salaries for railroad commissioners, and restriction of appointments to men with at least eight years of experience in the railroad business.

Members of the Traffic Club of Chicago made an inspection trip over the Chicago railway terminals on June 15 in a special train, leaving the LaSalle street station over the New York Central, going through the Union stock yards by the Chicago Junction, through the Clearing yard by the Belt Railway of Chicago, then to Blue Island via the Indiana Harbor Belt for inspection of the Indiana Harbor Belt icing plant and returning to the Calumet district via Indiana Harbor, Ind.

According to the Canal Record the earnings from tolls through the Panama Canal for the month of March were greater than the cost of operation and maintenance of the canal by $137,509. This gain reduced the deficit for the fiscal year beginning on July 1, 1914, to $123,588, which represents a loss of 4.09 per cent on the total outlay, not counting anything for interest on the investment or depreciation of the plant. It is stated that the deficit was further reduced during the month of April.

On the petition of the attorney general of Massachusetts, Judge Crosby in the Supreme Judicial Court of the state has issued a temporary injunction against the Boston & Maine and the New Haven railroads, restraining them from breaking a contract of 1912 whereby they agreed to absorb the switching charges on freight to and from the Commonwealth Pier in South Boston. The railroads had filed new rates, effective June 28, which added the switching charges to the straight Boston rates.

Car Surpluses and Shortages

The committee on relations between railroads of the American Railway Association in presenting statistical statement number 5, giving a summary of freight car surpluses and shortages for June 1, 1915, says:

"The total surplus on June 1, 1915, was 295,295, comparing with a surplus of 292,269 on May 1, 1915, and 242,572 on June 1, 1914. The surplus, as shown for May 1, includes figures reported since the issue of statistical statement number 4.

"The increases in surplus over May 1, 1915, are chiefly in groups 3, 5 and 6 (central, north and southeast) and group 10 (west) except coal cars. There is a decrease in the surplus of coal cars chiefly in groups 3 and 5."

The total car shortage on June 1, 1915, was 203, comparing with 966 on May 1, 1915, and 770 on June 1, 1914. The figures by classes are as follows:

Classes	Surplus	Shortage
Box	123,436	55
Flat	14,429	51
Coal and gondola	105,852	73
Other	51,578	24
Total	295,295	203

CLEANING CASTINGS.—In a leading article in the Electrical Review, dealing with lubrication troubles, it is stated that the difficulty with new turbine and engine bearings is frequently attributable to the fact that manufacturers do not clean the castings properly. Castings are never properly cleaned of sand, even externally, by the still common methods of brushing and coke rubbing, and in steam ports and passages it is hopeless to expect cleanliness from such antiquated methods. The most effective way for removing sand seems to be to pickle the castings. First, they are roughly cleaned and fettled and then hosed with weak hydrochloric acid. When sand is present this spreads the acid by capillary attraction, and the result of a few hours of acid action is to remove all sand and to leave the surfaces clean and free from hard siliceous scale. Afterwards the castings are washed with warm water dosed with soda to neutralize any remaining acid.

REVENUES AND EXPENSES OF RAILWAYS

MONTH OF APRIL, 1915

Name of road.	Average mileage operated during period.	Operating revenues			Operating expenses							Net operating revenue (or deficit).	Railway tax accruals.	Operating income (or loss).	Increase (or decr.) comp. with last year.
		Freight.	Passenger.	Total, inc. misc.	Maintenance: Way and structures.	Maintenance: Of equipment.	Traffic.	Transportation.	Miscellaneous.	General.	Total.				
Alabama Great Southern	309	$308,859	$71,161	$414,415	$49,750	$96,920	$10,783	$144,993	$2,689	$10,289	$308,303	$106,112	$15,156	$90,941	$48,345

Commission and Court News

INTERSTATE COMMERCE COMMISSION

The commission has issued another order, to take effect July 15, requiring that station agents receiving tariffs must note on each the date on which it was received; and must also keep a record of the date that all tariffs and supplements are received; also the date posted.

The Interstate Commerce Commission announces that after July 15 carriers must take care to make no changes in rates which have been ordered continued because the commission decides to suspend and investigate proposed new rates. Until the suspension has expired the rates, practices, etc., which are continued in effect by virtue of the suspension must not be changed in any particular.

Mixed Carload Shipments of Lime, Cement, and Plaster from Interstate to Arkansas Points

Investigation and Suspension Docket No. 554. Opinion by Commissioner Hall.

Proposed withdrawal of tariff provision under which mixed carloads of lime, cement and plaster are shipped "from interstate to Arkansas points" found not to be justified. Tariff withdrawing the provision ordered to be canceled, and carriers required to name such provision by other tariffs, upon the basis of the highest rated commodity contained in the mixture. (34 I. C. C., 124.)

Rates for Warming Potatoes Found Reasonable

Albert Miller & Company v. Northern Pacific. Opinion by Commissioner Hall:

Upon complaints alleging that defendants' rules and charges relating to the protection from cold of potatoes in transit are unreasonable and unjustly discriminatory: it is held that complainants have not shown themselves entitled to relief. Complaints dismissed. Rates 4 to 7 cents per 100 lb. for heating cars held to be fair. (34 I. C. C., 154.)

Erie Retains Chicago Water Craft

Upon applications of the Chicago & Erie and the Erie to continue their interest in and operation of certain tugboats, barges and other equipment used on the Chicago river; the commission, in an opinion by Chairman McChord, holds that the fact that the petitioners are parties to through all-rail route arrangements between the points served by the water equipment here involved makes it possible for the petitioners to compete for traffic with such water equipment within the meaning of the act; but that the service by water is being operated in the interest of the public, and that a continuance thereof will neither exclude, prevent, nor reduce competition on the route by water under consideration. The tariffs of rates applicable via this water route must be filed in accordance with the provisions of the act, to become effective by July 15, 1915.

Rates on Sugar to Arizona

Arizona Corporation Commission v. Atchison, Topeka & Santa Fe et al. Opinion by Commissioner Daniels:

The complaint attacks as unreasonable the rates on sugar and syrup in straight and mixed carloads from producing and refining points in California to all points in Arizona. Subsequent to the hearing the carriers published reduced rates on these commodities to many points of destination in the state. Except as to the rates to Phoenix and Prescott, the evidence does not show that the rates in effect, at the time of the hearing, on sugar and syrup in straight carloads, minimum weight 36,000 lb., were unreasonable to a greater extent than the amounts of the reductions since made. Rates to Phoenix and Prescott ordered to be established for the future upon a basis of not more than 5 cents per 100 lb. higher than the rates to the junction points. No finding is made as to the rates on sugar and syrup in mixed carloads. (34 I. C. C., 158.)

Ownership of San Francisco & Portland Steamship Company

Opinion by Commissioner Clark:

Upon application of the Oregon-Washington Railroad & Navigation Company for an extension of time beyond July 1, 1914, in which petitioner may continue to operate the San Francisco & Portland Steamship Company; it is held that a rail carrier does not necessarily have to reach a point in order to compete for traffic with water carriers that operate directly to that point, but such competition may exist by the rail carriers participating in joint rates. The O.-W. R. & N. does or may compete for traffic with the San Francisco & Portland Steamship Company within the meaning of the act. The operation of the steamships is in the interest of the public, and a continuance of such operation will neither exclude, prevent, nor reduce competition on the route by water. The application should be granted. All the rates and regulations of the steamship company covering traffic subject to the act moved by it in the operations considered herein must be filed with the commission and posted. (34 I. C. C., 165.)

Erie's Boats on Lake Keuka

Application of the Erie Railroad Company. Opinion by Chairman McChord:

Upon application of the Erie Railroad Company for authority to continue its interest in and operation of the Lake Keuka Navigation Company, it is held that the petitioner does not compete for traffic with the said Lake Keuka Navigation Company within the meaning of the act. The Erie Railroad owns the capital stock of the Erie Land & Improvement Company, which company in turn owns the capital stock of the Southern Tier Development Company, which company in turn owns the capital stock of the Lake Keuka Navigation Company, operating four boats serving the ports located on Lake Keuka, in the state of New York, which connect at Hammondsport with the Bath & Hammondsport Railroad, a subsidiary of the petitioner, and at Penn Yan with the central division of the Pennsylvania Railroad and with the New York Central. The navigation company furnishes the only means of transportation for the people living in the territory served. It does not appear that the rails of the petitioner, or any of its subsidiaries, serve the ports located on Lake Keuka in common with its said boats, nor does the petitioner join in through rates with other carriers reaching said ports. (34 I. C. C., 212.)

Rates to Coffeyville and Independence

Coffeyville Mercantile Company et al. v. Missouri, Kansas & Texas et al. Opinion by Commissioner Hall:

Upon reargument, it is held, that no occasion has been shown for modifying the original report and order. This case, reported in 33 I. C. C., at page 122, was reopened upon motion of the defendants and argued May 19. Complainants are wholesale and jobbing merchants at Coffeyville and Independence, Kan. In the original report the commission found that in the jobbing business they are in competition with merchants at Chanute, Parsons, Pittsburg and Fort Scott, Kan., and Kansas City, Mo., and ordered reductions to equalize with rates to Chanute and Parsons, with certain differentials. The chief objection urged by defendants to the original report of the commission is that, as alleged by them, it practically disrupts the rate fabric established in pursuance of the commission's decision in State of Kansas v. A. T. & S. F., 27 I. C. C., 673. But complainants have shown themselves entitled to relief, and such relief should not be denied simply because of the carriers' apprehension regarding the possible consequences. The readjustment tentatively suggested by defendants is manifestly beyond the scope of the present proceeding. The illustrations used to show the possible tendency of our decision herein are interesting, but seem to assume that all rates in this territory will be readjusted upon a differential basis, such differentials, apparently, being computed upon the basis of ton-mile earnings. The reports of the commission do not warrant the assumption that it has adopted such a theory. Nothing presented at the argument shows the occasion for any modification of our report and order in this case. The order requiring the establishment of the rates prescribed on or before June 15, 1915, will be left undisturbed.

Commissioner Daniels dissents. He says that the schedule of rates prescribed in this case is on the whole upon a basis lower than prescribed by the commission in State of Kansas v. A. T. & S. F., 27 I. C. C., 673, and below the scale of state prescribed rates in Missouri. While to some towns the rates reduced in the original report in this case were unjustifiably higher than to other nearby points, there is not sufficient evidence to declare the condemned rates unreasonable *per se*. Commissioner Clements also dissents. (34 I. C. C., 231.)

Southern Pacific Steamboats

Application of the Southern Pacific and the Central Pacific. Opinion by Commissioner Clark:

Upon application of the Southern Pacific Company and the Central Pacific Railway Company, under the provisions of section 5 of the act to regulate commerce as amended by the Panama Canal act, for an extension of time beyond July 1, 1914, during which petitioner may continue to operate boats on the Sacramento river and connecting waters, it is held that the Southern Pacific does not compete for traffic with its boat line; that the operation of the boat line is in the interest of the public and of advantage to the convenience and commerce of the people; that its continued operation by petitioner will neither exclude, prevent, nor reduce competition on the route by water, and that the application should be granted. The rates and regulations of the boat line governing its operations considered herein must be filed as required by the act and the regulations of the commission.

These boats engage principally in the handling of freight and passengers from and to the fruit and vegetable belt west of Sacramento, which, owing to topographical conditions, is, except to a very limited extent, inaccessible to any railroad line and is dependent almost entirely upon river service. There are six steamboats—the Apache, Modoc, Navajo, Fruto, Cherokee and Iroquois.

Fruit is shipped to Sacramento under local charges, consigned to various shipping firms and is there distributed through the medium of distributing organizations. It moves from Sacramento to eastern markets on new bills of lading, and there are no restrictions with respect to the outbound routing of shipments brought in by the boat line. In 1913, there were 149 craft of various kinds operating on the Sacramento river exclusively, and 167 operating in part on the Sacramento river and partly on other rivers, making a total of 316 boats on the Sacramento river, of which petitioner operates 6. The same report shows that for the year ended December 31, 1912, 202,015 passengers were carried by reporting lines, of which petitioner's boats carried 117,000. During the calendar year ended December 31, 1913, petitioner's boats carried 81,421 passengers. The tonnage carried by the four principal transportation companies on the Sacramento river for 1912 was 477,292 tons, of which petitioner's boats carried 109,097 tons, or a little less than one-fourth. There are several regular boat lines, also several irregular lines, in competition with that operated by petitioner. (34 I. C. C., 174.)

Rates on Hay to Chicago

Investigation and Suspension Docket No. 497. Opinion by Commissioner Hall.

Supplements to the Lowrey tariff governing switching in the Chicago, Ill., switching district, by which the Wabash proposes to discontinue its absorption of switching charges in that district on hay in carloads, allowed to become effective. Orders of suspension vacated.

The Lowrey tariff embodies an agreement between some 37 issuing and participating carriers under which they switch carload traffic, with some exceptions, to and from team tracks, industrial plants, warehouses, elevators and other points of destination or origin within the Chicago switching district therein described upon the line-haul rate to Chicago, unless that rate aggregates less than $15 for the carload, in which case the carrier receiving the line haul into or out of the switching district absorbs only so much of the switching charge of its connecting carrier as will leave it the same earning for that car as if it had received $15 for the line haul and paid the entire switching charge. More than 2,000 places in the Chicago switching district are designated by the carriers as points of origin and destination subject to the terms of this tariff.

From the inception of the agreement each issuing carrier has excepted designated commodities. Without enumerating these

it is sufficient to say that at the present time the exceptions made by the various carriers range from 2 to 16. The Wabash maintains 4, viz., coal, coke, grain and livestock, and now proposes to add hay as a fifth.

It alleges that the absorption by it of these switching charges on hay renders its transportation of that commodity to Chicago unremunerative. Records are shown of 77 shipments which originated at points in Missouri, Kansas, Oklahoma, Indiana and Ohio. The hauls averaged 267.6 miles, the rates ranged from 8 to 26 cents per 100 lb. and the average loading was about 25,000 lb. The total revenue received was $2,190, averaging $28 a car; and the total absorption paid was $676, averaging $8.79 a car, or about 31 per cent, leaving an average balance of $19.66 a car, which would yield average ton-mile earnings of 5.9 mills and car-mile earnings of 6.8 cents for the line haul. About 50 per cent of all hay transported to Chicago by the Wabash is there switched to points of delivery on the rails of other carriers.

Hay is delivered from the team tracks of the Wabash at two points only in the switching district. These are somewhat inaccessible, and consequently are not much frequented by purchasers of hay. For this reason it is difficult to sell hay from the team tracks of the Wabash in competition with that sold at points of delivery on other railroads, and hay sold at these points on the Wabash ordinarily brings from 50 cents to $1 less a ton than that sold at downtown team tracks on other lines. The commission merchants testify that, under the proposed supplements, shippers at points of origin on the Wabash will be at a disadvantage as compared with shippers on other lines in marketing their hay in Chicago and will seek other markets, such as St. Louis, Detroit and Cleveland.

The burden of proof of the reasonableness of rates increased after January 1, 1910, is upon the carriers, both as to the total or through charges and the separately established or separately stated charges which make up the total. And it is as much an increase of rate to give less service for the same amount as to charge a greater amount for the same service.

In *Board of Trade of Chicago v. A., T. & S. F.*, 29 I. C. C., 438, it was held that the failure of five carriers to absorb the switching charges on grain delivered to Chicago industries off their lines, while absorbing such charges in the cases of other commodities, did not constitute unlawful discrimination. The proposed cancellation of absorption of switching charges on sand and gravel from points in Wisconsin and Illinois to Chicago, Ill., and points in Indiana within the Chicago switching district was found to be justified. Upon the whole proof presented the respondent has justified the cancellation of the absorption of switching charges proposed by the suspended supplements. The orders of suspension will accordingly be vacated. (34 I. C. C., 150.)

STATE COMMISSIONS

The Public Utility Commissioners of New Jersey have refused to authorize the Fidelity Land Company of Beach Haven Terrace to extend a street across the track of the Barnegat & Beach Haven Railroad, declaring that it is the policy of the state to authorize no more grade crossings of steam railroads except where there shall be shown to be great public necessity.

The Texas Railroad Commission on June 1, resumed its hearing on the application of the railroads of Texas for a general advance in freight rates throughout the state. The case of the railroads was completed at the previous hearing, and this hearing was held to give shippers an opportunity to testify. Most of the shippers who testified last week said they were not opposed to an increase in revenue for the Texas roads, provided the increase be effected by an equal distribution among the different sections of the state, although some protested that the tariffs filed by the railroads would create discrimination against some sections. A series of resolutions was adopted by the shippers in attendance at the hearing that if it is the conclusion of the railroad commission that the present revenues are inadequate "then the measure of such inadequacy shall be justly apportioned over the entire state and on all classes of commodities where it can be consistently done upon some horizontal, or even percentage basis of distribution." Representatives of the railroads then presented a resolution endorsing this proposal and stating that the carriers would offer no objection to the plan, with the exception of a few items in the tariffs on which they wish to proceed with the hearing on the original plan. An agreement on these resolutions would remove from the controversy 29 of 37 subjects docketed for the hearing.

No More Temporary Doors

The New York State Public Service Commission, Second district, has refused to allow the railroads to cancel their regulation under which they supply temporary doors or bulkheads for freight cars. Tens of thousands of cars of potatoes and cabbages are annually shipped from western New York to the metropolitan markets and the practice of shipping apples and other perishable and semi-perishable produce is rapidly growing. Salt also comes under this regulation.

In an opinion by Commissioner Frank Irvine the Commission discusses at length the mechanical, economic and legal phases of the case. The present regulations were put into effect by an order of the Commission in 1909. Commissioner Irvine says that the broad question involved is whether these doors and bulkheads appertain to the car, which the carrier under common law and statute must furnish, or to the proper packing of the commodity to be shipped, which it is the duty of the shipper to supply. He finds that under a Court of Appeals decision they belong to the car. Referring to the practice of some of the western roads in equipping cars with permanent bulkheads and inside rigging, Commissioner Irvine finds that where the shippers are required to furnish this equipment for large shipments it is a total loss to them, while the railroads can recover it and use it again at small cost. Distinguishing these tariffs from dunnage allowances and lumber stakes—which the shippers must pay for—the opinion says that the latter are for a particular class or classes of shipments and are governed by particular conditions, while the demand for the equipment involved in this case is for a large general and growing class. If these equipments encourage delay in unloading through the practice of consignees in selling directly from the car the proper remedy of the roads is in demurrage and track storage charges. As to the allegation that but ten per cent. of the produce shipments are wholly intrastate and that the continuance of the allowances would be discriminatory against the roads reaching New York through New Jersey and Pennsylvania, Commissioner Irvine says that these roads have heretofore met this condition and will continue to do so. He says that recent decisions of the Interstate Commerce Commission, while not involving the exact point here involved, make use of the same reasoning and arrive at substantially similar results.

COURT NEWS

The Supreme Court of the United States has affirmed the decision of the Supreme Court of Pennsylvania against the Pennsylvania Railroad in the case of the Mitchel Coal & Coke Company, of Cambria, which had secured a verdict of $20,000 against the railroad company for alleged unlawful discrimination in the allowance of rebates.

The Supreme Court of the United States, taking a view contrary to that of the Supreme Court of Minnesota has annulled an order of the Minnesota Railroad & Warehouse Commission directing the Great Northern to install at Bertha, Minn., a platform scale for weighing livestock. It is held that the order was both arbitrary and unreasonable.

The New York State Court of Appeals, in a decision by Judge Hiscock, on a complaint by William R. Hearst, who resides on Riverside Drive, New York City, near the freight tracks of the New York Central Railroad, decides in substance that the smoke nuisance must be abated, and that the nuisances of noise due to switching of freight trains and offensive odors due to the practice of leaving cars of livestock standing a long time near residences, must be kept within reasonable bounds. The language of the opinion seems to indicate that Judge Hiscock intends not to condemn absolutely any of the practices of the road which were complained of; but only requires a high degree of care in avoiding excesses.

The New York State Court of Appeals has decided in favor of the railroad company in the suit against the New York, New Haven & Hartford to enforce an order of the Public Service Commission, Second district, annulling an advance in suburban fares made in 1910, the decision being on substantially the same grounds as those set forth in the similar suit against the New York Central, the decision in which was reported last week, page 1261.

In both of these cases the counsel for the Public Service Commission contended that the Public Service Commissions law of 1907 aimed to forbid such a review of the Public Service Commission's orders, as the orders in these cases were subjected to. Judge Cardozo dissented, in both the New York Central and the New Haven cases, but he wrote no opinion.

During the pendency of the suit the railroad has collected the higher rates, but with each sale has given thhe passenger a conditional rebate check. These checks will now become wastepaper.

Stipulation Against Riding in Car with Cattle

A contract for the shipmeut of livestock, provided that the person in charge should remain in the caboose while the train was in motion, and that a failure to do so should be prima facie evidence of negligence. It also stipulated that the responsibility of caring for the stock should be upon the person in charge. It is held by the Missouri Supreme Court that the latter stipulation did not authorize or require the person in charge to ride in the car with the stock, so as to allow a recovery by his widow for his death in a derailment while so riding. Rawlings v. St. Louis & S. F. (Mo.), 175, S. W., 935.

Crossing Accident—Contributory Negligence

In an action for personal injuries to the plaintiff it appeared that she started to walk across the tracks at a crossing in the city. Three tracks ran north and south; the one to the east being a storage track, the second a siding track, and that to the west a main single track. The plaintiff was familiar with the crossing, and testified that when she approached from the east there were coal cars standing on both the first and second tracks, close to the crossing on both sides, those on the second track being part of a train which had been separated; that before crossing each of these tracks she stopped, looked and listened, but could not see in either direction on account of the cars; that she heard nothing, except the puffing of an engine at her right (north); that as she passed over the second crossing she stooped forward to look to the northward, when she was struck by the overhang of an engine or its tender which was backing from the south. The distance between the rails of the second and main tracks was 7 ft. The Circuit Court of Appeals, second circuit, on a second appeal, held that on the evidence the question of contributory negligence was for jury, and affirmed judgment for plaintiff. New York, S. & W. v. Thierer, C. C. A., 221, Fed. 571.

Discharge of Railroad Employees—Proposed Legislation Criticized by Justices

In reply to questions put by the Senate of Massachusetts in respect to a pending bill which would prohibit railroads from discharging an employee by reason of information touching his conduct until after he has been given an opportunity to make a statement in the presence of the person furnishing the information, the justices of the Supreme Judicial Court of that state are of opinion that the proposed statute would violate the fourteenth amendment, prohibiting the state from depriving any person of life, liberty, or property, without due process of law. The right to contract, or to purchase or sell labor is part of the "liberty" guaranteed thereby. It would also violate the Massachusetts constitutional guaranties of the right to acquire, possess and protect property, which right includes the right to make reasonable contracts which will be under the protection of the law.

They consider that the proposed statute, having no reference to the safety of the traveling public, and applying only to one kind of carrier, "imposes a burden on railroads from which all other common carriers and employers are free. It singles out railroad employees and confers on them immunities and advantages enjoyed by no others who work for individuals and corporations, in a particular which has no relation to the kind of employment engaged in by them. In both respects it tends to destroy equality. It creates of railroad employees a specially privileged class, and subjects railroads, as to a matter having no special relation to their business, as distinguished from other kinds of business, to obstacles and burdens from which other employers are free. There is strong ground for the conclusion that the selection of railroads as the sole object of severely criminal legislation as to a matter having no particular relation to the management of railroads would be arbitrary and hence unwarrantable under the Constitution." *In re* Opinion of the Justices, 108 N. E., 807.

Railway Officers

Executive, Financial, Legal and Accounting

Charles A. Murray, assistant tax commissioner of the Northern Pacific, at Tacoma, Wash., has had his title changed to western tax attorney and commissioner.

Julian M. Bamberger, vice-president of the Salt Lake & Ogden, has been elected president and general manager, with headquarters at Salt Lake City, Utah, succeeding his father, Simon Bamberger, who resigned at the annual meeting. J. B. Bean, secretary and treasurer, was elected vice-president and treasurer, and E. J. Vail was elected secretary.

Operating

J. H. Nuelle, chief engineer of the New York, Ontario & Western, has been appointed also assistant general superintendent.

R. W. Howard, general manager of the New Orleans Great Northern has resigned. The duties of general manager will be performed by W. E. Farris, third vice-president, with office at New Orleans, La.

J. C. Tucker, whose appointment as assistant to the vice-president of the Erie, has previously been announced in these columns, began railway work in 1879 as a station helper on the Buffalo & Southwestern, now a part of the Erie. He became telegraph operator in 1880, and station agent in the following year. In 1883 he was transferred to the division headquarters and after six months' work there was appointed train despatcher. In 1887 he was made trainmaster, and in 1890 assistant trainmaster of the Buffalo division and branches of the Erie and of the Buffalo & Southwestern. The following year he was made trainmaster of that district. In May, 1901, Mr. Tucker was appointed superintendent of the Rochester division of the Erie, and in October of the following year superintendent of the New Jersey & New York, Greenwood Lake, Northern Railroad of New Jersey and branches, all of these being parts of the Erie. In May, 1903, he was appointed assistant superintendent of the New York division of the Erie, and in December, 1904, was made superintendent of the Alleghany division, and the following year had his authority extended over the Bradford division. He was transferred as superintendent to the Rochester division in 1907, and was made general inspector of transportation of the Erie on June 1, 1907. The following year he was made special representative on the general manager's staff and was appointed assistant to the general manager in January, 1914.

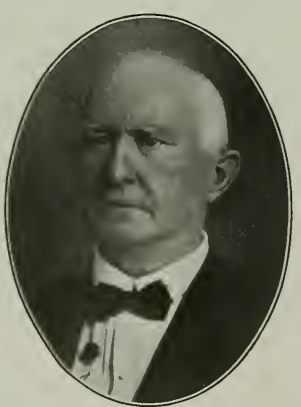
J. C. Tucker

A. A. Iams, whose appointment as superintendent of the Wellston-Delphos division of the Cincinnati, Hamilton & Dayton, with headquarters at Dayton, Ohio, has been noted in these columns, was born on January 31, 1874, at Englewood, Ohio, and received a common and high school education at that place. He entered railway service on December 15, 1890, with the Cincinnati, Hamilton & Dayton as yard clerk and operator at Dayton, Ohio, and has been with that company ever since. In 1898, he was made train despatcher at Wellston, Ohio, which position he held until 1905, when he was made chief train despatcher at the same place. In 1912, he was appointed trainmaster at Dayton, Ohio, from which position he is now promoted.

J. M. Cameron, whose appointment as general superintendent of the Alberta division of the Canadian Pacific, with headquarters at Calgary, Alta., has been announced, was born in December, 1867, and entered railway service in August, 1883, with the Canadian Pacific. He started as wiper, and was later made pumpman. He then went into the operating department as brakeman, from which position he resigned in 1888 to go with the Northern Pacific. In 1900, he re-entered the service of the Canadian Pacific as brakeman, and was soon made conductor, and later trainmaster at Nelson, B. C. He was then appointed superintendent at Moose Jaw and Medicine Hat, and on January 1, 1915, was appointed assistant general superintendent of the British Columbia division, from which position he is now promoted.

J. M. Cameron

John Charles Hagerty, who has been appointed general agent of the Baltimore & Ohio Southwestern, with headquarters at Cincinnati, Ohio, was born on May 4, 1854, at Cincinnati, Ohio. He entered railway service in 1869 with the Ohio & Mississippi as water boy, and in 1870, he worked as track laborer. He was promoted to foreman in 1872, and was employed as a switchman in 1874. Later in the same year he became a telegraph operator, having studied telegraphy at night, and in January, 1883, he was made train despatcher. He left railway service for a while, being engaged in newspaper work until March 9, 1893, when he was made chief despatcher of the Baltimore & Ohio Southwestern, which had absorbed the Ohio & Mississippi. On January 1, 1900, he was appointed trainmaster, and in October, 1904, was appointed superintendent of the Indiana division, with headquarters at Seymour, Ind., from which position he is now promoted.



J. C. Hagerty

Traffic

Alfred J. Ball has been appointed to the new position of eastern superintendent of the Empire Line of the Pennsylvania Railroad, with office at Philadelphia, Pa.

D. M. Bowman, assistant general passenger agent of the Cleveland, Cincinnati, Chicago & St. Louis, has been appointed general passenger agent, with office at Cincinnati, succeeding H. J. Rhein, resigned.

J. G. Smith, chief clerk in the general passenger office of the Missouri, Kansas & Texas of Texas, has been appointed general baggage agent, with headquarters at Dallas, Tex., succeeding W. A. Kellond, who has been transferred to Parsons, Kan., as general baggage agent of the Missouri, Kansas & Texas.

George M. Ball, manager of the Empire Line of the Pennsylvania Railroad, is to retire on June 30, under the pension regulations. The management of the Empire Line will be thereafter vested in the freight traffic manager. George M. Ball was born in Philadelphia in 1845. He began railroad work in 1868 with the Empire Transportation Company, and was made eastern superintendent of the company at Williamsport, Pa., in 1871, and was made manager of the Empire Line in 1881.

