Profile of the Colorado Division Between Phillipsburg and Goodland

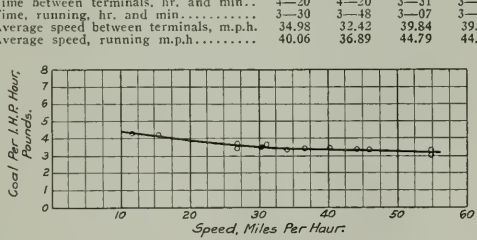
foot of grades. This is shown by reference to the profile. It will be seen, therefore, that a locomotive which can successfully and economically haul this train must have both a high starting tractive effort and a relatively high sustained tractive effort at high speeds.

The Mountain type locomotives were described in the *Railway Age Gazette* for January 9, 1914, on page 86. They weigh 224,100 lb. on drivers, and have a total weight of 333,100 lb., cylinders 28 in. by 28 in., 69-in. drivers, and a maximum tractive effort of 50,000 lb. In 14 of these tests the number of cars ranged from 10 to 16, with an average weight of 674 and 1,045 tons, respectively. In addition to these trips later tests were made with 19-car trains with a weight of 1,175 tons, exclusive of lading. The tests were made in regular service, the trains leaving Phillipsburg at 8:30 p. m. and arriving at Goodland at 12:45 a. m., giving a schedule running time of 4 hr. 15 min., and a schedule speed of 33 miles per hour. For the 10-car and 16-car tests the locomotive was equipped for taking indicator cards, determining temperatures in the steam chests and front end, steam pressures in the superheated and saturated steam chambers of the superheater header, and the draft, as well as for obtaining the steam consumption by the various auxiliaries. The tender tank and boiler were calibrated and the water was measured at all stops from the start of the test. The coal was delivered to the firemen in quantities of 100 lb., being loaded on the tender in bags for this purpose. The same engineer and firemen were used throughout the tests in order that the conditions would be as nearly as possible the same. A shield was built over the pilot for the protection of the observers, as shown in the illustration. This enclosure was lighted with electric lamps, the current being provided by the electric headlight generator.

The accompanying table gives the average results of three tests each, with an average of 10 cars and an average of 16 cars in both directions.

Test Results for the Mountain Type Locomotive

Items	Westbound 10 Cars	Westbound 16 Cars	Eastbound 10 Cars	Eastbound 16 Cars
Mileage	139.9	139.9	139.9	139.9
Tonnage	674	1,045	709	1,028
Ton-miles	94,292	146,196	99,190	143,817
Time between terminals, hr. and min..	4—20	4—20	3—31	3—33
Time, running, hr. and min.	3—30	3—48	3—07	3—10
Average speed between terminals, m.p.h.	34.98	32.42	39.84	39.48
Average speed, running m.p.h.	40.06	36.89	44.79	44.13



Curve of Coal Consumption

Coal used between terminals, lb.	18,133	27,033	10,943	13,433
Coal per gross 1,000 ton-miles, lb.	193.72	184.84	110.52	93.33
Coal per car mile, lb.	12.57	11.83	7.59	6.00
Coal per i. hp. hr., lb.	2.58	3.17	.....	.....
Coal per sq. ft. grate area per hr. (between terminals), lb.	72.26	99.57	49.77	60.45
Coal used at terminals, lb.	2,902	3,500	3,010	3,517
Water delivered to boiler between terminals, lb.	119,170	155,446	75,609	93,076
Water per i. hp. hr., lb.	16.98	18.29	.....	.....
Steam used in cylinders (net), lb.	106,807	140,606	58,090	70,231
Steam used per hr. in cylinders (open throttle), lb.	33,707	40,514	20,382	26,582
Steam used per hr. in cylinders (running time), lb.	30,591	37,074	18,960	22,891
Water evaporated per sq. ft. evaporating surface per hr., lh. (throttle open)	9.13	10.86	.....	.....
Water evaporated per sq. ft. total heating surface per hr., lb. (throttle open)	7.43	8.85	.....	.....
Steam used per pound of coal, lb.	6.57	5.76	.....	.....
B. t. u. absorbed per pound of dry coal.	8,539	7,525	.....	.....
Efficiency of boiler (dry coal)	67.74	59.70	.....	.....
Steam pressure—				
Boiler, lb. per sq. in.	182.5	181.1	.....	.....
Saturated steam chamber in header, lb. per sq. in.	172.9*	178.8	.....	.....
Superheated steam chamber in header, lb. per sq. in.	157.7	160.4	.....	.....
Steam chest, lb. per sq. in.	154.1	158.6	.....	.....
Initial in cylinder, lb. per sq. in.	145.6	152.9	.....	.....
Temperature at steam chest, deg. F.	580.8	598.3	.....	.....
Superheat, deg. F.	212.9	228.2	.....	.....
Smokebox temperature, deg. F.	511.7	538.9	.....	.....

*This pressure is low due to throttling.

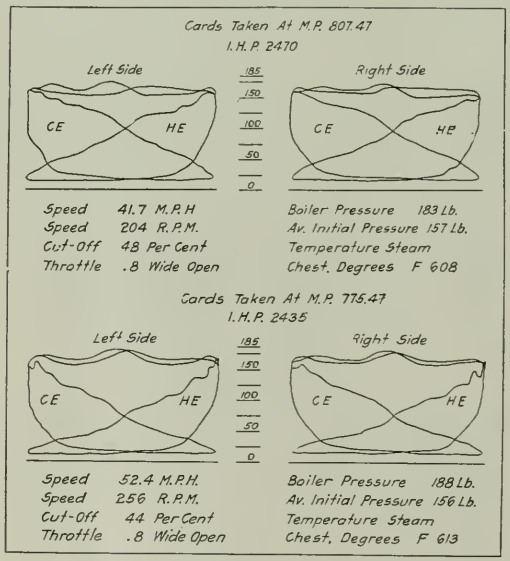
The power of the locomotive was not taken on the eastbound trips as the grade is mostly descending. This will account for the difference in the coal and water rates between the eastbound and westbound trips.

An inspection of these tabulated results shows that the loco-

motive operated more efficiently on the ton-mile basis with 16-car trains. In the tests with the 19-car trains, which were simply coal and water tests, this efficiency showed still greater increase, the average coal consumption per 1,000 gross ton-miles being approximately 138 lb. It will be noted that the coal consumption per indicated horsepower hour with the 16-car train was 3.17 lb. at the time maximum horsepower was developed. This is somewhat better than the theoretical rating applied to this locomotive, which is 3.25 lb. The water rate per indicated horsepower hour is also better than the theoretical rating, the tests showing it to be 18.29 in contrast to a theoretical rating of 21.6 lb. It was found that the maximum horsepower developed for short periods exceeded the theoretical rating, the former being 2,700 and the latter 2,613.

Another feature of the test which shows that the locomotive was not being worked to its full capacity with a 10-car train is the drop in pressure of approximately 10 lb. between the boiler and the saturated steam chamber in the superheater header This drop is explained by the fact that it was necessary to throttle the locomotive to keep from exceeding the speed limit with this load. The results also show how the superheat increased as the locomotive became more heavily loaded.

The fuel used in these tests was good quality Colorado coal



Examples of Indicator Cards Taken on the Tests

of mine run consistency. The approximate analysis, as taken from several different cars, was as follows:

Moisture	1.69 per cent
Volatile matter	36.69 per cent
Fixed carbon	47.58 per cent
Ash	13.45 per cent
Sulphur	.59 per cent
Total	100.00 per cent

The heat value obtained by the calorimeter was 12,604 B. t. u. for dry coal, and 12,593 B. t. u. for wet coal.

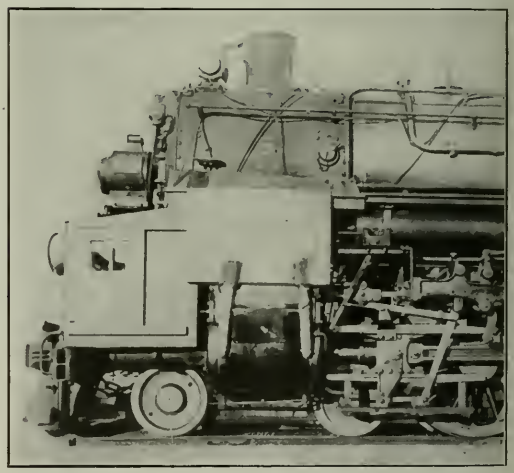
Exceptionally good performance with 19-car trains was shown on various occasions. On the ruling grade immediately out of Prairie View, going west, the locomotive, from a standing start at the foot of the one per cent grade, reached a speed of 23 miles per hour at a point 3.5 miles west. The locomotive was working at 50 per cent cut-off and carried full boiler pressure. With a 19-car train on the three-mile, 0.8 per cent ruling grade between Jennings and Dresden, the speed at the foot of the grade was 33 miles per hour and at the top 23 miles per hour, the locomotive working at 50 per cent cut-off and carrying full boiler pressure. These figures are not the result of one or two performances, but are quite representative of the performance of this locomotive.

With the 19-car train, no stop was made at the coal chute at Selden (a half-way station between Phillipsburg and Goodland), the locomotive arriving at Goodland with about three tons of coal on the tender. Under these unusual conditions, viz., maximum trains, running by coal chutes, etc., sacked coal was carried on the rear of the tank and an extra man was kept on the locomotive in case an emergency arose which would require using all the loose coal in the tank and some which was sacked.

The success attained by the engine crew in handling these large trains may be attributed partly to the efficiency of the crew, and partly to the design of the modern locomotive, including as it does such labor-saving devices as the superheater, brick arch, screw or power reverse gear, pneumatic fire door opener, and a tank with sloping coal sheets, so that 70 per cent of the coal is kept within reach of the fireman.

The following is a list of the general data for the locomotive used in the test:

Number	999
Type	4-8-2
Service	Passenger
Fuel	Bit. coal



Arrangement of the Indicator Reducing Motion and the Shield to Protect the Observers

Tractive effort	50,000 lb.
Weight, total	333,100 lb.
Weight on drivers	224,100 lb.
Weight on leading truck	57,500 llb.
Weight on trailing truck	51,500 lb.
Weight of engine and tender	490,500 lb.
Wheel base, driving	18 ft. 0 in.
Wheel base, total	38 ft. 11 in.
Wheel base, engine and tender	70 ft. 2¼ in.

Ratios

Weight on drivers ÷ tractive effort	4.48
Total weight ÷ tractive effort	6.66
Tractive effort × diam. drivers ÷ equivalent heating surface*	623.53
Equivalent heating surface* ÷ grate area	88.24
Firebox heating surface ÷ evaporative heating surface, per cent	7.58
Weight on drivers ÷ equivalent heating surface*	40.48
Total weight ÷ equivalent heating surface*	60.18
Volume both cylinders, cu. ft.	19.94
Equivalent heating surface* ÷ volume of cylinders	277.50
Grate area ÷ volume of cylinders	3.14

Tubes and flues, length	22 ft. 0 in.
Heating surface, firebox	287 sq. ft.
Heating surface, tubes and flues	3,805 sq. ft.
Heating surface, arch tubes	25 sq. ft.
Heating surface, total	4,117 sq. ft.
Superheating surface	944 sq. ft.
Equivalent heating surface*	5,533 sq. ft.
Grate area	62.7 sq. ft.

Tender

Water capacity	8,500 gal.
Coal capacity	14 tons

*Equivalent heating surface = evaporative heating surface + 1.5 times the superheating surface.

REMOTE SWITCHES MOVED BY BATTERY CURRENT

On the Northern Pacific, at Bozeman Pass Tunnel, 12 miles west of Livingston, Mont., there are two switches at the entrances of two side tracks, which are worked by electric motors controlled by the telegraph operator at the mouth of the tunnel, nearly a mile away. The motors are the low-voltage switch machines of the General Railway Signal Company, and were put in last November. With these the stopping of freight trains on the steep ascending grades for the purpose of having the switch set for the side track by hand is no longer necessary. The movement of a switch takes 23 seconds. C. A. Christofferson, signal engineer of the road, gives the following particulars of this installation.

Each of the side tracks is 4,500 ft. long, one east of the tunnel and one west, and each is used, when necessary by freight trains ascending toward the tunnel, which is at the summit. As pushing engines are used on both sides of the tunnel the number of movements is comparatively large, and economy of time is an important desideratum. The line through the tunnel is single track and the staff system is used. At the entrance of each side track a two-arm signal was installed, and there is a short track circuit section at the switch to serve the purpose of a detector. The control circuits for the signals are selected by the switch so as never to give a wrong indication. There is also a special relay, normally de-energized, to provide against danger from crosses between wires. Repeaters in the telegraph office, one for each signal arm, keep the operator constantly posted as to the position of the signals.

Trains are announced by a bell which is rung when the engine passes a point two miles away; and on this announcement, having received suitable instructions from the train despatcher, the operator sets the switch for the siding.

The switch machine is provided with an emergency crank which can be used by trainmen in case of failure of the electric circuit. Suitable provision is made for guarding against the application of power by the crank and by the electric current at the same time.

The battery, which works the signal arms as well as the switch machine, consists of seven cells of 20-ampere-hour lead storage battery, charged by 24 cells of 400-ampere-hour caustic soda battery. The time required for a complete operation of the switch machine, the signal, and the repeater in the telegraph office, is 31 seconds. The maximum current required is 4½ amperes, which is required to lock the switch.

The whole system has worked thus far without failure, and, of course, it makes a decided saving in the movement of heavy freight trains on ascending grades when they are required to take the siding. The company intends to try a device for setting switches, in situations like this, without the intervention of the operator; that is to say, by means of a contact rail, fixed on the ties some distance back of the switch, with a sliding contact on the locomotive which, when adjusted by the engineman, will close an electric circuit which will operate the switch and the signal.

CHICAGO, ROCK ISLAND & PACIFIC STOCKHOLDERS' MEETING

At the annual meeting of the stockholders held in Chicago on April 12, Charles Hayden of Boston, William J. Matheson of New York, W. E. Roosevelt of New York and N. L. Amster of Boston were elected directors, succeeding E. S. Moore, J. J. Mitchell, D. G. Reid and Roberts Walker. The election came at the close of a stormy meeting which lasted from noon until nearly 10 o'clock at night, in which Amster and his lawyers attempted to oppose the actions of the majority, represented by the Sheldon proxy committee, at every move.

Counsel for the Amster committee had previously made a written agreement with counsel representing the majority stockholders, by which it was provided that if the meeting were held in accordance with certain mutually agreed on conditions, the by-laws would be abided by and that no opposition would be put in the way of the election of directors by the representatives of the minority stockholders. As soon as the meeting had been called to order, however, a motion was made to appoint tellers other that those appointed by the board of directors. Mr. Amster claimed that he did not know of the agreement previously made by his representative. The by-laws provide that the board of directors and not the stockholders shall appoint the tellers and that the board of directors shall amend the by-laws, but there is no provision by which the stockholders can amend the by-laws. Mr. Amster and other representatives of the minority stockholders proposed the amendment of the by-laws and the motion was ruled out of order by the chairman. A motion was then made to adjourn until May 24 and at that time elect 13 directors, but this motion was ruled as out of order because of carrying the rider in regard to the 13 directors.

Finally a straight motion to adjourn was made. This motion was put to a vote, each share of stock having one vote, and a recess was taken during the counting of the vote. It was during this recess that Mr. Van Hall made the statement which is commented on in the editorial columns of this issue. The count of the vote on the question of adjournment showed—437,197 votes against adjournment and 151,579 for adjournment.

Representatives of the minority stockholders thereupon entered a protest against this vote on the ground that there had been no time for the Amster committee to circularize stockholders for proxies; on the ground of the complaint filed in the courts on April 9 (the substance of this complaint is given below); that the Sheldon committee had offered to put 10-cent revenue stamps on voting certificates, which was an illegal inducement to secure proxies; and finally that the Sheldon proxy certificates had not been stamped.

The election of directors then took place and by the concentration of their votes on one director the minority interests elected Mr. Amster, and the three other directors previously mentioned were elected by the majority.

A resolution was then adopted providing for the appointment of a committee of five stockholders to draw up a new set of by-laws for the company. A vote was then taken on the motion of a stockholder, who said that he represented neither minority nor majority interests, ratifying the proceedings of the meeting. The minority representatives voted against ratifying the proceedings, the majority and the independent stockholders voting in the affirmative. The vote, therefore, was carried in about the proportion as that of the vote against adjournment.

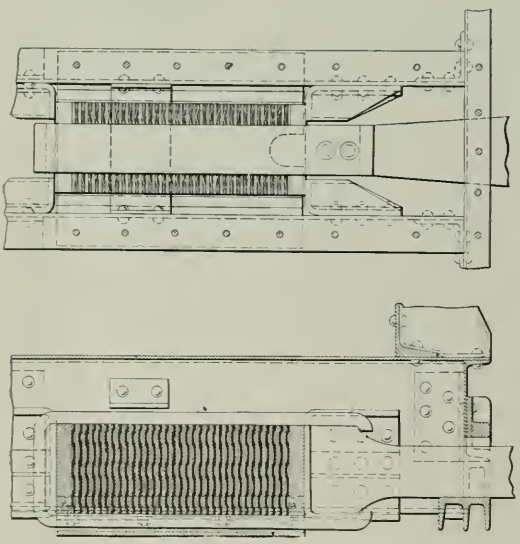
On April 9 counsel representing the minority interests filed a bill of complaint in the United States district court at Chicago

asking an injunction restraining the holding of the stockholders' meeting and the voting of the Sheldon committee proxies. The injunction was denied, although the bill of complaint is still before the court to be acted on. Summarized briefly the bill of complaint alleges (1) that the directors and officers unlawfully refused permission to stockholders to see the stockholders' list and at the same time gave the Sheldon committee, which represents the majority interests, the addresses of stockholders for the express purpose of permitting the Sheldon committee to circularize stockholders for proxies; (2) that the Sheldon committ secured proxies without revealing to the stockholders that they were used for the benefit of the present management; (3) that the division of the Chicago, Rock Island & Pacific board into three classes, with four directors each in two of the classes and five directors in the third class, is unlawful under Illinois statutes, which provide that directors should be divided into classes with three in each class; (4) that the present division of directors into classes deprives the minority stockholders of their rights under the Illinois constitution to the exercise of cumulative voting.

FRICTION SPRING DRAFT GEAR

The drawing below shows the plan and half-sectional elevation of the Slick friction spring draft rigging which was recently developed by the Carnegie Steel Company, Philadelphia, Pa.

The springs in this rigging are formed of comparatively thin, square or rectangular corrugated steel plates, the axes of the corrugations being parallel to each other. A number of these plates are used, the corrugations of each being placed at right angles to those of the two adjoining plates. The arched portions of the plates are thus in contact with each other, and each



Slick Friction Draft Gear

plate forms an abutment against which the adjoining plate operates. The device may be made either with single corrugated spring plates or where greater stiffness is desired the elements may be made up of two or more laminations each. The construction of the rigging is otherwise similar to that commonly used with other types of spring elements.

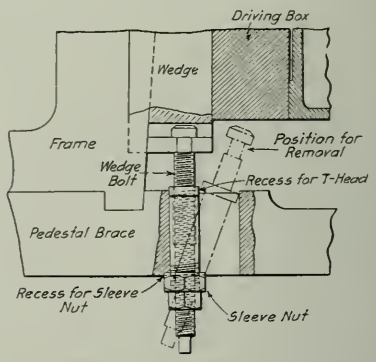
When under load the plates withstand stresses first by the spring action of the corrugated portions, which tend to flatten out under pressure, and in addition by the frictional resistance to the movement of the plates one upon another due to the flattening out of the corrugations. This action tends to dissipate a portion of the energy delivered to the draft rigging.

It is also claimed that the arch action of the corrugations tends to distribute the stress through the curved portion of each corrugation in such a way as to counteract to a certain extent the stress in the tension side of the plates. The depth of the corrugations is such that when each plate is flattened under load the stresses will be about equal to the proper working stress of the material.

LOCOMOTIVE WEDGE BOLT

A wedge bolt which may be applied and removed without taking down the pedestal binder is shown in the engraving. This device, which is manufactured by the Wine Railway Appliance Company, Toledo, Ohio, is made standard for all wedges on the locomotive, and in case of emergency may be renewed by the engineer while the engine is in service.

The pedetsal brace is provided with a slot, as shown in the drawing, through which is inserted a tee headed sleeve. The wedge bolt is screwed into this sleeve, which in its normal position becomes a rigid part of the brace, and the bolt is operated in the same manner as if the sleeve were not used. The top of



Wedge Bolt Removable with Binder in Place

the pedestal brace is provided with a recess for the reception of the tee head and the bottom of the brace is provided with a recess for the sleeve nut, which is threaded on the sleeve and holds it rigid within the pedestal brace.

It will be noted that the nut which locks the wedge bolt bears against the sleeve nut and acts as a lock nut for the sleeve as well.

To remove one of these bolts, all that is necessary is to back off the lock and sleeve nuts until the tee head on the sleeve can be lifted out of the recess in the top of the pedestal brace. The sleeve is then revolved through 90 deg. into the position shown by dotted lines, the head of the wedge bolt being slid out of the slot in the wedge at the same time. In order to do this the wedge must be drawn down into the position shown so that the slot in the wedge is clear beneath the driving box.

This device is in use on about 100 engines and is said to be giving excellent service.

Projected Railway from Fiume, Hungary, to Novi, Croatia.—A concession has been granted for the construction of a 25-mile railroad from Fiume to Novi, Croatia, passing through the towns of Susak, Buccari, Portore, Cirquenizzo and Selce. The Fiume branch of the Hungarian bank secured the concession, which was asked for before the war began. Work will probably not begin until normal times return again.

Maintenance of Way Section

No single practice is more conducive to economical maintenance of way work than starting operations early in the spring and taking full advantage of the seasons.

Start Your Work Early

With the present indications that continued retrenchment will be the order this year, it is all the more necessary that maximum results be secured from every dollar expended. Many roads have already entered actively upon their work and are now well advanced in their surfacing, tie renewals, etc. Those who are still holding back for the close of the fiscal year or other reasons should consider what this delay means in ultimate expenditure. Now is the time to start.

Approximately three per cent of all expenditures for maintenance of way and structures are for ties. With the exception of the roadway and track and the labor account, this is the largest single item in this group, being over three times that for rail. The importance of careful supervision in the renewal of ties to secure their full life, while at the same time maintaining the track in proper condition, is therefore evident. At this season of the year the track forces are very largely engaged in the renewal of ties. For this reason we devote a large amount of space in this issue to this and allied subjects.

The Season of Tie Renewals

At the closing session of the convention of the American Railway Engineering Association last month a resolution was adopted requesting the Board of Direction to consider a plan by which the conclusions of certain other associations working along the same lines should receive the endorsement of this association without discussion in detail before its conventions. While this resolution is so general in its character that it might apply to any technical association, it undoubtedly refers more particularly to those in the maintenance of way field and is the first step towards the co-ordination of the work of these societies. The other important associations in this field include the Railway Signal Association, the American Railway Bridge & Building Association, the Roadmasters' & Maintenance of Way Association, the Maintenance of Way Master Painters' Association, and the American Wood Preservers' Association, the latter association having among its members commercial as well as railway men. Each of these societies specializes in work covered in a general way by the American Railway Engineering Association. Up to the present time the only one of them whose work has been co-ordinated with that of the Engineering Association is the Railway Signal Association. As a result there has been more or less duplication of work and even direct conflict in recommendations. It is evident that such a condition results in a loss in efficiency and a possible confusion in standard practices. It is the experience of each one of these associations that many more subjects are presented to it for consideration each year than it is possible to study properly. There is, therefore, sufficient work for all to perform without this unnecessary duplification. It would not seem especially difficult to co-ordinate the work of these various associations to remove these conditions. The American Railway Engineering Association and the Railway Signal Association are now working in close co-operation and the reports presented to the two associations harmonize. A similar arrangement is gradually being perfected between the American Railway Engineering Association and the American Wood Preservers' Association. A somewhat different arrangement would be necessary with reference to the other associations because of the greater variety of the subjects within the scope of their investigations. It would seem practicable for an advisory committee composed of two or three officers of each association to consider the suggested lines of work for the different associations and to so harmonize them as to remove the present objections. This committee need not have any direct authority over the different associations, but could act in an advisory capacity only. In this way each of the associations would maintain its complete identity and independence while at the same time it would be informed regarding the contemplated work of other associations. There is a definite need for complete harmony in the recommendations of different associations on the same subject as well as for so planning the investigations that the greatest amount of information may be brought out. We believe the time is now ripe for the inauguration of some such plan as outlined.

Co-Ordination of Association Work

Fourteen papers were received in the contest on Bridge Construction Methods, which closed March 10. These papers were referred to W. H. Finley, chief engineer, Chicago & North Western, and C. F. Loweth, chief engineer, Chicago, Milwaukee & St. Paul, who awarded the first prize to I. L. Simmons, bridge engineer, Chicago, Rock Island & Pacific, Chicago, and the second prize to James H. Stack, secretary, The Thomson Bridge Company, San Francisco, Cal. Other papers were presented by: E. K. Barrett, supervisor of bridges and buildings and water service, Florida East Coast, St. Augustine, Fla.; C. M. McVay, engineer maintenance of way, Kanawha & Michigan, Charleston, W. Va.; E. M. Grime, supervisor, Northern Pacific, Dilworth, Minn.; J. B. Sheldon, supervisor bridges and buildings, New York, New Haven & Hartford, Providence, R. I.; J. J. Wishart, supervisor bridges and buildings, New York, New Haven & Hartford, Hartford, Conn.; L. C. Lawton, division engineer, Atchison, Topeka & Santa Fe, Newton, Kan.; J. E. Bebb, office engineer, Duluth, South Shore & Atlantic, Duluth, Minn.; S. C. Tanner, master carpenter, Baltimore & Ohio, Baltimore, Md.; C. V. Chamberlin, assistant supervisor of bridges, New York Central, Utica, N. Y.; W. L. Ratliff, supervisor bridges and buildings, Illinois Central, McComb, Miss., and E. W. Fair, supervisor bridges and buildings, Buffalo, Rochester & Pittsburgh, Du Bois, Pa. The prize-winning and others of these papers will be presented in the May maintenance of way section.

Contest on Bridge Construction Methods

SCREW SPIKES

IN spite of the fact that screw spikes are in service today on about 1,500 miles of main track, their use is still in its infancy. The first installation of any magnitude was one of a half mile on the Santa Fe near Topeka, Kan., in 1908. Since that time the mileage has risen to the figure given above and is increasing over 200 miles annually. The Santa Fe has over 150 miles of screw spike track and is now placing them in eight ties per rail on the western lines when laying new 90-lb. rail to secure a more rigid track construction. The Lackawanna is the largest user of screw spikes, having employed them exclusively in main tracks for both renewal and construction work for the past four years, until it now has over 12,000,000 in service. This line is one of relatively heavy grades and curvature with an average density of traffic of about 4,000,000 ton miles and 600,000 passenger miles per mile of line for the system, which figures are trebled if the main line only is con-

sidered, so that the service is unusually severe. For this reason the article by Mr. Ray describing the results secured from the use of screw spikes on the Lackawanna, which appears in another column, is of special interest.

Wherever introduced, the screw spike has encountered the opposition of the track men, who have pointed out numerous objections. The one most emphasized has been the difficulty of removing the spikes when necessary to replace rails following derailments or during relaying operations. The Lackawanna has a dense freight traffic on heavy grades, and therefore has its share of derailments. Therefore the conclusion of Mr. Ray that screw spikes have not been a disadvantage, but rather a decided advantage at such times, indicates that this fear has been exaggerated. It has been the experience of this road that by providing a stronger track the screw spikes have materially decreased its destruction as well as the delay to traffic while it was being repaired. Another threatened disadvantage that has not been encountered in the experience of the Lackawanna is difficulty in keeping the screw spikes tight. To offset these real or fancied disadvantages, screw spike track construction gives a stronger track, requires less maintenance after installation and greatly retards the destruction of the ties.

To secure the greatest advantages from the use of screw spikes in the conservation of ties corresponding standards must be adopted throughout the track construction. It is obvious that it is not economical to use screw spikes with untreated soft wood ties or without adequate tie plates. While not so obvious at first glance, it is also important that the ties be properly adzed and bored before treatment to retard destruction uniformly. It is interesting to note in this connection that the use of screw spikes has enabled the Lackawanna to secure sufficient resistance against track spreading by using a flat bottom tie plate and thus decreasing the abrasion of the tie.

Undoubtedly important modifications will be made in the use of screw spikes as their use is extended. At the same time the results obtained on the Lackawanna, the Santa Fe, the New Haven and other roads would indicate that they have proved their practicability. In general the relative economy depends upon the amount of money spent for maintenance. Where traffic is heavy and the expenditures for maintenance are correspondingly high, the savings resulting from the adoption of a more permanent form of track construction are of course greater than on lines of lighter traffic where a relatively long life is secured from the track materials. On the other hand, the Santa Fe is using screw spikes on its western lines where the rainfall is small and the resistance of timber to decay is relatively great, and where the ties customarily fail from mechanical wear. The subject is one of primary interest to all track men interested in ultimate economy in maintenance of way expenditures and in the strength of the track structure.

ORGANIZATION IN THE MAINTENANCE OF WAY DEPARTMENT

AT no time in our history has the subject of the organization of maintenance of way forces received more attention than at present. Much progress has been made in industrial establishments along certain lines following the reorganization of forces, as a result of which efficiency experts have urged their claims most vigorously on railway managements during the past few years. This has led to a greater interest in this subject on the part of railway men. As an example, one of the subjects assigned to the committee on Rules and Organization of the American Railway Engineering Association last year was a study of the science of organization, while other committees of this same association have been studying the economics of maintenance of way labor, leading largely to the same end, for three years.

The organization and methods of work of maintenance of way forces have changed to a surprisingly small degree during the past half century, expanding as the duties have increased but maintaining the same general character. This would tend to prove that the existing organization is the most efficient and places the burden of proof on the critics. However, up to the present time the railway managements have been forced to direct their energies primarily toward the development of facilities and methods of operation to handle the rapidly increasing business and many secondary practices have become standard without receiving a great deal of attention. With the more recent demands for economical operation has come the necessity for more efficient methods in all departments.

Numerous channels for investigation and experiment along this line have presented themselves. The bonus system which has been applied successfully in many commercial establishments and some railway shops has been attractive to some and has been tried on at least two roads to a limited degree. Other roads are reorganizing their forces on a permanent basis, giving their men employment throughout the year and rearranging their schedules of work with excellent results. Still other roads are investigating the possibilities of combining the various semi-independent groups of maintenance of way employees into one roadway organization and concentrating all ordinary maintenance of way work on a certain territory under this one force. Still other roads are devoting a great deal of attention to the installation of mechanical devices for many of the routine as well as the special problems usually performed by hand. While none of these plans has been developed sufficiently to enable one to say that it is entirely successful, they all have certain qualities which appear valuable when revised to adapt them fully to practical conditions.

It is the history of all important improvements that a certain amount of pioneering work must be done in opposition to general opinion. Many railway men believe that these various methods offered to increase the efficiency of maintenance of way forces are theoretical and that while present practices are not entirely satisfactory they are accomplishing as much as can reasonably be expected. The same opposition was shown a few years ago to the idea of the economy of heavy tonnage trains, to the creation of a favorable public sentiment towards the railways, and to the use of large locomotives, all of which goes to prove that the science of railroading is continually developing and that those who stand still are soon left behind. There is no reason to believe that the maintenance of way department differs from other railway departments, and while it is too early to determine just what results will be secured from these various experiments, they are entitled to sympathetic support in the hope that they may lead to ultimate success and economy.

NEW BOOKS

Masonry. By Malverd A. Howe, professor of civil engineering, Rose Polytechnic Institute. Size 6 in. by 9 in., 260 pages, illustrated, bound in cloth. Published by John Wiley & Sons, Inc., New York City. Price $2.

This book is entitled "A Short Text-Book on Masonry Construction, Including Descriptions of the Materials Used, Their Preparation and Arrangement in Structures." It is divided into three parts—Materials, Masonry and Specifications. The first part takes up natural building stones, their classification, tests, properties and methods of quarrying; also artificial building materials, including brick, terra cotta and plaster blocks, cement, sand, gravel and mortar. Part II takes up stone masonry, including ashlar, square-stone, stopewall, riprap and stone paving, brick and hollow tile masonry and concrete masonry, including the proportioning, mixing and depositing of concrete, surface finishing, waterproofing, etc. Part III contains the definitions and specifications for stone masonry, plain concrete, building brick, lime, sand and cement, adopted by the American Railway Engineering Association and a list of references to periodicals and books in which a more extensive discussion of the subject can be obtained.

Letters to the Editor

A GENERAL STORES DEPARTMENT

San Antonio, Tex.

To the Editor of the Railway Age Gazette:

In reading the article "Handling of Maintenance Material by the Maintenance Department," in the issue of February 19, it strikes me that Mr. Bowser has overlooked the very important feature that in the application of any principle the benefit to be derived by the property as a whole from the results thereof must be the governing factor, and has viewed his subject from the standpoint of mere convenience to those immediately supervising track, few of whom are yet of the belief that it is economy to have a superabundance of everything to avoid the absence of anything. It is my thought that 90 per cent of the maintenance of way officers of today would not favor the separate maintenance department store as outlined, and I doubt if 10 per cent of the general maintenance officers, who are responsible for final results, would approve such a plan.

Certainly there was need for the "general stores" system where it originated or the plan would not have been inaugurated, and it must have proven a decided betterment over previous practices on many roads, or it would not have been continued and broadened, nor would it have received so much favorable comment and apparently succeeded so well in many cases, as Mr. Bowser states. If this idea is correct, then why not allow the transportation, mechanical, signal and electrical branches of the service each to carry its own stores? Would he suggest five separate store organizations, each with its storekeeper for one or two divisions trying to order, receive, handle, distribute and account for its necessities separately and endeavoring to gather up and dispose of its scrap, usable second hand, and repairable material, similarly, as he has arranged for the maintenance department?

The "general store" system is not theoretical. Net results and consequent general adoption have proven it decidedly practical. Let one present the "each department order, handle, dispose of and account for its own material" plan to any management that has watched the results of a tried "general store" plan, and he can readily learn which is the theoretical and which the practical as viewed from the managerial platform. Did our experiences under the plan of "each user look out for himself and men," show that there was any effort to prevent getting heavy surpluses, any action toward getting rid of them when they did accumulate, or even that the material actually needed was not missing just as often, or possibly oftener, than under even an *ordinarily* supervised general store plan?

Can we find a general storekeeper, or say division storekeeper (the latter is the man closest to the division maintenance organization), "who probably possesses little or no intimate knowledge of the needs of the maintenance department?" If so, is he a real storekeeper? Generally he possesses an equal, and in some cases even a more correct knowledge than the user, of the quantity the latter will require in any given period. Why, "with the comparatively small territory supplied from his storeroom," should the division storekeeper serving all departments as a whole through the general stores system, not be able to keep in close touch with the needs for all work on his district?

After considerable study of this subject it is my thought that an up-to-date general stores system, with "live-wire" storekeepers, such as Mr. Bowser would have on the maintenance job, on proper divisions or districts, and departmental hedges all grubbed up and burned, or with these "store department Indians" camping on the "operating reservation," as Major Hine would have it, is one of the best railroad assets of the day from the stockholders' point of view.

H. C. Stevens,
Transportation Dept., San Antonio & Aransas Pass.

HOW THE N. R. A. EXHIBIT APPEARED TO A BRANCH LINE SECTION FOREMAN

Canadian Division, Section No. 10

To the Editor of the Railway Age Gazette:

Since seein' you at the show, thought p'raps you'd like to know, that I'd got back to No. 10, glad to be on job again. With my trip am very pleas'd. Good of the boss to send me. He paid expenses to and fro. Sure I'll be teachin' what I know and so perhaps efishency will bring a good return by me. Already I have had some talk with Vinelli, who is next my walk. He's a dago, inquisitive gape, but keeps his track in fair good shape, altho' old fashion, out-o-date. He's never made a trip, you see, after more efishency. Says he to me, "You comma back. I s'pose you see lotta 'bout track." "Oh, yes," I burst. Then he, quite sly, say "P'raps you learna tampa da tie." At which I, bulging with the know, say "It's a ceench, an easy go, the way they done it at the show." "How did they do it?" asks Vinell. "By wind." I then explain, and tell the hose and all. Vinell insist, that may be good but no use here, cause car is not equip for air. By gee, I'll surely have to see the man they call the M. C. B. And then he take a laugh at me. Next 'bout tie plates he want to know, which kind they like, at which I so, "While many plates good in their way, for modern track cut little hay." "Why no? What then?" he doth exclaim. "Steel and concrete ties the game." "On long muskeg," Vinell replies, "much too heavy. Cedar ties, a top of sawdust, much the best, lightly on the top to rest." "Are so," say I and know him right. (Permanent track fades out o' sight.) "What else you see at greata show?" "A weeder," I inform. "No hoe is now required. A sprinkler is the modern way." "How much she cost?" return Vinell. And I admit I cannot tell. But track do look so fine. I'll ask the boss for some for mine. "Had you enough of oil, or short were you last month?" is his retort. I have to 'low that for my car I had to borrow from afar. "To get your weeder is no show," says Vinelli, and he know. "Some crossings stunts I s'pose were shown." A flange guard seen, I then make known, and various bells and warnin' signs, and swingin' stops which engines winds, by weight they said. At which Vinelli smile and said, "Now what in h——l is any use for such round here? Have you a crossing on your beat?" "Have you one either?" I repeat. I tell him it's good to know these things ahead a little so when at last they really come we won't appear like country bum. I see some track jacks work so ease. Their wound up when you buy and these just keep on jacking up and down, and when you want the track to lift, under the rail you make a rift, put in the jack and up she goes. Electric current is the force. "Just tap the power line, of course," adds that Vinell.

"Fence posts we see, in tin and stone, no forest fire will ever burn." "What's that to you?" he say. "Goldurn, we ain't got fence on our secs." I know that well but still me vex. "You should a seen ottomatick signals block, and flashing lights for interlock, and frogs and crossings Maganeese." Here friend Vinelli interject, "Have you got switch light on your sec?"

From all of this you'll see I think, Vinell's a knocker, and by jink, quite like the speaker who consined nothing good to the human mind. Whereas with Foster I agree one must the future try to see and smile and smile for seven miles, Mulholland said. I spose he meant full length of section—his intent.

Now good night. Wife and I start on the task to keep time the way committee ask. This letter will I'm sure reveal the good of a trip like mine. I feel so much improved and ready now to keep my sec. in year two thou., by then at least I feel that we will want those things I saw, by gee. And, Meester, thank you for your say, I again attend A. R. E. A. Exhib. of track is just a play to shimming, shimming, all the day. Here's hoping you will get these lines.

Yours very truly,

M. J. Hines.

P. S.—Spoke to boss again today bout motor car for my sec. Will not tell you what he say. M. J. H.

Renewing Heavy Swing Span by Floating Into Place

Old North Western Bridge in Milwaukee Removed and New Span Weighing 800 Tons Placed in One Day

The placing in service of the new Chicago & North Western swing bridge over the Milwaukee river, in Milwaukee, Wis., on March 14, involved the simultaneous handling of two heavy spans on scows. The large amount of floating equipment necessary for such an undertaking and the care with which all details had to be worked out to safeguard the structures during the movement are noteworthy features.

This bridge is located about ¾ mile south of the Milwaukee passenger station on the main line to Chicago and about ¼ mile from the mouth of the river. It is a double-track structure, carrying all main line passenger trains and numerous freight and switching movements to and from the Milwaukee freight houses, the engine terminal just north of the river and the adjacent industries. Through freight trains use the belt line around the city.

The old bridge built in 1890 and operated by a gasolene engine was too light to carry the increasing wheel loads of modern equipment and the substructure also was in need of repair. Since another swing bridge could be built without the necessity for securing a new permit from the government, and the city and government officials were inclined to favor that type, it was decided to replace the old span by a new one of the same length, 240 ft., providing two clear channels of 90 ft. each.

It was essential on account of yard connections and the proximity of structures on the water front that the old alinement be retained on the new bridge, but in order to rebuild the center pier and the abutment it was necessary to remove the old bridge. It was, therefore, floated downstream about 60 ft. to a temporary location and traffic carried over it during the repair of the permanent substructure and the erection of the new bridge. The narrow right of way and the presence of elevators and docks close to the line limited the amount of this move so closely that the new bridge could not be erected in the open position on its permanent center pier. Falsework was therefore driven in line with the center protection pier upstream from the site to support the new bridge during erection.

The operation of placing this structure in position on the new substructure, without undue delay to traffic, required the movement of both bridges in one day. First the new span was blocked up on scows and floated out into the north channel, taken upstream to clear the falsework, then turned and brought down over the falsework to the permanent location. This movement could not be completed with the old span still in its temporary location on account of the difficulty that would then have been connected with the removal of the old bridge. So the new span was anchored about 100 ft. from the permanent location, while the old span was blocked up on scows and moved downstream a sufficient distance to clear the operations at the permanent location, after which the new bridge was brought down and centered on the permanent pier.

New Bridge in Final Location Before Scows Were Removed; Old Bridge Shown at Left Has Been Moved Downstream from Its Temporary Location

The moving of the old bridge to its temporary location on October 25, 1914, and of the new bridge to its permanent position, as mentioned above, were both carried out on Sunday, when river traffic could be stopped and the tracks cut between 10:15 a. m. and 4:00 p. m., during which time passenger trains were detoured around the belt line. In connection with the new work, a 56-lever General Railway Signal Company's all-electric interlocking plant was installed in a new tower, just north of the bridge, to govern movements across the river.

The first step in the renewal of the old bridge was the driving of piles for the temporary center piers, abutments and approaches on the downstream side of the bridge in its original location. At the same time, timber wedging and bracing was provided along the I-bar diagonal members in the two spans each side

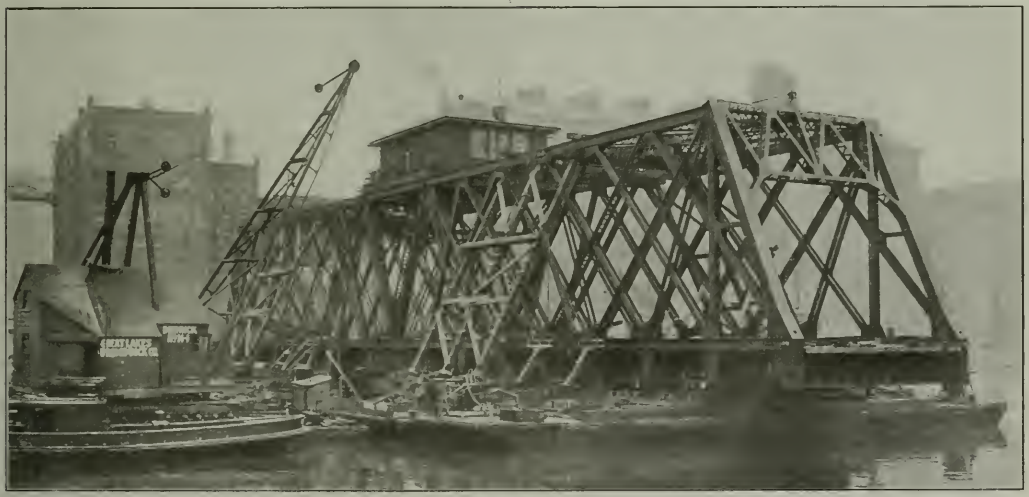
of the center in each truss, to allow them to take the compressive stresses, which would result in carrying the bridge on scows located in the two channels. The movement of this bridge was successfully made on a steel scow 100 ft. by 35 ft. by 8 ft., and a wooden scow 112 ft. by 33 ft. by 9 ft. The bridge weighed about 500 tons, making it necessary to place the blocking against the stringers in order to secure the 2 ft. greater height for distribution of the load on the scows and to reinforce the bottom chords of the trusses in the wooden scow.

The old substructure consisted of stone masonry on timber piles. In the reconstruction, new concrete bridge seats and backwalls were placed on the abutments and a new octagonal concrete top on the center pier, after removing the old masonry down to a level as near the water as possible. The new pier top has a diameter of 34 ft. and is reinforced by ¾-in. radial bars 6 ft. long and five ¾-in. bars 14 ft. long, placed parallel to four of the faces.

The new bridge is 237 ft. 6 in. long, center to center of bearings, 31 ft. wide between centers of trusses, and 32 ft. high between centers of chords. The trusses are of the quadruple intersection type, with a panel length of 14 ft. 9 in. The structure was designed for a live loading of Cooper's E-55, with the following impact allowances: With the bridge closed, $I = \frac{3}{4} L + \frac{L}{L+D}$ for the trusses and floor beams, and $I = L + \frac{L}{L+D}$ for the stringers; for the bridge swinging $I = 0.25$ D. The bridge is of the combination center and rim bearing type, the load being equally divided between the 2 ft. 6 in. phosphor bronze and steel center castings and the 64 rim bearing wheels. The estimated weight of the bridge, with the operating machinery, was about 800 tons.

The bridge will be operated normally by electricity. Two independent sets of machinery for turning have been installed, each driven by a 75-hp. motor, which can operate the bridge in the necessary time. In addition to this, an emergency plant is provided at the operating house, consisting of a 32-hp. Fairbanks-Morse gasolene engine, operating at 200 r. p. m., which can be connected to the operating shaft in case of failure of the electric power. This power is purchased from the local public service company and is brought to the operating house through a submarine cable and a drag cable on the center pier. A 15-hp. motor at each end of the bridge operates the end latch, end lift and rail lift at that end, both of these motors being operated through one controller in the machinery house on top of the bridge. Three sets of lights above the controllers indicate to the operator when the movements of the rail lift, the end latch and the end lift, respectively, have been completed. The machinery is interlocked from the signal tower and the separate circuits in the operating house are also interlocked.

The erection car was placed on the new falsework from the end of the old span in the open position by blocking up that span and extending the rails on blocking, and all steel was delivered to the site on scows without interruption to river traffic. Two girder spans were provided in the falsework to allow the placing of the barges on which the bridge was to be moved into position. The operating rack, tread rim bearing wheels and spider and the lower two center bearing castings were located on the new pier. To assist in centering the bridge on the bearings a 10-in. steel band made in three pieces bolted together was placed around the center on the pier. Two short sections of the operating rack at diametrically opposed points on the circle were omitted before the new bridge was put in place in order to allow the pinions on the bridge to be lowered into position without damage to either the rack or the pinion. The bridge was later turned by tugs to mesh the rack and pinion, after which the short sections were put in place to complete the circle. In order to provide for any difference in the deflection at the ends of the bridge from that computed in advance, the end bearings were set one inch below the calculated elevation and two ½-in. and several thinner shims were provided to adjust this height properly.

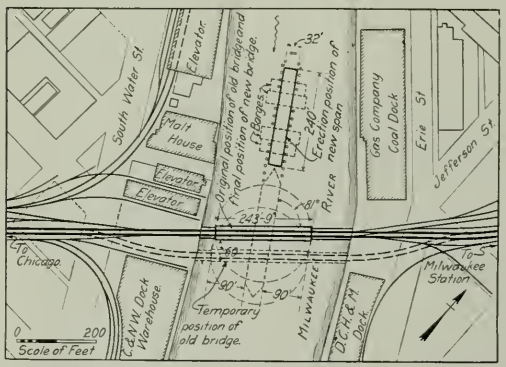


Floating the Milwaukee River Bridge on Four Scows Showing Diagonal Bracing for Distributing Loads on Two Main Scows

All preparations for the placing of the new bridge had been completed before February 21, and an unsuccessful attempt was made to carry out the work that day. The weather conditions and the surge in the river caused by winds from the lake prevented the movement of the span on the two succeeding Sundays, but on the next Sunday, March 14, the conditions were favorable and the movements were made with complete success. To make sure that enough time would be available on Sunday for the movements of both bridges, the water-filled scows were placed under the new bridge and the blocking wedged up by the Saturday night preceding the day of the movement. These scows were watched during the night by crews and tugs to protect the outfit from damage by passing boats and also to be ready to remove the wedges immediately

if any considerable change of river level occurred due to a shifting of the wind.

Four scows were used under this span instead of two, as originally planned, enough of the falsework being removed to provide clearance for the additional scows outside of the other two. The new bridge with all of the blocking on the scows made a total load of nearly 1,000 tons. The plan provided for carrying this load on a steel scow 35 ft. by 100 ft. by 8 ft., and a wooden scow 33 ft. by 110 ft. by 9 ft. These two scows had ample capacity to support this load but in order to distribute it more evenly over their length, and also to support the bridge more rigidly against tipping, diagonal bracing from the top and bottom chords to the scow decks was placed as shown in one of the illustrations. This bracing was designed to carry 60 per cent of the load of the bridge, the remaining 40 per cent being transmitted to the blocking from the floor beams directly over the scows. Two feet of combing was provided on the steel scow and one foot on the wooden scow as a precaution against filling with water on account of listing or washing. The two additional scows were used to give greater stability to the span during the movement and also to assist in supporting the load during the lowering of the bridge on its new center pier. When nearly submerged a steel scow



Location Plan of Milwaukee River Swing Bridge on the Chicago & North Western Showing Permanent and Temporary Locations and the Erection Position of the New Span

is not thoroughly reliable and for this reason it was considered advisable to have the additional scows in position to help support the load at this critical point. These two scows were 90 ft. by 24 ft. and 98 ft. by 24 ft., respectively. They were blocked up under the floor beams but carried no diagonal bracing.

As Saturday night passed without a change in weather conditions the pumping out of the scows to raise the bridge was started by 6:30 a. m., river traffic having been stopped at 6 a. m. Eight pumps were used in unwatering the scows, with leads of steam hose from tugs, etc. The new bridge had been erected 1.5 ft. above its permanent elevation and was lifted about 17 in. off the falsework by the scows. This lift was completed by 7:30, and during the following hour the bridge was shifted sideways into the north channel, taken upstream far enough to turn it across the channel and brought down over the falsework, the caps and blocking of which had been removed in the meantime to allow ample clearance for the operating pinions. These movements of the structure on the scows were accomplished by hand operated lines, the tugs and other floating equipment standing by in case of need. On the downstream movement the current was more than sufficient to move the scows, making it necessary to hold back continually on the lines. The floating outfit was tied up within 100 ft. of the permanent location of the bridge and men left to watch the scows while the movement of the old bridge was effected.

By 10.00 a. m. the old bridge had been wedged against the blocking on four water-filled scows, two in each draw. These scows were from 75 to 80 ft. long and 24 to 28 ft. wide, lashed together in pairs with continuous blocking over the two. The last train passed over the old bridge at 10:15, and immediately afterward the eight pumps were started pumping out the water. By 11:15 the old bridge, with the rack, tread, etc., had been lifted about 16 in. off its pier and removed downstream out of the way, where it was tied up during the remaining operations on the new span.

The final movement of the new span was begun about 11:25, the scows being kept parallel to the protection pier until the northeast corner of the span was about one foot from the west end of the north pier. It was then held stationary while the south end was swung downstream to bring the bridge parallel to its final position. Keeping this relative position, it was then floated over the center pier and held as nearly as possible in the true alinement. The centering ring on the center casting was adjusted so that its diameter was about 3 in. greater than the diameter of the casting on the bridge, and as soon as this casting had entered the ring three men were stationed at the joints to tighten up the bolts, thus accurately centering the bridge. This adjustment was made with the span about 6 in. above its final position. When the adjustment was correct the span was lowered to a bearing and the wedges on the scows were at once knocked out, releasing the scows soon after. Before 4 o'clock the track connections at the ends of the bridge had been completed, the end bearings adjusted and the power cable connected so that the first train was passed over the new bridge without delay. After this train had passed the bridge, the span was swung to mesh the pinions and the operating rack, the power was tested and the bridge operated at 5:20, allowing river traffic to be resumed according to schedule at 6:00 p. m.

During the centering of the new span the old bridge was floated downstream and was held on the scows for several days until a favorable opportunity offered for landing it endwise onto a dock. This landing was accomplished by sliding it on the floor beams on lines of rails placed on blocking at the proper height. The scows were removed one at a time and additional supports provided as necessary to carry the proportion of the weight of the bridge still over the water.

The design of the new bridge and the method of renewal were worked out under the direction of W. H. Finley, chief engineer, and W. C. Armstrong, formerly bridge engineer. H. M. Spahr was the resident engineer in charge of railway company's work in field. The substructure was built under contract by the Cleary-White Construction Company, Chicago, the superstructure was fabricated by the American Bridge Company and erected by the Bernhisel Construction Company, Chicago. The power equipment was installed by George P. Nichols & Brother, Chicago, and the Great Lakes Dredge & Dock Company handled the movements of the spans.

War Traffic on the Metropolitan Railway of England.—Since August the Metropolitan Railway, which connects with the Midland and Great Northern systems in the north of London and with the South-Eastern & Chatham, and London, Brighton & South Coast systems in the south, has been the means by reason of its lines under the "Circle," near Farringdon street, of conveying over these lines no fewer than 2,738 troop trains. During the despatch of the expeditionary force as many as 58 troop trains a day passed over the Metropolitan lines without any sensible interference with the ordinary passenger traffic. In addition to this burden during the first fortnight of February, 2,935 freight trains, equal to 210 a day, have passed over the Metropolitan lines, in addition to special trains with troops and government stores and the ordinary local passenger service throughout the day. This has been carried out without interference with normal traffic, except on one or two days of exceptional pressure, and without mishap of any kind.

Results of Five Years Extensive Use of Screw Spikes*

Lackawanna Has Over 12,250,000 Screw Spikes in Track, Giving Satisfactory Service Under Heavy Traffic

By G. J. Ray
Chief Engineer, Delaware, Lackawanna & Western

The general use of screw spikes in new construction and in maintenance on the Lackawanna was started early in 1910, and during the past five seasons 5,120,000 flat-bottom tie plates and approximately 12,272,000 screw spikes have been placed in new and old tracks. As would be expected, some mistakes were made at first, and no doubt later developments will change present practice somewhat. As a whole, however, the screw spike installation has proven very satisfactory, and no conditions have developed to cause any doubt of the ultimate success of the undertaking. Many minor difficulties which we had anticipated have not developed. It was fully expected that no small amount of trouble would be experienced from derailments, changing out broken rails, difficulty in gaging track on sharp curves, etc. It is a pleasure to state that, to the writer's knowledge, we have never had a derailment where the screw spikes have not been very much less damaged than the cut spikes in the same locality, and very seldom has a derailment broken off any screw spikes or damaged them to such an extent that they did not continue to hold the rail firmly in place. We have had many cases of derailments where it was not necessary to remove a screw spike, whereas nearly every cut spike on the damaged side of the rail was destroyed. Again, we have had some derailments where it is reasonably certain that bad accidents were prevented by screw spikes in some of the ties holding the rails in position, whereas the cut spikes in the other ties were destroyed. With the first tie plates used, without supports for the spike heads on the inside of the rail, we did have some spikes badly bent by derailed wheels, thus causing no little delay in their removal.

We have as yet had but few cases with screw spike construction where the tracks have been found to be wide gage, due to spreading the rails, and these have been on sharp curves, where shortleaf yellow pine ties were used in renewals and where only a few screw spike fastenings were placed per rail length. It should, of course, be understood that there are some exceptional places on the railway where any metal parts, irrespective of whether they are cut spikes, screw spikes, bolts, etc., even when thoroughly protected and reinforced by channel plates or other devices, will be cut off or will fail to hold track, but such exceptional cases should not be taken as evidence of the success or failure of any holding device. On the other hand, we have many cases where the rails could no longer be held to safe gage with cut spike fastenings, when the installation of screw spikes and flat-bottom tie plates have not only made safe track, but materially lengthened the life of the ties, bridge and switch timbers. A good many cases of this kind occurred in the Hoboken Terminal. Steam-seasoned creosoted switch and track ties were laid out of face in 1906; the rail fastenings consisted of cut spikes and Wolhaupter flange plates. After six years' service it was necessary in numerous instances to replace the plates and cut spikes with flat-bottom tie plates and screw spikes to get any further service out of the timber. At the present time, due to shattering of the timber, the screw spikes are failing to hold the rail, as might have been expected. As to relaying rail, or removing broken rails, it is to be expected that more time will be consumed in doing the work. In other respects the conditions are no different from those experienced with cut spikes.

It is not the intention to convey the impression that positive conclusions can be reached from the experience thus far gained. It does seem advisable, however, to relate more or less in detail the facts which have thus far developed, and from these facts draw such conclusions as the evidence will warrant.

The through passenger trains are handled by Pacific type locomotives, weighing 227 tons. Fast freights are handled by Pacific type locomotives, weighing 228 tons. The standard heavy freight engine is of the Mikado type, weighing 238 tons. The axle load per driver on passenger and fast-freight engines is from 62,000 to 63,000 lb., and 59,500 lb. on the Mikado engines.

REASONS FOR ADOPTING SCREW SPIKES

The Lackawanna first commenced to creosote crossties on an extensive scale in 1910. During 1910 and since that time all main and sidetrack renewals have been made with creosoted ties, with the exception of the chestnut ties which were available. These chestnut ties were used in side-tracks and on branch lines, where the service is light.

From 1905 to 1909 many bridge-tie renewals were made with longleaf yellow pine, treated with 12 lb. of creosote oil per cu. ft. These ties were steamed at a 25-lb. pressure for an average of eight hours before treatment. Wolhaupter flange tie plates (6 in. by 8½ in. by ⅜ in.) were placed on the bridge ties, with the idea of protecting them. The dimensions of the ties varied with the bridge structure and were from 8 in. by 8 in. to 10 in. by 10 in. and 8 in. by 16 in.

On the main-line bridges none of the treated bridge ties has lasted to exceed 8 years. Many of them were renewed in 6 and 7 years. In no case was the timber decayed, but the failure was due to the shattering of the wood fibers under the rail seat and tie plates. As stated above, these were all longleaf yellow pine ties, with a very small percentage of sap. We have attributed this failure to the fiber being injured by the steaming process before treatment, and to the destructive action of the flanges on the tie plates. Five hundred and thirty-five of these ties (8 in. by 12 in.) were placed on the deck-plate girder bridge No. 241.56, eastbound track, Buffalo division, in 1906, and had to be renewed in 1914. Untreated ties of the same size, and purchased under the same specifications, were placed in the westbound track of the same bridge in 1905 and are still in service and in fairly good condition. The old flange tie plates were removed from the deck of both tracks in 1910 and replaced with flat-bottom plates and screw spikes.

For several years past we have placed very few chestnut ties in main-line tracks. It was found that they did not last to exceed 5 or 6 years, on account of the rail and tie plates cutting through them very rapidly. These ties give excellent service and last many years in yard tracks or on branch lines where the traffic is light.

As far as possible, hardwood ties are used on curved track. Longleaf yellow pine ties are generally used throughout on straight track. They are used not because they are preferable to hardwoods, but on account of the difficulty of getting a sufficient supply of hardwoods. A considerable number of loblolly and wide-ringed shortleaf pine ties were treated and placed in various services. However, unless otherwise stated, sap longleaf pine ties are referred to where pine ties are mentioned here. A good many gum, beech and maple ties were treated and placed in 1910, many in sharp curves.

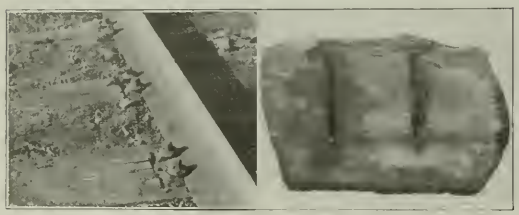
It was found, after some years' experience, that much dam-

*Abstracted from Bulletin 175 of the American Railway Engineering Association for March, 1915.

age was done to the ties by the use of flange tie plates. It was, therefore, concluded that their use should not be further considered, either in connection with treated or untreated timber. A good flange plate, or something equivalent thereto in actual holding power, is absolutely necessary to hold gage on many of the sharp curves. After a careful investigation of all available data on screw spikes, it was concluded to adopt them as a means of holding track to gage, and thus permit the use of a flat-bottom tie plate which would not destroy the fibers of the tie. Hence, since the spring of 1910, screw spikes and flat-bottom plates have been used generally in all ties placed in main tracks and in heavy-running yard tracks and leads, but not in light-yard tracks. In such tracks cut spikes and tie plates are used. In no case have screw spikes been used without tie plates.