Engineering and Rolling Stock

Roy W. Bond, superintendent of shops of the Boston & Maine at Concord, N. H., has been appointed general mechanical shop inspector, with office at Boston, Mass. Mr. Bond will report to the superintendent of motive power.

G. E. Sisco, whose appointment as master mechanic of the Toledo and Marietta divisions of the Central system of the Pennsylvania Lines West, has already been announced in these columns, began railway work in June, 1901, at the Fort Wayne shops of the Pennsylvania, Fort Wayne, Ind. At the end of the summer he returned to Johns Hopkins University, graduating in 1902, and again went to the Fort Wayne shops, this time as special apprentice. He was made foreman in 1906, and in September of the same year was transferred as foreman to the Allegheny shops. In June, 1910, he was appointed assistant master mechanic at the Allegheny shops. In January, 1912, he was made assistant engineer of motive power of the Southwestern system of the Pennsylvania Lines, with office at Columbus, Ohio, holding this position until his appointment as master mechanic.

W. H. Keller, whose appointment as master mechanic of the Baltimore & Ohio Southwestern at Cincinnati, Ohio, has already been announced in these columns, began railroad work on the Baltimore & Ohio as engine wiper in 1886. In the following year he became machinist apprentice on the Baltimore & Ohio at Keyser, W. Va., serving four years. He served as machinist at Keyser, at Cumberland, Md., and Grafton, W. Va., from 1891 to 1897. In that year he was appointed foreman at Jayenn, W. Va., and was later foreman at Wiston, W. Va., general foreman at Fairmont, W. Va., and later general foreman at Storrs. In 1912 he was transferred as general foreman from Storrs to Flora, Ill., and in 1914 was appointed division foreman of the Cincinnati, Hamilton & Dayton at Dayton, Ohio. In April, 1914, he was made acting master mechanic of the Cincinnati, Hamilton & Dayton at Indianapolis, and in February, 1915, was made assistant master mechanic at Cincinnati, which position he held when appointed master mechanic for the Indianapolis division of the Baltimore & Ohio.

H. R. Carpenter, whose appointment as assistant chief engineer of the Missouri Pacific-Iron Mountain System, with headquarters at St. Louis, Mo., has been announced, was graduated from the engineering course of Yale University in 1883. He entered railway service in 1884, working as rodman in the engineering department of the Union Pacific, and remained with that company for seven years, the last three of which he was in charge of location and construction work in the west. In 1891 he entered the service of the Denver & Rio Grande, and was engineer in charge of work in Colorado, New Mexico and Utah for four years. He left railway service at this time and went into private practice in Colorado for a period of four years. He then re-entered railway service and for the next four years was chief engineer of the Colorado Springs & Cripple Creek District Railway. He again went into private practice in Colorado for two years. In February, 1905, he was appointed assistant engineer of the Missouri Pacific-Iron Mountain System, in which capacity he worked for seven years. In 1912 he was appointed engineer of maintenance of way, with headquarters at St. Louis, Mo., and remained in that position until his recent promotion.

OBITUARY

Oliver Snyder, division superintendent of the Gulf, Colorado & Santa Fe, at Cleburne, Tex., died on June 6, in that city at the age of 45 years.

Charles Howard, formerly purchasing agent of the Chicago & North Western, died in Chicago, on June 13, at the age of 77 years. Mr. Hayward was born on October 15, 1837, entered railway service in 1879 with the Chicago & North Western, and was purchasing agent for many years.

Equipment and Supplies

LOCOMOTIVE BUILDING

THE CHICAGO GREAT WESTERN has ordered 5 switching engines from the Baldwin Locomotive Works.

THE SOUTHERN RAILWAY has ordered 2 Mikado type locomotives from the Baldwin Locomotive Works.

THE RED RIVER & GULF has ordered one ten-wheel type locomotive from the Baldwin Locomotive Works.

THE LIMA LOCOMOTIVE CORPORATION has received an order for eight Mikado locomotives from the Denver & Salt Lake.

THE WACCAMAW LUMBER COMPANY, Chevy Chase, Md., has ordered one Prairie type locomotive from the Baldwin Locomotive Works.

THE BALDWIN LOCOMOTIVE COMPANY has received an order from the Russian government for 250 locomotives for shipment within six months. The total price is said to be about $6,000,000.

THE RUSSIAN GOVERNMENT, it is understood, has in addition to the order for 250 locomotives from the Baldwin Locomotive Works ordered 100 locomotives from the American Locomotive Company and 50 locomotives from the Canadian Locomotive Corporation.

CAR BUILDING

THE QUANAH, ACME & PACIFIC is making inquiries for 25 40-ton box cars.

THE NORFOLK & SOUTHERN has ordered 24 ballast cars and one parlor car from the American Car & Foundry Company.

THE CHICAGO, ROCK ISLAND & PACIFIC receivers will apply to the court for permission to buy 4,000 freight cars, and will ask the court to rule on the method of financing this purchase.

It is understood that the Russian government has closed contracts for 22,000 cars as follows: 2,000 from the American Car & Foundry Company; 7,000 from the Pressed Steel Car Company; 3,000 from the Canadian Car & Foundry Company; 2,000 from the Eastern Car Company of Canada, and 8,000 from the Seattle Car Company

SIGNALING

The New York, New Haven & Hartford has authorized an expenditure of $600,000 for the installation of automatic block signals on its line, four-track, from Stamford, Conn., westward to the New York Central connections at Woodlawn, New York City, twenty miles. The controlled manual block system is now in use on this part of the road.

NO NAMES MENTIONED.—The New York Central Passenger Bulletin (L. F. Vosburgh, G. P. A.) has the following note concerning tickets for children: "We urge our ticket agents and doormen to be particular to see that the parents or guardians traveling with children between five and twelve years of age purchase half-fare tickets, and those over twelve full-fare tickets. We won't mention any names, but some agents and doormen 'pass the buck' to the conductors, and leave to the latter the necessity of explaining the rules and making cash collections on the train. This is a bad thing to do, as it opens the way for embarrassment on the part of the conductor and passenger, which, in the interests of all concerned, should be avoided. This hint as to the exercise of greater care on the part of ticket agents and doormen, who should whenever necessary tactfully call attention to the ticket requirements, will, we feel sure, have the desired result."

Supply Trade News

The Robinson Connector Company, of Washington, D. C., is about to move its main office to 187 Church street, New Haven, Conn., where the works of the company are located.

Joseph Battle has been appointed district sales manager, with office at Denver and territory including New Mexico, Colorado, Wyoming and the western portion of Nebraska, of the Terry Steam Turbine Company, Hartford, Conn.

J. B. Evans, engineer of sales installations of the General Railway Signal Company of Canada, Ltd., Montreal, Quebec, has left that company to become general manager of the National Concrete Machinery Company, Madison, Wis.

The Industrial Works, Bay City, Mich., have discontinued their Pittsburgh office. They now have agencies in New York; St. Louis, Mo.; Birmingham, Ala.; Montreal, Canada; San Francisco, Cal.; Los Angeles, Cal., and Seattle, Wash.

Willis C. Squire & Co., recently sold and delivered three automatic track inspectors to the Chicago Great Western. This road has had one of these inspectors in service on its lines for the past four years, and additional machines are required in order that track records can be made up for all divisions of the road.

Charles E. Chinnock, formerly vice-president and general manager of the Edison United Manufacturing Company, New York, died at his home in Brooklyn on June 12, at the age of seventy. Mr. Chinnock was at one time chief electrician of the Metropolitan Telephone Company, predecessor of the New York Telephone Company.

TRADE PUBLICATIONS

GAS AND GASOLENE ENGINES.—The Chicago Pneumatic Tool Company has issued a booklet describing its class A. G. "Giant" gas and gasolene engines. The book illustrates these engines in six sizes ranging in horsepower from 16 to 130.

AIR COMPRESSORS.—Ingersoll-Rand Company has recently issued a well illustrated pamphlet descriptive of the Ingersoll-Rogler steam driven single stage straight line air compressors. The illustrations show details of the machines in sections.

LOCOMOTIVE CRANES AND GRAB BUCKETS.—The Orton & Steinbrenner Company, Chicago, has recently issued its catalog No. 11, describing in detail the different types of cranes and grab buckets, and illustrating them in a wide variety of uses. Considerable data is also given regarding the capacities of various types of cranes under different conditions.

TRACTORS.—The Knox Motors Associates, Springfield, Mass., have just published a 16-page, well illustrated booklet setting forth the principles which apply in the hauling of heavy loads by tractors. There is also a very well illustrated discussion of the Knox tractor from the engineer's point of view and a brief set of specifications of the Knox model 35 tractor.

ELIMINATING GERMAN SHAREHOLDERS.—The directors of Pintsch's Patent Lighting Company, Ltd., an English company, regarding it as essential to eliminate from the company the only remaining connection, viz., the holding by German shareholders of a portion of the capital, have decided upon voluntary liquidation, and a resolution giving effect to that decision has been passed by the shareholders. The necessary permission to form a new company has been obtained. This new company will be registered under the name of the Patent Lighting Company, Ltd., and will consist entirely of shareholders of British nationality, the direction, management and staff being entirely British, as was the case in the old company. The new company will take over the assets of the old company, which include all the patent rights, and will carry on its business without intermission, all goods supplied being of British manufacture.—*Railway Gazette.*

Railway Construction

Bayfield Transfer Railway.—This company contemplates extending its line to Cornucopia, Herbster and Port Wing, Wis., along the south shore of Lake Superior, with Superior, Wis., as the ultimate western terminal. H. C. Hale, Bayfield, Wis., is secretary and general manager.

Illinois Central.—This company has started its track elevation work between One Hundred and One Hundred and Eleventh streets, at Chicago, Ill. The paving and sewer contract has been awarded to the Contracting and Material Company, Chicago, and the general concrete contract was awarded to John J. O'Heron & Co., of Chicago. The contract for the slabs has been awarded to the C. F. Massey Co., Chicago.

Northern Pacific.—This company will lay track on a grade that was constructed last year south of Beach, N. D., a distance of 26½ miles.

RAILWAY STRUCTURES

Albuquerque, N. M.—The Atchison, Topeka & Santa Fe is installing an 800-ton Fairbanks, Morse & Company mechanical coal chute at a cost of $20,500. It has also purchased two locomotive cranes for use at this point.

Amarillo, Tex.—See Wellington, Kan.

Bloomfield, Ind.—The Illinois Central will build a bridge over the White river near Bloomfield, Ind. It will be built of 52-ft. deck plate girder spans, which are now being taken from viaducts in the Hyde Park district of Chicago. It will also have a concrete pile trestle at each end. The masonry contract has been awarded to the Widell Construction Company of Minnesota, and the rest of the work will be done by company's own forces.

Deming, N. M.—The Atchison, Topeka & Santa Fe is enlarging its fruit icing plant at this place at a cost of about $3,500.

Florence, Kan.—The Atchison, Topeka & Santa Fe is installing a Fairbanks, Morse & Company mechanical coal chute at this place at a cost of $18,500. It is also making some changes in the yard and laying some additional track which will cost about $33,000.

Nonconnah, Tenn.—The Illinois Central will build some wooden car repair shop buildings at this place. The estimated cost of these new repair shops is about $150,000. Detail plans have not yet been prepared.

Philadelphia, Pa.—An officer writes that the Pennsylvania Railroad will increase the storage capacity of the grain elevator at Girard Point. The elevator, which was finished one year ago, has a capacity of 1,100,000 bushels, and it is planned to build additional bins to hold 1,000,000 bushels.

Prescott, Ariz.—The Atchison, Topeka & Santa Fe is constructing a seven-stall brick engine house at this place. The work has been begun.

St. Paul, Minn.—In addition to the 250-ft. counter-balanced swing span of the Chicago, St. Paul, Minneapolis & Omaha bridge, noted in the *Railway Age Gazette*, June 11, there are one 70-ft., six 80-ft., one 90-ft. and one 100-ft. deck plate girder spans requiring a total of 1,150 tons of steel. The contract for fabricating the girder spans was awarded to the Chicago Bridge & Iron Works, Chicago, Ill., and for the sub-structure was awarded to Guthrie & Company, St. Paul, Minn. A total of 2,774 cu. yd. of concrete, 45,696 ft. B. M. of timber, and 6,384 lineal ft. of piling are required. The total estimated cost is $225,000.

Wellington, Kan.—The Atchison, Topeka & Santa Fe is installing 100-ft. turntables at this point and at Amarillo, Tex. The cost of each is about $13,000.

Railway Financial News

Alabama & Mississippi.—This company has leased the Pascogoula Moss Point Northern. The Pascagoula Moss Point Northern runs from Pascagoula to Evanston, 42 miles. The Alabama & Mississippi runs from Vinerga Bend, Ala., to Leaksville, Miss., 17 miles.

Chicago, Rock Island & Pacific.—The Wall Street Journal says in regard to the petition which N. L. Amster has made to intervene in the Chicago, Rock Island & Pacific receivership that: "Judge Carpenter did not formally deny the petition of N. L. Amster to intervene in the Rock Island receivership, but strongly intimated that he would."

Cincinnati, Hamilton & Dayton.—The plan for the reorganization of the Cincinnati, Indianapolis & Western, which company is controlled by the Cincinnati, Hamilton & Dayton, has been approved by the bond holders' committee, of which William A. Read is chairman. The plan provides for a new company to have $12,000,000 first mortgage, 5 per cent 50 year bonds; $7,500,000 non-accumulative preferred stock and $7,500,000 common stock. The cash requirements are estimated at $4,053,200.

Grand Trunk.—This company has sold in London, with the permission of the British government $12,500,000 five-year 5½ per cent bonds at 99.

Missouri, Kansas & Texas.—E. R. Tinker, Jr., vice-president of the Chase National Bank, New York, has been elected a director of the Missouri, Kansas & Texas, succeeding George W. Davison, vice-president of the Central Trust Company, resigned.

Missouri, Oklahoma & Gulf.—It is reported that this company has made a trackage agreement for twenty-five years with the Houston & Texas Central and St. Louis Southwestern, which will give it an entrance into Fort Worth from Denison, Tex.

New York, New Haven & Hartford.—Judge William H. Hunt in the United States District Court has handed down the ruling that John L. Billard, who was under indictment for violation of the Sherman Anti-Trust Law in connection with the transfer of the Boston & Maine stock to the Billard Company, cannot be compelled to stand trial because he is entitled to immunity because of his testimony taken at Washington in the Interstate Commerce Commission's investigation of the New York, New Haven & Hartford case.

St. Louis Southwestern.—See Missouri, Oklahoma & Gulf.

The Houston & Texas Central.—See Missouri, Oklahoma & Gulf.

The Future of the Belgian Railways.—A great deal of attention has lately been given to plans for the rebuilding of Belgium. So far there has been little talk of the future of the Belgian railways, a matter which will also have to be taken in hand. The Belgians themselves destroyed points and signals and bridges as much as possible in order to render the lines useless to the Germans. It is improbable that much further damage has been done since the German occupation, but it may be taken for granted that when the German army is forced to evacuate Belgium, it will inflict as much destruction as possible, out of vindictiveness, as well as for the purely strategic reasons that always cause a retreating army to cut the lines of communication at its rear. In addition, the aggregate financial loss due to the destruction and looting of locomotives and rolling stock must amount to a very large sum. As Belgium's industrial and commercial revival will depend on the existence of adequate means of transport, it is obvious that an appreciable proportion of such war indemnity as Germany is made to pay will have to be devoted to the restoration of the Belgian railway system. Incidentally, it would be a very practical form of indemnity if Germany were made to surrender locomotives and rolling stock of an equivalent value and amount to those looted and destroyed during the war.—*Railway Gazette.*

VOLUME 58 JUNE 25, 1915 NUMBER 26

Contents

*Illustrated.

The story of the way in which the steam railways of Chicago came to the rescue of its people in their time of need during the recent strike on the traction system of that city, is told elsewhere in this issue. It is a remarkable narrative, disclosing a reserve of public spirit and efficiency possessed by the managements of the railways, whose existence the public of Chicago never fully appreciated before. The elevated and surface street car lines, which handle millions of urban and suburban passengers daily, were all suddenly forced to suspend operations. Within a single night the suburban business of the steam railways leaped from 125,000 to 625,000 people daily, an increase of 400 per cent. A growth of business which would have been large for a period of 10 years took place in 10 hours. And yet without any of the large increases in facilities and in employees which would have been made to handle this largely increased business if its growth had come normally, the railways dealt with it with hardly any more discomfort to their patrons than is often experienced during the rush hours on many urban and suburban lines, and without a single accident. On the streets all kinds of means of transportation were being operated at whatever rates those who ran them could extort from those using them. On the other hand, the steam railways carried the business at their regular rates, and in many cases for nothing because of the impossibility of collecting all the tickets and fares on the crowded trains. Never did the managements of the steam railways of this country show greater capacity for dealing effectively with a trying and difficult situation. The ignorant braying of blatherskites regarding "inefficiency" becomes ridiculous when confronted with the record of such an achievement. The recollection of the service rendered to them during this time by the steam railways ought to be, and probably will be, long held in grateful appreciation by the people of Chicago.

A Signal Service to the People of Chicago

"Safety First" has been amplified by Mr. McCrea, general manager of the Long Island, into "Safety First, Last and Always." This is a good idea. Mr. Richards, in preaching safety-first, has always implied, if he has not distinctly said, "Celerity Second"; but it is well to remind ourselves that the existence of the second postulate does not detract from the importance of the first one. "Safety-first" is a half truth; and the automobile fiends of Long Island cannot be subdued by anything less than whole truths and in heroic doses. "Safety first, with a margin," would be another useful variation. In a lawsuit recently tried on Long Island, concerning an automobile accident, in which two rich men were killed, the lawyers laid great stress on the fact (or the claim) that the passenger train, of seven cars, which wrecked the automobile (about midnight), was unlighted, except in the three rear cars; the persons approaching the crossing were deceived as to the nearness of the approaching train. In other words, believing that they had, say, two or three hundred feet leeway, they were justified in crossing the track ahead of a rapidly advancing train! It is not to be supposed that such vicious reasoning will affect even an anti-railroad jury; but in trial by newspaper it is, probably, not without its value. Failure to allow a little margin—to be a little more than safe—is the cause of half our troubles.

Be a Little More Than Safe

For many years the railroads have been kicking about too much regulation. Of late we have heard some complaints of this nature from men engaged in other lines of business. Some shippers have been heard to criticize certain acts of the Interstate Commerce Commission as being regulation of the shipper instead of the railroad. We have recently received from the secretary of state of New Mexico a pamphlet list of titles of bills enacted by the legislature of that state, which includes the following: "An act requiring railroads operating in New Mexico to compel locomotives transporting trains to use headlights." What dire penalty is to be imposed on the refractory, or perhaps, unrefractory locomotive, for violation of the act, is not stated. And now the dear public, in whose name and often without whose knowledge all of these regulations and restrictions have been enacted, are required by the Cummins law, as interpreted by the Interstate Commerce Commission, to sign a statement of the value of baggage offered for free transportation. No one ever heard of any difficulty being experienced by a passenger in making an affidavit as to the intrinsic or sentimental worth of any bag-

Who Is Being Regulated Now

gage that happened to meet the fate for which some trunks are predestined. But now that the statement is required in advance, if only to the effect that the value does not exceed $100, or if a charge of 10 cents is made for insurance in case the baggage happens to consist of something more than a few old clothes, Vox Pop and Pro Bono Publico begin to unlimber their heavy artillery. Many people ascribe this new regulation to a fiendish desire on the part of railroad officials to multiply red tape. They do not know that it represents simply an unexpected effect of another law intended to tie the hands of the railroads, and that while in some respects it may result beneficially to the roads, in others it adds to their troubles as well as causing some inconvenience to the public. Most of those who are "peeved" by this law have never given a thought to the fact that the railroads are continually harassed and put to unnecessary expense by numberless ill-advised laws which usually do not affect and have seldom come to the knowledge of the traveling public. It all depends on who is made the goat.

VETO OF PENNSYLVANIA EXTRA CREW REPEAL BILL

THAT large majority of the people of the United States who do not belong to labor unions should ponder the significance of the action of Governor Brumbaugh of Pennsylvania in vetoing the bill to repeal the extra crew law in that state. The railways carried on an extensive and vigorous advertising and publicity campaign to get this law repealed. They demonstrated that it increased railway expenses and did not increase railway safety. The proof was so complete that public sentiment favored the law's repeal, and both houses of the legislature acted accordingly. The labor unions all over the United States supported the railway brotherhoods in bringing to bear on Governor Brumbaugh a powerful pressure for the retention of the train crew law. Their influence proved more potent than the public sentiment of Pennsylvania. After a delay of several weeks Governor Brumbaugh has vetoed the repeal bill.

The governor in his veto message expresses the view that the extra man in a train crew promotes safety. If he really believes this he writes himself down an ass. He adds that if the railway companies can demonstrate to him within the next two years that the law is not fair it will be the duty of all officials to do justly by them. There is one public official of Pennsylvania to whom it will be impossible to demonstrate this. That is the present governor. He has shown that he is one of that common garden variety of American politicians with whom facts and arguments do not count and with whom nothing has any weight except the votes that they hope to get. To all appearances organized labor convinced him that the extra crew law was a good thing by impressing on his mind the notion that organized labor controls a great many votes.

If organized labor can exercise such an unwholesome influence over legislation affecting railways it will be only a matter of time until it will be exerting a similar influence over legislation affecting other industries. Indeed, its activities in regard to railway legislation already are indirectly affecting other industries. Every law affecting railways that labor gets passed increases railway expenses and thereby tends to increase the rates which the farmers, the manufacturers, the merchants and the other business men of the country must pay. Governor Brumbaugh's veto message was a move to maintain and increase the rates which the people of Pennsylvania must pay for transportation.

Inasmuch as the business interests of the country are so vitally affected by the legislation affecting railways and other classes of concerns which is being promoted by organized labor, it is plain that the time has come for all classes of business interests to organize to do battle with the labor lobby. The strength of union labor in dealing with spineless politicians of the Brumbaugh type results from the fact that it is organized. If the farmers, the merchants, the manufacturers and the other business men of the country do not want organized labor to get a strangle hold on the governments, of the nation and all of the states which it will be almost impossible to break the business interests must organize.

There is another lesson of great importance in this Pennsylvania incident. This is that it is easier, as well as better to keep bad laws off the statute books than it is to remove them after they have been passed. While the railways of Pennsylvania were fighting for the repeal of the extra crew law the railways of Illinois were fighting to prevent the passage of a train limit law. The two campaigns were carried on with equal success, so far as public opinion and the legislatures were concerned. In Pennsylvania the legislature passed a bill to repeal the extra crew law. In Illinois the legislature refused to pass the bill to limit the length of trains. But the ultimate results are entirely different, because in Pennsylvania the railways continue to be burdened by an unreasonable statute, while in Illinois the railways entirely escaped the burden sought to be imposed upon them.

It does not seem impracticable for the railways to enlist the business men of the country in a contest with organized labor to stop the passage of all these vicious and expensive measures for the regulation of railways. In Illinois the roads were energetically supported by the Illinois Manufacturers' Association and other organizations of business men. What is more needed than all, however, is that in some way all those who are being adversely affected by foolish and vicious labor legislation should unite to fight it to the bitter end, and to put out of public life once and for all, men of the Brumbaugh type, whose servility to union labor has become a public menace. Union labor constitutes a comparatively small minority of the people of the United States, but it is showing a power altogether disproportionate to its numbers. This was illustrated by the passage of the law at the last session of Congress to relieve labor unions of the operation of the Sherman anti-trust law. It is again illustrated by Governor Brumbaugh's cowardly veto of the Pennsylvania extra crew repeal bill. Unless the business interests of the country soon bestir themselves we shall soon have a government of, for and by the labor unions. The labor lobbyist is rapidly supplanting the political boss as the arbiter of our destinies.

NEW BOOKS

University of Illinois Bulletins. Bound in paper, 5½ in. by 9 in. Published by the University of Illinois Experiment Station, Urbana, Ill.

This is volume ten of the bulletin issued by the Engineering Experiment Station of the University of Illinois, most of which are noticed from time to time in these columns. This volume contains bulletins 68 to 74 inclusive, the subject of No. 68 being The Strength of I-Beams in Flexure, while that of No. 69 is Coal Washing in Illinois, No. 70 the Mortar Making Qualities of Illinois Sand, No. 71 Tests of Bond Between Concrete and Steel, No. 72 Magnetic and Other Properties of Electrolytic Iron Melted in Vacuo, No. 73 Acoustics of Auditoriums and No. 74 The Tractive Resistance of a 28-Ton Electric Car.

Records of Railway Interests in the War. Published by the Railway News, London. 88 pages, 8 in. by 13 in. Illustrated. Price one shilling.

The Railway News has published in book form a series of interesting articles reprinted from its regular issues describing the part that the British railways have taken and are taking in the great European war. This is a part of a series devoted to the railways of various countries. Among the articles are illustrated descriptions of ambulance trains for service on the continent, articles showing the number of employees of the various railways that have enlisted, the arrangements made by the railway companies for filling the places of their employees who have gone to war, and for the care of their families during their absence. Other articles describe various ways in which the railways have been affected by the war and statements are given showing the effects of the war on their business and revenues.

Letters to the Editor

PREMIUMS FOR FREIGHT TRAIN SPEED

PITTSBURGH, Pa.

TO THE EDITOR OF THE RAILWAY AGE GAZETTE:

I see by your issue of May 7 that W. T. Lechlider, superintendent of the Cleveland division of the Baltimore & Ohio, is giving freight trainmen special credit for making good time, using those credits to offset demerits and thus clear up a man's record.

This announcement suggests a number of very interesting questions. How about personal records that do not need "clearing up"? Why not let good men make their records still better? Why has the world waited so long to see this idea of merits tried? And why should there not be something more substantial than a book entry? Are "line and surface," "condition of frogs" and the elegance of the shoulder of the roadbed to remain forever in the future (as they have been in the past) the only features of railroading in which excellent work can be rewarded by something beyond and above the figures on the payroll? Progressive superintendents have proposed premiums for trainmen—actual, substantial money premiums—long since; how is it that such enterprising men do not get more attention from higher officers? Does the old notion that it is dangerous to encourage freight men to run faster than 15 miles an hour still have a good deal of influence?

When the 16-hour rule first went into effect a bunch of crews on a certain Eastern road, who had been averaging 18 hours, on a run of about 130 miles, at once adjusted themselves to the new rule. They shortened their time 11 per cent., with no trouble at all. Are the brotherhoods forever to go on working to make train-time slow, and no improvement be made in the process or instrumentalities which should tend to make it fast?

H. S. M.

THE FLAGMAN

HAILEYVILLE, Okla.

TO THE EDITOR OF THE RAILWAY AGE GAZETTE:

The article on "the new flagman" by Mr. Daniels in the Railroad Herald, which appeared in the *Railway Age Gazette* of May 7, touches a subject on which there has been an extensive amount of discussion.

The first thing to be considered is the kind of man to employ in train service. Too much care cannot be exercised in that direction, for the reason that a man of good qualities will eventually work himself into a more important position. If he is not ambitious he is not a fit subject for employment in any capacity. That a flagman has learned the road and has passed a satisfactory examination on the book and timetable is not enough to justify putting him out to protect a passenger train, unless he has had previous experience on other roads.

Would it be advisable to put a new man out to look after the rear of a heavily loaded passenger train? Has the conductor, who will, no doubt, be busy with transportation and looking out for his train orders, time, or will he take time to see that the flagman goes back far enough and that he understands when to come in, and how to use the flagging appliances?

No man should be sent out to protect a passenger train, or any other train for that matter, who has not had some practical experience on the road on freight trains; and, more than that, an experience long enough to have taught him thoroughly the importance of flagging. The new brakeman generally wants to go to work on the rear end, and the old heads generally want the head end. This is not the place for the new man to start; he should be put on the head end and given six months or a year there, before putting him on the rear.

It is true that some of the most serious collisions have occurred while old and experienced men were flagging; but this does not weaken my argument. There has been more or less leniency shown to flagmen, as well as others. Leniency is good, but it should not be indulged in too far. It is generally conceded that the matter of flagging is not given sufficient attention. To prove it, all one has to do is to make a trip over almost any railroad and ride on the rear end and notice the performance of the flagmen. There are officers, in different capacities, going over the road every day and surely some of them see this indifference on the part of the flagmen. If you mention it to them the answer, very likely, will be, "Oh, I hate to turn in the boys; you know it's not in my department," and so on. Just let them read of a serious collision, and see how soon they will condemn the man who was responsible; while, no doubt, they have seen the same thing on their own road, time and time again, and have failed to report it to the proper officer. Who is to blame?

A man, to do a job of flagging and do it properly and safely, must understand its importance above all things. If he is allowed to go on from day to day only half doing it, but a short time will elapse until something serious will occur, and then the individual man will be held responsible, while there are others, not called to account, who are equally responsible. It is the duty of every railroad employee, regardless of his position, to make a report to the proper officer of flagmen's negligence, wherever observed. The officer in charge is then responsible for dealing with the man who has violated the rules. With all classes thus recognizing their duty there will be better flagging all over the country.

J. L. Coss.

FACTOR OF ADHESION

SCRANTON, Pa.