It is necessary to have a tie plate of sufficient size to provide a safe bearing area for the weakest kind of wood used. As the main-track ties are 7 in. by 9 in. by 8 ft. 6 in., it was not considered advisable to make the tie plates wider than 7 in. Often the very best pole ties have a face at the rail seat of 7 in. or less, and, therefore, any excess in width of tie plate over 7 in. would be a waste of material. It is, therefore, quite evident that the tie plate must be of good length in order to provide a safe bearing area for all classes of wood.

The first tie plates which were rolled for our screw-spike construction were 7 in. by 10¼ in. by ½ in., with raised lugs to support the heads of two screw spikes and with an intermediate shoulder on the outside of the rail. The plates were smooth on the bottom, and did not have a shoulder or raised lug for the screw-spike head on the inside of the rail. The following season the plates were lengthened to 10⅝ in. and made ⅝ in. thick, with lugs for the inside screw spikes. Two holes were also punched for lag screws, one at each end. We had some doubt at first whether it would be possible to keep the flat-bottom plates from rattling and causing unnecessary noise in service. Furthermore, it would seem reasonable that the least possible wear between the tie plate and the tie would be the ideal condition. This can best be obtained by securely fastening the tie plate to the tie. If the raised lug for supporting the head of the screw spike is sufficiently high and of the proper shape to hold the head of the spike firmly, the tie plate will be held firmly to the tie, and most of the



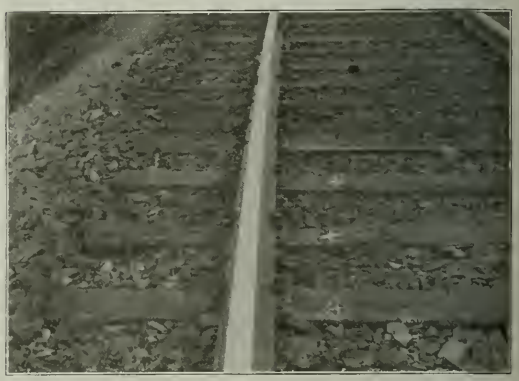
Two Pine Ties Marked = Placed in 1912, Gum Tie Marked + Placed in 1910 on 4 deg. Curve, With 5 in. Elevation on 1.4 Per Cent Descending Grade. Traffic Per Annum, 12,000,000 Tons. Track Held to Perfect Gage. Photograph at Right Shows Cross Section of One of These Pine Ties and Perfect Condition of Wood Under the Tie Plate

wear will take place between the rail and the tie plate, rather than between the tie plate and the tie. We had considerable difficulty at first in getting the lugs rolled sufficiently high to allow for play between the head of the spike and the rail base, and for this reason it was considered that the additional lag screws might be necessary in order to more securely hold the tie plate. These lag screws have not been used, excepting in certain cases for experimental purposes. It has been found that, with very few exceptions, tie plates do not rattle and plates with a good support for the screw-spike head can now be rolled.

It is quite evident that so long a plate must have considerable thickness to avoid the possibility of buckling. The first plates rolled were ½ in. thick; they were at once increased to ⅝ in. and about a year ago we again increased them to ¾ in. in thickness.

The holes for the screw spikes on the shoulder side of the tie plate are punched slightly back of the line of the shoulder, in order to prevent the neck of the screw spike from being cut by the rail base. This method was also found to be of great advantage in case of derailment, where the ties are slued. Otherwise, the base of the rail will cut into the screw spike, making it very difficult to remove from the tie.

At first some difficulty was experienced in getting the holes



The High Rail on a 7 deg. Curve With 8 in. Elevation Carrying 20,000,000 Tons Per Annum. No Indication of Lateral Movement of Tie Plates or Spikes or of Plates Cutting Into the Ties Which Were Placed in 1910

punched at the proper point on account of the great depth of metal through the lug of a thick tie plate. The hole must be punched from the top down, so as to keep the smallest diameter of the hole at the top of the lug, or directly under the screw spike head, and to prevent damage to the lug.

During the first two years that screw spikes were used, joint plates were made of malleable iron, angle bars were slotted for cut spikes, and one screw spike was used on the outside of the outer angle bar. Since that time all plates have been rolled, and screw spikes are used in anglebar slots, with one extra spike on outside of the anglebar.

SCREW SPIKES

The first change from the standard cut spike fastening was made in February, 1909, when a new double-track tunnel through Bergen Hill, Jersey City, was put in operation. This tunnel has a concrete roadbed, with short, creosoted, yellow pine ties. Flat tie plates (6 in. by 9 in. by ½ in.) were used, and the rail was fastened with a lag screw and clip. The plates, clips and screws were made at the company's frog and switch shop. New rail has now been laid on the tracks in question. The old fastenings have been replaced with heavy plates and screw spikes.

A heavy traffic is handled through this tunnel, including a large amount of refrigerator business. Although considerable difficulty from corrosion had been experienced in the old tunnel, the lag screws in question were firm in the wood, and no difficulty was encountered in removing them with socket wrenches. These lag screws held the rails to gage—there was no sign whatever of lateral movement.

We have been very careful not to vary the thread of the spikes used, on account of the possibility of destroying the threads formed in the wood, in case a new screw spike was inserted in an old hole. The size of the heads of the screw spikes have been somewhat increased from those first used, on account of the great deterioration from rust caused by

brine dripping at certain points on the line. This difficulty has not been experienced generally. The worst places were those in the immediate vicinity of icing stations. This is a difficulty which could and should be entirely eliminated by using containers under refrigerator cars, thus avoiding this unnecessary damage not only to track fastenings, but to bridge structures, interlocking, etc.

The first year that screw spikes were used, an "Ajax" hand

Chestnut Ties Placed in Tangent Track Carrying 12,000,000 Tons Per Annum in 1912. Ties Adzed and Bored Before Insertion, and Are Still in Excellent Condition

machine was used for boring all ties in the field. A template was used to spot the holes. Creosote oil was poured into all the holes as soon as bored. In 1911 a Greenlee Brothers boring and adzing machine was installed at the creosoting plant. This machine operated more or less successfully, but was not of sufficient capacity nor heavy enough in construction to successfully handle heavy hardwood ties. Accordingly, two new and larger machines, of the same make, were installed early in 1913. These machines have operated successfully, and have adzed and bored 5,000 ties per day without difficulty. During 1914 we adzed and bored 523,935 ties.

The cost per tie for adzing and boring, including the interest on the investment, depreciation, operation, running repairs, electrical current for operating the machines and trams while the latter are taking ties to and from the machines, does not exceed 1½ cents per tie. Holes are also bored for cut spikes used in yard and industrial tracks of light service.

Some service tests are being made with different kinds of linings. The Thiollier helical lining, a steel spiral screw of the same pitch as the threads of the screw spike with the inside diameter the same as the core of the spike, provides good holding power, but to date we have found considerable difficulty in applying the device. We are also using a malleable lining with inner threads to correspond to the pitch of the screw spike and outer threads to form a new contact with the fibers of the wood. The lower end of this lining is cut in three parts and spreads as the screw spike is forced into place. This device is not hard to apply. The old hole has to be enlarged and the lining inserted. All of the devices so far tested have been placed in new timber, as we have as yet had no occasion to make such applications in old ties where the screws have become loose.

A test has also just been started with plates bolted to soft pine ties. A strap holds the two bolts together on the bottom, while heavy nut locks of a special design hold the plate firmly to the tie. The rail is held in place by a hook shoulder on the inside and a screw spike on the outside. With longleaf yellow pine, birch, gum, oak and other hardwood ties, it is not thought that any such appliance will be necessary to get the full value of the ties, excepting, possibly, in some cases on sharp curves with excessive traffic. On straight track the rail can be regaged at any time that this is necessry by using the two spare holes in the plates and boring new holes in the ties. After nearly five years of service there is no indication that this will have to be done for some years to come, if at all.

COST

The following data are a summation of the labor costs in connection with the construction of the Lackawanna Railroad of New Jersey. These figures cover the entire line, amounting to a mileage of approximately sixty miles of main track:

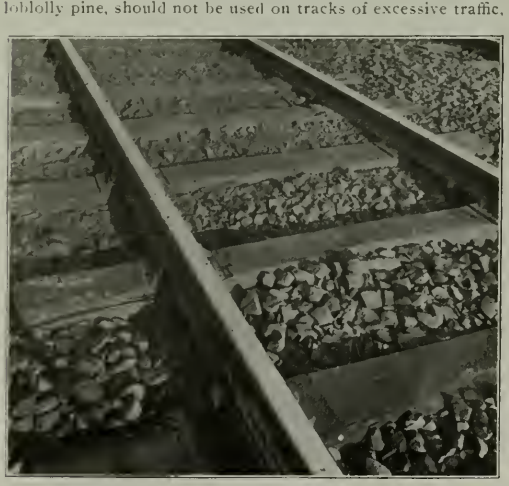
	Per mile
Cost of boring by hand in the field, 2,880 ties at $.035	$ 100.80
Cost of applying 11,520 screw spikes at $.019	218.88
Cost of laying track, less boring and placing screw spikes at $.085 per foot	448.80
Cost of surfacing 5,280 feet track at $.17 per foot	897.60
Average cost of labor per mile of main track	$1,666.08

The above figures include the entire labor cost for putting the track in finished condition, but do not include any labor cost for the distribution of materials. It will also be noted that the cost of boring ties in the field on the above work amounted to 3½ cents per tie, whereas the boring and adzing of ties, which is now done before treatment, has not cost to exceed 1½ cents per tie.

CONCLUSIONS AND PRECAUTIONS TO BE TAKEN IN APPLYING *Ties*

(1) Treated beech, birch, gum, hard maple, elm and probably other similar woods may be safely used with oak on sharp curves where the traffic is especially heavy.

(2) From an economic standpoint, softwood ties, such as loblolly pine, should not be used on tracks of excessive traffic,



Effects of a Derailment Where Screw Spikes Were Partially Used. Weber Joint Badly Damaged. All Cut Spikes Had to Be Replaced, But Original Screw Spikes Show No Damage

nor is it advisable to use them on sharp curves with moderately heavy traffic. An expensive fastening device, such as an extra large and heavy tie plate or chair, securely fastened to the tie by fastenings independent of the spikes securing the rail, with sufficient room for rail movement on the tie plate, thus reducing the movement between the plate and tie to a minimum, would probably make it practicable to use softwood ties on straight track and light curves with moderately heavy traffic. It is not believed, however, that loblolly pine, or similar ties, can be economically used with good results on heavy curves, regardless of the style of fastenings.

(3) As a rule, with woods which it will pay to treat, the

poorer the quality of the timber the more elaborate and expensive must be the fastening if the mechanical life of the tie is made to approach the life of the treated timber.

(4) The hardest track to maintain, from a tie standpoint, is that on sharp curves, elevated for high-speed trains, where the speed of freight trains is restricted on account of grade conditions. Where traffic is especially heavy, such curves should be provided with the best of hardwood ties.

Tie Plates

(1) Tie plates should be used on all ties where screw spikes are used.

(2) The tie plates should project well beyond the base of the rail on the outside and less on the inside to counteract the tendency of rail to roll out.

(3) As a rule, the required thickness of the tie plates will depend upon their projection beyond the base of the rail, and the traffic.

(4) Four holes should be provided for screw spikes, so that two extra holes will be available if needed.

(5) All holes should be punched from the top down and be as neat a fit for screw spikes as consistent, to make all screw spikes act together in resisting lateral pressure. The outside screw spikes should be so protected by the shoulder on the plate as to prevent the rail base from cutting into the screw spike neck; otherwise, in case of derailment and slued ties, it will be found impossible to remove the spikes without first straightening the ties.

(6) A raised lug, or shoulder, both inside and outside of the rail base, should be provided to give support to the screw-spike heads. This shoulder assists in holding gage and materially reduces the breakage of spikes and damage to track in case of derailment.

Spikes

(1) The size of screw spikes and the design of the thread should be carefully considered before a screw spike is adopted. Thereafter no changes should be made; otherwise the new screw spikes cannot be used in old holes without damaging the wood fiber.

(2) Where salt brine drippings are excessive, screw-spike heads must be made sufficiently large; otherwise there may be difficulty in the future in removing the screw spikes from the track, due to corrosion. During the nearly five years' service no screw spikes have been found that were rusted within the tie, and there was no rust to speak of below the head, although some spike heads were rusted so badly that they could not be removed with the standard tool.

(3) The screw-spike head should have tapering sides to prevent turning in the wrench socket after the size of the head has been diminished by rust.

(4) Any mechanical device for setting down screw spikes must automatically release when the screw spike is seated; otherwise the screw spike is apt to be damaged in case of hardwood or the wood fibers destroyed in case of softwood.

(5) Very little trouble is experienced by screw-spike heads breaking off, either on account of track movement or derailed equipment. The heads are, at times, damaged to considerable extent by derailments, but as a rule the spikes are not broken, nor is their holding power affected. Where screw spikes are broken off, a device for extracting the broken portion from the old hole without injury to the wood threads would be a valuable appliance.

(6) When screw spikes are fully seated, no further strain should be put on them, as this will tend to destroy the threads in the wood or injure the spikes.

Holes for Screw Spikes

(1) All ties should be bored at the treating plant before treatment. This can be done while the ties are being adzed, and not only insures that the holes are bored deep enough, but assures good treatment of all wood adjacent to the holes.

(2) Where the ties are bored before treatment, the track must be at proper gage before the ties can be placed.

(3) The holes for screw spikes should be of proper dimensions for the wood used, with due regard to the size of spike.

(4) A limited number of holes can be bored with one bit, after which its size will diminish so as to make it too small.

(5) Holes should be bored somewhat deeper than the length of the screw spike. There is no serious objection to boring the holes clear through the ties.

Gage

(1) With oak, birch, hard maple, gum or longleaf yellow pine ties, gage can be maintained with flat-bottom plates, using two screw spikes on tangents and two or three on curves.

(2) Heavy curves elevated for high speed, where heavy freight trains move at a slow rate of speed, are the hardest track to keep to gage.

(3) Double spiking should be done on the inside of the rail.

(4) Not only is the lateral and vertical resistance of a screw spike greater than that of a cut spike when both are first applied, but the lateral and vertical resistance of a loose screw spike is considerably greater than the lateral and vertical resistance of a loose cut spike.

(5) When the threads in the tie are entirely destroyed, a screw lining (any one of several different varieties) may be used with good results.

General

(1) All ties should be bored and adzed before treatment. This insures good gage, a perfect bearing for the tie plates and good impregnation under the rail and around the holes.

(2) In placing screw spikes, they should be driven by hammer only far enough to make the threads take hold. If rigid instructions are not enforced, laborers will overdrive spikes and so destroy the wood fibers near the top of the holes.

(3) Screw spikes with flat-bottom plates on hardwood ties will hold track to gage on sharp curves under heavy traffic. The holding power of screw spikes in hardwood ties is not materially reduced after more than four years' service.

(4) No screw spikes have ever been found so loose that they could be easily pulled out of the holes, and but few have been discovered which could be as easily extracted as a newly-driven cut spike. In no case, except with loblolly pine ties, have the threads in the wood been found weakened.

(5) Screw spikes in maintenance work can be used most economically where all rail is of a standard pattern, so that regaging of track is not necessary in relaying rail.

(6) Slight irregularities in frozen track are likely to throw an excessive strain on screw spikes where there are but a few mixed with cut spikes.

(7) The best results with the screw spikes can be expected in new construction, and where the number of screw spikes in tie renewals predominate over cut spikes.

(8) In relaying rail, cut spikes should never be driven in old screw-spike holes, if the holes are to be used again for screw spikes.

(9) No effort should be made to draw up a low tie with screw spikes when the roadbed and ballast are frozen solid.

(10) Screw spikes do not have to be set down continually, as do cut spikes, but should be gone over and set down properly after the plates are seated in the tie.

(11) Flat-bottom plates with raised shoulders or lugs for the screw-spike heads make but little noise and do not rattle at all where ties are adzed before treatment.

(12) It cannot be expected that the full life of all creosoted softwood ties, such as loblolly pine, will be realized without providing expensive fastenings from the start, and then it will probably be necessary to add some further device at a later date. Probably the most practical and least expensive device will prove to be one or the other of the lining devices to be placed in worn out spike holes.

(13) The use of screw spikes for the past five years has not made it necessary to increase the number of section men.

(14) Whether or not it will pay to use screw spikes will depend upon the cost of ties, their probable life and the amount of traffic.

The Effect of the War on Timber Preservation

Twenty-Five Per Cent Reduction in Creosote Supply Forces Use of Other Materials and Closing of Plants

One of the direct effects of the European war on the American railways has been the partial demoralization of the timber-treating industry following the cutting off of a large part of the supply of preservatives. The railways are the largest consumers of treated timber. Over 80 per cent of the total of 153,000,000 cu. ft. of timber treated in 1913 consisted of cross-ties, while over one-half of the remainder comprised piling, bridge timbers and other materials consumed directly by the railways. They are also large plant operators, owning directly 27 out of a total of approximately 95 plants in active operation, while they are the main customers of the others, contracting for the entire output of many of the privately owned plants. Any interference with the operation of these wood preserving plants is therefore of direct concern to the railways. Because of the wide variety of statements regarding present conditions in this field and the confusion resulting therefrom, we have communicated with the large operators and present the following information as a resume of the present situation.

THE MATERIALS USED

Ever since the inauguration of wood preservation on a commercial scale about 1885 the greatest attention has been devoted to the treatment of ties and the largest output of treated material has been in this form. Starting with about 120,000 ties in 1885, the output of treated ties has risen from year to year until it reached 2,800,000 ties in 1900, or 3.2 per cent of the total requirements of the railways. Since that date the industry has developed even faster, until in 1914, 41,075,655 ties were treated, which was nearly 30 per cent of the entire number used. Thus, both the absolute number of ties and the percentage of the total treated is increasing rapidly as the service results become more generally known and the cost of untreated timber increases. The growing scarcity of hard wood and the possibility of securing a relatively long life by treating the so-called inferior woods have also helped this increase.

The two preservatives most commonly used are zinc chloride and creosote oil, forming 97 per cent of the total quantity of all preservatives consumed. Zinc chloride was applied almost entirely at first, and it has been estimated that of the 15,000,000 ties treated previous to 1900, zinc chloride was injected into all but 500,000. Even as late as 1905 approximately 90 per cent of the ties were treated with this material. Since that date creosote has been more widely adopted, although the consumption of zinc chloride has continued to increase, until in 1913, 26,466,800 lb. of dry zinc chloride was used.

The creosote treatment has been in marked favor, especially during the past five years, and its used has increased rapidly. Nearly all of the new plants have been designed and built for this treatment. Starting with less than 3 per cent of the total output of treated ties previous to 1900, and with only 10 per cent in 1905, this increased to approximately 70 per cent of all the ties treated in 1913. This has naturally resulted in a very great increase in the demand for this oil. In 1903 about 8,000,000 gal. were used, which was increased to 56,000,000 gal. in 1908, 83,000,000 gal. in 1912 and 108,000,000 gal. in 1913, practically doubling in the last five years.

Creosote is a by-product of the distillation of coal tar. As such its production is only practicable commercially when there is a demand for pitch and the other primary products. A sufficient quantity of crude tar is produced in the United States to provide all the creosote needed for timber preservation. However, the normal price of creosote oil does not warrant the distillation of the coal tar for this product alone. As a result a quantity of tar is refined just sufficient to provide the pitch and other primary products for which there is home and export demand. This condition now retards the distillation of creosote and will continue to do so until the industries of this country are sufficiently developed to create a demand for the pitches and other coal-tar products.

Previous to 1905, when relatively small amounts of creosote were used in wood preservation, over one-half of the oil required was manufactured in the United States; but with the rapid increase in the demand the proportion of domestic creosote fell to 29 per cent in 1910 and 1911. Since that time the production of domestic creosote has been increased about 10,000,000 gal. per year, resulting from the increased activity of older firms and the entrance of new firms into this field. As a result the percentage of imported oil fell to 62 per cent in 1913. However, large as the recent increase in domestic production has been, it has not kept pace with the increased demand and the importation of foreign creosote has increased from year to year. The importation of foreign oils will therefore continue to be essential to the industry of wood preservation for many years to come.

The imported oil comes almost exclusively from England, Belgium and Germany. Germany furnishes about 15 per cent of our total requirements and Belgium a considerably less amount. Nearly half of all the oil used in this country comes from England. The total amount imported has risen from 38,000,000 gal. in 1908 to 51,000,000 gal. in 1911, and 66,000,000 gal. in 1913. This large surplus of oil available for export results primarily from the extensive demand and development of manufactories of coal-tar products in Europe, enabling creosote oil to be produced economically as a by-product.

THE RESULTS OF THE WAR

When the European war broke out last August the United States was consuming about 110,000,000 gal. of creosote annually, of which nearly 70,000,000 gal. was being imported. The plants along the south Atlantic coast depended almost entirely upon imported oil. Those along the north Atlantic coast were securing about half of their requirements from domestic sources, while those in the interior were using domestic oil very largely. The plants along the Pacific coast were also dependent almost entirely upon imported oil.

At the beginning of hostilities, embargoes were placed on the exportation of creosote from the belligerent countries. The English embargo was soon raised, but it is still impossible to secure any oil from Germany or Belgium, and this condition will undoubtedly exist until the close of the war, owing to England's control of the sea. While there is now no restriction on the shipment of oil from England, it is very difficult to secure boats to bring it to this country, as the British Admiralty has commandeered for its own uses many tank steamers formerly engaged in this service, even after they were loaded, and is still doing so. One recent report showed a list of over 85 tank steamers which had been withdrawn from commercial service in this way. Importers of creosote oil and railroads which purchase their oil abroad directly are both suffering from this condition. One railroad had two cargoes confiscated at sea last fall. Other roads have had boats taken repeatedly after being placed for loading and, in some cases, after being loaded. Thus, while large quantities of foreign oils are available and are accumulating in storage, they are largely unavailable for the plants in this country because of transportation conditions.

Consequently, the amount of oil imported for the six months from August, 1914, to January, 1915, inclusive, decreased to 17,000,000 gal. as compared with 27,000,000 gal. for the same period a year ago, a loss of 37 per cent, and it is still decreasing as the demands of the English government for tank steamers

become more urgent. Thus in January only 200,000 gal. of creosote oil was received in this country. As approximately 62 per cent of the creosote consumed in the United States is imported, this is equivalent to a total shortage of at least 25 per cent.

The effects of this situation on the individual plants in this country have varied widely. The most favorably situated are those which have contracted regularly in advance with domestic producers for their entire requirements. Thus, their source of supply is not disturbed and they have suffered no direct ill effects. In fact, from a competitive standpoint their condition has been improved. Other plants normally contract for a portion of their requirements with the domestic producers and import the balance. At times such as these the home manufacturers naturally favor their regular customers in the sale of oils previously uncontracted. Such plants are therefore affected by this shortage only to a limited degree.

The decrease in the supply is felt most seriously by those plants which secure a large part or all of their supply from abroad. Measures adopted by these operators depend largely upon the purposes for which their timber is treated. For those plants which treat piling, paving blocks, etc., which require a creosote treatment, there is no alternative but to close down when the supply of oil is exhausted, and a number of plants have already been forced to this extremity.

Various expedients have been adopted to conserve the supply of creosote. A number of plants have changed from the full cell to the Reuping or other empty cell processes to reduce the consumption of oil. At least two roads have reduced the unit quantities of oil injected into the timber without changing the process. There has also been a distinct tendency towards the adoption of other oils previously considered inferior, such as water-gas tar creosote. One large plant is planning to substitute up to 20 per cent of this for coal tar creosote. The addition of refined coal tar to creosote, which has met with increasing adoption during recent years, has received a decided impetus under present conditions.

Since, as stated above, over 80 per cent of all the timber treated consists of ties, and since over 25 per cent of all ties treated are impregnated with zinc chloride under normal conditions, the most obvious and readily applied method of relief in the treatment of crossties is the substitution of zinc chloride for creosote treatment. As a result a considerable number of large plants have been rearranged and are now preserving ties in this manner. However, this is not without its difficulty, as the cost of zinc chloride has risen materially, due to the increased demand and to the difficulty in securing spelter because of the war. The shortage of this material, however, has not been serious up to the present time.

Probably the most important single factor contributing to the relief of the shortage has been the depression existing in railway and commercial circles, making retrenchments in expenditures for improvements necessary, and holding up much new work. This has materially reduced the demand for treated timber, and thereby for creosote. Largely for this reason one road was enabled to close down its plant entirely for 2½ months. Another reduced the hours of operation from 20 to 10 per day, and several others have made similar reductions.

In view of the shortage of foreign creosote and the serious situation with which many of the plants have been confronted, there has naturally arisen a strong demand from the consumers for an increased output of creosote on the part of the domestic manufacturers. This demand has served to increase the price of the domestic oil at least 35 per cent, which has served as an incentive toward increasing the production. While the manufacturers are believed to be making strong efforts to produce the largest possible amount of creosote oil, the depression in general business conditions has caused a decreased demand for pitch and other primary products in this country and has very materially reduced the export sale. For this reason it is not commercially practicable to entirely or even largely offset the shortage resulting from the decrease in European importation by increased home production in so short a time.

Furthermore, the present conditions are but temporary, and at the close of the war the large quantities of creosote now accumulating in England and Germany will be released for shipment to this country. This will probably result in a material reduction in the price of oil even below that existing previous to the war. In spite of the evident advantages to the timber-treating industry of a greatly increased domestic production now, one can only expect to see a normal development in our domestic production which will keep pace with the home and export demands for pitch and other primary products. With the various relief measures which have been adopted, the situation should become little worse than now existing, even though the war continues for some time:

The following brief abstracts from information received directly from the larger railway treating plants in this country, show the wide variety of conditions existing.

"We have not substituted any other process of treatment. When our oil supply ran so low that there was likelihood of our running out, our plants were cut from 20 hours to 10 hours per day. We have arranged for the purchase of a few hundred thousand gallons of domestic creosote that will meet the A. R. E. A. grade 1 specifications. We have also contracted for some water-gas tar which we expect to use at the rate of 20 per cent. The latter plan was decided upon before the shortage of creosote became apparent."

"When the war broke out we had just received approximately one-fourth of our annual requirement of creosote oil. However, we immediately set about making changes that would conserve this supply and did not use a gallon more creosote than we had to in order to save the timber on hand ready for treatment. We immediately rebuilt our plants to use zinc chloride, and are now operating by that method, using the creosote we have only for bridge timber and piling."

"No definite measures have been adopted to relieve the shortage, although the retrenchment in renewal and new work has decreased the output of the plant. We are also experimenting with other processes, more with a view to decreasing the cost of treatment than of conserving the supply of creosote as our present stock is sufficient for at least 12 months."

"We have a sufficient supply of creosote on hand to operate our plant during 1915. We have reduced the quantity of creosote used from 3 lb. to 2 lb. per cu. ft., using the same quantity of zinc chloride, namely ½-lb. per cu. ft., and employing the Card process. We are considering the use of a certain percentage of water-gas tar creosote mixed with coal-tar creosote and zinc chloride. We have not in any way decreased our output. On the other hand, we have been and are working our plant to the maximum capacity."

"We have not changed our process, and while we have not decreased our crosstie output, we have postponed the treatment of some construction material, such as piling and dock timber. This postponement, however, is also partly due to the reduced earnings of our company for the past six months."

"During 1914 we received one shipment of 500,000 gal. of creosote by tank steamer from England. We experienced considerable trouble in securing this shipment and had two cargoes confiscated at sea by the English government."

"We have adopted no method to reduce the shortage except to reduce the quantity of oil left in the tie from 6 lb. to 5 lb. per cu. ft. This reduction was not due entirely to difficulty in securing creosote, for we believe that with our climate and soft pine ties, 5 lb. of creosote will preserve the tie against decay until it fails otherwise."

"We formerly used the full cell process on our material, but since August 1 we have used the Reuping process for all ties. We have also treated some ties with zinc chloride. We still treat most of the bridge timber by the full cell process. Unless boats can be chartered we will be short of oil this year."

"We have not been compelled to resort to any measures to

relieve the shortage, having sufficient oil on hand to treat our immediate requirements. However, should the price of the creosote we use rise too high we can resort to a heavy zinc chloride treatment for certain dimension timbers for inland use."

"The European war has not interfered with our creosote supply in any way, as all of the oil used in our plant is domestic."

"We do not know where our supply of oil is coming from this year or whether we will secure any at all. As soon as the war started we began to conserve our supply of creosote oil for only the most important work, and are now using considerable untreated timber."

"We have substituted for the Card process, chloride of zinc for the treatment of ties and will continue to use this until creosote can be purchased at a reasonable price."

"It has not been necessary for us to adopt any unusual measures to secure a supply of creosote oil, as our demands are covered by contract with plants in this country. We are curtailing our bridge work this year, so that we will not use more than two-thirds as much oil as we used last year."

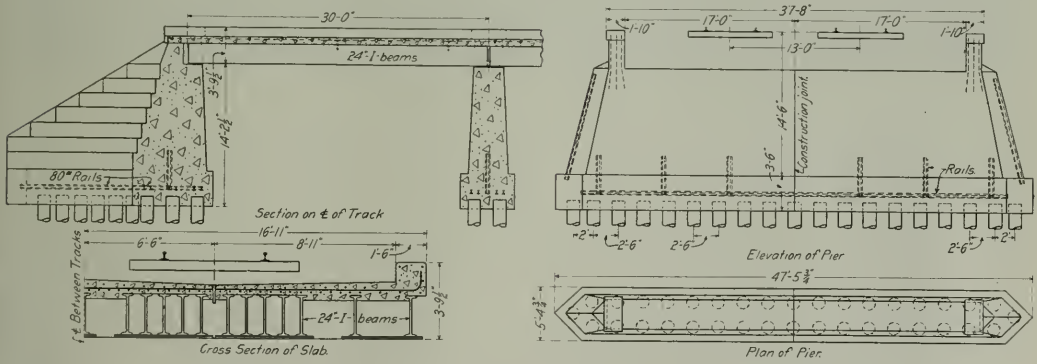
NEW B. R. & P. STRUCTURE ACROSS ALLEGHENY RIVER AT RIVERSIDE, N. Y.

During the past year the Buffalo, Rochester & Pittsburgh has replaced its old bridge across the Allegheny river at Riverside, N. Y., with a new structure designed according to the latest standards of this road. The old structure consisted of a gauntleted single track steel through pin-connected truss of the camel back type 212 ft. long supported on stone masonry with a double-track, frame-trestle approach 532 ft. 8 in. long. The truss was designed for Cooper's E-40 loading and weighed 212 tons. In addition to being gauntleted the old structure was too light for the modern equipment. It was replaced with a 212 ft. double-track, steel-riveted, through-Warren-truss span and a concrete and steel approach viaduct 504 ft. 4 in. long. The new truss span was designed for Cooper's E-60 loading and weighs 643 tons.

The pier and the abutment under the old single track span were of stone masonry supported on piles and designed for double track. Only short extensions were therefore necessary to comply with present standards. These were built of concrete, with which material the old masonry was also encased.

The viaduct consists of 17 spans each 30 ft. long supported on concrete piers resting on timber piles. The piles project 12 in. into a concrete cap 5 ft. 4¾ in. wide, 3 ft. 6 in. high and 47 ft. 5¾ in. long between extreme end points. These caps are reinforced longitudinally with four 80-lb. rails placed two over each pile. These caps are also bonded to the pier above by seven 4-ft. sections of rails set vertically at intervals of 6 ft. 6 in.

The deck of the viaduct consists of 25 24-in. 100-lb. I-beams arranged in clusters and supporting concrete slabs, as shown in the accompanying cross section. These slabs, which are 30 ft. long and 33 ft. 10 in. wide, were constructed in place in half sections for each track separately. An interesting feature of their design is the width of roadway provided. The tracks are spaced 13 ft. between centers, leaving a distance of 10 ft. 5 in. from the center of the adjacent track to the outer edge of the parapet. The tops of the slabs are sloped each way towards the center of each track where drainage outlets are provided at intervals of approximately 8 ft. The bottoms of the slabs ex-



Elevation and Sections of Buffalo, Rochester & Pittsburgh Steel and Concrete Trestle

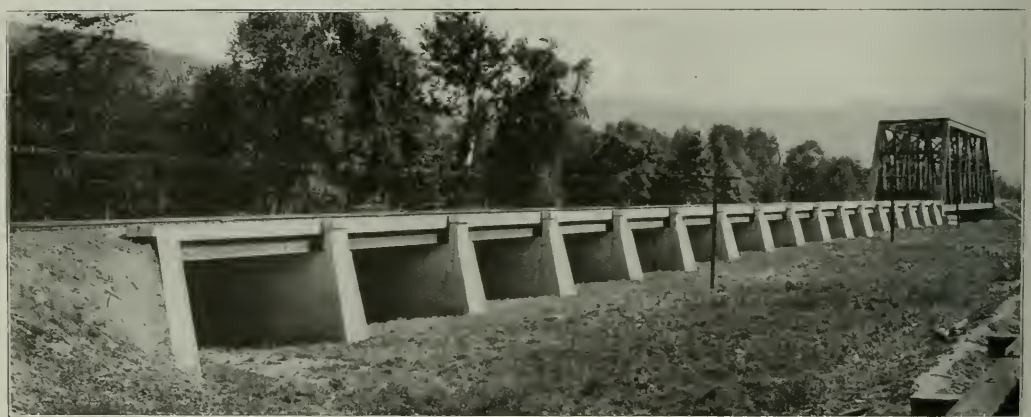
tend down to enclose the outer side of the upper flange of the outside I-beams of each cluster, locking the I-beams and the slabs into one unit.

In renewing the river span, traffic was carried on timber falsework. In the reconstruction of the approach viaduct, the east

Views of Completed Steel Span and Concrete Deck Approach Viaduct

second track was removed and the gauntlet extended across the viaduct. The new piers were so spaced that they did not disturb any of the old timber bents except for a short distance at the south end next to the river span, where it was necessary to place temporary timber bents. One-half of the structure was then built complete, after which the gauntleted tracks were shifted onto the new structure and the other half completed.

The plans for this work were prepared under the direction of E. F. Robinson, chief engineer, Buffalo, Rochester & Pittsburgh, and W. F. Pond, office engineer. The steel was fabricated by the American Bridge Company, and the truss span was erected by it. All other work was carried on by company forces under the direction of G. H. Stewart, master mason, and Charles Scott, supervisor of bridges and buildings.



New Buffalo, Rochester & Pittsburgh Bridge Across the Allegheny River

PRODUCTION OF RAILS IN THE UNITED STATES IN 1914

The Bureau of Statistics of the American Iron & Steel Institute has just issued a bulletin giving the production of rails last year based on statistics furnished by the various manufacturers. The most striking thing about these statistics is the decrease of over 1,557,000 tons, or 44. per cent in the production of rails as compared with the preceding year. This is the greatest reduction in the 18 years these statistics have been compiled, with the exception of 1908, when the output decreased 1,612,000 tons.

DANISH STATE RAILWAYS.—The report for the last financial year shows receipts amounting to $15,500,000 and an expenditure of about $13,000,000, in both cases the highest figures on record, the actual surplus being $2,425,000. The freight traffic shows an increase of 3.4 per cent and the passenger traffic of 1.2 per cent, compared with the previous year. The passenger traffic shows receipts of $6,700,000, of which about $1,050,000 arise from the through traffic. As regards the different classes in the passenger traffic, first class yields 0.1 per cent, second 8.6 per cent and third 91.3 per cent. At the end of the financial year in question the state railways in Denmark had a capital outlay of $79,000,000, of which capital the earnings represent about 3 per cent. As regards accidents during the year in question, there were killed, of passengers, railway servants and others, 31; 35 were severely injured, and 45 less severely.

Importance of Economical Methods of Renewing Ties

Three Timely Discussions Emphasizing the Possibilities for Conservation in this Important Expenditure

At this season of the year when the work of renewing ties is being actively pushed on most roads those in charge of this work can well afford to give it their personal attention because of the large amounts normally expended on this account and the resulting opportunities for waste or economy both in material and labor. The three discussions given below, prepared by men who have given this subject careful consideration, call attention to different phases of this problem, all of which are important.

AN ECONOMICAL METHOD OF RENEWING TIES

By "Roadmaster"

For a number of years I have followed the practice of jacking up the track 1½ to 2 in. when renewing ties and pulling out the old ties instead of digging them out and disturbing the original bed, as is commonly done. With this method I have materially reduced the unit cost of renewals, and this work has required less of the time of the section forces than the old method.

Many track men think that gravel or earth ballast will run under the ties when the track is jacked up. This is true only when the ballast is sandy or new, in which latter case the ties are also generally new and require few replacements. When the ballast has been in the track a year or longer it forms walls along the sides of the ties which are not easily disturbed. Although the track does not necessarily return at once to its original bed of its own weight unless the ballast is well packed or foul, this is an advantage, as the side-binding holds the track suspended until new ties are inserted. For this reason it is important that the new ties be put in before a train passes to avoid digging out the old bed afterward to get them in. The increasing use of tie plates resulting in reduced rail cutting is of assistance with this method, making it unnecessary to raise the track as great a distance as formerly as well as reducing the digging out of the old bed. In adopting this method I have found considerable difficulty in training the foremen to do this work properly, and it has been necessary to spend considerable time with them to insure that they understand and handle it correctly.

This method is equally applicable to dirt track and was originally developed here where less care is required than in ballasted track. I recall one section where two men with the foreman put in 1,250 hardwood ties in clay track in one month and left the old ties piled. This gang put in as many as 80 ties in a single day.

RENEWING TIES IN STONE AND EARTH BALLASTED TRACK

By P. J. McAndrews

Roadmaster, Chicago & North Western, Belle Plaine, Ia.

For the proper maintenance of track it is essential that good ties be provided and important that the work of renewing be done at the proper time. These considerations, taken in connection with the present high cost of the ties themselves and of the labor required to handle them, make the tie renewing program of a railway a matter of great importance. The exercise of good judgment and the use of systematic methods are necessary at each of the various steps from the date of making estimates until the completion of the season's work. Enough ties must be furnished to maintain the track properly and safely, but care must be taken to avoid the other extreme, which leads to a probable waste of material and labor. Supervising officers, to whom are entrusted the duty of making or approving requisitions for ties, have opportunity to and should observe conditions on their territory from time to time, thus being in a position to submit approximately correct estimates.

Before submitting estimates, section foremen and, if possible, supervisors should walk over their territories, carefully inspecting ties, marking such as appear decayed to the stage that would make renewal necessary the following season. A slight adze mark on a certain portion of each tie selected for renewal, having the adze marks uniformly at one end of all ties, serves well and need not be of such extent as to damage any ties which a later or more rigid inspection might decide to be serviceable for another season. An old and rather bad practice of examining ties for renewal consisted in the foreman sinking a pick deep into them and mutilating them so that quick decay would result. Ties must be carefully distributed along the track, with a view of saving expense that might be incurred later in handling long distances with a push car.

Where local conditions justify, I prefer to renew ties in stone ballast while giving the track a light general surfacing, making a lift of from one to two inches. The organization of a gang for this work depends on the number of men employed, the extent of the renewals and the density of traffic. The ties are distributed with a push car, unless they have been unloaded directly from a train along the track. I then employ a gang of from 10 to 16 men working under ordinary conditions where the renewals are not excessive. A part of this gang lifts the track, using two jacks, and tamping the good ties immediately. At the same time the remainder of the gang replaces the poor ties with new ones, also tamping them at once.

When the track is raised an inch or two, less labor is required to excavate ballast alongside and under the ties, while the general riding condition of the track is benefited through the new ties having substantially the same bearing as the sound ties that have been left in service.

To make tie renewals where track in stone ballast is not being raised, I prefer to distribute the ties and have the force organized so that one man with a claw bar pulls the spikes from the marked ties, except when a number of poor ties are bunched, when sufficient spikes are left to keep the track safe; one or more men with shovels and chopping axes remove the ballast from both sides of the ties just inside of the rails, and then chop off the tie to be removed so it can be taken out without making any side excavation. After the removal of the old tie, sufficient ballast may be shoveled aside to permit the new ties being pulled to place, but care must be taken to avoid digging too deep, which always results in having loose ties for some time after. The new tie should be carefully tamped and a portion of the ballast replaced, leaving the ends of the tie and a space near the rails only partially filled so that the tie may again be tamped a few days later if found loose, which is quite often the case. I believe the plan of chopping out the old tie is more economical than the tedious and expensive method of excavating the ballast alongside of it and digging a trench to knock it into for removal from under the rails.

The use of tie tongs should be insisted upon in all handling of new ties. New ties should be spiked to proper gage. Before tamping them they must be adzed so that the rails or tie plates have proper bearing. In replacing ballast, forks should be used and no dirty material placed around the new ties. Old ties must be gathered up daily and disposed of as directed.

In renewing ties in earth-ballasted track the following plan is recommended: The gang should be paired off and each pair provided with a claw bar, pick, raising bar or chisel pointed bar (unless the claw bar has a chisel end), shovels and two hard wood blocks tapering from a point to a thickness of about 3 in.

and from 2 to 3 in. wide. To remove the old tie have the dirt dug away from on top of and about half way down the sides by one man, while the other pulls the spikes from the tie to be removed and starts them up on a sound tie on each side. Raise the rails and insert one of the blocks under each rail a sufficient distance to permit the decayed tie being removed without fouling the rails. The height necessary to raise the rails will depend on the kind of dirt and the extent to which the rails may have cut into softwood or unplated ties. After removing the old tie the bed should be prepared for the new one, removing only enough dirt from the old bed to permit the new tie being placed and left "stiff," holding the rail a little high until a few trains pass and settle it.

The height at which the track may be held on the new tie must be governed by the kind of soil in the roadbed and its condition at the time. The force of men usually employed on earth ballasted lines being few, foremen have an opportunity to watch the work closely, and with their knowledge of local conditions they can usually lay new ties so that they will bed themselves to a good bearing under the rails.

Where the old bed is not disturbed and the new tie placed thereon, without any loose material being used under it, care must be taken not to leave the rails too high, as the new tie will settle but little if placed on the old "crust." With this method of raising rails in making tie renewals the track is quite often pulled out of line and after spiking the track it should be lined where necessary.

PROPER SUPERVISION OF TIE RENEWALS

By A. W. Tabert

Roadmaster, Chicago & North Western, Allis, Wis.

Now that the section forces are largely engaged in renewing ties, it is worthy to note that there is no more fruitful field of economy in maintenance expenditure than in the renewal of ties, as this is the largest single item in the cost in track maintenance other than labor. It is apparently more neglected than any other item largely because it requires constant and immediate supervision to prevent the renewals of good ties.

It is natural that if the choice of ties for renewal is left to the foreman he will use all he can get, unless it is made to his interest to save them. Thus, ties are frequently taken out of the track which would have given several more years' service. After removing them it is too late to tell by inspection whether or not they should have been left in track, as they are generally split and otherwise injured in removing them. A certain section foreman who was replacing a string of perfectly good ties with new ones, replied to the question why he was taking out good ties: "I had plenty of new ones on hand and I wanted to get rid of them as soon as possible." This is the attitude of many section foremen. The difficulty of obtaining a sufficient number of ties in certain seasons makes the men put in all they can when ties are plentiful.

Under no circumstances should badly decayed or broken ties be left in the track for this is not true economy. When it becomes necessary to renew a large percentage of ties in any one season it is usually because they have been neglected. As "a stitch in time saves nine," so a tie in time may save others. For instance, we take out switch ties on a busy lead which are spike-killed, rail-cut, etc. These ties can be used by turning them over and putting them in on some track where there is not so much switching. Also the ties that are taken out of side-tracks, such as "big old cedars," can be turned over and used at the tail ends of spurs or "lazy" tracks that are not used very often, and then merely for storing cars. There are various side-tracks, especially stub end sidings, storage tracks, car-repair tracks, freight-house tracks or industry tracks that are infrequently used for the movement of locomotives but quite generally for standing cars. In such cases a great many second-hand ties which must necessarily come out of a main line may be used to advantage. A roadmaster should without fail watch this feature closely enough to be sure that he is getting the maximum efficiency in the use of track ties.

If we get interested in this we can save our company money on ties. When we realize that it takes approximately 150,000,000 ties per year we can appreciate the immense expenditure involved. Any reduction that can consistently be made in the tie renewal item for either side or main track ought to have our personal attention.

The usual manner of putting in ties is to employ three or more men. When the tie is put into the track in its proper position one man measures it before it is spiked, with a mark made previously on the handle of his spike maul or pick to see if the end is the proper distance from the rail. It usually is not. The other men then stand idle waiting for the first man to place it in the proper location. When the spiking gang comes along the men will again measure the tie from the end to be sure it is the correct distance from the rail as frequently the ties are moved before they are spiked. Assuming that he and his two assistants find the tie distance correct, they have lost from one to two minutes.

To overcome all this delay let the foreman make a mark with chalk, measuring from the end of the tie to the line where the outside base of the rail will come. In this way the tie can be placed in the proper position by the first men, and the spikers will see that it is in the proper place as the chalk mark will still be there. Another method which I have used in spacing ties when track is being surfaced is to have one man put a chalk mark on the base of the rail commencing at the first bolt in the joint and measuring off 21 in. along the entire rail to give the center of the tie. Then one or two men can go along with the lining bars and locate the ties at the chalk marks.

ABSTRACT OF ENGINEERING ARTICLES

The following articles of special interest to engineers and maintenance of way men, to which readers of this section may wish to refer, have appeared in the *Railway Age Gazette* since March 12, 1915:

Canadian Pacific Terminal Improvements at Vancouver.—The construction of a new passenger station and a pier for coast steamers recently completed by the Canadian Pacific at Vancouver, was described and illustrated in the issue of March 19, page 614.

Notable Structures on the Spokane-Ayer Cut-Off.—The interesting features of the Spokane river bridge, the Snake river viaduct and the Hangman creek viaduct on the O.-W. R. & N. line entering Spokane, were described and illustrated in the issue of March 19, page 623.

The Railways and the Steel Companies.—An editorial commenting on the purchase of rails by the Illinois Central and other roads from the Algoma Steel Company at a lower price and to higher specifications than could be secured from mills in this country, was published in the issue of March 26, page 682.

Rock Island Track Elevation Work at Chicago.—The progress made during the first year's work in elevating certain sections of the Rock Island's line in the city of Chicago involving unusually high retaining walls, a complicated three-level structure at the crossing with the Western Indiana, a novel suburban station and other interesting features, was described in the issue of March 26, page 690.

New Line from Lewistown, Mont., to Great Falls.—The Chicago, Milwaukee & St. Paul has completed a 138-mile line providing an entrance into Great Falls and opening up a large agricultural district. The construction details of this work were described in an illustrated article in the issue of April 2, page 734, and in an editorial in the same issue, page 728, the recent tendencies in the use of concrete ballasted deck construction for long bridges was discussed, as illustrated by the practice on the long viaducts built on the Milwaukee's new line.

Reconstruction of the Jersey City Terminal Yards.—The important yard changes and the installation of an electro-pneumatic interlocking system in the Jersey City terminal of the Central Railroad of New Jersey which were completed on March 20, were described in the issue of April 9, page 787.

Rolling Resistance of Cars Over Switches and Frogs.—A discussion of the results of tests made to determine the actual resistance of modern cars in passing over switches and frogs in a bump yard as abstracted from a paper by C. L. Eddy, assistant professor of railway engineering, Case School of Applied Science, Cleveland, Ohio, in a bulletin of the A. R. E. A., was published in the issue of April 9, page 796.

Concrete Work on the Arizona Division of the Santa Fe

This Material Is Being Used in the Construction of Bank Protection, Bunk Houses, Bridges, Sign Posts, Etc.

The Arizona division of the Santa Fe, extending from Seligman, Ariz., to Mojave, Cal., and including four branch lines, presents some maintenance problems which have been handled in a manner which it is thought will be of general interest to those who have to do with concrete. This division ranges in altitude from less than 500 ft. to over 5,600 ft. elevation, with like variations in climate. All of it is desert country subject to violent rain storms, commonly referred to

A Blanket Protection Wall Some Distance from the Track

as cloudbursts, in the summer time. The roadbed is constructed for the most part of sand and gravel, which disintegrates readily under the action of water.

The extensive use of concrete on the division had its beginnings in trying to meet these conditions, but owing to certain favorable as well as unfavorable conditions and also to the personnel of the division forces one thing has led to another until the pile driver is nearly obsolete, and concrete brakeshoe boxes, crossing, yard-limit and other signs are being tried out, while a section laborer's concrete bunk house has been made standard.

BANK PROTECTION WALLS

To handle storm water a system of "A" surface ditches was constructed years ago reaching out from a bridge to an apex

Wing Walls Extending Out from a Bridge Opening

and coming back to the next bridge. There are miles of these ditches costing many thousands of dollars. The statement is probably not far from true that on one branch line there is as much yardage in the ditches as in the road bed they protect. Some of them where the soil contains clay are good yet, but others have been known to give way in one violent storm and many have been rebuilt from one to several times.

About two years ago it became necessary either to rebuild the ditches protecting about 14 miles of roadbed especially subject to washouts, or to adopt some other form of protection, and it was decided to try out on a large scale what had already been done on a small scale in the immediate vicinity of the bridges, viz., line the roadbed with a concrete blanket on the slope of the embankment. Eventually about 25 miles of line was so protected at a cost less than would have been required to restore the ditches, and it looks as though washout troubles have been practically eliminated on this territory and that repairs should be nil, barring accidents. The method of construction as well as the finished wall is well shown in the accompanying photographs.

Where the wash is likely to scour, the blanket is carried down to the bottom on a 1½ to 1 slope. This involves a great deal of grading. Where the wash does not scour, the slope wall is carried a foot or so below the bed of the wash

New Type of Concrete Pier and Slab Construction

and turned straight down in the form of a toe wall, as narrow as can be dug. On this division a toe wall can usually be dug from 14 to 18 in. wide. On a great deal of this territory the material which comes out of the trench is put back in the form of concrete. Therefore, it is cheaper to fill the trench with concrete than to build forms. However, a sheet of metal is dropped into the trench where it is too wide, and

Concrete Slab Opening With a Concrete Hand Rail

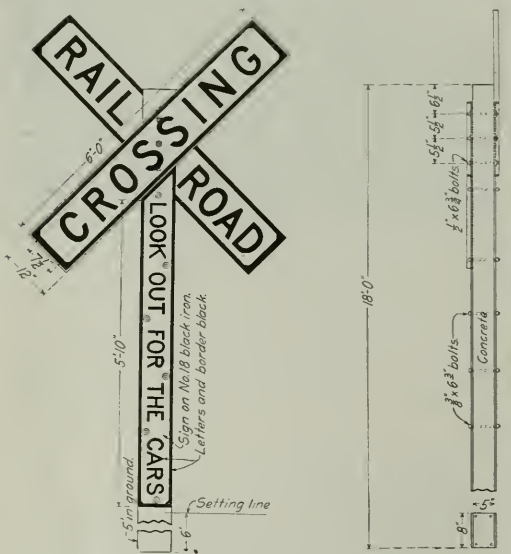
blocked against the side, answering the purpose of a form and keeping the wall the desired width.

Above the toe wall, the bank is sloped off on a 1½ to 1 angle with shovels. A 2-in. by 6-in. piece secured to stakes driven in the ground is laid along the top of the slope, defining the upper limit of the wall. Wire mesh is laid on the

slope and tied to mesh embedded in the toe wall. Parting strips, about 4 ft. apart, are then run down the slope from the 2 by 6 timber at the top to define the slope and skid against. No other forms are used.

The concrete is applied with shovels and skidded off against the parting strips. The greatest care should be taken to see that the mesh is pulled up and kept uniformly in the middle of the concrete. At the head banks of bridges and where water strikes it hard the blanket is made 6 in. thick. Where it is to encounter a rather gentle side wash the thickness is reduced to 4 in. or less.

Figures are not now available showing the cost of all of this work, but one stretch of 8.67 miles cost, per sq. ft., for labor $0.077 and for material $0.038, a total of $0.115. Another stretch of 1.75 miles cost for labor $0.062 and for material $0.031, a total of $0.093 per sq. ft. These had toe walls and no gravel or crushed rock was hauled in. The weather only was unfavorable, being very hot. Another stretch of about 0.75 mile, which was out in the country and not built against the roadbed, cost for labor $0.09 and for material $0.034, a total of $0.124 per sq. ft., the weather and the distance from the track being unfavorable and gravel being obtained on the spot. A wall 400 ft. long, sloped to the bottom, built about 1,500 ft. from the track, cost for labor $0.156 and for material $0.045, or a total of $0.201 per sq. ft. It is expected that many



Concrete Crossing Post With Steel Arms

more miles on this division will be protected in like manner in the future.

BRIDGES

In 1913 a 112-ft. reinforced concrete slab deck bridge was built under the main line and a siding at Klondike, Cal., from plans furnished by the bridge engineer. The bridge has seven 16-ft. spans. The plans, which were new designs, were general plans and did not contemplate a sidewalk and hand rail. In this particular instance it developed that a sidewalk and hand rail were necessary and these were added by making slight change in these plans. The ends of the piers were bracketed near the top, and this bracket was increased sufficiently to support the ends of the sidewalk slabs. The guard rail was abolished, the sidewalk serving that purpose, and the inner edge of the sidewalk slab was supported for its entire length on the outer edge of the deck slabs. In the case of this particular bridge an angle iron was used for a hand rail, the uprights being embedded in the ends of the piers and intermediate uprights being bolted by eye-bolts to the reinforcing of the sidewalk slabs. The iron was afterward painted the color of concrete and sanded. Crushed rock was used in the deck and sidewalk slabs and in the upper 3 ft. of the piers. The balance of the piers was made from gravel taken out of the excavation.

The slabs were cast at the site of the work and were put in place with a wrecker, U-bolts being provided for this purpose in the reinforcing. The photographs show construction of the bridge and the way the slabs were handled. The bridge cost $30.87 per running foot.

Another type of bridge that has been used in late construction more than any other on this division has a standard

The Concrete Crossing Post With Metal Cross Arms

creosoted ballast deck on concrete piers. This type of bridge is peculiarly suitable for this territory and is the result of the special conditions prevailing. The violent rains and the soluble nature of the soil render frame bents impracticable. Hard material, including gypsum, hard pan, cemented gravel, or heavy boulders, make it impossible to secure sufficient penetration of piles without digging holes or trenches to set them in, with the result that it is nearly, and in some cases wholly, as cheap to build concrete piers of the material at hand as it is to set piles. Material for the deck and the piers is always in stock, available on short notice, no special plans or supervision are necessary and there is no waiting for steel to be delivered. The creosoted timbers on the concrete last so many years that such a structure is practically a permanent water way. The piers are made strong enough so that when the deck does eventually wear out, steel, or even slab decks, may be substituted, if desired.

SIGNS

Experiments are also being made with concrete and metal signs. These signs are purely experimental as yet, but the results so far indicate that wooden signs cannot compete with concrete and metal, if the latter can be made in quantities by machinery. So far they have been made by hand.

One of the most practical results obtained with this type of sign, and one which might escape notice, is that anyone, say, the section foreman, can detach the metal bearing legend in a moment, attach a fresh one and ship the old one to the shop to be repainted. The large saving in this feature alone, over the prevailing method of sending a painter over the road on a speeder, needs only to be mentioned to be appreciated. This and the tendency hunters have for shooting holes in signs are the considerations that led to abandoning the idea of making them wholly of concrete. In climates where metal corrodes too readily wood may be substituted for the metal parts which bear the legend.

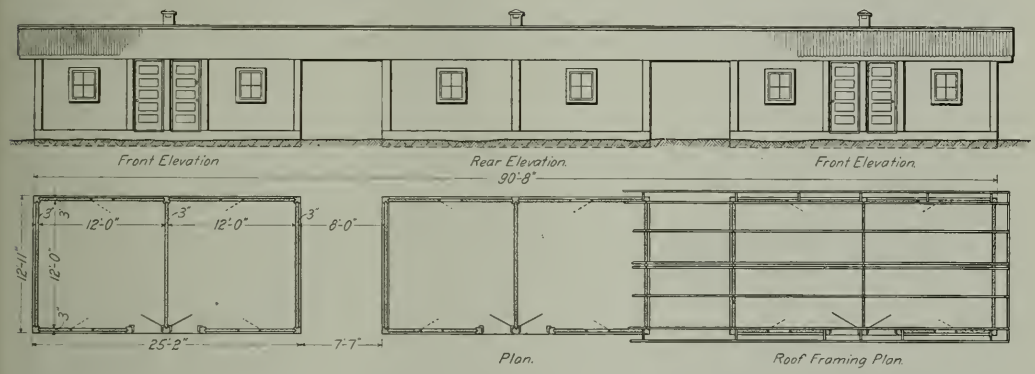
The following is a table showing the cost of these signs made by hand as compared with the store department price of wooden signs:

Kind of sign	Number made	Cost at Needles	Store department prices: Topeka	Cleburne	San Bernardino
Highway crossing	12	$3.72	$4.81	$4.75	.....
Station sign	18	1.90	1.62	1.72	$1.17
Yard Limit sign, tentative Y shape	4	2.73	2.32	.....	.....
Whistling sign	18	1.90	1.63	1.60	.94
Section limit board	14 posts / 28 signs	.75	.....	.80	.68
Station name board	3	4.45	.....	.....	.....
Rail rests	12	.50	.....	.....	.....

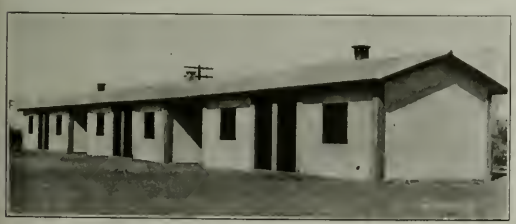
Signs made in Topeka, Cleburne and San Bernardino carrying overhead shop charges, while those at Needles do not.

BRAKEHOSE CELLARS

The campaign for "Safety First" led to the design of concrete cellars for brakehose and air valves in the train yards and many of them have been installed in the terminals at Needles and Barstow from plans shown herewith. The cover of the cellar is of metal, flush with the surface of the ground, and eliminates what has heretofore been a considerable hazard. These boxes were made at Needles at a cost of $1.98 each, and were then shipped to points where needed.



Plan and Elevation of Standard Concrete Bunk House



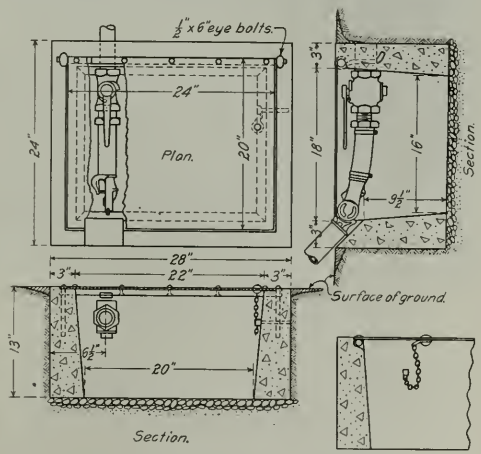
Standard Concrete Bunk House

REINFORCED CONCRETE BUNK HOUSE

Perhaps the most striking and satisfactory result so far, of the use of concrete, is the house for section laborers. The section laborers on this division are Mexicans and their bunk houses have heretofore been built of ties with oiled dirt roofs. For this class of labor it became highly desirable, if not necessary, to provide some form of habitation which could not be burned down and which would provide more sanitary living quarters.

The conditions mentioned at the beginning pointed to concrete construction as being the solution and, with generous backing on the part of the management, experiments have been carried on until such satisfactory results have been achieved, both as to meeting the needs and as to cost, that this type of house has been adopted as standard on the Coast Lines.

The first two houses were built by the unit system, the side, end and roof slabs being poured one on top of the other with building paper between. This required very little form work and made cheap construction, but had some undesirable features. It was difficult to ship the thin slabs, and to load, unload and set them up without breaking them. For the first house, at Needles, the slabs were poured at the site of the house. The second was poured at Needles, shipped 130 miles and set up. These cost $645.06 and $654.38, respectively.



Concrete Brake Hose Cellar

The next two were built on the unit system except that it had been decided that concrete was not the proper material for the roof and corrugated asbestos was substituted. These houses cost $612.39 each. The present method is to cast the pilasters in units and, after setting them up similar to the way that studding is set up for a frame house, the walls are poured. The roof is made of galvanized corrugated iron and is ceiled with Schumacher's wall board, a practically fireproof composition.

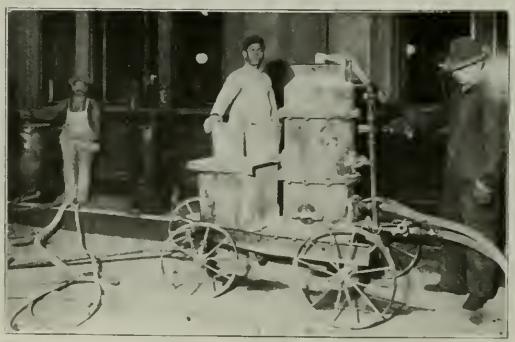
Thirteen houses have been constructed on the division and more are under construction. Four typical houses, the construction of what is thought to be the ultimate design, cost an average of $664.54, all the costs quoted being without freight or rental charges.

Two pump houses have been constructed along the same lines as the bunk houses, but the cost figures are not available.

These various uses of concrete have been developed under the general direction of W. H. Oliver, assistant engineer, and J. W. Wood, general foreman of bridges, of the Atchison, Topeka & Santa Fe, Needles, Cal.

PREVENTING CORROSION OF STEEL UNDER SEVERE CONDITIONS

The steel substructure of the Cortlandt street ferry terminal of the Pennsylvania in New York City was recently coated with a thin layer of cement and sand applied with a cement gun, to protect it from rust. This work is unusual in that the steel work is subjected to exceptionally severe conditions and no reinforcement was used in the Gunite. The first floor of this ferry terminal consists of a steel frame work with wooden floor beams and floor. The steel was given a coat of linseed oil paint before shipping, and after erection was cleaned with wire brushes and given two additional coats of a standard paint. It is about 4 ft. above high water, which at this point is very salty, and in addition, the steel is exposed to large quantities of steam which escape from the drip and drain pipes through the bulkhead wall at low tide. The surface of the steel is therefore wet at all times.



Cement Gun and Two Kelley Sand Blast Machines at Work in Cortlandt Street Ferry Terminal, New York

The paint which was first applied soon came off; the steel was again cleaned and asphaltum applied, but after about six months this could be dusted off with a broom. After this nothing was done for three years, when it was found that some action was necessary, as a coating of scale and rust had formed which could be pulled off in layers 3/32 in. thick. In consultation with the Cement Gun Company, Inc., New York, the proposal was made that the steel be covered with a wire mesh reinforcing, and Gunite be applied over this to a thickness of 1½ in. This proposal proved to be too expensive, however, as the placing of the reinforcement on the 220 steel girders and numerous tie beams was made very difficult by the layout of the wooden floor beams, and the thickness of Gunite would have been greater than that needed for the protection of the steel.

The question of coating steel without reinforcement was then taken up, and an exhaustive preliminary test made to see whether such an application of Gunite would be practical and satisfactory. It was found that the design of the steel work provided amply for the additional load, so that the ability of the Gunite to withstand the conditions existing was the only point to be determined. A piece of 4-in. by 4-in. angle 2 ft. long was sand-blasted to the gray metal and left with a smooth surface. As the steel work under the building was very badly pitted by corrosion it was evident that, after cleaning, the surface would be rougher than the test sample and would, therefore, afford a better bonding surface.

About one hour after the sample was cleaned, it was coated with a 1:3 mixture of cement and sand applied with a cement gun to a thickness of from ¼ in. to ½ in. The sample was then stored in moist salt air for three days, then submerged in salt water from the river for three days, then carried into a cold storage house nearby in the pan containing the salt water and the sample. Here the sample was taken out, placed in a clean, dry, wooden box on a sheet of white paper and stored at an even temperature of 5 deg. below zero for 48 hours. At the end of that time no cement had flaked off, and as it was coated with ice it was taken into a warm room and allowed to thaw out over night. In the morning no flaking had occurred and the sample was then placed on top of the boiler in a power house, where the temperature was 110 deg. F. It was left for three days, after which a microscopic examination showed it to be intact. No hair cracks were visible and no cement had flaked off. After it had cooled it was given a 2-ft. drop on a wooden floor and then on a concrete floor. Another microscopic examination failed to reveal cracks or checks, so to find out whether the water had penetrated the coating the sample was given a 10-ft. drop on a concrete floor, which broke the coating from the outside of the angle but not from the inside. There were no signs of corrosion, the neat cement bond and the glazed cement finish being evident.

As a result of the satisfactory nature of this test two sand-blast machines and a cement gun were put to work on the terminal. All the steel was first sand-blasted to the gray metal and then coated with Gunite to a thickness of ¼ in. to ½ in. The work was started early in October, 1914, and completed in January, 1915. An examination of the work after four months showed no signs of cracking and gave every indication of a strong bond.

The Pennsylvania has recently purchased a cement gun equipment to repair concrete-protected overhead steel bridges on which the concrete has been cut away by the action of locomotive blasts. This purchase was made after a two years' test of steel protected with Gunite under severe conditions, the test beams being located in the West Philadelphia station, directly over the point where many locomotives stop. There is quite a grade at this point, and on starting, the locomotives subject the beams to the full force of the blast No erosion or disintegration of the Gunite coating has occurred since this test was inaugurated.

SUPREME COURT AND THE POST OFFICE DEPARTMENT.—It is a pity, perhaps, that the principle of rate fixing by public service commissions recently enunciated by the United States Supreme Court, cannot be applied with equal rigor to the government's own enterprises. A state cannot compel a railroad to transport either passengers or particular commodities, says the court, at rates which do not yield reasonable compensation. If the post office department were managed on that principle, second-class mail matter and rural delivery service would have to pay postal rates sufficient to wipe out the heavy deficits which they now are responsible for each year.—*Springfield Republican.*

American Railway Engineering Association Committees

A Complete List of Names of Members Appointed and Subjects Specified for Investigation and Report

The Board of Direction of the American Railway Engineering Association has selected the personnel of the new committees and the subjects for investigation and report during the coming year as follows:

Committee I—Roadway

1. Make critical examination of the subject matter in the Manual, and submit definite recommendations for changes.
2. Continue the study of unit pressures allowable on roadbed of different materials, co-operating with Special Committee on Stresses in Railroad Track.
3. Report on the prevention and cure of water pockets in roadbed.

W. M. Dawley (chairman), Erie; J. A. Spielmann (vice-chairman), B. & O.; J. R. W. Ambrose, G. T.; A. F. Blaess, I. C.; S. P. Brown, C. N.; B. M. Cheney, C. B. & Q.; Ward Crosby, C. C. & O.; W. C. Curd, M. P.; Paul Didier, B. & O.; S. B. Fisher, M. K. & T.; Frank Merritt, G. C. & S. F.; L. G. Morphy, B. & A.; F. M. Patterson, I. C. C.; W. D. Pence, I. C. C.; W. H. Petersen, C. R. I. & P.; A. C. Prime; H. J. Slifer; J. E. Willoughby, A. C. L.; W. P. Wiltsee, N. & W.

Committee II—Ballast

1. Make critical examination of the subject matter in the Manual, and submit definite recommendations for changes.
2. Report on the economical and efficient depth of ballast, co-operating with Special Committee on Stresses in Railroad Track.
3. Methods and cost of applying ballast—
   (a) Ballasting by contract.
   (b) Mechanical tamping and shoulder formings.
4. Efficiency of various stone and gravel ballasts.

H. E. Hale (chairman), President's Conference Committee on Valuation; I. M. Meade (vice-chairman), A. T. & S. F.; L. W. Baldwin, I. C.; D. P. Beach, P. L. W.; W. J. Bergen, N. Y. C. & S. L.; Carl Bucholtz, Erie; T. C. Burpee; O. H. Crittenden, I. & G. N.; J. M. Egan, I. C.; T. W. Fatherson, C. G. W.; H. L. Gordon, B. & O.; G. H. Harris, M. C.; C. C. Hill, M. C.; S. A. Jordan, B. & O.; William McNah, G. T.; S. B. Rice, R. F. & P.; E. V. Smith, B. & O.; D. L. Sommerville, N. Y. C.; F. J. Stimson, G. R. & I.; D. W. Thrower, I. C.; R. C. White, M. P.

Committee III—Ties

1. Make critical examination of the subject matter in the Manual, and submit definite recommendations for changes.
2. Report on the effect of tie plates and track spikes on life of crossties.
3. Specifications for cross and switch-ties.
4. Metal, composite and concrete ties.

L. A. Downs (chairman), I. C.; F. R. Layng (vice-chairman), B. & L. E.; C. C. Albright, Purdue University; M. S. Blaiklock, G. T.; W. J. Burton, M. P.; W. A. Clark, D. & I. R.; S. B. Clement, T. & N. O.; E. D. Jackson, B. & O.; E. P. Laird, A. C. L.; E. R. Lewis, D. S. S. & A.; J. B. Myers, B. & O.; A. J. Neafie, D. L. & W.; J. V. Neubert, N. Y. C.; R. J. Parker, A. T. & S. F.; J. G. Shillinger, Rutland; I. O. Walker, N. C. & S. L.; H. S. Wilgus, P. S. & N.; Louis Yager, N. P.

Committee IV—Rail

1. Make critical examination of the subject matter in the Manual, and submit definite recommendations for changes.
2. Report on rail failures, statistics and conclusions.
3. Report on effect on rail of defective equipment and improper maintenance.
4. Continue special investigation of rails.
5. Track bolts and nutlocks.

J. A. Atwood (chairman), P. & L. E.; R. Montfort (vice-chairman), L. & N.; W. C. Cushing, P. L.; E. B. Ashby, L. V.; A. S. Baldwin, I. C.; Chas. S. Churchill, N. & W.; J. B. Berry; G. M. Davidson, C. & N. W.; Dr. P. H. Dudley, N. Y. C.; C. F. W. Felt, A. T. & S. F.; L. C. Fritch, C. N.; A. W. Gibbs, P. R. R.; C. W. Huntington, M. & S. L.; John D. Isaacs, S. P.; Howard G. Kelley, G. T.; C. F. Loweth, C. M. & S. P.; H. B. MacFarland, A. T. & S. F.; C. A. Morse, C. R. I. & P.; J. R. Onderdonk, P. & O.; J. P. Snow; F. S. Stevens, P. & R.; A. W. Thompson, B. & O.; R. Trimble, P. L.; Geo. W. Vaughan, N. Y. C.; M. H. Wickhorst.

Committee V—Track

1. Make critical examination of the subject matter in the Manual, and submit definite recommendations for changes.
2. Continue the study of Economics of Track Labor.
3. Study the relation between worn flanges and worn switch points, with a view to correcting the causes and decreasing the number of derailments due to the combination of worn switch points and worn flanges on wheels.
4. Present specifications and designs for cut- and screw-spikes.
5. Report on guard rails and flangeways and effect of increase of 1/8-inch thickness of wheel flanges.

J. B. Jenkins (chairman), B. & O.; G. J. Ray (vice-chairman), D. L. & W.; Geo. H. Bremner, I. C. C.; J. F. Burns, L. & N.; H. M. Church, B. & O.; Garrett Davis, C. R. I. & P.; J. M. R. Fairbairn, C. P.; T. H. Hickey, M. C.; E. T. Howson, *Railway Age Gazette*; L. J. F. Hughes, C. R. I. & P.; E. L. Ingram, University of Pennsylvania; T. T. Irving, G. T.; J. R. Leighty, M. P.; H. A. Lloyd, Erie; A. C. Mackenzie, C. P.; P. C. Newhegin, B. & A.; F. B. Oren, I. C.; R. M. Pearce, P. & L. E.; H. T. Porter, B. & L. E.; E. Raymond, A. T. & S. F.; W. G. Raymond, State University of Iowa; L. S. Rose, C. C. C. & S. L.; H. R. Safford, G. T.; C. H. Stein, C. R. R. of N. J.; A. H. Stone, K. C. T.

Committee VI—Buildings

1. Make critical examination of the subject matter in the Manual, and submit definite recommendations for changes.
2. Report on coaling stations.
3. Report on freight house scales.
4. Report on ashpits.

M. A. Long (chairman), B. & O.; G. H. Gilbert (vice-chairman), Q. & C.; G. W. Andrews, B. & O.; J. P. Canty, B. & M.; D. R. Collin, N. Y. C.; W. H. Cookman, P. R. R.; C. G. Delo, C. G. W.; W. T. Dorrance; C. H. Fake, M. R. & B. T.; A. T. Hawk, C. R. I. & P.; P. B. Roberts, G. T.; W. S. Thompson, P. R. R.

Committee VII—Wooden Bridges and Trestles

1. Make critical examination of the subject matter in the Manual, and submit definite recommendations for changes.
2. Continue the study of design of docks and wharves.
3. Report on comparative merits of ballast deck and reinforced concrete trestles.
4. Continue the study of the use of lag screws in trestle construction.

E. A. Frink (chairman), S. A. L.; W. H. Hoyt (vice-chairman), D. M. & N.; H. Austill, Jr., M. & O.; J. E. Barrett, L. & H. R.; H. C. Brown, Jr., I. C.; E. A. Hadley, M. P.; F. G. Hoskins, B. & O.; H. S. Jacoby, Cornell University; A. O. Ridgway, D. & R. G.; I. L. Simmons, C. R. I. & P.; D. W. Smith, H. V.; W. F. Steffens, N. Y. C.

Committee VIII—Masonry

1. Make critical examination of the subject matter in the Manual, and submit definite recommendations for changes.
2. Report on cost and method of constructing concrete piles.
3. Report of cost, appearance and wearing qualities of surface finish of concrete.
5. Report on design of foundations for piers, abutments, retaining walls and arches in various soils and depth of water (not including pneumatic foundations).

F. E. Schall (chairman), L. V.; F. L. Thompson (vice-chairman), I. C.; R. Armour, G. T.; John C. Blye; H. A. Cassil, B. & O. S. W.; T. L. Condron; J. K. Corner, L. E. & W.; L. J. Hotchkiss; Richard L. Humphrey; W. S. Lacher, C. M. & S. P.; C. P. Richardson, C. R. I. & P.; R. A. Rutledge, A. T. & S. F.; G. H. Scribner, Jr.; F. P. Sisson, G. T.; Joh Tuthill; J. J. Yates, C. R. R. of N. J.

Committee IX—Signs, Fences and Crossings

1. Make critical examination of the subject matter in the Manual, and submit definite recommendations for changes.
2. Report on principles governing the use of railway signs.
3. Continue the study of concrete fence posts.

W. F. Strouse (chairman), B. & O.; G. E. Boyd (vice-chairman), D. L. & W.; R. B. Abbott, P. & R.; H. E. Billman, M. P.; E. T. Brown, B. & O.; A. C. Copland, C. & O.; Arthur Crumpton, G. T.; J. T. Frame; L. E. Haislip, B. & O.; Marc Johnson, I. C.; L. C. Lawton, A. T. & S. F.; G. L. Moore, L. V.; Thomas Quigley, I. C.; C. H. Splitstone, Erie.

Committee X—Signals and Interlocking

1. Make critical examination of the subject matter in the Manual, and submit definite recommendations for changes.
2. Continue the study of economics of labor in signal maintenance.
3. Report on signal installations on single-track roads.
4. Present, for approval, specifications adopted by the Railway Signal Association, which, in the judgment of the Committee, warrant consideration.
5. Requisites for switch indicators, conveying information on condition of the block to conductors and enginemen.

C. C. Anthony (chairman), P. R. R.; J. A. Peabody (vice-chairman), C. & N. W.; Azel Ames; H. S. Balliet, N. Y. C.; C. A. Christofferson, N. P.; C. E. Denney; C. A. Dunham, G. N.; W. J. Eck, Southern; W. H. Elliott, N. Y. C.; G. E. Ellis, K. C. T.; M. H. Hovey; A. S. Ingalls, N. Y. C.; A. M. Keppel, Washington Terminal Company; H. K. Lowry, C. R. I. & P.; J. C. Mock, M. C.; F. P. Patenall, B. & O.; D. W. Richards, N. & W.; A. H. Rudd, P. R. R.; W. B. Scott, Sunset Central Lines; A. G. Shaver; Thos. S. Stevens, A. T. & S. F.; W. M. Vandersluis, I. C.

Committee XI—Records and Accounts

1. Make critical examination of the subject matter in the Manual, and submit definite recommendations for changes.

2. Report on the use of small forms on cardboard or other suitable material for use of fieldmen in making daily reports, to the end that supervision may be facilitated and efficiency encouraged.

3. Continue the study of feasible and useful subdivisions of Interstate Commerce Commission classification accounts 202 and 220, with a view to securing uniformity of labor costs, separating the items in accordance with such forms as are promulgated by the I. C. C. during the year.

4. Investigation of methods for reproducing maps and profiles on drawing linen for permanent record.

W. A. Christian (chairman), I. C. C.; M. C. Byers (vice-chairman), W. M.; F. J. Bachelder; W. S. Danes, Wabash; Lester Bernstein, B. & O.; G. D. Hill, I. C.; Huntington Smith, N. Y. C. & S. L.; Henry Lehn, N. Y. C.; J. H. Milburn, B. & O.; J. W. Orrock, C. P.; J. C. Patterson, Erie; H. C. Phillips, A. T. & S. F.; J. H. Reinholdt, M. & St. L.; R. C. Sattley, C. R. I. & P.; Guy Scott, P. L.; H. M. Stout, N. P.; Frank Taylor, C. P.; J. M. Weir, C. R. I. & P.; W. D. Wiggins, P. L. W.; J. H. Prior, Public Utilities Commission of Illinois.

Committee XII—Rules and Organization

1. Make critical examination of the subject matter in the Manual, and submit definite recommendations for changes.

2. Report on clearance for maintenance of way structures under assignment from the Committee on Maintenance of the American Railway Association, conferring with other committees.

3. Continue the formulation of rules for the guidance of field parties.

4. Continue the study of science of organization.

G. D. Brooke (chairman), B. & O.; F. D. Anthony (vice-chairman), D. & H.; R. P. Black, K. & M.; L. L. Beal, A. B. & A.; Ralph Budd, G. N.; J. B. Carothers, B. & O.; S. E. Coombs, N. Y. C.; C. Dougherty, Q. & C.; B. Herman, Southern; A. J. Himes, N. Y. C. & St. L.; Jos. Mullen, C. C. C. & St. L.; E. T. Reisler, L. V.

Committee XIII—Water Service

1. Make critical examination of the subject matter in the Manual, and submit definite recommendations for changes.

2. Report on cost of pumping water by various methods.

3. Report on protection for water stations against freezing.

A. F. Dorley (chairman), M. P.; J. L. Campbell (vice-chairman), E. P. & S. W.; J. T. Andrews, B. & O.; C. A. Ashbaugh, G. C. & S. F.; F. T. Beckett, C. R. I. & P.; M. C. Blanchard, A. T. & S. F.; C. C. Cook, R. & O.; R. H. Gaines, K. C. S.; W. C. Harvey, C. G. W.; E. G. Lane, B. & O. S. W.; W. A. Parker, St. J. & G. I.; R. W. Willis, C. B. & Q.

Committee XIV—Yards and Terminals

1. Make critical examination of the subject matter in the Manual, and submit definite recommendations for changes.

2. Report on handling of freight in double-deck freight houses and cost of operation.

3. Continue study of typical situation plans of passenger stations and approaches, and methods of operating same.

4. Continue the study of classification yards.

E. B. Temple (chairman), P. R. R.; B. H. Mann (vice-chairman), M. P.; W. G. Arn, I. C.; H. Baldwin, C. C. C. & St. L.; G. H. Burgess, D. & H.; A. E. Clift, I. C.; L. G. Curtis, B. & O. C. T.; H. T. Douglas, Jr., C. & A.; A. C. Everham, K. C. T.; R. Ferriday, C. C. C. & St. L.; G. H. Herrold; D. B. Johoston, P. L.; H. A. Lane, B. & O.; L. J. McIntyre, N. P.; A. Montzheimer, E. J. & E.; H. J. Pfeifer, T. R. R. A.; W. L. Seddon, S. A. L.; C. H. Spencer, I. C. C.; E. E. R. Tratman, Engineering News; E. P. Weatherly; W. L. Webb, C. M. & St. P.; C. C. Wentworth, N. & W.; J. G. Wishart, C. R. I. & P.

Committee XV—Iron and Steel Structures

1. Make critical examination of the subject matter in the Manual, and submit definite recommendations for changes.

2. Continue the study of methods of protection of iron and steel structures against corrosion.

3. Continue the study of the relative economy of various types of movable bridges.

4. Continue the study on secondary stresses and impact.

5. Continue the study of column tests.

A. J. Himes (chairman), N. Y. C. & St. L.; O. E. Selby (vice-chairman), C. C. C. & St. L.; J. A. Bobland, G. N.; W. S. Bouton, B. & O.; A. W. Buel; A. W. Carpenter, N. Y. C.; Charles Chandler, I. C.; C. L. Crandall, Cornell University; J. E. Crawford, N. & W.; A. Chas. Irwin, C. M. & St. P.; J. M. Johnson, I. C.; B. R. Leffler, L. S. & M. S.; W. H. Moore, N. Y. N. H. & H.; P. B. Motley, C. P.; Albert Reichmann, American Bridge Company; J. W. Reid, C. & A.; A. F. Robinson, A. T. & S. F.; H. B. Seaman; C. E. Smith, M. P.; H. B. Stuart, G. T.; G. E. Tebbetts, K. C. T.; F. E. Turneaure, University of Wisconsin; L. F. Van Hagan, University of Wisconsin.

Committee XVI—Economics of Railway Location

1. Make critical examination of the subject matter in the Manual, and submit definite recommendations for changes.

2. Establish a rational basis for determining the relative efficiency of various locations.

3. Report on effect of curvature on cost of maintenance of way and equipment.

4. Report on train resistance at speeds exceeding 35 miles per hour.

5. Report on fuel consumption per horsepower hour.

John G. Sullivan (chairman), C. P.; C. P. Howard (vice-chairman); F. H. Alfred, P. M.; R. N. Begien, B. & O. S. W.; Willard Beahan, L. S. & M. S.; D. F. Crawford, P. L. W.; Maurice Coburn, Vandalia; A. C. Dennis; R. D. Gardner, S. N. E.; A. S. Going, G. T.; F. W. Green, Louisiana & Arkansas; P. M. LaBach, C. R. I. & P.; Fred Lavis; J. de N. Macomb, Jr., A. T. & S. F.; C. W. P. Ramsey, C. P.; S. S. Roberts; E. C. Schmidt, University of Illinois; A. K. Shurtleff, Engineering Committee of the President's Conference; H. J. Simmons, E. P. & S. W.; H. R. Talcott, B. & O.; L. L. Tallyn, D. L. & W.; Walter Loring Webb; H. C. Williams, L. & N.; M. A. Zook, I. C. C.

Committee XVII—Wood Preservation

1. Make critical examination of the subject matter in the Manual, and submit definite recommendations for changes.

2. Continue the study of the effect of water in creosote.

3. Continue the study of the relation of amount of preservative and depth of penetration to the resistance of materials against decay, and also the penetration of preservatives.

4. Continue the compilation of service test records.

5. Report on drying process of wood preservation.

Earl Stimson (chairman), B. & O.; E. H. Bowser (vice-chairman), I. C.; F. J. Angier, B. & O.; W. A. Fisher, A. C. L.; C. F. Ford, C. R. I. & P.; Dr. W. K. Hatt, Purdue University; V. K. Hendricks, St. L. & S. F.; George E. Rex, A. T. & S. F.; E. A. Sterling; Lowry Smith, N. P.; C. M. Taylor, C. R. R. of N. J. and P. & R.; C. H. Teesdale, Forest Products Laboratory; T. G. Townsend, S. O.; Dr. Hermann von Schrenk.

Committee XVIII—Electricity

1. Make critical examination of the subject matter in the Manual, and submit definite recommendations for changes.

2. Continue the study of the subject of clearances of third rail and overhead structures, conferring with other committees.

3. Continue the study of electrolysis and insulation and its effect upon reinforced concrete structures.

4. Report on water power for electrical railway operation.

5. Continue the study of maintenance organization with relation to track structures.

George W. Kittredge (chairman), N. Y. C.; J. B. Austin, Jr. (vice-chairman), L. I.; D. J. Brumley, I. C.; R. D. Coombs; A. O. Cunningham, Wabash; Walt Dennis, C. R. I. & P.; R. H. Ford, C. R. I. & P.; George Gibbs, P. R. R.; G. A. Harwood, N. Y. C.; E. B. Katte, N. Y. C.; C. E. Lindsay, N. Y. C.; W. L. Morse, Jacksonville Terminal Company; W. S. Murray; J. A. Peabody, C. & N. W.; Frank Rhea, I. C. C.; J. R. Savage, L. I.; Martin Schreiber, Public Service Railway; H. U. Wallace, Northern Colorado Power Company.

Committee XIX—Conservation of Natural Resources

1. Continue the study of tree planting and general reforestation.

2. Present specifications for southern yellow pine, conferring with other committees and associations.

3. Continue the study of resources of iron ore, coal, fuel-oil and timber.

4. Report on water power for railway electrical operation.

C. H. Fisk (chairman); William McNab, G. T.; R. H. Aishton, C. & N. W.; Moses Burpee, Bangor & Aroostook; F. F. Busteed, C. P.; A. L. Davis, I. C.; W. A. Hammel; A. L. Moorshead, Erie; Francis Lee Stuart, B. & O.; S. N. Williams, Cornell College; R. C. Young, L. S. & I.

Uniform General Contract Forms

1. Make critical examination of the subject matter in the Manual, and submit definite recommendations for changes.

2. Report on siding agreements.

3. Report on agreement forms for interlocking and railway crossings, conferring with Committee on Signals and Interlocking.

E. H. Lee (chairman), C. & W. I.; C. A. Wilson (vice-chairman); C. Frank Allen, Massachusetts Institute of Technology; W. G. Atwood, I. C. C.; John P. Congdon; Thos. Earle, Pennsylvania Steel Co.; J. C. Irwin, B. & A.; R. G. Kenly, M. & St. L.; C. A. Paquette, C. C. C. & St. L.; J. H. Roach, L. S. & M. S.

Grading of Lumber

1. Make critical examination of the subject matter in the Manual, and submit definite recommendations for changes.

2. Report on grading rules for white and Norway pines.

3. Specifications for southern yellow pine. (A. S. T. M.)

4. Specifications for timber to be treated in co-operation with the Committee on Wood Preservation.

Dr. Hermann von Schrenk (chairman); B. A. Wood (vice-chairman), M. & O.; W. McC. Bond, B. & O.; D. Fairchild, N. P.; W. H. Norris, Maine Central; J. J. Taylor, K. C. S.

Stresses in Track

A. N. Talbot (chairman), University of Illinois; W. M. Dawley (vice-chairman), Erie; A. S. Baldwin, I. C.; J. B. Berry; G. H. Bremner, I. C. C.; John Brunner, Illinois Steel Co.; W. J. Burton, M. P.; Chas. S. Churchill, N. & W.; W. C. Cushing, P. L.; Dr. P. H. Dudley, N. Y. C.;

H. E. Hale, President's Conference Committee; Robt. W. Hunt; J. B. Jenkins, B. & O.; George W. Kittredge, N. Y. C.; P. M. LaBach, C. R. I. & P.; C. G. E. Larsson, American Bridge Co.; William McNab, G. T.; G. J. Ray, D. L. & W.; Albert Reichmann, American Bridge Co.; Earl Stimson, B. & O.; F. E. Turneaure, University of Wisconsin; J. E. Willoughby, A. C. L.

THE DISTRIBUTION AND CARE OF CROSSTIES*

By E. F. Robinson

Chief Engineer, Buffalo, Rochester & Pittsburgh

The question of the distribution and care of crossties is one of the most important that we have to deal with in track maintenance and one that has been given a great deal of thought and attention by our present engineering organization. We have a timber-preserving plant at Bradford, which was placed in service during the summer of 1910, and since that time practically all cross and switch ties placed in our tracks have been treated with creosote, with the exception of ties renewed in unimportant side tracks.

In outlining our present practice, we considered it necessary to begin at the beginning, that is, with the purchase of the untreated ties. We are very particular in the selection of our ties, both as regards the manufacture and the character of timber, and nothing but first-class material is accepted. With a view of securing uniform treatment and a uniform roadbed, we accept nothing for treatment but sawed ties of uniform dimensions, excepting in some cases where we have been unable to secure sufficient local ties for our supply. We have found it necessary to purchase yellow pine hewn ties from the South, but this applies to a limited extent only. So far we have been able to secure practically all ties locally from points near our line, mostly beech, maple, hickory, red oak and chestnut. After the selection of the ties, we give careful attention to the piling and seasoning before treatment, separating the different classes of timber into groups, as our experience in treating may dictate. I am a firm believer in thoroughness in the treatment of ties, and am strongly of the opinion that in treating some classes of timber to refusal and others with from 10 to 12 lb. of creosote oil per cu ft., we are working in the right direction, especially in view of the precautions taken in the handling and protection of ties after treatment, details that unfortunately are entirely disregarded on a great many roads.

After the ties are treated they are either piled in the storage yard at our timber-preserving plant, or shipped out along the line, depending upon conditions. Usually in the fall and early spring months, before we wish to distribute ties along the track for renewals, we ship them out from the plant as treated and pile them in standard piles at stations and adjacent to sidetracks where they can be reloaded easily for distribution by the section men. During the summer months the piles are covered with a layer of earth to prevent rapid drying out, but during the winter months they are left uncovered.

We require our men to be very careful in the handling of treated ties; they are not allowed to throw them over the sides of cars on top of each other in piles, neither are they permitted to throw them down embankments promiscuously when distributing for renewals. We require the use of tongs in pulling ties into the track, and absolutely prohibit the use of shovels, picks or any other tools for this purpose. We also prohibit the use of spike mauls or like tools for bucking the ties around in the track.

As sawed ties do not require adzing for tie plates, and as what few hewn ties we treat are adzed at the plant before treatment, it is not necessary for the track men to use an adze on them; but we realize, of course, that in a few years, as the tie plates will settle more or less into the ties, it will be necessary to adze them to some extent when laying new rail or when rolling rail in on curves. Every treated tie that goes into our tracks, both on tangents and curves, is plated with a Goldie shoulder tie plate, size ½ in. x 7 in. x 9 in., and these plates are applied to the ties, using the Ware tie-plate gage and surfacer and beetles, before the ties are placed in the track. Where it is necessary to pull spikes, all holes in treated ties are plugged with creosoted tie plugs, and before driving the plugs in place, hot creosote is poured into the spike holes, the men driving the plugs being provided with goggles to avoid injury to the eyes. Where it becomes necessary to adze treated ties, the cut surfaces immediately receive a brush treatment of hot creosote oil.

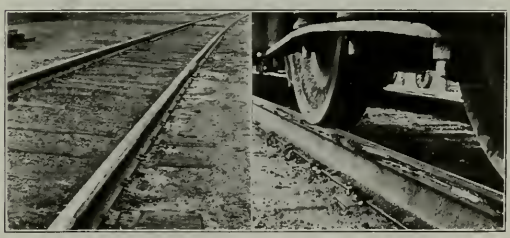
A galvanized nail is applied to the ties at the timber-preserving plant, indicating the class of timber, and when the ties are placed in the track dating nails are applied, showing the year. Section foremen are required to submit a daily report, showing the number of ties of each class placed in the track between each mile post, and a condensed record is kept in this office. In the case of the removal of treated ties from the track from any cause whatever, the foremen are required to report, giving sufficient data as regards location, etc., to enable us to trace out the life of the ties removed.

With the exception of providing our men with goggles to protect the eyes, we have not thought it necessary to adopt any method of protection against poisoning, except to call the attention of our foremen to the necessity of using extreme care in the handling of treated ties, especially in the case of men having skin abrasions or any form of skin disease. When we first commenced using treated ties, we had a large number of cases of poisoning, but this trouble seems to be disappearing as our men become more familiar with the handling of the treated timber.

*Abstracted from Appendix A to the report of the Committee on Ties of the American Railway Engineering Association.

EFFECT OF CANTING THE LOW RAIL ON CURVES

In our issue of August 21, 1914, page 351, we discussed the practice of canting rails and the advantages and disadvantages resulting therefrom. In that article we referred particularly to the detrimental effect of canting the inner or low rail on curves, as this brings the line of contact between the rail and the wheels on the outer edge of the head, causing excessive pressure and flowing of the metal. This condition is strikingly shown by the two accompanying photographs recently taken within a few minutes of each other at the same location. The one on the left shows the condition of a Bessemer rail canted inward slightly on the low side of a 3 deg. 30 min. curve after being in the track eight months. The elevation at this point was 3¼ in. and the gage 4 ft. 9⅛ in. This curve was within station limits near a water tank where many trains stop and the speed was therefore slow. The photograph on the right shows the contact of a car wheel on the outer edge of the rail with light showing between the inner edge of the rail and the wheel tread.



Condition of Low Rail on Curve (on Left) and Condition Causing It (on Right)

A SUCCESSFUL EXAMPLE OF TREE PLANTING*

The catalpa plantation of the Illinois Central at Harahan, La., is located seven miles north of New Orleans, on the main line of the Illinois Central, and consists of 200 acres set apart from land already acquired by the railroad company. The soil is the well known alluvial deposit of the Mississippi river bottom land, of great depth, and having good drainage and sub-irrigation. The planting was made in the spring of 1902, at which time 173,000 one-year seedlings of the Catalpa Speciosa were planted. The trees were planted 4 ft. apart, with the expectation that the close planting would promote a straight growth until such time as the trees had become sufficiently large for fence posts, thinning them out as they became of such size, leaving the trees that were to grow into size for crossties approximately 12 ft. apart.

The handling of the plantation was at first entrusted to outside parties, who, on account of lack of familiarity with the soil and labor conditions, incurred a greater expense, in

View in Illinois Central Catalpa Plantation at Harahan, La.

the first few years, than is now felt to have been necessary, in the cultivation and upkeep of the plantation, although, due to the exceedingly fertile soil, an unusual expense would necessarily be incurred in the first few years in the protection of the seedlings from the rank growth of grass, weeds and underbrush, which had a tendency not only to smother the seedlings, but presented a fire risk in the fall of the year, from which latter cause considerable injury was incurred on several occasions.

When the trees were first planted, it was with the theory that when the catalpa tree is cut back at an age of from three to five years, the sprouts which will spring from the stump will be straight, more hardy and generally better than if the original tree be allowed to mature. Carrying out this theory at Harahan, a considerable number of young trees were cut back, but the few sprouts that grew were inferior to the original plant and showed no superior qualities as to straight growth. While this theory may be applicable to a catalpa tree growing in an isolated position, experience at Harahan plantation proved that when catalpa trees are planted closely together the shadows cast by their tops, together with atmospheric conditions and probably sub-surface influence, produce a different effect, and the stump produces sprouts with short life and very slow growth.

In 1906 the practice of cutting back the young trees was abandoned and the growth having advanced considerably, cattle were allowed to graze throughout the plantation, with the result that the growth of grass and weeds was kept down, danger from fire was eliminated, the trees became sturdy and straightened up well in their growth, and heavy expenditures for upkeep were no longer necessitated. This practice is continued at the present time. While this might not be successful under other conditions, it has given the best results in the particular condition of climate and soil and character of trees at this particular plantation.

At the 1914 convention of the American Railway Engineering Association the Illinois Central exhibited a standard 6 in. by 8 in. by 8 ft. crosstie, and two 6-ft. fence posts cut from a single catalpa tree grown on the plantation in 12 years from the seed, but the tree from which these were cut was one of the largest in the plantation, being probably twice the size of the average tree. It was given as an illustration of the possibilities under the most favorable conditions.

The financial status of the plantation as of June 30, 1914, was as follows:

Cost of 200 acres of land in 1898	$ 1,466.67	
173,000 seedlings	1,346.66	
Preparing land and planting	2,537.96	
Cultivation	3,030.13	
Total first year ending June 30, 1903		$ 8,381.42
Cultivation, 1904		4,805.25
Cultivation, 1905		1,643.76
Cultivation, 1906		2,334.65
Fencing and fire protection, 1907		525.40
Cultivation and thinning, 1907 to 1914		606.92
Taxes and interest charges to 1914		8,055.70
Total cost to June 30, 1914		$26,353.10
Credit—rent from pasture and fence posts cut		1,102.92
Net investment		$25,250.18
Present value:		
150,000 posts, first class, at 20 cents	$30,000.00	
150,000 posts, second class, at 10 cents	15,000.00	
	$45,000.00	
Less cost of making at 5 cents each	15,000.00	
Net value		$30,000.00

The value of posts obtained by thinning has now reached a point where, added to rent received from owners of stock pastured, an annual revenue is obtained which pays for the small annual expense of supervision and for taxes, and meets the annual interest charges due to the heavy expenditures of the first four years of the life of the plantation. The total investment in 1922 is estimated at approximately $25,600. If conditions continue as at present there should be obtained from the plantation at that date not less than:

260,000 posts at 25 cents	$ 65,000.00
130,000 ties at 75 cents	97,500.00
Total	$162,500.00
Deduct cost of making	45,500.00
Net value	$117,000.00

The land has appreciated so that its value in 1914 was not less than $50 per acre, or for the 200 acres, $10,000. In 1922 the land will probably be worth not less than $150 per acre, or a total of $30,000, but it is land bought and held for future terminal expansion, and is being used with a view of getting the greatest return from it pending the date at which such expansion becomes necessary.

The results, however, seem to justify further development along these lines, and the subject is being looked into with a view of carrying the experiment further.

*Abstracted from a statement by A. S. Baldwin, chief engineer, Illinois Central, in the report of the committee on The Conservation of Natural Resources of the American Railway Engineering Association.

General News Department

In Canada all passengers by railroad now have to pay a tax on both railroad and sleeping car tickets.

The Southern Railway and the Seaboard Air Line have agreed to use their own tracks in common between Raleigh, N. C., and Cary, 12 miles. Each road has a single track, and the new tracks will be operated as a double track railway. There are no stations between Raleigh and Cary, except flag stops and a passing track.

The Globe Express Company is going out of business about June 1; and will be succeeded on the Denver & Rio Grande by the Wells-Fargo and on the Western Pacific by the American Express Company. The American, which operates over the Union Pacific, will then have a continuous line from the Atlantic to the Pacific.

The Virginia Railway & Power Company, operating electric cars in Norfolk, Va., announces that it will reward each conductor and motorman who has gone through the last six months without an accident, with a new suit of clothes. The names of the employees of the company who are to receive this favor are printed in a local newspaper.

A conference on the proposed purchase by the state of California of the Western Pacific Railroad, now in receivership, was held last week in the office of Governor Johnson of California. After the meeting the governor said, "All there is to say is that we have been considering the matter and when our study is completed a statement will be made."

The carferry "Ontario No. 2," of the Grand Trunk Railway, was successfully launched at the yards of the Polson Iron and Shipbuilding Company last week. The vessel was designed by William Newman, is of steel and will cost $500,000. It is to run between Coburg, Ont., and Charlotte, N. Y. It is 318 ft. long, 54 ft. beam and 20.5 ft. molded depth. She has capacity for 30 loaded 70-ton cars. Her speed will be 17 miles an hour. The vessel is built as an ice breaker and is expected to make her way through ice 4 ft. thick.

Postmaster General Burleson has issued another notice, dated last Sunday, replying to some criticisms of the railways' mail committee. He says that on important through routes between New York and Chicago the government pays the carriers $903,359 for tonnage which if carried by express would net the railways only $452,352 a year. He says that Mr. Peters' comparison between express rates and mail rates, using as an illustration express shipments of one pound each, is not fair; and in particular that the small packages make up but a very small proportion of the merchandise carried by express.

To its slogan, "Safety First," the Pennsylvania Railroad has added "courtesy first," and is to have some lectures at Philadelphia on two days this week for the benefit of employees on the Philadelphia terminal division and for passenger trainmen of other divisions who run to and from Philadelphia. Among the employees who have been notified to attend the courtesy meetings are assistant station masters, clerks in ticket offices, ticket examiners, ushers, elevator attendants, checkmen, station patrolmen, telephone operators, cab starters, package, parcel and ladies' room attendants, station porters, and clerks and others in freight agents' offices. Similar lectures will be given at other terminals.

A special committee of the Michigan legislature appointed to investigate rumors that the railroads were spending money improperly to influence the passage of the 2½ cents a mile passenger fare bill, after several hearings has rendered a report, in which it says: "There has been no improper conduct on the part of the representatives of the railroads, and there exists no grounds upon which to base the slightest suspicion that any agent or representative of the railways has made corrupt use of money. There never existed any so-called slush fund or publicity fund of $300,000, or $100,000, for the purpose of putting the fare bill through the legislature, but there has existed a fund, designated as publicity fund, of about $15,000, which was expended honestly and legitimately."

Among the worst of the innumerable acts of wanton vandalism committed by the different warring factions in Mexico, the destruction wrought on the property of the National Railways in Monterey by the Carrancistas on the eve of their recent evacuation of the city probably caps the climax. When the near approach of the Villa forces made it apparent to the Carranza followers that they would have to abandon the town, it was decided to celebrate their coming departure with an orgy of anarchy. Locomotives were sent out to gather up all the box cars on the adjacent divisions of the railway and bring them to Monterey for the purpose of making a bonfire of them. These cars—more than 600 in number—were hauled into town and lined up on the extensive division terminal tracks. On the last night the Carrancista officers gave an elaborate ball in the handsome passenger station of the National Railways, which ended with a mock ceremony in which the torch was applied to the costly passenger station and to the 600 box cars. Within a few hours all of this valuable property was in ruins.

Street Car Disaster in Detroit

A press despatch from Detroit, Mich., reports 15 persons killed and 20 injured on the afternoon of April 14, in a collision between a Detroit City street car and a string of freight cars pushed by a switching engine on the Detroit, Toledo & Ironton. The street car was heavily loaded with passengers homeward bound from their day's work. As the car approached the railroad crossing it stopped and the conductor ran ahead to see if the track was clear. He signaled the motorman to wait, but apparently the latter, who is said to have been inexperienced, misunderstood his meaning. He applied the power and the car ran rapidly down an incline and on to the railroad tracks.

Alaska Railway Authorized

Secretary Lane of the Interior Department announced on Saturday that the President had adopted the Susitna route for the proposed railway to be built by the Government to the interior of Alaska, and that he had decided to buy the Alaska Northern, extending from Seward inland 71 miles, which will be a part of the Government line. This line will be extended from its northern terminus northward through the Susitna valley across Broad Pass and down the Tanana river to Fairbanks, a total distance of 471 miles from Seward. A branch will also be run from Matanuska Junction eastward into the Matanuska coal fields, 38 miles. The Alaska Northern was purchased for $1,150,000, while the estimated cost of the entire system is $26,800,000. Seward is at the head of Resurrection Bay, about 300 miles west of the boundary between Alaska and the Dominion of Canada. Secretary Lane announced that construction work would be begun at once and that probably 40 miles could be completed this year.

Railroad Legislation in Maine

Laws pertaining to the railroads in the state of Maine passed by the session of the state legislature, recently adjourned, provide for but few changes over previous legislation.

Several amendments were made to the Public Utilities law of 1913, viz., permitting railroads to carry, free, police officers, firemen in uniform, municipal fire apparatus, editors and regularly employed reporters of newspapers; giving the Public Utilities Commission full power to investigate all accidents resulting in death or personal injury, on the premises of all public utilities; and where the utility is a common carrier and an accident occurs, it is required that it shall transport all witnesses over its lines free of charge; free transportation for the members of the commission, their employees and agents is provided; the commission is required to provide for a chief inspector of utili-

ties, who shall be "a practical railroad man" and perform such duties as the commission may require, at a salary left to the discretion of the commissioners; and amendments giving the commission all authority formerly held by the state railroad commission.

Laws were passed authorizing railroads to give passes as usual to their employees, even if the employee holds a public office; requiring railroads to issue 500-mile books at the same rate as thousand-mile books; and providing for disposing of all inflammable material along the railroad rights-of-way. Under the last law, anyone cutting any forest growth on property adjacent to the right-of-way of a railroad must clear away and dispose of all slash and debris within 50 ft. of the right-of-way. The laws passed are subject to the referendum, and do not become operative until 90 days after the adjournment of the legislature.

Legislation Affecting Railways

The lower house of the Michigan legislature has passed the bill establishing a sliding scale of passenger fares for railroads in the state, ranging from 2 to 3 cents a mile, according to the earnings of the railroads. The vote was 24 to 6. The bill provides that roads earning less than $1,200 a mile may charge three cents.

Next Wednesday, April 21, will be "Railroad Day" at Springfield, Ill., arrangements having been made to give the railroads a hearing before the House and the Senate committees on public utilities on the bills pending before the legislature to increase passenger fares generally throughout the state to the basis of 2½ cents a mile. The roads are planning to send a large delegation of railroad officers, headed by President C. H. Markham of the Illinois Central. The presidents of all the principal roads have signified their intention of being present.

The executive committee of the Chicago Association of Commerce has adopted a resolution opposing the extra crew and train limit bills pending in the Illinois legislature. The association's committee on legislation had recommended the adoption of the resolution at a previous meeting. "We believe these bills raise questions of public concern," said Charles L. Dering, president of the association. "It is evident that any unnecessary burden placed on the carriers must ultimately be borne by the shippers, thereby increasing the cost of transportation which eventually reflects upon the consumer."

Railroad Men's Improvement Society

At the semi-monthly meeting of the Railroad Men's Improvement Society, held at 90 West street, New York, on April 8, a paper was presented by C. E. Hildum, auditor of freight accounts of the Erie, entitled: The Audit Office Settlement Idea The Railroad Men's Improvement Society is a railroad club having a membership of over 300 of the younger men from the general offices of several of the railroads centering in New York City. Meetings are held on the second and fourth Thursdays of each month, usually in the rooms of the Trunk Line Association at 143 Liberty street, New York, and at these meetings papers are presented on subjects of interest to railroad men.

MEETINGS AND CONVENTIONS

The following list gives the names of secretaries, dates of next or regular meetings, and places of meeting of those associations which will meet during the next three months. The full list of meetings and conventions is published only in the first issue of the Railway Age Gazette for each month.

Air Brake Association.—F. M. Nellis, 53 State St., Boston, Mass. Next convention, May 4-7, 1915, Hotel Sherman, Chicago.

American Association of Freight Agents.—R. O. Wells, Illinois Central, East St. Louis, Ill. Annual meeting, May 18-21, 1915, Richmond, Va.

American Railway Association.—W. F. Allen, 75 Church St., New York. Next session, May 19, 1915, New York.

American Railway Master Mechanics' Association.—J. W. Taylor, 1112 Karpen Bldg., Chicago. Annual meeting, June 9-11, 1915, Atlantic City, N. J.

American Society for Testing Materials.—Prof. E. Marburg, University of Pennsylvania, Philadelphia, Pa. Annual meeting, June 22-26, 1915, Hotel Traymore, Atlantic City, N. J.

American Society of Civil Engineers.—Chas. Warren Hunt, 220 W. 57th St., New York. Regular meetings, 1st and 3d Wednesday in month, except July and August, 220 W. 57th St., New York.

American Society of Mechanical Engineers.—Calvin W. Rice, 29 W. 39th St., New York. Next spring meeting, June 22-25, 1915, Buffalo, N. Y. Annual meeting, December 7-10, 1915, New York.

Association of American Railway Accounting Officers.—E. R. Woodson, 1300 Pennsylvania Ave., N. W., Washington, D. C. Annual convention, April 28, 1915, Piedmont Hotel, Atlanta, Ga.

Association of Railway Claim Agents.—C. W. Egan, B. & O., Baltimore, Md. Annual meeting, May 19, 1915, Galveston, Tex.

Association of Railway Electrical Engineers.—Jos. A. Andreucetti, C. & N. W., Room 411, C. & N. W. Sta., Chicago. Semi-annual meeting with Master Car Builders' and Master Mechanics' Associations. Annual meeting, October, 1915.

Association of Railway Telegraph Superintendents.—P. W. Drew, Soo Line, 112 West Adams St., Chicago. Annual meeting, June 22-25, 1915, Rochester, N. Y.

Association of Transportation and Car Accounting Officers.—G. P. Conrad, 75 Church St., New York. Next meeting, June 22-23, Niagara Falls, N. Y.

Canadian Railway Club.—James Powell, Grand Trunk, P. O. Box 7, St. Lambert (near Montreal), Que. Regular meetings, 2d Tuesday in month, except June, July and August, Windsor Hotel, Montreal, Que.

Car Foremen's Association of Chicago.—Aaron Kline, 841 Lawler Ave., Chicago. Regular meetings, 2d Monday in month, except June, July and August, Hotel La Salle, Chicago.

Central Railway Club.—H. D. Vought, 95 Liberty St., New York. Regular meetings, 2d Friday in January, May, September and November. Annual meeting, 2d Thursday in March, Hotel Statler, Buffalo, N. Y.

Engineers' Society of Western Pennsylvania.—Elmer K. Hiles, 2511 Oliver Bldg., Pittsburgh, Pa. Regular meetings, 1st and 3d Tuesday in month, Pittsburgh.

Freight Claim Association.—Warren P. Taylor, R. F. & P., Richmond, Va. Annual meeting, June 16, 1915, Chicago.

General Superintendents' Association of Chicago.—A. M. Hunter, 321 Grand Central Station, Chicago. Regular meetings, Wednesday, preceding 3d Thursday in month, Room 1856, Transportation Bldg., Chicago.

International Railway Fuel Association.—C. G. Hall, C. & E. I., 922 McCormick Bldg., Chicago. Annual meeting, May 17-20, 1915, Hotel La Salle, Chicago.

Master Boiler Makers' Association.—Harry D. Vought, 95 Liberty St., New York. Annual convention, May 25 to 28, 1915, Chicago, Ill.

Master Car Builders' Association.—J. W. Taylor, 1112 Karpen Bldg., Chicago. Annual meeting, June 14-16, 1915, Atlantic City, N. J.

New England Railroad Club.—W. E. Cade, Jr., 683 Atlantic Ave., Boston, Mass. Regular meetings, 2d Tuesday in month, except June, July, August and September, Boston.

New York Railroad Club.—Harry D. Vought, 95 Liberty St., New York. Regular meetings, 3d Friday in month, except June, July and August, 29 W. 39th St., New York.

Niagara Frontier Car Men's Association.—E. N. Frankenberger, 623 Brisbane Bldg., Buffalo, N. Y. Meetings, 3d Wednesday in month, New York Telephone Bldg., Buffalo, N. Y.

Peoria Association of Railroad Officers.—M. W. Rotchford, 410 Masonic Temple Bldg., Peoria, Ill. Regular meetings, 3d Thursday in month, Jefferson Hotel, Peoria.

Railroad Club of Kansas City.—Claude Manlove, 1008 Walnut St., Kansas City, Mo. Regular meetings, 3d Saturday in month, Kansas City.

Railroad Men's Improvement Society.—J. B. Curran, Erie R. R., 50 Church St., New York. Meetings, alternate Thursdays, October to May, Assembly Rooms of Trunk Line Association, 143 Liberty St., New York.

Railway Club of Pittsburgh.—J. B. Anderson, Room 207, P. R. R. Sta., Pittsburgh, Pa. Regular meetings, 4th Friday in month, except June, July and August, Monongahela House, Pittsburgh.

Railway Electrical Supply Manufacturers' Association.—J. Scribner, 1063 Monadnock Block, Chicago. Meetings with Association of Railway Electrical Engineers.

Railway Signal Association.—C. C. Rosenberg, Myers Bldg., Bethlehem, Pa. Stated meeting, May 26-27, 1915, Hotel Astor, New York. Annual meeting, September 14-17, 1915, Salt Lake City, Utah.

Railway Storekeepers' Association.—J. P. Murphy, N. Y. C. R. R., Box C, Collinwood, Ohio. Annual meeting, May 17-19, 1915, Hotel Sherman, Chicago.

Railway Supply Manufacturers' Association.—J. D. Conway, 2136 Oliver Bldg., Pittsburgh, Pa. Meetings with Master Car Builders' and Master Mechanics' Associations.

Railway Telegraph and Telephone Appliance Association.—G. A. Nelson, 50 Church St., New York. Meetings with Association of Railway Telegraph Superintendents.

Richmond Railroad Club.—F. O. Robinson, C. & O., Richmond, Va. Regular meetings, 2d Monday in month, except June, July and August.

St. Louis Railway Club.—B. W. Frauenthal, Union Station, St. Louis, Mo. Regular meetings, 2d Friday in month, except June, July and August, St. Louis.

Salt Lake Transportation Club.—R. E. Rowland, David Keith Bldg., Salt Lake City, Utah. Regular meetings, 1st Saturday of each month, Salt Lake City.

Southern & Southwestern Railway Club.—A. J. Merrill, Grant Bldg., Atlanta, Ga. Regular meetings, 3d Thursday, January, March, May, July, September, November, 10 a. m., Piedmont Hotel, Atlanta.

Toledo Transportation Club.—Harry S. Fox, Toledo, Ohio. Regular meetings, 1st Saturday in month, Boody House, Toledo.

Traffic Club of Chicago.—W. H. Wharton, La Salle Hotel, Chicago.

Traffic Club of New York.—C. A. Swope, 291 Broadway, New York. Regular meetings last Tuesday in month, except June, July and August, Hotel Astor, New York.

Traffic Club of Pittsburgh.—D. L. Wells, Gen. Agt., Erie R. R., 1924 Oliver Bldg., Pittsburgh, Pa. Meetings bi-monthly, Pittsburgh. Annual meeting, 2d Monday in June.

Traffic Club of St. Louis.—A. F. Versen, Mercantile Library Bldg., St. Louis, Mo. Annual meeting in November. Noonday meetings October to May.

Train Dispatchers' Association of America.—J. F. Mackie, 7122 Stewart Ave., Chicago. Annual meeting June 15, 1915, Minneapolis, Minn.

Transportation Club of Detroit.—W. R. Hurley, Superintendent's office, N. Y. C. R. R., Detroit, Mich. Meetings monthly, Normandie Hotel, Detroit.

Utah Society of Engineers.—Frank W. Moore, 1111 Newhouse Bldg., Salt Lake City, Utah. Regular meetings, 3d Friday in month, except July and August, Salt Lake City.

Western Canada Railway Club.—L. Kon, Immigration Agent, Grand Trunk Pacific, Winnipeg, Man. Regular meetings, 2d Monday, except June, July and August, Winnipeg.

Western Railway Club.—J. W. Taylor, 1112 Karpen Bldg., Chicago. Regular meetings, 3d Tuesday in month, except June, July and August, Karpen Bldg., Chicago.

Western Society of Engineers.—J. H. Warder, 1735 Monadnock Block, Chicago. Regular meetings, 1st Monday in month, except January, July and August, Chicago. Extra meetings, except in July and August, generally on other Monday evenings. Annual meeting, 1st Wednesday after 1st Thursday in January, Chicago.

REVENUES AND EXPENSES OF RAILWAYS

MONTH OF FEBRUARY, 1915

Name of road.	Average mileage operated during period.	Operating revenues			Operating expenses						Net operating revenue (or deficit).	Railway tax accruals.	Operating income (or loss).	Increase (or decr.) comp. with last year.
					Maintenance									
		Freight.	Passenger.	Total, inc. misc.	Way and structures.	Of equipment.	Traffic.	Transportation.	Miscellaneous.	General.	Total.

Traffic News

The Erie, in co-operation with Cornell and Alfred Universities is running a farmers' demonstration train in western New York.

The date for the appearance of Illinois railroad officers before the senate and house committees on public utilities in behalf of the 2½-cent passenger fare bill has been postponed until Wednesday, April 21.

The Central of Georgia has posted in its stations notices to farmers calling on them for information concerning any surplus oats or wheat which they may be likely to have at the end of the season, the agricultural department of the road being prepared to assist, where desired, in finding nearby markets for surplus grain.

A new passenger train from St. Louis to the Pacific coast, to be called the "Scenic Limited," was put into service on April 12, over the Missouri Pacific, the Denver & Rio Grande and the Western Pacific. The train will leave St. Louis at 2 p. m. daily, arriving at Kansas City at 9:30 p. m., Pueblo, Colo., at 2:15 p. m. the following day, Salt Lake City at 1:30 p. m. the third day, and San Francisco at 5:45 p. m. the fourth.

The New York State Public Service Commission, Second district, has received notice from the principal railroads that beginning May 1 party tickets for ten or more persons traveling together will cost about 2¼ cents a mile, or 2½ mills more than at present; that the minimum charge for a special train will be increased from $50 to $75 and the minimum charge for a special car will be increased from 25 fares to 40 fares.

The Baltimore & Ohio, with a view to encouraging the exportation of coal by showing the opportunities for extending this trade as a result of the European war, is circulating a pamphlet issued by the National City Bank of New York. The pamphlet shows the tremendous proportions of the coal industry as well as the destruction of commerce and financial loss which the countries at war have suffered through the interruption of their coal trade. Coal operators in the United States have an advantage as a result of the Panama Canal route. It seems certain that coal produced in the United States can be sold profitably at Cristobal coaling station at the Atlantic end of the canal at one dollar a ton less than the price charged at Port Said station of the Suez Canal. Over 500,000,000 tons of coal was produced in this country in 1913, which was about 40 per cent of the world's output. It is estimated that all of the coal produced in the United States to the present time is about one-half of 1 per cent of the total supply of the country, which is calculated to be more than three trillion, five hundred billion tons.

Missouri Business Men Ask Help for Railroads

A large delegation of members of commercial clubs and business men's organizations held a meeting at Moberly, Mo., on April 8, in response to an invitation sent out by the Moberly Commercial Club for a conference to devise some means to assist the railroads in bettering their financial condition. Nearly 150 representative business men attended the meeting. Thirty-five went from St. Louis in a special car and 20 from Trenton in a special car. Festus J. Wade, president of the Mercantile Trust Company of St. Louis, was one of the principal speakers, and short talks were made by others, all favoring a resolution requesting the Missouri Public Service Commission to grant the request of the railroads for an increase in state freight and passenger rates. A committee was appointed to prepare resolutions to be presented to the commission.

Car Surpluses and Shortages

The American Railway Association's Committee on Relations Between Railroads, Arthur Hale, chairman, has issued statistical statement No. 3 giving a summary of freight car surpluses and shortages for April 1, 1915, with comparisons.

The total surplus on April 1, 1915, was 313,421; on March 1, 1915, 322,290, and on April 1, 1914, 141,525.

The surplus for March 1, 1915, shown above, includes figures reported since the issue of statistical statement No. 2 (published in the *Railway Age Gazette* of March 12, page 486).

The total shortage on April 1, 1915, was 348; on March 1, 1915, 543, and on April 1, 1914, 2,013.

The figures by classes of cars follow:

Classes	Surplus	Shortage
Box	93,400	208
Flat	19,472	50
Coal and gondola	145,069	33
Other	55,480	57
Total	313,421	348

Passes in Texas

J. H. Hill, president of the General Managers' Association of Texas, in a statement relative to the suit against 41 Texas railroads filed by the attorney general of Texas, seeking to declare unconstitutional the exceptions or exemptions of the Texas anti-pass law, says that all passes issued by the roads since the enactment of the law on July 1, 1907, have been in accordance with opinions issued by the attorney general's department interpreting the exemption section, and that since the passage of the act there has never been a prosecution for the illegal issuance of a pass. The calculations of the attorney general as to the amount of revenue the roads have lost by issuing passes, he says, are entirely fanciful and based on the violent assumption that all persons who have traveled without paying fares would have traveled to the same extent and paid fare if they had not had passes. He says the common assumption that doing away with passes has increased the revenues of the roads is not proved by the figures.

For the year ended June 30, 1908, the year following the enactment of the law, with 500 more miles of railroad, the passenger revenue of the Texas lines increased only $23,671, while according to the attorney general's statement the free travel had decreased 26.5 per cent. For the six fiscal years ended June 30, 1913, Mr. Hill says, the total mileage traveled on passes in Texas was 752,571,281, of which 71 per cent represented travel by employees and members of their families over the roads on which they were employed, and 26 per cent by officers, agents and employees of other railroads, making 97 per cent of the total traveled by railroad employees and their families. A large part of this travel was by employees in the discharge of their duties, and the rest was represented by travel for pleasure, a large proportion of which would not have taken place without the passes. About 2 per cent of the total represented travel by public officials of the state of Texas, and about one-half per cent by officials of the United States, the remaining one-half per cent representing passes issued for charitable purposes, or for other purposes allowed by the law. Since 1907, he says, the general managers of the Texas railroads have supposed that this transportation was issued under the declared policy of the state of Texas, and if they have made a mistake it has been contributed to by the action of the attorney general's department.