TO THE EDITOR OF THE RAILWAY AGE GAZETTE:

I read the original communication on the above subject by "Mechanical Engineer," and noted the later comments thereon appearing in your issue of May 7, 1915.

It seems to me that Mr. Givin has more or less side-stepped the subject, to discuss the comparative merits of various wheel arrangements. Incidentally I agree with much that he has to say. For instance, it seems to me that many roads are following the prevailing fashion in wheel arrangements for no better reason than to be considered up-to-date. Any time given to a study of their peculiar traction problems, will, in such cases, be time well spent.

The question of selecting a factor of adhesion is, beyond doubt, of very considerable importance, but, like most problems, is best worked out by individual systems. The final result, in such an event, is much more likely to be satisfactory. This result is almost sure to be the outcome of compromise. So many factors should influence a decision that only with full knowledge of conditions of topography, traffic, equipment, schedule, shop facilities, as well as financial status and general policy, can a well balanced judgment be rendered. To illustrate, a big and wealthy road, secure in possession of heavy through traffic, on high class right of way, may standardize its power to meet the varying conditions of each division. This might mean quite widely divergent types, with, among other things, extreme conditions in factor of adhesion, each type giving the best results in its own territory or service.

A less fortunate road embodying the same conditions, but with thinner traffic, fewer engines, poorer road bed and less capital, might find it advantageous to concentrate on one or two standard types of power for the sake of reducing maintenance charges. This would result in an average engine that developed its full efficiency only over certain divisions or during certain parts of a run.

Here is another concrete case. There are two high class roads running passenger trains out of New York City, and both ar-

rive at the same goal, but by different routes. The first is a straight line but mountainous, the second more circuitous but fairly level. The first road has developed a satisfactory locomotive, with comparatively small wheels and a high factor of adhesion, which gets there. On the second the wheels are high and the factor of adhesion low, or comparatively so. Both are right. To make the schedules on the level road, the small wheeled power would show an unnecessarily high cost of maintenance, while the power with the high wheels and low factor of adhesion would never in the world make running time on the hills.

Slow freight service is best served by a good high factor of adhesion. This is a matter entirely independent of type or wheel arrangement, and becomes increasingly desirable in mountainous regions. The same is true of passenger locomotives operated in the same districts, especially if the stops are frequent.

With multiple cylinders, equal results could be obtained with a lower factor, or superior traction with the same adhesion. Today 20 miles per hour for slow freight is considered the maximum economical speed, while 25 miles per hour up a 1½ per cent gradient, with eight modern steel coaches is also good time for passenger trains. With usual proportions, under normal weather conditions, and at speeds not exceeding those mentioned above, it requires a factor of adhesion approaching five to satisfactorily absorb the tractive effort.

Therefore, I conclude with some reservations, that a high factor of adhesion is desirable, except under special conditions. Some of these are: sustained high speed, approximately level country and a sufficient demand for such high speed service to keep a considerable group of power in continuous operation. This last condition predicates a railroad doing a large through passenger and fast freight business. Gordon Baxter,

Delaware, Lackawanna & Western, Scranton, Pa.

WHY COST OF OPERATION HAS DECREASED ON THE FRISCO

Springfield, Mo.

To the Editor of the Railway Age Gazette:

By taking their employees into their confidence, the officials of the St. Louis & San Francisco are obtaining wonderful results in more economical and efficient operation. The novel and heretofore unheard of proposition of the official and employee meeting in common to discuss economical operation is an innovation adopted by the latter-day officials of the Frisco; to date the results obtained are almost unbelievable. These results were not accomplished by "absent treatment," but by the laying on of hands: friendly hands that gave the grip of encouragement.

The first educational meetings were in connection with the safety first movement; these were followed by other get-together meetings, and then came the freight claim preventive movement which was described in recent issues of your journal and which promises to show a saving of $200,000 for the fiscal year. This saving would not have been possible had it not been for the responsiveness of the men and the educational features developed by the use of the freight claim preventive postal cards,* calling the officials' attention to various causes of claims that would only have to be known to them to be eliminated. These cards were sent in with the distinct understanding from the general manager that no discipline would be applied to the party at fault. By this understanding and assurance the men did not feel that they were being made "snitches" or "spotters" against each other, and the fact that the company lived up strictly to its promise inspired the men to more confidence in the officers. Today, the employee does not fear or hesitate to send in cards to his superior, calling his attention to something that should not be; and at the same time he does not feel that he is snitching on his fellow workman.

*See *Railway Age Gazette*, April 16, 1915, page 818.

At meetings of the freight claim preventive committees the proposition of ventilation and refrigeration of cars was put plainly and forcibly before the men; facts were analyzed and the men brought to realize from a dollar standpoint what improper ventilation or refrigeration meant to the company. A card was posted in each caboose, showing at just what temperature certain commodities would freeze. Instructions as to ventilation were constantly before the men on duty. The men feel that the Frisco interests are their interests. A damage to freight handled under ventilation and refrigeration can by improper care run into dollars quicker than almost any other commodity transported by freight. The men know this, and feeling toward the company as they do, claims on this character of freight were far less this winter than ever before, and during the strawberry and peach handling this summer our percentage of loss through mishandling I am sure will be the lowest ever.

A contented man is generally a courteous man, and a courteous man makes friends, and friends and good service means increased business. Therefore 25,000 contented Frisco employees means increased revenue.

That the men appreciate the treatment accorded them can be best illustrated by their action in coming to the company's assistance to obtain increased freight and passenger rates at the hands of the law makers of the various states in which the Frisco operates. Our efforts along this line were not barren of success, for in no state where the Frisco operates was a line of adverse legislation passed. In our effort to assist the company in getting an increase of rates, personal interviews in many cases were necessary with the voters that their expression of sentiments on the subject could be called to the attention of their senator and representative. To obtain these interviews, it was necessary in many cases to endure hardships; but we did not have a passenger conductor, brakeman, fireman, engineer or a man on freight, or in the shops, or offices, or on the section who hesitated one moment to drive or walk through rain and snow that he might render assistance to the company to gain for it the increased revenue. Loyalty to the railroad by its employees can only be brought about in one way, and the Frisco officials have adopted that one way.

We are being educated as to the cost of material used and handled by us, and it will not be long before the men as a whole will know the value of the goods they are handling. Knowing the cost of material used will in a great many cases decrease the amount used. A child is destructive because of lack of knowledge, and seniority and organization has kept in the employ on many a railroad men of the children's minds. If it is necessary for us to keep them let us educate them. Educate the man so he will take pride in his work, for a man who prides himself on his work is ashamed to do a poor job, and a man who is ashamed to violate the rules does not violate them. At present too much of the green trainman's education and training is left largely with the crew he happens to be with. Start them right, teach them right and they will do right.

It will only be a short time when railroads will have bureaus of employment and instruction. In the employment of men keep in mind moral character, moral stamina, and remember that high ideals are as necessary and valuable on a railroad as in any other walk of life. And, also, that it is better to put iron in a man's courage than tears in his eyes, and that personal interest means more contentment which in turn produces better work, therefore increased efficiency and more profits.

F. D. Wrightsman,
Conductor.

The Simplon Tunnel of Switzerland.—On the second Simplon tunnel, 12 miles in length, with a maximum grade of .7 per cent, 46.2 per cent of the total length has now been fully excavated on the south and north side together. During February last 6,850 cu. ft. were excavated and 4,250 cu. ft. lined with masonry on the south side. Altogether 44.4 per cent of the tunnel is now complete.

Nineteen Years' Development Work on the Santa Fe

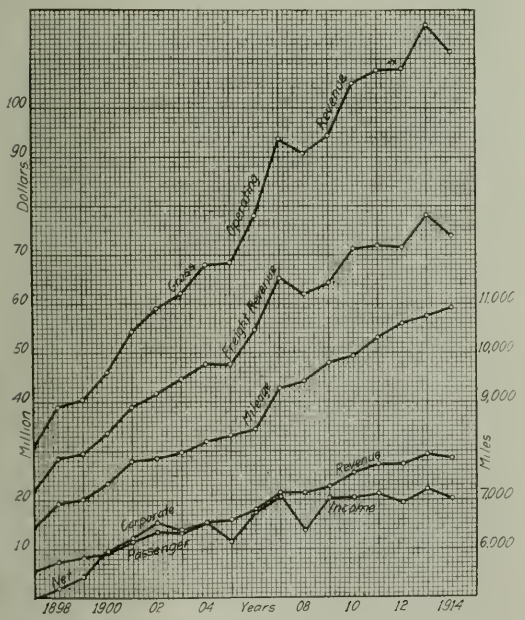
Part 2—A Description of the Various Methods Used to Build Up the Traffic and to Handle It Economically

This, the second of two articles, describes the methods by which freight and passenger traffic have been developed, the methods of operation, relations with employees and the financial results secured. The first article, which appeared in last week's issue, described the causes leading to the receivership, the condition of the property at the time of the reorganization and the policies governing expenditures for the building of extensions and for the maintenance of the property.

FREIGHT TRAFFIC

The gross operating revenues of the Santa Fe for the fiscal year previous to the reorganization were $28,814,853, or $4,446 per mile of line. Last year they had increased to $111,109,770 or $10,186 per mile of line. Thus, in this period the revenues had increased 350 per cent, while the use of the property per unit of length had more than doubled.

Referring to freight traffic only, for the fiscal year immediately preceding the reorganization the business aggregated



Relative Increases in Freight and Passenger Revenues, Corporate Income and Mileage of the Santa Fe Since 1897

1,673,407,050 ton miles, earning $19,561,659. Last year it amounted to 7,316,271,630 ton miles, earning $73,638,388. In other words the traffic increased 337 per cent in this period, while the revenue increased 276 per cent. The increase in traffic in the entire Western district in which all of the Santa Fe System is located, as reported by the Interstate Commerce Commission for the fiscal years 1896 and 1913 (the figures for 1914 not being available, but being less than those for 1913), is 276 per cent, while the revenue increased 200 per cent. Thus the traffic on the Santa Fe has increased over 20 per cent faster than the average for all the roads in this territory.

One of the principal purposes of the Strong administration in laying out the lines of the system was the development of a diversified business. The result is shown in an interesting manner by the present classification of the traffic. Fruits from California comprise 5 per cent of the total tonnage, grain from the middle west 6 per cent, livestock and products of animals from the same territory 6 per cent, ore and bullion from New Mexico 12 per cent, manufactured products mainly from Kansas City and Points east, 16 per cent, etc. This leads to relatively small fluctuations in traffic, and partially accounts for the fact that the Santa Fe is now showing an increase in business, while other roads, particularly in the east, show heavy decreases.

From a traffic standpoint the Gulf lines bear an interesting relation to the rest of the system. While originating considerable grain, cotton, lumber and other traffic, practically all of it goes to Galveston and other ports, and with the exception of lumber and a small amount of vegetables during certain seasons, the Gulf lines deliver practically no business to the remainder of the system. On the other hand, the parent lines deliver a large amount of business to the Gulf lines, including merchandise, wheat and export products.

The Santa Fe has shown itself a very strong competitor for traffic wherever it has gone. For example, 57 per cent of the total output of citrus fruits of southern California is loaded on Santa Fe tracks and 48 per cent of it is brought east by this road. This traffic alone amounted to over 20,000 cars for the Santa Fe last year. It also brought east over 2,000 cars of green fruit from the San Joaquin valley, over 2,000 cars of cantaloupes from the Rocky Ford, Colo., district and over 700 cars of apples and other fruit from Canyon City, Colo. It secures almost an equally large proportion of the wheat traffic from Kansas, while nearly one-half of all the livestock entering Kansas City is brought in by this road.

Such traffic is secured and held today primarily by service, for a road has no other inducement to offer. The high standards of maintenance of way and equipment enable the Santa Fe to give a high grade of service. Aside from regularity of operation, courteous treatment of shippers and other elements of service which are to be expected from every road, numerous special methods have been adopted to aid in securing traffic. One method which has assisted materially is that of furnishing consignees advance information regarding the arrival of shipments. This has meant the development of a complete and accurate system of car records and reports. As soon as freight is loaded at Chicago, Kansas City and other important terminals, duplicate copies of the waybills are prepared showing all information except weights and charges. These waybills are sent by United States mail to the agents at the various destinations. Ordinarily deliveries of time freight from Chicago are made at Denver on the fourth morning and at San Francisco on the tenth morning following loading.

In common with the practices on a number of other roads, passing reports are made out as the trains leave each important terminal. The special feature of the Santa Fe system consists in sending copies of these passing reports not only to the superintendent of transportation, but also to the agents at all important traffic points for which these shipments are billed. Receiving the waybills in advance of the shipments the agent at destination can ascertain the car number in which any shipment is loaded. The passing reports give him the location of the cars at any time. In this way he is able to inform a shipper when any shipment will reach him and the consignee can plan accordingly. It has been found that while the average patron desires prompt service he is more interested in securing regu-

larity of service and knowing when he may receive any definite shipment and the road which can give him this has a preferred claim on his business.

As a definite illustration of the value of such service and of the care with which it is being followed out in the regular routine, it recently became highly desirable to locate a shipment originating in Connecticut and turned over to the Santa Fe at Chicago by another road. The inquirer had only the date the shipment left the eastern factory, but in spite of the fact that the connecting line was unable to ascertain if the shipment had yet reached Chicago, within three hours it was located in a train west of Dodge City, Kan.

Another practice which has been found profitable from a traffic standpoint is that of the higher executive and operating officers making special trips over the lines with the traffic officers as often as opportunity permits, stopping for a few minutes at the various towns along the line and meeting the shippers. Many such trips have been made, and the personal contact of these officers with the present and prospective patrons has created a very friendly attitude which has been reflected in the traffic. One of the most recent trips was made over the Superior branch, late last fall, by the president, the vice-presidents, the general manager and the local officers. Similar visits are also made by the executive and operating officers to various towns on the occasion of the opening of new stations, etc. Also, the publicity agent devotes a large part of his time to calling on the patrons along the line, informing them of new improvements being made, additions to the service, etc.

From 8 to 10 demonstration trains of various kinds are operated annually through the agricultural territory in the central western states. One of the most recent was a general farming special, which was run through the state of Arizona in December, in conjunction with instructors from the state university.

PASSENGER TRAFFIC

The passenger traffic has shown as great an increase as the freight traffic. In the year preceding the reorganization the passenger revenue was $5,896,765, while last year it reached the total of $28,497,233, an increase of 383 per cent. Here, as with the freight traffic, the Santa Fe is a strong competitor, as is shown by the fact that it secures 51 per cent of the entire passenger business in and out of Kansas City, while in spite of the fact that it is the long line, it gets a very considerable portion of the business from Chicago and Kansas City to Denver. While it reaches nearly all of the important cities of the southwest, it traverses long stretches of practically unsettled country in western Texas and west of Albuquerque. Its passenger revenue per mile of road for 1914 of $2,600 is therefore high, comparing with $2,382 for the Burlington and $1,958 for the St. Paul. A considerable portion of this traffic is transcontinental business between Chicago, Kansas City and southern California, as is shown by the fact that the average length of haul per passenger is 87.5 miles, as compared with 55.5 miles for the St. Paul and 49.1 miles for the Burlington. The development of this transcontinental traffic is indicated by the fact that the average length of haul per passenger in 1896 was 68.2 miles. Five daily trains are run from Chicago to southern California throughout the year, in addition to a weekly excess fare train during the winter. The California Limited has been run in as many as eight sections this winter.

One strong asset of the passenger department which is unique on the Santa Fe is the Harvey hotel and dining car system. This company, which has a close working arrangement with the Santa Fe, operates a chain of 16 hotels at various important terminals west of Kansas City, in addition to 35 dining and lunch rooms. It also operates the Santa Fe's dining cars. The popularity of the dining rooms and hotels is such that only one train running west of Kansas City carries a dining car, all others stopping for meals at these various dining rooms. Because of the high standards of service maintained, this is an asset rather than a disadvantage in the solicitation of traffic and is instrumental in securing a considerable amount of passenger business. Another strong asset of the passenger department in soliciting transcontinental business is the location of the Grand Canyon of Arizona on its lines.

OPERATION

Having outlined the manner in which the property has been extended and improved and the traffic developed, it will be instructive to note briefly some of the details of its operation by which the net returns have been changed from a deficit of $4,433,380 in 1895 to a net corporate income of $20,183,965 last year. The operation of the property is in charge of a vice-president with supervision over the entire system, the largest mileage in this country under the direct charge of one man. The system is then subdivided into four grand divisions, the Eastern, the Western, the Gulf and the Coast Lines, with limits at Newton, Kan., Purcell, Okla., Sweetwater, Tex., and Albuquerque, N. Mex. Each grand division is in charge of a general manager, who is given broad authority to handle matters within his territory, and who has a complete staff of engineering, mechanical and operating officers assisting him.

One commonly accepted index of the efficiency with which a road is operated is the revenue freight train load. This has been increased from 115 tons for the six months ending June 30, 1896, to 364 tons for the last fiscal year, or 216 per cent in 18 years, which is highly creditable. The revenue freight train load of the St. Paul is 380 tons and the Burlington 479 tons. A comparison of the traffic of these roads shows that agricultural products form 20 per cent of the tonnage of the Santa Fe and 21.7 per cent on the St. Paul and the Burlington. Likewise, products of the mines furnished 37.3 per cent of the traffic of the Santa Fe, 25 per cent of that of the St. Paul and 40.9 per cent of that of the Burlington, while manufactured products afforded 17.6 per cent of the business of the Santa Fe, 17.5 per cent of the traffic of the St. Paul, and 15.5 per cent of that of the Burlington. Thus, in this general comparison the traffic on the three roads is quite similar and does not account for the differences in the train load.

However, the average revenue per freight train mile on the Santa Fe was $3.55 last year as compared with $3.07 on the St. Paul and $3.50 on the Burlington, indicating that there is probably a difference in the character of the traffic not shown by the general classification. This is further shown by the average revenue per ton, which was 1.007 cents on the Santa Fe, 0.8078 cents on the St. Paul and 0.729 cents on the Burlington. Also, in spite of the relatively low train load, the average operating ratio of the Santa Fe for the past five years was 66.22 as compared with 68.54 on the Burlington and 70.15 on the St. Paul. While the average rates may be somewhat higher in the Santa Fe territory than received by the other roads, this low train load is found to be caused very largely by the character of the traffic handled when it is analyzed more closely.

As stated above, fruits and vegetables comprise practically 6 per cent of the tonnage of the Santa Fe. The larger part of this traffic originates in California and is hauled to Kansas City or Chicago. Since the average haul on all traffic on the system last year was 292 miles, this fruit and vegetable traffic furnished much more than 6 per cent of the business, measured in ton-miles, and its influence on the train loading was therefore correspondingly greater. A heavy l. c. l. movement westbound to Denver and the Pacific coast also tends toward the same result. Even east of Kansas City over 75 per cent of the freight handled is time freight. West of Albuquerque so large a proportion of the traffic is of this character that frequently there is not enough dead freight to fill trains out to the time freight tonnage rating.

This expedited traffic requires rapid handling and a schedule of 8 days is maintained from Los Angeles to Chicago. The character of much of this traffic also prevents holding it at a terminal for several hours until trains can be filled out to economical

tonnage. The relatively heavy grades west of Albuquerque, over which all transcontinental freight must be hauled, and those between Albuquerque and Trinidad over which the heavy ore traffic and other business between Colorado and New Mexico points must be moved, also reduce the train loading on these districts.

Another factor tending to decrease the train loading is the necessity of running pick-up trains on the originating districts in the fruit country without regard to tonnage to save delay to this fruit. This traffic is brought into Bakersfield from the San Joaquin Valley and into San Bernardino from southern California, where it is consolidated into full trains for movement to Kansas City and Chicago. In some instances trains from the two districts are further consolidated at Barstow to give the fruit preferred movement. The fruit traffic moves most heavily during the winter months, and frequently 200 cars are forwarded from San Bernardino daily during the height of the season. However, the late summer movement is increasing from year to year, and this business now rarely falls below two train loads daily, even during the summer. An equally important condition tending towards low train loads is the large proportion of branch line mileage on which daily train service must be given, whether full tonnage is available or not. In view of these conditions adverse to heavy train loading, the revenue train load of the Santa Fe makes a very favorable comparison with that of the other western roads.

Another problem with which the operating department is confronted is the reduction of empty car mileage because of the lack of balance of the traffic. While much westbound l. c. l. and other business is loaded into refrigerator cars, it is still necessary to haul many such cars empty westbound. In the same way there is very little return loading for box cars eastbound, although it is hoped that this latter condition will be materially improved when the lumber begins to move eastbound from the country along the recently completed Northwestern Pacific lines north of San Francisco. In spite of these unfavorable conditions, 70 per cent of the revenue freight car mileage is loaded, as compared with 68 per cent on the Burlington and 74 per cent on the St. Paul.

Because of the large proportion of time freight handled, a relatively high average mileage per car per day is to be expected. For October, 1914, this figure was 33.6 miles, while it averages about 23 miles for the entire country. Because of the character of the traffic, special attention is also directed to this subject. The method of keeping track of cars in transit has been referred to previously. Another means adopted to keep cars moving is a 12-hour delay report on which is shown all cars of time or dead freight detained at any point over 12 hours. Special attention is then given these delayed cars until they are again started moving.

Contrary to general practice, the agents at the important terminals on the Santa Fe are given charge of all operations at those points. This practice exists at all terminals, except Pueblo, La Junta and Denver, and the agent has charge of yard operations, as well as traffic matters, being practically a superintendent of terminals. The combination of all duties in one officer in this way has worked out very satisfactorily.

One of the subjects which have been given a great deal of attention by the operating officers of the Santa Fe is that of the reduction of loss and damage claims. When the campaign on this subject was started five years ago, 1.6 per cent of the freight revenue went for the payment of these claims, and this was as low as the average for other roads operating in this territory. In spite of the fact that these claims have shown a distinct tendency to increase on most roads recently, the campaign conducted on the Santa Fe has resulted in a reduction in them on this road of 25 per cent. For the last six months of 1914 the proportion of freight revenues returned in payment for damage claims was reduced to the unusually low figure of 0.83 per cent. The campaign has been conducted under the supervision of a system loss and damage committee. Semi-annual meetings are held at which the sole topic for discussion by the operating and traffic officers is methods for the reduction of such claims. Similar meetings are also held on the grand divisions and on the local divisions. At the latter meetings it is common to invite certain locomotive engineers and conductors to attend. This method was described in detail in the *Railway Age Gazette* of August 7, 1914, so we will not refer further to it here.

RELATIONS WITH EMPLOYEES

Another policy of the present management has been the promotion of cordial relations with the employees. One important factor to this end has been the fixed practice of making all official appointments from among men already in the service of the road. When Mr. Ripley was given charge of the property he brought only three or four men with him, and since that time all positions have been filled by promotion from the ranks. While applications for positions are continually being received from men on other roads, the invariable reply is that the only way to secure those positions is to enter the ranks and take chances with other employees.

Retaining the proper class of employees has been a problem on all the roads operating in the southwest. For this reason, the Santa Fe has given special attention to the development of a system of reading rooms at nearly all the division points over the system, and about 25 different terminals are now equipped in this way. One man has supervision of these various reading rooms, with a separate manager in direct charge at each point. They are equipped with reading rooms, dormitories, bowling alleys, baths, etc. Various glee clubs and other entertainers present programs from time to time. Nominal charges are made for beds and for the use of the billiard tables and bowling alleys, but all other facilities are free to employees. The railroad company provides the buildings and their maintenance and operation, spending nearly $90,000 on this last year. It also co-operates in the support of three railroad Y. M. C. A.'s at places not provided with reading rooms.

A pension system similar to that of several other roads has been in force since 1907, with provision for a minimum monthly payment of $20 and a maximum of $75. On June 30, last, 346 employees were carried on this roll. Three separate hospital associations are maintained by contributions from employees, one on the Eastern and Western lines, one on the Gulf lines and the third on the Coast lines, and company hospitals are located at ten important terminals.

While not by any means confined to the Santa Fe, this road has been a strong advocate of apprentice courses in the mechanical department, adopting the system now in effect for machinist apprentices in 1908. This course covers four years. On November 30, 1914, 549 machinist apprentices were enrolled, while 865 apprentices had been graduated up to that date. A $12,000-building was completed at Shopton (Ft. Madison), Iowa, last year, with class rooms, laboratories, baths, etc., for the use of the apprentice students. A similar course lasting three years has recently been started for carpenter apprentices in the car department at Topeka and Shopton, while it is now planned to inaugurate in the near future a course whereby men may be trained for official positions in the mechanical department.

SUMMARY

Thus, in the 19 years since the receivership the property has been entirely rebuilt and improved, the mileage has increased over 70 per cent, the number of locomotives has increased over 120 per cent, while the tractive power has increased even faster and the number of freight cars has increased 150 per cent. The density of traffic has more than doubled, while the present facilities are ample to handle a considerable further increase in traffic. This has been accomplished by the expenditure of over $298,000,000, for which over $217,000,000 of "new money" has been raised. With all these improvements the capitalization per mile of line has decreased from $61,500 in 1896 to a little less than $57,000 per mile, practically 50 per cent of which is represented

by stock, while the fixed charges consume but 11.6 per cent of the gross revenue. This work has been carried on from year to year without any suggestion of irregularities, or criticism of methods of financing or operation.

RAILWAY MILEAGE OF THE WORLD

A world-wide reduction in railway construction was experienced during 1913 as compared with 1912, according to the annual railway statistics of the world compiled by Archiv fur Eisenbahnwesen, the official publication of the Royal Prussian Department of Public Works. The railway mileage of the entire world for 1913 was 684,614 miles, an increase of 15,009 miles for the year, as compared with an increase of 16,770 miles reported for 1912. The gain in mileage was also less than that for 1911, and even less than that for 1908. The increase in 1911 was 15,078 miles; in 1910, 14,387; in 1909, 14,139, and 1908, 16,672. How pre-eminently the United States is the railway nation of the world is shown by the fact that over 37 per cent of the entire mileage falls within its borders. The increase for the United States, as compiled by this publication, was 4,979 miles, or almost one-third of the entire gain for the year; while out of the entire 15,009 mile increase, 9,910 miles were contributed by the two Americas.

Railway systems of the five great geographical divisions of the earth compare in miles of operated line, as follows:

	1913.	Gain in 1913.	Gain in 1912.
Europe	214,665	2,238	2,296
North and South America	353,467	9,910	10,181
Asia	67,051	1,486	1,376
Africa	27,472	994	1,375
Australia	21,959	381	1,489
Total	684,614	15,009	16,717

Asia, it will be noted, was the only continent to show a larger increase in 1913 than in 1912.

The overwhelming leadership of the United States as a railway nation is shown more clearly in a comparison of individual countries, for after its 254,769 miles (including 653 for Alaska), Germany is second with only 39,513 miles, while European Russia is third with 38,563. Then follow in order, British East India, 34,572; France, 31,737; Canada, 29,233; Austria-Hungary, 28,641; Great Britain, 23,385; Argentina, 20,593; Mexico, 15,805; Brazil, 15,491; Italy, 10,933; Spain, 9,517; Sweden, 8,984, and Japan, 6,811.

In relative growth, however, the United States has not held its own, for while the world mileage in 5 years increased 9.6 per cent, our railways increased 7.7 per cent. This, however, exceeds Europe's growth of only 4.9 per cent. The Americas, as a whole increased 10.9 per cent in mileage in 5 years, while Asia increased only 8.8 per cent. Africa takes the leadership here with a growth of 32.3 per cent, the high spot being German East Africa, with 209.3 per cent. Australia's mileage increased 16.8 per cent.

Belgium remains at the head of the list in proportion of railway mileage to area, having 48.1 miles per 100 square miles. Next are Saxony with 34.1; Luxemburg, 32.5; Baden, 25.6; Alsace-Lorraine, 23.3; Great Britain, 19.3; all Germany, 19.0; Switzerland, 18.8; Bavaria, 18.2; Württemberg, 18.0, and Prussia, 17.5.

Though in this comparison the United States has only 7.1 miles per 100 square miles (including Alaska), many of its states are better provided than European countries. New Jersey having 30.7 miles; Massachusetts, 26.2; Pennsylvania, 25.7; Ohio, 22.4; Illinois, 21.4, etc.

Persia is still at the foot of the list with less than 1-200th mile per 100 square miles.

In relation to population, Western Australia leads the world with 72.5 miles per 10,000 inhabitants. Europe has only 4.9 miles, its best single record being Sweden with 16.4 miles. The United States, in contrast has 26.2 miles per 10,000 inhabitants. China is poorest with less than ½ mile per 10,000 population.

GOVERNOR BRUMBAUGH VETOES PENNSYLVANIA EXCESS CREW LAW

Governor Brumbaugh of Pennsylvania announced this week that he had vetoed the bill which was passed by the recent legislature to repeal the "full crew" law of that state (*Railway Age Gazette*, April 2 and May 14).

The governor, after reviewing the campaign carried on by the railroads to secure the passage of the bill, says that members of the legislature informed him they had been subjected to the pleadings of a "large and persistent lobby." The extra man required by the present law above the number willingly carried by the companies, he says, has added materially to the safety of the traveling public.