Traffic Through Sault Ste. Marie Canals

Lieut. Col. Mason M. Patrick, of the U. S. Army, has issued the annual statistical report of lake commerce passing through the canals at Sault Ste. Marie, Michigan and Ontario, during the season of 1914. The total freight traffic of 55,369,934 short tons for the season of 1914, when compared with the season of 1913, shows a decrease of 31 per cent, or 24,348,410 tons, and the net registered tonnage of 41,986,339 shows a decrease of 28 per cent, or 16,003,376 tons. All the items of freight show a decrease when compared with the season of 1913, except salt and copper. The total number of passengers was 59,801, a decrease of 17,393. The passages through both canals numbered 18,717, showing a loss of 5,078, or 21 per cent. The total lockages numbered 13,502, a loss of 3,365, or 20 per cent.

The season of navigation continued for a period of 7 months and 28 days, during which time the average monthly freight traffic was 6,979,403 short tons, and 5,292,396 tons net register. The mean depth of water through the canals and locks limited the safe draft to about 19 feet until after the opening of the new third lock and canal.

The traffic through the American canal was 50 per cent of the total freight, 59 per cent of the total net registered tonnage

and 50 per cent of the total number of passengers carried, the amounts being 27,771,467 tons of freight, 24,690,381 tons register and 29,792 passengers. Compared with the season of 1913, there was a decrease of 9,250,734 tons of freight, or 25 per cent; 7,372,238 tons register, or 23 per cent; and 10,704 passengers, or 26 per cent. The American canal opened April 20 and closed December 17, 1914, making the length of its season 242 days.

The traffic through the Canadian canal was 50 per cent of the total freight, 41 per cent of the total registered tonnage and 50 per cent of the passengers carried, the amounts being 27,598,467 tons of freight, 17,295,958 tons register and 30,009 passengers. Compared with the season of 1913, there was a decrease of 15,097,676 tons of freight, or 35 per cent; 8,631,138 tons register, or 33 per cent; and 6,689 passengers, or 18 per cent. The Canadian canal was opened April 20 and closed December 14, 1914, making the length of its season 239 days.

The general summary for American and Canadian canals is as follows:

Total freight carried, tons	55,369,934
Total tons net register	41,986,339
Total mile-tons	46,112,251,781
Total valuation placed on freight carried	$634,800,268
Total amount paid for freight carried	$27,597,099
Total number of registered vessels using canals	813
Total number of passages by unregistered craft carrying freight	375
Total valuation placed on registered vessels	$134,631,700
Total number of passengers transported	59,801
Average distance freight was carried, miles	832.8
Average cost per ton for freight transportation	$0.50
Average cost per mile per ton, mills	.60
Average value per ton of freight carried	$11.46
Time American canal was operated, days	242
Time Canadian canal was operated, days	239
Freight carried by—	
Registered vessels, tons	55,285,213
Unregistered vessels, tons	84,721
American vessels, per cent	91
Canadian vessels, per cent	9
Passengers carried by—	
American vessels, per cent	48
Canadian vessels, per cent	52

American Association of Passenger Traffic Officers

The sixtieth annual convention of the American Association of Passenger Traffic Officers was held at San Francisco, Cal., beginning on Thursday of this week. The program includes reports from the executive committee and the various standing committees and special committees, including the committees on adjustments of disputes relative to division of passenger fares; printing of folders and other advertising matter, and economical distribution thereof; telegraph code applicable for use in passenger traffic departments; operation of and charges for dining cars; additional charge for checking baggage; revision of joint tariffs; improved method of making sleeping car reservations; additional fare for sleeping or parlor car passengers, and additional charge for passenger occupying section in sleeper; and reports from co-operating associations. Topics for discussion under the head of new and miscellaneous business included: expense of special train service for organized party business; operation of unnecessary sleeping cars on through trains; advance in passenger fares, those made and under contemplation with an exchange of views as to conditions and progress being made; economics in operation of city ticket offices and in passenger service; improved method of handling reports of territorial committees on subjects which have been referred to them by the American Association of Passenger Traffic Officers; and relations of passenger traffic officers with the Interstate Commerce Commission and with state, railroad and utility commissions. The annual address was presented by O. P. McCarty, passenger traffic manager of the Baltimore & Ohio.

A large party of members of the association and their families left Chicago on Sunday evening, April 11, in a special train, which was practically a duplicate of the Overland Limited, the route being over the Chicago & North Western, the Union Pacific and the Southern Pacific. The itinerary provided for spending several hours at Salt Lake City enroute, and after a stop of about four days at San Francisco, where in addition to attending the convention the party will visit the Panama-Pacific Exposition, the party will proceed by special train to Los Angeles, stopping at Del Monte, Paso Robles and San Bernardino. After spending four days in Los Angeles and vicinity, including a trip to the Panama-California Exposition at San Diego, the return trip will be made from Los Angeles over the Atchison, Topeka & Santa Fe, a stop of one day being made at the Grand Canyon, and the party will arrive at Chicago on April 29.

Commission and Court News

INTERSTATE COMMERCE COMMISSION

Rates on Coal to St. Paul and Minneapolis

Daly Coal Company et al. v. Chicago & Alton et al. Opinion by Commissioner Clements:

The commission finds that the rates, increased ten cents a ton on May 30, 1914, on bituminous coal from mines in Illinois and Indiana to St. Paul and Minneapolis, Minn., are not unreasonable. (33 I. C. C., 467.)

Minimum Weight on Calves

Irvin Kibbe v. Abilene & Southern et al. Opinion by Commissioner McChord:

The commission finds that the minimum carload weight of 22,000 lb. on calves from Greta and other Texas shipping points to points in Colorado, Kansas, Illinois and other states is discriminatory against such points of origin. A minimum of 17,000 lb. is prescribed for the future. (33 I. C. C., 415.)

Rates on Corrugated Galvanized Sheet Iron to Pacific Coast Points

California Corrugated Culvert Company v. Alabama Great Southern et al. Opinion by the commission:

It is found that a rate of 95 cents per 100 lb. on corrugated galvanized sheet iron in carloads from Middletown, Ohio, to Pacific coast points is reasonable, but that it is discriminatory in that it exceeds the rate of 85 cents between the same points on plain galvanized sheet iron. No reparation is awarded. (33 I. C. C., 445.)

Rates on Grain Between Points in Oklahoma and Kansas

Opinion by Commissioner Harlan:

The commission finds that the carriers have not justified a proposed cancellation of joint rates on grain and grain products moving from points on the line of the Chicago, Rock Island & Pacific in Nebraska and Kansas to points in Oklahoma on the St. Louis & San Francisco. Had the joint rates been cancelled rates equal to the sum of the intermediate rates would have applied which would have been from one-half cent to 13½ cents per 100 lb. higher than the rates at present in effect. (33 I. C. C., 452.)

Joint Fares with the Grand Rapids, Grand Haven & Muskegon

Howard P. Damon et al. v. Crosby Transportation Company et al. Opinion by Commissioner McChord:

The commission finds that the Crosby Transportation Company in selling through tickets via its boats and the line of the Detroit, Grand Haven & Milwaukee, between Milwaukee, Wis., and Grand Rapids, Mich., and refusing to sell through tickets between the same points via the line of the Grand Rapids, Grand Haven & Muskegon, discriminates against the latter. The Detroit, Grand Haven & Milwaukee is a subsidiary company of the Grand Trunk, and the Grand Rapids, Grand Haven & Muskegon is an electric line which parallels it. (33 I. C. C., 448.)

Railroad Ownership of The Dalles, Portland & Astoria Navigation Company

In re Spokane, Portland & Seattle's ownership of the Dalles, Portland & Astoria Navigation Company. Opinion by Commissioner Clark:

The Spokane, Portland & Seattle operates a line from Portland, Ore., to Spokane, Wash. From Portland to Pasco, Wash., it follows the north bank of the Columbia river, and for substantially the same distance is paralleled by the main line of the Oregon-Washington, which follows the south bank. The railway is the sole owner of the stock of The Dalles, Portland & Astoria Navigation Company, which owns and operates two

steamboats on the Willamette and Columbia rivers between Portland and Dalles, Ore., a distance of approximately 95 miles. The route from Portland is down the Willamette river, 12 miles to its mouth, and thence up the Columbia river, paralleling the rail line of the petitioner.

The commission finds that the navigation company does and may compete with the rail line within the meaning of section 5 of the Panama Canal Act.

It was shown that attempts had been made at different times to operate independent boats between Portland and The Dalles, but that with the exception of a single boat, now in operation, all had failed. It was admitted that so long as the boats of the navigation company were operated, it would be impossible for another boat line to exist on this route. What is known as the lower Columbia river is navigable only from Portland to Celilo, Ore., a point 11 miles above The Dalles. The Celilo canal, which is being constructed by the United States government, will, however, permit boats to pass from the lower to the upper river, and will allow navigation even up to Pasco. An attempt had already been made by an independent company to operate boats above Celilo in connection with boats below, but this attempt also had failed. The commission believes that it is clear from the record that through water transportation cannot be established or maintained between the upper and lower rivers so long as the Spokane, Portland & Seattle owns or controls the navigation company. It was shown that new capital could not be secured to establish and operate a boat line in competition with a railroad-owned boat line, and that a through line could not profitably operate unless it could secure a certain amount of the traffic in the lower river, particularly the passenger traffic.

The commission holds that the continued ownership by the petitioner of The Dalles, Portland & Astoria Navigation Company would not be in the interest of the public and of advantage to the convenience and commerce of the people, and that it would exclude, prevent or reduce competition on the water route here considered. The railway will not be allowed to continue its ownership of the navigation company after June 1, 1915. (33 I. C. C., 462.)

Carriers Should Waive Demurrage at Galveston

E. E. Clark, of the Interstate Commerce Commission, has rendered an opinion on the controversy between the railroads and shippers regarding the assessment of demurrage at Galveston on grain for export, which grew out of the accumulation of demurrage charges on account of the difficulty of obtaining boats last summer. A conference of the parties was held before the commission at Washington on March 25. The carriers reaching Galveston last summer established tariffs providing for the collection of demurrage at Galveston on grain for export. On the breaking out of the war the exporters were disappointed in getting ships to take the grain from Galveston, and the embarrassment was further accentuated by the burning of a large elevator at Galveston in November. A considerable congestion of export grain ensued, accompanied by the accrual of a very large amount of demurrage. The Galveston commercial interests had insisted that it is unjustly discriminatory against the port of Galveston for the carriers to assess demurrage on export grain at that port, so long as similar assessment was not provided for at the port of New Orleans. Mr. Clark said that under the circumstances the tariff should be cancelled, the earlier the better, and the commission will permit such cancellation on one day's notice. He also expresses the opinion that under the circumstances it would be just and proper to relieve the shippers and exporters from the obligation to pay the demurrage accrued and accruing on this export grain, but that this should be done in a lawful and proper manner, that the carriers should present to the commission formal request for authority to waive the collection of these demurrage charges upon the ground that in normal times the carrier would not deem it proper to assess such demurrage at Galveston while none is assessed at New Orleans, and because of the difficulties created by the war. "I do not deem it at all necessary," he said, "that the carriers should admit that the principle of demurrage on export grain is wrong or a mistaken one. The request should be considered in the light of unusual and unprecedented circumstances."

STATE COMMISSIONS

The Texas Railroad Commission on May 3 will resume its hearings on the application of the railroads in the state for 15 per cent advance in freight rates.

The Arkansas Railroad Commission last week refused to accept and file the tariffs received from the St. Louis & San Francisco, putting into effect three-cent passenger rates on that road in Arkansas, following the decision of Judge Trieber of the United States district court holding the two-cent fare law confiscatory. The commission announced that it would appeal from the decision to the United States Supreme Court, and that pending the appeal the three-cents-a-mile tariff would not be accepted.

A hearing on the application of the Kansas railroads for increases in their freight and passenger fares was begun before the Kansas Public Utilities Commission last week. The first witness was James Peabody, statistician for the Atchison, Topeka & Santa Fe. He presented statistical exhibits making a division of expenses between freight and passenger service and line and terminal expenses to show that the railroads are losing money on passenger service. He also showed that the handling of traffic on local trains was more expensive than on through trains. W. J. Black, passenger traffic manager for the Atchison, Topeka & Santa Fe, also testified.

The New York Public Service Commission, second district, holds that a paper package need not be received as baggage, no matter how well it may be disguised with a cardboard suitbox inside the paper, and straps and cords and handles outside. The complainant in the case was a woman, Sara W. Lyons, and the New York Central was the road which refused to check her package. In its order the commission tells of the necessarily rough handling that baggage must be subjected to. Not knowing the contents of paper packages, the railroad contended that its baggagemen would have to handle such material much more slowly and carefully than that in leather or other stronger containers. The commission recognizes the right of the railroad to require that baggage be enclosed in substantial containers. Adequate protection is not afforded by the paper-wrapped cardboard box.

PERSONNEL OF COMMISSIONS

Joseph L. Bristow, formerly United States senator from Kansas, has been appointed chairman of the Kansas Public Utilities Commission, succeeding C. F. Foley. Mr. Bristow was born in Wolfe county, Kentucky, on July 22, 1861. He was clerk of the district court of Douglas county, Kansas, from 1886 to 1890, and for the next five years was owner and editor of the Salina (Kansas) Daily Republican, from 1895 to 1905 of the Ottawa (Kansas) Herald, and since 1903 he has been owner and editor of the Salina Daily Republican Journal. He was private secretary to Governor Morrill of Kansas from 1895 to 1897, fourth assistant postmaster general from 1897 to 1905, and secretary of the Republican state committee from 1894 to 1898. In 1900 he had charge of the investigation of Cuban postal frauds and the reorganization of the Cuban postal service, and in 1903 he conducted the postal investigation under the Roosevelt administration. In 1905 he was special commissioner of the Panama Railroad, and in 1909 he was elected United States senator from Kansas, serving one term, which expired this year.

J. L. Bristow

COURT NEWS

In the United States district court at Cairo, Ill., on April 6, the Mobile & Ohio was fined $900 for violation of the federal quarantine restricting the transportation of cattle.

The Supreme Court of the United States, in a decision handed down this week, has annulled as arbitrary and unconstitutional the statute of Wisconsin, adopted in 1911, providing that if four or more passenger trains are run each way daily (except Sundays) by a railroad, at least two of them shall be stopped at every postoffice village having 200 inhabitants.

The Supreme Court of Illinois has granted a motion of the Illinois Public Utilities Commission for permission to file a petition for mandamus to compel the Chicago & North Western to comply with an order of the old railroad and warehouse commission. The question involved is whether the orders of the old commission can be made effective by the public utilities commission which succeeded it.

The United States District Court at Huntsville, Ala., has dismissed 34 suits against the Louisville & Nashville for damages based on the charge of neglect in the transportation of cotton at the time of the notorious Knight-Yancey bill-of-lading frauds several years ago. These suits were brought by cotton brokers in England, Germany, France and Italy. A suit against the road brought by the National Park Bank of New York City is still pending in the court of Morgan county, Ala.

Reconsignment Charge—Shipper Must Prove Damage

The Circuit Court of Appeals for the Second Circuit holds that though a carrier was guilty of discrimination in making a reconsignment charge of $2 at a point where the plaintiff reconsigned hay, while it permitted reconsignment free at another point, this did not necessarily entitle the plaintiff to recover $2 per car as damages, in the absence of proof that he in fact suffered the loss. It was not enough to show that various items of $2 had been paid; for aught that appeared the money may have come out of the ultimate buyers. Without affirmative proof to show damages, the hay company was not entitled to a verdict. (Lehigh Valley v. American Hay Co., C. C. A., 219 Fed., 539.)

Twenty-Eight Hour Law—Separate Offenses

Ten separate actions brought by the government against the Oregon Short Line, for violations of the 28-hour law, turned upon the two following questions: (1) If a carrier confines animals in a car for more than the time named in the statute (28 or 36 hours, as the case may be), and thereupon puts them into pens of inadequate size and insufficiently equipped for feeding and watering, is it guilty of two offenses? and (2), if the carrier consolidates into the same train consignments loaded at different times, and thereafter, before the expiration of the period of 28 hours, unloads the entire train into pens of insufficient capacity and without proper facilities for feeding and watering, does it commit more than one offense?

The Federal District Court of Idaho, S. D., considered that both questions might be referred to one controlling consideration, whether the mere unloading of stock into inadequate pens, of itself, constitutes an offense. The act of Congress does not prescribe at what points stock pens shall be maintained, or how they shall be equipped. The carrier may fully comply with its terms without any pens at all. The offense consists in confining the stock beyond the period of 28 hours without feeding, etc. The confinement does not constitute an offense until it passes the prescribed limit. The holding of stock in unfit pens is equivalent to holding them in cars which are deficient in similar particulars. The court held that in unloading stock into improperly equipped pens, after they have been confined in transit without food and water for more than 28 hours, the carrier only continues and aggravates the offense; it does not commit a new one. In effect, the confinement in the cars is deemed to continue until the stock are unloaded into suitable pens and there fed, watered and rested. But where consignments, unloaded simultaneously, were received by the carrier at different hours, the unlawful confinement of each consignment constituted a separate offense. (United States v. O. S. L., 218 Fed., 868.)

Railway Officers

Operating

P. F. McManus, superintendent of the Joliet division of the Elgin, Joliet & Eastern, has been appointed general superintendent, with headquarters at Joliet, Ill., and his former office has been abolished.

D. S. Brigham has been appointed trainmaster of the Boston & Albany, with office at Beacon Park, Mass., vice Sheridan Bisbee, promoted to fuel supervisor in charge of all matters pertaining to the use of fuel, with headquarters at Boston.

Traffic

F. L. Word, having been assigned to other duties, the office of live stock freight agent at Atlanta, Ga., has been abolished on the Southern Railway, the Virginia & Southwestern, the Georgia Southern & Florida, the Hawkinsville & Florida Southern and the Macon & Birmingham.

T. B. Montgomery, general agent of the Chicago, Milwaukee & St. Paul, at Pittsburgh, Pa., has been appointed assistant general freight agent, with headquarters at Minneapolis, Minn., succeeding F. E. Otis, deceased, and E. H. Spence succeeds Mr. Montgomery as general agent at Pittsburgh.

W. H. Tayloe has been appointed passenger traffic manager of the Southern Railway, the Virginia & Southwestern and the Northern Alabama, with office at Washington, D. C., vice S. H. Hardwick, who has resigned the office of passenger traffic manager, on account of ill health, and has been appointed general agent, passenger department, with office at Montgomery, Ala.

Gerrit Fort, whose appointment as passenger traffic manager of the Union Pacific System, including the Oregon Short Line and the Oregon-Washington Railroad & Navigation Company, with headquarters at Chicago, has already been announced in these columns, was born November 12, 1865, at Cedar Rapids, Iowa. He began railway work in the fall of 1884 as clerk to the superintendent of the Burlington, Cedar Rapids & Northern at Cedar Rapids. From January, 1887, to September, 1889, he was clerk to the auditor of the Wabash at Chicago under the receivership; was then for two years assistant rate clerk in the general passenger department of the New York Central & Hudson River at New York, and from September, 1891, to January, 1897, was chief clerk of that department. He left the New York Central to become secretary of the Central Passenger Association at Chicago, resigning in September, 1900, to go to the Union Pacific as assistant general passenger agent. Mr. Fort returned to the New York Central Lines in June, 1907, as assistant to the vice-president, and in February, 1910, he was made general passenger agent of the lines east of Buffalo. In July of that year he again entered the service of the Union Pacific as passenger traffic manager, with office at Omaha, Neb. His jurisdiction was extended over the Oregon Short Line in December, 1910, and on April 1 he was appointed also passenger traffic manager of the Oregon-Washington Railroad & Navigation Company, and his headquarters removed to Chicago, as above noted.

Gerrit Fort

F. R. Perry, general agent of the passenger department of

the Canadian Pacific at Boston, Mass., has been transferred in the same capacity to New York, succeeding W. H. Snell, promoted, and E. F. L. Sturdee, assistant district passenger agent at Toronto, Ont., succeeds Mr. Perry.

J. L. Burnham, division freight agent of the Northern Pacific at St. Paul, Minn., has been appointed assistant general freight agent; L. R. Capron has been appointed assistant general freight agent, and W. A. Cleland has been appointed division freight agent; all with headquarters at St. Paul. J. C. McCutchen has been appointed general agent of the freight department at Milwaukee, Wis., vice C. T. Noonan, deceased.

Engineering and Rolling Stock

J. M. Kerwin has been appointed general foreman, locomotive department, of the Rock Island Lines, at Cedar Rapids, Iowa, in place of M. B. McPartland, transferred.

V. E. Hunter has been appointed general foreman of the Texas Midland, with headquarters at Terrell, Texas, succeeding A. C. Miller, whose title was master mechanic.

George A. Butler has been appointed acting assistant engineer of the Belleville division of the Grand Trunk, with headquarters at Belleville, Ont., vice C. S. Ogilvie, who has enlisted for active service abroad.

Purchasing

Major Charles E. Dole, assistant purchasing officer of the Panama Isthmian Canal Commission, has been appointed purchasing officer of the Alaskan Engineering Commission, with headquarters in the Alaskan building, Seattle, Wash. This is the board that will build the government railroad in Alaska.

Edward J. Roth, whose appointment as purchasing agent of the Chicago, Indianapolis & Louisville, with headquarters at Chicago, has already been announced in these columns, was born on March 4, 1882, at Rochester, Minn. He began railway work with the Chicago, Burlington & Quincy, in 1902, and was employed in the store department of that road until April, 1914, at that time holding the office of assistant general storekeeper. He then went to the Chicago, Indianapolis & Louisville, as supply agent, which position he held until his recent promotion to purchasing agent, as noted above.

OBITUARY

Henry L. Millis, manager of the Western Livestock Express, Chicago, died at his home in Chicago on April 2.

James McGee, master mechanic of the Lorain, Ashland & Southern, with headquarters at Ashland, Ohio, died at his home in Lorain on April 6, aged 56 years.

M. C. Roach, superintendent of the New York division of the Lehigh Valley, with headquarters at Jersey City, N. J., died on April 12, at his home in Passaic, N. J., at the age of 46.

David James Mackey, formerly from 1881 to December, 1892, president of the Evansville & Terre Haute, died on April 9 at Evansville, Ind., aged 82 years. Mr. Mackey was president also of the Louisville, Evansville & St. Louis from April, 1889, to 1894.

Henry W. Poor, president of Poor's Railroad Manual Company, died at his home in New York City, April 13, at the age of 71. He was a director of the Missouri, Kansas & Texas; and, as a banker, had other important railroad interests; but he is best known to readers of the *Railway Age Gazette* by his connection with Poor's Manual of Railroads, a name which has been a household word in railroad offices for nearly half a century. He was born in Bangor, Me., his father being Henry V. Poor, who was editor of the American Railroad Journal (now the Mechanical Edition of the *Railway Age Gazette*), from which he retired in 1863. Henry W. Poor was graduated from Harvard College in 1865, and in 1868 became a partner with his father in the banking firm of H. V. & H. W. Poor; and in that year the first number of the Manual was issued. This annual publication, still an essential part of the equipment of the railroad officer's library, was, until the establishment of the statistical office of the Interstate Commerce Commission, in 1887, of still more importance than now; for it was the only source of detailed information concerning the financial affairs and history of the railroads of the United States.

Equipment and Supplies

LOCOMOTIVE BUILDING

The Pennsylvania Equipment Company, Philadelphia, Pa., is in the market for one second hand 45-ton six-wheel switching locomotive and one second hand 70-ton Consolidation type locomotive.

CAR BUILDING

The Virginian Railway is in the market for 500 underframes.

The Wilkesbarre & Hazleton is in the market for 10 coaches.

The New York Municipal is asking for bids on 100 more steel subway cars.

The Pennsylvania Lines West are inquiring for 150 underframes for cabooses.

The Western Maryland is contemplating the purchase of a number of passenger cars.

The Chicago & North Western is reported to be in the market for 2,500 freight cars and 50 passenger cars.

The Ponca Refining Company, has ordered 100 tank cars from the American Car & Foundry Company.

The New York, Westchester & Boston has ordered 15 multiple unit passenger coaches from the Pressed Steel Car Company.

IRON AND STEEL

The Southern has ordered 3,700 tons of steel rails from the Tennessee Coal, Iron & Railroad Company.

The Government Railways of the Union of South Africa have ordered 30,000 tons of steel rails from the Dominion Iron & Steel Company.

The Pittsburgh, Cincinnati, Chicago & St. Louis has ordered 767 tons of steel for a bridge over its tracks at West Lake street, Chicago, from the Chicago Bridge & Iron Company.

Coal Car Shortage in New South Wales.—Colliery managers in the neighborhood of Sydney are complaining of damage to trade caused by a shortage of railway cars. Only a short while ago some of the pits were idle, although orders were plentiful. One colliery was operated but 14 hours in two weeks.

Irish Railways' War Bonus.—Trouble has arisen over the claim that Irish railwaymen of the wages staff should receive the same war bonus as has already been granted by arrangement with the government on English and Scottish railways. That arrangement includes adult wage-earning employees in the grades embraced in the conciliation scheme, a bonus of 3s. (75 cents) a week being granted where the wages are under 30s. ($7.50) a week, and of 2s. (50 cents) a week where the wages are 30s. and over. The position of the railways in Ireland is peculiar as they are neither parties to the conciliation scheme, nor under government control. In answer to appeals from their employees for some concession to meet the increased cost of living, individual companies voluntarily gave assistance some weeks back. The Great Northern, Midland (Northern Counties Committee), and Belfast & County Down have sanctioned allowances varying from 2s. to 1s. a week to all permanent adult members of their staffs, while the Great Southern & Western allowances are 1s. 6d. and 1s., and the Dublin & South-Eastern is allowing 1s. a week in many cases. The difficulty in which the Irish companies are placed is that they have no government subsidy, and their circumstances vary so much that they cannot be treated as a unit for the purpose of fixing a uniform bonus.

Supply Trade News

Merrill G. Baker has been appointed assistant general manager of sales of the American Vanadium Company.

A. Munch, who has been factory manager of the Maywood, Ill., plant of the Hewitt Company, Chicago, has been appointed to the new position of service engineer for the same company.

The Chicago Pneumatic Tool Company, Chicago, has moved its New York office from 50 Church street to 52 Vanderbilt avenue, and its Boston office from 191 High street to 185 Pleasant street.

Edwin S. Jarrett, formerly vice-president of the Foundation Company, New York, and Ralph H. Chambers, formerly chief engineer and general manager of the same company, have formed the Jarrett-Chambers Company, Inc., contractors, with offices at 30 East Forty-second street, New York.

Announcement was made in this column last week that the annual meeting of the former employees of the New York Central Signal department would be held at the Hotel Astor in New York on May 26. It is now announced that this date has been changed to May 27.

Charles R. McCormick & Co., manufacturers and cargo shippers of creosoted lumber, ties and piling, with main office at San Francisco, Cal., and mills, creosoting plant and ship yards at St. Helens, Oregon, have opened an office at 17 Battery place, New York, with C. E. Bland as New York manager.

The Reliance Equipment Company, Inc., Mobile, Ala., has been incorporated in that city, and has opened offices at 112 N. Water street. The company will solicit railway business in Alabama, Mississippi, Florida and Louisiana, and will specialize in rails, track tools, equipment, waste and general supplies for railway machine shops. The president of the company is James H. Zelnicker, and the vice-president and secretary, William J. Zimmern.

Judge George H. Bingham in the United States Court for the district of Massachusetts at Boston, handed down a decision on March 13, 1915, sustaining the validity of patent No. 741,385, owned by the Terry Steam Turbine Company, Hartford, Conn., which has been involved in the suit entered about two and one-half years ago by it against the B. F. Sturtevant Company, Hyde Park, Mass. The suit alleged that the B. F. Sturtevant Company was building a steam turbine which infringed this Terry patent.

The Canadian Car & Foundry Company is reported to be working on an order for shrapnel and other ammunition for Russia said to amount to $80,000,000, of which $20,000,000 has already been advanced. A part of this business has been let to American companies. The Westinghouse Electric & Manufacturing Company and the American Rolling Mill Company, Middletown, Ohio, are also reported working on orders for shrapnel. The Westinghouse Air Brake Company is reported to have received an order for 1,000,000 shrapnel, valued at $20,000,000 from France.

The receivers of the United States Light & Heating Company, Niagara Falls, N. Y., announced to Judge Hazel of the United States District Court of the Western District of New York in Buffalo on March 30 that a complete reorganization of the company was now assured through the efforts of the stockholders protective committee which represents a controlling share of the preferred and common stock. The proposed reorganization plan was given in this column last week. The receivers have made application advising Judge Hazel to wind up the receivership and transfer the business and the property to the reorganized company. It is understood that necessary notification to the stockholders and others will take some time and that the receivership will probably not be discontinued before some time in June. The plant at Niagara Falls has been doing a larger volume of business during the last two months than for a year past and orders booked for future deliveries are considered very satisfactory. The receivers of the company are James A. Roberts, of New York; James O. Moore, of Buffalo, N. Y., and J. Allan Smith, of Niagara Falls, N. Y.

J. W. Cowper and F. D. Huntington announce the incorporation of the John W. Cowper Company, Inc., engineers and contractors, with office in the Fidelity building, Buffalo, N. Y. It is the purpose of the company to execute complete contracts in building construction. Mr. Cowper was for a number of years engineer of maintenance of way on the Cleveland, Cincinnati, Chicago & St. Louis. From 1900 to 1904 he was with James Stewart & Co. as superintendent of construction on the British Westinghouse plant at Manchester, England, and other structures in Great Britain, including the Savoy hotel in London and the Midland hotel in Manchester. He was then with the same firm for several years in this country, and for the last six years has been vice-president of Worden-Allen & Company, Milwaukee, Wis., and the Lackawanna Bridge Company, from which positions he resigned on April 1. Mr. Huntington, the other member of the company, graduated from Cornell with the class of 1900. He was originally with Westinghouse-Church-Kerr & Company. He also was connected with James Stewart & Co., in England and this country, and later was general superintendent and manager of the Warring, White Company, London. For a time he was in charge of building construction on the Brazil Railway at Rio de Janeiro, this latter engagement lasting until the beginning of the war last fall.

Edward N. Hagar, of Chicago, formerly president of the Universal Portland Cement Company, who resigned from that corporation about two months ago for the purpose of organizing a new cement combination, has recently said with reference to the proposed company that, "The company will be capitalized not in excess of $25,000,000, with a possible minimum of $20,000,000. The stock will be all of one class. There will be no bonded indebtedness. Should the company require additional working capital or money for plant extensions in the future, that will be provided out of earnings. The object of the company is to establish a chain of plants over the country. These plants will be obtained by purchase where practicable, or by building where necessary. For years the cement industry has been hampered as a result of freight rates. Manufacturers have been unable to handle business, successfully in territory beyond a radius of 150 or 200 miles from their plants. The present plan involves what may be termed a 'coast-to-coast' cement company, with plants located at advantageous points throughout the country. The entire country will be divided into territories which may be described within circles, each circle touching the adjacent circles, with a plant as near to the center of the circle as possible. In this way the company will be enabled to overcome the hampering cost of freights for long distances and will be enabled by reason of the magnitude of the output, to compete successfully with any other producer of cement."

TRADE PUBLICATIONS

Electric Railway, Light and Power Materials.—The Drew Electric & Manufacturing Company, Indianapolis, Ind., has recently issued catalog No. 3, a 208-page book devoted to illustrations and descriptions of electrical fixtures and construction materials. The book also gives the prices of the various apparatus.

Boiler Makers' Tools.—A 40-page catalog has recently been issued by the J. Faessler Manufacturing Co., Moberly, Mo., which is devoted to the general line of boiler makers' tools manufactured by this company together with special flue cutting and countersinking tools. The catalog is well illustrated and contains price lists as well as information concerning the operation of the various tools.

Forging Hammers.—Catalog No. 66 of the Chambersburg Engineering Co., which has just been issued, is devoted to a representative line of the different types of steam hammers manufactured by this company. This is a 64-page, 8½-in. by 11-in. catalog in which the features of Chambersburg hammers are described in some detail. It contains a complete index of machinery built by this company, including equipment not shown in this catalog as well as the line of hammers which the catalog covers. It is exceptionally well illustrated.

Railway Construction

Canadian Pacific.—On the Kettle Valley Lines, which is building extensions in British Columbia, the section from Midway, B. C., via Penticton and Princeton, to a junction with the Nicola sub-division of the Canadian Pacific at Merritt, 272 miles, and with the main line at Spences Bridge, 312 miles, is expected to be open for passenger traffic in June; the section from Mons Junction southwest to Hope will not be completed until 1916. The opening of the Kettle Valley Lines will give the Canadian Pacific another alternative route to and from the Pacific coast, by way of the Crowsnest Pass, Kootenay Landing, Nelson, Midway, Penticton, Princeton and Spences Bridge, and the distance between Winnipeg, Man., and Vancouver, B. C., via this new route will be 1,811 miles, as compared with 1,484 miles via the main line through Calgary and Banff, and 1,657 miles via Dunmore Junction, Crowsnest, Kootenay Landing, West Robson and Revelstoke.

Chester & Lancaster (Electric).—Residents of Joanna, Pa., are said to be back of a project to build a high speed electric railway from Blue Ball, Pa., east via Churchtown and Elverson to Phoenixville, about 35 miles. Jacob Hartz, Blue Ball, is said to be interested.

Erie & Southwestern (Electric).—Organized in Pennsylvania, it is said, by residents of Erie, Pa., to build an electric line from Erie, southwest via Weis Library, Sterretania, Platea, Cranesville, Albion, Springboro, Conneautville and Exposition Park to Conneaut Lake, about 40 miles. Surveys for the line have been made. H. C. Allen, Erie, may be addressed.

Furman & Yemassee.—Incorporated in South Carolina with $10,000 capital and headquarters at Furman, S. C. The plans call for building from Furman, on the Southern Railway, east via Grays to Yemassee on the Atlantic Coast Line and the Charleston & Western Carolina, about 22 miles. J. H. Adams, W. P. Ellis and H. Weindal are said to be interested.

Kettle Valley Lines.—See Canadian Pacific.

Long Island.—The report of this company for the year ended December 31, 1914, shows that work was continued on the tunnel section at East New York of the Bay Ridge improvement, and it is expected that all the work will be completed during 1915, except the yard, float bridges, etc., at Bay Ridge, which are to be finished before the New York Connecting Railroad is completed, and connection made with that railroad at Fresh Pond junction. The New York Connecting will be completed by the end of 1916. Very little construction work was carried out on the Jamaica improvement during the year, and there yet remains work to finish this improvement, consisting of completing tunnels under tracks, passenger storage tracks and freight tracks; also, street paving, sewers, etc. The North Side division improvement, including the elimination of grade crossings, laying of second track and the electrification of lines, has been completed. It is planned to complete work on the Woodside-Winfield cut-off in 1915. This will eliminate a number of grade crossings, besides improving the alinement by cutting out 150 degrees of curvature. Some progress was made in the elimination of grade crossings at Bushwick Junction and a settlement as to the grade line through Hollis and Queens was agreed upon with the authorities. This work and the elimination of crossings through Richmond Hill will be started the latter part of 1915, if financial conditions permit. A new passenger platform and shelter was built at Hunters Point avenue, on the tracks leading to Long Island City, and new stations were built and put in operation during the year at Murray Hill, at Holtsville and at Dunton.

Louisiana Roads (Electric).—A company is being organized in Louisiana, it is said, to build an interurban line from Rayville, La., to a point 22 miles south. T. J. Coenen, president, Progressive League, Rayville, is said to be interested.

New York Subways.—The New York Public Service Commission, First district, opened bids on April 9 for the construction of Section No. 4 of Routes Nos. 4 and 36, which includes the part of the Broadway subway in the borough of Manhattan in Seventh avenue between Fifty-first and Fifty-ninth streets. The lowest bidder was the Litchfield Construction Company, Brooklyn, N. Y., who offered to do the work for $1,937,509.

Oneida & Western.—This company, which started work about two years ago on a line from Oneida, Tenn., northwest, has eight miles of track laid and open for freight service. The route as projected for the first 15 miles is along Pine creek to its affluence with the Big South fork of the Cumberland river nine miles, thence along that river for 2.5 miles, and then up White Oak creek. The work is heavy, involving the handling of between 15,000 and 20,000 cu. yd. to the mile, and about 80 per cent is solid rock work. The maximum grade will be 2 per cent and the maximum curvature 20 deg. There will be six steel bridges on the line aggregating 595.5 ft.

Virginian Railway.—Surveys have been made to build a 6-mile line from Stone Coal Junction, W. Va., to mines on Stone Coal creek, but the company is not yet ready to carry out the construction work.

Bids were asked for recently by the Virginian Railway for the construction of the Devils Fork branch from mile post 7.5 on the Winding Gulf branch, and extending about 1.16 miles up Devils Fork in West Virginia. The company expects to let contracts for this work about April 16.

RAILWAY STRUCTURES

Chicago, Ill.—The Pittsburgh, Cincinnati, Chicago & St. Louis has awarded a contract for the steel for a bridge over its tracks at West Lake street, to the Chicago Bridge & Iron Company.

Columbia Cross Roads, Pa.—The Pennsylvania Railroad is now having repairs made to three small bridges on the Elmira division, and is also installing new superstructures. One of the bridges is near Columbia Cross Roads and the other two bridges are in Lycoming county.

Philadelphia, Pa.—The following bridges have been authorized by ordinance, to be built in Philadelphia, and bids for the work will be asked for in the near future. At Fifth street over four tracks of the North Pennsylvania Railroad, to be 70 ft. wide and cost about $70,000; at Diamond street over six tracks on the Connecting Railway, to be 60 ft. wide and cost $75,000; at Cambria and "A" streets over 13 tracks of the Richmond branch of the Philadelphia & Reading, to be 52 ft. wide and cost $62,000, all are to be skew bridges with steel floors, and concrete substructures and encasements. At Fifty-eighth street a 60 ft. reinforced concrete arch, 30 ft. wide to cost $18,000 is to be built over the Baltimore Central, and at Whitby avenue a bridge 80 ft. wide with steel floor and concrete substructure and encasement to cost $42,000 will be built over four tracks of the Baltimore Central. There will also be constructed at Third street, under two tracks of the Philadelphia & Newtown Connecting Railroad a steel superstructure to be 50 ft. wide, with concrete abutments to cost $32,000, and at Fisher avenue under two tracks of the North Pennsylvania Railroad, a steel superstructure with concrete abutments to cost $32,000.

Pittsburg, Pa.—The Baltimore & Ohio has decided to eliminate the Liberty avenue grade crossing in Pittsburgh at a cost of $750,000. Bids for carrying out the work will probably be asked for in the near future.

Spartanburg, S. C.—Contracts have been given by the Southern Railway to M. M. Elkan, Macon, Ga., and R. B. Tufts, Norfolk, Va., to construct a passenger subway under the tracks at the Spartanburg station. The subway will be 30 ft. wide, and will extend 110 ft. from the outside of the station building. It is expected that the work will be completed in six months.

Stonington, Conn.—The New York, New Haven & Hartford and the town of Stonington will jointly build a pony truss span over the tracks of the N. Y. N. H. & H., with deck I beam approach span at a point 1.5 miles west of Stonington on the Providence division. The bridge is to be of steel construction on concrete supports with wooden floors, and will require about 50 tons of steel. The cost of the bridge is $6,500, and of the approach $5,500. Contracts for the work have not yet been let.

Railway Financial News

Atlanta, Birmingham & Atlantic.—A committee, consisting of George C. Clark, S. L. Schoonmaker, Percy R. Pyne and R. G. Fessenden, has been formed, and asks the deposit of the $5,761,000 joint Atlantic & Birmingham Construction Company and Atlanta, Birmingham & Atlantic Railroad collateral 5 per cent notes due May 1. The railroad has been sold under foreclosure, but is still being operated by a receiver.

Chicago, Rock Island & Pacific.—See editorial comment and account of the stockholders' meeting in other columns of this issue.

Memphis Railway Bridge & Terminal.—This company, which is controlled by the St. Louis, Iron Mountain & Southern, the St. Louis Southwestern and the Chicago, Rock Island & Pacific, and is to build a bridge across the Mississippi river at Memphis, has been given permission by the Missouri Public Service Commission to issue $7,500,000 5 per cent bonds.

Missouri, Kansas & Texas.—Holders of the $19,000,000 2-year 5 per cent secured notes of the Missouri, Kansas & Texas, which mature on May 1, 1915, are asked to extend these notes for one year at 6 per cent interest. Holders of a majority of the notes have already agreed to this extension. Noteholders are asked to deposit their notes before April 26 with the Central Trust Company, New York. It is also announced that a committee of the board of directors, consisting of Horace E. Andrews, George W. Davison, Lewis B. Franklin, A. J. Miller and Frank Trumbull, have been appointed by the board to work out a plan for a readjustment of the financial position of the company. In the notice to noteholders Mr. Trumbull, chairman of the board, says:

"The present emergency is not due to lack of earning power, as the property is showing increases both in gross and net earnings and a surplus over all fixed charges, but is due to the maturing at an unfavorable time of this large amount of capital obligations. Any plan necessarily involves action by the stockholders of the company, in order to provide for the payment of the notes and the consequent protection of their interest in the property. It has been impossible to work out a definite plan in time for submission to the stockholders at their recent annual meeting, as a large proportion of the stock is held abroad and foreign holders could not be consulted in time.

"The committee is proceeding diligently and hopes to make an announcement at an early date. The plans under consideration contemplate an issue, to be offered to stockholders, of securities carrying a contingent charge or of preferred stock, which latter has only become practicable through the enactment by the Kansas legislature of an act shortly to become effective authorizing such issues upon consent of the holders of three-fourths of the stock."

Missouri Pacific.—Directors have asked the holders of the $24,845,000 3-year 6 per cent secured notes which were due June 1, 1914, and extended to June 1, 1915, to further extend these notes with the same collateral and at the same rate of interest to June 1, 1916. An announcement was made by George Gould that he had not agreed to extend his notes or those of the Gould estate, but had the matter under consideration.

New York, New Haven & Hartford.—A syndicate, composed of J. P. Morgan & Co., the First National Bank and the National City Bank, all of New York, and Kidder, Peabody & Company and Lee, Higginson & Company, both of Boston, has bought $27,000,000 one-year 5 per cent collateral notes of the New York, New Haven & Hartford, secured by the following collateral:

98,132 shares Old Colony 7 per cent stock at 150	$14,719,800
9,551 shares Providence & Worcester 10 per cent stock at 200	1,910,200
5,246 shares Boston & Providence 10 per cent stock at 230	1,206,580
4,867 shares Providence, Warren & Bristol 6 per cent stock at 120	584,040
971 shares Norwich & Worcester 8 per cent preferred, at 150	145,650
291,622 shares Ontario & Western at 26	7,582,172
$1,500,000 Central New England 1st 4s at 75	1,125,000
$13,000,000 Harlem River & Portchester debenture 5s at 100	13,000,000
Total	$40,273,442

The receipts from the sale of this note issue will be used to pay off $30,000,000 notes, falling due on May 1. These notes are $20,000,000 New York, New Haven & Hartford collateral notes, and $10,000,000 Harlem River & Port Chester 5 per cent notes. Thus, as *The Wall Street Journal* points out, $3,000,000 of the maturing notes will be paid for out of current funds, and this is the first reduction in the New Haven floating debt since 1911. The new notes are being offered to the public at 99¼ to yield 5¾ per cent.

Oakland, Antioch & Eastern.—Jesse W. Lilienthal, president of the United Railroads of San Francisco; H. A. Lardner, of the J. G. White Engineering Corporation; C. Osgood Hooker, F. H. Beaver and A. Haas have been elected directors, and Henry T. Scott, president of the Pacific States Telephone Company, and H. A. Mitchell have retired from the board.

Toledo, St. Louis & Western.—The protective committee for the preferred and common stock, J. S. Bache, chairman, announces that more than 70 per cent of the outstanding stock has been deposited with the committee and that the time for making deposits has been extended to May 1 and that after that time deposits will be received only on the payment of 50 cents a share.

Vandalia.—This company, operating 910 miles of line, inclusive of the line of the Terre Haute & Peoria which it leases, in the fiscal year ended December 31, 1914, had net income, after the payment of expenses, rentals, taxes and interest of $282,559 as against $369,259 in 1913. The increased net was primarily due to the business depression resulting in a decreased carriage of bituminous coal which normally constitutes over 50 per cent of the total freight tonnage.

The Vandalia is controlled by the Pennsylvania Company. It operates lines from Indianapolis, Ind., to East St. Louis, Ill.; from Rockville, Ind., to South Bend; from Logansport, Ind., to Butler; from Indianapolis to Vincennes, giving it a total main line of 609 miles, and in addition it has branches aggregating 30 miles. The Terre Haute & Peoria operates lines from Farrington, Ind., to Decatur Junction and from Maroa, Ill., to Farmdale, a total of 145 miles. The Vandalia also operates 16 miles jointly with the Chicago & Eastern Illinois from Otter Creek Junction, Ind., to Rockville, and it has trackage rights, totaling 109 miles, over a number of roads which give it access to Terre Haute, Peoria and Toledo.

In 1914 the Vandalia earned freight revenue per mile of road of $8,093 and passenger train revenue per mile of road of $3,625, these being decreases respectively of $771 and $220. The ton mile rate in 1914 was 6.17 mills as against 6.59 mills in 1913, the total ton mileage carried being 1,193,096,783, an increase of 15,436,065 tons. The company estimates that the average cost per ton mile was 5.20 mills, a decrease of .23 mills and that the net revenue per ton per mile was 0.97 mills as against 1.16 mills in 1913. The average trainload of revenue freight in 1914 was 397 tons, and in 1913, 381 tons. The average passenger receipts per passenger mile in 1914 amounted to 2.137 cents, and in 1913 to 2.134 cents.

The Vandalia controls the Terre Haute & Peoria by lease and the figures given above include the combined operations of both companies. The Vandalia lost $271,150 by the operation of its leased line, an increase of $18,573 over 1913. The Vandalia has been paying 4 per cent dividends, but no dividend was declared in 1914. On December 31, 1914, there was cash on hand of $1,205,454 or $272,164 more than on December 31, 1913. The total current liabilities at the close of the year were $1,404,784.

Wabash.—George J. Gould, Edward T. Jeffery and Winslow S. Pierce, as directors of the Wabash, on October 15, 1913, are held liable by the appellate division of the Supreme Court of New York for $5,133,307, with interest, for illegal bond transactions which took place in 1906. Suit was brought by James Pollitz on behalf of himself and other stockholders.

Western Maryland.—An agreement has been reached between the Western Maryland and the Baltimore & Ohio by which the Western Maryland is to get trackage rights to a connection with a line which it proposes to build from a point in Somerset county to a point in Westmoreland, which line taps properties of the Consolidation Coal Company. The Consolidation Coal Company is understood to be controlled by John D. Rockefeller, who also controls the Western Maryland.

The Railway's Interest in Correct Weight

The correct determination and recording of weights is a matter of direct concern to the shipper as well as to the railway, and this subject was a topic of active discussion among various shipper's organizations previous to the recent Interstate Commerce Commission hearings on this subject. Mr. Maegley's plea for less secrecy with reference to weights, calling every weight by its right name, and for the participation of the carriers in the determination of the weights of the receiver and the shipper is therefore of general interest to the patrons of the railways as well as to the railways themselves. Unless there is co-operation between the shipper and the receiver of grain and the railways, it is very difficult to locate and correct discrepancies. It would seem that they can best be discovered and corrected by the carrier, since it is a neutral intermediary between the shipper and the receiver. In the reduction or elimination of any class of claims for losses it is first necessary to make a diagnosis of their causes. Only by some joint co-operation, such as that suggested can the proper analysis be made. It is to the ultimate interest of all concerned that legitimate claims be reduced to the minimum, for money paid for the payment of such claims is an economic loss from which no one benefits. Joint committees representing the grain dealers and the railways are now studying this subject and it is to be hoped that their deliberations may result in the evolution of some practicable plan whereby legitimate claims may be reduced to the minimum and others made impossible.

Foreign Government Short Term Financing

Both France and Germany and some of the neutral countries have successfully bid for American short-term money. In recent years the American railroads have been heavy bidders for short-term money at continually advancing prices. It has been recognized, however, both by the railroad managements and the bankers that railroad financing by means of short-term notes was a temporary and an uneconomical expedient. Within the next few years, therefore, American railroads will, both for purposes of meeting maturing short-term notes and for new capital, have to sell a very large amount of long-term bonds and will have to sell them almost exclusively in the American market. Any short-term financing which railroads are compelled to do at present is in competition with the short-term financing of the European governments. Will the long-term bonds of American railroads have to be sold in this country in competition with long-term bonds with which the European governments will meet the maturing notes which they are now selling over here? The proceeds of the sale of foreign government notes are not, of course, leaving the United States, but are being used by the belligerents to pay for war supplies, and by the neutral countries to pay for foodstuffs. There is no gold being exported from the United States to Europe, but foodstuffs and manufactured materials are being exported. This, of course, is a transfer of wealth for which the United States reecives credit. When the short-term European notes fall due the European governments will have the choice either of attempting to sell long-term bonds in the United States to American investors or of selling their bonds to their own investors. In the latter case there will necessarily have to be a transfer either of gold or of some form of wealth from Europe to America to liquidate the debts which Europe is now contracting. Europeans hold a very large amount of American railroad securities. The European investor could ship back to America American railroad securities, thus liquidating the European debt to America, and take in exchange European government bonds. American investors would then be called on to take not only the American railroad securities which were issued to refund short-term notes and to raise new capital, but also the old securities which had been sold in Europe.

Government Versus Railway Securities

Of course, the extent to which the foreign investor sells his holdings of American railroad securities in order to buy European government bonds will depend in part on inducements in the way of interest, security, etc., which the European government bonds will hold out to investors, but also in part to the security of American railroad bonds and their attractiveness as an investment. It might well be that an English or French holder of first mortgage bonds of a strong American railroad company would prefer to retain these bonds even in the face of an offering of European government bonds with a comparatively high rate of interest, but this could only conceivably be so if American railroad credit as a whole were to be much higher in

a year or two from now than it has been in the last few years. On the other hand, the price at which American railroad refunding operations and the raising of new American railroad capital can be accomplished will depend directly on whether or not the two to four hundred million dollars of American railroad securities now held in Europe are dumped on the American market. In other words, it apparently behooves the American railroad managements to be fore-handed in preparations for meeting competition for new capital. To successfully improve railroad credit railroad managers must under our present form of government have the active co-operation of the Interstate Commerce Commission, and although the co-operation of state commissions is hardly to be hoped for, yet there must be a minimum of opposition on the part of these railroad regulators. Railroad managements and the bankers handling their securities will have to make a strong bid for the confidence of investors; but the investors' attitude will be very materially affected by that of the Interstate Commerce Commission and of national and state legislatures. There is, therefore, a vital need for mutual confidence as between railroad managers and railroad regulators and the public.

A SECRETARY OF TRANSPORTATION

FROM different sources there has come recently the suggestion that the industry of transportation should be given representation in the President's cabinet. Ray Morris, in an article in the Yale Review, and Chairman Elliott of the New Haven, in an address at Norwich, Conn., have pointed out the desirability of such action.

Labor has recently been given representation in the cabinet by the creation of the office of secretary of labor. The three greatest industries in the country are agriculture, manufactures and transportation. Agriculture is given representation through the secretary of agriculture, and manufactures and commerce are given representation through the secretary of commerce. The secretary of the treasury, to a large extent, represents the banking interests. Not only is railway transportation one of the three great industries of the country, but in its magnitude it is a peculiarly American industry. The largest railway mileage in any country in the world, except in the United States, is in Russia, which has 50,000 miles; and the mileage of the United States is five times that of Russia. The mileage of the railways of the United States largely exceeds that of all the railways owned by governments in the world. In no other country has railway transportation been developed to such a magnitude either absolutely or relatively, and in no other does the prosperity of the public depend to so great an extent on the prosperity and progress of railway transportation. Yet, while we have secretaries of labor, of commerce, of agriculture and of the treasury, and while many other countries have ministers of railways, the railway industry of this country is conspicuously unrepresented in the President's cabinet.

What is the explanation of this condition of affairs? The functions of the secretaries of labor, of agriculture, of commerce and of the treasury, are wholly in some cases and largely in others, to promote the welfare of the classes or the industry which they represent. Congress thought that by having special government departments to promote the welfare of the laboring class and of the agricultural, manufacturing, commercial and financial interests, the welfare of the public in general would be furthered. But, by some peculiar process of reasoning, it concluded that in the case of the railway industry, what was needed was not a governmental policy of encouragement, but a governmental policy of regulation and repression. It thought it would be advantageous to the public for the other large industries to make large profits, but that it would be advantageous to the public for the profits of the railways to be narrowly restricted. The state legislatures have thought the same way; in fact, the public has thought the same way. Consequently, for years the federal government has been following the policy of fostering other industries and regulating, and repressing the railway industry. It has tried to fix a minimum for the prosperity of other industries and a maximum for the prosperity of the carriers. The effects on the public welfare have not been good. The policy of railway repression has not only injured the railway industry, but has reacted unfavorably on all other classes of industries and tended to counteract the effects of the government's attempts to foster them.

The railways ought to continue to be regulated. The Interstate Commerce Commission should be maintained and should continue to arbitrate between the shippers and the railways regarding rates, and perhaps it should arbitrate between the railways and their employees regarding wages. But, as has been done in the cases of other industries, there should be created an administrative department of the government whose function it should be to study the railway industry and its needs sympathetically and to try to foster its development. Perhaps to this administrative department should be transferred a large part of the administrative duties now performed by the Interstate Commerce Commission. But the primary, fundamental duty of the proposed department should be to foster the industry and not to restrict burden and oppress it.

The public is awakening to the fact that it does not pay any class or classes for the railways to be treated as if they alone among all the great industries are a proper object for attack and repression. Perhaps therefore the time is now ripe for the creation of an administrative department of the government devoted to the interests of transportation.

THE ROCK ISLAND'S FINANCING AGAIN

THE Chicago, Rock Island & Pacific was placed in the hands of receivers on Tuesday. The immediate cause of the receivership was the unwillingness of the directors or bankers to personally extend further aid to the company to help it meet its May 1 interest charges without some assurance that they would not have to continue to carry the company indefinitely. They had already personally helped the road out of its April 1 difficulties.

It has been apprehended for a long time that the condition of the Chicago, Rock Island & Pacific Railway Company would become so serious as to result in its being placed in the hands of receivers. The Railway Company, it should be understood, is the underlying operating company and not either of the two holding companies. The net earnings of the company and the dividends paid by it have been declining while its taxes, interest and other outgo have been increasing. In 1914 it had a deficit of over $1,400,000 and its case seemed hopeless. After the recent annual meeting the outlook seemed more hopeful but the receivership so long feared has at last come both suddenly and unexpectedly. The company found it was unable to get the bankers to let it have certain money which it expected to raise and this rendered it unable to meet certain debts which would soon become due.

The *Railway Age Gazette* recently has published several editorials on the Rock Island situation. A correspondent whose friendship it long has valued, and whose good opinion it desires to deserve and retain, has written chiding us for the editorial entitled "The Chicago, Rock Island & Pacific—1902 to 1915," published in our issue of April 9. He finds the editorial not at all convincing as an argument that the financial operations of the Rock Island "are defensible even in their intentions, which, from my reading of the article, I judge you to defend." He says that the property was capitalized entirely beyond its earning capacity, and that it seems to him that "any argument that tries to defend this procedure on a technicality weakens the whole case of all honest and wise railroad managers." He adds, "Your defense, or what appears to be your defense, of these operations certainly very much weakens the influence that your arguments will have with one of your readers, and it seems to me that it must weaken the influence that your arguments will have with other readers."

Since our correspondent interprets the editorial he criticizes

as a defense of the financing of the Rock Island, we are not surprised that it tends to weaken the influence that our arguments have with him. If other readers place the same interpretation on it, it will doubtless tend to weaken our influence with them also. But such an interpretation is erroneous. The editorial was not, and was not intended to be, a defense of the financing of the Rock Island. No paper has more severely condemned the financial structure built up on that road by Messrs. Reid and Moore than has the *Railway Age Gazette*. That structure was built up to give a few men control of a large property by means of a small investment, and it ought not to be possible for the control of so large and important a property to be thus secured and held. One of the effects has been to injure the Rock Island's credit, and the injury to its credit has interfered with its needed development. The worst effect of the Rock Island financial structure was that it made it essential to the maintenance of the solvency of the holding companies that the operating railroad company should continue to earn and pay four per cent dividends. In other words it turned a contingent liability into a fixed liability, thereby rendering it impracticable for the operating company even temporarily to suspend or reduce its dividends. In consequence earnings which otherwise might have been devoted to improvements which would have increased the earning capacity of the property were paid out in dividends and the property's development did not keep pace with the development of competing railways in the same territory. There can be no serious question that if the Rock Island property had not been loaded down with one holding company after another, and had not suffered losses through the Frisco and Alton transactions, it would be a better property today, both in the service it renders to the public and in the profits it earns. The issuance of railway securities should be so regulated as to make impossible such financial transactions.

But the *Railway Age Gazette* can entertain the views above expressed, and at the same time refuse to be blinded to other facts and circumstances affecting the situation of this property besides those mentioned. The purpose of the editorial in our issue of April 9 was to point out certain of these other facts and circumstances. The main point sought to be established was that the entire financial structure was based on the hope that the road's profits would increase, or at least not decline; that, as a matter of fact, the profits had actually declined; and that this, and not the holding companies, was the *main* cause of the troubles that have overtaken the property. Are not these facts? Between 1907 and 1914 the dividends paid by the underlying company declined from $4,116,728 to $1,871,763, or $3,344,965. What was the cause of this decline? The following figures explain, and more than explain, it. Between 1907 and 1914 gross earnings increased from $60,238,420 to $68,208,113. Meantime operating expenses and taxes increased from $42,720,180 to $54,315,578. Taxes alone jumped from $1,676,000 to $3,316,000, or about 100 per cent. The result was a reduction in net operating income of $3,635,705, which substantially exceeds the reduction in the dividends paid.

The more the figures are studied the more clearly it appears that if the two holding companies had never come into existence at all it would have been impossible for the management to have offset the increases in operating expenses and taxes by any increases in the efficiency and economy of operation that were within its power.

The facts show, then, that the Rock Island has been subjected to two sets of adverse influences. One of these has grown out of its peculiar financing. The other has grown out of increases in its operating expenses and taxes which have caused it to suffer more severely than many other properties because it has been so situated that it has not enjoyed as large an increase as some of them in its gross earnings. Is it defending the financing of the property to call attention to the fact that the plight to which it has been brought is chiefly due, not to its unwholesome financing, but to increases in its operating expenses and taxes?

It is not the policy of this paper to defend the mistakes made or the wrongs done by railway managements. It is our policy to try to present all the facts regarding the railway situation in their true proportions. This is made the more necessary because many persons who discuss these matters seize upon and use only those facts which may support their prejudices or serve their own special purposes. The reckless and, as it has turned out, foolish financing of the Rock Island has been harped upon so much that most people have become convinced that this has been the only thing that has got the property into trouble. This persistent exaggeration of certain features of the case has made it necessary to call attention forcibly to other and equally important features, and this is all the *Railway Age Gazette* has meant to do in the editorials on the Rock Island which it has recently published.

The final bankruptcy of the property is the natural result of the operation of the two sets of influences that have been acting upon it. If the holding company superstructure had never been erected it might have had to reduce or suspend its dividend, but it would probably be a solvent property today. If on the other hand there had not been such an enormous increase in wages, taxes and other expenses it would have been able to have earned and paid sufficient dividends to support the holding company superstructure. With the two sets of influences acting on it, it was unable to continue to stand up. The outcome may properly be denounced as a natural result of the sort of financing of which the Rock Island has been the victim, but it may also with equal propriety and justice be denounced as a natural outcome of the sort of regulation to which the Rock Island and other railways have been subjected.