"It has been proclaimed that the loss of life since the present law became operative has been substantially reduced, if not eliminated, so far as passengers are concerned, and that this is due not so much to the manning of the passenger trains as to the fact that freight trains do not menace passenger traffic. The additional man is not always busy, but he is needed when the unusual occurs, and his presence may save life or property, or both."

Referring to the argument of the railroads that the full crew law added to the cost of operation, the governor cites the fact that the companies have within a year received increased freight rates by action of the Interstate Commerce Commission, and adds:

"They had scarcely secured the increased rate until steps were taken to repeal this law."

The governor says the railroad companies deserve fair consideration, and that if "they can demonstrate to him within the next two years that the law now in operation is not fair to them and to employees, it will be the duty of all officials to do justly by them."

President Rea of the Pennsylvania Railroad in a statement on Govenor Brumbaugh's veto of the "Extra Crew Law" repeal said:

"Speaking for the Pennsylvania Railroad Company, the most important transportation agency of our state, and with 32,000 of its 92,500 stockholders living within the state, I can only say that we are surprised and disappointed at the governor's action in vetoing the bill for the repeal of the so-called full crew law, which was passed by the legislature to correct a gross injustice to the railroads of the state and relieve them and the public of the enormous and wasteful expenditure which the extra crew law imposed on them.

"There is no well-founded reason or fact given in the veto to justify it, and, while I am entirely satisfied that the public should form its own judgment, it seems proper that particular attention should be directed to the fact that the very purpose of the bill, namely, to empower the Public Service Commission of the state to require railroad corporations to employ an adequate number of men upon their trains, is singularly ignored in the veto, notwithstanding that it practically meets every objection advanced by the government.

"The financial condition of the railroads throughout the country today is already well known, and on economic grounds alone there never has been any valid reason why they should be bound by statute to employ a stipulated number of men on passenger and freight trains irrespective of necessities or conditions. The legislature has adjourned and therefore the action of the governor in the exercise of his power has re-imposed this injustice on the public and the railroad companies for at least another two years, and places upon them an unwarrantable burden during that time of $2,700,000."

French Somaliland Railway.—According to a telegram received in Paris from the governor of French Somaliland, the railway connecting Dijibut with Adis-Abeba was completed on April 21.

Transportation in Chicago During a Traction Strike

For Three Days Steam Railroads Handle Over Six Hundred Thousand Passengers Daily Without Accident

The railroads entering Chicago made a remarkable record last week in handling an unprecedented number of passengers into and out of the business district during the strike of the motormen and conductors of the surface and elevated roads. The strike lasted from midnight on Sunday, June 13, until about 11:00 a. m., on Wednesday, June 16. During that time the surface lines operated no cars and the elevated lines made practically no attempt to carry passengers. As a result a population of about 2,500,000 was suddenly made dependent upon the steam railroads for transportation, except such as was afforded by automobiles, motorcycles, bicycles, omnibuses, motor trucks, wagons and carriages, and the steam roads were called upon over night to handle an increase of traffic which ordinarily would take years to develop.

The steam railroads normally carry about 125,000 suburban passengers daily, in addition to about 75,000 through passengers into and out of the city. During the first two days of the strike it is estimated that they handled about 625,000 a day in the suburban service, or about five times their regular business. Moreover, although this volume of traffic was thrown upon the roads almost without warning it was accommodated so successfully as to arouse general favorable comment, and without an accident of any kind being reported. In fact, after the roads had had time to adjust their facilities to the situation, several of them could easily have handled even greater crowds with success.

The steam roads entering Chicago radiate from the central business district in all directions, except toward the east. The bulk of the suburban traffic is handled by three roads, the Illinois Central running south along the lake shore; the Chicago & North Western, which has three lines out of the Chicago passenger terminal, one running directly north, one running northwest and one running west, and the Chicago, Rock Island & Pacific, running south and serving that portion of the south side lying west of the territory served by the Illinois Central. Most of the other roads also have some suburban business.

The elevated roads have one line to the south side with two branches into the territory served by the Illinois Central and one into that served by the Rock Island, and lines to the north, northwest and west, serving a territory which is reached by the North Western and other lines. The surface lines also radiate in all directions. The steam roads, of course, carry many passengers from points farther out from the city than the termini of the surface and elevated lines, and from many points they carry passengers in direct competition with the surface and elevated lines. The traction lines also carry many people from points that are beyond convenient walking distance from the steam lines, especially within a radius of three to five miles of the central district, where the steam roads are elevated and have fewer stations.

View of Crowd in Concourse of Chicago & North Western Passenger Terminal During the Monday Evening Rush

During the strike people living too near the business district to be within convenient reach of the steam road stations either walked to and from the city or patronized the hundreds of jitney busses and other vehicles that were pressed into service. From some outlying points where the distances between the steam lines are greatest many people also used vehicles of some sort to reach the steam roads.

ENORMOUS INCREASE OF TRAFFIC WITHOUT WARNING

If the roads had had definite fore-knowledge as to when the strike would begin, the achievement would have been considered less extraordinary, but they had only about six hours' notice after the strike was actually called. Conferences had been held during Sunday afternoon and evening in the mayor's office in the effort to reach a settlement and the traction companies had asked that the final decision be withheld until after a directors'

meeting on Monday. It was late in the evening when the labor leaders gave instructions to the men to leave their work. The strike had been threatened for over a week and the roads that would be called upon to handle the largest traffic had taken more or less active steps toward preparing for the emergency, but after the strike had been threatened and postponed two or three times many believed that the controversy would be settled.

Therefore, the task with which the roads were confronted presented a problem unique in their experience. The most difficult part of it was that of taking care of the Monday morning rush. Although every available car had been pressed into service there had not been sufficient time to complete arrangements. There was no way of ascertaining how big a crowd would have to be handled. Most of the regular patrons of the traction lines did not know that their usual means of transportation would be unavailable until they read their newspapers in the morning. Therefore the rush for the steam roads was concentrated into a very short space of time, and a large part of the people were unfamiliar with the steam road facilities and were without tickets, as well as being more or less panic-stricken because of their uncertainty as to whether they could be taken care of.

In addition to the inbound rush many roads were called upon to transport large numbers of people at the same time to outlying industries. Stations which normally handle two or three hundred passengers, distributed over a period of two hours, were stormed between seven and eight by thousands of people crowding to buy tickets and clamoring for information about the time of trains. Many stations did not have an adequate supply of tickets or of change, nor were there enough ticket sellers to handle them if they had been available. At stations with turnstiles or gates lines of people often extending for a block or more were formed. At others people crowded into the trains without tickets and swamped the collectors with so many cash fares that they were unable to take up all of the tickets. At some stations people had to wait as much as an hour while loaded trains passed without stopping, or if they did stop men climbed on to the roof of the coaches and the engines and tenders. On some roads whose terminal facilities were inadequate for the additional trains run there were delays on the way downtown, but the rush crowd had been taken care of by 9 o'clock.

In most cases the people were agreeably surprised to be taken care of as well as they were and the public generally accepted the situation with good nature, endeavoring to aid the roads in meeting the situation. During the day the roads were able to make more adequate arrangements. Additional equipment was obtained, additional ticket supplies were furnished, signs were posted in the stations urging the public to buy 10 or 25 ride tickets, and indicating where trains were to be found, extra ticket booths were erected and new plans were made for the handling of trains. The evening crowds, however, presented new problems because they were concentrated at the downtown terminals and on Monday there was a great deal of confusion and congestion, many people having to wait as long as an hour for trains. By Tuesday the arrangements were working smoothly, the people knew where to look for trains and were not so afraid of being left and so did not crowd so much as on the day before, and more of them had tickets. As a result there was very little congestion.

The strike was called off early Wednesday morning, but the surface and elevated lines did not get their service restored until nearly noon and the steam roads handled large numbers of extra passengers even after that time, partly because so many had purchased commutation tickets and partly because many people who had formerly used the local lines after having been introduced to the steam road service decided to continue to use that service.

ILLINOIS CENTRAL

The Illinois Central, which normally handles the largest suburban service in Chicago, about 40,000 passengers a day, competes directly with several surface car lines and also with the line of the South Side Elevated road as far south as Sixty-third street. This road naturally handled the largest crowds during the strike, as it operated the only railroad service in this territory. The Illinois Central's regular daily suburban service is 279 trains a day. During the strike it handled 311 trains in each direction, or a total of 622, and during the three days of the strike it transported a total of 678,640 passengers; 248,800 on Monday; 252,560 on Tuesday, and 177,280 on Wednesday. The officers had estimated it would be necessary to prepare for about 280,000 passengers a day. On Chicago Day during the World's Fair in 1893, the Illinois Central handled 1,000,000 passengers, but in that case arrangements had been made in advance and the traffic was fairly evenly distributed over the entire day, so that during the rush hours in the morning and evening it probably handled a larger traffic during the street car strike than in 1893. The road had made some preparations, but had not considered that a strike was seriously threatened until Sunday afternoon. The principal difficulty was in not being able to locate enough ticket sellers in time to handle the greatest rush on Monday morning. The additional force put on during the strike included 34 ticket agents, 40 ticket collectors, 20 directors, 50 engineers, 50 firemen, 30 conductors, 60 trainmen, 10 switchmen, 5 switch tenders and 15 supervising officers.

The entire movement was handled without a derailment or an engine failure. The suburban trains are operated on four tracks, of which two are used for express and two for local trains normally, but for about 60 ft. just south of the Randolph street terminal all trains must pass over a single track; therefore a derailment on this track would have resulted in very serious congestion.

The size of the regular trains was practically doubled, through coaches being used in some cases and regular schedules were abandoned. During the morning and evening rush hours, from about 7:30 to 9:00 or 9:30, trains were despatched on each of the four tracks every five minutes, making nearly one train to the minute. During the middle of the day a 15-minute schedule was maintained. Under ordinary conditions between 5 and 6 o'clock at night there are 78 distinct movements from Randolph street in one hour. In the morning many trains after arriving at Randolph street and being unloaded were backed to some of the stations nearest to the city in order to handle crowds northbound that could not be accommodated on northbound trains leaving Sixty-seventh street. Ordinarily the Illinois Central suburban service ends at 1:00 a. m., but during the strike trains were run throughout the night to accommodate night workers who ordinarily use the surface or elevated cars.

The first rush on Monday morning caused considerable congestion. At some of the principal stations the crowds were standing in long lines waiting to buy tickets. As soon as possible extra ticket sellers were placed at the various stations. During the day 40 temporary ticket booths were erected at the various stations from Randolph street south to Sixty-seventh street, and at the downtown stations a number of ticket clerks mingled with the crowds selling tickets. For express trains tickets were collected at the gate. At both the Randolph and Van Buren street stations downtown four temporary booths were erected. Large signs were placed in all the stations urging passengers to buy 10 or 25 ride tickets in order to save time and money.

An officer was placed at each suburban station to keep in touch with the situation at that point and advise the superintendent of terminals at the downtown office. These included a number of operating men and also a number of general officers. One man was stationed at Sixty-seventh street to supervise the work of turning engines to avoid delays, and another one at Randolph street.

As approximately 2,000 people are employed in the Illinois Central's general offices, most of whom use its suburban service, the offices were closed at 4 o'clock instead of 5, and opened an hour earlier than usual in the morning, so that the rush hour

traffic would not be complicated by this addition, and in the evening special trains were made up at 4 o'clock to accommodate the office forces.

CHICAGO & NORTH WESTERN

The Chicago & North Western had made some preparation in anticipation of the strike two or three days before it was actu-

Entrance to Randolph Street Terminal, Illinois Central

ally called, and had made some arrangements for having extra equipment available. On Sunday night, when it was known definitely that the strike had been called, coaches were ordered in from St. Paul, Omaha and South Dakota. The North Western normally handles about 50,000 passengers a day. On Tues-

Suburban Station During the Rush Showing Temporary Ticket Booth

day, the second day of the strike, it estimated that it handled 194,300 suburban passengers in 288 trains between 6:00 a. m. and midnight, in addition to 93 regular through trains to and from points outside the suburban district, with about 14,000 passengers. The capacity of the terminal has been estimated at 250,000. The number of trains and passengers handled on the different lines on Tuesday, is shown in the following table:

	Trains			Passengers		
	North and west	South and east	Total	North and west	South and east	Total
Milwaukee Line ...	66	72	138	46,200	45,400	91,600
Barrington Line ...	35	36	71	24,500	23,700	48,200
Galena Division	40	39	79	28,000	26,500	54,500
Totals	141	147	288	98,700	95,600	194,300

As soon as the strike appeared imminent rush orders were placed for thousands of extra tickets between the various suburban stations and Chicago, but on Monday some of the stations ran out of tickets. The most difficult rush to handle was that on Monday morning before complete preparations had been made, and on Monday evening, when a very large percentage of the passengers were still unfamiliar with the terminal. In the morning an attempt was made to adhere to the regular schedule of local and express trains, adding extra cars to trains and running the trains in sections, but by evening it was decided to abandon the regular schedules. Many trains were so fully loaded that they were obliged to omit station stops, leaving crowds waiting at the stations. From some stations trains

Increasing the Efficiency of the Tender

were loaded and rushed into the city without attempting to make other stops. Hundreds of people were carried free. On Monday afternoon the rush began about 4 o'clock, and the Chicago passenger terminal with its many entrances was jammed to its capacity. Newspaper men with counters estimated that people were entering the station at the rate of 500 per minute at 4:30. Trains were despatched as fast as they could be placed in the terminal. At times as many as 12 tracks were used for loading at once, and the rush hour crowd had been completely taken care of by 7 o'clock.

As soon as they could be printed, large signs were posted all over the station, bearing the words "Passengers, give us a little time and we will take you home." Other large signs were hung at the gates to the trainsheds showing the tracks from which the trains would leave and the stops to be made by each train. A large canvas sign was stretched across the concourse with the words "Buy your tickets now for tonight."

On Tuesday the arrangements had been so perfected that the crowds were handled without difficulty and many thousands more could have been taken care of. Outbound trains were

despatched at intervals of about 3½ minutes. The trains were made up just outside of the station ready to back in as fast as the track was cleared, with six to ten cars to a train. About 100 clerks from the general offices were sent to the passenger terminal wearing caps or badges, and each was given a series of small cards, duplicates of the placards hung at the gate to each track, showing which tracks the trains would leave from and all stops to be made. This proved a most effective plan. These men were scattered through the crowds at various points throughout the terminal and directed the passengers to the proper tracks, telling them that a train would leave at once, and were of great assistance in promoting an orderly movement of the crowd. In a balcony overlooking the trainshed and concourse a train announcer with a megaphone shouted directions for reaching the trains, and advised the people to take their time and not crowd.

Five or six extra ticket sellers were placed at the principal suburban stations during the rush hours, many of them clerks from the ticket auditor's office. At all stations within the zones within which most of the traffic is ordinarily handled by the elevated and surface lines temporary ticket booths were erected and the stations were operated on the "pay-as-you-enter" plan. These booths were placed at all stations between Chicago and Oak Park, on the Galena division, Irving Park on the Wisconsin division, and Ravenswood on the Milwaukee divison. Extra ticket sellers were on duty at the ticket windows in the terminal two at each window. Many people who had only bought single ride tickets in the morning stopped while in the terminal and bought commutation tickets in order to save time on the return trip in the evening. During the evening rush incoming trains were unloaded at the Washington street entrance to the station just outside the trainshed, so that trains were backed into the terminal empty.

On Wednesday morning the traffic was handled on regular schedules, with extra sections and extra cars.

The photograph of the crowd in the North Western terminal shown herewith was taken during the height of the rush on Monday evening before all arrangements had been perfected and before the crowds became familiar with the arrangements. This shows less than one-half of the concourse. It will be noted from the faces that can be distinguished that the crowd was accepting the situation good humoredly. The officials of the North Western have received several hundred letters commending the way in which they handled the situation, many of the people stating their intention to continue to use the North Western.

CHICAGO, ROCK ISLAND & PACIFIC

The Chicago, Rock Island & Pacific which normally handles between 15,000 and 18,000 passengers daily in its suburban service, with 39 trains each way between Chicago and Blue Island, handled over 15,000 extra passengers in each direction a day during the first two days of the strike, making a total of about 30,000 extra passengers a day. This was accomplished while adhering strictly to the regular schedule by putting extra cars on the regular trains and by operating four extra trains during the morning and evening rush hours at 15 minute intervals, between Washington Heights and Chicago, sandwiching them in between the regular trains.

The entire movement was handled by C. B. Pratt, superintendent of the Chicago terminal division. Mr. Pratt began making preparations several days before the strike was called. In the middle of the preceding week he called in a trainmaster and outlined a plan for handling the additional traffic if the strike should occur, which was carried out later in detail. It was thought that practically all of the people who were in the habit of using street cars to go into and out of the city live north of Washington Heights. One Hundred and Third street, and that the emergency could thus be met by operating extra shuttle trains between Washington Heights and Chicago. Mr. Pratt kept in touch with the situation by telephoning one of the newspapers, and about 2 o'clock, Sunday afternoon, he was told that the strike seemed to be inevitable. The cars and locomotives had been provided for and were ready at Blue Island. The extra crews were then arranged for and a trainmaster and a road foreman of engines were stationed at Blue Island all Sunday night. Monday morning four trains were started from Blue Island about 5:00 a. m. for Washington Heights and left Washington Heights for the city at 5:30 and every 15 minutes thereafter, with six cars in each train and a collector for each two cars. Three extra ticket sellers were placed on duty at the La Salle street station downtown and three at the Englewood station, and two extra men were placed in the information bureau. The plan was adhered to until after the strike had been declared off on Wednesday morning, and the entire service was operated with a maximum delay to any regular suburban train of 11 minutes on Monday and 10 minutes on Tuesday. The morning rush on Monday lasted until about 9:30, when the extra trains were taken off and placed in readiness for the outbound rush in the afternoon on storage tracks just outside the La Salle street station. There they were ready to back in for the evening rush, which began about 4 o'clock, as many offices were closed at that time.

The greatest difficulty in handling the crowds was experienced on Monday evening, but by Tuesday evening the people were handled practically without confusion. On Monday the bulk of the crowd had been taken care of, and the depot was on a normal basis by 6:30 p. m. On Tuesday the rush began about 4:30 and the station was clear by about 6:10. On Tuesday evening between 4:45 and 5:55, 22 trains of six cars each, including 10 regular trains and the 4 extra trains which made three round trips each, were backed into the station, loaded and despatched on two tracks. At an average of 100 people per car this made a total of 13,200 in a little over one hour.

On Monday morning between 7:20 and 9:00, six extra trains were run, in addition to the regular trains. On Tuesday morning seven extra trains were run during this time.

During the rush an engine was placed just outside the trainshed ready to back into the rear end of a train just as soon as it entered the station. Then the train was run out leaving the first engine, which was then backed out and placed in readiness to take out the next train. On Wednesday morning one train was despatched out loaded in just three minutes after it had arrived in the terminal loaded, and at other times trains were on their way out in from three to five minutes after their arrival. On Wednesday afternoon the Rock Island cut the extra service in two and on Thursday morning was able to handle its passengers by running eight-car instead of six-car trains on the regular schedule.

A road foreman of engines was stationed at Washington Heights, and a trainmaster at Englewood, while Mr. Pratt took charge at the La Salle street station. An extra train was placed on the track adjacent to the one on which the regular trains stood, and the gates from the concourse were thrown open long enough to let in about enough people to load the extra train. Then Mr. Pratt walked along beside the train, and if it was not fully loaded he told the gateman to let in more passengers. As soon as the extra train was despatched the gates were thrown open again for the regular train.

A count was kept of the tickets sold to inbound passengers. On Monday 9,898 tickets were sold; on Tuesday, 10,036, and on Wednesday, 6,342. A large proportion of these were commutation tickets, and most of them represent extra passengers. On Monday a great many people paid cash fares on the trains at the rate of three cents a mile. One collector reported 52 cash fares from one car, between Englewood and Chicago, which, of course, meant that a large number escaped paying fare altogether. On Monday evening large signs were posted in the stations advising people to purchase tickets in advance and save money by avoiding the necessity of paying the cash fare rate. Large placards were also hung on the ends of the

trains giving, in three-inch letters, the names of the stations at which the trains would stop, in addition to the regular train indicators in the concourse.

CHICAGO & WESTERN INDIANA

The normal suburban traffic on the Chicago & Western Indiana averages about 4,000 passengers a day, handled on 15 trains. As soon as the strike order was sent out Sunday night the operating officials were called together by the general superintendent for a conference. This lasted throughout Sunday night and arrangements were made for the operation of special trains, in addition to the regular trains at intervals of about 10 minutes during the rush hours of the morning and evening.

The men to handle these trains were got together in various ways, some were picked up in automobiles and others living nearer to the road were handled on a special train called for this purpose. The first special suburban train left the outer terminal at Dolton about 5:30 a. m., arriving at the Dearborn station about 6.10 a. m., and the special service, together with the regular trains, were operated close together without interruption until about 9:00 a. m., when the stations were all practically cleared. Trains throughout the day were run at intervals of 30 minutes to one hour.

The service was increased beginning about 4:00 p. m. to take care of the crowd homeward bound, and while the limited facilities at the Dearborn station, in most instances, prevented placing more than one train in the shed at a time, the loaded trains were pulled out and empty trains set with such regularity that the immense crowd was entirely cleared out of the station on Monday evening by 7:30 p. m., and on Tuesday evening by about 6:45 p. m.

The Chicago & Western Indiana operated in all 42 extra trains, handling at least 30,000 passengers daily, in addition to the regular traffic. While all trains were crowded, and at times the people were even held back for a short period in the concourse and waiting rooms, this unusual crowd was disposed of without great inconvenience to anyone and without accident.

CHICAGO, BURLINGTON & QUINCY

The Chicago, Burlington & Quincy, which normally handles each way between Chicago and intermediate stations to Riverside about 2,500 people per day, estimates that during the rush periods of the strike it handled each way to and from this district about 17,000 people, or 34,000 people each day, counting inbound and outbound passengers. The principal part of the rush was to intermediate stations up to and including Riverside. Beyond Riverside the additional business was handled by regular trains, all of which had some additional equipment. The rush period was between the hours of 4:30 and 6:40 p. m. Between those hours the Burlington ordinarily had 16 suburban trains leaving the Union depot. During these rush hours four additional trains were added, as that was about all the trains that could be sandwiched in between the regular trains and find track accommodations at the Union depot, where the facilities for handling a rush of that kind are somewhat limited. Inbound from Clyde and intermediate stations in the morning there were five special trains, in addition to the regular suburban trains. Additional coaches were placed on all of the 16 regular trains in the rush hours, and these with the special trains made some 75 additional cars in suburban service.

PENNSYLVANIA LINES

The Pennsylvania lines ordinarily handle but very little suburban business in the Chicago territory, but when it became known that the street car strike would probably be called at Sunday midnight, immediate arrangements were made to take care of the people employed at the several industries along the lines, as it was realized that the Pennsylvania would have to supply the means of transportation to take the place of the surface lines and elevated lines on which they usually travel. By placing additional coaches on all of the regular trains, and scheduling a number of extra trains, and making additional stops at convenient locations, all of these people were accommodated very satisfactorily. During the three days about 75 additional coaches were used and about 50 extra trains were run, carrying about 10,000 passengers, which is about four times the normal number.

There was a great crowd at the Union station in the evenings, but by giving preference to the suburban passengers, and with the assistance of the special city officers, in addition to the railroad forces, the people were handled with comparatively little confusion and absolutely no accidents.

CHICAGO, MILWAUKEE & ST. PAUL

The Chicago, Milwaukee & St. Paul does not operate a very extensive suburban business, but during the strike it operated a number of extra suburban trains into and out of an old station at Kinzie and Kingsbury streets because of the congestion in the Union Station. On Monday morning it was somewhat swamped by the unusually large number of people who tried to avail themselves of its facilities for getting down town, but by Tuesday arrangements were so perfected that the people were handled with little confusion, and during the three days the company handled about 50,000 suburban passengers.

GRAND TRUNK

For several days before, the Grand Trunk held at Elsdon several coaches in readiness for use if the strike was called. On Monday coaches were moved empty for several hundred miles in order to accommodate the suburban passengers along its lines in the southwestern part of the city. During the three days of the strike, in addition to the regular suburban trains, the Grand Trunk operated 20 special trains with an average of 8 cars per train, and handled a total of 31,331 suburban passengers. Of this total it was estimated that 24,731 had used the line on account of the absence of their usual transportation facilities. The 20 special trains handled a total of 9,403 passengers.

CHICAGO & ALTON

The Chicago & Alton handles a very small portion of the suburban traffic under normal conditions, as it serves a very limited territory of suburban homes. Since to a very considerable extent the people living in the southwest part of the city would be unable to get from their homes to their business in Chicago and back unless special service were furnished, two special trains were run in the morning from the Harrison street yard, one to Brighton Park and the other to Argo, the latter a point 13 miles out from Chicago. Return service was furnished from Argo to Chicago, leaving Argo at 5 p. m. Arrangements were also made to stop all of the regular trains at Halsted street, Thirty-first street, Thirty-seventh street, California avenue, Brighton Park, Corwith and Glenn, and the morning trains on Monday, Tuesday and Wednesday carried about 5,000 people into the city, handling as many on the returning trains on Monday and Tuesday nights.

BALTIMORE & OHIO CHICAGO TERMINAL

The Baltimore & Ohio Chicago Terminal, over which the trains of the Baltimore & Ohio, the Pere Marquette, the Chicago Great Western and the Minneapolis, St. Paul & Sault Ste. Marie enter the Chicago terminal, operates very little suburban service and has few stations within the city. The company did not anticipate that there would be a strike, and when at 7 p. m. on Sunday it received definite assurance that the strike would be called there were a great many details to be worked out. It succeeded in securing 33 coaches from various roads during the night, clerks were called out to act as collectors and a suburban train service was put into operation at 6 a. m. on Monday. It was necessary to use switch engines for this service, temporarily, at least, interfering seriously with the freight operations. On Monday this company ran 17 special trains between Forest Park on the west and Sixty-ninth street on the south and the Grand Central station. Additional coaches were also added to the suburban

trains from Chicago Heights to Chicago. The tenant trunk lines also arranged to pick up suburban traffic at various points on the line. On Tuesday 16 special trains were run. Arrangements were also made to honor B. & O. C. T. tickets on the Baltimore & Ohio trains. On Wednesday morning seven additional trains were operated. It is estimated that not less than 18,000 people were handled on these special trains between Monday morning and Wednesday morning.

WABASH

The Wabash, which uses the terminals of the Chicago & Western Indiana, normally handles about 700 people a day in suburban service. During the strike it put 10 extra coaches on its suburban trains, but did not operate any special trains. On Monday it handled 5,812 passengers; on Tuesday 5,710, and on Wednesday morning 3,308 passengers, making all regular stops between the Dearborn Station and Hamilton Park.

NEW YORK CENTRAL

The New York Central ordinarily handles comparatively little suburban service. During the strike extra trains were operated to the Union Stock Yards, both from Chicago and from Englewood, in the morning and the evening to accommodate several hundred people employed in the packing houses. The regular and through service was heavily patronized, but it was not necessary to add much extra equipment. Local and suburban trains which normally handle 4 and 5 cars were increased to 10 and 12 cars, which were very heavily loaded but which were easily handled with this company's large locomotives. Extra train collectors and ticket selling facilities were provided and the extra traffic was handled without difficulty.

THE INTERCHANGE PROBLEM IN YARD OPERATION

By E. C. Tucker

Yardmaster, Norfolk & Western, Portsmouth, Ohio.

In the operation of terminals and team track districts, economy of operation is secured by the reduction in the number of switches per car required to handle or forward each individual car. This should be considered for each car the entire time it is within the terminal superintendent's jurisdiction to get to the best results. Duplication of work is many times the cause of high terminal operating expense. It may be present in duplication of reports, records, switch movements, and many other ways.

The best aid to economy in yard operation is system. As far as practicable there should be a certain time, place and manner of performing every part of the work each day, with certain employees to perform it. If the same employees perform a certain service each day, they become familiar with every phase of that part of the work, so that it is performed in the shortest time and more correctly.

The movement of traffic between the classification terminal and the point of receipt or delivery to the connecting lines has a great influence on the terminal yard. Whenever possible advance notice of the volume of traffic expected and the approximate time it will arrive and be ready for the connecting line should be given to the connecting line officers in charge. This is especially necessary in preventing congestion on both the home line and the foreign line tracks during a period of sudden heavy movement of traffic.

Where a terminal delivers considerable or all of its traffic to several connecting lines, the cars destined to connecting lines having the greater volume of traffic should come into the terminal yard classified according to the connecting line, so that the entire cut of cars may be together in the incoming train and may be placed by the road or yard switching crew direct on the receiving track of the connecting line with practically one switch for the entire cut of cars, and within a short time after the cars arrive in the home line terminal yard.

Where there are connecting lines handling a relatively small amount of traffic the cars routed via these lines receive the best movement if they are received at the terminal yard in a joint classification, currently, to be classified after arrival, instead of being held at the distant classifying yard, waiting for a sufficient number of cars of each classification to accumulate and be forwarded. If the connecting lines averaging the smaller amounts of traffic are offered the small collections of cars at more regular intervals during the day they can more readily accept their interchange as it is offered, thus keeping each receiving line open for traffic and also reducing delays to the cars and overcoming more or less congestion in the home line terminal yard.

Usually two tracks are assigned for the traffic of each connecting line, for delivery and receipt, respectively. The receipt of cars should be considered just as important as the delivery of cars. It frequently occurs that the yardmaster will deliver cars to a connection but will fail to pull the receiving track at the same time. This is not fair to the connecting line. It causes delay to traffic routed via the home line, and additional expense of the switching crew by requiring two movements to this particular connecting line's transfer, which could have been covered by one. Before delivery is made of any cars to the connecting line some arrangement should be made to have all cars and bills checked so that correct billing is promptly delivered covering every car placed on the connecting line receiving track.

Since freight solicitors secure traffic for foreign lines as well as for the home road, the connecting line should be prompt in receiving all freight which reaches the junction point in any manifest trains. The transfer should be cleared at the proper time to receive this preference freight, sufficient interest having been taken so that arrangements are made by the connecting line not only to receive it as soon as offered, but to forward it in its manifest trains. When high class freight misses the schedule, both lines stand to lose the traffic and both lines should, therefore, work together and protect the business secured by their commercial agents.

A clear seal record should be kept, especially of the time cars are received and delivered. Both lines should be interested in securing these records as promptly after cars are set on transfers as possible. Many cars are pilfered on interchange and other tracks annually, but on account of an imperfect seal record the lost freight cannot be checked to either line, delaying the claim of the shipper and creating considerable labor in the claim department.

It is frequently noticed that one road will apparently hold a perishable shipment even though the connecting line is anxious to receive it for movement, and will fill the transfer to the connecting line, placing the perishable last in the track in an effort to compel the connecting line to receive the entire draft of cars, even though they may be unable to handle them successfully just at that time. This will usually work more harm than it does good, sometimes delaying the perishable load or manifest train, and invariably acting against any harmony in working of interchange tracks.

The handling of perishable or refrigeration shipments demands the most careful and exacting attention at interchange points. The billing should be checked for proper transportation information and the shipments themselves should be carefully examined as regards refrigeration and if additional icing is required, even though not called for by billing, the cars should be iced and that information recorded on the billing and otherwise as may be desired. No car under refrigeration should be allowed to leave the terminal until it is known to be iced sufficiently to protect the shipment to the next re-icing station, and in case of considerable distance between such stations, allowance should always be made for unforeseen delays.

Promptness in handling cars to and from transfers reduces per diem, and per diem, from a yardmaster's viewpoint, should mean a loss of earnings rather than a gain. Reduction of per diem will increase track space, which is a big item in prompt and economical handling of traffic through the yard.

Steel Passenger Equipment for the Union Pacific

Includes Dining, Baggage-Buffet, Chair, Baggage, and Postal Cars of Arch Roof Type; I-Beam Center Sills Used

The Union Pacific has, during the past year, added to its equipment a large number of all-steel cars for passenger train service. These cars were built by the Pullman Company and include dining, combination baggage-buffet, chair, baggage and postal cars and coaches.

The dining cars are 72 ft. 6 in. long over the end sills and 80 ft. 5 in. long over the platforms when coupled. They are mounted on six-wheel trucks with 11-ft. wheel base, the wheel base of the car being 67 ft. 9½ in. The weight of the car, complete, is about 148,000 lb., and there is seating capacity for 30 passengers.

The combination baggage and buffet cars are 75 ft. long over the end sills and are mounted on six-wheel trucks; the total wheel base of the car is 67 ft. 9½ in. The seating capacity is 28, and the weight of the car ready for service is about 139,000 lb. The bodies of the chair cars and the coaches are the same, the length over end sills being 70 ft., the length over platforms when coupled, 77 ft. 11 in., and the wheel base 65 ft. 3½ in. These cars are also mounted on six-wheel trucks and the weight of the car complete is about 138,000 lb. Some of these cars are equipped with a smoking room in one end, in which case the seating capacity of the chair cars is 70, while without the smoking room it is 72; when equipped with a smoking room the coaches have a seating capacity of 82, and this is

Arrangement of the Frame Members in the Body and Ends; Union Pacific Steel Dining Car

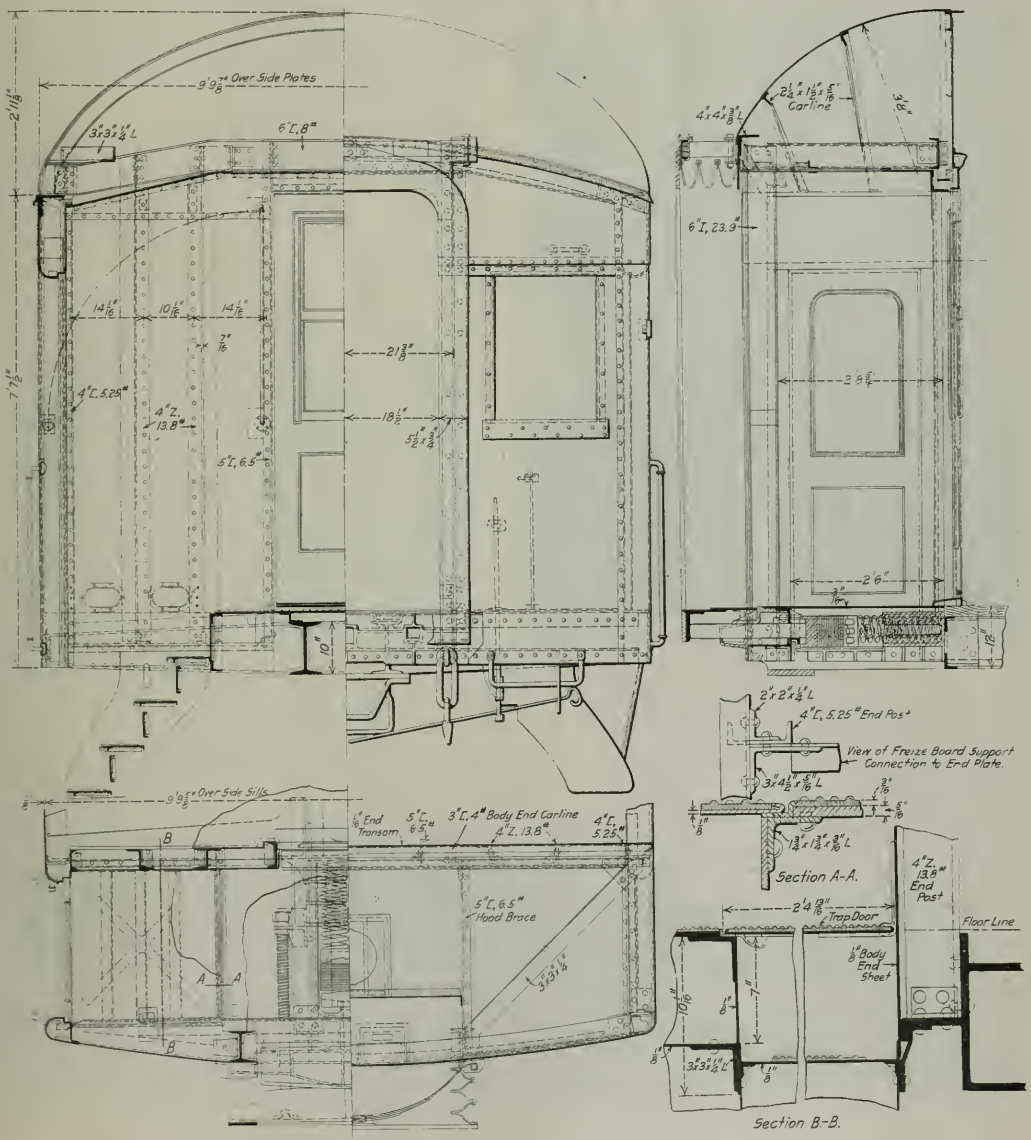
changed to 84 in the case of a car without a smoking room.

The baggage cars are 69 ft. 07/8 in. long over end sills, 71 ft. 11 in. long over the platforms when coupled, and have a wheel base of 64 ft. 07/8 in. They are mounted on four-wheel trucks and weigh about 106,000 lb. The postal cars are 60 ft. 1½ in. long over end sills, 63 ft. long over the platforms, with a wheel base of 55 ft. 1½ in. These cars weigh about 111,600 lb. The design of the six-wheel and four-wheel trucks is the same for all of the cars on which they are used.

The arch type of roof is used in all of this equipment, the suction type of ventilator being employed, the ventilation being satisfactory in every way. As the type of construction is similar in all of the cars, the framing for the dining car alone is shown in the illustrations.

UNDERFRAME

The center sills consist of two 15-in., 60-lb., I-beams placed at 16 in. centers and extending between the platform end sills. A 22 in. by ¼ in. top cover plate is used and the sills are given ⅜ in. camber. The body bolsters are steel castings; there are three cross bearers employed between the bolsters. The distance between truck centers is 56 ft. 8 11/16 in. Two sets of diagonal braces consisting of 4-in., 5.25-lb., channels are placed between



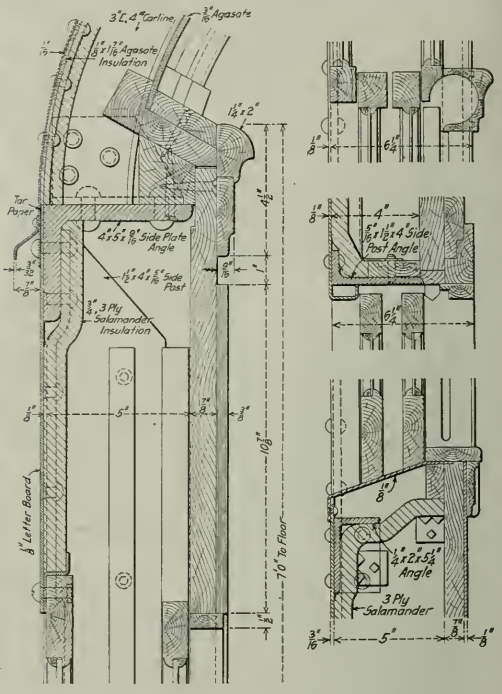
Platform and Vestibule Construction; Union Pacific Steel Dining Car

the center and side sills, and channels of the same size and weight are also used to support the floor stringers, which are 2½-in. by 2-in. by ¼-in. angles. The side sills are 3½-in. by 8-in. angles, a 3/16-in. plate being riveted to the side sill and to the belt rail, which is a ¼-in. by 2-in. by ¾-in. angle with the

Interior of Union Pacific Reclining Chair Car

2-in. leg on top, to which is riveted a 3/16-in. by 1⅜-in. by 2-in. angle. The 3/16 in. steel sheathing extends to a point just above the connection between the two belt rail angles, and ⅛-in. sheathing is used on the car body above this point.

posts consisting of 4-in., 13.8-lb., Z-bars. The vestibule door posts are 6-in., 23.9-lb., I-beams, braced at the top to the body corner posts by 3-in. by 3-in. by ¼-in. angles, while a 6-in.,



Some of the Dining Car Construction Details

8-lb., channel forms the vestibule end plate. The end sheathing of the car body is ⅛ in. thick.

FLOOR AND INTERIOR FINISH

Above the floor stringers is placed .04 in. galvanized iron, above which is a layer of ¾-in. Magnesite. Next to this is a

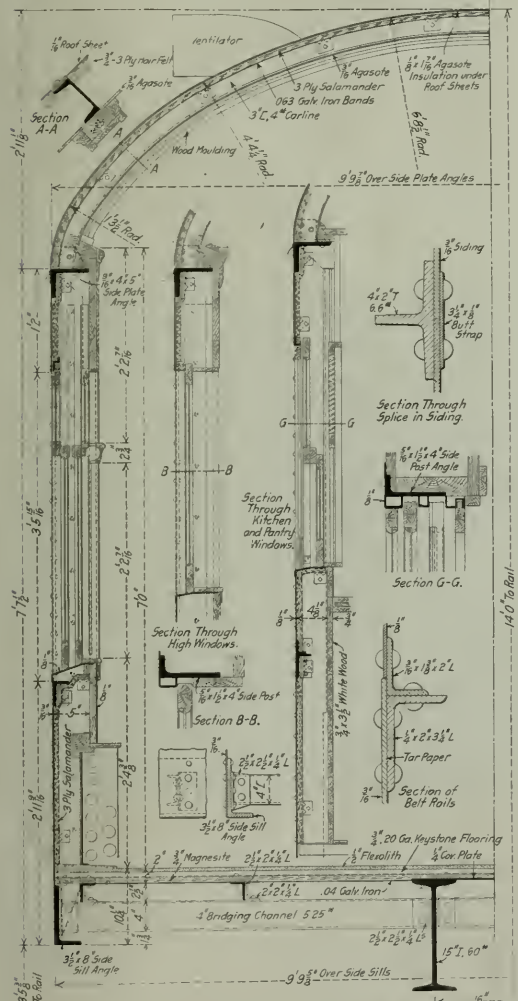
Union Pacific Steel Baggage and Express Car

BODY AND END FRAMING

The body side posts are 4-in. by 1½-in. by 5/16-in. angles and the side plate is a 4-in. by 5-in. by 9/16-in. angle. The carlines are 3-in., 4-lb., channels extending through between the side plates, and the end plate is a 4-in. by 2¼-in. by ⅜-in. angle. The body corner posts are 4-in., 5.25-lb., channels and the door posts are 5-in., 6.5-lb., channels, there being two intermediate

layer of ¾-in., No. 20 gage Keystone flooring, above which is placed the final flooring, which is ½ in. Flexolith. Three-ply Salamander insulation is applied to the inside of the steel sheathing and the interior finish and the window frames is of mahogany. Mahogany is also used in the baggage-buffet cars, but the interior finish of the chair cars and coaches is steel. The headlining is 3/16 in. Agasote.

The special equipment used includes New York air brake equipment, Chicago Car Heating Company's vapor system, Commonwealth cast steel truck frames, Creco brakebeams, Pitt couplers, Sessions friction draft gear, Waugh-Forsyth buffing device, Acme vestibule diaphragms, Utility ventilators, Transportation Utilities Company's window fixtures, National trap doors, Hale & Kilburn seats, Adams & Westlake's sanitary bubbling water fountains and white metal washstands, Duner flush closets, Johns-Manville Salamander hair felt insulation, Key-



Cross Sections of the Dining Car

stone floors, Rausch bag racks in the postal cars, Edison storage batteries and Gould axle lighting generators.

The following table gives some of the principal dimensions of the dining car:

Length over end sills	72 ft. 6 in.
Length over platforms, coupled	80 ft. 5 in.
Distance center of bolster to end sill	7 ft. 10¼ in.
Wheel base of car	67 ft. 9½ in.
Wheel base of truck	11 ft. 0 in.
Width over side sills	9 ft. 9⅝ in.
Width over side plates	9 ft. 9⅞ in.
Width over-all at eaves	9 ft. 11⅞ in.
Height top of rail to underside of side sills	3 ft. 3⅜ in.
Height top of rail to top of platform	4 ft. 3½ in.
Height top of rail to outer side of roof sheets	14 ft. 0 in.
Seating capacity	30

CENSORSHIP OF RAILWAY MESSAGES*

By W. W. Hall

Superintendent of Telegraph, Missouri, Kansas & Texas

I have for years been trying to eliminate unnecessary telegraphing. Requiring the managers of the offices to send in those messages which, in their opinion, contain superfluous words has not proved very successful. In August, 1912, I tried using symbol letters and file numbers in telegrams, according to a plan which had been used on the Santa Fe; and I issued a circular to agents and to others concerned, asking them to put a letter and a number at the end of every message, thus saving words in the reply. Each agent or officer was also called on to number his messages from 1 up to 999. At the same time an effort was made to have messages sent by train whenever practicable; and finally the vice-president in charge of operation authorized me to employ a telegraph censor. Offices were called upon to send in a whole day's business and the messages were carefully examined. Using a stereotyped form of letter proved unsatisfactory, and it was found best to dictate a separate letter in every case. Some departments resented this action of the telegraph department; but to these I got the vice-president to send letters, signed with his own name. This at once produced astonishing results; everyone began to wake up to the fact that there was a real campaign on to reduce telegraphing. Some of the heads of departments were displeased, but we are still sending some of these letters to the vice-president's office for signature.

A telegraph code is very useful, but most codes are too voluminous. We have one, adapted from one in use on the New York Central, containing less than 200 cipher words. With this code, in connection with the use of the file number and letter, we have reduced our telegraphing about 50 per cent. If I were to make a new code I would abandon the attempt to have the cipher word suggest the meaning of the sentence which it represents. A code should consist of uncommon English words of not over five letters.

Besides reducing the number of messages the messages are much shorter, and recently I have found operators handling 85 messages an hour. Many of these messages consisted only of a symbol letter, file number and two or three additional words.

The practice of using special envelopes for sending telegrams by train—envelopes marked "MAILGRAM"—is abused; the envelopes will be used for such a variety of letters that they fail to command respect. On the M. K. & T. a more systematic plan has been adopted. At important offices all messages filed after 4 p. m. are written and filed in duplicate, and where these messages can reach destination by mail before 9 o'clock the next morning the original is sent forward, in an envelope, the messages being numbered and all for one place being put in one envelope addressed to the manager of the telegraph office. A telegram is sent to him giving the numbers of messages to be expected on a given train, and this he acknowledges. Receiving the telegrams, he delivers them in the usual manner, and many of the recipients never notice but what the message came by wire. There may be some objection to leaving it to the discretion of the telegraph manager to send telegrams by train, but in more than a year we have had only a few complaints on this ground. The telegraph department assumes responsibility for the delivery of the messages. If the envelope should be carried by the telegraph manager would at once report the fact; and in such case the sending office, having the duplicates, sends them by wire. In more than a year we have had only five cases where messages were carried by.

Large numbers of reports covering the movement of fast

*Abstract of a paper read before the annual meeting of the Association of Railway Telegraph Superintendents at Rochester, N. Y., June 22.

freight, formerly sent by wire, are now sent by train. This policy is followed at all offices within a radius of 400 miles of headquarters.

THE VALUE OF PUBLICITY FOR RAILROADS*

By Oswald Garrison Villard
President of the New York Evening Post

As the son of a railroad president, the completer of a great transcontinental line [the Northern Pacific] it gives me much pleasure to address this gathering of railroad men. I was but 11 years old when it was my good fortune to travel on one section of the first through train between St. Paul, Minn., and Portland, Oregon; but nothing in all my life stands out more clearly than the events of that wonderful journey. That was a triumphal progress which was celebrated in every town along the line. Ours were honors rarely accorded even to a President, or a conqueror returning from the scene of his victory. No hamlet so humble but had its decorations and its parade. No state but offered its official hospitalities to the men who had forged that iron bond between East and West, who had conquered apparently insuperable barriers. It was the birth of an empire that we celebrated and those that officiated thereat were welcomed as among the greatest benefactors of their times. I dwell upon this occurrence of 32 years ago not to blow the trumpet for the men who did this wonderful thing, but to recall to your minds what was the attitude of the public towards railroad men in that day. How rapidly the scene changed! Within a decade everybody had forgotten all that acclaim and praise and all the promises of everlasting gratitude. We began to hear murmurings from press and public that all was not well; then came suspicion and accusation. Next a torrent of abuse and lo! we had swung directly to the opposite extreme and the railroad man had become a public enemy.

Now it is undeniable that the railroads themselves were in large part responsible for this revolution; not only because some of them have even until this date stuck to practices never in themselves justifiable, but also because they failed to realize that all our business conditions were undergoing a sea-change; that the day of unlimited freedom from governmental control was at an end and that the era of regulation, for better or for worse, was at hand. . . .

It is not my purpose to award praise and blame for all that has gone on during these years of tribulation. I am merely here to urge upon you one remedy for existing conditions, one already partly tried and found successful, but one that has only just begun to do its beneficial and efficacious work. That remedy is publicity. From my double point of view of an editor and as one who grew up in an atmosphere of great railroad achievements, that seems to me the truest and best way to right wrongs and to end intolerable conditions.

Primarily, of course, publicity can be of value to the railroads only if they have nothing to conceal. The railroad manager who would profit by wise publicity must believe in it sincerely and then be perfectly willing to let daylight play upon any part of his and his company's activities. This presupposes the abandonment of the old secret chamber and the old method of affecting public opinion through controlled newspapers and the influencing of public officials, legally or illegally, properly or improperly. . . .

It was not only from the common legislative striker that the railroads suffered. There is even one historic case where a President of the United States demanded free transportation by special train across the continent for himself, his official following, and a large party of newspaper men carried with him to exploit his triumphal tour. In this trip some $75,000 of the stockholders' money was paid out because the railroad did not have the good sense and the nerve to say no to some of the demands of its guest, or to go to Congress and demand reimbursement. . . .

The value of the advertising columns has been as little understood as the legitimate opportunities offered by the editorial and news pages. Such clever advertising as "Phoebe Snow" has appeared only occasionally.

A railroad which advertised with us withdrew its advertising when we faithfully reported the complete breakdown of its service one cold winter. . . . The obvious procedure, if our statements were untrue, was to have called us publicly to account, either through the courts of law or by demanding that the railroad's case be printed in full; or if we refused, then in newspapers of much larger circulation, or by inserting advertisements setting forth the facts. But the railroad sought refuge in silence and alienated its patrons by a refusal to give them information to which they were clearly entitled.

Very satisfactory has been the change by some railroads from the old-fashioned press agent, often merely a lobbyist and go-between, to so able and useful a type as Ivy L. Lee, long connected with the Pennsylvania Railroad, whom it was always a pleasure for editors to see. Even more striking evidence of the change in railroad sentiment has been the advertising campaign conducted in various states against the two-cent fare law and the outrageous extra-crew statutes. If those campaigns were not as successful as they should have been, the policy is none the less the correct one. Incidentally, the railroads have discovered that they have, themselves, enormous opportunities for legitimate publicity which they have never heretofore utilized, such as dining car bills of fare, the usual advertising folders, timetables, and the station bulletin boards. Unquestionably the use of these has had considerable to do with the marked improvement in the relations of railroads and the public and the courts, now so striking as to make it possible to say that the current of popular opinion has again begun to run in the railroad's direction. Even more striking is the campaign for fair play which has been carried on by President Elliott, of the New Haven Railroad since he took up his present task. I have never been able to understand why railroads that were playing the game squarely have not each taken a man like Mr. Lee, made him vice-president, and told him to do nothing else than to be a link between the press, the public and the railroad. If a high official were to appear occasionally at the small towns along the road and make friendships among the business men and show the railroad's interest in that town, and its desire to co-operate and to give a better and better service, there would speedily be stored up a reservoir of good-will and friendliness upon which the railroads could draw large drafts in time of need. Such a man would find that honest editors are not inaccessible, that they do not want to be dined or wined or kow-towed to, but that they can be influenced by the railroads precisely as anybody else can influence them and get their support, namely, by the presentation of facts and arguments. If such an official could not convert editors he could not convert the public. It is gratifying to record that other railroads beside the New Haven are beginning to move along these lines.

The railroads need the newspapers not only for protection against unjust laws, but because they are the best possible defense against the growing danger of labor-union aggrandizement on the one hand and government encroachments on the other. Few newspapers, like the Evening Post, are non-union; hence they are themselves deeply sympathetic sufferers at the hands of labor union extortionists, save where, as in New Orleans, they have at the risk of their existences and at a very heavy cost, thrown off the yoke. The railroads should realize that the newspapers of conscience and character are their chief allies, just as they should know that the greater the freedom and the independence in criticism which a newspaper shows the better it can serve their just interests. The public knows a mealy-mouthed organ, afraid to say its soul is its own, and cares little about its opinion. One has only to consider the agitation for government ownership now going on to realize the vital necessity that exists that the relations of the railroad and the newspaper should be put on the highest possible plane of mutual good-will, respect, and honorable co-operation.

*Extracts from an address before the 37th Semi-Annual Dinner of the American Railway Guild, New York City, May 18.

The Julian Train Control and Automatic Stop

A Description of the Demonstration Made on the Queen & Crescent and of the Equipment Required

The first public demonstration of the automatic train control and cab signal system of the Julian-Beggs Signal Company, Terre Haute, Ind., was given on the Queen & Crescent on May 18, to officers of that road and a number of invited guests. The demonstration also covered the speed control system which this company has developed, an installation on the private car of General Manager H. Baker being used for this test. The speed control system was described in the *Railway Age Gazette* of March 16, 1915.

As mentioned in the previous article, the speed control instrument is belt-connected to an axle. It has a series of contact segments arranged for any desired series of predetermined speeds, and a dial switch, on which is set the desired limiting speed. A series of platinum points are moved up and down over the contact segments by the piston of the recorder, which is raised as the speed increases. As these platinum points rise above the segment corresponding to the speed indicated on the dial switch, the normally closed cir-

Speed Recorder on the Locomotive

cuit through a solenoid magnet holding closed a valve in the air-brake train line or in a connection from the equalizing tank is broken, allowing this valve to open and the air to escape to the atmosphere, thereby setting the brakes. As the speed of the train is reduced the platinum points again make contact with the segments, completing the circuit, energizing the magnet, and closing the air valve.

The train control and cab signal system utilizes a similar speed recorder and air valve in connection with a roadside contactor and a third rail to control the speed of the train automatically, depending on the condition of the track ahead, and also to give the enginemen distinctive clear, caution and stop signals in the cab. This system, as developed at present, requires the following equipment: On the locomotive, a 12-volt storage battery, three standard relays, a light-signal with three lenses, a speed recorder mounted on the pilot and belted to one of the axles of the front truck, an electro-pneumatic valve connected in the air brake line from the equalizing tank, a push-button release for closing the engine circuit after the train has been stopped, a commutator on the reverse lever to change the wiring connection when the engine is to be run backward, and an armored conduit with the necessary junction boxes, for connecting the wiring on the cab to the tender; on the tender, two curved shoes attached to the journal boxes of the forward truck on each side, and mechanical circuit breakers with horizontal arms, also attached to the truck on each side; and on the roadside, a contactor box attached to the ends of the ties on each side of the track; one rail, about 6 ft. long, about 2 ft. outside the running rail and supported by brackets on the ends of the ties at a proper height to engage the circuit breakers on the tender; a 16-volt battery at the signal location, and the necessary line wire and trunking to connect the battery, the track relay and the track contactor box.

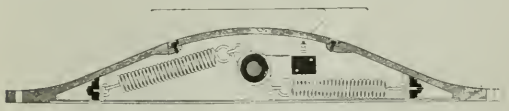
The section between Erlanger, Ky., and Crittenden, 18 miles, on which this train control system is installed, is equipped with three-position, a.c. upper-quadrant automatic block signals, controlled by three-position, polarized track relays. As these relays have one contact which was not in use, it was utilized for the control of the cab signal and automatic stop system. While this is a double-track line, only the southbound track is equipped with this system, 18 blocks being installed. The track contactors are located about 600 ft. north of (in the rear of) the signals in each case in order to allow an engine running at the caution speed to be stopped automatically by the device before passing a stop signal.

The complete circuits on the roadside and on the engine and tender are shown in the accompanying sketch. In the position shown, the engine is approaching a proceed signal, two blocks in advance being unoccupied. When the engine shoe strikes the track contactor the circuit is completed from the roadside battery through the front contact of the track relay, the track contactor, engine shoe and coil of the clear relay, to ground. This picks up the clear relay, completing a stick circuit from the engine battery through the two circuit breakers, the first back contact on the caution relay, the first front contact on the clear relay and the coils of this relay, to ground. Current can then flow from the engine battery through the second front contact of the clear relay, the upper contact segment on the speed recorder, the dial finger moving over this segment, the solenoid actuating the air valve, and back to ground.

The length of the contact segment can be adjusted for any desired speed, 48 miles being used on the Q. & C. installation. As soon as the speed exceeds this rate, the dial finger passes off the end of the segment, the circuit is broken and the brakes are applied through the de-energizing of the air valve magnet. As soon as the speed has been decreased to a point below a specified limit, the circuit is again completed, and the brakes released. After passing a clear signal and until the next track location is reached, the white light burns, as it is included in a circuit from the engine battery through the third front contact of the clear relay, to ground.