DELAWARE & HUDSON

THE Delaware & Hudson is generally classed with the financially strong roads of the country, and quite properly so. Even in the calendar year 1914 the company earned net income available for dividends of $4,608,000, or 10.84 per cent, on the outstanding $42,503,000 stock. The company can earn a margin of safety over its 9 per cent dividend rate in a year such as 1914, when it was adversely affected by loss of both freight and passenger business, on the one hand, and by increased operating expenses from causes beyond the control of the management, on the other, because the profit is concentrated on a comparatively small volume of stock; the company has had to pay in the past a low rate of interest for borrowed money and has pursued a liberal policy toward betterment and upkeep. The net earnings on the value of the property used in public service are not high. It was brought out in the anthracite case before the Interstate Commerce Commission that the net operating income of all of the anthracite roads, that is, the total amount available for interest charges, rentals, dividends, etc., after the payment of operating expenses and taxes, amounted to 5.06 per cent on the book cost (the actual cost was probably greater and the rate of return therefore less) of the property devoted to public use. It is so obvious that it is to the public interest for American railroads to get their new capital at the cheapest possible price, and that the reason why such a road as the Delaware & Hudson has in the past been able to do so has been that its earning power has left a fair margin of safety even in times of depression, that it hardly needs reiteration here.

Many of the adverse circumstances which affected the Delaware & Hudson's operating results in 1914 were foreseen and commented on in the annual report for 1913. Briefly summarized, these adverse circumstances were: a loss in bituminous coal tonnage of 355,000 tons, the total carried in 1914 being 2,052,000 tons; in ore tonnage a loss of 313,000 tons, the total tonnage carried in 1914 being 465,000 tons; a loss in miscellaneous tonnage of 919,000 tons, the total carried in 1914 being 715,000, all due to the business depression, the loss in bituminous coal tonnage being of course directly traceable to the shutting down of business in the New England mills and industries; a loss in passenger revenue amounting to $331,000, the total earnings from passenger busi-

ness being $2,947,000 in 1914; and increased expenses of $77,000 due to the operation of the full-crew law for an entire year as against four months in the previous year; increases in wages amounting to about $136,000, due to results of arbitration, and increases in general expenses due to valuation expenses and compliance with requests for information, etc., from the commission.

A favorable factor during the year was the increase in the tonnage of coal mined by the coal mining department, amounting to 230,000 tons, the total mined in 1914 being 7,401,000 tons. There was a loss of a little over 4½ working days in the coal mines due to strikes, as compared with about 54½ days lost in 1913. There would have been no loss of time in either year if the miners had lived up to their agreement to leave disputes to arbitration before striking. There was, as would be expected, a larger tonnage of anthracite coal shipped over the road, the total in 1914 being 9,211,000 tons, an increase of 299,000 tons as compared with 1913. Despite the larger amount of coal mined, however, the revenues from the coal mining department amounted to $15,517,000 as against $16,045,000, and net revenue amounted to $964,000 as against $1,297,000. Presumably the payment of a tax of 2½ per cent on the value of anthracite when prepared for market imposed by Pennsylvania and which went into effect on June 28, 1913, accounts for part of the loss in revenue in the face of the increased tonnage of coal mined. The company is now testing the validity of the Pennsylvania tax in the courts.

Transportation expenses in 1914 amounted to $8,603,000, comparing with $8,585,000 in 1913. The enforced increases in expenses previously mentioned in part explains why it was impossible to reduce transportation expenses proportionately to the reduction in freight and passenger business handled.

The large falling off in tonnage of ores probably also had its effect on the increased transportation expenses per ton-mile and this is reflected in the trainload figures. The revenue trainload was 518 tons in 1914, a decrease of 24.5 tons from the average in 1913, and the total trainload, including company freight, was 557 tons, a decrease of 27.7 tons as compared with 1913. Since the number of loaded cars per train was almost the same in 1914 as in 1913—20.58—and the tons of revenue freight per loaded car pretty nearly as great—25.17 as against 26.14 in 1913—the loss in ore tonnage was a considerable factor in the increased proportion of empty car mileage—this tonnage moving in the direction of the empty car movement.

In 1914 $1,670,000 was spent on maintenance of way, a decrease as compared with the 1913 expenditure of $117,000; and $3,650,000 was spent on maintenance of equipment, a decrease as compared with 1913 of $104,000. In the early part of 1914 there was some very bad weather in the part of the country traversed by the Delaware & Hudson, and the removal of snow and ice in 1914 cost $101,000 as against $18,000 in the previous year. At least a part of the smaller expenditure on maintenance of way apparently represents work more economically done, since the amount spent for rails in 1914 was $73,000 as against $41,000 the year before, and for ties, $273,000 as against $287,000, while applying track material cost but $139,000 in 1914 as against $224,000 the year before; although, on the other hand, there was $8,000 spent for ballast as against $17,000 the year before, and $85,000 spent for "other track material" as against $107,000 the year before. The smaller amount spent for betterments entailed smaller charges in expenses for "replacement in kind."

More was spent for repairs of locomotives and somewhat more for repairs of freight cars in 1914 than in 1913; but the decrease in total maintenance of equipment expenditures is accounted for by the fact that but $31,000 was charged for freight-train car renewals in 1914 as against $316,000 in 1913.

During 1914 the Delaware & Hudson spent $1,821,000 for additions and betterments. Of this, $15,635 was for the installation of block signals between Plattsburg, N. Y., and Rouses Point, and $29,950 on the program of installation of distant signals at the end of the double tracks and for passing track leading from single track line and the extension of overlaps to a minimum distance of 2,000 ft., where distant signals were not in use.

The company sold during the year $4,500,000 first and refunding mortgage 4 per cent bonds at 95. At the end of the year the company had $1,968,000 cash, as compared with $1,647,000 at the beginning of the year, and had on special deposit $1,055,000, of which all but $10,000 represents the unexpended balance from the proceeds of the bond sale mentioned above. Loans payable amounted to $3,019,000 at the end of the year as compared with $4,500,000 at the beginning of the year. The Delaware & Hudson had advanced for construction and acquisition of new lines $5,085,000 as compared with $4,275,000 at the beginning of the year. The greater part of the advances made during the year were for the Wilkes-Barre Connecting Railroad.

The following table shows principal figures in 1914 and 1913:

	1914	1913
Average mileage operated	904	904
Merchandise freight revenue	$8,153,086	$8,794,429
Coal freight revenue	10,844,093	11,436,960
Passenger revenue	2,946,665	3,277,929
Total operating revenue	22,595,029	24,153,495
Maint. of way and structures	1,670,364	1,787,614
Maintenance of equipment	3,649,673	3,753,963
Traffic expenses	314,327	305,966
Transportation expenses	8,602,636	8,584,722
General expenses	811,453	778,042
Total operating expenses	15,048,452	15,210,307
Taxes	671,119	623,107
Operating income	6,875,457	8,320,081
Gross income	7,979,068	9,683,485
Net income	3,169,527	4,926,977
Income from coal mining department	1,357,955	1,188,426
Net corporate income	4,607,863	6,174,736
Dividends	3,825,270	3,825,270
Surplus	782,493	2,349,466

NEW BOOKS

Statistics of Railways of the United States, 1903 to 1913. Bulletin No. 75, issued by the Bureau of Railway Economics, Washington, D. C. 81 pages, 6 in. by 9 in. Bound in paper.

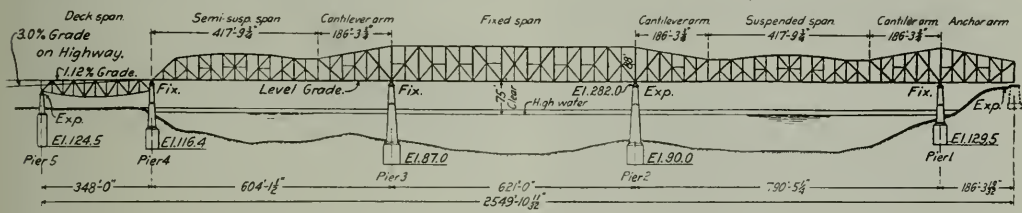
Last year the Bureau of Railway Economics issued in Bulletin No. 66 a compilation of the statistics of the railways of the United States for the years 1900 to 1912, with the purpose of presenting in a form adapted for convenient reference the principal aspects of railway operation, as shown by official statistics. With Bulletin No. 75 the bureau has begun what is intended to be an annual series of similar statistics for the latest 10-year period for which the official figures are available. The railway tabulations are based upon official data published by the Interstate Commerce Commission for each fiscal year ended June 30, 1903, to 1913, and tabulations concerning population and area are based upon the reports of the census bureau. The bulletin contains 76 tables, classified under the following heads: Population and Area, Railway Mileage, Capital Securities and Dividends, Revenues, Expenses and Taxes, Employees and Compensation, Equipment, Freight Traffic Statistics, Passenger Traffic Statistics and Accidents, the various tables under each head giving the principal details for each year. Where such a division is suitable the figures are reduced to a mileage basis. The arrangement of the tabulations renders this bulletin of especial advantage from the standpoint of convenient reference, because it brings together in comparative form the figures for 11 years, thus doing away with the necessity for consulting the different volumes of the Interstate Commerce Commission statistics, and especially because all of the statistics are compiled for the three territorial districts now used by the commission. Prior to 1911 the Interstate Commerce Commission presented the statistics of railways by 10 territorial groups. Beginning with 1911, it has presented the statistics in three districts, eastern, western and southern, representing the three important traffic areas. The statistics given in this bulletin respectively for the three districts for the years prior to 1911 are combinations of the statistics originally published by groups. This makes it possible to obtain an accurate comparison of the statistics for the various years without the necessity of recasting the group figures. The bulletin is published in such a handy form that it should be indispensable to all who have frequent occasion to study the railway statistics and should be on the desk of every railway man, economist and foreign newspaper man who has current need for such compilations.

Substructure of the New "Harahan" Bridge at Memphis

Construction Methods Used to Build Piers for Mississippi River Bridge to Carry Three Roads and a Highway

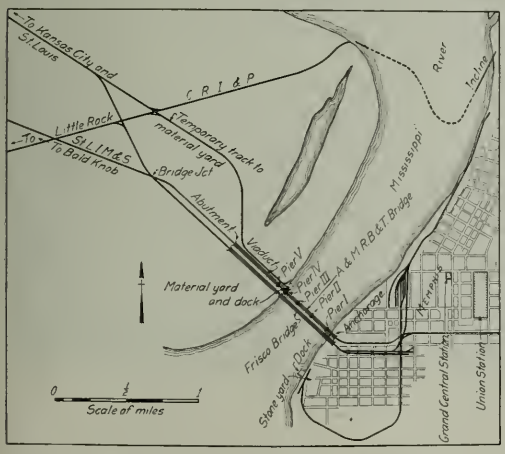
By M. B. Case
Resident Engineer, Arkansas & Memphis Railway Bridge & Terminal Co., Memphis, Tenn.

All traffic on the four roads extending west from Memphis, Tenn., must now pass over a single-track bridge completed in 1892 for the Kansas City & Memphis Railway & Bridge Company, which has since become a part of the Frisco system. In order to provide more adequate facilities, a new bridge is now being built by the Rock Island, the Iron Mountain and the Cotton Belt systems through a joint organization named the Arkansas & Memphis Railway Bridge & Terminal Company. Work was commenced in June, 1913, as mentioned in a preliminary description of the plans for this bridge in the *Railway Age Gazette* of October 31, 1913, and the substructure was entirely completed in January, 1915, slightly more than 18 months after the preliminary work was started at the site.



Elevation of New Mississippi River Bridge at Memphis

Active preparation for the erection of the superstructure of the main bridge is now under way. False work is being placed under one anchor arm, and derricks for unloading and storing the heavy truss members are being erected. The erection of the main bridge and the viaduct approach will be under way during the coming season.

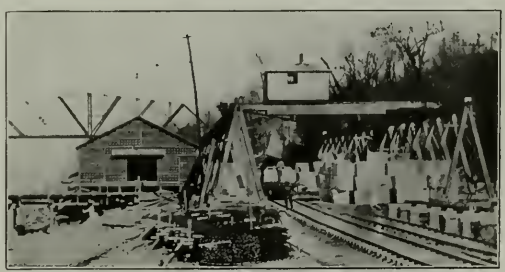


Sketch Map of Bridge Location Showing Material Yard, Stone Yard, Temporary Track, Etc.

THE NEW BRIDGE

The bridge will carry two railroad tracks spaced 14 ft. center to center located between trusses spaced 34 ft. 6 in., and two roadways 14 ft. wide on brackets outside of the trusses. The main bridge is 2,550 ft. long from the anchorage pier on the Tennessee bluff to Pier 5 located 345 ft. back from the low bank on the Arkansas side. Beyond this point a tower and girder viaduct continues over the bottom land for a distance of 2,363 ft. to the west abutment. The tracks are here carried onto an earth embankment 55 ft. high at the abutment, which extends westward on a tangent about ¾ miles to Bridge Junction, where the elevation is about 25 ft. above the general level of the bottom land.

The tracks ascend from the yards in Memphis on a 1.1 per cent grade to Pier 1, and run level to Pier 4, where they descend on a 1.126 per cent grade over the viaduct and the embankment, the necessary vertical curves being provided. The roadways start at Pier 4 to descend to the Arkansas bottoms on a 3 per cent grade along the viaduct until reaching an elevation above high water, about 23 ft. above the ground, when they run level for a short distance to the west abutment and then turn to the down stream side of the Frisco embankment on a single roadway structure to be provided by the county.



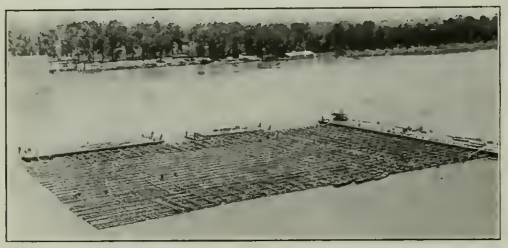
Stone Yard, Traveling Crane, Cement House and Dock on the Tennessee Shore

The center line of the new bridge is 200 ft. up stream, and parallel to the existing structure. Pier 1 on the Tennessee shore, and Piers 2 and 3 in the river are directly above the corresponding piers of the old bridge, while Pier 4 on the Arkansas shore is 17 ft. toward the river from the center line of the old pier in order to permit the duplication between Piers 3 and 4 of the cantilever arm and suspended span used between Piers 1 and 2.

The piers are supported on pneumatic caisson foundations

resting on a very hard blue clay over-laid by several softer strata of clay having slightly variable characteristics. Above this is a bed of sand covered with the shifting alluvial silt of the Mississippi river. The caissons for Piers 2 and 3 are 42 ft. by 90 ft. by 51 ft.; for Pier 1, 40 ft. by 80 ft. by 59 ft.; for Pier 4, 31 ft. by 77 ft. by 62 ft., and for Pier 5, 25 ft. by 46 ft. by 81 ft. The height from the bottom of the foundation to the coping of Pier 2 is 192 ft., and of Pier 3, 195 ft.

The shafts of Piers 1, 2 and 3, resting on the caisson foundations, are 42 ft. long between the shoulders with pointed noses extending up to the starling coping a short distance above high water elevation. The up-stream nose or cut-water is fine-pointed from the mud line to the starling coping, and above this level the piers have semi-circular ends, both of which have a quarry face. The piers are built of 1:2½:5 concrete, faced with a light gray granite with the exception

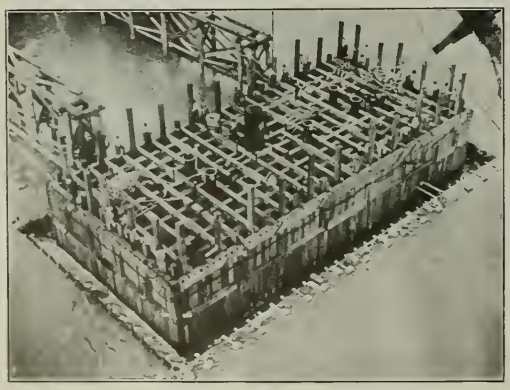


Laying a Willow Mat Over the Site of Pier II to Reduce the Tendency to Scour

of the three courses under the coping which have granite backing as well as facing. The stone was laid in Flemish bond with few exceptions, and the courses were 3 ft. thick up to the starling, with 30 stones in a course. Above this level the courses are reduced in thickness to a minimum of 2 ft. under the belting course.

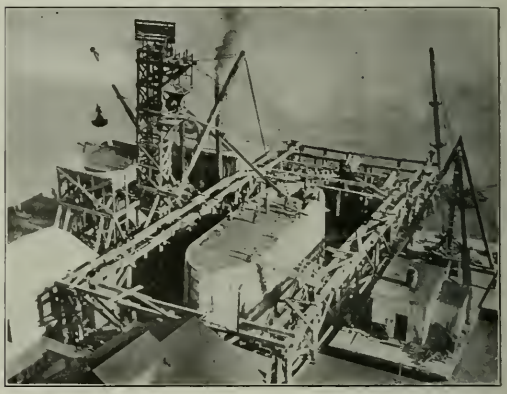
CONSTRUCTION PLANT

The most convenient ground available for the large storage and timber framing yard necessary was on the Arkansas



Launching the Timber Caisson at Pier III

bottom land along the viaduct. This location furnished ample space at small expense, and permitted the quick and cheap delivery of material to barges for transportation to the piers. Although this ground was likely to be overflowed between February and June, a material yard on the high Memphis bluff would have caused considerable expense and delay in delivering material and supplies on the river, and did not furnish suitable ground for building the large number of barges required. The first preliminary construction consisted in building about two miles of track from the old Rock Island Hopefield line to the west bank of the river, as shown in the



The Concrete Mixing and Placing Outfit Working on Pier II

sketch map. This line connected with two tracks extending onto a dock equipped with a derrick for transferring material to boats.

The first three months were occupied almost entirely with the building of 15 barges, a part of which carried the various rigs needed in the construction and the rest were for use as cargo boats. In addition to these barges constructed on

Placing the Upper Courses of Granite Facing on Pier II

the work six more were purchased second-hand, and several others and a small steam boat were chartered from time to time as required to keep the work going without delay. A screw propeller tug and two launches completed the marine equipment. The rigs built on these barges consisted of an air compressor plant, a concrete mixing and delivering plant, a pile driver, three derrick barges and two mat weaving outfits.

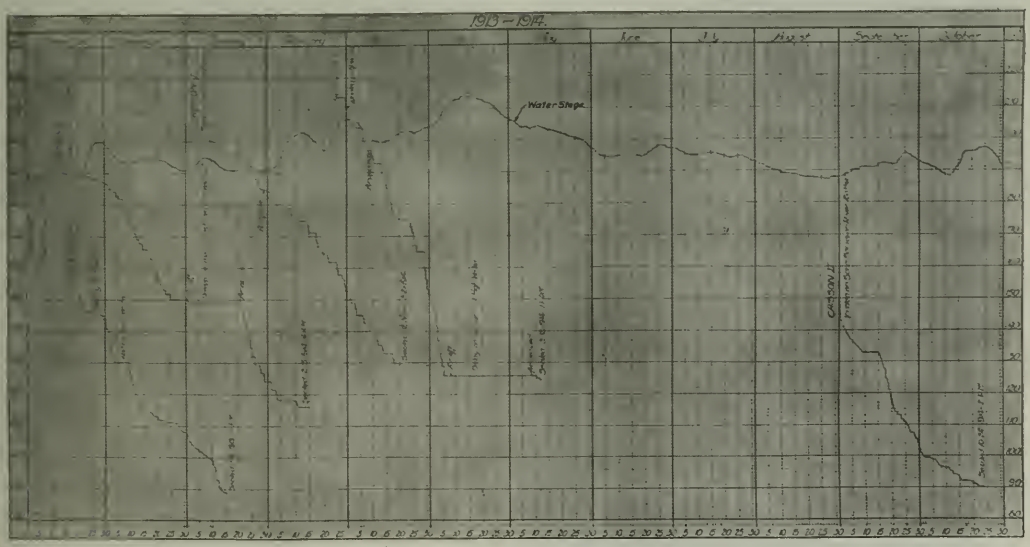
The granite for the piers was cut at the quarry and shipped from Stone Mountain, near Atlanta, Ga. This naturally called for storage on the east side of the river. A storage yard was obtained a short distance below the bridge on the

Tennessee side below the bluff but above high water. This yard was equipped with a traveling crane which unloaded the granite as received and later delivered it onto push cars which could be run out onto a dock with a derrick to lower it onto the barges by which it was delivered to the piers. A cement house of 3,000 bbl. capacity, for storage of a reserve supply, was also located on this ground next to the river. The greater part of the cement was delivered by

Piers II, III, IV and V Completed, Showing Also the Old Frisco Bridge

boat from St. Louis and unloaded into two covered barges of 1,500 bbl. capacity each. Cement intended for the storage house was shipped by rail, and used only when the deliveries by boat were delayed or suspended by the river conditions. This was but a small part of the 59,000 barrels used, and hopper which discharged into a 1-cu. yd. mixer. Cement was elevated to the measuring hopper in a small car pulled up an inclined track by a line leading to a spool on the tower hoisting engine. The cement car ran back on a track extending under the roof of the cement barge which was moored below the mixing plant, thus reducing the handling of the cement and the loss and damage of sacks during wet weather. This barge carried a 60-hp. locomotive type boiler furnishing steam to the mixer engine and tower hoist. Ample steam was available for heating water and sand during chilly weather to hasten the setting action of the concrete, although low temperatures are not common at Memphis.

The compressor barge for the pneumatic caisson foundations carried four locomotive type boilers with a combined capacity of 300 hp., with the necessary pumps and feed water heaters. Three low pressure compressors with a capacity of 2,500 cu. ft. of free air per minute furnished air for the caissons, and one smaller machine furnished high pressure air for the boring tools and hammers used on the timber construction. A 25-kw. direct-connected generator furnished current for lights and for an elevator operated in the main shaft of the two deeper piers. The so-called hospital lock, for the use of the pressure men in relieving occasional cases of bends or after effects of the air pressure by recompression, was located on this barge. The compressors discharged directly into a small air receiver during cool weather, but during the warmer months the air passed through a series of cooling pipes before entering the caisson.



Progress Chart Showing Rates of Sinking Caissons at the Five Piers

could be delivered directly into the barge houses by chuting down an incline.

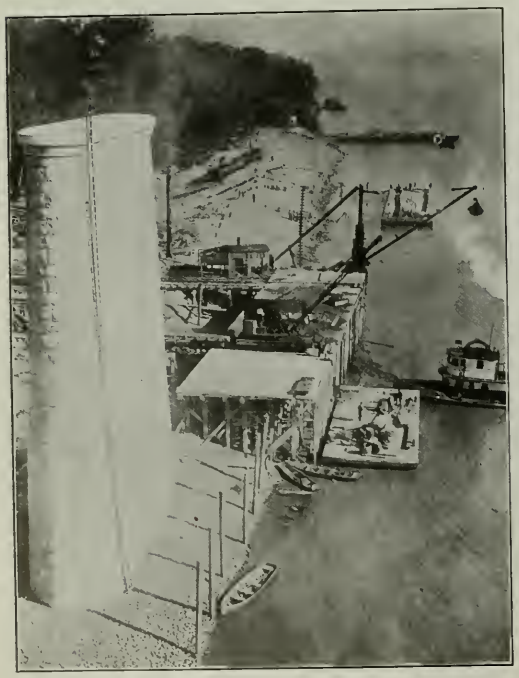
The concrete mixing plant was carried on a barge 36 ft. x 100 ft. equipped with the familiar tower and chute for the delivery of concrete. Mississippi river washed sand and screened gravel were furnished by a local firm. This material was handled on the bridge company's barges of 275 cu. yd. capacity, and was raised into the hoppers over the mixer by a clamshell bucket and derrick located on the corner of the mixing plant barge opposite the mixer. These hoppers had a capacity of 50 cu. yd. of sand, and 70 cu. yd. of gravel. The material ran by gravity into a measuring These were submerged in the river and supported alongside the barge. This plant was used for Piers 3, 1 and 2 in the order named. Another compressor plant built on the Arkansas shore west of Pier 5 was used for Piers 4 and 5.

SINKING CAISSON FOR PIER 3

Preliminary construction of barges and plant had advanced so that construction of the caisson for Pier 3 was started in September, 1913. This caisson was built up 14 ft. in a 54 ft. by 100 ft. by 11 ft. pontoon before launching. The weight of the caisson was distributed over the bottom of the pontoon by transverse loading beams consisting of two 12 in. by 12 in.

timbers well keyed and bolted together to act as a single beam 24 in. deep. These beams rested on longitudinal 12 in. by 12 in. timbers of the pontoon, and received the weight of the caisson at the cutting edge and center bulk-head. The pontoon was built with a longitudinal joint to provide a means of separating the two halves and withdrawing them from under the caisson after the pontoon had been flooded and the caisson floated. The bolts in this joint were removed just before flooding the pontoon. After the pontoon was submerged, the halves were pulled from under the caisson, the sliding surface being the top of the longitudinal timbers on the pontoon and the bottom of the transverse loading beams. The latter were afterwards pulled out by lines attached for that purpose before flooding the pontoon. The buoyancy of the timber in the pontoon was reduced very materially by loading it with pig iron immediately before flooding. The launching of this caisson was accomplished without trouble.

A well braced pile dock had been driven around three sides of the pier site previous to the launching of the caisson, which proved very satisfactory for holding it in position until well landed on the river bed and afforded a convenient and economical staging for the caulkers and the work of planking the sides of the crib during the sinking. It also furnished a location for a derrick on the upstream end of the pier, thus



The Arkansas Shore Showing the Completed Pier IV, the Dock from Which Construction Material Was Handled to Barges and Shore Protection Extending Up Stream

getting a maximum amount of plant into position to work on the pier at one time.

A 6-ft. shaft, with a lock at the bottom a short distance above the roof of the caisson, was equipped with an electric elevator for handling the gangs in and out of the caisson, and in addition to this a 3-ft. shaft with a ladder and Morison lock was provided. Five 2-ft. material shafts were used for locking out the clay excavation and for passing in concrete when sealing the caisson. These material shafts were equipped with short vertical locks taking a bucket of 9 cu. ft. capacity handled by a derrick, the hoisting rope running through a packing gland in the top doors of the lock. These locks were very economical of air required for lockage.

While the sinking was in sand which was handled through 4-in. blow pipes, the rate of sinking nearly always depended upon the progress of building up on top, but when the clay excavation was reached sinking usually depended on the rate

Placing Concrete in Steel Pedestal Forms for Western Approach Viaduct

at which the locks could remove the spoil from the working chamber. After the harder clay was reached, the progress depended upon the rate of excavating the clay ready to be locked out. The accompanying diagram shows the rate at which the sinking proceeded on the various piers, as well as the immersion at various stages of the work. The highest air pressure required was 48 lb. on Pier 2, which continued for several days while the immersion was 107 ft. Pier 3 required 45 lb. just previous to sealing the working chamber.

In building up the piers, no difficulty was experienced in setting and backing one course each day. The water and sand were heated during chilly weather to hasten the setting action, so that the concrete was well hardened for the masons to work over on the following day.

OTHER PIERS AND THE APPROACH VIADUCT

The design of Pier 2 and the general construction methods followed differ but little from those described for Pier 3. Because of the much deeper water at Pier 2 (50 ft. as compared with 30 ft) it was necessary to use a removable cofferdam 15 ft. high as an extension to the crib. This was done to permit the landing of the caisson on the river bed, and to increase the buoyancy of the pier until sufficient friction and bearing was developed to carry the weight of the granite masonry. Because of the swifter current and consequent tendency to scour, the bed of the river was prepared to receive the caisson by sinking a willow brush mat 200 ft. by

300 ft. in size placed centrally over the site of the pier. The design and construction of this mat differed in no way from those placed by the Mississippi River Commission on other parts of the river. After the dock was driven through the mat 29,000 burlap sacks filed with sand were deposited at the pier site to reduce the depth of the water about 8 ft., and to give an even bearing on which to land the caisson.

Willow mats extending 150 ft. on both sides of the bridge axis were afterwards sunk and covered with rip rap for the entire distance between Piers 2 and 3 to protect the false work from scour during the erection of the 621 ft. fixed span, which also forms the anchorage for the 790 ft. cantilever span towards Pier 1, and for the cantilever arm and semi-suspended span towards Pier 4. After the completion of this channel mat work the same plant was used to place a mat along the Arkansas bank extending 1,000 ft. above the bridge.

The 76 pedestal foundations and the west abutment were built during the summer of 1914. The pedestals each contain 53 cu. yd. of concrete and rest on a 13 ft. by 13 ft. footing block supported by 16 30-ft. reinforced concrete piles of octagonal section, 16 in. between faces at the top, and tapering to 12 in. at the point. The reinforcement consists of 8 7/16-in. square twisted bars, spiral wound with No. 4 iron wire about 2½ pitch. The piles were cast on the Arkansas dock using 1:2:4 concrete from the river mixing plant, and were removed to the storage yard by a locomotive crane after 48 hours, where they were cured 30 days or more before driving. The concrete in the pedestals was made from crushed rock delivered on cars, and was mixed by a plant rigged on a flat car with tower and spout delivery. This car ran down the center line of the viaduct, and the four pedestals of a tower could be poured from one position of the plant. One of the accompanying illustrations shows the plant working on the last of the pedestals, and the steel forms used for the pedestal shafts.

Ralph Modjeski is the consulting engineer in charge of the design and construction of the bridge, and W. E. Angier is assistant chief engineer. The Union Bridge & Construction Company, Kansas City, Mo., were the contractors for the entire substructure, including the channel mats and bank protection work. They were represented in Memphis during the first season's work by H. K. Seltzer, vice-president and chief engineer, and later by J. F. Wilhelm, engineer of construction.

FRICTION SPRING DRAFT GEAR

On page 832 of the *Railway Age Gazette* for April 16, 1915, there was published an article with the heading given above, descriptive of the Slick friction draft gear. The first paragraph of this article read as follows: "The drawing below shows the plan and half-sectional elevation of the Slick friction spring draft rigging which was recently developed by the Carnegie Steel Company, Philadelphia, Pa." Through an unfortunate error the name of the manufacturing company was given incorrectly; the Slick friction draft rigging was developed by the Cambria Steel Company, Philadelphia, Pa.

A New Railway for India.—The government of India has granted a concession to the Khoolna Bagirhat Light Railway to build a 20-mile, 2½-ft. gage line from the east bank of the Rupsa river, opposite Khoolna, the terminus of the central section of the Eastern Bengal Railway to Bagirhat, the headquarters of the most important subdivision of the Khoolna district and a place of considerable importance. The present communication between the two places is unsatisfactory, steamer service having been discontinued because of the silting of the River Bhairab, which runs parallel to the proposed railway. The country through which the line will pass is populous. The line will be operated by the Eastern Bengal Railway.

NEW ENGLAND AND THE NEW HAVEN ROAD*

By Howard Elliott
Chairman of the Board of Directors and President of New York, New Haven & Hartford

In discussing the railroad and public utility question the opinion is sometimes expressed that the public cannot be expected to pay a return upon any more capital than was originally invested in a prudent manner. But is this the whole story, and who is to decide today what was prudent 10, 20, 50, even 100 years ago, as in the case of the Norwich & Worcester road? Must we not, as long as we stick to the theory of private ownership of public utilities, allow those private owners to make their investments with the hope of a profit inasmuch as they have to assume the burdens that come with increased values and take all the risks of loss?

Prudence, if carried to an extreme, may stop all progress. What would be the conditions in America, in the United States today, if Christopher Columbus, Amerigo Vespucci, Vasco Nunez de Balboa, John and Sebastian Cabot and daring spirits like them had been prudent? Emigrants to the west who followed were not always prudent, but they helped to make an empire. Where would our great American manufacturing and transportation enterprises be if men of enterprise, ingenuity and resource throughout the whole period of wonderful development of the last 50 years had not had the courage to enter unknown and untried fields of human endeavor and really been imprudent on many occasions?

It is so easy to look back, criticize and point out the mistakes of others, and so hard to look ahead, do constructive work, and take the chance of failure in the hope of producing results that are to benefit a whole community and a whole country.

Under private ownership we have built up in this country a very remarkable system of railroads, public utilities and large industries. They furnish more of comfort and convenience to the people of the United States than are obtained anywhere else on the globe. In doing this great work, the private owners have made mistakes, of course, and a few men have made great fortunes—comparatively few, if you take the trouble to count up, when the vast number of men engaged in the constructive work of the last 50 years is considered. Only 357,598 persons in our population of 95,000,000 had an income of $4,000 or more, according to the report of the commissioner of internal revenue for 1913, and the greater proportion of these were in the $4,000 class. Because of these mistakes; because of a few great fortunes; because the growth of these great businesses has been very rapid and some of the men guiding them have not always grown as rapidly and considered carefully enough the rights of the public, there has been developed a system of regulation by state and national commissions. This is right and proper because human nature is such that people with power, unless checked, sometimes exercise that power unwisely. The regulators, however, given great power by the people, are human, too, and the business of regulating the public service corporations and the business enterprises is new, and men are trying to find out the best way to do it.

In the evolution of the regulatory system, mistakes are being made, and the absence of a check upon the vast powers of the various commissions has led to some arbitrary exercise of those powers and some harm has been done by this regulatory system. I am glad to say that some of the state and national commissioners, particularly in New England, realize the seriousness of the situation and the great responsibility that accompanies the unusual powers that have been delegated to them and that they are acting accordingly and are now trying to protect the public service corporations and business of the country.

VALUATION

A very important problem before the country today is that

*From an address to the members of the Eastern Connecticut Development Committee and of the Civic Associations of Norwich, New London, Willimantic, Putnam and Danielson, at Norwich, Conn., on April 8, 1915.

which involves the fair valuation of railroads and public service corporations.

This matter is very vital to the New Haven road and to the welfare of New England because of the present disturbed and depressed condition of the transportation business. The Interstate Commerce Commission under the direction of Mr. Prouty and with the hearty co-operation of the company has just begun the valuation of the New Haven.

In 1910 a valuation of the New Haven property was made under the direction and by authority of Massachusetts. The engineer in charge reported to the state authorities that there was a value at that time in the properties of $101,000,000 above the par value of securities outstanding. In arriving at his result the engineer did not include anything for intangible assets such as those taken into account by the supreme court of Washington.

WORLD CHANGES AND TERMINALS

The country has grown since 1910, and certain world changes are coming, which will increase rather than decrease the value of the New Haven property.

One result of the European war will be to make the United States the leading commercial and financial power of the world. Furthermore, it will increase the commercial importance of industrial centers in New England and New York. The value of the New Haven road today, with its important terminals in all these cities, is certainly no less than it was in 1910. Terminals in great cities are hard to obtain and it is slow work developing them. The great South Terminal station at Boston and the approaches over and through which 35,000,000 people go to and from their homes each year, and the great freight yards and docks in Boston, because of their location and use by the public, have a value far above the original cost which in some cases was incurred many years ago. The same may be said of important terminal properties in Providence, Hartford, New London, New Haven and many other places. Terminals are hands and feet to the railroad; without them the road is as helpless as is the man.

The much discussed New York, Westchester & Boston road has been most costly, but looking ahead a few years this entrance to the city of New York through this road will be of great value in facilitating business between New England points and that city by taking some of the local short-haul business off the main line which at times is overtaxed.

When the valuation of the company's property is made, I firmly believe that on any fair basis there will be more than enough value found in these great terminals, above what they now stand on the books of the company, to offset the losses that will probably be sustained in selling the properties under the decree of the federal court. It is especially important to the general financial health of New England that all reasonable elements of value shall be taken into account in arriving at the value of the New Haven road because its securities are such an important part of the financial fabric of New England.

Recently the commissions, state and national, have permitted the New Haven to make several increases in passenger rates. People naturally do not like to pay more, but it seems better for New England to place more of the burden of supporting her railroads on the passenger travel and in that way make it less necessary to advance the freight rates on raw materials, manufactured articles and food products.

An examination of the passenger train earnings of the company for two periods of two weeks each shows how many passenger trains are being run that contribute nothing directly to the financial upkeep of the road.

	July 18-31, 1914		January 18-31, 1915	
Trains earning per mile:				
50 cents a mile or less...	619	25.2 per cent	670	31.9 per cent
50 cents to $1.....	660	26.9 per cent	618	29.5 per cent
$1 to $2	621	25.2 per cent	494	23.5 per cent
Over $2	557	22.7 per cent	316	15.1 per cent
	2,457	100 per cent	2,098	100 per cent

In the two weeks in January there were 257 trains running daily, except Sunday, that earned 25 cents a mile or less.

In the eight months ending February 28, 1915, the average cost of running all classes of trains, freight and passenger, was, without taxes, $2.04 and for so-called "transportation expenses" (nothing allowed for maintenance of way and equipment and administration) the average cost was $1.13. Thus, you see that out of the 2,000 to 2,500 trains run every day, more than half fail to make the average cost of running without taking any account of maintenance or overhead charges; and this, too, in spite of the fact that during the past year the company has discontinued many of the poorer paying trains. This non-remunerative service is a direct contribution to the general development of New England business as a whole.

GENERAL OBSERVATIONS

This New England railroad situation, with conflicting laws in different states, calls attention very forcibly to the desirability of a federal incorporation act for those railroads the majority of whose business is interstate. Exclusive federal jurisdiction over corporate affairs and of finance would not interfere with the rights of the states in matters of local regulation. A simplification of the relations between the railroad and one central governmental agency as to corporate and financial questions would save a great deal of time and energy now used by officers in appearing before many different state organizations, and give them that much more to devote to details of management and to constructive work for efficiency, economy and improved service to the public.

The present condition of the American railroads is due in part to an effort on the part of the country to fix rates and service by regulation, and at the same time have them fixed by competition, thus creating an almost impossible condition, somewhat destructive of results and values. It is a question how far it is to the public interest to apply the so-called anti-trust law to the transportation business. Well organized, prudently managed and wisely regulated combinations of railroads may, in the long run, produce greater efficiency and service to the public than excessive competition, with the resulting duplication of facilities and increased expenses.

A SECRETARY OF TRANSPORTATION

To day the government recognizes some of the great commercial activities of its population by departments and cabinet officers, such as the secretary of the treasury, secretary of agriculture, secretary of commerce, and secretary of labor. The transportation business of the United States is next to agriculture in importance, in volume, and in its relation to the welfare of the whole country, and it should have a defender in the councils of the cabinet.

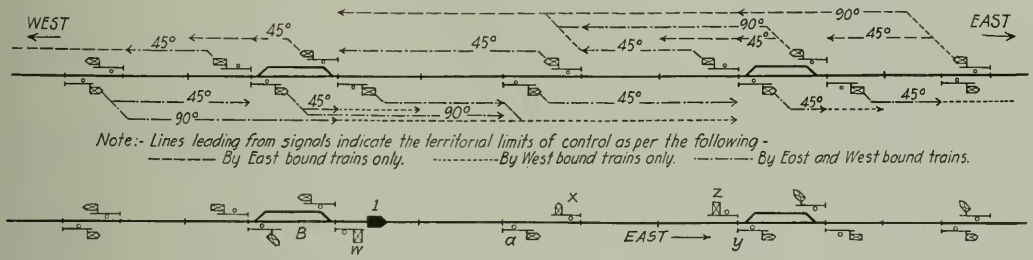
I believe it would be well to have a department of transportation, with a secretary of transportation at the head of it, who would be a member of the cabinet. Such a man would of necessity have to champion somewhat the rights and privileges of the transportation business just as the secretaries of the treasury, commerce, and labor speak for their particular subjects. Such an officer would have a wholesome balancing effect between the demands of the public and of the regulatory organizations on one side, and any errors of policy and management on the part of the owners of the property on the other side. These are great questions which require the careful thought of just such organizations as your development committee. They may not seem to affect you very much, but until they are settled and settled right they do affect everyone in the United States.

With a settlement of this great transportation question on a "live and let live" basis, there will be more time for the great machinery of the railroad organizations to do constructive work in helping to build up the territories served by their roads not only to the advantage of the manufacturer, but what is even more important, to the farmer, a subject to which your committee is paying very proper and effective attention.

THE ENGLISH NATIONAL UNION OF RAILWAYMEN.—Advanced figures published by the National Union of Railwaymen show that at the end of last year it had 273,362 members.

AUTOMATIC BLOCK SIGNALS ON THE WESTERN MARYLAND

In connection with a general program of extension and improvement, the Western Maryland recently completed the equipment with automatic block signals of the 61-mile single-track section of its road between Big Pool, Md., and Cumberland. This is an important single track line between a number of lines on the east which converge at Hagerstown, Charlton and Cherry Run, and two heavy-traffic lines on the west which join near Cumberland. A portion of the line signaled passes through a very rough district, necessitating many deep cuts and tunnels, as well as nine crossings of the Potomac river. The railway followed the banks of this river, crossing and recrossing to obtain the most advantageous locations. The signals through the tunnels were put in service first, before construction was started on the other parts of the line, usually four signals at each tunnel.



Arrangement of Automatic Block Signals on the Western Maryland; Single Track

The 61 miles of track between Cumberland and Big Pool includes 38 miles of tangent and 23 miles of curve, with 3,182 deg. of curvature. The maximum curve is 6 deg., and the maximum grade is 0.3 per cent. Considering the ruggedness of the country, these standards are quite low, and the gradient is so low that it was not necessary to consider it in the location of the signals. Serious difficulties were encountered, however, because of curves, rock cuts, tunnels and bridges. There are five tunnels with a total length of 10,144 ft. There are 23 bridges, 9 crossing the Potomac river with a total length of 6,464 ft., 4 over the Chesapeake & Ohio canal with a total length of 387 ft., and 2 separate crossings of the Baltimore & Ohio with a total length of 370 ft. All other bridges total 875 ft., giving a grand total of 8,005 ft. of bridges

A short time ago the company put in effect on this section of the road the telegraph block system; but recently most of the telegraph was superseded by telephone, at which time it was possible to effect a reduction in the number of employees concerned in despatching trains, some offices being discontinued. There was no further reduction in this force when the automatic signals were installed.

The signal system used is the Union Switch & Signal Company's "A. P. B." system, providing against opposing movements to the siding in advance and rear protection the same as on double track. The rules of this road, however, allow no movements past either an absolute or a permissive automatic signal on single track without sending a flag ahead. When a train encounters a signal at stop it must be flagged through to the next signal or to the next telephone where communication may be had with the despatcher. Control from the train order signals at the stations is carried back through one automatic, or if it is very close, through a second automatic signal, so that the engineman is given ample notice to stop for orders. The general arrangement by which signals are successively changed as a train passes over the road is shown in the accompanying drawing.

Because of the curvature, cuts and tunnels it was found difficult to get good locations for intermediate signals and provide a good view for the engineman, and therefore, except in two cases, there is but one intermediate signal in each direction. The intermediate signals are staggered, and the maximum protection was obtained by arranging the circuits so that the intermediate signal for the movement in the opposite direction stays at stop until the rear of the train proceeds far enough to secure the indication of the starting signal for the opposite direction at the next siding. This is explained in the lower part of the drawing. Thus if a following train has left the siding in the rear (B), the leading train will not secure a proceed signal to back up. Should two trains, one eastbound and the other westbound, pass starting signals at the same time and proceed toward the center of the block between sidings, they would be stopped by the intermediate signals before meeting.

For example, in the drawing, train No. 1 when it passes x would, under certain arrangements, allow that signal to go to

Intermediate Signal at Entrance to Tunnel

A Five-hundred-foot Wire Span

the clear position; but in this scheme of signaling it remains in the stop position until the rear of the train has passed signal *y*. If, then, a following train had passed *B*, it would hold signal *z* at stop and warn the leading train not to back up.

In this arrangement it is necessary to hold signal *x* at stop, as noted, because signal *w* assumes the diagonal position when the rear of train No. 1 passes signal *a;* and if signal *x* assumed a proceed position when the rear of the train passed, it would be possible for the train to back up, under a clear signal at *x*, at the same time that a following train proceeded past caution signal *w*. In other words, as the block from signal *w* to signal *x* has no preliminary, one of these two signals must be held in the stop position against opposing movements.

On account of the possibility of slides in the rock cuts where the rock is constantly spalling off, emergency knife switches were provided, located in boxes attached to the sides of the signal cases. These boxes are locked with standard switch locks. If the track is found obstructed the knife switch may be opened, which will set the signals in both directions at stop.

The night color indications are white for clear, green for caution and red for stop. Signals are double-case ground-mechanism, three-position, upper-quadrant, low-voltage style S, operated by direct current. Switch indicators are used only at ends of passing tracks which are long enough to accommodate a train of some size and where there is no double signal location. Switch indicators are of the semaphore type, unilluminated at night.

BSCO battery is used for both line and track circuits, 16 cells being provided for the signals, and 3 cells in multiple, with re-

High Post to Make Signal Visible Beyond Hill

sistance in the positive lead, for track circuits. At double signal locations, both banks of battery are placed in one Massey style C well, while at single locations they are placed in a style K well.

Before putting the installation into operation, the signal department prepared a chart showing a typical arrangement of signals and the operation while a train was passing through a section. A track layout was also prepared giving the location of all side tracks, signal numbers and approximate distances between signals. These were used in instructing the trainmen and were made as simple as possible.

Each signal maintainer has a helper. He has a gasolene motor car, and in addition to looking after the signals he takes care of all lamps, batteries, highway crossing bells and outlying telephones. Signal maintainers are required by the operating department to pass an examination on train rules and train orders, and the movements of the motor cars are made on orders from the despatcher. The work was installed under contract by the Union Switch & Signal Company. E. E. Bradley, signal engineer of the Western Maryland, had supervision over the design and construction and is in charge of maintenance.

CONTINUOUS HOME ROUTE CARD RECOMMENDED

The committee on relations between railroads, of the American Railway Association, has accepted the recommendation of the Association of Transportation and Car Accounting Officers to submit for general use a continuous home route card, for use with freight cars when away from the home road; and Secretary W. F. Allen, acting in behalf of the committee, has issued a circular giving the rule proposed for the guidance of station agents and yardmasters, in the use of the cards, and showing also a fac-simile of the proposed card. This card is 3¾ in. wide and 9½ in. long; a reduced reproduction of the face of the card is shown herewith. There are spaces for thirteen notations of transferences of the car from one road to another; the back of the card has 17 more spaces, making 30 in all. When the car has been transferred from one road to another 30 times (if it has not then reached home) the rules provide for the use of a second card, to be attached to the first, and containing spaces numbered from 31 to 62 inclusive.

The committee has not yet presented its formal recommendation to the association, but in view of the desirability of a gradual introduction of the plan, it is recommended that all members begin using the new card on May 1, 1915.

The first and perhaps the most important feature of the regulations is a requirement that the road owning the car shall prepare the card, and deliver it with any car delivered to a connection. In case this card is lost the road losing it should at once make a new card to go with the car for the rest of its journey.

Until action by the association the use of this substitute card will be optional. The committee intends, however, to recommend a rule for the use of such cards. As a substitute card shows an incomplete record of the car since it left its home, it may not afford full information for the car's return; but in that case the receiving road can return the car to the delivering road or to the road making the substitute card.

The committee calls attention to the desirability of having uniform stamps for making notations on the cards; and Secretary Allen (75 Church street, New York City) will take orders for rubber stamps, ink pads, etc.

A number of important railroad systems have used continuous home route cards for some time, within their own territories, and have found the plan very satisfactory. Knowing the route by which a car has come, an agent can often save miles of car-haul, and perhaps days of per diem charges, by sending a car back to the delivering road by a shorter route. The proposed rule will require that the short route be used whenever it can be done without creating empty mileage in excess of the original loaded haul.

The Real Value of a Freight Locomotive*

As Determined By the Transportation Department; Each Movement Must Be Carefully Studied and Analyzed

By N. D. Ballantine
Assistant to Second Vice President, Rock Island Lines

In studying the value of a locomotive, time is an essential factor, and any study which does not take into consideration all the factors affecting the machine, that is the entire time from its purchase to the scrap pile, fails to fully accomplish the task. It may be profitable to scrap and replace, or modernize; the new locomotive may not be profitable if it be a radical departure from established custom or not properly designed for the purpose for which it is to be used.

This is said with a full realization that there are many small roads or light divisions of trunk lines where the freight service is practically fixed by arbitrary local or through freight runs, concerning which the superintendent can readily keep all such information in his head or a vest pocket memorandum book, and no amount of records or statistics made therefrom will bring about a reduction in expense incident to train service, engine mileage or miles per day per engine. Where such a condition exists the amount of labor to keep the data is insignificant, but it is of value to have all data on a large system kept uniformly that the aggregate may be obtained, as during a serious congestion or an unusual condition, it may be of value to the distributing officer, who cannot work intelligently by a rule of thumb.

With respect to the cost of producing such data my opinion, based on experience, indicates that where all other data of a similar nature is discarded and all work on the one system on a number of light divisions, no increased labor expense can properly be charged on divisions having 75 to 100 freight locomotives assigned. A $60 to $75 a month clerk can summarize the data in from six to eight hours work per day. The work of summarizing and working out averages for 21 divisions in the general office can be done in from 30 minutes to one hour's time per day.

Considering a modern freight locomotive worth from $25,000 to $30,000 with a potential gross freight revenue, when actually moving freight, of from $75 to $100 an hour, does it not seem to warrant a complete analysis of its use while in the hands of the various departments? Consider also the ever present tendency to shift blame from one department to another. If a potent factor in producing friction between departments is due to an absence of definite information as to all the facts, is it not worth while to produce the data so that each department has first hand opportunity for introspection so far as concerns the locomotive detention while in its possession, and realizes that the same data is correlated into the whole, from which the general officer can intelligently "judge the quick or the dead."

There is a growing tendency towards the introduction of abnormally large power units. Any radical departure from well established practices or customs in railroad service naturally carries with it changes which in their ramifications beneficially or adversely affect many departments. As an illustration, consider as a maximum, a given sized locomotive, with main and passing tracks, bridges, yards, clearances, turn-tables, coal chutes, water cranes, roundhouses, shops and roundhouse machinery to properly handle them. If one or more locomotives are purchased of from 30 per cent to 60 per cent greater tractive power, with dimensions necessitating a change in any or all of the above mentioned factors, then the additional expense incident to such changes should be considered whether charged to additions and betterments or operation.

The principal object in the purchase of new locomotives is doubtless to take care of the "peak load," to decrease the cost of operation and facilitate the movement of traffic. After they are purchased the operating man need not bother himself about the interest, taxes, insurance and depreciation. They are "with us always," but his problem is to so utilize the power as to reduce the cost to a minimum during periods of light traffic, and during the "peak of the load" to move the traffic as cheaply as possible, but move it. Congestion of traffic is as dangerous to a railroad, as is pneumonia to an individual, and it is to avoid this condition and clearly point out the economics for each division during times of heavy demand that it is so essential to have reliable and current data produced during the entire period. Assuming that the peak of the load extends over a period of three to four months, it is evident the excess number of locomotives, or their equivalent, to take care of this load, have no earning power during eight or nine months of the year, but are a liability and expense; during the three or four months of heavy demand, their earning power is quite a variable factor. In fact during this period only is the opportunity present to obtain the maximum return from the investment, hence the importance of a time study with a view of having as few engines as possible tied up to protect a heavy movement.

While records or statistics therefrom do not necessarily of themselves bring about economies, it is submitted that with a problem containing so many unknown factors, many of which are very important and substantially affect the net results, if they can be set out and their proper relations ascertained, at least some operating men should be able to interpret them and knowingly effect economies in transportation. They are not a cure-all but an index or pointer to those who can read and interpret.

As an illustration of some of the methods by which such data can be used, let us take some data which for the sake of argument we will say are typical for a given division of 480 miles with 60 per cent of its mileage branch lines, all of it single track, with a train density of 14 per day, seven freight and seven passenger, and with 52 freight engines assigned and an average of 41 engines available.

Mechanical department, total		14 hr. 03 min.
Roundhouse		7 hr. 46 min.
Classified repairs		2 hr. 50 min.
Running repairs		3 hr. 27 min.
Terminal detention		3 hr. 27 min.
Regular schedule		2 hr. 06 min.
Stock, fruit, etc.		07 min.

Accidents, washouts, etc.		01 min.
Block signals		02 min.
Engine failures		03 min.
Car failures		03 min.
Miscellaneous		18 min.
Weather conditions		.....

The average tractive power of the engines was 37,700 lb., the gross tons per train mile averaged 858 tons, the average miles per engine per day on assigned basis 63.8 and on available basis, viz., excluding those in shops 79.3. The average speed between terminals was 9.8 miles an hour and when actually running 17.5 miles an hour. The delays between terminals per 100 freight

*Abstract of a paper presented at the Western Railway Club meeting, April 20, 1915.

train miles was 4 hr. 29 min., of which 1 hr. 27 min. was meeting trains, 2 hr. 18 min. station work and 44 min. miscellaneous items. Overtime was $90 per day, $20 of which was terminal overtime, and $70 road overtime. The gross freight earnings of each engine was 76 cents a minute while running and $176 per day.

From the division of time shown above, it will be noted that the mechanical department had the power 58.5 per cent of the total time, and that the balance of the time, that is 9 hr. 57 min., it was in the hands of the transportation department, 65 per cent of it is between terminals and 36.6 per cent actually running. This, of course, considers all trains, locals, mixed and through, the schedules of which are fixed; when traffic is heavy it is easier to increase the miles per day by reducing the terminal delays. It is fair to assume under normal conditions that if the transportation department can utilize one-third of the time the power is in its hands, in moving traffic under stress of heavy traffic, this proportion can be increased. We know from experience that it so works out in practice and that it can utilize the power for at least 50 per cent of the time it is in its possession. The question then comes, "What can be done to increase the actual running time or revenue producing period?" What increased return can be expected?

Assuming the average earnings per gross ton mile to be 2.94 mills, and the average engine to haul 858 gross tons per train at 18 miles an hour when actually running, the earnings would be $44 gross. One half an hour increased use per day would mean an increase of $22 per day for each hour's decrease in delay on the part of either the mechanical or transportation department. Put in another way, let us assume the average detention to all engines was reduced one hour. This would give the transportation department 52 engine hours, from which we should expect it to utilize 26 hours actually running and moving freight. As the average running time per locomotive per day was 3 hr. 38 min., this would be equivalent to an increase of about seven engines, increasing engine mileage 455 miles hauling 858 gross tons per train mile, and earning an equivalent of 2.94 mills per gross ton mile, or $1,148 per day. At the same time this additional train mileage would produce 12,285 more car miles per day based on handling 27 cars per train. Assuming that the average miles per car per day was 24.6 miles prior to the time this improvement occurred, this is equivalent to increasing the car supply approximately 500 cars, and the miles per day 12.5 per cent—a cash equivalent from a per diem standpoint of $225 figured at the current per diem rate of 45 cents per day, which item might properly be credited against any increased cost necessary to bring about the reduction in freight car delay and increase its utilization.

There is an important relation between transportation expense and the cost of freight equipment, namely that for every dollar spent for freight transportation, from 30 to 40 cents in addition is spent for the freight car in which it is moved; the items included in this comparison are shown below:

Transportation Expense (For each $1.00)	Cost of Freight Cars 30 to 40 cents
Under I. C. C. Classification	Which, in the case of foreign or private line cars is not a charge to operating expenses, but to the hire of equipment account; in case of owned equipment operating expenses are only affected to the extent of the net cost of repairs, renewals and depreciation, including insurance. A very considerable sum represented by the funded debt or mortgage and the taxes are not charged to operating expenses.
Supervising transportation	
Station service	
Yard service	
Road engine service	
Train service	
Other transportation expenses	
Accounts 371 to 420 inclusive	

The basis generally adopted for the comparison of the maintenance of freight cars is the freight car mile. Under M. C. B. rules the owner of a car is charged with practically all expense of its maintenance except that which may result from accident or unfair usage, and this expense for the railroads varies roughly from three-quarters of a cent to one and one-quarter cents, or, say, a general average of one cent per car mile. If road A is a heavy borrower of freight cars, its maintenance of equipment expense will be materially reduced as the owner of the car will be paying directly, or indirectly, for repairs to cars, the expense for which is charged to his maintenance of equipment account, while the money received from A as a rental is credited to the loaning roads' hire of equipment account. Road A at the same time charges the amount to hire of equipment, which however, is not an operating expense. The net result then of loaning equipment is to increase the hire of equipment account at the expense of maintenance of equipment, the former being an "income account" and the latter an "operating expense." If the car mile is a controlling factor in the cost of repairs, it will readily be seen that if the borrower so handles the car as to make an average of 45 miles per car per day with it, the owner will have to spend all the car per diem received from the borrower to keep up the repairs while he is using it, receiving nothing for interest or taxes. While this may be a slightly different angle from which the subject is viewed by many operating men, the reason for it is undoubtedly due to the fact that our accounting methods do not properly reflect in operating expenses the influence which the ownership of freight cars has on the net return from the investment therein. Its proper relation to the operating man and his operating expenses would seem to be worthy of considerable emphasis, when the amount involved represents the equivalent of 30 to 40 per cent of the total amount spent for conducting transportation expenses.

Reverting now to the net return from a decrease in delay to freight power, keeping in mind the typical division, let us set down the tangible debits and credits as far as we can.

		Dr.	Cr.
455	Engine miles, repairs at 15.2 cents per mile	.....	$69.16
390,390	Gross ton miles at 2.94 mills revenue	$1,148.00	.....
12,285	Freight car miles, repairs at .7 cent	.....	90.19
500	Freight car days at 45 cents per day	225.00	.....
	Yard service at 21.9 cents per mile	.....	99.64
	Road engine service at 40 cents per mile	.....	182.00
	Train service at 16.2 cents per mile	.....	73.71
	Other transportation expenses at 16.4 cents per mile	.....	74.62
		$1,373.00	$589.32

Considering the above items alone and without going into the detail accounts, the locomotive would appear to produce a return of 233 per cent of the expenses incurred. Included in the above items, however, are a number of factors which will not increase the cost as much as indicated, for the reason that many of them do not vary in a direct relation with the train miles. For example, under yard service accounts, at least 30 per cent of the items going to make it up, such as yard masters and clerks, switch and signal tenders, yard supplies, operation of fuel station, water, lubrication and operation of joint yards would not vary directly as the train miles. If the yards were not working to their capacity, there might be an increase only in fuel, water and oil, and that only perceptible. Under road engine service the engine house handling, operation of fuel stations, water and other supplies, items approximating 12 per cent of the amount, would not be directly affected. Under train service expense the items other than train supplies, cleaning, heating, icing, watering, coopering and grain dooring freight cars, as well as detouring freight trains, represent 16 per cent of such expense and do not necessarily vary directly as the train miles. Under other transportation expenses, such items as block signals, interlockers, crossing flagmen, drawbridge operation, telegraph and telephone operation, stationery and printing, and operation of joint tracks, amounting to approximately 20 per cent of the items, would not be affected appreciably.

30 per cent of yard service expense	$33.20
12 per cent of road engine service expense	21.70
16 per cent of train service expense	11.75
20 per cent of other transportation expense	14.90
	$81.55

Deducting 81.55 from the $589.32 leaves $507.77, or considered from this standpoint the return would be 240 per cent instead of 233 per cent on the first premise.

In the above calculation no consideration is given the question of track maintenance, as it is rather an intangible, although

an important factor. However, additional expenses on this account should of course be deducted from the $507. It should be clearly understood that this method of figuring costs, is not a proper one for the purposes of rate making, as it eliminates a large number of items of fixed or current expenses which would not vary regardless of the manner in which the traffic is handled, but which items should be included in any method of computing entire costs of service. The above outline in a general way indicates what economies or increase in utilization might be expected from improving given conditions.

Let us now consider the comparison of results from a change in method of handling through freight power, viz., from slow to higher speed, with consequent decrease in gross tons per train. For the purpose of this comparison we will assume the data is obtained from an analysis of the locomotive utilization, together with the gross tonnage and unit cost figures carefully produced and not based upon general averages of such units. It might be opportune at this time to point out the great difficulty in attempting to forecast results of a change in working conditions. For example a trainmaster once said to me, "The meeting points on a single track railroad vary as the square of the number of trains run; that is, if you double the number of trains you quadruple the number of meeting points." A little thought indicates the statement by itself is incomplete and misleading, as two very important factors are omitted, namely, the time of day at which the trains are to be run, and the average speed at which they are to run between terminals. It can readily be shown from a theoretical point, as well as in practice, that it is possible to double the number of trains run and decrease the number of meeting points or delays incident thereto. Hence just what effect a change in the number of trains will have on the question of delays due to meeting trains is an indeterminate factor. But if the data is known for a particular division with given facilities and a given train density, the actual effect may be readily found, and at the same time, any other unusual factors which may be injected into a given day or interval of time, can be shown and its bearing on the whole noted. It is a fact, however, if tonnage is unbalanced, and a reduction of 15 per cent in the average tons per train be made, the train density will increase 30 per cent. The important thing to watch when a reduction is made, say for the purpose of cleaning up a congestion, is whether the increased speed between terminals with less tonnage, combined with the mechanical and terminal delays enables the production of an increase in gross ton miles per day with given power? Secondly, what is the variation in tonnage and cost?

For the purpose of simplifying as much as possible we will disregard expenses incident to maintenance of way, traffic, general and fixed charges, such as supervision, station service, etc., confining ourselves to those items which are appreciable and readily allocated, such as engine repairs, car repairs, wages of engine and trainmen, fuel, water and lubrication. It also includes interest on locomotive at 6 per cent and depreciation at 5 per cent, and interest on the caboose at 6 per cent and depreciation at 4 per cent.

	In Direction Traffic. Consolidation Locomotives.		
	Slow Frt.	Fast Frt.	Per cent variation
Percentage distribution of time:			
Mechanical department	34.84	37.19	.....
Terminal	33.37.	31.44	.....
After call time	0.98	1.18	.....
On road running	23.22	23.73	.....
On road running	(5.6 hr.)	(5.7 hr.)	.....
Road delays	5.59	6.46	.....
	100 per ct.	100 per ct.	.....
Miles per locomotive day	83.5	80.5	Dec. 3.5
Miles per hr. when running	19.2	20.9	Inc. 9.
Miles per hr. between terminals	14.5	16.3	Inc. 12.
Per cent efficiency engine loading	91.7	68.6	Dec. 21.
Cost per 1,000 gross ton mile, in cents:			
Fuel	12.8	16.6	Inc. 29.5
Wages train and engine crew	13.6	16.8	Inc. 22.
Total, as above outlined	40.3	50.1	Inc. 24.
Cost per train mile in cents	61.5	57.	Dec. 7.3
Gross ton miles produced per day	153,968	130,000	Dec. 15.2

Cost car repairs at $23.10 per 1,000 G.T.M.	$35.40	$30.00	Dec. 15.2
Cost trans. service and repairs as above	62.00	65.00	Inc. 4.8
	$97.40	$95.00	Dec. 2.5
Add equivalent value per diem on 33 cars at 28 cents per day deducting 17 cents for repairs based on 25 miles per day at 7 mills per mile		9.24	
		$104.24	Inc. 9.3

From the above exhibit, it would seem that regardless of the fact that the reduction of tonnage enabled the fast freight trains to get over the road at an increase in speed of 9 per cent when running and 12 per cent between terminals, combined with a reduction in terminal delay, the mechanical department was unable to turn the power promptly enough and the net result of such handling was a decrease of 15 per cent in the gross ton miles, equivalent to $70.46 decrease in gross freight revenue, an increase in engine repairs and transportation service cost of 24 per cent, a decrease in cost of car repairs, but an increase in loss of use of cars, making a net loss from all the items considered of 9.3 per cent. Regardless of the above, it should be noted that the cost of engine repairs and transportation expense was 7.3 less per train mile.

Comparisons along the basis above outlined made between engines of different types, say Consolidation, Mikado or Mallet, would undoubtedly reveal interesting information, providing it was kept currently and not spasmodically when all concerned were keyed up to concert pitch. Tests made under such conditions are not typical, nor do they generally extend over a sufficient length of time to really be comparable. I have seen cases where engines with 44 per cent greater capacity when in slow freight service with relatively the same loading efficiency as the smaller engines would yield under stress of traffic but 9 per cent more gross ton miles per day. When put in fast freight service they would yield 21 per cent more than the smaller engine, indicating that the larger engine was able to produce more ton miles when assigned to fast freight service. But what about the effect on the track, bridges and equipment and cost of operating at high speeds versus slow speed. Surely the field is a large one and the opportunities inviting.

In view of the fact that the mechanical department necessarily must hold the power for some time, and that when all other factors remain the same, the running time diminishes rapidly as the distance between terminals decreases, it would seem that special attention toward keeping the engines on the road by changing crews without roundhousing would be worthy of investigation, as many divisions are 150 miles long. If engines can, and they do, make successful trips of that length, can it not be stretched another 50 and make "turn around" engine runs with pooled crews, getting 200 miles out of an engine between roundhousing instead of 100 miles on divisions of that length. Suppose we assume a division of 100 miles where the engines now are being roundhoused at the end of every trip and the average detention is 8 hours. If we could eliminate the mechanical delay of one roundhousing and turn the engine promptly upon arriving, allowing the transportation department two hours for call time, and 25 per cent longer for the roundhouse work when the engine gets back to its home terminal, this would increase the utilization per day 12 per cent and not involve any modification in tonnage or expense. This is on the assuming, of course, that the power is turned out in proper shape, as there would be no economy in slighting the work in the roundhouse or shop and have it reflected in an increase in cost of transportation which would more than offset it. There is surely no more economical investment than power well kept up. It is by far the largest element in fuel economy.

While I may seem to have specialized on the mechanical department detention, there are other directions where economies can be obtained and the results just as clearly shown, such as despatching, coal and water stations, passing tracks, telegraph or telephone offices, sufficient crews, schedules of trains and many others. Station work can be checked to determine when it is more economical to put on a switch engine than it is to have the

road crews do the work and so on ad infinitum. I trust this rough outline may raise questions and bring out some new thoughts which will suggest other ways through which we can obtain a better understanding of the transportation problem and the real value of a locomotive.

ACCURACY OF GRAIN WEIGHTS*

By F. C. Maegly

Assistant General Freigbt Agent, Atchison, Topeka & Santa Fe, Chicago, Ill.

Weighing, grading and remitting are the three principal problems of the grain shipping business. There should be a closer understanding between the shipper, carrier and receiver of grain concerning these three problems. The carrier is really a partner of both the shipper and the receiver of grain. Carelessness, error, or cheating on the part of anyone of these affects all.

Many shippers and receivers provide themselves with suitable grain weighing scales, and safe elevator equipment between scales and cars at the points of loading and unloading. Where such shippers and receivers weigh the entire contents of each car with care and accuracy, and are careful to properly apply the cooperage, the grain shortage evil is conspicuous by its absence.

The carriers usually weigh grain en route upon their first most convenient track scale. The net weight so determined, by the use of gross, marked tare, and a proper allowance for the grain doors used, is sufficiently accurate for the purpose of assessing the carriers' freight charges, but is not sufficiently correct for buying and selling grain.

The buyer and the seller of grain almost invariably agree upon the terms of sale, both as to grades and weights—that is to say, either the shipper's or the receiver's, or some other agreed or established weights and grades, govern the transaction. Even in the case of cross-town movement of bulk grain, where the opportunity of loss from the car is practically eliminated, the buyer and seller agree either that the loading or the unloading weights shall govern.

If the shipper and the receiver would be more inclined to make a confidant of the carrier, checks to prove the efficiency of both the loading and the settlement-term weights could then be made more positive. For example, if the carrier's agent were given a carefully ascertained shipper's loading weight, and the information that the shipment has been sold on the basis of receiver's unloading weight, efficiency tests could be developed which would soon develop the prevailing accuracy of such weights, and particularly of the controlling weight. Such tests would be made with extraordinary care.

Various grain shipping organizations are now recommending that shippers provide themselves with scales of recognized standard, and with elevator loading and unloading equipment that is safe against possible loss or confusion of weights between scales and cars; so that a shipper's certificate of loading weight may be furnished with the shipping instructions for each car shipped; such certificate to show the scale, the dates and drafts weighed, the total weight, the signature of the weigher, and a positive declaration identifying such actual weights with the car and shipment.

Each shipper should maintain permanent and complete record of all of his weights of first entry, and should enter upon such record for each car the outturn reported to him by his customers. The shortage or the overrun, as the case may be, should be extended for each car. The receiver of grain should also maintain a complete and permanent record of all of the unloading weights for each car, and to carry out the program of co-operation, the receiver also should furnish the carrier's delivering agent promptly with a written certificate, or declaration of his unloading weights, said certificate to set forth the scale, the dates and drafts weighed, the total weight, the signature of the weigher, and a positive statement identifying such actual weights with the particular car and shipment. Under such a plan, the carrier would be in the strongest possible position to co-operate to the full limit with shipper and receiver, in the effort to bring about the elimination of error and the establishment of the proper standard of accuracy.

The grain carrying roads are giving serious thought to this problem, and I am sure that it will be solved with the co-operation of the grain-shipping and receiving organizations. For over two years experiments have been tried by means of an extra slip carried with way-bills for bulk grain, the same showing: (1) The name of the shipper, station, elevator, scale, car number and initials, car inspected by, and the shipper's certified loading weight. (2) The in transit record of railroad track scaling; the leakage and loss of grain from car, if any, and (3) the consignee, destination, scale and declared unloading weights.

It is contemplated hereafter to have the delivering agent extend the difference between the shipper's and receiver's declared weights, and to require the prompt investigation of excessive discrepancies; but to intelligently investigate excessive discrepancies, the carriers must have a prompt report of the shipper's loading and unloading weights. To this end, the shippers and receivers must provide suitable scales and elevator loading and unloading equipment that is safe against loss or mixup of weights, between cars and scales, at both ends of the transit.

The carrier's record referred to is yet in the experimental stage. It is returned by the destination agent to the proper officer on whose district the shipment was loaded, so that after the lapse of a short time the carrier has before it the history of the accuracy, or inaccuracy, of the weights declared by each shipper of grain. To make that record more effective, and to provide a proper stimulus for greater effort to each individual shipper and receiver, would it not be desirable to have a medium to which the data made up from such cumulative record could be submitted, if necessary, for an expression of approval, or for recommendations as to means necessary to improve results that are not creditable? The comparisons referred to are rendered more valuable by various efficient and impartial grain weighing departments at several of the important grain centers, like Chicago, Kansas City and St. Louis. At the markets named, the existing Board of Trade organizations have established efficient grain weighing departments. An impartial competent tally weighman is present and actually witnesses and records every weight certified by such weighing departments. At busy elevators, in addition to the tallyman stationed at the hopper scale, another tallyman is located down stairs to check the condition of each car, and to supervise its complete unloading and the sweeping of the entire contents into the elevator unloading pit, and delivery to the hopper scale, before the signal to weigh is transmitted from the downstairs floor to the weighman who is located in the top of the elevator. These tallymen are fortified by suitable Board of Trade regulations.

Let us join in a campaign to call every weight by its right name. If it is the shipper's weight, let us call it "shipper's weight." If it is a board of trade weight, let us make sure that it is in fact a weight witnessed and recorded by an efficient, impartial board of trade tallyman. If it is a state weight, let us make sure that an impartial, efficient employee of the state, not interested directly or indirectly in the shipment, actually performed the weighing, or tallied and recorded the weight. If it is a shipper's or receiver's weight, covered by an agreement between shipper and carrier's weighing bureau, let us call that weight the "shipper's agreement weight," or the "receiver's agreement weight," as the case may be. But do not let us fool ourselves, or each other, by calling weights by any other than their real names.

A bill was recently introduced in one of the state legisla-

*Abstract of a paper read before the Kansas Farmers' Cooperative Grain Dealers' Association, Wichita, Kan., March 3, 1915.

tures, requiring the carriers to install a railroad track scale at every station producing 100 or more cars of grain per year. The advocates of this legislation had figures to show that 400 additional track scales would have to be installed by the railroads operating in the state referred to. The total cost of said scales would be approximately $1,500,000, on which the annual interest at 5 per cent would be $75,000. The annual cost of up-keep would exceed $75,000 additional and the annual taxes would be considerable. The cost of the time lost by trains and switching crews in pulling cars to and from the scales and spotting them at industries would add another very great item, to which we must add the delay to all the other freight while passing trains are occupied with such weighing service; also, the expense and interruption to the industries themselves by pulling the cars away from their plants, in order to get to and from the scales with other cars to be weighed, whether for the industries so disturbed or their neighbors.

And then a very large percentage of the shippers located at these 400 additional track scale stations would continue to invoice their grain on the basis of their own and not the track scale weights; and they would continue to sell their grain, as at present, on the (usually destination) weights and grades per agreement between buyer and seller. One state having such a law on the statute books has proved the accuracy of the statement just made, in that the grain shippers who are located at stations equipped with railroad track scales do not use the railroad weights for invoicing purposes.

THE CITIZEN'S RESPONSIBILITY*

By Frederic B. Lincoln
General Superintendent, Erie Railroad

Civic responsibility, as the question resolves itself today, looks a good deal like individual responsibility. The railroads have been making a strenuous attempt lately to enlist the interest of the people in the economic questions connected with the relations of the public to the carriers, but with not very encouraging results. There is not as yet much evidence of comprehension on the part of the people most affected. The general public seems to have but little realization of the extent to which the transportation problem affects the individual citizen. Transportation is the second greatest industry in the country and engages the energies of a fourth of our population. Even the simple question, that of reasonable passenger and freight rates, but a part of the broader problem, has but little attention given to it by the average busy professional or commercial man.

The interdependence of business and transportation and all the important commercial interests, is, however, self-evident when one examines the facts and the observing citizen must agree that co-operation between different interests is of the utmost importance. Co-operation thus far has been greatly lacking. The remedy is simple; the only demand upon the business man is that he give these matters a moderate amount of attention. A very little real study will put his thoughts in the right channel.

The question needs to be studied on broad lines; commerce is subject to regulation by 48 states and the federal government. At present there is very little harmony. It is the duty of the citizen, through the law makers, to cure this defect.

Are you and your neighbors in Newark and Texas and Paterson and Oregon and Passaic and Chicago—for you are all neighborhood friends in this matter—are you going to let this thing drift as it has in the past, or are you going to further perfect this representative organization of yours and through it strengthen the hand of your State Chamber of Commerce and make that a moving spirit in that increasingly powerful body, The Chamber of Commerce of the United States of America, to the end that through active and intelligent organization some reasonable restraint may be put upon class legislation that is almost wholly responsible for the halt in our country's development and the business depression we are facing today? Above all, are you, as average citizens, going to apply to these transportation questions the small measure of time and thought necessary to insure an intelligent direction to those charged by you with legislating the business and social welfare?

*From an address before the Nutley Board of Trade, Nutley, N. J., April 8.

FRISCO SEAWALL AT CAPE GIRARDEAU, MO.

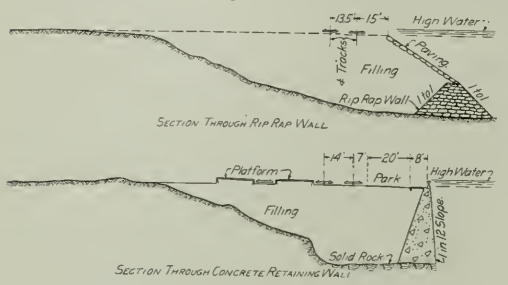
The St. Louis & San Francisco is now reclaiming a considerable area from the Mississippi river at Cape Girardeau, Mo., permitting the straightening of the main line and providing more space for yard and team tracks. At the present time the river makes a considerable indentation at this point and the tracks follow closely around the foot of the bluff. The improvements consist of the construction of a concrete wall out in the river 600 ft. long at the north end and 600 ft. long at the south end with a heavy rip-rap wall 620 ft. long between. The area between this wall and the present tracks will be filled, after which the tracks will be laid on the new location and a new depot erected. A considerable area will also be given over to the city for park purposes across the track from the station and also immediately south of the station.

The concrete wall, which varies in height up to 37 ft., is of a plain gravity section 3 ft. wide on top, requiring a total of 11,000 cu. yd. of concrete. It was built in a maximum depth of water of 13 ft. The concrete was mixed adjacent to one of the tracks on shore, elevated by a tower and spouted into bottom-dumping buckets on a barge on the water. These buckets were then picked up by a derrick on the barge, lowered into forms and opened. The wall at the north end opposite the station is surmounted by an ornamental concrete balustrated protecting a sidewalk.

The rip-rap wall which is located in the water for the entire

View of Concrete Wall and of the Construction Outfit

distance is 6 ft. wide on top and has a maximum height of 20 ft., with a slope of 1:1 on each face. While the concrete wall is located parallel to the track with its top 3 ft. below the top of rail, the rip-rap wall is located on the slope line some distance out in the stream with its top a maximum of 24 ft. below the



Typical Sections of Wall and Embankment

top of rail. On the completion of the wall and of the filling behind it, the slope above the wall will be paved with rip-rap on a 1½:1 slope.

This improvement, which is estimated to cost about $240,000, is being handled under the direction of F. G. Jonah, chief engineer of the St. Louis & San Francisco.

THE CHICAGO, ROCK ISLAND & PACIFIC RECEIVERSHIP

On the application of the American Steel Foundries Company President H. U. Mudge and Jacob M. Dickinson were on April 19 appointed receivers of the Chicago Rock Island & Pacific Railway Company. This is the owning and operating company.

T. M. Schumacher, chairman of the Chicago, Rock Island & Pacific Railway, has issued the following statement:

"The appointment of receivers for the Chicago, Rock Island & Pacific Railway Company by the U. S. Federal Court in Chicago upon the application of creditors was assented to by the president of the railroad because of the absolute inability of the president or the company to give assurances to creditors that their obligations would be met when due.

"Just previous to April 1 in order to meet requirements of $1,600,000 on that date, strenuous efforts were made to secure from various banking institutions in New York a temporary loan. This loan was finally secured at the last moment by the personal endorsement of five of the directors. It is apparent that the company cannot continue raising funds by such a method.

"It is necessary to obtain approximately $2,000,000 on May 1, and with a much less active and attractive collateral from a banker's standpoint upon which to borrow. Furthermore, on July 1 an additional $2,000,000 will be necessary. The short time loan of $2,500,000, due April 30, would only be renewed by the present holders upon absolute assurance from the board that its finances for the balance of the calendar year 1915 have been arranged.

"As such assurance could not be given, it would have been necessary also to meet this $2,500,000 on April 30, making a requirement of $4,500,000 on that date.

"It is very essential for the proper development and economical operation of this property that many grades should be reduced, that a large amount of new steel rails should be immediately laid for the safety of both passenger and freight traffic, and that 5,000 freight cars should be ordered. While car equipment notes could be issued for 80 per cent of the cost of the freight cars, $1,000,000 would be required for the other 20 per cent.

"A receivership at the present time is merely to obtain the protection of the court that the company's physical condition and equipment may be improved, its temporary loans continued and an opportunity be given for working out a comprehensive and permanent plan for financing to preserve for the shareholders the valuable equity believed to be in the property.

"Stockholders should not be confused nor led into the belief that this appointment of a receiver means any immediate foreclosure of the property or the immediate assessing of the stock. It simply means that the way is being prepared for the working out, as above outlined, of some comprehensive plan which will permit this property to grow and expand on good, sound lines to the ultimate benefit of the shareholders."

Answering the American Steel Foundries' petition, the Chicago, Rock Island & Pacific Railway admits each and every allegation of the bill of complaint, and adds:

"Believing it to be its duty to its officers, directors and stockholders to protect its property and business and to treat the same as a trust fund for the security of its creditors and stockholders, the company hereby consents to the appointment of receivers of all its property and consents further that such receivers take possession and operate all such property under order of this court."

The petition of the American Steel Foundries Company sets forth that the creditors are so scattered that it fears isolated attachment suits to the injury of the propery as a whole, so that it might become disrupted and disorganized, whereby security holders and the public would be injured. The complainant frequently demanded payment of $15,818 due to it for materials furnished the railway, but the company pleaded financial inability to pay. Continued operation as an entity under this court's protection is essential to its ability to pay hereafter. Interference of a court of equity for the protection of its rights and the rights of all parties in interest is immediately required, and there is a necessity for immediate appointment of receivers.

N. L. Amster, who was elected a director representing the minority interests, is quoted as saying:

"I would call this Rock Island receivership a huge joke if it were not for the fact that it has brought untold hardship and loss to thousands of innocent and helpless investors.

"The company has never in its history been less in need of a receivership than at this time. The physical condition of the property is now universally admitted to be in better shape than ever before. The earnings of the company, according to the last statements filed with the Interstate Commerce Commission, are far in excess of last year, and larger than ever before. This too in face of the business depression through which we have passed the last year. Now, with business expansion and general prosperity, on the threshold of which this country is just entering, everybody admits that the railroad earnings will be greatly increased. How, in the face of all this, the management could consent to a receivership is beyond my comprehension, and such action is entirely opposed to my feeling in the matter.

"I have practically arranged for a two year $6,000,000 loan, secured by $11,400,000 of the company's refunding and other good negotiable bonds. This would have paid off this $2,500,000 Central Trust loan, the $1,494,000 Choctaw serial notes coming due May 1, and the $1,600,000 Bankers Trust Company loan coming due in September, and would have put the company beyond any possibility of straining any of its securities, but this receivership has put a wet blanket temporarily over this negotiation."

The Chicago, Rock Island & Pacific has a $2,500,000 note, due April 30, and has maturing May 1, $1,494,000 gold bonds of 1912. The June requirements are very small, but in July they exceed $3,000,000, with $4,500,000 more maturing before the end of 1915. The following table summarizes interest and principal maturities up to and including July, 1916:

1915		1916	
May	*$4,997,700	January	$2,739,000
June	104,500	February	8,377,300
July	3,195,000	March	247,500
August	884,900	April	2,662,900
September	247,500	May	2,165,100
October	2,608,800	June	104,500
November	962,400	July	3,176,100
December	83,500		
		Total	$32,496,700

*Includes the $2,500,000 note due April 30.

The above total of $32,000,000 includes $11,600,000 of equipment trust and short term indebtedness.

An Effective Freight Claim Preventive Crusade

Part III—Some of the Schemes Which Have Helped to Reduce Payments $17,000 a Month Since Last June

In the two previous articles of this series we discussed the early development of the campaign on the St. Louis & San Francisco for the reduction of loss and damage to freight and the organization of the so-called freight claim preventive committees which have stirred the employees over the entire system to exert their individual efforts toward cutting out the useless waste, due in many cases to carelessness or thoughtlessness in the handling of freight.

In this, the third and last article of the series, certain methods will be described which have done much to maintain an intense interest in the campaign, and which are more or less novel. It is comparatively easy to launch a movement of this sort, but the hard fight comes after the first novelty has worn off and the scheme becomes more or less commonplace. This issue has been met squarely and straight from the shoulder. The superintendent of freight loss and damage claims lives on the road, and being on the fighting line, as it were, is able to watch the progress of the campaign critically and to keep a perfect stream of ammunition headed from his headquarters to the men who are responsible for results.

SIGNS

A slogan was first adopted: "A One Hundred Thousand Dollar Reduction in Claim Payments for the Fiscal Year." Then followed the placing of signs at such points on the railroad prop-

A Typical Freight Claim Preventive Sign at the Memphis Yards on the Banks of the Mississippi

erty as to attract the greatest possible number of those whom it was desired to interest in the campaign. These signs were of various sorts, a typical one reading: "Prevent Loss and Damage to Freight and Avoid Claims." Sign posts were in some cases erected to carry them; in other cases they were placed on the side or the roof of a building; they have even been worked into the designs of the flower beds at the stations. In some instances electric signs have been erected similar to those which are sometimes used in connection with the safety first movement. Signs were also stenciled on the doors of cabooses, and pertinent suggestions were introduced in one form or another on bulletin boards.

RUBBER STAMPS

A number of special rubber stamps were made and distributed over the system to be used on all correspondence interchanged between those who had anything whatever to do with the movement and handling of freight. The first one of these read:

> An ounce of prevention is worth a pound of cure. Watch what you are doing in order to prevent claims.

The wording on several of the more novel of these stamps is reproduced below:

T R Y
T o make a better showing in freight claim payments,
R educe errors—
Y ou can if you try.

There is no more opportune time than the present to better freight handling. Will you help?

It is easier to prevent errors in freight handling than to correct them, and it is less expensive too.

59% of our freight claims are for amounts $5.00 and less. You are interested and can help reduce claim payments by watching the small leaks.

> Loss and damage freight claim payments is 3.2% of total transportation expense. Help reduce this large item.

Don't talk war; talk claim prevention.

> Careful marking and packing of freight will prevent its becoming lost or damaged.

Freight is half way there when properly marked and packed.

REMINDERS

Closely allied to the messages on these stamps were an extensive series of brief reminders. These were printed on small sheets of paper and as in the case of the rubber stamps were sent out from time to time during the progress of the campaign. In some instances the value of the reminder lay in the terse way in which the message was conveyed; in others it might lay in the peculiar arrangement or wording. Reminder No. 4 was of this sort and read as follows:

A great many claims are
V ery easily overcome
O n all railroads
I f the employees
D ecide to co-operate.

C ut down
L oss and damage
A nd prevent claims
I n all classes of freight.
M any claims are caused by
S mall irregularities which can be corrected.

Reading down the first line of each of these two arrangements we have the words "Avoid Claims," the letters being bold face in order to throw these two words into relief.

Reminder 330 was of a similar type but designed to emphasize the advisability of promptly filling out and sending in the postal cards which were referred to in the second article of this series. It read as follows:

P revent claims by filling out the cards
O f every case or bad situation you know should be corrected.
S end the cards to your Preventive Committee.
T ake time to do this on every case you run across.
A stitch in time will save nine.
L et us all work together—claim prevention.

C atching errors should be our aim, and a $100,000 reduction in claim payments will be easy.
A sk your Freight Claim Preventive Committee for a supply of cards if you have none.
R ough handling of freight cost us last year $70,593.82.
D efective cars cost us last year $72,544.12.
S ee if you cannot help us to cut this down by reporting all bad cases on the cards.

Other typical reminders were:

No. 282—Are you aware that loss of package freight cost the company $60,000 last year? Help to reduce this; see that each and every package is plainly and properly marked.

No. 340—Errors may sometimes not cause claims, but they cost us money in the way of stationery which otherwise would be saved. Watch this leak.

No. 342—Claim prevention is something to which we can all contribute our efforts with good results. Considering the fact that 59 per cent of all claims received are for amounts of $5 and less, you will readily see that close co-operation is necessary. Help reduce claim payments $100,000 this fiscal year.

A large number of these reminders were suggested by committee men or interested employees. The following acrostic was developed on the River and Cape division and was used by the freight claim preventive committee to good advantage:

P revent loss and damage to avoid claims.
R ough handling of cars causes claims.
E veryone is urged to do their part.
V ery few cards are being turned in by yardmen; let us hear from you.
E arnest co-operation is desired from all employees.
N o discipline will be applied for matters reported to the committee.
T his company paid out $435,503.91 in claim payments in the fiscal year of 1913-1914.

C laims are costing this company over $2 for each minute of each working hour, 26 days per month.
L et each one of us remember the slogan: "Reduce Claim Payments $100,000."
A void claims and have better satisfied patrons.
I n reporting small matters, much good can be gained.
M oney saved in claim payments means reduction in transportation expenses.
S witchmen, will you do your part?

BULLETINS

In addition to these reminders, circulars and bulletins were sent out at more or less regular intervals. Claim bulletins addressed to agents, train and yard employees called attention to certain specific abuses which had come to the attention of the claim department and which could have been avoided with a little effort or by a more intelligent handling. Typical paragraphs from two or three of these bulletins follow:

We recently paid four claims for damage to bottles moving in as many cars and earning in revenue less than $300. These claims were filed for breakage which could be the result of nothing except rough handling in transit inasmuch as the bottles were carefully packed and properly loaded and braced under the supervision of employees of this company. The four claims aggregated approximately $550 and left us heavy losers on the traffic handled. In this case carelessness somewhere proved very expensive.

We were required to pay $131.76 for damage to 300 sacks of cotton seed meal loaded in a defective car. Car Inspector at point of origin passed the equipment as fit for this loading and his employer, the company, had a right to expect that the roof would protect the consignment to its destination. However, on arrival at destination, almost the entire load was found to be watersoaked from a leaky roof which Car Inspector at that point declared to have been of long standing, and it was necessary for us to pay the amount mentioned. Surely, the car could not have been in first class condition when originally loaded although it was passed as such.

A car of cotton seed oil recently delivered us in switching service was bit hard enough in the terminal to shift the tank on car frame, breaking steam pipe and requiring transfer. Loss of oil and cost of transfer amounted to nearly $100 which was caused entirely by carelessness in switching.

A claim was recently filed on a car of plate glass which moved about 450 miles without noted exceptions. In the next 200 miles it was set out five times for rebracing and replacing a shifted load. Glass worth more than $1,700 was broken and claim for its value paid. It is very apparent that the car had unusually rough handling on several occasions after it was first set out for rebracing, or the employees repairing the braces performed their duties in a very inefficient manner. Needless to say the loss could have been avoided had every one given this car of glass the same careful handling and attention that would have been given it had it been the property of those who were handling it.

Another series of circulars sent out by the superintendent of freight loss and damage claims is addressed specially to agents and concerns the proper methods of classifying and handling certain commodities, such as eggs, poultry, food products and a variety of commodities which require special attention both as to packing and handling.

EDUCATIONAL BULLETINS

Possibly the most interesting and inspiring of the different series of circulars are those known as "educational bulletins." These are largely suggestive and ordinarily are short and to the point. The following extract from Bulletin 4, for instance, cites certain specific instances where serious damage was avoided, thus preventing claims for loss or damage.

This office has issued periodically claim bulletins showing specific cases where the Frisco has paid out money in freight claims due to transportation errors, and I am thinking that it would be well to issue a circular covering cases where on account of activity of employees, claims have been prevented.

Not long ago my attention was called to a case where a conductor was ordered to pick up a car of race horses for a short haul; after putting the car in the train it was found that it was off center. Conductor immediately decided that it would not be safe to move; shipper offered serious objections to any delay, claiming horses were scheduled for a certain race meet, and further objected to transfer to the only available car, which was a stock car, claiming horses would catch cold. At the conductor's very timely suggestion, blankets were produced by shipper, stock car lined with same, horses transferred and handled forward with but one hour's delay, obviating a claim on a carload of high priced animals.

An employee at one of the smaller stations noticed a car of wheat in a

Prevent Loss and Damage to Freight and Avoid Claims

MY AIM IS

IMPROVEMENT OF THE SERVICE

BY

LOADING—No defective cars that would result in damage.
STOWING—Packages properly, giving consideration to weight, shape, size, nature of contents and station order
TRUCKING—With trucks not loaded too high or too wide so that they are liable to bump against warehouse door or car door and topple over, making certain the freight is so loaded that it will rest secure until it reaches car or warehouse, as the case may be.
CHECKING—Freight carefully to see it is properly marked and packed in accordance with classification requirements, and that shipping ticket or bill of lading is legible and complete.
BILLING—Legibly all articles shown on ticket or bill of lading.
HANDLING—Cars carefully, avoiding carelessness in starting and stopping trains and in switching
DELIVERING—Freight only to authorized persons, using care to safeguard the Company's interests
PREVENTING—Loss and damage to freight, thereby avoiding claims.
REMEMBERING—That better transportation means better pleased patrons and more business for the Frisco.

"YOUR CO-OPERATION IS REQUIRED IN ORDER TO REDUCE CLAIM PAYMENTS $100,000.00"

A Heavy Card of About This Size and Bearing the Above Inscription Was Distributed to Advantage in the Early Stages of the Campaign

passing train leaking grain; he flagged the train and had the conductor set car out; repairs were made and further loss avoided.

At one of our larger stations, a shipment of household goods was received, with certain pieces in bad order; claim clerk called upon a repair man to ascertain the cost of repairs, and was informed as to what the cost would be including certain material. He was further told that the material necessary would be furnished free of cost, providing our forces at the platform made the repairs. The proposition was readily accepted by the claim clerk, and the broken pieces repaired, with all cost eliminated.

A mixed car of stock with partition broken, was noticed moving through a terminal; car was set out, partition repaired promptly, and a heavy claim no doubt avoided as the bad condition was noted before any of the animals had become injured.

I have just received a bad order report from one of the larger stations covering damage to floor and bran account wet. Check of contents shows 28 sacks of flour more or less damaged. Delivering agent carefully inspected the shipment, and advised consignee that he would take up the damaged flour and pay him invoice price for it, at the same time making arrangements to sell all of the flour at invoice price, thus avoiding any loss.

Owing to the alertness of one of the receiving clerks at a large platform, claim was avoided account of shortage to a shipment of coats. When shipment was received, receiving clerk noted case had appearance of having been opened, and refused to sign for shipment until invoiced. The result was we have an actual check of contents of the shipment when received, and are in position to decline claim when presented.

It is the kind of interest shown in the above mentioned cases that is going to assist in bringing about the $100,000 decrease in claim payments this fiscal year. I hope each will give claim prevention careful consideration and endeavor to contribute his share towards the reduction mentioned.

Circular No. 7, addressed to all employees who have to do with the handling of freight, was more extensive and outlined 37 physical causes which lead to loss and damage. Extracts from this circular follow:

I wish to call your attention to the 37 items noted below, which are the principal causes that lead to loss and damage claims. They are not listed in the order of their relative importance. You can study these items with profit to yourself and to the company:

1. Rough handling in starting and stopping trains, in switching at stations, on the road, and particularly in yards.
2. Damage caused through improper stowage.
3. Livestock and perishable freight delayed in transit.
4. Failure to re-ice perishable shipments properly before starting and while in transit.
5. Loading freight liable to be damaged by water in cars with leaky roofs, or cars that are not otherwise water tight.
6. Freight stolen in yards, in transit and in depots.
7. Failure to keep proper seal record of cars received from connecting lines and otherwise.
8. Failure to properly check freight to and from drays and to and from cars.
9. Rough handling of freight by employees in loading and unloading from cars.
10. Failure to properly inspect cars before permitting them to be loaded with grain, to know that they are in fit condition.
11. Failure to record on waybills and make report of all freight damaged, over and short.
12. Signing bills of lading without positive knowledge that freight has been received.
13. Failure to see that all package freight is properly marked in accordance with marks shown on B/L and wayhills.
14. Freight damaged in handling.
15. Freight freezing account box car service and failure to note proper exceptions when received.
16. Concealed damages, concealed shortages.
17. Damages account negligence of employees.
18. Damaged when received from connecting lines and no exceptions noted.
19. Damaged when received from shippers and no exceptions noted.
20. Careless checking of freight to and from connecting lines.
21. Frail packages, improper packing, etc.
22. Damage caused through wrecks, derailments, etc.
23. Failure to load into car for which checked and billed, going forward later, but not accompanied by billing.
24. Erroneous and improper loading.
25. Failure to take proper exceptions against freight received not in good shipping condition.
26. Failure to safeguard the company's interest in delivering freight in a damaged condition to consignees.
27. Failure to inspect shipments of live stock and to take exceptions against when received in a damaged condition from connections.
28. Failure to trim down, brace and block off freight before closing car doors.
29. Failure to remove freight on platforms to a safe place when exposed to the rain.
30. Delivering order shipments without surrender of the original B/L.
31. Failure of yard clerks to examine cars before reporting them as empty and to make a list of any packages found in cars.
32. Carelessness in the matter of making and sending out arrival notices.
33. Failure to inspect stock cars before loading to see that they are in proper condition in every way to receive live stock.
34. Failure before loading to properly inspect and clean cars.
35. Claims caused through misrouting and account of incomplete wayhills.
36. Failure to compare wayhills with bill of lading or shipping ticket.
37. Inaccurate and illegible bills of lading or shipping tickets.

These causes are what we call preventable causes. In other words, if our employees will co-operate along the lines of claim prevention we can reduce claim payments fully 50 per cent, which will mean over $200,000 reduction.

The following paragraph, taken from Circular 8, addressed to all trainmen, enginemen, yardmen, carmen, and others concerned is typical not only of the other information contained in this circular, but as to a large part of the information which is sent out in this way to the various employees engaged in the handling of freight:

Seventy per cent of the claims received are for amounts less than $10. And 60 per cent are for amounts less than $5. Therefore it is the small claims that go to make up the large sum we pay out yearly, and which has averaged close to $500,000 during the past five years. The average

Prevent Loss and Damage to Freight and Avoid Claims

MY AIM IS

IMPROVEMENT OF THE SERVICE

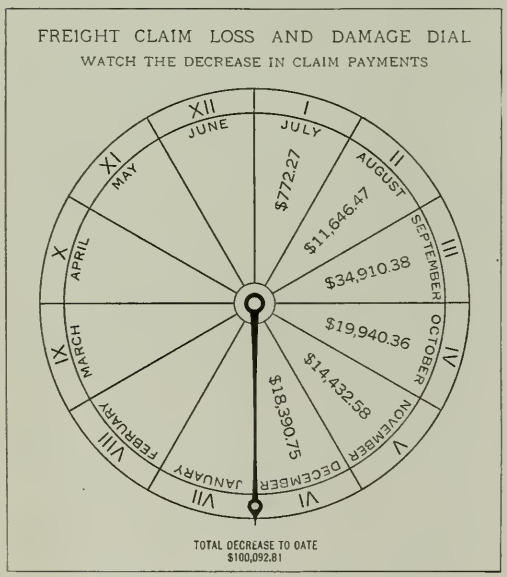
"Your Co-operation is Required in order to Reduce Claim Payments $200,000"

Inscription Which Appears on Frisco Blotters for Use of Employees and Patrons

amount of every claim received is $10. Therefore if we bring about a decrease in claim payments of $100,000 we will receive 10,000 less claims. This would mean approximately 20 per cent less work for the employees on this railroad who have to handle correspondence in connection with claims. It would mean less OS&Ds. It would be hard to estimate the amount of labor and stationery saved, but the benefit would be large.

We have already mentioned the co-operation which has been sought from the patrons of the road by inviting them to some of the freight claim preventive meetings. In Circular 9, addressed to the patrons and coming from the office of the superintendent freight loss and damage claims, the freight claim prevention campaign was briefly described and suggestions and co-operation were asked for.

One of the illustrations shows the inscription on a blotter. These blotters have been distributed to all of the employees, and 10,000 have been printed for distribution to patrons. When an agent or traffic department representative gives these blot-



The Dial Bulletin Which Was Issued January 15

ters to patrons he has an opportunity to explain to them the efforts which are being made to get their freight to destination without loss or damage.

Another illustration shows what has been designated as the freight claim loss and damage dial. It shows the decrease in claim payments by months as compared with the previous year and indicates that for the first six months of the present fiscal year a decrease of over $100,000 had been made. It is planned to issue these dials each month until the close of the fiscal year, thus keeping the men posted in a simple way as to the progress which is being made.

The loss and damage pyramid bulletin is also of interest and was issued early in December, 1914, to cover the performance of the previous five months. A large rubber stamp has also been gotten out within the past few weeks and is reproduced in one of the illustrations. It shows that up to February 27, 1915, $146,920.35 had been saved in freight claims as compared with the previous year and that a further reduction of only $53.079.65 is needed to reach the $200,000 mark. Revised stamps will be sent out from time to time as new data is available.

Hand bills have been furnished to the agents which are to be signed by them personally and enclosed with correspondence to patrons. These are apparently securing good results in developing a more friendly feeling on the part of the patrons toward the road. The wording is as follows:

To Our Patrons:

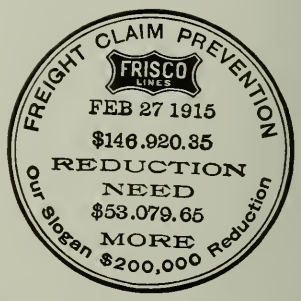
Care and promptness are the chief requisites in handling freight, and by giving first class service in this respect, the Frisco hopes to retain the good will of its patrons.

Our employees having to do with the handling of freight fully realize the annoyance to all concerned incident to loss and damage and have endeavored to remove the causes leading to same; as a result, there is a very large decrease in the number of freight loss and damage claims filed.

We feel that our patrons will appreciate our efforts towards giving them better service and will co-operate with us in any way possible in removing any causes for loss or damage that come under their control. Particularly can conditions be improved in this respect by seeing that freight that is tendered for shipment is properly packed and carefully marked.

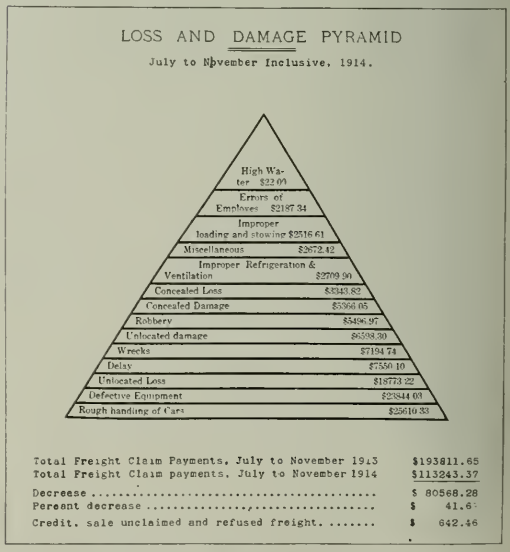
Your suggestions will be gratefully received.

Agent.



A Special Rubber Stamp Used on Railway Correspondence

All members of the freight claim preventive committees have been furnished with business cards similar to the one repro-



Freight Claim Loss and Damage Pyramid Bulletin

duced herewith, which they are expected to use in the solicitation of business. All of the members of these committees are urged to use their influence in securing business for the road and to interest other employees in this work.

Naturally the enthusiastic work of the freight claim preventive committees and the employees has attracted the attention of the press and much desirable publicity has been obtained from the

notices of the progress of the work and the accounts of the meetings which have been held at more or less regular intervals at each of the more important points on the system.

SPECIAL CLAIM PREVENTION DAYS

Handbills were distributed to all employees late in February announcing that the ninth and tenth days of March and April had been set aside as special claim prevention days, the idea being to absolutely prevent on these days errors of any kind which result in loss or damage to freight. In addition to the handbills, rubber stamps were distributed to be used on company correspondence and bearing the message: "Don't forget that March 9th and 10th are special claim prevention days." On March 9 the superintendents sent wires to all freight train crews emphasizing the importance of preventing loss and damage to freight.

On the handbill announcing the special claim prevention days appeared the following reminders:

The RECEIVING CLERK may help by seeing that he receives all the freight he signs for. He is the man to reject consignments improperly prepared for shipment.

The TRUCKER may help by careful trucking, and by being sure that the freight is loaded in the proper car.

The STEVEDORE or LOADER may help by careful stowing and bracing and by supervising the work of the loader.

The CAR INSPECTOR and WAREHOUSE FOREMAN may help by choosing suitable cars for loading, and by seeing that cars selected are free from nails and other projections, and from oil or other refuse which may injure the lading.

The SWITCHMAN may help by avoiding unnecessary movements of the car, by careful signaling, and by making smooth couplings.

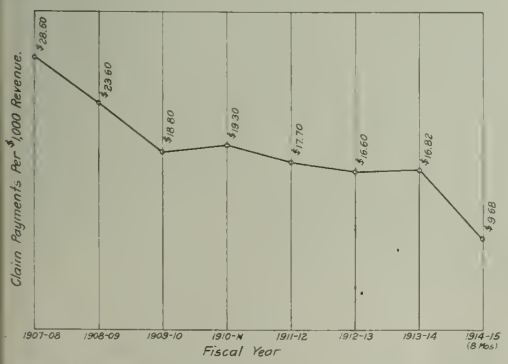
The ENGINEER may help by prompt and careful observance of signals, and by avoiding sudden and hard applications of air.

The CONDUCTOR and BRAKEMAN may help by unloading and loading freight as though it were their own property, being cautious to see that it is put off at its correct destination, and by reporting instances of improper loading.

Thus far the records show that very few claims have been filed for loss or damage which occurred on these days. The plan created much enthusiasm and undoubtedly inspired the employees to greater efforts and resulted in much good. Voluntary reports have been received from a number of stations and employees calling attention to the fact that they did not make any errors in these special days.

SPECIAL MEETINGS

A new scheme is just being tried out, that is the holding of joint meetings of the freight claim committees wherever it is possible. For instance, a joint meeting of the Eastern and the Northern divisions and Springfield Terminal committees was held at Springfield, Mo., on March 24. A goodly number of patrons were present, as well as a large number of employees. Talks were made by general officers, division officers, and employees. This month there will be a joint meeting at Memphis of the Southeastern, the Ozark and the River and Cape divisions and the Memphis Terminal committees. There will also be a joint meeting a little later at Monett, Mo., of the Eastern, the Central, the Kansas, and the Southwestern division committees.



Graphical Presentation of the Freight Claim Payments Per $1000 Freight Revenue for the First Eight Months of the Present Fiscal Year and for the Seven Previous Years

RESULTS

The results of the freight claim preventive campaign for the first eight months were discussed in the first article in this series and are shown graphically in the accompanying diagram as compared to the records for the previous seven years. The saving in the prevention of friction between the patrons and the railroad representatives and in the reduction in transportation expenses due to the better service which has resulted cannot be estimated, but must have been large. This is reflected by the following data:

Claims Received for First Eight Months of Fiscal Year	1913-14	1914-15
July	3,785	4,627
August	6,441	4,426
September	5,076	4,750
October	5,216	5,262
November	5,336	4,195
December	6,662	4,202
January	5,822	4,289
February	5,126	4,076
Total	43,464	35,827

This shows that the number of freight claims for the first eight months of the fiscal year 1914-15 decreased 7,637, or 17 per cent, as compared to the same period for the previous year.

The statement following shows the decrease in the number of

FRISCO LINES

NOTICE!

The Slogan of the Freight Claim Preventive Committees has been realized—the $100,000 reduction in Freight Claim Payment has been made.

Our Slogan now is "A $200,000 reduction in Claim Payments this fiscal year." Every dollar of this can be made if each employe will help.

REMEMBER!

Money saved is money made. Stop a leak. Stop a shipment going wrong and last but not least—STOP A CLAIM.

CENTRAL CLAIM PREVENTIVE COMMITTEE

(These were printed in several colors)

One of a Number of Campaign Hand Bills

OS&Ds, refused and unclaimed freight reports, and L. C. L. tracers received during the first eight months of the present fiscal year as compared with last year:

	1914-15	1913-14	Decrease	Per cent
Overs	15,955	26,625	10,670	40.1
Shorts	14,858	22,493	7,635	33.9
Damages	35,225	39,054	3,829	9.8
D/Rs	13,826	16,557	2,731	16.5
LCL Tracers	3,590	6,787	3,197	47.1
Total	83,454	111,516	28,062	25.1

In other words about 30,000 fewer investigations were started in the freight loss and damage claim department. This means roughly that from 60,000 to 70,000 fewer letters were sent out

by that department and that the agents and trainmen have had much less correspondence to attend to. Is it any wonder that they are boosters for the new order of things?

CONCLUSION

In the first article of this series certain statistics were given which indicated that for several years the freight loss and damage claims had steadily decreased on the Frisco per thousand dollars of gross freight revenue until a certain point was reached in 1912-13, beyond which it seemed almost impossible to go. Impressed by the results gained in the educational campaigns which had been waged in the safety first movement and later in the effort to better the train and car loading and improve the freight movement, it was decided to inaugurate a similar effort to reduce the waste due to the loss and damage to freight. It was estimated that it might be possible by a strong effort to save $100,000 in the fiscal year 1914-15. The importance of giving more attention to the education and training of employees is indicated in no uncertain terms by the fact that the goal which was set at a high point (many believed it to be beyond reach) was reached in six months and the indications are that double the saving, which was originally aimed at, will be made. Does it pay to educate employees fully as to their duties and to inspire them by various means to do better and more efficient work? The experience of the Frisco, not only in this campaign, but in the others which we have described during the past year, surely proves that it does.

THE ALASKAN GOVERNMENT RAILWAY

As announced in our issue of last week, the government has selected the route for its proposed railway from the coast into the interior of Alaska and has authorized the inauguration of work at once. The route adopted extends from Seward on Resurrection Bay across Kenai Peninsula and the head of Cook Inlet, ascending the valley of the Susitna river, crossing the Alaska mountains through Broad Pass and then descending the Tanana river to Fairbanks, a total distance from Seward of 471 miles. The Alaska Northern extending from Seward inland 71 miles to Turnagain Arm has been purchased by the government for $1,150,000, or $16,000 per mile. A branch will also be built from Matanuska Junction to the Matanuska coal fields, a distance of 38 miles. A terminal will be built at Ship Creek on Cook Inlet, which will serve as the outlet for the Matanuska coal, and as a base for the construction of the road.

It is expected that about 40 miles of line will be constructed this year. Because of climatic conditions and the difficulty of getting equipment in to the line most of the grading will be done by station men on small contracts. The experience gained by this method this year will aid in determining the method to be followed in building the remainder of the road later.

The estimated cost of the entire line is $26,800,000, or $57,000 per mile. In the bill passed by Congress last year, authorizing the construction of this line, it was provided that the

Proposed Location of the Alaskan Government Railway

total expenditure for the Alaska railways should not exceed $35,000,000. An appropriation of $1,000,000 was made last year for the work of the commission, half of which was expended in making the surveys. An appropriation of $2,000,000 has been made to carry forward the work this year.

W. C. Edes, chairman of the Alaska Engineering Commission, will have immediate charge of this work, with headquarters at Seward, Alaska. Lieutenant Frederic Mears and Thomas Riggs, Jr., the two other members of the commission will continue the surveys.

Recent Developments in Steam Locomotives*

Increases in Power; Improvements in Economy; Advantages of Superheating, Brick Arch and Mechanical Stoking

By George R. Henderson
Consulting Engineer, Baldwin Locomotive Works, Philadelphia, Pa.

The development of the steam locomotive in the last 10 or 15 years has been brought about mainly for two very good reasons: increase in power and increase in economy. These have been subdivided, the first into improvements in tractive effort and horsepower and the second into economies in fuel and labor. The means of obtaining these various factors are best shown by the accompanying table:

Locomotive Development

For increase of

- **Power**
  - Tractive effort
    - Wt. per driving axle, 40,000—70,000 lb.
    - No. of driving axles, 4—12
    - Tractive effort, 40,000—160,000 lb.
  - Horsepower
    - Size of boiler, 3,000—9,000 sq. ft. H. S.
    - Steam pressure, 180—240 lb. per sq. in.
    - Superheat, 50 deg.—250 deg. F.
    - Horsepower, 1,500—3,000
- **Economy**
  - Fuel
    - Compounding, saving 20%
    - Superheating, saving 25%
    - F. W. heating, saving 10%
    - Arches, etc., saving 5%
    - } 35%
  - Labor
    - Oil fuel
    - Power reverse
    - Coal pushers
    - Fire door operators
    - Grate shakers
    - Mechanical stokers
    - } Reduce labor and increase capacity

Let us examine, briefly, the changes under these different items.

The weight on driving axles has almost doubled, but the weight of rail has also been increased, say from 70 to 100 lb. per yard, and as each pound per yard is good for a wheel load of 300 lb., when the rail is properly supported, we find that the rail has kept pace with the unit wheel load, which, of course, is a necessary requirement. As in the contests for mastery of guns and armor, so have railroad activities increased track weight and wheel loads, the one necessitating or permitting the other to also advance. But the tractive effort of the locomotive has not been kept down to the comparatively meager increase in weight of rail. Then, too, only the largest roads have been able to afford the expense of such heavy track, and those roads which still use 70 or 80 lb. rail also need greater tractive effort. So it has come about that the number of driving axles to a locomotive has been greatly increased.

With the advancements made in boiler pressure and size, superheating has been prominent as a means of still further increasing output, and a great deal of success has been gained in this direction. The benefit of this operates in two ways, primarily to prevent or reduce cylinder condensation, and after that point has been obtained, the increased volume of superheated steam results in more work being performed with the same quantity of water.

At 50 per cent *real* cut-off, 90 deg. F. superheat will reach the point of saturation about the end of the stroke, when the initial pressure is 200 lb. gage, and with 33 per cent *real* cut-off, about 170 deg. F. superheat are required; any further superheat will give economy by expanding the steam to a greater specific volume than when saturated. In ordinary practice, 100 deg. F. superheat will give about 16 per cent more work or volume than saturated steam and 200 deg. will give about 33 per cent more. The diagram will explain the practical working in locomotives.

Let us consider a locomotive whose tractive effort and velocity relation are typified by curve *A*, the boiler supplying dry saturated steam. If we desire to apply a superheater to this boiler, we must reduce the evaporative heating surface about 25 per cent, so that less saturated steam would be available, considering that the coal consumption or rate of firing is maintained constant per square foot of evaporative heating surface, or 75 per cent as much as in curve *A*. This is shown by curve *B*.

Now apply the superheater elements and with 200 deg. superheat, our tractive effort will rise to curve *C* (same as *A*), but with 25 per cent less coal. Now if we increase the coal consumption to its original amount per square foot of grate surface, which has not been altered, the curve will be shown at *D*, or about 33 per cent more work for the same coal as in curve *A*. The upper curves show the corresponding change in horsepower, for superheating, but this will also depend upon the actual size of the boiler. Ordinarily, in estimating heating surface, it is customary to take the evaporative heating surface plus one and one-half times the superheating surface, and call this the equivalent heating surface of the boiler. As the superheating surface is ordinarily about 22 per cent of the evaporative surface, this places the equivalent surface equal to what the same boiler would have in heating surface, if no superheater had been applied. Roughly, we may determine the horsepower of the boiler by dividing the equivalent heating surface by x, where x equals:

Fuel	Coal	Oil
Non-superheater locomotives	2½	2
Superheater locomotives	2	1½

Thus, by combining the increase in boiler size and superheating benefits, we find an improvement of 3 or 4 times in the available horsepower—a figure that harmonizes with the advancements made in tractive effort.

Among the devices which operate for economy, a part save in fuel and a part in labor only, but the saving in fuel is also a saving in labor, although the latter is not always accompanied by a financial saving. Therefore, only the fuel economies result in a direct benefit in expenses, and the fireman gets the benefit of all—fuel and labor saving devices together.

Compounding was one of the first radical methods of saving fuel, and this appeared in two cylinder compound locomotives. The low pressure cylinder soon assumed such a diameter, however, that it became impractical, and four-cylinder compounds resulted, both as tandem, superimposed and balanced. The saving in fuel was about 20 per cent, but in some cases this was more than offset by the increase in maintenance. With articulated locomotives, however, the practical advantage of low pressure steam in the flexible pipe leading to the low pressure cylinders, is perhaps as great as that of fuel economy.

The Triplex locomotive of the Erie Railroad is a six-cylinder compound, the right high pressure cylinder exhausting to the two front low pressure cylinders, and the left high pressure cylinder sends its used steam to the two rear low pressure cylinders, the ratio of compounding being two. The economy of a compound engine is produced mainly by the reduction of cylinder condensation, owing to the later cut-off used and the smaller temperature variations throughout the stroke.

The economy in superheating is likewise produced by the reduction or elimination of cylinder condensation, in connection with the increased volume of superheated steam, as already explained. This can be accomplished in a simple cylinder as well as in a compound, and if we remove cylinder condensation by means of superheat, we cannot expect to obtain, in addition, the thermal advantages of compounding. In other words, having removed the condensation losses by superheating, there is no condensation left which can be removed by compounding. There are mechanical advantages in articulated and similar locomotives, which are sufficient to justify the combination and the reduction of pressure in the flexible pipes by this means is quite important.

The coal consumption with superheated steam is represented by

*From a paper presented before the New York Railroad Club, April 16, 1915.

the Locomotive Superheater Company to be about as follows:

Deg. F. Superheat	Lb. Coal per hp. hour	Deg. F. Superheat	Lb. Coal per hp. hour
0	3.5	150	3.1
50	3.4	200	2.7
100	3.3	250	2.2

This indicates about 25 per cent saving at 200 deg. superheat, as shown in the diagram.

Feedwater heaters have been used to a limited extent; they have been of various types, from heating the water in the tank to heating just before entering the boiler. If a pump is used to draw the heated water, there may be difficulty on account of the steam generated by the pump suction; this may be overcome by supplying the hot water under a head sufficiently great to prime the pump and allow for frictional resistance in the pipes. Water may be heated from 100 to 140 deg. in this way, at an economy of 10 per cent.

Brick arches and similar arrangements also promote fuel economy, and while 10 per cent has often been claimed, it has been set in the statement at 5 per cent, as so much depends upon the arrangement and maintenance. In bad water districts, where flue trouble is excessive, it may not be practical to keep arches in the fireboxes, as they interfere with access to the flues.

Summing up, then, these various modes of obtaining fuel

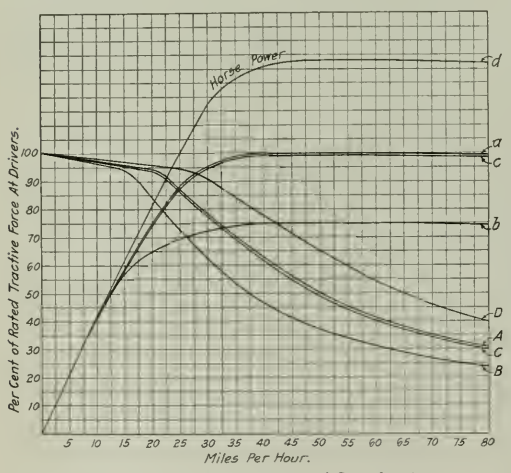

Diagram Showing Advantages of Superheating

economy, we must bear in mind that it will not be possible to realize the sum of the savings shown, but that if we were to combine all of them in a single locomotive we might expect 35 per cent saving over a simple, saturated steam locomotive, without either feedwater heater or brick arch. This is a large economy, however, and well worth the first cost of application and maintenance.

As the items just enumerated reduce the fuel consumption, they will reduce the fireman's labor in the same proportion. There are other means of reducing the manual labor, however, which do not bring a direct return for the money invested, except in so far as they permit a greater output of power, due to the reduction of labor per unit of power generated. Fuel oil is one of the most important of these methods, and while in some localities its price is prohibitive, yet in others it is actually a source of economy, being cheaper than coal. In general, it will permit about 25 per cent greater steam output from the boiler. Where the cost of fuel is too great, a mechanical stoker may be used, and by this means it is possible to put in the firebox twice as much coal as can be supplied by an average fireman.

Coal pushers, fire-door openers, grate shakers, etc., seem rather trifling in themselves, but a trip on a large modern locomotive, where the fireman is supplying coal at the rate of 6,000 lb. an hour, or 100 lb. per minute, will demonstrate the importance of utilizing all these adjuncts in order to get the best work out of the engine. It is a case where a number of small items produce a large result, both in the time saved and in affording greater conveniences to the men.

DISCUSSION

G. M. Basford, chief engineer, railroad department, Jos. T. Ryerson & Son.—During the past ten years improvement in the steam locomotive has been unparalleled in engineering progress. We are so close to this development as to render it impossible to realize its extent and its importance, or to comprehend the possibilities of improvement in railroad operation, which improved economy and the increased capacity due to that economy, renders available. Mr. Henderson says that he has merely scratched the surface of his subject. A very long paper would be required to do more than that. In this generation of human activity the steam locomotive has been brought from a relatively low to a very high position as an efficient, powerful machine. It now takes its place among the great improvements in marine and stationary practice, which the same generation has brought. It is fitting that attention should be directed to this fact. It is important that our electric friends should bear in mind the fact that the steam locomotive of today is on an entirely different basis, as to efficiency, from the steam locomotive of the day when electric locomotives were first introduced. Our electrical friends will find that they have an entirely different competitor to meet and they will probably discover that the day for general use of electric locomotives is put far into the future by the development covered by this paper.

In 18 years the steam passenger locomotive has increased threefold in tractive effort. In 16 years the freight locomotive has also increased three-fold in tractive effort. The largest figure for indicated horsepower produced on the Pennsylvania Railroad testing plant at the St. Louis Exposition ten years ago was 1,641. This was developed by New York Central, Atlantic type locomotive No. 3000, and was considered a marvelous record at the time. Published records of recent performance of a Pennsylvania Railroad Pacific type locomotive show 3,184 indicated horsepower from the same testing plant at Altoona; possibly this plant has produced a larger figure which has not yet been published. This statement reveals an astonishing increase in power. A record of 3,580 indicated horsepower has been made by a very large freight engine at a speed of 15 miles per hour in road service. A prediction of these figures would have astonished everybody ten years ago.

Increased capacity has been accompanied by improved economy. The best record of the St. Louis tests in 1904 showed 16.6 lb. of steam and 2.01 lb. of coal per indicated horsepower per hour. The latest published figures from the Altoona test plant show 14.6 lb. of steam and 1.8 lb. of dry fuel per indicated horsepower hour. In ten years a reduction of 10 per cent in fuel and 12 per cent in water has been effected, which averages 1 per cent per year for the last ten years. No contemporary development in engineering has produced such an improvement. This is specially interesting from the fact that the best record of the St. Louis tests was made by a European locomotive, which, at the time represented the best engineering practice of the world. It is also of interest to note that this European locomotive was equipped with a superheater and a brick arch. This means that the improved economy mentioned has been obtained by a development with and of these important features.