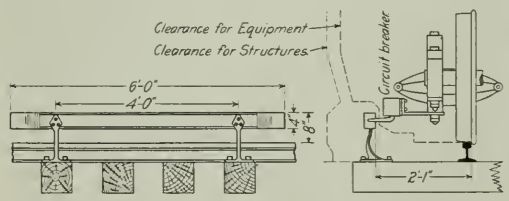
The function of the third rails, not shown in the wiring diagram, is to break the holding circuit on the engine by engaging the horizontal arm of one of the circuit breakers, shown above the engine shoes. The breaking of this circuit de-energizes any relay that may be energized at the time, and puts out any of the lights that may be burning. This prevents any indication from being carried improperly into the next block without the proper control from that block. If

the next two blocks are clear after the circuit is broken, the circuits previously described are again established and the train continues at full speed. If, however, only one block in advance is clear and the signal 600 ft. ahead is at caution, the polarized track relay will be reversed, allowing current from the roadside battery to flow through the back contact of the track relay, the track contactor on the opposite side, the engine shoe, the coils of the caution relay, and back to ground. The pick-up of the caution relay closes a stick circuit from the engine battery, through the two circuit breakers, the first



Sectional View of Track Contactor

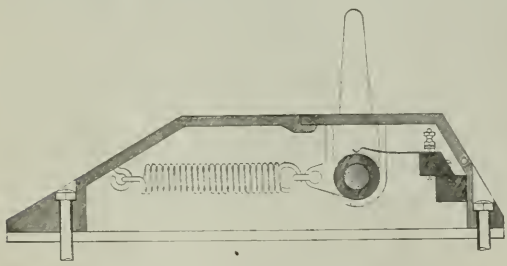
front contact and the coils of the caution relay and back to ground. Until this circuit is broken by the next third rail, therefore, current flows from the engine battery through the second back contact of the clear relay, the second front contact of the caution relay, the second contact segment on the speed recorder, the dial finger, air valve solenoid, and to ground. The length of this contact segment is adjusted for the desired caution speed, which in this installation is 25



Side and End Elevations of Contact Rail

miles an hour. If that speed is exceeded, the brakes are automatically set; and again released as soon as the speed has decreased below that rate. Also throughout this block the green light burns, being in a circuit from the engine battery through the third back contact of the clear relay and the third front contact of the caution relay.

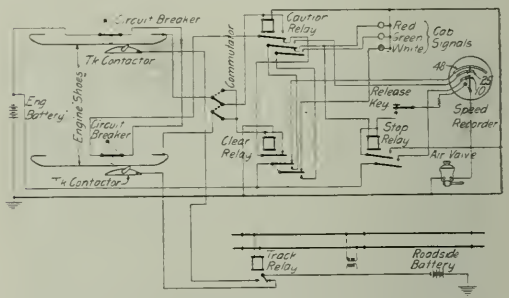
When the train approaches a stop signal, the block ahead being occupied, the engine circuits are broken by the circuit breaker as described above, and as the track relay is de-



Circuit Breaker Mounted on Tender Truck

energized, the circuit from roadside battery to engine cannot be completed when the engine shoes pass over the track contactors. This de-energizes the solenoid holding the air valve closed, exhausts air and applies the brakes; and as there is no circuit through the speed recorder, the train is brought to a full stop. When it has stopped, the dial hands on the speed recorder will have made contact with the fourth segment, allowing the circuit through the air-valve solenoid to be closed by operating the release key. In this case the current flows from the engine battery through the second back contact of the clear relay and the second back contact of the caution relay, the coils of the stop relay, release key, speed recorder, air valve magnet, and to ground. As soon as the stop relay is picked up by closing the release key, the stick circuit through the coils and the first front contact of this relay is completed, and also the circuit from battery through second front contact of the stop relay and the third contact segment on the speed recorder. This segment is arranged to allow a speed of 10 miles an hour until the next indication is received.

The air valve in this system, which has been worked out in connection with the Westinghouse Air Brake Company, has an opening of 3/8 in. to the atmosphere, causing a reduction of brake line pressure of 12 lb. to 15 lb. An auxiliary or pilot valve has also been developed for use on a freight locomotive, or in a caboose in connection with the speed control system, having a maximum opening of 1¼ in., which, however, by a manual valve in the head, can be reduced to secure the desired opening for use on shorter trains. In this valve



Track and Engine Circuits, Julian Train Control System

the electro-pneumatic pilot valve controls a balanced type air-controlled valve opening the air line.

In the demonstration referred to above, a special train was run from Ludlow, Ky., to Williamstown, and return, the train control system being in operation between Erlanger and Crittenden, 18 miles, and the speed control system being demonstrated over the remainder of the run. A freight engine with two cars was sent ahead of the special train with orders to stop at intervals, and the special was run as close to it as possible under the control of the automatic system. The system operated correctly in every instance. The party included H. Baker, general manager, Queen & Crescent; W. S. Andrews, general superintendent of transportation; W. T. Caldwell, superintendent; C. E. Rickey, superintendent of terminals; W. H. Dooley, superintendent of motive power; D. M. Case, superintendent of signals; C. F. Jones, supervisor of signals, and W. S. Melton, superintendent of telegraph; John E. Beggs, president of the Julian-Beggs Signal Company; M. R. Julian, the inventor, and M. H. Hovey, the company's signal engineer.

New Railway Lines in Belgium.—It is reported from Amsterdam that at many places the Germans are constructing new railway lines. A new line has been laid from Aix-la-Chapelle through the Belgian village of Wonck, in the Jeker valley, with the object of giving further railway access to Brussels. This line crosses the Maas near Visé. The line from Selzaete to Moerbeke is to be double tracked and probably also the Selzaete-Eecloo-Bruges line.

Some Important Considerations in Right of Way Valuation

A Discussion of the Principles of Valuation That Should Govern in the Selection of Right of Way Multiples

By Halbert P. Gillette
Consulting Engineer, New York, N. Y.

Ever since the decision in the Minnesota rate case there has been concern among railway officials and appraisers over the apparent exclusion of right of way multiples. For the purpose of this discussion we may define a right of way multiple as the factor by which the ordinary selling price per acre of land must be multiplied to get the acreage price paid for it when taken for public use under the exercise of the right of eminent domain. The use of a right of way multiple, therefore, is a convenient method of estimating severance damages, special value for railway purposes, etc., and it may even be taken to include overhead costs involved in securing the right of way.

The testimony in favor of right of way multiples failed to convince Justice Hughes. I believe it failed for two reasons: First, because a "right of way multiple" was treated, and even spoken of, as a "hold up factor"—a sort of piratical tax which, as Justice Hughes said, should not be recognized in a court even though it may exist as a fact; second, because the whole theory of reproduction cost of right of way was based on an untenable hypothesis, involving the absurdity of assuming the existing railway to be non-existent in order to conceive the cost of buying the existing right of way.

My object in this paper is to outline briefly a tenable theory of right of way valuation that can not be criticized adversely without abandoning all existing theories of commercial valuation. To do this I will first discuss the fundamental theory of land values. Then I will show how the general theory can be simplified for ordinary application to railway right of way valuation. Finally I will outline the elements of value that go to make a right of way multiple.

The value of land is the capitalized prospective ground rental derivable from it. Ground rental is measured by the economic advantage in position and in mineral and other marketable content of the given land, contrasted with land that barely pays operating expenses. Since the days of Ricardo there has been no serious dispute on this economic generalization. All land and all land entitles, such as coal, natural gas, water, etc., can be valued in no other way than by capitalizing the excess of their income over that obtainable from land that yields nothing in excess of actual operating expense plus fixed charges on the buildings and plant. Once this fact is clearly grasped, the proper methods of determining the value of land and land entitles become evident.

It may he said that the best test of land value is the price at which it sells in an open market. This is ordinarily true where there are frequent sales in a market and where the land is sold for the use under consideration. But even in such a case the sales are based on capitalized prospective rental, so that, in the final analysis, we come back to land income as the basis of land value.

In a very interesting pamphlet entitled The Valuation of Railroad Right of Way, Frank W. Stevens, special counsel for the New York Central, offers some suggestive thoughts as to the special value that attaches to right of way. He also cites many court decisions showing that land taken by condemnation must be valued upon its most advantageous prospective use. Two facts seem to be legally established: (1) That land may have a *special value* for particular purposes (such as reservoir sites, rights of way, etc.) and that this special value is recoverable by the owner where the condemnation occurs. (2) The consequential damages to the owner are also recoverable.

Let me first indicate how the value of land for special purposes is ascertainable. The following rules are perfectly general, and apply equally to a reservoir site, a railway right of way, a farm, or a city lot:

(1) For a given use the value of a given piece of land, A, exceeds that of the next available piece of land, B, by the capitalized difference in their respective *net earnings* after deducting therefrom the interest, depreciation and taxes on the buildings and plant used in production, as applied to that use.

Expressed algebraically this rule is:

$$V - v = \frac{(G - E) - (g - e) - (F + f)}{r}$$

In which V and v = values of the two land parcels.
G and g = gross earnings of same.
E and e = operating expense.
F and f = fixed charges (interest, depreciation and taxes) on buildings.
r = interest rate suitable to express normal return.

(2) If the gross earnings of the two pieces of land, A and B, are identical, then the value of A exceeds B by the capitalized difference in their respective *operating expenses* after deducting therefrom the interest, depreciation and taxes on the buildings and plant used in production; or

$$V - v = \frac{e - E - (F + f)}{r}$$

(3) If the gross earnings and investment in buildings and plant are identical for A and B, then the value of A exceeds B by the capitalized difference in their respective operating expenses; or

$$V - v = \frac{e - E}{r}$$

(4) If the gross earnings, the investment in buildings and plants, and the operating expenses for A and B are identical, then the value of A equals the value of B, or the *value* of an owned piece of land, A, is ascertainable by determining the *cost* of securing an alternative piece of land, B; or V = v.

As I conceive it, this last rule (4) is the one that a railway should ordinarily seek to apply in measuring the value of the right of way that it owns. Yet no such rule was presented to the Supreme Court in the Minnesota rate cases. Instead, the court was asked to conceive the existing railway plant as nonexistent and then to conceive what it would cost to *reproduce the existing* right of way. Confronted with such an impossible hypothesis Justice Hughes said:

"Moreover, it is manifest that an attempt to estimate what would be the actual cost of acquiring the right of way, if the railroad were not there, *is to indulge in mere speculation.* . . . The values of property along its line largely depends on its existence. It is an integral part of the communal life. *The assumption of its non-existence,* and at the same time that the values that rest upon it remain unchanged, *is impossible* and cannot be entertained."

Here we have an admirable illustration of the losing of an important point in a case almost entirely as a result of an incorrect theory of valuation. Suppose, instead of presenting to the court the hypothesis of non-existence of the railway, the court had been asked to consider the probable cost of securing right of way for a railway parallel to the existing railway, could the court have rejected such a proposition as "mere speculation" or "impossible"? The facts are that many a right of way has

been purchased under just such conditions, hence the assumption is not speculative or impossible. Moreover the test of *value* of A that is had by ascertaining the *cost* of securing an alternative, B, is a test that every man is accustomed to apply. The man who is intending to buy a city house and lot applies such a test repeatedly. Our rule (4) above given, is precisely such a test of value, as, in fact, are also the more general rules (1), (2) and (3).

If we approach the question of right of way value from this logical point of view, we can show at once that not only must there be paid the farm acreage price for farm land contiguous to the existing railway, but a considerable sum in addition to cover consequential damages. Also it can be then shown that land purchased at "retail," in small parcels, such as are bought for right of way, costs more per acre than land purchased "wholesale," as in buying an entire farm. Picturing, then, the process of buying a right of way approximately parallel to the existing right of way, we see at once that the following elements affect the purchase price:

(1) Severance damages resulting from the severance of associated parcels of land that can be more economically operated as a whole than in segments.

(2) Incidental damages resulting from noise, smoke, shutting off of view, etc., as a result of building a railway near places of habitation and business.

(3) Loss of income to the land owner during the period required for him to move to a new site and to establish a business equal to that lost as a result of being compelled to move.

After the purchase of the right of way is effected there comes not only the cost of removing existing buildings, but the loss of value of these buildings which were paid for by the railway. Where right of way is purchased through urban and suburban property, it is not merely the value of bare land that is involved, but also that of buildings and improvements. Although this is quite evident the moment we adopt the theory of testing the value of an existing right of way, A, by estimating the probable cost of a parallel right of way, B, it is not evident when the theory of wiping out the existing railway is adopted.

To sum up, a proper right of way multiple must provide not only for all consequential damages to the owner of the property, but must also provide for the value of buildings and improvements and the cost of removing them from the right of way.

I agree with Mr. Stevens that a railway right of way possesses value because of its superior economic location. There really can be no question on this point. Wellington's entire book on the economics of railway location is an exposition of the value of a given location as determined by capitalizing the profits securable from it. Part of the differences in value between different locations is attributable to the skill of the locating engineer, but the largest part is inherent in the topography and the productive character of the country. The question for the courts to decide is this: To whom belongs the right of way value due to its superior economic location? Is it the property of the public or the property of the railway? The value of the right of way is deducible by the rules above given.

Right of way values are analogous to water right values, particularly in that both depend largely upon topography. In deciding adversely to the contention that water rights possessed value for rate-making, it was held by the lower courts in California that capitalizing profits to ascertain value of water rights constituted circular reasoning, and water right values thus ascertained were therefore rejected. But the United States Supreme Court has recently reversed this decision, holding that water rights must be valued and included in the total value used as a rate making base. I see no cardinal difference between such a decision and one that would affirm that a railway is entitled to all the special value that inheres in its right of way by virtue of its economic location. Water rights possess value because of their economic location, and if this value is to be considered as part of a rate making value, wherein does it differ in principle from allowing a similar value due to the economic location of a railway right of way? If there is a difference, and if an economic railway location of right of way has no special value to be allowed in rate making, what becomes of the logic of the decisions relating to special value cited by Justice Hughes in his Minnesota decision? In fact what real meaning is there in his own language when he says:

"If, in the case of any such owner, his property had a *peculiar value or special adaptation for railroad purposes,* that would be an element to be considered."

There can be no "peculiar value or special adaptation for railroad purposes," except a value based on the capitalized excess net income securable with the given right of way as compared with some alternative right of way. Therefore, if we properly interpret the decisions of the Supreme Court itself, we find ample justification for applying rules (1) to (4) above given.

When railway and public service commissions assert that it is always untenable to establish any sort of value for rate making by capitalizing any sort of income, they go directly counter not only to court decisions but to their own decisions in every case where *land* value is involved. What, indeed, is the acreage value of a farm if it is not capitalized income? Yet the same commission that unhesitatingly allows a right of way value based on farm acreage price, will contend that it never capitalizes any income in establishing a rate making value, because that would involve circular reasoning!

Brooks Adams, in the Spokane Rate Case, unsuccessfully attempted to prove that every railway company has been a trustee or agent, and as such should be held accountable for all past transactions. Not only has the Interstate Commerce Commission rejected this theory of *past* agency relationship, but so has the Supreme Court. Justice Hughes was particularly emphatic on the point when he said:

"As the company may not be protected in its actual investment, if the value of its property be plainly less, so the making of a just return for the use of the property involves recognition of its fair value if it be more than its cost. The [railroad] property is held in *private ownership*, and it is that property, and not the original cost of it, of which the owner may not be deprived without due process of law."

Had the agency theory been sustained, the actual cost of right of way and not its present value would have been prescribed. The instant the agency theory as to past relations is thrown out, there remains no other way to appraise right of way than as private property owned by the railway. This would inevitably result in giving to a railway the full special value inherent in its lands as essential parts of an economic transportation plant.

EDUCATING THE PUBLIC TO BUY TICKETS

The Illinois Central and the Yazoo & Mississippi Valley are conducting a campaign to secure the co-operation of the public in purchasing tickets before boarding trains, to eliminate the practice of paying fares on trains. Some time ago a pamphlet was issued by T. J. Foley, general manager, addressed to the people of Mississippi, giving the reasons why the convenience of the entire public would be best served if people would take pains to purchase tickets beforehand. On June 1, Mr. Foley issued a circular addressed to all agents and passenger conductors on this subject, as follows:

"When it can reasonably be avoided, passengers should not be permitted to get on trains without tickets. One of the principal reasons that some passengers continue paying fare on the train is because it is an "old custom," not because it is more convenient for them.

"Collecting cash fares, consulting tariff book, making change and issuing receipts for fares detracts the attention of the conductor from very responsible duties; therefore, it is better for the passenger, for the employees and for the railroad companies to work out a system whereby passengers will no more think

of getting on a train without a ticket than they do of going into a theater, circus, baseball game or many other places without a ticket.

"Beginning June 1, 1915, these companies will inaugurate a thorough campaign to secure the co-operation of the public so that, after they have decided to make a trip, their first thought will be to reach the station in time to provide themselves with tickets. There are some points where a ticket agent is not located; other places where ticket agent is not on duty for night trains, and there will also be extreme cases where a passenger reaches the station at the last minute to board a train which it would not be advisable to delay long enough to enable passenger to purchase a ticket. In such cases it will, of course, be necessary to make collection on the train.

"It is fully appreciated by the management that it will take considerable time and patience to impress upon the patrons and also upon employees, that in nearly every case the "old custom" of paying fare on trains instead of at ticket office can be eliminated.

"With the hearty co-operation of agents and trainmen, these companies have been able to overcome many undesirable practices, such as excessive loss and damage to freight and baggage, damage to livestock on right of way, unwarranted overtime in train and station service, and have also materially reduced accidents of every description; all of which has led us to believe that you will enthusiastically assist in the elimination of the practice of passengers getting on trains without tickets, which has proven very detrimental to both the companies and their valued employees.

"To accomplish the desired results will be a huge task for the station masters, ticket agents, and passenger conductors and trainmen. Recognizing this, I have directed division officials that special attention must be given this subject, soliciting suggestions from agents and passenger conductors as to whether or not additional facilities are necessary, if more help is needed, or concerning anything which in their opinion might be of assistance in speedily making it known to the public that, from every viewpoint, it is preferable that they purchase tickets from the agent rather than pay on the trains.

"To be successful in this movement, it is essential that the employees be in hearty accord with it, and in explaining to the public that they should have tickets before boarding trains they do so in the most courteous manner. You are asked to bear in mind that it is not the intention to annoy or inconvenience those patronizing our trains, neither is it desired to attempt to make it compulsory in every case for passengers to have a ticket before getting on trains at points where ticket offices are open. In attempting to make it compulsory, you would no doubt encounter an occasional person who would feel that his rights were being imposed upon, and argue that it is one of his prerogatives to decide for himself where he will pay his railroad fare. However, I am thoroughly convinced that it will only be an occasional patron who will take this stand, and such a patron will no doubt have personal reasons for endeavoring to avoid purchasing a ticket.

"On branch line trains and main line local passenger trains, the conductor will use his own judgment in holding the train at a station for a minute or two if necessary in order to enable passengers who are not familiar with the requirements, and who attempt to board train without tickets, to provide themselves with same."

GASOLENE MOTOR MAIL AND BAGGAGE CAR

A gasolene motor mail, baggage and express car has recently been built for the Union Pacific by the McKeen Motor Car Company, Omaha, Neb. It is 70 ft. long, has a wheel base of 44 ft. 2 in., and is equipped with a motor of sufficient power to permit hauling a standard steel railway coach as a trailer. The arrangement is the conception of officers of the Union Pacific, developed with the purpose of providing greater facilities for handling branch line passenger traffic than are possible with single unit motor car trains.

The body of the motor car back of the engine room is divided into two compartments; a mail compartment 15 ft. long and the baggage and express compartment 38 ft. 3⅛ in. in length. The trailer car has a seating capacity of 78 passengers. The motor train will go into service between Kearney and Stapleton, Neb., a distance of 103 miles, where it will make a round trip each day, displacing a steam train consisting of three cars and a locomotive. The seating capacity of the steam train is 70 passengers, the advantage in seating capacity thus being with the motor car train.

The 300-hp. reversible engine truck in use on the motor car is known as type D, and is an enlargement of the builders' latest model type C truck, rated at 200 hp. The engine is reversed by compressed air, the control of which is placed on the right side of the engine near the throttle and brake valve, thus enabling the motorman to operate the car without leaving his seat. The motor truck has a wheel-base of 10 ft. and carries a weight of 33,800 lb. on the drivers. The maximum tractive effort is 8,200 lb. The car is said to have made a speed of 55 miles an hour on its initial trip.

Union Pacific Gasolene Motor Train for Branch Line Service

ENGLISH RAILWAYMEN'S NEW DEMAND.—The secretary of the National Union of Railwaymen has announced that the society has decided to apply for a revision of the agreement entered into in February with the railway companies on the question of war bonuses for the operative grades of railwaymen. The present agreement, which was made for a period of three months, and which was then to be subject to review, provided a war bonus of 3s. (75 cents) a week to men earning less than 30s. ($7.50) and 2s. (50 cents) to those whose wages were above that amount. It has already been announced that the executive committee of the Associated Society of Locomotive Engineers and Firemen has also decided to ask for an increased bonus.

General News Department

The arbitration board of Massachusetts has awarded the 4,000 employees of the Bay State Street Railway Company an increase in wages for conductors from 24.5 cents to 30 cents an hour, and has granted a minimum wage of $2.25 a day to all other employees, and these other employees' hours of labor are reduced from 59 to 54 weekly without loss of pay.

Discussion has been going on for some time between the representatives of the freight clerks on the New York, New Haven & Hartford and the management, and a strike was threatened last week. While no official announcement has as yet been made by the employees, it is understood that both sides to the controversy have agreed to accept mediation, and that G. W. W. Hangar, assistant commissioner of the United States Board of Mediation and Conciliation, is to act as mediator.

J. P. Morgan & Co., New York, have made the following announcement: "The Rothschilds in Paris have arranged to borrow in this market for a period of one year a considerable amount of money, the proceeds of which the Rothschilds will make available to the French government here for the payment of its commercial obligations in this country. The loan will be secured by high grade American railway bonds to be lodged with J. P. Morgan & Co. in New York. It is impossible to state at this time the amount of the loan."

The Western Rate Case Arguments at Washington

On Tuesday, June 22, the series of final hearings in the Western rate advance case was begun before the Interstate Commerce Commission at Washington, D. C. Tuesday was largely taken up by opening statements made by C. C. Wright, representing many of the roads, and Clifford Thorne, representing state railroad commissions.

Legislation in Illinois

The Illinois legislature, which has just adjourned, passed three laws to regulate railroads, a bill requiring all railroads to provide emergency chests for first aid to the injured on all trains, an amendment to the workmen's compensation act, applying its provisions to transportation companies, a bill amending the public utilities act to permit railroads or transfer companies to give or sell transportation to newspapers or magazines in exchange for advertising, and to issue free or reduced transportation to mail carriers, policemen and firemen, and members of the general assembly.

New Railroad Laws in New Hampshire

An act has been passed by the legislature of New Hampshire, to go into effect on October 1, 1915, requiring that all railroads transporting lumber within the state, which is loaded therein, shall equip cars with stakes and wire, when needed, details to be regulated by the Public Service Commission.

A law was passed requiring towns to erect signs at the approach to railroad grade crossings, as noted elsewhere in this issue.

Crossing Signs Maintained by Towns

In New Hampshire the highways throughout the state are being fitted out with signs at the approach to railroad crossings indicating the distance, in feet, to the crossing; and, in accordance with an act of the legislature, the work promises to be entirely finished by August 17 next.

The Public Service Commission started this movement last year and induced a considerable number of cities and towns to put up the signs; and, to make the matter uniform, secured at the last session of the legislature a special act specifically putting this duty on the cities and towns with a penalty of $1 a day for neglect in each case.

By an order of the commission the signs must be of enamelled metal with white letters on a dark blue background, the size of the sign to be 24 in. by 12 in. The sign is to be put up not less than 300 nor more than 500 ft. from the crossing; but the Public Service Commission has authority to suspend this and other regulations where it may be desirable to make an exception to the rule.

Grade Crossing Accidents Classified

The Long Island Railroad operates a heavy passenger traffic in a level country, near a large city. The frequency of highway crossing accidents in the territory of that company has long been noticeable. General Manager J. A. McCrea has published a statement showing that in the 4½ years since January 1, 1911, there have been 507 of these accidents. In that period 40 persons were killed and 111 injured, for none of which casualties the railroad company was responsible. Of the people killed 24 were in automobiles, 12 in wagons and carriages and 4 on bicycles and motorcycles. In 42 of the 507 accidents no person was injured. In 157 cases automobile and wagon drivers defiantly ran their machines and vehicles through lowered gates.

Mr. McCrea is urging the state of New York to follow New Hampshire in requiring every city and town to maintain warning signs on highways approaching crossings. (See article above.) He calls attention to the fact that the railroad cannot maintain signs at a distance from a crossing, nor has it the right to erect them.

The new signs of the Long Island road have been noticed in these columns. Mr. McCrea says: "We want to go 'Safety First' one better, and make it 'Safety First, Last and Always.' About 300 of our 600 grade crossings are protected by flagmen and gates, and we are spending at the present time $25,000 a month to protect these crossings."

New Subways Opened in New York

New York City has opened two subways this week; the Fourth Avenue subway, so-called from the Manhattan bridge southward through Brooklyn, about three miles toward Coney Island; and the Steinway tunnel from Forty-second street, Manhattan, under the East river to the borough of Queens. This last mentioned tube was finished about eight years ago, but has remained unused because of disputes about ownership and operation. It will be operated by the Interborough Rapid Transit Company with free transfers to and from the existing subway of that company running north and south in Manhattan. The Fourth Avenue subway, Brooklyn, will be operated by the New York Consolidated Railroad Company, which is controlled by the Brooklyn Rapid Transit Company. For the present the Fourth avenue trains will run to Coney Island over the Sea Beach Railroad, but eventually will have a connection with elevated lines running through New Utrecht avenue and Gravesend avenue.

Credit Where Credit is Due

The poem published on page 1377 of the Daily *Railway Age Gazette* of June 16, entitled "The Lament of the Foreign Bad Order Empty Car," which was read by Secretary Taylor at the Master Car Builders' convention at Atlantic City as anonymous, was written by E. E. Betts, superintendent of transportation of the Chicago & North Western and included by him in a series of bulletins issued to the members of the Chicago General Superintendents' Association by the committee on the Promotion of the Proper Handling of Equipment, of which Mr. Betts is chairman, for the purpose of calling atention to some of the methods in vogue for handling bad order cars. Mr. Betts says he is not so anxious about credit for his authorship as he is that somebody shall pay some attention to it. "It was reported as an amusing communication," he says, "all of which may be true. At the same time it was hoped that the moral would sink into some of our head mechanical men who would be aroused as to the necesity of taking some action to put a stop to the wanderings of the aforesaid foreign bad order empty cars."

REVENUES AND EXPENSES OF RAILWAYS

MONTH OF APRIL, 1915

Name of road.	Average mileage operated during period.	Operating revenues: Freight.	Passenger.	Total, inc. misc.	Operating expenses: Maintenance: Way and structures.	Of equipment.	Traffic.	Transportation.	Miscellaneous.	General.	Total.	Net operating revenue (or deficit).	Railway tax accruals.	Operating income (or loss).	Increase (or decr.) comp. with last year.

The Greatness of the Pennsylvania

The award of the grand prize to the Pennsylvania Railroad at the Panama-Pacific International Exposition at San Francisco, was announced last week. In supplying information to the Jury of Awards, the company gave the following striking figures:

The freight service rendered by the Pennsylvania system in a year is the equivalent of one ton carried 36,900,000,000 miles; the passenger service is equivalent to one person carried 4,500,000,000 miles. The system's receipts are a million dollars a day; it pays out in wages half a million daily, and for supplies a quarter million. Its employees in normal times number upwards of 250,000, and its payrolls indirectly support 1,000,000 persons. It traverses 13 states and the District of Columbia and supplies transportation service to more than half the population of the United States. Its 4,500 stations include eight of the ten largest cities in the country.

The company's exhibit at the exposition includes a huge model of New York City showing the railroad approaches, a relief map of the entire territory served by the Pennsylvania lines, constructed on a scale of two miles to the inch, making it the largest topographical map in the world, models of Pennsylvania station in New York City and the Union station at Washington, and a moving picture theater.

MEETINGS AND CONVENTIONS

The following list gives the names of secretaries, dates of next or regular meetings, and places of meeting of those associations which will meet during the next three months. The full list of meetings and conventions is published only in the first issue of the Railway Age Gazette for each month.

AMERICAN ASSOCIATION OF DEMURRAGE OFFICERS.—F. A. Pontious, 455 Grand Central Station, Chicago. Next meeting, July 21, 1915, Milwaukee, Wis.

AMERICAN ASSOCIATION OF RAILROAD SUPERINTENDENTS.—E. H. Harman, Room 101, Union Station, St. Louis, Mo. Next meeting, August 19-20, 1915, San Francisco, Cal.

AMERICAN RAILROAD MASTER TINNERS, COPPERSMITHS AND PIPEFITTERS' ASSOCIATION.—W. E. Jones, C. & N. W., 3814 Fulton St., Chicago. Annual meeting, July 13-16, 1915, Hotel Sherman, Chicago.

AMERICAN RAILWAY TOOL FOREMEN'S ASSOCIATION.—Owen D. Kinsey, Illinois Central, Chicago. Annual meeting, July 19-21, 1915, Hotel Sherman, Chicago.

AMERICAN SOCIETY FOR TESTING MATERIALS.—Prof. E. Marburg, University of Pennsylvania, Philadelphia, Pa. Annual meeting, June 22-26, 1915, Hotel Traymore, Atlantic City, N. J.

AMERICAN SOCIETY OF CIVIL ENGINEERS.—Chas. Warren Hunt, 220 W. 57th St., New York. Regular meetings, 1st and 3d Wednesday in month, except July and August, 220 W. 57th St., New York.

ASSOCIATION OF RAILWAY ELECTRICAL ENGINEERS.—Jos. A. Andreucetti, C. & N. W., Room 411, C. & N. W. Sta., Chicago. Semi-annual meeting with Master Car Builders' and Master Mechanics' Association. Annual meeting, October, 1915.

ENGINEERS' SOCIETY OF WESTERN PENNSYLVANIA.—Elmer K. Hiles, 2511 Oliver Bldg., Pittsburgh, Pa. Regular meetings, 1st and 3d Tuesday of each month, Pittsburgh.

GENERAL SUPERINTENDENTS' ASSOCIATION OF CHICAGO.—A. M. Hunter, 321 Grand Central Station, Chicago. Regular meetings, Wednesday, preceding 3d Thursday in month, Room 1856, Transportation Bldg., Chicago.

INTERNATIONAL RAILWAY GENERAL FOREMEN'S ASSOCIATION.—Wm. Hall, 1126 W. Broadway, Winona, Minn. Next convention, July 13-16, 1915, Sherman House, Chicago.

INTERNATIONAL RAILROAD MASTER BLACKSMITHS' ASSOCIATION.—A. L. Woodworth, C. H. & D., Lima, Ohio. Annual meeting, August 17, 1915, Philadelphia, Pa.

NIAGARA FRONTIER CAR MEN'S ASSOCIATION.—E. N. Frankenberger, 623 Brisbane Bldg., Buffalo, N. Y. Meetings, 3d Wednesday in month, New York Telephone Bldg., Buffalo, N. Y.

PEORIA ASSOCIATION OF RAILROAD OFFICERS.—M. W. Rotchford, 410 Masonic Temple Bldg., Peoria, Ill. Regular meetings, 3d Thursday in month, Jefferson Hotel, Peoria.

RAILROAD CLUB OF KANSAS CITY.—Claude Manlove, 1008 Walnut St., Kansas City, Mo. Regular meetings, 3d Saturday in month, Kansas City.

RAILWAY TELEGRAPH AND TELEPHONE APPLIANCE ASSOCIATION.—G. A. Nelson, 50 Church St., New York. Meetings with Association of Railway Telegraph Superintendents.

SALT LAKE TRANSPORTATION CLUB.—R. E. Rowland, David Keith Bldg., Salt Lake City, Utah. Regular meetings, 1st Saturday of each month, Salt Lake City.

SOUTHERN ASSOCIATION OF CAR SERVICE OFFICERS.—E. W. Sandwich, A. & W. P. R. R., Atlanta, Ga. Next meeting, July 15, 1915, Atlanta. Annual meeting, January, 1916.

SOUTHERN & SOUTHWESTERN RAILWAY CLUB.—A. J. Merrill, Grant Bldg., Atlanta, Ga. Regular meetings, 3d Thursday, January, March, May, July, September, November, 10 A. M., Piedmont Hotel, Atlanta.

TOLEDO TRANSPORTATION CLUB.—Harry S. Fox, Toledo, Ohio. Regular meetings, 1st Saturday in month, Boody House, Toledo.

TRAFFIC CLUB OF CHICAGO.—W. H. Wharton, La Salle Hotel, Chicago.

TRAFFIC CLUB OF PITTSBURGH.—D. L. Wells, Genl. Agt., Erie R. R., 1924 Oliver Bldg., Pittsburgh, Pa. Meetings bi-monthly, Pittsburgh. Annual meeting, 2d Monday in June.

TRANSPORTATION CLUB OF DETROIT.—W. R. Hurley, Superintendent's office, N. Y. C. R. R., Detroit, Mich. Meetings monthly, Normandie Hotel, Detroit.

Traffic News

The Oregon Short Line has announced that the serving of liquors in its dining cars will be discontinued on July 1.

The Great Northern has been awarded the gold medal at the Panama Pacific Exposition for the exploitation of scenic attractions, agricultural developments and industrial resources.

The western transcontinental railways have filed with the Interstate Commerce Commission their new tariffs of rates to intermediate western points in accordance with the decisions of the Interstate Commerce Commission, effective on July 15.

The Railroad Commission of Alabama has changed from July 1 to November 30, 1915, the time for the expiration of the term of its order allowing the principal roads of the state to charge 10 per cent above the tariff rate on certain commodities named in the "Eight Group Act."

The Nashville, Chattanooga & St. Louis is placing tablets at various points on its line marking points of interest, such as the scenes of battles during the civil war, so that passengers may easily recognize them from the car windows. The markers are of cast metal painted white with black lettering, and are mounted on railroad rails set in concrete. The markers also indicate the names of the principal streams crossed.

Not all of the summer travel to mountains and seashore is in the northern states. The Southern Railway reports a new train, put on last week, between Jacksonville, Fla., and Columbia, S. C., leaving Jacksonville at 8 p. m., and arriving at Asheville, N. C., at 2:10 p. m., with corresponding return schedule; sleeping cars between Jacksonville and Asheville, and between Savannah and Asheville. This week two sleeping car lines were established between New Orleans and Asheville; one via Montgomery and Atlanta and the other via Birmingham and Chattanooga; and two sleeping car lines between Memphis and Asheville, one starting in the morning and the other in the evening. Next Monday there will be a new train between Atlanta and Asheville.

The United States Public Health Service has been studying the experiences of the western and southwestern states in connection with tuberculosis and the large number of persons who go from the east to that region to improve their health; and while the need of very particular precautions in the sanitation of cars is emphasized, as always in discussions on this topic, the report declares that the degree of communicability of the disease has been overestimated. Medical statistics are notoriously unreliable. Something like 10,000 consumptives go west every year to die, says the report; and of those who die 46 per cent live less than six months after arrival. The tuberculous population of western Texas and New Mexico is said to be more than 50,000. In Albuquerque, N. M., the consumptive population which has come there from other states numbers more than 2,000; in El Paso over 2,000, and in San Antonio 3,500.

The Chicago, Rock Island & Pacific on June 19, put in effect new service to San Francisco via its Rocky Mountain Limited train from Chicago to Omaha, the Union Pacific to Ogden and the Southern Pacific from Ogden to San Francisco. No change will be made in the Rocky Mountain Limited service between Chicago and Colorado. The train leaves Chicago at 10:00 a. m., and leaves Omaha at 12:40 a. m., arriving at San Francisco at 9:30 a. m. the third morning. Returning, the train leaves San Francisco at 2:20 p. m., and arrives at Chicago at 2:50 p. m. New service was also announced in connection with the Colorado-California Express, which leaves Chicago at 10:30 p. m., and which will run west of Denver on the Union Pacific and Southern Pacific, arriving at San Francisco at 9:30 a. m., the fourth morning. Returning, the train leaves San Francisco at 2:20 p. m. and arrives at Chicago at 7:55 a. m.

Commission and Court News

INTERSTATE COMMERCE COMMISSION

The Interstate Commerce Commission has announced a hearing to be held at Chicago, beginning on July 19 and continuing for about two weeks, in connection with the western rate advance case. Evidence is to be taken at these hearings on advances on a number of commodities which have been filed since the beginning of the main hearings in the case. The hearings on July 19 to 24 will be devoted to agricultural implements, canned goods and furniture, proposed changes in rules and practices relating to general transit rules on grain and milling of grain in transit. July 26 to 31 will be devoted to beer and liquor, boots and shoes, cement, clothing, granite and marble, iron and steel, wire, lumber, lime, machinery, oil, paper, steel rails, cross ties, structural iron, sugar, sand, stone and other commodities. Evidence will also be taken on proposed changes in rules.

Rates to or from Certain Points in the Chicago Switching District

Opinion by Commissioner Clark:

The Lowrey tariff, of 1910, provided, with some exceptions, for the application of Chicago rates to and from industries, and other stations located within the Chicago switching district, whether or not such industry, or station was located upon or directly connected with the line performing the road haul. The Merchants Lighterage Company, and the Chicago Warehouse & Terminal Company, were and are parties to the Lowrey tariff and shipments to or from the stations of the lighterage company or of the tunnel company move as through shipments, these companies receiving divisions or allowances from the through rates.

It has now been proposed to cancel these arrangements with resulting increases in the rates to the stations of these companies, but this cancellation the commission refuses to allow.

The tunnels of the Chicago Tunnel Company, the stock of which is owned by the Chicago Warehouse & Terminal Company, are under the streets of the main wholesale and retail district. They aggregate about 60 miles, are 7.5 ft. high and 6 ft. wide, contain tracks of 2 ft. gage and are electrically operated. Access to the tunnels from the surface is afforded by 58 elevators which connect with the stations of the various railroads entering Chicago, 19 elevators connected with commercial houses and five elevators at so-called universal stations.

The tunnel company has two classes of freight stations: One, "universal" stations, at which less-than-carload shipments are received from and delivered to the public generally; the other, "commercial" stations, which are analogous to private sidings.

The tunnel company receives its compensation out of the through rates, without limitation as to the amount of freight taken from or delivered to the line-haul carriers, if the freight originates or is delivered at its universal stations. On that originating at its commercial stations it receives no compensation from the line-haul carriers unless certain minimum quantities are delivered to it by one shipper, or by it to one consignee from one of the line-haul carriers, in one day, nor unless the gross revenue accruing to the line-haul carrier and its connections on the required minimum quantity of freight equals or exceeds $15.

The eastern lines, such as the Erie, the Wabash, the New York Central, and the Pennsylvania, do not propose to withdraw the arrangement for through rates in connection with the tunnel company to or from its universal stations.

The lighterage company operates two boats on the Chicago river. It maintains universal stations and also serves certain industries at docks or landings not used by other shippers.

Both the lighterage and tunnel companies file tariffs and reports with the commission and have long been recognized as common carriers. Neither of them has had gross earnings sufficient to pay operating expenses and fixed charges.

In general, Chicago rates apply on shipments to and from all points within the Chicago switching district. Various universal stations for the receipt and delivery of less-than-carload freight are maintained by railroads reaching this district, to or from which Chicago rates are applied, the carriers compensating each other for the necessary switching service. The commission sees no substantial difference between the services performed by the tunnel and lighterage companies and those performed by the line-haul carriers for each other or those performed for the line-haul carriers by the several belt-line or industrial railroads within the switching district, and finds no good reason for placing the shippers served by the tunnel and lighterage companies at a disadvantage as compared with other shippers and consignees in the Chicago district.

The line-haul carriers believe that they are within their rights in cancelling the through rates because the service rendered by the tunnel and lighterage companies is a service beyond the rails of the line-haul carriers, for which they have a legal right to insist upon an additional charge. Since the line-haul carriers, however, join with each other and with various industrial and belt-line railroads in applying Chicago rates to and from industries in the switching district, the commission fails to see how discrimination could be avoided if they refused to accord the same rates and services to industries served by the tunnel and lighterage companies. The situation in Chicago is such that no single carrier can adequately serve the public with its own rails. It must enter into arrangements with other carriers which are in essence extensions of its rails. Transportation activities in and rates to and from Chicago are subject to conditions of intense competition. All this has led to the establishment and long maintenance of arrangements between the trunk lines themselves and with numerous terminal and belt lines in the Chicago district, which, have long included the tunnel and lighterage companies. No sufficient justification has been shown for singling them out from among the other terminal carriers or agencies in the Chicago switching district for the withdrawal of the uniform application of the Chicago rates.

For each rate, a carrier offers and obligates itself to perform a certain amount of service. If the service so offered and for a long time performed in consideration of that rate includes taking the property transported from a given point and delivering it at a given point, the delivery at that point is in no sense a "free service."

Commissioner Harlan, in a dissenting opinion, notes that the tunnel line cannot interchange equipment and that to accord joint rates to it is to extend transportation in interstate commerce "to the very basements of the private commercial establishments located along the tunnel." Whatever the value of the tunnel as a relief to congestion, it nevertheless offers a shipper's service and not a railway service. It does not differ in any particular having legal significance from the service performed by transfer and teaming companies in all the large cities.

So far as less-than-carload traffic is concerned, and such traffic only is handled by the tunnel company, the shippers of this country, as a general rule, bear the burden of getting it to and from the freight stations of the railroads. The trunk lines, however, several years ago, undertook to take this burden from shippers in Chicago, along the line of the tunnel and the route of the lighterage company, and to assume it themselves. In the tariffs now under suspension they have attempted to withdraw this free service and to put the burden back upon these shippers, where it properly belongs, and where, until a few years ago, it rested.

The free trap-car service which the carriers are endeavoring under other tariffs to withdraw is involved in another proceeding in which those tariffs are under suspension. But having here sanctioned the continuance of the free tunnel service partly because of the free trap-car service, the commission may later be compelled, under the reasoning of the majority report, to sanction and require the continuance of the free trap-car service partly because of the free tunnel service. These vastly important questions are thus pursued around a circle, and the dealing with them piecemeal, as in the majority report, and without relation to the broad general principles involved, makes any constructive consideration of them possible.

There can be no real regulation of interstate transportation without an affirmative course of action on the part of the commission itself in dealing with such matters. If the

commission refrains from upholding the carriers' efforts to get rid of one free service because it finds in existence another free service, without taking the steps necessary to strike both down as unlawful, the efforts of some railway officers to conform their practices to the requirements of the law will continue to be hampered by other officers who are willing to make the concessions necessary to obtain it. By constantly extending these free services to particular shippers in large communities, their cost becomes so great that relief is finally sought through an increase in the line-haul rates, which all shippers must pay, as was pointed out in the recent Five Per Cent Case (31 I. C. C., 351), where it was said that a substantial part of the increases had "been due to the increase in the special services performed for shippers at terminals and elsewhere without the imposition of any charge or for an inadequate charge."

"In the view I take of this case it presents a question of great public importance having two phases; one, the economic principle that our transportation costs should be placed where they properly belong, and the other a question of law, the right of a carrier performing a special service to make a charge for it. This right I regard as also a duty and the failure to perform it a violation of the act. And therefore in enforcing the integrity of the act it is the plain duty of this commission affirmatively to see to it that free services, of the special and private character involved on this record, are not performed by these servants of the public at the expense of the public." (34 I. C. C., 234.)

Carriers Must Furnish Tank Cars

Pennsylvania Paraffine Works v. Pennsylvania Railroad. Opinion by Commissioner Meyer:

The commission holds that it has the power to require carriers to furnish all necessary equipment, both ordinary and special, upon reasonable request. The question of what is a reasonably adequate car supply is an administrative one of which the commission alone can take original jurisdiction. A shipper's request for cars especially suited for the transportation of his products would not be reasonable if the cars must be prepared for shipment in a manner which is peculiarly within the technical knowledge of men connected with that industry, or if the movement of the commodity is a dangerous operation which can be safely performed only by men engaged in its production; but the shipment of petroleum products in tank cars does not call for such technical knowledge as would render unreasonable complainants' request that defendant furnish these cars. Tank cars are the only proper cars to use in the shipment of petroleum. The decision holds that all cars used by carriers, whether they be owned by the carriers themselves or leased from private car lines or from shippers, must be distributed without discrimination.

Commissioner Clark dissents, holding that the provision of section 1 of the act, that it shall be the duty of every carrier "to provide and furnish such transportation upon reasonable request therefor," did not enlarge the obligations or duties laid upon the carriers in this respect by the common law. There is no language in section 1 which indicates a legislative intent to expand the common-law duty of carriers to furnish facilities for transportation. If the act confers upon the commission power to order a carrier to enlarge its complement of cars and to award damages against it if it fails to comply with such order, it seems logically and necessarily to follow that the commission has the same power to order enlargement of terminal facilities, increase in the number of locomotives, and extension of tracks or branches. "I think that this power is vested in the courts and not in the commission." Commissioner Clements concurs in this dissent. Commissioner Harlan files a separate dissenting opinion wherein he says: "I concur in the general thought underlying the dissenting report herein of my brother Clark, namely, that the language in the act upon which the majority report is largely based is simply declaratory of the general duty of carriers at common law to furnish such cars and other facilities as are reasonably necessary to enable them to fulfill other public obligations, but does not impose upon this commission any such administrative duty or any such jurisdiction and power as are asserted in the majority report and in the order accompanying it." (34 I. C. C., 179.)

PERSONNEL OF COMMISSIONS

G. H. Byers, chief engineer of the Puget Sound & Willapa Harbor, at Raymond, Wash., has been appointed assistant engineer of the Pacific district of the Interstate Commerce Commission board of valuation engineers, with headquarters at San Francisco, Cal.

COURT NEWS

On the application of the Illinois Central and the Yazoo & Mississippi Valley, Judge Niles, of the United States district court, has issued a temporary injunction restraining the enforcement of the electric headlight law passed by the Mississippi legislature in 1912.

The United States Supreme Court has set aside a judgment of the supreme court of Pennsylvania giving the Clark Brothers Coal Mining Company a verdict for $124,443 against the Pennsylvania Railroad, representing triple damages for discrimination in car distribution. The United States Supreme Court held that the coal company, having applied to the Interstate Commerce Commission for redress and having obtained $31,000, could not now have recourse to the courts.

In the Federal Court at Jackson, Miss., June 15, a temporary injunction was granted restraining all district attorneys in Mississippi from prosecuting the Illinois Central and the Yazoo & Mississippi Valley for violating a headlight law passed by the legislature in 1912. The law stipulates that all locomotives operating on main lines in the state shall be equipped with high-power headlights. The case will be argued next month, when the roads will seek a permanent injunction.

In the United States District Court at Los Angeles, July 11, Judge Bean handed down a decision, in favor of the Government, in the suit against the Southern Pacific to recover 6,300 acres of land, alleged to contain oil, in Kern county, Cal., valued by the Government at over fifteen million dollars. Another suit, involving oil lands in the same region, of much greater value, is still pending. In the case now decided the Government charged that the affidavits produced by the railroad company to the effect that the land was not mineral but was agricultural, had been fraudulently obtained.

The Supreme Court of the United States, reversing the decision of the lower court, holds that the Adams Express Company was not violating the Webb-Kenyon law, regulating the transportation of liquor in interstate commerce, when it carried liquor into Kentucky for the personal use of the consignee. The destination of the liquor was in so-called dry territory; but the Kentucky Court of Appeals has held that the prohibition law of the state did not apply to liquor intended for the personal use of the consignee. In this case there was no evidence that the liquor was to be used otherwise.

Decision Against the Lackawanna in the Commodities Clause Case

The United States Supreme Court, in an opinion by Justice Lamar, has directed the government to bring new proceedings against the Delaware, Lackawanna & Western to stop the present plan by which the company sells coal through the Delaware, Lackawanna & Western Coal Company. This overrules the United States district court which had found in favor of the railroad. The full decision is not as yet available, but the following two paragraphs are taken from the New York Herald's report of the decision as handed down verbally:

"The railroad company, if it continues in the business of mining, must absolutely dissociate itself from the coal before the transportation begins. It cannot retain the title nor can it sell through an agent. It cannot call that agent a buyer while so hampering and restricting such alleged buyer as to make him a puppet subject to the control of the railroad company.

"If the railroad sells coal at the mouth of the mines to one buyer or to many it must not only part with all interest, direct or indirect, in the property, but also with all control over it or over those to whom the coal is sold at the mines. It must leave the buyer as free as any other buyer who pays for what he has bought. It should not sell to a corporation with officers and offices in common, for the policy statutes require that, instead of

being managed by the same officers, they should studiously and in good faith avoid anything either in contract or in conduct that remotely savors of joint action, joint interest or the dominance of one company by the other. If the seller wishes by a lawful and bona fide contract, whose provisions as to delivery and otherwise are not in restraint of trade, to sell all of its coal to one buying company, then that one buyer can be bound by reasonable terms and requirements to pay according to the contract. But such buyer should otherwise be absolutely free to extend the business to buy when, where and from whom he pleases, and otherwise to act as an independent dealer in active competition with the railroad company."

Discrimination Between Stations—Supplying Stock Scales Not Compulsory

The United States Supreme Court, in a case already briefly reported, holds unreasonable and arbitrary an order of the Minnesota Railroad & Warehouse Commission directing the Great Northern to erect within 45 days a six-ton scale in its stock yards at the village of Bertha, Todd county. This decision reverses that of the state supreme court (122 Minn., 55), which had affirmed the order on the ground that stock raisers who would otherwise market their stock at Bertha sometimes took it to Hewitt or Eagle Bend, a longer distance, in order to have the use of the scales installed at those places; that such scales tend to draw the stock business to and concentrate it at the places where they are located.

It appeared that six-ton scales installed by the railroad at 54 of its 259 stock-shipping stations in Minnesota were not used in transactions between carrier and shippers. The court sustained the railroad's contention that it should have had the opportunity of eliminating the discrimination between the stations by discontinuing the use of the scales at Eagle Bend and Hewitt. "The business of a railroad," the court said, "is transportation, and to supply the public with conveniences not connected therewith is no part of its ordinary duty. . . . It by no means follows, simply because a railroad voluntarily supplies a convenience at some stations which attracts trade, that it can be commanded positively to do likewise at other places along the line. A railroad's possessions are subject to its public duty, but beyond this and within charter limits, like other owners of private property, it may control its own affairs. Discontinuing the use of existing scales would abate the alleged discrimination and probably entail little, if any, outlay. The commission's order precluded use of this method to bring about lawful conditions and therein, we think, was plainly arbitrary and unreasonable." Decided June 14.

Employees' Liability Act—"Interstate Commerce"

A mechanic worked principally in running a machine where he shaped parts to be used in the repair of locomotives in immediate need of repair, and generally, but not exclusively, in the repair of locomotives used in interstate commerce. While engaged on a Sunday in moving the countershaft which supplied power to the shaping machine, his hand, while over the rail on a girder which he was drilling, was cut off by the wheels of a traveling crane moving on the girders. It was held by the New York Court of Appeals that he was not employed in interstate commerce and so could not recover in an action for his injury. The court distinguished Pedersen v. D. L. & W., 229 U. S., 146, 33 Sup. Ct. 648, where it was held that a person directly engaged in assembling material for the immediate repair of a bridge necessarily used in interstate commerce by a carrier is engaged in interstate commerce. From this holding, the court said, it does not follow that a person engaged at a shaping machine in a repair shop is engaged in interstate commerce; at least until it appears that the work he is doing is for the immediate repair of a locomotive or other instrumentality engaged in interstate commerce. Making parts to be used in a locomotive is a step further removed from commerce than the assembling of parts for the locomotive, and corresponds to the work of making bolts and rivets for use in bridge repairs. The plaintiff, in moving the countershaft, was doing millwork that in itself had no immediate or direct connection with commerce. Shanks v. D. L. & W. (N. Y.), 108 N. E., 644.

A car inspector was inspecting a train which ran on a division of an interstate road wholly within the state when he was struck and killed by another train of the same division. In an action under the federal employers' liability act there was no evidence that any passenger or baggage on either train was destined for a point in another state, though the time-tables of the company expressed a readiness to transport interstate passengers over that division and transfer them to interstate trains. The federal district court, E. D. Pennsylvania holds that there could be no recovery under the act. Boyle v. Pennsylvania, 221 Fed., 453.

The federal employers' liability act does not make an employer an insurer of the lives of its employees, and does not give a right of action unless negligence is shown. A conductor was caught between a doorpost of a freight house and the doors of a refrigerator car. The freight house had been used continuously for 15 years without injury to any employee. In an action for his injuries there was no evidence of faulty or unusual construction of the freight house. The Michigan Supreme Court held that the company was not negligent, under the act, for maintaining a defective place of work. The conductor was familiar with the surroundings and the manner of performing his duties, and knew of the nearness of the track to the doorpost. It was held that he assumed, as a matter of law, the risk of injury by being caught between a car and the doorpost. Miller v. Michigan Central (Mich.), 152 N. W., 235.

In an action for the death of a member of a shifting crew in the defendant's freight yard it appeared that the deceased handled both interstate and intrastate commerce, but at the time he met his death he was aiding in the movement of empty cars on a siding of a local private manufacturing company. The ultimate use to which the cars were to be devoted, and their ultimate destination when loaded was not shown. The deceased had been sent out as flagman. The character of the oncoming train which caused his death was not shown. The federal district court, E. D. Pennsylvania, held that he was not shown to have been engaged in interstate commerce so as to allow of recovery under the act. Shanley v. Philadelphia & Reading, 221 Fed., 1012.

Interstate Commerce in Intoxicating Liquor

The Adams Express Company was indicted for violation of the Kentucky statute by the delivery of intoxicating liquor from Tennessee to persons in Kentucky. The liquor was for the personal use of the buyers. The United States Supreme Court had this statute under consideration in Louisville & Nashville v. Cook Brewing Co., 223 U. S. 70, when the statute, as applied to interstate shipments, was held void as an attempt by the state to regulate commerce among the states. Such, the court says, must still be the fate of the statute, unless the Webb-Kenyon Act requires a different result. The Wilson Act did not prevent shipment of liquor in interstate commerce for the use of the consignee, provided he did not undertake to sell it in violation of the state laws. The court holds that the Webb-Kenyon Act does not prohibit all interstate shipment or transportation of liquor into so-called dry territory, but prohibits it only where the liquor is to be possessed, sold, or used in violation of the local law. The facts showed that the liquor was not to be used in violation of the state laws, therefore the Webb-Kenyon Act had no application. Judgment of conviction was reversed.—Adams Express Co. v. Kentucky (decided June 14).

Crossing Accidents—Care Required of Passengers in Vehicles

Action was brought for injuries to a passenger in a buggy, the wife of the driver, the buggy having been smashed into by a train at a crossing, in which the Circuit Court of Appeals, Sixth Circuit, held the plaintiff chargeable with contributory negligence barring recovery. It was held that where a driver and his passenger were both looking and listening for a train as they approached a crossing, the negligence of each while so engaged was the negligence of both. Where the plaintiff, as they approached the crossing, was looking out for her own safety and using her own eyes and ears for the purpose of determining whether trains were approaching, wholly independent of her husband, she was responsible for her own personal negligence in failing to see a train which might have been seen by exercising reasonble

care while looking. Although the doctrine that the negligence of the driver of a vehicle is imputable to his passenger has been generally discarded, it by no means follows that because a person is not controlling the vehicle, and because she is not responsible for the driver's negligence, she is not obliged to exercise due care for her own safety. Erie v. Hurlburt, C. C. A., 221 Fed. 907.

Plant Facility Subsequently Becoming Common Carrier is Bound by Published Rates

A railroad originally constructed as a plant facility in connection with ironworks was subsequently chartered as the Crane R. Co. under the Pennsylvania general railroad laws, which gave it a right of eminent domain. It was owned and operated by an independent company having track connection with other railroads and transporting freight for the public. Prior to the incorporation of the railroad the Central of New Jersey had an agreement with the ironworks, whereby the former paid to the ironworks 6 cents a ton on all cars hauled by the iron company to and from its works and other industrial establishments located along the line of the iron company's tracks to the Central of New Jersey's tracks. Following its incorporation the Crane company filed schedules of rates specifying a charge of $2 a car for all cars transported over its lines from and to connecting lines. In a suit to recover the difference between this rate and that stipulated in the agreement with the ironworks, the defense was that the Crane company was a plant facility of the ironworks and as such bound by the agreement. It was held, however, by the Pennsylvania Supreme Court, that the Crane company was a common carrier and not a mere plant facility. The court quoted the decision in the Tap Line Cases, 234 U. S. 1, 34 Sup. Ct., 741. The plaintiff, being engaged in interstate commerce and bound to accept shipments from the public, was required to file tariffs showing rates binding on all parties. Judgment for the plaintiff was affirmed.—Crane R. Co. v. Central of New Jersey (Pa.), 93 Atl., 1076.

Unexplained Boiler Explosion—Doctrine of Res Ipsa Loquitur

A locomotive engineer sued for injuries caused by the dislocation of a boiler flue, followed by an explosion and the throwing of hot water and steam upon him. The railroad company's contention was that, conceding that the plaintiff brought himself within the rule of *res ipsa loquitur* (the occurrence speaks for itself), the explanation offered by the company, and supported by two expert witnesses, without contradiction, was sufficient to overcome the presumption of negligence on the part of the company, and that it then became the duty of the plaintiff, as a condition of recovery, to establish the company's negligence.

There was evidence that the boiler at the time of the accident was carrying a steam pressure of 200 lb.; that it was just on the point of "popping"; and that at this time the engineer turned on the injector. It was the theory of the two experts that, the water being low in the boiler, the injection of cold water caused a contraction of the tube in question, drawing it away from the fastening at the end, and producing the leak which generated steam in the firebox, and forced off the doors of the furnace, producing the injuries complained of. This testimony was not disputed. The New York Appellate division, third department, holds, by a divided court, that this evidence supported a verdict for the plaintiff.

Justices Kellogg and Smith dissented, on the ground that the engineer had the control and management of the boiler, and the facts showed that the cause of the explosion was either a defect in the boiler itself or the improper management of it by the engineer. If a bystander, or an employee, having nothing to do with the boiler, had been injured by the explosion, the doctrine of *res ipsa loquitur* would have applied and indicated the company's negligence, for it would be equally responsible for either cause. But here the circumstances unexplained might point as directly to the negligence of the engineer as to a defect in the boiler. Therefore the engineer gained no advantage from the doctrine, except perhaps by confining the proof in the first instance to the allegation that he was not negligent, and therefore the boiler must have been defective. In order, therefore, to prove negligence of the company, it was necessary for the engineer to establish that the boiler was defective; in other words, that his conduct did not cause the explosion. Francey v. Rutland, 153 N. Y. Supp., 151.