It is impossible to credit this improvement to any one or to several economy-increasing factors. It is due to co-operative development of a lot of factors, all of which tend to increase economy and, therefore, increase capacity. The most important of these factors may be enumerated as follows:

For the last five years boilers have been designed with reference to the steam required for maximum cylinder horsepower. This method has replaced empirical formulas. Firebox design has greatly improved. Much has been done to increase the effectiveness of draft appliances and exhaust nozzles. Greater at-

tention has been paid to enlarged air openings under the grates. Superheating requires no comment in this connection. Compounding has been worked out in connection with superheating with promise of still further development. Feedwater heating has become a practical success. Fire-brick arches have taken a place of great prominence in locomotive design and in operation, particularly with respect to combustion. The author of the paper specifically mentions 5 per cent as being creditable to the arch; in this connection it is important to observe that the arch contributes to the saving of the superheater and helps to secure the advantages of improved boiler design. The arch renders high superheat possible; these factors help and supplement each other.

Mechanical stokers have become a necessity on locomotives of great power. Stokers certainly contribute to increased capacity in addition to the saving they may make. Improved valve gears help the cylinders in economy and in capacity. Labor saving devices for enginemen and firemen produce an economy and increased capacity in that they enable enginemen to secure the utmost capacity from an engine. We are just beginning to consider the use of high grade alloy steels to reduce weights. They offer means of reducing static weights considerably, but more important is the possibility of reducing the dynamic effect of counterbalance weights by reducing reciprocating weights. Herein is a very fertile field for future endeavor. Yet to come is powdered fuel as the most promising possibility of the future.

We hear much about improved economy of locomotives, but do not hear enough about the possible increase in capacity, which the improved economy permits. An improvement of 25 per cent in economy offers a theoretical increase of 33⅓ per cent in capacity. Assume 6,000 lb. of coal per hour as a figure for coal consumption. If 4 lb. of coal are required per i. h. p. per hour our 6,000 lb. of coal would generate 1,500 i. h. p. If an economy of 25 per cent in fuel is effected, 3 lb. would generate a horsepower for an hour and 6,000 lb. of fuel would develop 2,000 instead of 1,500 i. h. p. This would be an increase of 33⅓ per cent in capacity effected by an economy of 25 per cent in fuel. In other words, if one has $6,000 to spend for items of anything which cost $4 each, he may buy 1,500 items for $6,000. If the price is reduced to $3 each he can buy 2,000 of them, which means an increased buying capacity of 33⅓ per cent for a reduction of 25 per cent in price. This is the ratio of the theoretically possible increase in capacity corresponding with improvements in economy.

I have records showing in actual service an average of 36 per cent saving in coal per ton mile for seven different railroads. This saving effected an average increase of 63 per cent in tons hauled per train. This represents the difference between very large, modern locomotives as compared with smaller ones of earlier design. In another case, seven railroads show an average saving of coal per ton mile of 27 per cent, which led to 34½ per cent increase in load hauled per train, also representing large, modern engines as compared with smaller and older ones. These are figures which actually appear on the treasurer's records. It is one thing to provide economy producing factors, and it is another thing to get these economies into the figures of the treasurer. We must all take our hats off to the men who have effected these great results.

J. P. Neff, vice-president, American Arch Company.—The subject treated in the paper is of vital importance to operating men, as well as to motive power men; in fact it has a greater bearing upon operating than mechanical matters as practically all of the benefits of the recent developments in locomotives tend toward reduction of the cost of conducting transportation, the prime operating account.

I will not attempt to discuss this paper in its entirety, but the author makes a statement that I cannot allow to go unchallenged. In his analysis, we find under the second item, "Economy," first division, "Fuel," that brick arches have been given fourth place and have been credited with a saving of 5 per cent. Elsewhere the author makes the statement that "Fire arches and similar arrangements also promote fuel economy, and while 10 per cent has often been claimed, it has been placed in the statement at 5 per cent as so much depends upon the arrangement and maintenance."

It seems to me that if qualifications are to be made it would be advisable to make the same qualifications for the other three fuel saving devices, that is, the diagram might be constructed to read: "Compounding, saving claimed 20 per cent, realized 10 per cent; superheating, saving claimed 25 per cent, realized 15 per cent; feedwater heating, saving claimed 10 per cent, realized 5 per cent. The summation of the realized percentages would then give the 35 per cent which he shows as the total for all fuel saving devices. This suggestion is made on the same grounds, that "so much depends upon the arrangement and maintenance." Many compounds of fifteen years ago have been simpled because the realized saving was more than offset by certain disadvantages in maintenance and operation. Some of the earlier types of superheaters have not shown a realized saving sufficient to give a net result in their favor, and have given way to more efficient type. Ten or fifteen years ago the arrangement and maintenance of brick arches was not what it is today, and Mr. Henderson's statement regarding these arches would be quite true for conditions fifteen years ago.

I believe that I know where Mr. Henderson secured some of his bad impressions on the brick arch subject, and I think I know something of why he has stated that "in bad water districts where flue troubles are excessive, it may not be practical to keep arches in the fireboxes, as they interfere with access to the flues." About 15 years ago, when Mr. Henderson was assistant superintendent of motive power of the Chicago & North Western, I was division foreman of one of the worst water districts on the system and in a general motive power meeting I made an eloquent appeal for the privilege of removing arches and arch tubes from the locomotives on my division, and received permission to discard them. There were three very good reasons for that action at that time:

First, it was impossible to maintain arch tubes for any length of time, the life being in the neighborhood of three months, due to the scaling up, which we were unable to prevent.

Second, the class of engines on that division had very shallow fireboxes, and the arch tubes were located in the tube sheet only 13 in. from the bottom of the mud-ring, giving about 6 in. clearance between the arch and the grate surface at the front end of the firebox. This was a very bad arrangement and impractical from a firing standpoint.

The third reason was that we had a type of brick arch at that time which, when tube attention was necessary, was entirely destroyed.

Therefore the benefits which we got from a badly arranged arch was not sufficient to give us a net saving, due to the high cost of maintenance of arch tubes and brick. Today, however, in this same bad water district, arches are being run successfully, and are showing a good net result; but they have arches of a practical arrangement from the firing standpoint, they have arch tube cleaners which maintain the tubes free from scale and greatly reduce the cost of arch tube maintenance, and they have a different type of brick which can be removed and reapplied, thereby greatly reducing the cost.

In this same bad water country the Chicago, Milwaukee & St. Paul find that it pays to use arches. Furthermore, the Soo Line, operating in this same bad water country, which is as bad as any in the United States, have, after a year's careful experimenting on several locomotives, decided that it is a paying proposition to run brick arches; but the arrangement is of the latest type and the maintenance is of the high standard prevailing today throughout the country. Many other instances might be mentioned, but the three given should be sufficient, as they represent the worst water conditions in this country. Many roads that would not consider arches ten years ago are now making them standard, even in their worst water districts, simply because the arch tube cleaner has made it possible to run arch

tubes with safety. In the last five years at least 12,000 locomotives have been equipped with arches.

It is not fair to attempt to express the whole virtue of fire arches in percentage of fuel saving, for the reason that the amount of fuel saving depends not so much upon the arrangement and maintenance (which today is of a high standard), but rather on the conditions of operation. When burning a low volatile grade of coal at a low rate of combustion, a low fuel saving must result, but when burning ordinary bituminous coal at a high rate of combustion a high fuel saving does result from fire arches. Just what the average of all conditions over the country would be is impossible to say. We do not make a claim of 10 per cent fuel saving for fire arches, but we do claim, and can very well prove, that a properly designed brick arch in a bituminous coal burning engine makes a 10 per cent better locomotive. A locomotive equipped with an up-to-date arch will easily give 10 per cent more indicated horsepower hours per ton of coal than the same engine not so equipped. When the limit of sustained horsepower depends upon the endurance of the fireman, this limit can even be raised 15 per cent by the use of a properly arranged arch. Many road tests have proved this and indisputable testing plant figures in this country, as well as abroad, verify this figure. I have heard many road foremen state that an engine equipped with an arch is good for one more car in passenger service than the same engine not so equipped, when speaking of the ability of the engine to make a rigid schedule.

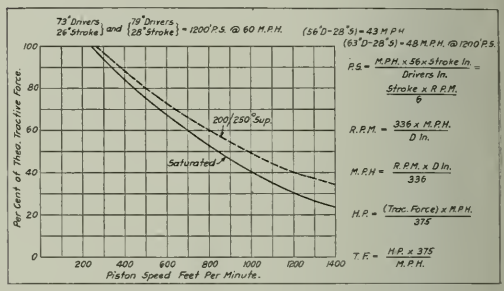
I would therefore suggest that Mr. Henderson revise his diagram putting fire arches where they seem, to me, to belong, in the class of "Capacity Increasers," using the conservative figure of ten per cent.

L. R. Pomeroy, of the United States Light & Heating Co., said that the use of a wide firebox and a more rational arrangement of the parts in modern locomotives had done much to increase capacity and produce economical results. Mr. Pomeroy made use of the accompanying figures and diagram, which is taken from that published in the *Railway Age Gazette*, January 15, 1915, page 96, to show that mechanical stoking is necessary in order to realize the full capacity of large modern locomotives:

Item		4-6-2 P. R. R. class K-4s 1	2-10-2 B. & O. 2	2-10-2 Erie 3
1	Weight on drivers, lb.	200,000	336,800	327,250
2	Tractive force, lb.	41,845	84,500	83,000
3	Diameter of drivers, in.	80	58	63
4	Boiler pressure, lb.	210	200	200
5	Cylinders, diam. and stroke, in.	27x28	30x32	31x32
6	Evap., h. s., sq. ft.	.....	5,573	5,801
7	Superheat., h. s., sq. ft.	.....	1,329	1,377
8	Equiv., h. s., sq. ft.	5,766	.....	.....
9	Grate surface, sq. ft.	70	88	88.1
10	Horsepower by approx. formula (boiler pres.) x 0.017 x (cyl. dia.)	2,600	3,000	3,200
11	Horsepower from diagram	2,700	3,100	3,100
12	Tract. force at 60 m. p. h. (for 4-6-2)	15,700	.....	.....
13	Tract. force at 35 m. p. h. (for 2-10-2)	.....	34,500	34,000
14	Piston speed at 60 m. p. h.	1,180	.....	.....
15	Piston speed at 35 m. p. h.	.....	1,080	1,000
16	Coal per hour at rate of 2.7 lb. coal per hp. hr. given by Mr. Henderson as appropriate for superheat of 200 to 250 deg. F.	(2,600 hp.) 7,020	(3,000 hp.) 8,100	(3,200 hp.) 8,640
17	Coal per hour as checked from given water rate of 21.6 lb. per hp. hour, with varying rates of combustion: (6, 7 and 8 lb. water per lb. coal)			
	4-6-2, 2,600 hp. x 21.6 ÷ 6 = 9,360			
	2,600 hp. x 21.6 ÷ 7 = 8,000			
	2,600 hp. x 21.6 ÷ 8 = 7,000			
	Average	8,120	.....	.....
	B. & O. 2-10-2,			
	3,000 hp. x 21.6 ÷ 6 = 10,800			
	3,000 hp. x 21.6 ÷ 7 = 9,255			
	3,000 hp. x 21.6 ÷ 8 = 8,100			
	Average	.....	9,385	.....
	Erie 2-10-2, 3,200 hp. x 21.6 ÷ 6 = 11,500			
	3,200 hp. x 21.6 ÷ 7 = 9,850			
	3,200 hp. x 21.6 ÷ 8 = 8,650			
	Average	.....	.....	10,000
18	Coal per sq. ft. of grate per hr. (Item 16 ÷ Item 9.)	100	92	97.5
19	Reduction in tractive force due to 5,000 lb. per hour	29%	38%	48%

The Master Mechanics' Association Locomotive Dictionary shows a No. 3 scoop as representative. The manufacturers rate such a shovel for ordinary bituminous coal, as 19½ lb. per shovel; at 5,000 lb. of coal per hour such a shovel would mean 256 scoops per hour, 4.26 per minute, or 1 shovelful every 14 seconds. These figures show quite conclusively that 5,000 lb. per hour is a fair assumption for comparison as a "fireman rating."

On this assumption (5,000 lb. per hour as the working limit



Relation of Speed Factor in Saturated and Superheated Steam Locomotives, with Some Convenient Formulas

for average firing) the practical realization of these designs of locomotives is somewhat short of the design expectancy, viz.:

P. R. R. 4-6-2 ..... $1 - \frac{5000 \times 100}{7020} = 29$ per cent less

B. & O. 2-10-2 ..... $1 - \frac{5000 \times 100}{8100} = 38$ per cent less

Erie 2-10-2 ..... $1 - \frac{5000 \times 100}{8640} = 48$ per cent less

The logic of the comparison is obvious. To realize the possibilities of design the fireman must be supplemented by some form of stoker, or oil fuel used.

B. P. Flory, superintendent of motive power, New York, Ontario & Western, referred to the advantages produced in the modern locomotive by the use of outside valve gears.

C. E. Chambers, superintendent of motive power, Central Railroad of New Jersey, stated that while superheaters undoubtedly increase capacity and economy there is an undoubted increase in maintenace costs, a point which should not be lost sight of.

Mr. Henderson illustrated his talk with a number of lantern slides, which included a proposed locomotive of the 2-8-8-8-8-2 type with the cab at the front end. In closing he referred to the 107 locomotives which the Baldwin Locomotive Works have recently built for the French government. These engines weigh about 14 tons each, have a firebox in the middle and a smoke stack at either end, and are for use on rough track in moving guns, etc.

LET THE INTERSTATE COMMERCE COMMISSION RULE*

By T. C. Powell
Vice-President, Cincinnati, New Orleans & Texas Pacific

The makers of the constitution could not in the nature of things anticipate the immense development of our internal transportation system. In those days transportation by water was the most important method and the limited movement on land was incidental to the water transportation, and in so far as the constitutional convention and Supreme Court were able to base their opinions upon known conditions, they provided the proper government of common carriers by water and the individual states have never had much to say about the regulations on the navigable rivers and waters of the United States.

The legislators and jurists of the eighteenth century did not have an opportunity of passing upon the regulation of

*From an address at the annual dinner of the Friendly Sons of St. Patrick on March 17, 1915.

steam and electric railroad facilities, and even when the first state railroad commissions were created, there was so little precedent to guide them that each state commission wanted to extend authority over each railroad which entered or passed through that particular state, and wanted to regulate each of these railroads as far as they extended, even into other states.

Fortunately, most of the railroad systems were short and there were only two or three commissions and the conflict of authority did not assume any great importance. Now, we have a commission in nearly every state. During the last two years there were introduced into the state legislatures over 1,700 bills regulating railroads. These diverse opinions, sectional jealousies, also the lack of information and honest variations in judgment have wrought "confusion worse confounded."

One state law requires screens for car windows and the adjoining state declares screens to be an offense against the law. One state demands that the railroads handling freight within its borders shall give preferential rates on native-grown commodities, while another state traversed by the same railroad insists that its citizens shall enjoy the lowest rates in existence, "and poured 'round all" is the national authority of the Interstate Commerce Commission.

No business man believes that this condition favors the development of commerce. It would be much better for the railroads and the stockholders thereof, who are numbered by the thousands, and the public who are not stockholders, and particularly for the business men, if by constitutional amendment the several states would agree to give up this destructive individual authority and place the responsibility for the proper regulation of all common carriers by land and water on all classes of traffic, within and without the borders of each of the several states, in the hands of and under the jurisdiction of a national commission.

If this country is to resume its commercial standing and to go forward to greater prosperity, such an amendment to the constitution must be approved by the several states. I hope such action will come soon, because, as it appears to me, this is the only thing that will forestall governmental ownership and operation of our railroads.

HEARING ON WESTERN FREIGHT RATE ADVANCES

The western freight rate advance hearing at Chicago before Commissioner Daniels during the past week has been devoted to testimony of shippers and their representatives and rate experts of western state railroad commissions protesting against the proposed advances in the rates on specific commodities. Testimony on the advances on cotton piece goods was given on April 12 and 13, and on coal and coke on April 14, 15 and 16. This was followed by testimony on grain and grain products from April 17 to 21, and on fruits and vegetables on April 22 and 23.

That the increase in rates on cotton piece goods would operate to place manufacturers of overalls at St. Joseph, Mo., at a further disadvantage in selling in competition with prison-made garments was testified by H. G. Krake, manager of the traffic bureau of the Commercial Club of St. Joseph; J. D. Richardson, president of the Richardson Dry Goods Company; R. W. Powell, vice-president of the Britton Dry Goods Company; T. C. Holland, secretary and treasurer of the Wheeler & Motter Mercantile Company, and R. L. Campbell, vice-president of the Tootle-Campbell Dry Goods Company. Mr. Krake said that at present the rate on cotton piece goods from the Mississippi river to St. Joseph is 32 cents. The short line mileage from Quincy, Ill., is 204 miles; from Jefferson City, Mo., 125 miles; from St. Louis and Sedalia, 204 miles; from St. Louis the rate is only 17½ cents, and the railroads are asking to advance the rate to St. Joseph to 37 cents without any change in the rate to Jefferson City and Sedalia, he said. Mr. Richardson said his company sells goods in competition with the prison-made garments of Jefferson City, and that the disadvantage would be increased by the difference in rates. Other testimony on cotton piece goods was given by C. C. Wilbur, traffic manager of M. E. Smith & Co., Omaha, and D. E. Nettels, traffic manager of the Postex Cotton Mills of Post City, Tex. S. H. Johnson, assistant freight traffic manager of the Chicago, Rock Island & Pacific, was called to give some brief testimony in rebuttal.

General testimony on coal rates was given by representatives of the Illinois Coal Operators' Association, followed by representatives of the Iowa shippers. F. H. Harwood, vice-president of the New Kentucky Coal Company of Chicago, testified in opposition to the proposed advance of 10 cents per ton on coal from the Indiana and Illinois mines to points in Iowa, Missouri and Minnesota. He said the advance would result in greater tonnage moving via Duluth and the Great Lakes from eastern coal fields. Charles N. Moderwell, also representing the Illinois Coal Operators' Association, said that the advance would curtail the market for Illinois coal in the Northwest. The Illinois and Indiana coal industry is in such condition that it cannot stand an advance unless it is uniform, he said. W. B. Martin, commissioner of the Dubuque Shippers' Association, said that the proposed advances on eastern and Illinois and Indiana coal to the west bank of the Mississippi river involve the same amount of advance that was under consideration by the Interstate Commerce Commission in the eastern five per cent rate case. At that time, he said, the roads sought to advance the rates to Chicago, and in addition to advance the rates from Chicago to the river by five cents per ton. Both increases were denied, but the carriers are now seeking to increase the rates from Chicago 10 cents per ton.

Representatives of a number of Chicago packers having plants on the Missouri river opposed the application of southwestern railroads for an increase in the rate on slack coal from the Pittsburg, Kan., mining district to Omaha, South Omaha, St. Joseph and Sioux City. W. W. Manker, assistant traffic manager of Armour & Co., and R. O'Hara, rate expert for Swift & Co., presented figures to show that existing rates from these fields were on a higher basis than from competitive fields for similar distances. Mr. Manker said that the proposed rates from Missouri and Kansas to Missouri river points where Armour & Co. have packing plants would mean an advance of from $10,000 to $12,000 a year to Armour & Co. The total freight charges paid on fuel by this company, he said, amount to $278,000 per year. J. O'Halleran, representing a sugar refinery at Clinton, Iowa, protested against the advance from Franklin county, Illinois, which he said was unreasonable. He thought the earnings per car under the present rates were sufficiently remunerative. F. J. Danner, traffic manager of the Davenport, Iowa, Commecial Club, testified against the proposed advances in coal rates on behalf of the members of his association, and presented a table showing the tonnage of coal consumed by the various industries. The largest consumer of coal on this list was the Bettendorf Company of Bettendorf, Iowa. A. P. Humburg, commerce attorney of the Illinois Central, asked the witness if he had heard of a letter written by President Bettendorf of this company to Clifford Thorne, vigorously advocating the granting of the advances in rates. The witness said he had heard of the letter and that he had no authority to represent the Bettendorf Company in this proceeding.

C. E. Childs, commissioner of the traffic bureau of the Sioux City, Iowa, Commercial Club, presented figures to show that coal pays more per car than certain other commodities, including livestock and packinghouse products. He said he thought the roads would have a much better argument to advance those rates. D. L. Kelley, rate expert of the South Dakota Railroad Commission, testified that the proposed advance in rates on bituminous coal would seriously retard the industrial development of South Dakota, which, he said, is now held in check by the in-

ability to secure an ample fuel supply upon a reasonable transportation basis.

Mr. Kelley submitted several exhibits covering rates on coal from the docks and mines to representative points in South Dakota, with the earnings, volume of tonnage and comparisons with rates in other sections of the country to show, he said, that the haul to South Dakota consuming points is from two to three times the average haul on bituminous coal for the entire country, but that notwithstanding that situation the rates per ton mile are higher. He said the proposed advances would cost coal consumers of South Dakota alone over $91,000 a year.

John E. Sargent of Kansas City, representing a large number of coal mines in the Southwest, testified that the coal interests are not opposed to the requests of the railways for increased rates, but are interested in the competitive relationships. "I have nothing to say as to whether the railways should or should not get the increase they ask for," he said, "except that possibly the railways need more revenue as much as we. What we do say is that there should be an absolutely uniform advance." Mr. Sargent then described the difficulties arising because of the conflict of state regulation with interstate rates, especially with reference to the situation at Kansas City, where the state line separates two large consuming points which are adjacent. He said it would mean ruin to the Missouri coal mines if the interstate rates are raised and the state rates are not advanced. E. R. Trotter of Kansas City, testified as to the displacing of coal by fuel oil, and said that the proposed advance on coal would place it at a further disadvantage as compared with oil. J. C. Storm of Amarillo, Tex., took the stand as an individual protestant to describe what he termed an unfair situation as to the rates in general applying to Amarillo. He compared rates on numerous commodities to a number of cities, showing other cities had lower rates. "All coal rates are too low," he said, "but when you put them up you ought to take it off of something else. If coal is shipped at these low rates somebody else must pay the fiddler."

The grain interests began their opposition to the advances on grain on April 17. A. E. Helm, commerce counsel of the Kansas Public Utilities Commission, made an opening statement defending the action of the western state railroad commissions in protesting against the proposed increases and declaring that the railroads were seeking to levy an additional toll upon one of the most profitable products they handle. Judge Helm said that in reply to the testimony offered by the carriers it was proposed to show that the relative proportion of the products of agriculture handled by the western railways is much greater than that handled by the eastern roads, and that the present rates on these commodities are higher than the average of rates on all tonnage, while the operating ratio is lower than upon almost any other class of carload freight moving in substantial quantities. He also said it was proposed to show that the exhibits offered by the carriers contained many substantial errors and do not reflect representative conditions; that the exhibits to be filed by the protestants will show that both the present and the proposed rates on grain and grain products are very much higher than the rates upon these commodities for similar distances in Central Freight Association territory, and that the percentage of excess of these rates over the grain rates for similar distances in the East is greater than the percentage of excess of class rates in the West over the class rates in General Freight Association territory. "We shall show," he said, "that the products here involved now sustain more than their full share of the burdens of transportation, and that any addition to these charges will be unreasonable and unjust to the farmers of the West who pay the freight on these commodities."

W. M. Hopkins, formerly manager of the transportation department of the Chicago Board of Trade, testified that the grain rates should not be advanced because a saving equal to the proposed increase might be effected if a more economical method of handling grain were practiced by the carriers, and that grain already pays more than its share of the total transportation charges. Mr. Hopkins said that grain is a very profitable commodity for the carriers, because the great grain fields are located in the Central West, thus giving the carriers a long haul and a large revenue on grain seeking eastern or southern territory of consumption. He also presented figures in reply to statements made by E. B. Boyd, chairman of the Western Trunk Line Committee, while on the witness stand for the carriers, that the proposed rates on grain were lower than the rates in the Northwest or in the territory east of Chicago.

To illustrate what he called the uneconomical methods of handling grain, Mr. Hopkins mentioned the unsatisfactory character of many of the cars furnished for grain loading, failure to furnish receipts, unnecessary delays in road haul movements, delays at terminals and unnecessary switching. The claims for loss and damage, he said, should not be given consideration as justification for imposing higher transportation charges, because the losses that arise are due to negligence of the carriers.

"The carriers claim that grain is not paying its share of the transportation costs," he said. "In 1914, the average freight revenues of the North Western, Burlington, Great Western, St. Paul, Rock Island, Illinois Central and Minneapolis & St. Louis were $57,072,122. Had all the traffic paid wheat rates, the revenue would have been $90,127,414; had it paid corn rates, $76,254,889. Against an average revenue per ton of freight of $1.65616, wheat shows, $2.60 and corn $2.20. The average ton mile revenue was 7.7 mills; wheat paid 11.87 and corn, 10.05 mills. The average revenue on freight per train mile was $2.92159; wheat paid $10.01503 and corn $7.53931. The average revenue per car mile on all traffic was 13.906 cents, against 47.33 on wheat and on corn 35.63. The average revenue per loaded car, all traffic, was $29.7619; the average revenue per loaded car on wheat was $103.7566, and on corn, $78.0329."

"Isn't most of the corn moved in the winter months, when transportation costs are high?" asked T. J. Norton, general attorney of the Atchison, Topeka & Santa Fe.

"I think that is true," replied Mr. Hopkins.

Mr. Norton also brought out that under transit arrangements, although the grain may come into a milling point in heavy carloads, yet the flour which moves out on the balance of the same rate makes a very light carload. The witness admitted that although the farmer pays the freight to the point of purchase, a great quantity of grain is sold before its destination is known and the freight from elevator to destination then is not paid by the producer. It was also shown that the witness, in his comparison of grain rates in western and eastern territory, had compared local rates with proportions of through rates in a manner which has been declared improper by the Interstate Commerce Commission.

E. H. Hoagland, of Topeka, Kan., introduced figures covering the amount of grain originating in the states affected to show the tonnage of grain traffic.

"How much of the Kansas corn crop is moved out of the state?" asked Mr. Norton.

"About one-sixth, probably," replied Mr. Hoagland.

"Yet you have used the entire crop figures to determine the density of corn tonnage per mile of line," pointed out Mr. Norton. "You have made no calculation which considers the small load of flour as against the large load of wheat, both of which move on the same through rate?"

The witness stated he had not taken this into consideration. Other witnesses who opposed the advance in grain rates included G. R. Hall, of the Duluth Board of Trade, and J. H. Schaefer, of the Iowa State Retail Merchants' Association.

Railway Extension in Northern Manchuria.—The survey and investigation of the proposed railway line from Chinchow in Shengking Province to Taonanfu in Mongolia are reported to have been completed. It is said that the Chinese engineer who had charge of the survey will probably be appointed chief engineer for the construction of the line.

General News Department

The Interstate Commerce Commission has begun valuation work on the Puget Sound line of the Chicago, Milwaukee & St. Paul.

The bill to repeal the full crew law of New York, which has been before the legislature of that state for several weeks was passed by the Senate on April 20 by a vote of 30 to 18.

The bill to repeal the full crew law, which has been before the legislature of Pennsylvania for several weeks was passed by the lower House on April 19 by a vote of 135 to 68, substantially a two-thirds majority. Representative Palmer, of Schuylkill, in a speech opposing the bill said that if the law were repealed the employees would retaliate on the railroads and secure legislation ten times more drastic than the full crew law. The bill gives specific authority to the Public Service Commission to decide as to the proper number of men to be employed in manning railroad trains.

The Wisconsin assembly has passed a bill prohibiting the giving or offering of any gratuity by patrons of any hotel, restaurant, barber shop or public service corporation engaged in the transportation of passengers. The penalty is a fine of from $5 to $25. The lower house of the Minnesota legislature has passed a similar bill.

The Pacific Mail Steamship Company announces that it has cancelled all sailings of its vessels after November 2, 1915, November 4 being the day on which the new seamen's law goes into effect, imposing restrictions which will make the operation of the company's vessels unprofitable. This company operates 19 vessels, 5 of them in the trans-Pacific trade. The vessels running to Asiatic ports have Chinese crews. No freight contracts will be made beyond July 31.

The Lehigh Valley reports that 289 regular freight trains run during the month of March made a record of being on time 98.4 per cent. Eight daily through freight trains leaving either Jersey City or Buffalo, arrived at their terminals every day on time. The New York State Public Service Commission, Second district, has advised the management that a recent ten-day check of l. c. l. freight between Buffalo and Geneva gave the Lehigh Valley 100 per cent for delivery on scheduled time.

Chairman Walsh of the federal Commission on Industrial Relations has excused Robert T. Lincoln, chairman of the board of directors of the Pullman Company, from going to Chicago to testify in its investigation of the wages and conditions of employment of Pullman conductors and porters. Mr. Lincoln had sent a letter stating that he would be unable to appear at the Chicago hearing on account of his health. At first Chairman Walsh said that a writ of attachment would be issued for Mr. Lincoln, but later he announced that the commission would hear Mr. Lincoln's testimony when it holds its next public hearing at Washington on May 6.

A Texas correspondent writes: "Governor James E. Ferguson plans to gain a first hand knowledge of the condition of the railroads of Texas and their traffic possibilities. He has just finished a tour of the Texas line of the Kansas City, Mexico & Orient, accompanied by a party of officers of that road. The governor was impressed very favorably with the wonderful strides of agricultural development. In his younger days Governor Ferguson was a bridge builder on the Santa Fe, and he is favorably disposed towards railroad investments in Texas. His attitude towards this class of corporations is something of a novelty in a governor of this state."

In the United States District Court at New York on Wednesday the government made a motion for the modification of the recent order, granting bills of particulars to William Rockefeller and eleven other directors, past and present, of the New York, New Haven & Hartford concerning the indictment found against them for violating the Sherman anti-trust law. Assistant Attorney General Swacker asked the court to disallow the request of the directors for particulars on 22 points, and to modify it on others. The order of Judge Hunt required the government to furnish the directors with information as to the acts which it intended to prove, that the defendants had done or were in the act of doing in the three years immediately before February 26, 1915, the date of the indictment, in furtherance of the alleged conspiracy.

One of the small economies practiced by a number of railroads recently has been to print on the face of envelopes used for railroad mail 12 different spaces for the addresses, so that the envelopes may be used 12 times by using a new space each time for the address and crossing out the names previously used. Heavy Manila paper envelopes are used, of such quality that they do not wear out for some time. An officer of the Baltimore & Ohio has sent us an envelope of this kind which is estimated to have traveled 10,000 miles, and has contained 12 communications between various offices on the Baltimore & Ohio system. The envelope is somewhat soiled but is otherwise in good condition. The Rock Island lines have been using this plan for some time where large envelopes are required. Each envelope bears the instructions, printed in large type: "Do not seal unless absolutely necessary. Use one square for address in each case. When empty return to stationery department, Chicago, for further use. (Do not roll.)"

Accident Record—Correction

An officer of the Pennsylvania advises that the details in the account of a derailment on that road at Morris Junction, Pa., February 25, reported in the *Railway Age Gazette*, April 2, page 746, were not correctly given. The train was a freight, not a passenger, and the damage was slight; and no persons were injured.

Continuous Home Route Card

The continuous home route card, to go with a freight car when away from home until it is returned to the owning road, which has been recommended for general use by the committee of the American Railway Association, and which is described on page 884 of this paper, will, on May 1, be put in use, in their exchanges with each other, by the following roads: Bessemer & Lake Erie; Buffalo, Rochester & Pittsburgh; Baltimore & Ohio; Buffalo & Susquehanna; Cleveland, Cincinnati, Chicago & St. Louis; Chicago, Rock Island & Pacific; Chicago & Eastern Illinois; Chicago, Indianapolis & Louisville; Central of New Jersey; Central New England; Chesapeake & Ohio; Cincinnati, Hamilton & Dayton; Delaware & Hudson; Delaware, Lackawanna & Western; Erie; Grand Trunk; Grand Rapids & Indiana; Hocking Valley; Illinois Central; Indiana Harbor Belt; Lehigh & Hudson River; Lehigh & New England; Long Island; Lehigh Valley; Lake Erie & Western; Michigan Central; New York, New Haven & Hartford; New York Central; New York, Chicago & St. Louis; Pennsylvania; Pennsylvania Lines West of Pittsburgh; Pittsburgh & Lake Erie; Pittsburgh, Shawmut & Northern; Philadelphia & Reading; Toledo & Ohio Central; Wheeling & Lake Erie; Western Maryland.

International Engineering Congress

Volume IV of the transactions of the International Engineering Congress, which will be held at San Francisco in September, will comprise an important series of papers on the general subject of "Railways and Railway Engineering." This field will be treated under seven principal topics covering the relation of railways to social development; the present status of railways; the economic factors governing building of new lines, location; the physical characteristics of road including track and roadbed; bridges; tunnels; terminals; construction methods; signals; road equipment, including motive power other than electric; rolling stock in general; floating equipment; electric motive power in general.

Approximately 27 papers are expected for this volume, pre-

pared by authors representing 9 different countries. The list of authors includes many of the most eminent names in this field of engineering work throughout the world.

The volume will be well illustrated with charts, diagrams and half-tones, and will contain discussions contributed by leading American and foreign engineers.

The transactions of the congress as a whole will include nine or ten other volumes, covering the various fields of engineering work.

Operating Revenues and Expenses of Express Companies

The following statement, which is subject to revision, has been compiled by the Interstate Commerce Commission from the monthly reports of operating revenues and expenses of the principal express companies for December, 1914. (The express companies have three months in which to make reports to the commission.)

A.—For the Month of December

Meeting at Franklin Institute

A paper on Locomotive Stokers was presented at the Franklin Institute, Philadelphia, on Wednesday evening, April 21, by W. S. Bartholomew, president of the Locomotive Stoker Company, Schenectady, N. Y. Lantern slides were employed showing in detail the construction of the various types of stokers now in service and a brief history of the development of mechanical stoking as applied to locomotives was given. There are now in successful service over 600 Street stokers, about 400 Crawford underfeed stokers and about 20 each, of the Standard and the Hanna types. Mr. Bartholomew gave some figures showing the increase in tonnage effected by the use of mechanical stokers on large locomotives. The paper was discussed by representatives from the Baldwin Locomotive Works, the Chicago, Burlington & Quincy and the Baltimore & Ohio.

Association of Passenger Traffic Officers

At the annual meeting of the American Association of Passenger Traffic Officers held in San Francisco on April 15 and 16, Alexander Hilton, passenger traffic manager of the St. Louis & San Francisco was elected president and C. M. Burt, general passenger agent of the Boston & Maine, vice-president. W. C. Hope, general passenger agent of the Central of New Jersey, was re-elected secretary.

MEETINGS AND CONVENTIONS

The following list gives the names of secretaries, dates of next or regular meetings, and places of meeting of those associations which will meet during the next three months. The full list of meetings and conventions is published only in the first issue of the Railway Age Gazette for each month.

Air Brake Association.—F. M. Nellis, 53 State St., Boston, Mass. Next convention, May 4-7, 1915, Hotel Sherman, Chicago.

American Association of Freight Agents.—R. O. Wells, Illinois Central, East St. Louis, Ill. Annual meeting, May 18-21, 1915, Richmond, Va.

American Railway Association.—W. F. Allen, 75 Church St., New York. Next session, May 19, 1915, New York.

American Railway Master Mechanics' Association.—J. W. Taylor, 1112 Karpen Bldg., Chicago. Annual meeting, June 9-11, 1915, Atlantic City, N. J.

American Society for Testing Materials.—Prof. E. Marburg, University of Pennsylvania, Philadelphia, Pa. Annual meeting, June 22-26, 1915, Hotel Traymore, Atlantic City, N. J.

American Society of Civil Engineers.—Chas. Warren Hunt, 220 W. 57th St., New York. Regular meetings, 1st and 3d Wednesday in month, except July and August, 220 W. 57th St., New York.

American Society of Mechanical Engineers.—Calvin W. Rice, 29 W. 39th St., New York. Next spring meeting, June 22-25, 1915, Buffalo, N. Y. Annual meeting, December 7-10, 1915, New York.

Association of American Railway Accounting Officers.—E. R. Woodson, 1300 Pennsylvania Ave., N. W., Washington, D. C. Annual convention, April 28, 1915, Piedmont Hotel, Atlanta, Ga.

Association of Railway Claim Agents.—C. W. Egan, B. & O., Baltimore, Md. Annual meeting, May 19, 1915, Galveston, Tex.

Association of Railway Electrical Engineers.—Jos. A. Andreucetti, C. & N. W., Room 411, C. & N. W. Sta., Chicago. Semi-annual meeting with Master Car Builders' and Master Mechanics' Associations. Annual meeting, October, 1915.

Association of Railway Telegraph Superintendents.—P. W. Drew, Soo Line, 112 West Adams St., Chicago. Annual meeting, June 22-25, 1915, Rochester, N. Y.

Association of Transportation and Car Accounting Officers.—G. P. Conrad, 75 Church St., New York. Next meeting, June 22-23, Niagara Falls, N. Y.

Canadian Railway Club.—James Powell, Grand Trunk, P. O. Box 7, St. Lambert (near Montreal), Que. Regular meetings, 2d Tuesday in month, except June, July and August, Windsor Hotel, Montreal, Que.

Car Foremen's Association of Chicago.—Aaron Kline, 841 Lawler Ave., Chicago. Regular meetings, 2d Monday in month, except June, July and August, Hotel La Salle, Chicago.

Central Railway Club.—H. D. Vought, 95 Liberty St., New York. Regular meetings, 2d Friday in January, May, September and November. Annual meeting, 2d Thursday in March, Hotel Statler, Buffalo, N. Y.

Engineers' Society of Western Pennsylvania.—Elmer K. Hiles, 2511 Oliver Bldg., Pittsburgh, Pa. Regular meetings, 1st and 3d Tuesday in month, Pittsburgh.

Freight Claim Association.—Warren P. Taylor, R. F. & P., Richmond, Va. Annual meeting, June 16, 1915, Chicago.

General Superintendents' Association of Chicago.—A. M. Hunter, 321 Grand Central Station, Chicago. Regular meetings, Wednesday, preceding 3d Thursday in month, Room 1856, Transportation Bldg., Chicago.

International Railway Fuel Association.—C. G. Hall, C. & E. I., 922 McCormick Bldg., Chicago. Annual meeting, May 17-20, 1915, Hotel La Salle, Chicago.

Master Boiler Makers' Association.—Harry D. Vought, 95 Liberty St., New York. Annual convention, May 25 to 28, 1915, Chicago, Ill.

Master Car Builders' Association.—J. W. Taylor, 1112 Karpen Bldg., Chicago. Annual meeting, June 14-16, 1915, Atlantic City, N. J.

New England Railroad Club.—W. E. Cade, Jr., 683 Atlantic Ave., Boston, Mass. Regular meetings, 2d Tuesday in month, except June, July, August and September, Boston.

New York Railroad Club.—Harry D. Vought, 95 Liberty St., New York. Regular meetings, 3d Friday in month, except June, July and August, 29 W. 39th St., New York.

Niagara Frontier Car Men's Association.—E. N. Frankenberger, 623 Brisbane Bldg., Buffalo, N. Y. Meetings, 3d Wednesday in month, New York Telephone Bldg., Buffalo, N. Y.

Peoria Association of Railroad Officers.—M. W. Rotchford, 410 Masonic Temple Bldg., Peoria, Ill. Regular meetings, 3d Thursday in month, Jefferson Hotel, Peoria.

Railroad Club of Kansas City.—Claude Manlove, 1008 Walnut St., Kansas City, Mo. Regular meetings, 3d Saturday in month, Kansas City.

Railroad Men's Improvement Society.—J. B. Curran, Erie R. R., 50 Church St., New York. Meetings, alternate Thursdays, October to May, Assembly Rooms of Trunk Line Association, 143 Liberty St., New York.

Railway Club of Pittsburgh.—J. B. Anderson, Room 207, P. R. R. Sta., Pittsburgh, Pa. Regular meetings, 4th Friday in month, except June, July and August, Monongahela House, Pittsburgh.

Railway Electrical Supply Manufacturers' Association.—J. Scribner, 1063 Monadnock Block, Chicago. Meetings with Association of Railway Electrical Engineers.

Railway Signal Association.—C. C. Rosenberg, Myers Bldg., Bethlehem, Pa. Stated meeting, May 26-27, 1915, Hotel Astor, New York. Annual meeting, September 14-17, 1915, Salt Lake City, Utah.

Railway Storekeepers' Association.—J. P. Murphy, N. Y. C. R. R., Box C, Collinwood, Ohio. Annual meeting, May 17-19, 1915, Hotel Sherman, Chicago.

Railway Supply Manufacturers' Association.—J. D. Conway, 2136 Oliver Bldg., Pittsburgh, Pa. Meetings with Master Car Builders' and Master Mechanics' Associations.

Railway Telegraph and Telephone Appliance Association.—G. A. Nelson, 50 Church St., New York. Meetings with Association of Railway Telegraph Superintendents.

Richmond Railroad Club.—F. O. Robinson, C. & O., Richmond, Va. Regular meetings, 2d Monday in month, except June, July and August.

St. Louis Railway Club.—B. W. Frauenthal, Union Station, St. Louis, Mo. Regular meetings, 2d Friday in month, except June, July and August, St. Louis.

Salt Lake Transportation Club.—R. E. Rowland, David Keith Bldg., Salt Lake City, Utah. Regular meetings, 1st Saturday of each month, Salt Lake City.

Southern & Southwestern Railway Club.—A. J. Merrill, Grant Bldg., Atlanta, Ga. Regular meetings, 3d Thursday, January, March, May, July, September, November, 10 a. m., Piedmont Hotel, Atlanta.

Toledo Transportation Club.—Harry S. Fox, Toledo, Ohio. Regular meetings, 1st Saturday in month, Boody House, Toledo.

Traffic Club of Chicago.—W. H. Wharton, La Salle Hotel, Chicago.

Traffic Club of Newark.—John J. Kautzmann, P. O. Box 238, Newark, N. J. Regular meetings, 1st Monday in month, except July and August, The Washington, 559 Broad St., Newark.

Traffic Club of New York.—C. A. Swope, 291 Broadway, New York. Regular meetings last Tuesday in month, except June, July and August, Hotel Astor, New York.

Traffic Club of Pittsburgh.—D. L. Wells, Gen. Agt., Erie R. R., 1924 Oliver Bldg., Pittsburgh, Pa. Meetings bi-monthly, Pittsburgh. Annual meeting, 2d Monday in June.

Traffic Club of St. Louis.—A. F. Versen, Mercantile Library Bldg., St. Louis, Mo. Annual meeting in November. Noonday meetings October to May.

Train Dispatchers' Association of America.—J. F. Mackie, 7122 Stewart Ave., Chicago. Annual meeting June 15, 1915, Minneapolis, Minn.

Transportation Club of Detroit.—W. R. Hurley, Superintendent's office, N. Y. C. R. R., Detroit, Mich. Meetings monthly, Normandie Hotel, Detroit.

Utah Society of Engineers.—Frank W. Moore, 1111 Newhouse Bldg., Salt Lake City, Utah. Regular meetings, 3d Friday in month, except July and August, Salt Lake City.

Western Canada Railway Club.—L. Kon, Immigration Agent, Grand Trunk Pacific, Winnipeg, Man. Regular meetings, 2d Monday, except June, July and August, Winnipeg.

Western Railway Club.—J. W. Taylor, 1112 Karpen Bldg., Chicago. Regular meetings, 3d Tuesday in month, except June, July and August, Karpen Bldg., Chicago.

Western Society of Engineers.—J. H. Warder, 1735 Monadnock Block, Chicago. Regular meetings, 1st Monday in month, except January, July and August, Chicago. Extra meetings, except in July and August, generally on other Monday evenings. Annual meeting, 1st Wednesday after 1st Thursday in January, Chicago.

Traffic News

The National Industrial Traffic League has announced that its postponed spring meeting will be held at the Hotel Chisca at Memphis, Tenn., on May 13 and 14.

At the Western freight rate hearing in Chicago, on Wednesday of this week, Commissioner Daniels announced that the commission would not submit to the carriers the 38 questions propounded by Clifford Thorne, but would submit a list of its own, which would include a part of the subjects embraced in Mr. Thorne's list.

Trains 31 and 32 of the Southern Railway, formerly running through between Washington, D. C., and Jacksonville, Fla., now run only between Charlotte, N. C., and Savannah, Ga. The Jacksonville sleeping car will be run between Savannah and Jacksonville on Atlantic Coast Line trains 83 and 82. Trains of the Southern Railway south of Savannah run over the tracks of the Atlantic Coast Line, and the announcement of the discontinuance of trains 31 and 32 appears to have led to a report that the trackage contract had been terminated; but this is not the fact, as other trains of the Southern still use the A. C. L. tracks in this territory.

W. B. Biddle, receiver and chief traffic officer of the St. Louis & San Francisco, announced last week that freight tariffs approximately 30 per cent higher than the present Arkansas commission tariffs will be put into effect in Arkansas within the next 10 days, as the result of the decision by the United States district court at Little Rock, granting a perpetual injunction against the enforcement of the commission freight tariffs and the state two-cent fare law. Mr. Biddle said that the rate applied is based upon the Minnesota scale and that the rates proposed with the increased passenger rates, will yield a return estimated at 3.6 per cent on the company's investment in Arkansas.

The Baltimore & Ohio Railroad, according to a new slogan, is the "Best & Oldest Railroad," and on the Cleveland division, this phrase has been adopted and used in official communications and bulletins. J. W. McCombs, agent at Uhrichsville, Ohio, uses it in soliciting the routing of orders of traveling salesmen. . . "One of our plans," says Mr. McCombs, "is to talk to salesmen, inquiring whether they did any business in our city and asking them whether the routing had been specified. Usually we find that there has been no preference expressed and the salesmen are asked to favor this company, while we acquaint them with our service. Nine out of ten salesmen will go through their order books and favor us with their business. I carry a pad of routing orders with me and have found that the plan has secured a large amount of revenue for this station."

E. Pennington, president of the Minneapolis, St. Paul & Sault Ste. Marie, has issued a pamphlet entitled "Why Railroad Passenger Fares Should be Raised and Why a Raise Will Help Your Pocketbook. A Frank Talk to the People and Their Lawmakers," which discusses in a popular way the reasons why the railroads need greater revenues and why passenger fares should be advanced. The pamphlet is divided into seven chapters, as follows: When and by Whom Built; Value and Capitalization; Who Owns the Railroads?; Services Performed and Pay Received; What the Money Goes for and Who Gets It; Passenger Service Underpaid; What More Pay Means. Under the head of "Wages," the names are given of a large number of conductors, engineers, firemen, brakemen and switchmen employed on the Minneapolis, St. Paul & Sault Ste. Marie, the Chicago, Milwaukee & St. Paul and the Chicago, St. Paul, Minneapolis & Omaha during the year 1914, with figures showing, for each man, the amount of wages actually received.

The arguments, as presented at Chicago, for and against the "trap-car" tariffs which were filed by the principal railroads and suspended by the commission, were reported in the *Railway Age Gazette*, April 2 and 9. The subject was again taken up at a hearing before the commission at Washington on Monday of this week. Statements on behalf of the railroad companies were made by George S. Patterson and William D. McHugh. John D. Burchmore appeared for the Industrial Traffic League.

Those opposing the imposition of a charge for trap-car service declared that the tariffs as filed were a hodge-podge of discriminations, excessive charges and unworkable provisions. The proposed minimum of $2 a car in Trunk Line territory, and $4 in Central Freight Association territory, by the difference between them, cause many discriminations. In cities where large numbers of automobiles are made, the shippers save the railroads large sums by loading automobiles at the factories, their men being more skillful than the railroad workmen; and now, they say, it is proposed that the shipper shall pay $4 for the privilege of saving the railroad company $4. Mr. Patterson, summarizing the points in favor of the charges said: "The trap-car saves drayage running from 30 cents to a dollar a ton; gives additional time under the car service rules; enables the loading of carloads and less-than-carloads from the same point in the warehouse regardless of weather conditions, without drayage; enables the shipper to locate at any distance he desires from the freight house without incurring additional drayage expense; secures expedition in the movement of cars to transfer points and, finally, saves the rough handling incident to drayage.

Senator Bryan Opposed to Public Ownership

N. P. Bryan, United States Senator from Florida, was one of the principal speakers at the second annual banquet of the Jacksonville (Fla.) Traffic Club on April 12, speaking on the subject of "Government Ownership."

"There is no reason for the government of the United States to engage in private business," he said. "Government ownership destroys private initiative. . . . The business of the government is politics and in conducting its own business it has no respect for revenues and profits. It is awfully easy to be generous with other people's money. While business men in all lines have been economizing in every way possible during the present war and hard times, see what happened at the postoffice department! This is one great business of the government that really shows a profit. The postmaster general wanted to save the trifling sum of $7,000,000, but 44,000 rural postal employees objected, they wanted their pay raised, and they got it. When 44,000 people in hard times like these can affect the entire nation, what would happen if the million and one-half federal employees united with the three million other employees now working for private concerns and were suddenly transported under government ownership? They would control the balance of power in the country. There would soon be no business—it would be all politics. You cannot legislate for New York state, and make those laws suit the people of Florida."

Other speakers at the banquet were Charles H. Mann, president of the Jacksonville Chamber of Commerce; W. B. Stillwell, of the Southern Pine Company, Savannah, Ga., and W. E. Kay, assistant general counsel of the Atlantic Coast Line.

Illinois Railway Officers Urge Higher Passenger Fares

A large delegation of Illinois railway officers appeared at a hearing before the senate and house committees on public utilities of the Illinois legislature on Wednesday to urge the passage of the bill to increase the state passenger fare from 2 to 2½ cents a mile. President C. H. Markham of the Illinois Central presented the arguments of the railroads in an address in which he pointed out that the railroads have stated their case to the people and that petitions signed by over 75,000 voters of the state, as well as resolutions passed by 101 different commercial and civic organizations, favoring an increase in the passenger fare upon proper showing by the railroads that an increase is reasonable have been addressed to the legislature. He said that there are only 13 out of 48 states in the union that have in effect a maximum passenger rate of two cents a mile, and their population per mile of railroad averages 472. In Illinois the population per mile is 491. In eight eastern states with a population per mile of 1,036 the average maximum fare per mile is 2½ cents, while for the remaining 27 states the fare ranges from 2½ to 6 cents. To show that the 2-cent law has not stimulated travel, he pointed out that the increase in passengers carried per mile for the year ending June 30, 1907, compared with the year ending June 30, 1903, was 22.73 per cent, while for the year ending June 30, 1913, the increase in passengers carried per mile over 1909 was only 17.43 per cent.

To show that the 2-cent a mile rate in Illinois has not been profitable to the railroads he presented compilations covering 13 of the principal lines with an aggregate mileage of 7,753 miles, or 60 per cent of the total, and a valuation within the state of Illinois of $590,204,336, or an average per mile of $76,122. The total net income of these roads was equivalent to 3.99 per cent on the valuation fixed for the purpose of taxation, and the passenger proportion of the value was $175,473,651, and net railway operating income for the year 1914 from passenger traffic was equivalent to a return of 3.6 per cent on the value. Assuming that passenger traffic should earn a return of 7 per cent, he said, the passenger traffic earned 7 per cent only on 51.42 per cent of the value as fixed for taxation, leaving $85,238,671 of value on which no return whatever was earned. "This conclusively proves," he said, "that a maximum passenger rate of two cents is entirely inadequate and it is extremely doubtful whether a 2½-cent rate would yield a fair return on the value of the property devoted to public use in the transportation of passengers."

A. J. Earling, president of the Chicago, Milwaukee & St. Paul, presented an argument against train limit legislation. Hale Holden, president of the Burlington, presented an argument in favor of 2½-cent passenger fares and against the train limit bill. Among other railway executive officers who appeared before the committee were Presidents Gardner of the Northwestern; Felton of the Chicago Great Western, and Bierd of the Alton; A. M. Schoyer, vice-president of the Pennsylvania Lines, and Receivers W. I. Jackson of the Chicago & Eastern Illinois; E. F. Kearney of the Wabash, and W. L. Ross of the Toledo, St. Louis & Western.

Six Months Operation on the Panama Canal

The first half year of commercial operation of the Panama Canal was completed on February 14, the canal having been opened to commercial traffic on August 15, 1914. During that period, according to the Canal Record, 496 vessels other than canal vessels and launches passed through the canal, carrying a total of 2,367,244 tons of cargo. Their distribution over the most important routes is shown in the following table:

Route.	Number of vessels	Cargo tonnage
United States coastwise, eastbound	97	499,439
United States coastwise, westbound	109	493,272
United States Pacific coast to Europe	66	444,855
Europe to United States Pacific coast	16	59,516
South America to United States and Europe	69	378,386
United States and Europe to South America	31	128,922
United States Atlantic coast to Far East	48	287,782
Far East to United States Atlantic coast	2	14,500
Miscellaneous routings	13	60,572
Vessels without cargo	45	.....
Total	496	2,367,244

Of the total, 252 vessels moved eastbound, carrying 1,340,625 tons and 244 vessels moved westbound carrying 1,026,619 tons. Slightly over 41 per cent of the cargo handled was in movement between ports of the United States. Over 21 per cent of all cargo was in movement between the Pacific coast of North America and Europe, and approximately 21 per cent was on the route between the west coast of South America and the seaports on the Atlantic seaboard of the United States and Europe. Traffic between the Atlantic seaboard and the Far East amounted to over 12 per cent of the total. The six principal commodities passing through the canal were, in order of their tonnage: Grain, nitrates, coal, refined petroleum products, lumber and cotton, and these six commodities together formed approximately one-third of the total tonnage. The grain shipments amounted to 303,124 tons, of which all but 15,733 tons were shipped from the east coast of the United States and Canada. Nitrates shipped from the west coast of South America to various ports in the United States and Europe amounted to 204,441 tons. Coal, all moving to the Pacific coast, aggregated 151,745 tons, of which 83,081 tons were shipped from the Atlantic seaboard and 68,664 tons from the United Kingdom. Shipments of lumber amounted to 56,078 tons. All but 600 tons were from the west coast of North America. Cotton shipments amounted to 38,239 tons, from the Atlantic seaboard of the United States to the far East.

The toll levied during the six months period amounted to $2,126,832.

A press despatch from Panama, April 15, says that up to April 1 tolls on the canal amounted to $2,894,300; and that the total cost of operation and maintenance during the same period was $3,020,000, leaving a deficit of $125,700.

Commission and Court News

INTERSTATE COMMERCE COMMISSION

Rates on Coke to Canton, Ill.

Parlin & Orendorff Company v. Cleveland, Cincinnati, Chicago & St. Louis, et al. Opinion by the commission:

The commission finds that a carload rate of $1.60 a ton on coke from Indianapolis, Ind., to Canton, Ill., is not unreasonable or discriminatory. Complaint dismissed. (33 I. C. C., 442.)

Rates for Compartments

Alfred Mosely v. Atchison, Topeka & Santa Fe. Opinion by the commission:

The commission finds that defendant's passenger-fare rule under which a minimum of one and one-half first class tickets is required for the exclusive use of a compartment on "California limited" trains is not unreasonable. (33 I. C. C., 521.)

Rates on News Print Paper to Oklahoma Points

Corporation Commission of Oklahoma v. Atchison, Topeka & Santa Fe et al. Opinion by Commissioner Hall:

The commission finds that the fifth class rate of 57 cents a 100 lb. on news print paper from Galveston to Oklahoma City is unreasonable and the following rates are prescribed for the future: to Oklahoma City and McAlester, 38 cents; to Muskogee and Lawton, 40 cents, and to Tulsa, 42 cents. (33 I. C. C., 503.)

Rail-and-Water Rates Through Gulf Ports on Grain

Tampa Board of Trade v. Alabama & Vicksburg et al. Opinion by Commissioner Meyer:

The commission finds that the joint through rail-and-water rates on grain and grain products, from Ohio and Mississippi river crossings and other points of origin to Tampa, Fla., via New Orleans and the Gulf & Southern Steamship Company and via Mobile and the Mallory Steamship Company are unreasonable in so far as they exceed the present rail rates to the ports by more than 10 cents per 100 lb. (33 I. C. C., 457.)

Telegraph and Cable Rates

W. N. White Company v. Western Union Telegraph Company. Opinion by Commissioner Hall:

The commission finds that defendant's standard rates for the transmission of messages by telegraph from New York to San Francisco and by cable from New York to points in England are not unreasonable or discriminatory. The attack on the San Francisco rates was based chiefly on the fact that press messages are accorded lower rates. The decision says: "The right of carriers subject to the act to initiate their charges is too well established to need citation of authority. Such charges are prima facie reasonable, except where otherwise provided by law. Congress has here provided that messages may be classified into 'day, . . . press, . . . and such other classes as are just and reasonable,' and that different rates may be charged for the different classes." (33 I. C. C. 500.)

Rates on Asphaltum, etc., from Pacific Coast Points to Atlantic Ports

Opinion by the commission:

The Southern Pacific and its affiliated lines are authorized to establish a rate of 40 cents a 100 lb. in carloads, minimum 80,000 lb., on asphaltum, barley, beans and canned goods from San Francisco, San Pedro and Wilmington, Cal., moving over the Sunset Gulf route via rail to Galveston, Tex., and steamer thence to Charleston, S. C., Baltimore, Md., Philadelphia, Pa., New York and Boston, Mass., while continuing higher rates from, to and between intermediate points.

Relief from the fourth section was asked because of the competition of water carriers using the Panama Canal. It was shown that this route had lost to the canal route since July 1, 1914, two thirds of its former proportion of asphaltum traffic, three-fourths of its proportion of bean traffic, and two-thirds of its proportion of traffic in canned goods. It was also shown that this very low rate was at least sufficient to cover the "out of pocket" cost on this traffic. (33 I. C. C., 480.)

Ownership of Schooner Pasadena

Opinion by Commissioner Clark:

The schooner Pasadena is owned by the Albion Lumber Company, a corporation, all the stock of which is owned by the Southern Pacific. It is operated principally between Albion and San Francisco, and primarily for the purpose of moving the lumber company's products to market. It also operates between other ports.

The commission finds that so long as the line of the Northwestern Pacific (in which the Southern Pacific owns a one-half interest) between Albion and Christine is not extended to connect with its line between Willits and Sausalito, neither it nor the Southern Pacific does or can compete with the Pasadena in its operation between the ports of Albion and San Francisco, and that the continued ownership and operation of the Pasadena by the Southern Pacific through the Albion Lumber Company between Albion and San Francisco is not and will not be in violation of section 5 of the act to regulate commerce, as amended by the Panama Canal act.

It is further held that in operating the boat between San Francisco and San Pedro and Redondo the Southern Pacific may compete with the Pasadena. In so far as the petition seeks a continuance of this service, it is denied as of May 1, 1915. (33 I. C. C., 476.)

STATE COMMISSIONS

The Board of Public Utilities of New Jersey, having considered a complaint of lack of drinking water on excursion trains between Camden and Atlantic City, recommends that suitable coolers be provided in at least one car of every three on excursion trains.

The California Railroad Commission has issued an order approving a modified traffic agreement between the Southern Pacific and the San Pedro, Los Angeles & Salt Lake by which the latter company will be permitted to engage in local passenger and freight business on the Southern Pacific line between Riverside and San Bernardino. Heretofore the Salt Lake line, although having traffic rights between those points, was not permitted to handle local traffic.

PERSONNEL OF COMMISSIONS

James O. Carr, Republican, of Schenectady, a member of the legal department of the General Electric Company, has been appointed a member of the New York State Public Service Commission, Second district, to succeed Martin S. Decker, Democrat, whose term expired on February 1. Mr. Carr has been with the General Electric for fifteen years.

COURT NEWS

Commutation Tickets—Violation of Stipulations

The Supreme Court of New Jersey holds that the right of a carrier to take up a commutation ticket improperly used is not limited to the occasion when it is presented. If the condition has been violated, the ticket may be taken up subsequently when presented by the owner himself. Trupin v. Central of N. J. (N. J.) 93 Atl. 93.

Pullman Porter Not Railroad Employee

The Supreme Court of the United States, in an action for personal injuries by a Pullman sleeping car porter on an interstate train against the railroad company, holds that the plaintiff was not an employee of the railroad within the meaning of the federal employers' liability act. It was insisted for the plaintiff that he should be regarded as the employee of the railroad because of the fact that, in the case of passengers coming on the train after three o'clock in the morning, he received the railroad

ticket or fare, which he placed in an envelope and afterwards gave to the train conductor. This, however, was an obvious accommodation to the passengers in the Pullman car, and in any event it was merely an incidental matter which could not be deemed to qualify the character of the plaintiff's employment as viewed from the standpoint of the statute.—Robinson v. B. & O. (April 5).