Railway Officers

Executive, Financial, Legal and Accounting

Arthur S. Piers, real estate agent of the Canadian Pacific at Montreal, Que., has been appointed manager real estate department, with office at Montreal, in charge of the company's real estate and buildings not used exclusively for railway purposes, or administered by the general executive assistant at Vancouver, and the department of natural resources.

Edward A. Haid, whose appointment as general attorney of the St. Louis Southwestern, with headquarters at St. Louis, Mo., has already been announced in these columns, was born on November 4, 1881, in St. Louis, Mo., and graduated from the grammar schools of that city. He was graduated from the Benton (night) school of law in June, 1904, and entered the general practice of law on January 1, 1905. He left the general practice of law on February 4, 1907, to become chief clerk in the law department of the St. Louis & San Francisco. On December 1, 1912, he was appointed assistant general attorney of the St. Louis Southwestern at St. Louis, Mo., which position he held at the time of his recent appointment as general attorney of the same road, with headquarters at St. Louis, as above noted.

Edward A. Haid

Operating

J. A. Baldwin, acting superintendent of the Nashville, Chattanooga & St. Louis, at Atlanta, Ga., has been appointed superintendent of the Western & Atlantic division, with headquarters at Atlanta.

Edward E. Taylor, trainmaster of the Gulf, Colorado & Santa Fe, at Galveston, Tex., has been appointed division superintendent, with headquarters at Cleburne, Tex., succeeding Oliver Snyder, deceased. D. W. Nettleton, chief train despatcher at Temple, Tex., has been appointed trainmaster at Galveston, Tex., succeeding Mr. Taylor. H. S. Taylor succeeds Mr. Nettleton as chief train despatcher at Temple, Tex.

George W. Kirtley, whose appointment as general superintendent of transportation of the Erie, with headquarters at New York City, has already been announced in these columns, was born at Panora, Iowa, and was educated in the public and high schools of his native town. He began railway work in 1897, as a clerk in the office of the district passenger agent of the Northern Pacific at Des Moines, Iowa. From 1898, to 1900, he served as clerk in the office of the general passenger agent of the same road at St. Paul, Minn., and then to 1901, as clerk in the office of the general superintendent of the Chicago, St. Paul, Minneapolis & Omaha at St. Paul. He was then to 1902, secretary to the general superintendent of the Baltimore & Ohio, at Chicago. From 1902, to 1903, he was secretary to the general superintendent of transportation of the same road, and in 1903 entered the service of the Erie as chief clerk to the general superintendent at Cleveland, Ohio. In 1904, he was appointed assistant superintendent of transportation at New York City, remaining in that position until 1908, when he became superintendent of car service at the same place. Two years later he was appointed superintendent of transportation, which po-

sition he held at the time of his recent appointment as general superintendent of transportation of the same road as above noted.

Traffic

F. W. Whipper has been appointed assistant general passenger agent of the Cleveland, Cincinnati, Chicago & St. Louis, with headquarters at Cincinnati, Ohio, succeeding D. M. Bowman promoted.

George Merki has been appointed chief inspector of the joint rate inspection bureau and the weighing and inspection bureau of the Central Freight Association, with headquarters in the Transportation building, Chicago, succeeding Paul P. Rainer, deceased.

Engineering and Rolling Stock

L. A. Hardin, general foreman of the Chicago & North Western at Boone, Iowa, has been appointed assistant master mechanic at South Pekin, Ill.

R. H. Howard, formerly general manager of the New Orleans & Great Northern, has been appointed chief engineer of maintenance of way of the Wabash, with headquarters at St. Louis, Mo.

E. B. De Vilbis, electrical engineer of the Pennsylvania Lines West, at Fort Wayne, Ind., has been appointed assistant engineer of motive power, with office at Toledo, Ohio, and W. E. Stockbridge, motive power inspector at Fort Wayne, Ind., has been appointed electrical engineer, succeeding Mr. De Vilbis.

OBITUARY

J. E. Gimperling, Sr., formerly superintendent of the Cincinnati, Dayton & Ironton and the Cincinnati, Dayton & Chicago, died at Dayton, Ohio, on June 14, at the age of 84 years.

M. E. Sherwood, division master mechanic of the Michigan Central, at Jackson, Mich., was accidentally shot and killed at that place on June 4. His age was 46 years.

William L. Breyfogle, formerly president of the Louisville, New Albany & Chicago, now the Chicago, Indianapolis & Louisville, and later president of the Bedford Belt Railway, died at Hillsborough, a suburb of San Francisco, Cal., on June 17, at the age of 68 years.

INDIAN RAILWAY NOTES.—The Balasand bridge on the Kissengunge line of the Darjeeling-Himalayan Railway has recently been completed. It has 14 spans of 40 ft. each and is a fine piece of engineering work. The Mahananda bridge on the same line cannot be completed at present, as the war has interfered with the delivery of girders. It is now proposed to get over the difficulty by constructing a temporary floating bridge. The Kissengunge-Matigora section, 62 miles long, has been opened for traffic; it is of narrow gage, runs from Siliguri via Nuzalbaree, thence along the boundary of Nepal and opens up a rich tract of the country.

THE PRIESKA-UPINGTON RAILWAY OF SOUTH AFRICA.—The electric light was brought into requisition and played an important part in the construction of the Prieska-Upington Railway, South Africa; the track of 142 miles was laid in record time, the average rate being equal to 2.25 miles per day. The maximum mileage completed in any one day was 3.25 miles. When once the work was properly set going it was carried on day and night, an up-to-date electric light generating plant enabling operations to be continued after sunset. This plant, which was headed by two powerful searchlights, travelled along the line as the rails were laid, driven by a locomotive, and carrying everything necessary for the generating of electricity. The lights were arranged on a long arm, which could be, and was, under perfect control, so that the light could be thrown in almost any direction within the half-radius of a circle. The speedy construction of the line was considered necessary in order to facilitate the movement of troops towards the German southwest border. The line is now being extended beyond Upington, and it is possible that the record established in the laying of the Prieska-Upington section may be eclipsed.

Equipment and Supplies

LOCOMOTIVE BUILDING

THE INTERCOLONIAL is inquiring for 20 locomotives.

THE BULGARIAN STATE RAILWAYS are in the market for 10 locomotives.

THE CUMBERLAND & MANCHESTER is contemplating the purchase of a locomotive.

THE BELGIAN STATE RAILWAYS have ordered 20 locomotives from the American Locomotive Company.

THE VERDE TUNNEL & SMELTER RAILROAD has ordered one superheater six-wheel switching locomotive from the American Locomotive Company. This locomotive is to have 21 by 26-in. cylinders and 58-in. driving wheels.

THE CENTRAL RAILWAY OF BRAZIL has ordered 3 Pacific and 3 Consolidation type locomotives from the American Locomotive Company. The Pacific type locomotives will have 21½ by 28-in. cylinders, and 68-in. driving wheels; and the Consolidation type locomotives will have 22 by 24-in. cylinders and 50½-in. driving wheels.

THE RUSSIAN GOVERNMENT which, as reported in the *Railway Age Gazette* of last week, has ordered 250 locomotives from the Baldwin Locomotive Works, 100 from the American Locomotive Company, and 50 from the Canadian Locomotive Company, is also understood to have ordered 50 locomotives from the Lima Locomotive Corporation. The locomotives ordered from the Baldwin Locomotive Works are to be Decapod type locomotives for freight service. Those ordered of the American Locomotive Company are to be of the same type and are to have 25 by 28-in. cylinders, 52-in. driving wheels, and a total weight of 197,000 lb. The Baldwin Locomotive Works is also reported to have received an order for 365 traction engines from the Russian government.

CAR BUILDING

THE SEABOARD AIR LINE is inquiring for 4 dining cars.

THE INTERCOLONIAL is in the market for 1,000 steel underframe box cars.

THE CUMBERLAND & MANCHESTER intends to purchase a number of flat cars.

THE CHICAGO, ST. PAUL, MINNEAPOLIS & OMAHA is inquiring for 1,500 40-ton box cars.

THE CHICAGO & NORTH WESTERN has revived inquiries for 1,500 steel underframe box cars.

THE LAKE SUPERIOR & ISHPEMING has ordered 400 ore cars from the Cambria Steel Company.

THE CHILE EXPLORATION COMPANY, South Bethlehem, Pa., has ordered 40 ore cars from the Pressed Steel Car Company.

THE NEW YORK CENTRAL is said to be contemplating the purchase of a large number of freight cars. This item has not been confirmed.

THE CINCINNATI, HAMILTON & DAYTON has revived an inquiry for 1,000 40-ft. 40-ton steel underframe box cars and 1,000 50-ton hopper cars.

THE RUSSIAN GOVERNMENT is reported to have ordered 57,400 car wheels on axles from the Baldwin Locomotive Works for delivery within 90 days.

THE CHICAGO, ROCK ISLAND & PACIFIC has ordered 2,500 40-ft. 40-ton box cars from the Pullman Company, 1,000 from the Bettendorf Company and 500 from the Haskell & Barker Car Company.

THE PENNSYLVANIA EQUIPMENT COMPANY, Philadelphia, Pa., is in the market for 100 80,000 to 100,000-lb. capacity all steel or

steel underframe gondola cars, 1 or 2 60,000 to 70,000-lb. capacity box cars and a number of second-hand 3-ft. gage coal and flat cars.

The British Government is reported to have given the Canadian Car & Foundry Company a large order for box cars. This item has not been confirmed, and may possibly have been confused with the order which this company is supposed to have received from France.

The French Government is reported to have ordered 2,500 cars from the Standard Steel Car Company, and 1,000 from the Canadian Car & Foundry Company. The total order includes 10 and 20-ton flat and box cars. The French government is also said to be in the market for 345 passenger cars.

IRON AND STEEL

The Chesapeake & Ohio is negotiating for additional rails.

The Cuba Railroad has ordered 7,000 tons of rails from the Lackawanna Steel Company.

The Chicago, Milwaukee & St. Paul has ordered 516 tons of steel for through girder spans from the Wisconsin Bridge & Iron Company.

The Paducah & Illinois has ordered 540 tons of steel for trusses and frames for the Metropolis bridge, at Metropolis, Ill., from the Kenwood Bridge Company.

The Southern Railway has ordered 2,100 tons of rail from the Tennessee Coal, Iron & Railroad Company, and 6,000 tons from the Pennsylvania Steel Company.

The New York Central has ordered 1,500 tons of rails from the Illinois Steel Company in addition to the 15,500 tons reported in the *Railway Age Gazette* of May 28.

The Trans-Mississippi Terminal Railway has ordered 209 tons of steel for a passenger station and terminal buildings, at New Orleans, La., from the Virginia Bridge & Iron Company.

The St. Louis & San Francisco has ordered 21,212 tons of 90-lb. open hearth rails from the Tennessee Coal, Iron & Railroad Company, and has also placed an order for 205 tons of steel for four 77-ft. deck plate girder spans with the American Bridge Company.

The Pennsylvania Lines East & West of Pittsburgh, which were reported in the *Railway Age Gazette* of June 11, as having ordered 155,500 tons of rail, divided the order as follows: 69,700 tons from the Carnegie Steel Company, 34,850 tons from the Cambria Steel Company, 34,850 tons from the Pennsylvania Steel Company and 8,050 tons each from the Bethlehem Steel Company and the Lackawanna Steel Company.

MACHINERY AND TOOLS

The New York Central is inquiring for a number of machine tools.

The Pennsylvania Railroad is in the market for a few machine tools.

The Interborough Rapid Transit is said to be contemplating the purchase of machine tools.

The Baltimore & Ohio is said to be contemplating the purchase of a large number of machine tools.

The Maine Central has ordered one 35-ton crane from the Northern Engineering Works, Detroit, Mich.

The Lehigh Valley has ordered a 72-ft., 233-ton electrically operated locomotive transfer table and an electric tractor for a 100-ft. turntable from George P. Nichols & Brother, Chicago, for installation at Sayre, Pa.

Railroad Construction Projects in Switzerland.—Altogether 78 railway projects exist in Switzerland for which concessions have already been granted, besides a great many others which have not yet reached the stage of having a formal demand made for a concession. These 78 railway projects, for which concessions have been obtained, will for the most part probably never be carried out, at any rate, not for 15 or 20 years to come.

Supply Trade News

A. S. Baldwin has been appointed works manager of the R. D. Nuttall Co., Pittsburgh, Pa.

Frederick C. Lavarack of the Signal Accessories Company, will also represent the sales department of the Hayes Track Appliance Company in New York city and the east.

F. W. McIntyre, for the past four years connected with the Chicago office of the Niles-Bement-Pond Company, has been transferred to the Boston office, where he was formerly located.

The American Locomotive Company and the Westinghouse Air Brake Company have received permission to manufacture munitions of war in the former plant of the Texoleum Company at Kenilworth, N. J.

The American Locomotive Company is said to be planning to establish a branch plant in Cincinnati for the filling of war orders. According to the reports, if a suitable plant cannot be rented a new one will be erected.

Ira C. Rogers has resigned from the position of assistant purchasing agent of the Pittsburgh & Lake Erie, and has been appointed general purchasing agent of the International Steam Pump Company, New York.

The transportation department of the Panama-Pacific International Exposition at San Francisco has awarded the Rail Joint Company, New York, the only medal of honor presented for rail joint products.

At a meeting of the board of directors of Berry Brothers, Detroit, Mich., held on May 26, Orrin S. Goan was elected president and a director succeeding Frank W. Blair, who has resigned because of other business interests.

The Safety Car Heating & Lighting Company, New York, has been awarded a gold medal by the International Jury of Awards at the Panama Pacific International Exposition for its "Underframe" car lighting electric equipment.

M. A. Hudson has resigned as vice-president of the J. E. Lonergan Co., Philadelphia, Pa., to become manager of the western branch of the United Roofing & Manufacturing Company, with headquarters at 933 Marquette building, Chicago.

The Public Belt Railway Commission of New Orleans has just ordered from the Weir Frog Company of Cincinnati, 175 sets of manganese insert frogs, guard rails and switches. This order is for the full normal requirements of the Commission.

A three-story, 80-ft. by 600-ft addition is to be made to the boiler shop of the Eddystone, Pa., plant of the Baldwin Locomotive Works. The new shop is to be a woodworking shop, and it is said will be used in the manufacture of rifle stocks.

R. M. Newbold, formerly with the Adams & Westlake Company, has been appointed western manager of the railroad department of the Willard Storage Battery Company, succeeding P. D. Smith, who has resigned to accept service with another company.

The Kincaid Stoker Company, Cincinnati, Ohio, has been incorporated, with $50,000 capital stock, to manufacture mechanical stokers for use on locomotives, ships and in power plants. John Kincaid, Napoleon DuBrul, D. S. DuBrul and Clarence DuBrul, are the incorporators.

W. C. Irwin, formerly connected with the engineering department of the city of St. Louis, has been appointed district representative of the Kalamazoo Railway Supply Company, in charge of the St. Louis office at 304 Frisco building, succeeding W. D. Waugh, resigned.

The Harvey Company, 113 South street, Baltimore, Md., has recently been incorporated under the laws of Maryland to sell equipment and supplies to railroads, contractors, shop and engine building companies, etc. J. Edward Harvey, who has been elected president of the new company, was formerly vice-presi-

dent of the South Baltimore Steel Car & Foundry Company, Baltimore, Md., and at one time proprietor of the Eastern Railway Supply Company.

Richard S. Brown, formerly a salesman of railway apparatus, connected with the Boston office of the Westinghouse Electric & Manufacturing Company, died in New York June 5. Mr. Brown was 76 years of age and had been in the service of the Westinghouse company since 1890.

The American Car & Foundry Company will spend more than $50,000 in improvements to its Milton, Pa., plant. Included are new shops, 100 by 350 ft. in size, a 120-ft. extension to the steel storage yard, a 100-ft. extension to the tank car plant and the addition of some machinery.

Harrison G. Thompson, a vice-president, and manager of the railway department of the Edison Storage Battery Company, Orange, N. J., has been appointed general sales manager, and as such will henceforth have charge of all sales including the railway, house lighting and commercial departments.

H. C. Crawford, eastern traffic manager of the Cambria Steel Company at Philadelphia, has been appointed traffic manager of that company, succeeding William A. Sproul, who has resigned, effective August 1, after 25 years of service with the company, to take charge of the bureau of transportation and traffic of the Philadelphia Chamber of Commerce.

David A. Thomas, the well-known Welsh coal mine owner, has been appointed to represent the munition department of Great Britain in the United States and Canada. He will probably make his headquarters in Ottawa and New York, and will deal directly with makers of arms and munitions, co-operating in so far as possible with J. P. Morgan & Co.

The Chambers Valve Company, New York, announces that among other recent orders it has received orders for Chambers throttle valves for installation on 42 locomotives of the Missouri, Kansas & Texas, 55 of the Chicago, Burlington & Quincy, 15 of the Western Maryland, 12 of the New York, Ontario & Western, and 2 of the El Paso & Southwestern.

The Chicago Great Western has ordered 1,150 sticks of treated piling from the Central Coal & Coke Company, 400,000 ft. of long leaf pine from the Bell Lumber Company, 850,000 ft. of untreated Douglas fir from Washington points and 350,000 ft. of yellow pine from Louisiana points. All the timber will be treated by the International Creosoting & Construction Company, at Texarkana, Tex.

The Hagar Portland Cement Company has been incorporated under the laws of Maine, with $20,000,000 capital stock, for the purpose of acquiring and operating a chain of cement plants between the Atlantic coast and the Rocky mountains. Edward M. Hagar, recently president of the Universal Portland Cement Company, was elected president; Morris Metcalfe, vice-president; B. H. Rader, vice-president and sales manager; Gordon Wilson, secretary and in charge of cost accounting; Leonard Wesson, assistant to president in operation and construction; J. P. Beck, assistant to president in extension work; C. W. Lyon, engineer of economies, and J. H. Barbazette, superintendent of construction. Pending the election of a permanent treasurer the office will be filled by Gordon Wilson. The general offices of the company are located at 208 South La Salle street, Chicago.

The Ingersoll-Rand Company, New York, on June 1 opened a new branch office at 139 Townsend street, San Francisco, Cal., with a view to giving closer attention to the needs of present and prospective users of Ingersoll-Rand machinery. H. L. Terwilliger, president of Harron, Rickard & McCone, the present Ingersoll-Rand agents, has resigned from that position to become district manager of the territory handled by the Ingersoll-Rand Company's San Francisco and Los Angeles offices, with headquarters in the former city. H. G. Mitchell, formerly secretary of Harron, Rickard & McCone, has been elected president of that company, succeeding Mr. Terwilliger, and arrangements have been made whereby the company will continue to handle Ingersoll-Rand machinery and co-operate in other ways with the Ingersoll-Rand Company after the expiration of the agency contract on July 22.

Railway Construction

Athabasca & Fort Vermillion.—Announcement is made that surveys are to be started at once preliminary to actual construction of the line from Athabasca, Alta., northwesterly to Trout Lake and to Fort Vermillion, about 300 miles. J. M. Kernan, J. V. Rawle, J. Dalganeau, Athabasca; S. Clarke, Fort Vermillion, and K. Keith, Edmonton; D. A. Thomas, and A. G. McKay are interested. (April 23, p. 913.)

Cumberland & Manchester.—A contract has been given to T. J. Vermillion & Son, Barbourville, Ky., for grading and track laying on a section of three miles, and additional contracts are to be let shortly. The plans call for building from Barbourville, in Knox county, Ky., north via Cannon, Girdler, Hopper and Woollum to Manchester, 24 miles. An extension from Manchester is projected to Beattyville, about 30 miles, but this extension will not be built at the present time. The maximum grades to Manchester will be about 1 per cent, and the maximum curvature 8 deg. There will be four steel bridges on the line. The company expects to develop a traffic in lumber, coal, livestock, farm products and salt. Charles F. Heidrick, president, Brooksville, Pa. (June 4, p. 1181.)

Cumberland Railroad.—An officer writes regarding the reports that construction work would be resumed soon on an extension from Wheeler, Ky., southwest to Jellico, Tenn., about 24 miles, that it has not yet been definitely decided when construction work on this line will be resumed. The company now operates a line from Artemus, Ky., south to Wheeler, 10.2 miles.

Easton & Washington Traction.—This company, operating an electric line, from Easton, Pa., east via Washington, N. J., to Port Murray, has decided to build an extension northeast via Hackettstown to Lake Hopatcong, 19 miles.

Mascot & Western.—Track laying was finished recently, it is said, on this line from the Mascot Copper Company's property in Cochise county, Ariz., to the main line of the Southern Pacific. T. N. McCauley, president, Chicago; C. S. Henning, chief engineer, Dos Cabezos, Ariz. (February 19, p. 350.)

Missouri, Kansas & Texas.—This company is reducing grades on 3.1 miles of its line between Canadian and Eufaula, Okla., and is extending its bridge over the Canadian river at that point, as was reported in the *Railway Age Gazette*, May 21. The general contract has been awarded to the List & Gifford Construction Company, Kansas City, Mo., and the steel contract for the bridge to the Wisconsin Bridge & Iron Company. The work is now in progress.

Nashville, Springfield & Northern.—Incorporated in Tennessee to build a railway from Nashville, Tenn., connecting Springfield, Clarksville and Franklin, Ky., about 80 miles. E. G. Stribling, president, Nashville; W. B. Myers, vice-president, Goodlettsville, and R. C. Leonard, secretary and treasurer, Nashville.

New York Subways.—The New York Public Service Commission, First district, has awarded the contract for the construction of Section No. 1 of Route No. 29, the Nostrand avenue subway in the borough of Brooklyn, to the Newman & Carey Company, Brooklyn, the lowest bidder, who offered to do the work for $2,073,303. Section No. 1 covers that part of the line extending from Eastern Parkway southward under Nostrand avenue to a point about 220 ft. south of Church avenue.

Peoples Railroad Company.—Plans are being made by this company, which now operates a one-mile line at Fairhope, Ala., it is said, to build an extension east to Robertsdale, about 14 miles. The headquarters of the company are at Fairhope.

White Sulphur & Huntersville.—This company plans to build a line from White Sulphur, W. Va., northeast via Montague, Mapledale, Divide, Alvon and Shryock to a point 27 miles from White Sulphur, with a branch from a point near Shryock to Neola. The company expects to develop a traffic in lumber, but has not yet decided when the construction work will be carried out. T. J. Shryock, president, Baltimore, Md.

Yazoo & Southern.—Organized in Chicago with $3,000,000 capital to build a railroad from Yazoo City, Miss., east to Carthage, about 60 miles. W. C. Murphy, Yazoo City, P. R. McDonough and W. Kissock, Chicago, are the projectors and directors, and G. U. Nichols and S. Murphy, Chicago, are directors. (See Mississippi Roads, May 14, p. 1033.)

RAILWAY STRUCTURES

Baltimore, Md.—The Pennsylvania Railroad will ask for bids soon for installing some of the new coal handling facilities to be provided at Canton, Baltimore, which are expected to increase the tonnage of coal exported through Baltimore. The improvements to be carried out at Canton include a concrete bulkhead pier, machinery for loading coal into vessels, a coal dumper, thawing house and extensive freight yards for loaded and empty cars. The new pier is to be 942 ft. long and 66 ft. wide, and the coal handling machinery on the new pier will be capable of loading at least 6,000 tons of coal in ten hours. The thawing house will have a capacity of 30 cars, and there will be a tributary yard with a capacity of 79 cars. The loaded car yard is to have 36 tracks with a capacity of 620 cars, and the empty car yard is to have a capacity of 139 cars, with shop car tracks to hold 28 cars additional.

Bessemer, Ala.—The Alabama Great Southern will at once build a new station at Twentieth street, Bessemer, to cost $30,000. The building is to be of brick construction with Spanish tile roof, and cement floors. The company's forces will carry out much of the construction work. (May 28, p. 1140.)

Fredericton, N. B.—According to press reports, the Intercolonial has under consideration the question of building a new superstructure on the bridge over the St. John river at Fredericton.

Kinnickinnick, Wis.—The Chicago & North Western has awarded the contract for the pile foundation of its elevator at this place, to the Walsh Construction Company, Davenport, Iowa.

New York.—The War Department has granted permission for the construction of a bridge over the Bronx river at Westchester avenue in the borough of the Bronx. The bridge is to be built to carry the tracks of the Pelham Bay Park branch of the Lexington avenue subway, which at this point runs on an elevated structure. The plans call for a permanent bridge with a clearance of 61 ft. above mean high water.

Ottawa, Ont.—Bids are wanted until June 25, by J. W. Pugsley, secretary, Department of Railways and Canals, Ottawa, it is said, for improvements on the main line of the Intercolonial Railway as follows: Construction of abutments and piers at St. Henri river bridge, Riviere du Loup subdivision, and subways at Little Metis, Camphellton subdivision, and at Hampton, St. John subdivision.

Spartanburg, S. C.—The Southern Railway is asking for bids for work on a modern freight terminal, to include separate inbound and outbound warehouses with ample team track facilities at Spartanburg. The work is to be started at once, and the improvements will cost about $100,000. The new facilities will consist of a one story inbound freight house, 40 ft. by 198 ft., with a two story office section 40 ft. by 52 ft., to be of brick construction with concrete floor, fireproof roof, and equipped with rolling steel doors; the outbound freight house will be a one story structure 22 ft. by 250 ft., with concrete floor and base, frame construction and fireproof roof. There are to be four house tracks, with a capacity of 32 cars, and four team tracks with a capacity of 29 cars. A 20-ton Pillar crane will also be provided for handling heavy freight.

The Dalles, Ore.—The Oregon-Washington Railroad & Navigation Company will build a 12-stall roundhouse, a 40-ft. by 60-ft. storehouse, a 30-ft. by 40-ft. powerhouse, and a 50-ft. by 60-ft. machine shop. The powerhouse, machine shop and roundhouse will be brick buildings with mill interior, and the storehouse will be a corrugated, galvanized building on wood frame.

Bagdad Railway.—A Constantinople telegram states that 40 miles of the Bagdad Railway from Tellebiad to Tuan east of the River Euphrates have been opened to traffic.

Railway Financial News

Chesapeake & Ohio.—The following statement was issued by the board of directors on June 17:

"The board of directors at a meeting today decided not to declare at this time any dividend upon the stock of the company. While the gross earnings are the largest in its history, there has been a marked change in the character and direction of traffic carried, entailing a large decrease from hire of equipment and larger payments to other lines. The surplus for the year has also been unfavorably affected by decreased income from the Hocking Valley Railroad Company and the Kanawha & Michigan stocks.

"Advance figures indicate that earnings on the stock for the current fiscal year will be equivalent to about 4 per cent. A dividend of 1 per cent was paid on December 31, 1914, and the remainder has been devoted to improvements, payments on equipment, etc., thus enhancing the value of the property represented by the stock, thereby also complying with the terms of the note agreement of March 16, 1914.

"The $4,029,200 realized from the sale of the Kanawha & Michigan Railway stock was deposited with the trustee of the company's first lien and improvement mortgage, to be expended for improvements or investments which are permitted under the terms of that mortgage. The directors concluded that the very best use to which this special fund can be put, particularly at a time of low cost, is to invest it in the construction of a line nearly 30 miles in length, crossing the Ohio river east of Portsmouth, Ohio, and have accordingly authorized contracts for the bridge and for the line referred to. This line is to connect with the Norfolk & Western at Waverly, Ohio, from which point trackage rights have been arranged with the Norfolk & Western to a connection with the Hocking Valley near Columbus, Ohio.

"It is expected that this construction, which it is hoped may be completed by November 1, 1916, will not only restore to the Hocking Valley line a coal tonnage equivalent to that formerly received from the Kanawha & Michigan, but that it will also furnish a greatly needed additional outlet for coal originating on the Chesapeake & Ohio lines destined for the lakes and the northwest and will facilitate the significant development of coal lands in the territory served by the company.

"Such a connection is unqualifiedly considered the one important thing to be done for the Chesapeake & Ohio and will place it in a more commanding position than ever before, because it will have a short line from eastern Kentucky and a large part of West Virginia to Lake Erie. It is estimated that the cost of this new construction, including the Ohio river bridge, will not exceed $4,500,000. The present outlook for business is excellent."

Chicago, Rock Island & Pacific.—Judge Carpenter, in the federal court, has approved the issue of equipment trust certificates to pay for 85 per cent of the cost of 4,000 box cars, and has approved the payment of the remaining 15 per cent in cash by the receivers. The court has also approved the payment of $125,000 due to the Trinity & Brazos Valley. The Rock Island and the Colorado & Southern use the Trinity & Brazos Valley jointly from Dallas, Tex., to Houston, and the $125,000 represents the semi-annual payment of the Rock Island's share of the lease.

Colorado & Southern.—See Chicago, Rock Island & Pacific.

Missouri Pacific.—Brown Brothers & Company, New York, are asking holders of the collateral trust 5 per cent bonds due 1917 and the collateral trust 5 per cent bonds due 1920 of the Missouri Pacific to communicate with them, giving their addresses and holdings, with a view to concerted action for the protection of their interests in the plan which is now under discussion for a reorganization of the Missouri Pacific finances.

Brown Brothers & Company are also asking holders of the St. Louis, Iron Mountain & Southern refunding 4 per cent bonds to send their names and holdings to the firm.