Unguarded Space Between Platform and Cars—Negligence and Contributory Negligence

Action was brought in the federal courts by a passenger on the New Haven road, who was injured at the Grand Central Terminal, New York, in attempting to alight from a car. The station platform was constructed for the new cars, from which the passenger can step to the station platform on the same level. But with the old style of cars there was a distance of 3 ft. between the station platform and that of the car. The company had porters to bridge this open space by putting down a movable bridge over which the passengers could pass. On the occasion in question no board or plank had been put in place, and in stepping from the car the plaintiff fell into the opening. The open space being only 3 ft., he could easily have stepped across it had he observed it. Although some twelve passengers preceded him, he was the only one who fell. He testified that he could have seen the open space had he been looking, but that he did not look. He relied on the bridge being there as usual. One of the company's defenses was contributory negligence. It was held by the circuit court of appeals for the Second circuit, that negligence of the company and contributory negligence of the plaintiff were both questions of fact for the jury, which found for the plaintiff.

Hours of Service Law

In an action for a violation of the hours of service law in the district court of Idaho a locomotive engineman was regularly employed in moving interstate commerce; but for a period of 59 days was on a work train, wholly within the state of Idaho, filling (not repairing) a bridge on an interstate line; and thereafter he went back into interstate commerce. On the work train he was permitted to remain on duty more than 16 hours. It was held that the road was not thereby guilty of a violation of the act. The court said that this was not a case where there was a commingling of service, where the employee was one hour or one day at work in interstate and another hour or another day in intrastate. If the contention of the government were correct, an employee who has once rendered service such as is covered by the act must always be deemed to be within the provisions thereof, regardless of the time which has elapsed since he ceased to render such service, at least so long as he remains in the employ of the same company. United States v. Chicago, M. & St. P., 219 Fed. 632.

Failure to Give Crossing Signal—Frightening Horses

The Supreme Court of South Carolina holds that a statute requiring the sounding of bell and whistle 500 yards from railroad crossings and public places was intended for the protection of persons using the highway or public place, and did not give a right of action to the plaintiff, who was working in a field near the track, and about 200 yards from the crossing when injured by fright of his horse by the passing of a train which had failed to give the crossing signal. The court distinguished the case from that of Clifford v. Southern Railway, 87 S. C. 325, where the plaintiff was traveling along the highway, and was on the crossing before she had any warning of the approach of the train, and had just cleared the track when the train passed, without signal, and missed the hind wheels of her buggy only a few inches. Her horse was so frightened that he threw her out and injured her. In Miss Clifford's case, the company owed her the duty, in her situation, to give the crossing signals. In this case, the company owed no such duty to the plaintiff, because his injury had no connection with the use or intended use of the crossing. In some of the cases such statutes are given a more restricted construction than that of the South Carolina court, and it is held that the signals are required to protect travelers only against actual collision with passing engines or cars. Hutto v. Southern Ry. (S. C.) 84 S. E. 719.

"Attractive Nuisance" Doctrine

In an action for personal injuries to a child the plaintiff based his right to recover on the "turntable" cases, or the "attractive nuisance" doctrine. The defendant railroad company maintained over a street a viaduct and a retaining wall 20 inches wide, with a smooth surface on top. One end of the wall was about 28 inches above the street, and from that end it gradually ascended until it reached a height of 15 ft. Children found the wall attractive, and were in the habit of climbing upon it; which fact was known to the defendant. The child injured climbed upon the wall and fell into the street below. It was held by the Kentucky Court of Appeals that the railroad company did not maintain a dangerous instrumentality attractive to children; it need not construct barriers to prevent children from climbing on the wall, and was not liable for the child's injuries. The only sense in which the wall could be said to be dangerous was that it was easy to climb, and easy to fall from; but so is every tree, pole, fence, ladder or railing. If spikes had been placed on it, as suggested, and the child had been injured by them, there would have been greater reason for holding the defendant liable. If a fence or guard rail had been constructed at the lower end of the wall, it would only have added to the danger by furnishing something else to fall from.—Coon v. Kentucky & I. T. (Ky.) 173 S. W. 325.

Wooden Coal Cars Not Dangerous Appliances—Customary Use

While engaged in unloading a wooden coal car, the trap doors in the bottom of which had become swollen with the wet coal and damp weather, an employee, after striking a refractory door with his iron bar, fell through the opening with the coal into the bunkers below, receiving injuries from which he died. In an action for his death it was shown that the cars used were such as were commonly used by all railroads for such purposes, and that trap doors quite commonly became swollen so as not to open by the removal of the fasteners; and it was not shown that there was any other method of forcing open the doors which would be attended with less danger than the method used. The Supreme Court of Washington, therefore, held that it was not negligence in itself to use the cars. An employer can, without becoming an insurer against accidents to his employees, make use of the common appliances in the prosecution of his business. The question in such cases is not, Would something else have been better? but is rather, Are the appliances and methods used inherently dangerous, and are the dangers concealed from the employees? (Bjornsen v. Northern Pacific (Wash.), 146 Pac., 575.)

Free-haul and Pay Lines—Rates Chargeable for Through Shipment

In an action by the Southern Pacific against the government the appeal to the United States Supreme Court presented but a single question of law, as to the legal rate of compensation to which the company was entitled for the transportation of government property and troops over a continuous line of road, part of which is free-haul and the remaining part is pay-line. Between August, 1897, and March, 1902, the railroad transported for the United States persons and property over the free-haul part of its line from Roseville Junction to Portland, a distance of 664 miles "from points on either side thereof to points on the other side; for example, from San Francisco . . . to Portland, via Rosedale Junction." For such services the company charged nothing for haulage over the free portion of the road, but exacted the local rate between San Francisco and Roseville Junction. The government insisted that it was entitled to the benefit of the San Francisco-Roseville proportion of the through rate. The company argued that, while there is a continuous rail line between San Francisco and Portland, the line itself, from the standpoint of compensation or pay to the company, breaks at Roseville Junction; south of that point it is pay line; north thereof it is free-haul. The court decided that this proposition was erroneous, and that it was not the character of the movement that fixed the rate, but the rate which determined the character of the movement. Apart from this, it held that to accept the company's proposition would give rise to a violation of the act of Congress governing the movement of traffic over the pay line, which gives the government the right to ship over the road at rates not to exceed the amounts paid by private

parties. Judgment for the government was therefore affirmed.—Decided April 12, 1915.

Stopping Passenger Trains at Small Stations—Invalid Statute

The decision of the Supreme Court of the United States reversing the Supreme Court of Wisconsin as to stopping through trains at small stations was briefly noticed in the *Railway Age Gazette* April 16, page 868. The case was brought up by the railroad, the Chicago, Burlington & Quincy, asking a review of the judgment of the State Court, which had sustained an order of the railroad commission requiring the railroad, under a state law, to stop two of its passenger trains, each way daily, at Cochrane. The statute requires a station to be maintained at every village having a post office and containing 200 inhabitants, within one-eighth of a mile of the road, and if four or more trains were run each way daily to stop at least two. The daily passenger service at Cochrane was one passenger and one freight, carrying passengers, each way. The population of the village is about 260. The court holds that the test of the statute was purely artificial. The number of trains cannot be determined by the local needs of a village. This railroad runs only interstate trains. The line is through a sparsely settled country, and 90 per cent of the business is interstate, and the trains assigned to intrastate business are not self-sustaining. The revenue at Cochrane from the passenger traffic for the year ending July, 1911, was only $1,752, of which $986 was from intrastate and $766 from interstate business. The court held the statute invalid and reversed the judgment of the Wisconsin Supreme Court.—Decided April 12, 1915.

Interchange of Cars With Electric Road

In the early part of the year 1908 petitions were filed before the Michigan Railroad Commission by certain merchants of Ortonville and Goodrich, asking for a connecting track between the Michigan Central and the Detroit United at Oxford for the interchange of cars under section 7 (b) of Michigan Public Acts 1907, No. 312, providing that "where it is practicable and the same may be established without endangering the equipment, tracks or appliances of either party, the commission may require steam and interurban railroads to interchange cars, carload shipments, less than carload shipments, and passenger traffic. . . ." The Michigan Central answered denying that it would be practicable to construct and maintain such a physical connection, and denying the authority of the commission. The Detroit United denied the practicability of interchanging carload shipments (supposing a track to have been established), without unreasonable expenditure of money in changing its road and equipment. There was a full hearing. The commission found the construction and maintenance of the connection to be feasible and the expense of construction $500. It also found the proposed interchange to be reasonable from the point of view of the Michigan Central. An order was made requiring the connection to be made, and thereafter an interchange in accordance with the provisions of section 7. The physical connection was installed, and no question was afterwards made respecting this. But the Michigan Central complied, to the extent of installing the physical connection, under protest. The Detroit United was willing and able to accept cars and carloads of freight [for delivery within belt line limits] but the Michigan Central had so far refused to deliver freight to the Detroit United. There was no controversy on the other parts of the order. The Supreme Court of Michigan (168 Mich. 230) awarded a peremptory writ of mandamus directing the Michigan Central with respect to intrastate traffic, to make the interchange. This judgment was brought under review by the Supreme Court of the United States. The court holds that the state has power to make a reasonable order requiring a carrier to permit empty or loaded cars owned by it to be hauled from its line on the connecting line for the purposes of loading or delivery of intrastate freight, and the same with the cars of other carriers. The order was held only to apply to intrastate traffic, to which the jurisdiction of the commission is limited, and the presumption must be indulged, until the contrary is made to appear, that the state will not so construe or enforce the order as to interfere with or obstruct interstate commerce. The judgment was affirmed.

Railway Officers

Executive, Financial, Legal and Accounting

D. E. Hedges, auditor of the Tennessee, Alabama & Georgia at Chattanooga, Tenn., has resigned.

M. A. Johnson has been appointed auditor of receipts of the Missouri, Kansas & Texas of Texas, with headquarters at Dallas, Texas, succeeding S. H. McCartney, resigned.

The appointment of H. U. Mudge, president of the Chicago, Rock Island & Pacific, and Jacob M. Dickinson as receivers of that road is commented on elsewhere in this issue.

S. H. McCartney, auditor of receipts of the Missouri, Kansas & Texas of Texas, has been appointed secretary and auditor of the Nevada-California-Oregon, with headquarters at Reno, Nev.

Edward S. Moore has resigned as vice-president in charge of purchases of the Chicago, Rock Island & Pacific, with office at Chicago. At the annual meeting on April 12, he declined re-election as a director, and he also declined re-election as vice-president.

H. I. Miller, chairman of the board of the Buffalo & Susquehanna Corporation, receiver of the Buffalo & Susquehanna Railway, vice-president of the Mexico North Western and of the Denver & Salt Lake, has been elected also president of the Tennessee & North Carolina, with headquarters at New York. Mr. Miller resigned recently as president of the New Orleans Great Northern.

William E. Farris, who has been elected third vice-president of the New Orleans Great Northern in charge of operation, with headquarters at New Orleans, La., was born on November 22, 1870, at Sandborn, Ind., and was educated in the common schools. He began railway work on August 1, 1891, as a telegraph operator and agent on the Evansville & Terre Haute. He remained in the service of this company at various places until April, 1905, when he was appointed agent in charge of the Evansville & Terre Haute and the Chicago & Eastern Illinois terminals at Terre Haute, Ind. On December 31, 1910, he resigned from that position to go to the Buffalo & Susquehanna as assistant general freight and passenger agent; one month later he was promoted to general freight and passenger agent, and subsequently served also as purchasing agent of the same road until his recent election as third vice-president of the New Orleans Great Northern, as above noted.

W. E. Farris

L. R. Wood, assistant auditor of the Oregon Short Line, has been appointed auditor, with headquarters at Salt Lake City, Utah, succeeding C. J. McNitt, who has been retired under the pension rules of that company on account of continued ill health. P. L. Williams, general attorney of the Union Pacific for Utah and general attorney of the Oregon Short Line, with office at Salt Lake City, will be retired on May 1 under the pension system of the Union Pacific, and will be succeeded by George H. Smith, who has been assistant to Mr. Williams.

Walter P. Cooke, first vice-president and general counsel of the New Orleans Great Northern at Buffalo, N. Y., has been elected president, with headquarters at Buffalo, vice H. I. Miller,

resigned. Charles I. James, second vice-president at Baltimore, Md., has been elected first vice-president with headquarters at Baltimore; A. C. Goodyear, third vice-president at Buffalo, has been elected second vice-president with headquarters at Buffalo, and W. E. Farris, general freight and passenger agent, and purchasing agent, of the Buffalo & Susquehanna at Buffalo, N. Y., has been elected third vice-president of the New Orleans Great Northern, with headquarters at New Orleans, La.

Operating

J. E. Lovejoy has been appointed assistant superintendent of the Phoenix division of the Arizona Eastern, with headquarters at Phoenix, Ariz., vice J. G. Lindsay, assigned to other duties.

John Kirk, superintendent of terminals of the Elgin, Joliet & Eastern at Gary, Ind., has been appointed superintendent of the Gary division, with office at Gary, and C. H. Doorley, assistant superintendent of terminals at South Chicago, Ill., has been appointed superintendent of terminals at East Joliet, Ill.

W. H. Davidson, assistant trainmaster of the Delaware & Hudson at Albany, N. Y., has been appointed trainmaster of the Champlain division, with office at Plattsburg, vice J. H. Galivan, deceased. F. R. Griffin, assistant trainmaster at Plattsburg, has has been appointed assistant trainmaster of the Saratoga division, with office at Albany, vice Mr. Davidson, and the office of assistant trainmaster, Champlain division, has been abolished.

Traffic

The office of division freight agent on the Southern Railway at Selma, Ala., has been discontinued, and E. M. Jordan has been appointed commercial agent, with headquarters at Selma.

Engineering and Rolling Stock

H. B. Cartwright, acting assistant engineer of the Seaboard Air Line at Jacksonville, Fla., has been appointed assistant engineer, with office at Jacksonville, vice L. R. Hoyt, assigned to other duties.

H. H. Vaughan, assistant to vice-president of the Canadian Pacific at Montreal, Que., at his own request, has been released from the immediate supervision of the construction and maintenance of locomotives and cars, in order that he may devote his attention to important contract engagements that he has become interested in. He is being retained as consulting engineer, and W. E. Woodhouse, superintendent of motive power, Eastern Lines, at Montreal, has been appointed chief mechanical engineer.

Samuel Tobias Wagner, whose appointment as chief engineer of the Philadelphia & Reading with headquarters at Philadelphia, Pa., has already been announced in these columns, was born in 1861 in Philadelphia. He graduated from the University of Pennsylvania in 1881 with the degree of bachelor of science, and was awarded the senior civil engineering prize; and three years later the degree of civil engineer was awarded to him. Mr. Wagner was in the employ of the Phoenix Iron Company consecutively as draftsman, assistant superintendent of shops and superintendent of shops until 1893, except for about one year when he was resident engineer of erection on the construction of the Louisville & Jeffersonville bridge over the Ohio river. From 1894 to 1900 he was assistant engineer on behalf of the city of Philadelphia in charge of the design and construction of the Pennsylvania avenue subway and tunnel, on the line of the Philadelphia & Reading in Philadelphia. After that he was engaged for a number of years in the installation of the water supply for the city of Philadelphia. Mr. Wagner entered the service of the Philadelphia & Reading in 1902 as assistant engineer, and was engaged on grade crossing work and other improvements in Philadelphia until his recent appointment as chief engineer, as above noted.

S. T. Wagner

B. J. Schwendt, signal engineer of the Toledo & Ohio Central, and the Zanesville & Western, has been appointed superintendent of telegraph and signals of the same roads, retaining jurisdiction over the signal department, with headquarters at Columbus, Ohio, effective on April 1, 1915. Mr. Schwendt was born July 25, 1884, at Greenspring, Ohio, and obtained his early education in the grammar and high schools of that place. In March, 1902, he went to work for the Minot Light & Telephone Company, Minot, N. Dak., as assistant plant fireman, from which position he was advanced by successive steps to station helper, electrician, wireman, lineman, installer, and in August, 1903, was given charge of the telephone department. During the first three months of 1903 he was granted leave of absence and was employed by the ice contractor of the Great Northern, cutting, shipping and housing ice at points between Larimore, N. D., and Seattle, Wash. In November, 1903, he entered Ohio State University at Columbus, graduating in 1907 with the degree of mechanical and electrical engineer. During the summer months of 1905-6 he was employed by the Allis-Chalmers Electrical Company, in the Bullock works at Cincinnati, Ohio, as winder and assemblyman. In June, 1907, he entered the service of the Union Switch & Signal Company and was engaged in the installation of electric and mechanical interlockings and automatic signals on the Pennsylvania lines West, the Baltimore & Ohio, and the Erie. During this time he served in various capacities, from laborer up. In March, 1909, he was appointed supervisor of signals for the Toledo & Ohio Central, Hocking Valley, Kanawha & Michigan, and the Zanesville & Western, with headquarters at Columbus, Ohio. On January 11, 1912, he was appointed signal engineer of the Toledo & Ohio Central and Zanesville & Western.

B. J. Schwendt

OBITUARY

Robert S. Brown, district passenger agent of the Baltimore & Ohio Southwestern at Louisville, Ky., died on April 21, at his home in that city at the age of 61.

Charles E. Potts, formerly until July, 1913, assistant treasurer of the Chesapeake & Ohio at Richmond, Va., died at his home in Ashland, on April 19, at the age of 63.

Charles Walter Rhodes, assistant treasurer of the Baltimore & Ohio, died suddenly on April 14, in Baltimore, Md. He was born on January 28, 1853, near Westminster, Md., and in February, 1869, entered the service of the Baltimore & Ohio.

Burton Johnson, formerly from January, 1897, to November, 1906, general freight agent of the Wisconsin Central, died at his residence in Chicago on April 18, aged 62 years. Mr. Johnson entered railway service in 1879 with the Chicago & North Western as a clerk in the general freight department and remained with that road until January, 1897, at which time he held the position of second assistant general freight agent. He then went to the Wisconsin Central as general freight agent.

Colonel Alexander Boyd Andrews, first vice-president of the Southern Railway, with office at Raleigh, N. C., died on April 17, at his home in that city. He was born on July 23, 1841, in Franklin county, N. C., and from 1859 to 1861 he served as purchasing agent, paymaster and general superintendent for the contractor on the Blue Ridge Railroad. After the Civil war he leased, equipped and operated a railway ferry for the Raleigh & Gaston, now a part of the Seaboard Air Line, and the Petersburg Railroad, now a part of the Atlantic Coast Line, at Gaston, N. C. From July, 1867, to November, 1875, he was superintendent of the Raleigh & Gaston and the Raleigh & Augusta, and then was superintendent of the North Carolina division of the Richmond & Danville. He was elected president of the Western North Carolina in 1881, and completed that road. From 1878 to 1880 he was also superintendent of the Atlantic & North Carolina, now a part of the Norfolk Southern, and superintendent of the North Carolina division of the Richmond & Danville. In 1883 he was appointed assistant to president of the Richmond & Danville, remaining in that position until 1886, when he was elected third vice-president, and from December, 1889, to June, 1894, was second vice-president of the same road. From July, 1892, to June, 1894, he was also general agent for receivers of the same road. He then went to the Southern Railway as second vice-president, and since October 1, 1895, was first vice-president of that road, also of the Mobile & Ohio, and the Alabama Great Southern, and president of the Danville & Western, Blue Ridge, Tallulah Falls, and Augusta Southern.

A. B. Andrews

Ivory Coast Railway.—The railways on the Ivory Coast will have in the future a great effect on the commercial development of the Ivory Coast. The scheme for the railways in this colony is that one railway (the main line) starting from Abidjan is to go to Bouake, and from there be pushed on to Bobo-Dioulasso, crossing the river Volta in the Upper Sudan. A branch line will run from Dimbokoro to Daloa (in the administrative circle of Upper Sassandra), and passing through Man (Touba circle) will connect with the railway of French Guinea.

Indian Railway Operation.—The ratio of operating expenses to traffic receipts on the railways of British India stood in 1912 at 48.92 per cent. In consequence of the rise in wages in India the ratio has shown a certain tendency to increase of late years; but in 1912 it experienced a considerable reduction and approximated to the level at which it stood ten years previously. The course taken by the ratio during the decade ending with 1912 inclusive was as follows:

Year	Per cent	Year	Per cent
1903	47.52	1908	60.24
1904	47.36	1909	56.06
1905	47.85	1910	53.10
1906	49.89	1911	53.17
1907	51.42	1912	48.92

The ratio has fluctuated considerably upon the principal Indian lines, being affected by their extent, their situation and current local labor conditions. Upon the Bengal & North-Western (one of the most prosperous of the Indian systems) the ratio was 34.16 per cent in 1912; upon the Bengal Dooars, 36.05 per cent; upon the Bengal & Nagpur, 45.74 per cent; upon the Bombay, Baroda & Central India, 49.67 per cent; upon the Burma, 59.47 per cent; upon the East Indian, 37.62 per cent; the Eastern Bengal, 59.14 per cent; the Great Indian Peninsula, 53.96 per cent; the Madras & Southern Mahratta, 54.53 per cent; and the South Indian, 51.68 per cent.—*Engineering.*

Equipment and Supplies

LOCOMOTIVE BUILDING

The Kansas City Southern is reported to be in the market for 6 switching locomotives.

The Rapid City, Black Hills & Western has ordered one Prairie type locomotive from the Baldwin Locomotive Works.

The Algoma Lumber Company, Algoma, Ore., has ordered one Prairie type locomotive from the Baldwin Locomotive Works

The Champion Lumber Company, Philadelphia, Pa., has ordered 2 90-ton Shay geared locomotives from the Lima Locomotive Corporation.

The Pennsylvania Lines West have issued inquiries for 50 freight locomotives. These are in addition to the 144 locomotives which will be required by the Pennsylvania Lines East of Pittsburgh.

The Pennsylvania Railroad has issued inquiries for material for 76 road and 68 switching locomotives, which it will build in its Juniata shops. As the Pennsylvania Lines West have also issued inquiries for 50 locomotives, this will make a total for all the Pennsylvania Lines of 194 locomotives.

The Illinois Central has ordered 4 Mikado type locomotives from the Lima Locomotive Corporation. These are in addition to the 50 Mikado type locomotives recently ordered from the same company. They will have 27 in. by 30 in. cylinders, 63-in. driving wheels, a total weight of 284,400 lb., and a weight on drivers of 213,100 lb.

CAR BUILDING

The Lehigh Valley will reinforce 2,000 freight cars with steel underframes.

The Wilkesbarre & Hazelton has ordered 10 interurban cars from the J. G. Brill Co.

The Chicago, Indianapolis & Louisville is having 300 box cars rebuilt by the Haskell & Barker Car Company.

The St. Louis, Troy & Eastern has ordered 300 gondola cars from the American Car & Foundry Company.

The Chicago & North Western, which was reported in the *Railway Age Gazette* of last week, as being in the market for 2,500 freight and 50 passenger cars, has issued inquiries for 2,000 steel underframe box cars, 50 steel underframe caboose cars and 50 all-steel passenger cars. These cars are to be delivered this summer and the estimated expenditure will be about $3,000,000.

The Pennsylvania Railroad's passenger equipment program calls for 146 all-steel passenger cars divided as follows: 30 coaches, 54 combination passenger and baggage cars, 42 baggage and mail cars, 15 baggage and express cars and 5 horse express cars. Bids were asked on Saturday for building 90 of these cars and inquiries issued for materials for the other 56, which will be built in the company's shops at Altoona. This equipment will be purchased for replacement purposes. As the Pennsylvania Lines West have also asked prices on 35 all-steel passenger cars, there will be a total for all the Pennsylvania Lines of 181 cars.

The Pennsylvania Railroad has issued inquiries for 7,643 freight cars, to be built by outside companies and for materials for 2,102 freight cars to be built at the company's shops at Altoona. The freight car program calls for 2,000 all-steel box cars, 2,500 gondola cars, 4,919 coal and coke cars, 224 refrigerator cars and 102 flat cars. The company plans to build in its car shops at Altoona, 1,000 of the 2,000 box cars, 1,000 of the 2,500 gondola cars and all of the flat cars. These 9,745 freight cars will be for replacement purposes only. As the Lines West have also issued inquiries for 6,500 freight cars, the total freight

car requirements for all the Pennsylvania Lines aggregate 16,245 cars.

The Pennsylvania Lines West have issued inquiries for 6,500 freight cars and 35 all-steel passenger cars, these being in addition to the 9,745 freight cars and 146 passenger cars which will be required by the Lines East of Pittsburgh. The Lines West have some 90,000 freight cars, with an annual normal vacancy of 5,000 cars. Last year the Lines West ordered no new cars. Any cars which will be ordered this year will be replacements and not additions. The 6,500 freight cars will include 100 refrigerator, 1,500 gondola, 2,500 box, 2,300 hopper and 100 miscellaneous cars. The 35 passenger cars will be divided as follows: 6 dining cars, 10 coaches, 10 baggage and mail cars, 2 postal cars and 7 baggage cars.

IRON AND STEEL

The Lehigh Valley is in the market for a car wheel borer.

The Pennsylvania is in the market for two 100-ton electric cranes.

The Chicago, Rock Island & Pacific is in the market for approximately 30,000 tons of rails.

The Bay State Street Railway has ordered 1,200 tons of girder rails from the Pennsylvania Steel Company.

The New York, Chicago & St Louis has ordered 1,500 tons of bridge material from the Pennsylvania Steel Company.

The Delaware, Lackawanna & Western has ordered a 25-ton gantry crane from the Toledo Bridge & Crane Company.

The Missouri, Oklahoma & Gulf is reported to have ordered 2,000 tons of rails from the Tennessee Coal, Iron & Railroad Company.

The Chicago, Burlington & Quincy is inquiring for three wheel presses, a forging machine, a double-ended punch and shear, a 5-ft. radial drill, six shapers, one slotter, 11 lathes of various kinds and sizes, tool grinders, saws, etc., and two 240-hp. water tube boilers.

SIGNALING

The New York Central has contracted with the General Railway Signal Company, Rochester, N. Y., for the complete installation of a 224-lever electric interlocking plant at Tower 31, Utica, N. Y. This machine will be the G. R. S. standard model 2 with unit levers. The switch movements will be Model 4, giving a dynamic indication, and the signals Model 2A.

Steel Cars in Egypt.—All-steel passenger cars are being adopted on the Egyptian State Railways. A first consignment of a recent order for 30 has been received from Leeds, England.

Why Not Investigate Merchants?—It is an easy matter and quite the popular one to roast the railroads, but how about the big merchants? It is announced in Chicago that Sears, Roebuck & Company recently declared an annual dividend of $20,000,000 and yet we have not heard of anyone who is in favor of a law curbing the rapacity of this octopus. We are told that the great mercantile house of Marshall Field & Company of Chicago took in more money last year than the entire system owned by the great Atchison, Topeka & Santa Fe Railway Company, and neither Congress nor any state legislature has been asked to get after Marshall Field & Co. and demand the conduct of the business on what is termed a reasonable return for the money invested, and nobody has had the temerity to arise and demand that Sears, Roebuck & Company or Marshall Field & Co. be made to give a full accounting as to capitalization, profits and the like. The Iowa Farmer does not know whether the railways are losing money. The claim is made that they are unable to get further credit. . . . They declare that they are able to prove this contention to the satisfaction of any unprejudiced jury if given an opportunity. Why not treat them as any other business enterprise would be treated and permit them to at least present the argument that will substantiate their contention for an advance in rates?—*Iowa Farmer.*

Supply Trade News

Munn & Co., patent attorneys, have removed their offices to the Woolworth building, New York.

Wilber H. Traver, manager of the mining department of the Chicago Pneumatic Tool Company, died in Houghton, Mich., on April 15.

The Du Pont Fabrikoid Company, Wilmington, Del., has moved its New York sales office from 90 West street to Room 1614 Equitable building, 130 Broadway.

William F. Gillies, formerly in charge of the New York sales branch of the Ingersoll-Rand Company, New York, has been appointed branch manager of the same company at Pittsburgh

The White Enamel Refrigerator Company, St. Paul, Minn., has been awarded an order for Bohn all-steel collapsible bulkheads, Hatch ventilators and plugs for 500 refrigerator cars for the Atchison, Topeka & Santa Fe.

R. Harvey White, formerly signal engineer of the Chicago Railway Supply Company, Chicago, and at one time editor of The Signal Engineer, has joined the selling force of the National Carbon Company, Cleveland, Ohio.

A. J. Poole, formerly superintendent of motive power of the Seaboard Air Line, has become associated with the Galena Signal Oil Company in the capacity of railway expert, with headquarters in Atlanta, Ga., effective April 15.

W. B. Carnes, formerly in charge of the New York office of the Lima Locomotive Corporation, has been appointed western representative, with offices in the McCormick building, Chicago. He has been succeeded in New York by William T. Middleton.

The Bucyrus Company, South Milwaukee, Wis., has moved its southern sales office from Birmingham, Ala., to 1105 Hennen building, New Orleans, La. E. L. Byron, southern sales manager, will remain in charge, and R. S. Byron will be associated with him.

Marvin F. Wood, formerly of Wood & Van Nest, now has offices at Room 414, 30 Church street, New York. Mr. Wood is representing the new Washrite Compound for cleaning the exterior of passenger and baggage cars, and for polishing the interiors of cars and buildings.

Alexander Taylor has been promoted from assistant secretary to secretary of the Lake Superior Corporation, the Algoma Steel Corporation and subsidiary companies, succeeding Thomas Gibson, who recently became president of the Lake Superior Corporation. Mr. Taylor has also been made a director.

Luther Steadman Bent, at one time president of the Pennsylvania Steel Company and a director in numerous corporations, died of paralysis on April 19 at his home in Overbrook, Pa., at the age of 86. Mr. Bent became manager of the Pennsylvania Steel Company in 1874, and in 1880 was made president. He held that office until 1896, when he retired.

The Westinghouse Electric & Manufacturing Company has received an order from the Chicago & Milwaukee Electric for 15 quadruple equipments of type No. 557-A, 140 hp. motors with double end type "HLF" control. These equipments are to be placed in high speed passenger express service between Chicago and Milwaukee. The cars will be arranged for train operation.

The American Locomotive Company, which has been negotiating for some time for a large contract for shrapnel, is now supposed to have closed contracts with the Russian government for shrapnel aggregating $65,000,000 in value. The company has purchased $500,000 of the special machinery which will be necessary, and has had options on $500,000 worth more of such machinery for several weeks.

The Firth Sterling Steel Company, McKeesport, Pa., is running double time on the manufacture of shrapnel shells, turn-

ing out about 2,500 daily, and the National Tube Company, the Pressed Steel Car Company and a number of other companies in the Pittsburgh district are also said to be turning out from 1,000 to 3,500 shrapnel, each, daily. The Standard Steel Car Company is about to start work on a large order for shells.

Lee H. Parker has been appointed president of the Spray Engineering Company, Boston, Mass. Mr. Parker has had a wide experience in the engineering field, having been for a number of years with the General Electric Company, and for the past ten years with the Stone & Webster Engineering Corporation. He also has had considerable executive experience in representing large London interests in South America for many years.

The Lackawanna Steel Company has closed contracts for delivery to the Allies of 50,000 tons of shrapnel steel. According to the terms of the agreement 5,000 tons must be shipped every ten days. It has been reported that this company since the beginning of the war has received orders for 500,000 to 600,000 tons of shrapnel, the total value of these orders being estimated at from $22,500,000 to $27,000,000. The Carnegie Steel Company and the Crucible Steel Company of America have also obtained large orders for shrapnel steel.

Merrill G. Baker, whose appointment to the position of assistant general manager of sales of the American Vanadium Company was announced in the *Railway Age Gazette* of last week, was formerly assistant to the general manager of sales of the Cambria Steel Company. Mr. Baker was born in Indiana county, Pa., in 1880, from which his parents moved to Johnstown, Pa., in 1884. He worked his way through preparatory school, paying his expenses by doing night work as a telephone operator, and later attended Dickinson college, from which he graduated with the class of 1904. He entered the employ of the Cambria Steel Company on January 3, 1905. He worked in various of that company's operating departments until July, 1906, when he entered the sales department. In September, 1912, he was appointed assistant to the general manager of sales in charge of the rail and structural departments.

John S. Griggs, Jr., electrical and mechanical engineer, and David Moffat Myers, mechanical engineer, have consolidated their practices and formed the firm of Griggs & Myers, with offices at 110 West 40th street, New York. Mr. Griggs was for 12 years senior partner of the consulting firm of Griggs & Holbrook, New York. He has been in practice as a consulting engineer in New York for 20 years, and has made steam and electrical installations in several important office buildings and industrial plants. Mr. Myers was formerly mechanical engineer for the United States Leather Company, New York, in charge of the efficiency work in its steam plants. In 1906 he started a private consulting practice. He has specialized on the efficient operation and design of industrial plants, with special reference to steam and fuel economy and to the use of exhaust steam in the production of high over-all efficiency. He is also the author of "Preventing Losses in Factory Power Plants."

In the *Railway Age Gazette* of last week it was stated that the Westinghouse Air Brake Company was reported to have received an order for 1,000,000 shrapnel from France. An officer of the company has said: "We have just closed a contract with representatives of the French government for 1,000,000 three-inch shrapnel shells, cartridge cases and time tubes, for what is known as the 75-millimetre Schneider gun. This gun shoots 16 shots a minute, and is considered one of the most effective implements of war of the French army and navy. The contract aggregates $20,000,000, and we have one year in which to complete it. We are about ready to begin work on the contract, and are completing the installing of machinery in three of our buildings which have heretofore been unoccupied. The shrapnel is in three parts. One part is the steel shell, another the cartridge case and the third the timefuse tube. We will do all the work on the shrapnel except placing in them the explosives. That will be done on the other side of the water. It requires skilled mechanics to manufacture these shells, every part of which must be in perfect order when delivered. We will be able to turn out daily from 3,500 to 5,000 completed shells by working double turn. The contract is enormous, of course, and we are very glad to get it. It means much for the financial condition of this section. We will manufacture only the one-size shrapnel shells for the reason that our present contract will keep us busy for the next 12 months."

Railway Construction

Alma & Jonquieres.—The Quebec legislature has granted this company an extension of time in which to build from Herbertville, Que., northwest to Lake St. John, between Great Discharge and Little Discharge, 20 miles; also to build from St. Joseph de Alma easterly to Jonquieres, 30 miles. The company was organized in 1912, and Canon & Parent, Quebec, were the solicitors.

Athabasca & Fort Vermillion.—Incorporated in Alberta with $1,000,000 capital, to build from Athabasca, Alta., northwesterly to Trout Lake and to Fort Vermillion, about 300 miles. J. M. Kernan, J. V. Rawle, A. E. Walsh and J. Dalganeau, Athabasca; S. Clarke, Fort Vermillion, and J. Keith, Edmonton, are interested.

Central Canada.—This company, which is building a line from a junction with the Edmonton, Dunvegan & British Columbia at McLennan, near Round lake, Alta., northwesterly to the Peace river crossing has track laid to Paul's, about 30 miles, it is said, and grading on the remaining 22 miles to the Peace river crossing is now under way. J. D. McArthur & Co., Winnipeg, Man., has the contract to build the line. W. R. Smith, Edmonton, Alta., chief engineer. (December 11, p. 1107.)

Chesapeake & Ohio.—A contract has been given to Rinehart & Dennis to build a section of 28 miles of the Chesapeake & Ohio Northern through the Little Scioto valley in Ohio. (April 9, p. 811.)

Chesapeake & Ohio Northern.—See Chesapeake & Ohio.

Currituck & Dare.—A charter has been granted in North Carolina to build a line from the Virginia-North Carolina state line south to a point in Dare county. No work has as yet been done and the company has not yet completed its organization. W. H. Gallop, Jarvisburg, N. C., may be addressed.

Edmonton, Dunvegan & British Columbia.—This company, which is building from Edmonton, Alta., north and then west via Dunvegan to the western boundary of Alberta, about 415 miles, has been completed to Round lake, 150 miles from the British Columbia boundary, and grading has been finished to Smoky river, an additional 30 miles. Work was started last year on the section from Smoky river to Spirit lake, 65 miles, and surveys were under way from that point west to the British Columbia boundary. The J. D. McArthur Co., Edmonton, Alta., is carrying out the work. (December 4, p. 1067.)

Fellsmere Farms Company.—See Fellsmere Railroad.

Fellsmere Railroad.—An officer of this company, which operates a line from Sebastian, Fla., in St. Lucie county, Fla., south and west to a point west of Fellsmere, 9.94 miles, writes that under the name of the Fellsmere Farms Company, an extension is being built to Broadmoor, 3.5 miles. The track is being laid on a marl fill, made with a dipper dredge through an area of deep muck lands; there will be two trestle bridges over canals on the line. The company expects to develop a traffic in farming produce, etc. (March 26, p. 770.)

Gulf, Florida & Alabama.—Grading work was resumed recently on the extension building from the present northern terminus at Broughton, Ala., north to Kimbrough, and track laying will be started in about three weks. Work is also under way on a bridge over the Alabama river near Kimbrough, and the company plans to build a new coal pier at Pensacola, Fla. (December 18, p. 1165.)

Huron & Northwestern.—Articles of incorporation have been filed in South Dakota by this company with a capital of $25,000 and headquarters at Huron. The plans call for building a railway from Huron northeast through the counties of Beadle, Spink, Clark and Day to Roslyn, 105 miles. The incorporators include F. W. Henderson, Summit, S. D.; W. Pelham, Sioux Falls, S. D.; C. E. Wolfe, F. Budack, Wahpeton, N. D., and C. B. Adams, Chicago, Ill. The same interests have also incorporated the Huron Investment & Construction Company, with a capital of $50,000.

Illinois Central.—This company has awarded a contract for

200,000 cu. yds. of filling required on trestle work on the Indiana division near Bloomfield, Ind., to H. W. Nelson, Chicago.

Kent Coal & Railway Company.—Application has been made in New Brunswick for incorporation to build a railway from Rexton, N. B., southwest to a point on the Intercolonial between Kent Junction and Adamsville, thence via Chipman to Minto, about 80 miles; also to build from Rexton to Richibucto Head. Inches & Hazen, solicitors, Fredericton, N. B.

Kentucky Roads.—Construction work on the line from Barbourville, Ky., north to Manchester, about 25 miles, will be started in May, it is said, and it is expected that the work will be finished and the line put in operation this coming autumn. C. L. Heidrick, Brooksville, Pa., will make the surveys, and E. W. Gerheart, Traders bank building, Scranton, Pa., is said to be interested. (April 2, p. 767.)

New York Subways.—The New York Public Service Commission, First district, has awarded the contract for the construction of Section No. 4 of Routes Nos. 4 and 36 to the Litchfield Construction Company, the lowest bidder at $1,937,509. This section is a part of the Broadway subway in the borough of Manhattan in Seventh avenue, between Fifty-first and Fifty-ninth streets. (April 16, p. 871.)

Ontario Roads Electric.—The Ontario legislature has passed acts authorizing the Hydro-Electric Power Commission of Ontario to investigate, report on, construct and operate electric railways under certain conditions, and some 300 municipalities have asked for surveys and reports on the feasibility of constructing lines through their districts. The commission has made preliminary surveys on about 1,500 miles of line chiefly in southwestern Ontario and expects to issue reports to the municipalities in the near future. A report on the construction of a 100-mile line in the district immediately north and east of the city of Toronto has been made, and the ratepayers in 11 municipalities have passed by-laws and their councils have signed contracts with the commission asking for the construction of a line about 80 miles long through this district. This work will probably not be started until the government has announced whether or not it will grant subsidies to these railways, and until the city of Toronto has arranged for a satisfactory entrance to the heart of the city. The city officers of Toronto are now working on this proposition. Frederick A. Gaby, Toronto, is chief engineer of the Hydro-Electric Power Commission.

Smoky Valley & Peace River.—The Alberta legislature has been asked for a charter by this company to build from the Canadian Northern near the junction of Solomon creek and the Athabasca river in Alberta, northerly and westerly to the junction of Sheep creek with Smoky river, thence north through the Peace river country to a junction with the Canadian Northern Western near Dunvegan. Short, Woods, Biggar & Collisson, Edmonton, Alta., are solicitors for applicant.

Texas Roads.—Surveys are now being made, it is said, for building a line from Marfa, Tex., on the Southern Pacific north via Fort Davis to Toyahvale, on the Pecos Valley Southern, about 55 miles. B. Q. Musgraves, of Fort Worth, and associates are said to be making the surveys.

RAILWAY STRUCTURES

Chicago, Ill.—The Illinois Central has just awarded a contract for the concrete work for its new viaduct over Seventy-ninth street, to the Bates & Rogers Construction Company, Chicago. A contract for 100,000 cu. yds. of grading in connection with this improvement was awarded to J. D. Lynch, Monmouth, Ill.

The Pennsylvania Lines have awarded a contract for the foundation work on the new freight terminal which they will build in Chicago.

Hamilton, Ohio.—The Cincinnati, Hamilton & Dayton is contemplating the erection of a four-stall engine house at this point.

Pensacola, Fla.—See Gulf, Florida & Alabama, under Railway Construction.

Washington.—The Great Northern has awarded a contract to Henry & McFee, Seattle, Wash., for the construction of 1,500 ft. of snow shed on the west slope of the Cascades between Tye and Embryo. The estimated cost of the work is $225,000.

Railway Financial News

Boston & Maine.—The lower branch of the New Hampshire state legislature has rejected a bill providing for the relief of the Boston & Maine as suggested by the joint state public service commissions of New Hampshire, Massachusetts and Maine. The Springfield Republican says that representatives of the Boston & Maine have decided to abandon all efforts to obtain from the present legislature any enabling act for the reorganization of the road. Both House and Senate had previously passed an amended so-called Eastman bill providing for the incorporation of the New Hampshire subsidiaries of the Boston & Maine in the event of the failure of the Boston & Maine reorganization plan. This bill is awaiting the signature or veto of the governor. The legislature voted to adjourn on Wednesday.

Chicago, Rock Island & Pacific.—See an account of the receivership in another column of this issue and also editorial comments thereon.

Indiana Harbor Belt.—This company in the fiscal year ended December 31, 1914, had operating revenues of $3,329,172, an increase of $25,263 over 1913. Its operating expenses of $2,401,613 were $98,686 less than in the previous year, so that the net operating revenue was $124,049 greater. The gross income was $116,813 greater. The deductions from gross income, however, totalling $1,282,076, were $232,082 greater than in 1913, so that there was a deficit for the year's operations of $347,890 as against a deficit of $232,621 in 1913. The stock of the Indiana Harbor Belt is owned 30 per cent by the New York Central, 30 per cent by the Michigan Central, 20 per cent by the Chicago, Milwaukee & St. Paul, and 20 per cent by the Chicago & North Western. The road operates a total mileage of 110 miles in the Chicago switching district. Of this, 45 miles is main line and branches, 27 miles is operated under contract, and 37 miles under trackage rights, there having been an increase of five miles in 1914 because of addition trackage rights secured in the Union Stock Yards district.

The increase in operating revenue above noted was due primarily to an increase in l. c. l. traffic brought about by the partial opening of Gibson Transfer on January 22. The decrease in operating revenue includes a decrease of $54,057 in transportation expenses made possible by improved terminal facilities at Norpaul and Blue Island, and by the use of heavier and more efficient locomotives. The company was required to pay $172,360 more in hire of freight cars because of the abolition, effective January 1, of the intermediate per diem reclaim, and the placing of the cars of the company's proprietary lines on the per diem instead of the mileage basis, effective April 1. There was also an increase of $54,801 in interest on unfunded debt made necessary by additional advances by proprietary lines amounting to $620,000 for working funds and construction expenditures.

In 1914 the company derived earnings from switching service of $3,210,904. The total number of revenue earning cars handled was 749,346, as against 667,857 in 1913, there having been an increase of 26,909 loaded interchange cars, an increase of 85,657 empty interchange cars and a decrease of 31,077 cars received from industries. The average receipts per car were $4.285, as against $4.736 in 1913 and the switching revenue per mile of road was $29,852, as against $30,165 in the previous fiscal year.

Nashville, Chattanooga & St. Louis.—James H. Crichlow, of Murfreesboro, Tenn., has been elected a director, succeeding Colonel N. C. Collier, deceased.

New York Central.—Stockholders have ratified the resolution of the directors authorizing the issue of $100,000,000 20-year 6 per cent convertible debenture bonds and an increase of $100,000,000 in the capital stock to provide for the conversion of the bonds. These are the debenture bonds which were recently sold by the Morgan syndicate.

ANNUAL REPORT

THE DELAWARE AND HUDSON COMPANY—EIGHTY-FIFTH ANNUAL REPORT

GENERAL OFFICE.

New York, N. Y., April 12, 1915.

To the Stockholders of
The Delaware and Hudson Company:

The President and the Board of Managers submit the following statements of the affairs of the Company for the year ended December 31, 1914:

The results from operation of the Coal Mining Department were:

Year.	Coal Mined.	†Revenues.	‡Expenses.	Net Revenue.
1914	7,400,695 tons	$15,517,041.94	$14,553,052.94	$963,989.00
1913	7,170,553 "	16,045,308.03	14,748,615.71	1,296,692.32
Decrease	*230,142 tons	$528,266.09	$195,562.77	$332,703.32

† Excluding dividends received from stock of Coal Companies owned.
‡ Excluding taxes.
* Increase.

The results from operation of the Railroad Department were:

Year.	Miles Operated.	Operating Revenues.	‡Operating Expenses.	Net Operating Revenues.	Percentage of Expenses to Revenues.
1914	903.99	$22,595,028.50	$15,048,452.04	$7,546,576.46	66.60
1913	903.99	24,153,494.73	15,210,306.85	8,943,187.88	62.97
Decrease.		$1,558,466.23	$161,854.81	$1,396,611.42	*3.63

‡ Excluding taxes.
* Increase.

RAILROAD DEPARTMENT.

REVENUES AND EXPENSES.

The general distribution of the Operating Revenues and of the Operating Expenses of the Railroad Department was as follows:

	1914.	1913.	Increase or Decrease.
REVENUES:			
From Coal Freight Traffic	$10,844,092.56	$11,436,959.90	—$592,867.34
" Merchandise Freight Traffic (including switching)	8,153,085.76	8,794,428.57	—641,342.81
" Passenger Traffic	2,946,665.48	3,277,928.68	—331,263.20
" Express Traffic	324,725.08	334,279.74	—9,554.66
" Transportation of Mails	137,374.27	121,793.50	15,580.77
" Miscellaneous Sources	189,085.35	188,104.34	981.01
Total Operating Revenues	$22,595,028.50	$24,153,494.73	—$1,558,466.23
EXPENSES:			
For Maintenance of Way and Structures	$1,670,364.05	$1,787,613.86	—$117,249.81
" Maintenance of Equipment	3,649,672.52	3,753,963.16	—104,290.64
" Traffic Expenses	314,327.01	305,965.69	8,361.32

FINANCIAL.

CAPITAL STOCK AND FUNDED DEBT.

The Capital Stock of The Delaware and Hudson Company on December 31, 1914, was $42,503,000; no additional shares were issued during the year.

The Debentures of 1914, originally amounting to $2,500,000, have been reduced by payments of $200,000 per annum, and were completely retired on January 1, 1914, by the payment of $100,000.

The Public Service Commission, of New York, Second District, on October 9, 1913, as stated in the Annual Report for 1913, authorized the issue of $4,500,000, First and Refunding Mortgage Gold Bonds, at 95 or better, this Company having applied, on March 26, 1913, for authority to issue $5,000,000. The full amount thus authorized was sold early in 1914, at 95. The proceeds amounted to $4,275,000, of which $2,685,000 was applied, as hereinafter noted, to reduction of Floating Debt; and the remainder, $1,590,000, in accordance with the application to and authority from the Commission, to expenditures which were, at the date of the application, yet to be made for specific additions and betterments then in progress. Accordingly, the latter amount was deposited with the Farmers' Loan and Trust Company as Trustee. Expenditures amounting to $627,646.02 out of this fund have been made and the deposit correspondingly reduced. The application is still under consideration, by the Commission, as to the $500,000 not yet authorized.

FLOATING DEBT.

The Floating Debt of the Company was $3,018,533.51 on December 31, 1914, a decrease of $1,481,466.49 during the year. The amount on December 31, 1913, $4,500,000, was reduced to $1,815,000 by the proceeds from of $2,827,000 First and Refunding Mortgage Bonds, that portion of the issue of $4,500,000, previously referred to applicable to expenditures prior to 1914. Subsequently, this debt was increased $1,203,533.51, in part to finance, temporarily, additions and betterments and in part for advances to subsidiary companies (principally the Wilkes-Barre Connecting Railroad Company), which will hereafter be repaid.

SINKING FUNDS.

There was paid during the year to the Trustee under the First and Refunding Mortgage the sum of $311,440, being one per cent of the par value of the First and Refunding Mortgage Gold Bonds outstanding on June 1, 1914, making the total paid to December 31, 1914, $1,484,990. In accordance with the terms of the trust agreement, this sum has been expended in additions and betterments to the property covered by the mortgage.

A summary of the operations of the Sinking Fund under the First Lien Equipment Trust Indenture, from the date of its creation to December 31, 1914, follows:

RECEIPTS:

Annual payments to Trustee, years 1908 to 1914, both inclusive, at $650,000 per year	$4,550,000.00
Interest on cash balances and investments	256,730.05
Total receipts	$4,806,730.05

DISBURSEMENTS:

Equipment acquired as follows:		
One hundred and two locomotives	$2,433,460.28	
Five milk cars	15,217.82	
One gas electric car	25,217.46	
One Pintsch gas transport car	2,319.78	
Two gasoline tank cars	1,944.45	
One bridge-erecting car and trailer	14,534.62	
One steam wrecking crane	14,002.90	
One snowplow	5,040.42	
Twenty-two cabooses	23,034.42	
Total equipment		$2,534,772.15
Three hundred fifty-seven (357) The Delaware and Hudson Company First Lien Equipment Bonds of 1922 purchased and retired (including accrued interest)	362,896.77	
Securities and cash in hands of Trustee	1,909,061.13	
Total disbursements		$4,806,730.05

In accordance with the ordinance passed on May 9, 1899, and amended on May 10, 1910, $200,769.51 has been accumulated during the year in the Coal Department Sinking Fund. This has been applied to the purchase of coal lands in the Wyoming region and to the reimbursement of the Treasury for advances to The Schuylkill Coal and Iron Company and the Shanferoke Coal Company for the acquisition of similar lands in the Schuylkill region.

DIVIDENDS.

On December 31, 1914, a dividend for the year 1915, upon the outstanding $42,503,000, of Capital Stock of the Company, at the rate of nine (9) per cent upon the par value thereof, amounting in the aggregate to $3,825,270, was declared, out of the earnings of the current and preceding years, payable as follows:

Two and one-quarter (2¼) per cent upon the Capital Stock, in favor only of stockholders of record on February 25, 1915, and payable on March 20, 1915.

Two and one-quarter (2¼) per cent upon the Capital Stock, in favor only of stockholders of record on May 29, 1915, and payable on June 21, 1915.

Two and one-quarter (2¼) per cent upon the Capital Stock, in favor only of stockholders of record on August 28, 1915, and payable on September 20, 1915.

Two and one-quarter (2¼) per cent upon the Capital Stock, in favor only of stockholders of record on November 27, 1915, and payable on December 20, 1915.

COAL MINING DEPARTMENT.

During 1914, this Company mined 7,400,695 long tons of anthracite, out of a total of 68,342,601, including output of washeries, produced in the region. This is 230,142 long tons more than in 1913, notwithstanding that early in 1914 severe storms interfered with operations to the extent of about 200,000 tons reduction of output. The number of breaker hours worked was 46,159, a decrease of 193.

During 1914, five separate strikes caused temporary idleness at one or more collieries, the total loss being equivalent to closing one colliery for 42 hours or 4 6/9 working days of nine hours each. This compares with 54 5/9 working days of nine hours each in 1913. The idle time in both years would have been avoided had the employees continued at work and permitted the differences to be adjusted in the orderly manner provided by agreement.

In the report for last year reference was made to the tax of 2½ per cent of the value of anthracite when prepared for market, imposed on and after June 28, 1913, by the State of Pennsylvania. The legality of this tax is now before the courts for determination.

A new washery was completed and placed in operation, to reclaim coal from the culm bank at Marvine Colliery in the northern part of Scranton. The work of connecting the underground operations of Plymouth No. 2 with Plymouth No. 5 has been completed and it is intended to abandon Plymouth No. 2 breaker and handle all the output through Plymouth No. 5. An electric plant at Olyphant Colliery, Olyphant, Pa., has been erected, and furnishes light to five collieries located at Scranton and Olyphant and a portion of the power required at Olyphant and Eddy Creek collieries, located at Olyphant, and Marvine Colliery, at Scranton. Additions are contemplated which will enable it to furnish power to other collieries in the same vicinity.

Development work was continued and facilities increased during the year, in order to maintain the output.

The charges therefor, to Extraordinary Expenses of the Coal Mining Department, amounted to $782,644.57 as against $970,535,80, in 1913, as follows:

STATEMENT SHOWING AMOUNTS EXPENDED ACCOUNT EXTRAORDINARY EXPENSES YEAR 1914.

Sinking shafts and sbaft improvements	$36,390.19
Tunnels and new openings	130,812.98
New engines, new boilers, boiler houses and fittings	103,093.79
Rope haulage, slopes, planes and ropes	41,120.15
Concrete barns, etc	2,427.70
New pumps and new pump rooms	53,068.78
Electric plants and machinery	240,969.44
Other new buildings	31,097.22
Conveyors	30,143.91
Improvements to breakers and washeries	41,516.18
Miscellaneous	72,004.23
Total	$782,644.57

RAILROAD DEPARTMENT.

OPERATING REVENUES.

The decrease in operating Revenues, as compared with 1913, was $1,558,466.23. The revenue from Coal traffic decreased $592,867.34; the revenue from Merchandise traffic decreased $641,342.81; the revenue from Passenger traffic decreased $331,263.20; and the revenue from Miscellaneous sources increased $7,007.12.

OPERATING EXPENSES.

The decrease in Operating Expenses, as compared with the year 1913, was $161,854.81. Maintenance of Way and Structures Expenses decreased $117,249.81; Maintenance of Equipment Expenses decreased $104,290.64; Traffic Expenses increased $8,361.32; Transportation Expenses increased $17,913.47, and General Expenses increased $33,410.85.

The ratio of Operating Expenses to Operating Revenues in 1914 was 66.60 per cent and compares with 62.97 in 1913.

CAUSES AFFECTING INCOME.

The report for 1913 contains a statement of the causes then adversely affecting railway revenues and enhancing railway expenses. Many of these causes had then recently been accentuated and estimates of their effect upon an whole year's operations were given. Experience has demonstrated that these estimates were not excessive. All these causes were in full force during the year 1914. Moreover, the whole period was characterized by severe depression in the general business of the country and, in the territory occupied by your lines, the weather conditions of the early months of the year were exceptionally adverse, the cost of removing snow and ice being approximately $83,000 greater than the previous year.

The increase in Transportation Expenses of $17,913.47, in the face of a considerable decline in traffic, is a direct consequence of the conditions explained in last year's report, and which are not within the control of the management.

The so-called Full Crew law of the State of New York was in operation during the entire year, as compared with but four months in 1913, and resulted in an increase in expenses of $77,080.33. During the whole year this statute added $117,790.83 to the Transportation Expenses of the Company. The total cost of compliance with the law, since it became effective on September 1, 1913, to the end of 1914, was $158,501.33. The cost for eleven roads, including the principal lines in New York, during the first year that this law was in force was $1,149,843.90. In view of this wholly unnecessary expense which does not in the slightest measure contribute to safety, the Presidents of the railways affected have presented to the Governor and the Legislature a petition for repeal. Three bills, with that object in view, are pending. The cost of compliance with the so-called Full Crew law of Pennsylvania aggregated $37,351.79, as compared with $40,194.49 for 1913. It is significant that the people of Missouri by a referendum vote, recently defeated a similar Full Crew law by 324,085 votes against it to only 159,593 in its favor. Attempts to enact similar statutes have failed in the legislatures of Colorado, Delaware, Virginia and Ohio and have been vetoed by Governor Foss of Massachusetts and Governor Cruce of Oklahoma. A proposed statute of the same character was referred to the Railroad Commission of Connecticut by the State Assembly and the former, in a very strong opinion, condemned it both as to its theory and its consequences if enacted.

In the Report for 1913, reference was made to awards of arbitrators granting increases in rates of pay and modified working conditions to locomotive engineers, effective on May 1, 1912; to locomotive firemen, effective on May 1, 1913, and to conductors and trainmen, effective on October 1, 1913. As the outcome of long negotiations with the engineers and firemen, relative to the meaning and application of the awards, the Operating Expenses of 1914 include further allowance to them of $23,495.28, on account of services performed in 1912 and 1913, which is in addition to the increases in expenses for those years stated in former annual reports. The award to the firemen, in effect during eight months of 1913 and the entire year 1914, resulted in a comparative increase in expenses of $11,666.12. The award to the conductors and trainmen, in effect during three months of 1913 and the entire year 1914, resulted in a comparative increase in expenses of $100,810.10. Increases in rates of pay were also granted to other classes of employees.

The increases shown under General Expenses were caused chiefly by the demands occasioned by the important cases before the Interstate Commerce Commission, by required compilations of special information desired by that body and by work undertaken in connection with the Federal Valuation of railway property.

RAILWAY MAIL PAY.

The conditions under which the mails are carried over the lines of this system continued to be unsatisfactory, as they are generally throughout the United States. The injustice of grossly inadequate returns for these services has lately been accentuated by the extension of the parcel post, on January 1, 1914, to include fifty pound packages within the first two zones and twenty pounds for longer distances. This increase in the weights carried was not accompanied by any increase in the payments to the railways although it has resulted in diverting to the mails a large quantity of express traffic for which the railways were formerly compensated, under their contracts with the express companies, and has, in a smaller degree, even encroached upon the freight movement. Under the system of payment now in force the payments for the several mail routes operated by this Company were fixed, against its protest, for a period of four years beginning with July 1, 1913, in accordance with a weighing conducted during the early months of 1913. As the parcel post was then just inaugurated, had had little time for development, and the maximum weight carried was eleven pounds, it follows that, unless the law is changed, this Company will carry the parcel post mail until July 1, 1917, practically without compensation.

No action in rectification of railway mail pay has been taken by Congress. The Joint Congressional Committee on Railway Mail Pay, of which former Senator Bourne is Chairman, after an investigation which lasted two years, recommended a new basis of payment which it stated would add approximately $3,000,000 per year to the mail pay of the railways, and the Committee said:

"We believe our suggested rates are certainly not too high from a governmental standpoint, though they may be too low from a railroad standpoint."

The Joint Committee also sustained the objections of the railways to quadrennial weighings, to free messenger service and to free compartment cars for mail purposes. Notwithstanding these facts, the House of Representatives added a "rider" to the measure containing appropriations for the postal service which, if it had become a law, would have very materially reduced the mail pay, that the Joint Committee had reported was already too low. Fortunately the "rider" was not accepted by the Senate.

In 1907, by an arbitrary executive act which reversed the practice of forty years, the divisor used to determine the "average daily weight" which is the basis of mail pay on every railway was increased from 90 to 105, thus reducing the resulting averages and greatly reducing the mail pay of all companies. In a decision rendered on May 18, 1914, in Chicago & Alton Railroad vs. United States, the Court of Claims of the United States decided that this change was one which the Postmaster General had authority to make. Appeal from this decision is now pending in the Supreme Court. The steps necessary to protect the interests of this Company, in case the principle of law involved should be determined favorably to the railroads, have been taken.

Interstate Commerce Commission.

The Interstate Commerce Commission's inquiry concerning rates, rules, regulations and practices in the transportation of Anthracite, begun in 1912, continued throughout the year. Taking testimony was concluded in October, and briefs were filed and arguments heard during January, 1915. No decision has yet been announced. In the advanced rate case, hereinafter referred to, the Commission recognized the contention that th investment in property devoted to public use, rather than the par value of stocks and bonds, must be the proper basis for computations intended to test the reasonableness of the returns derived from the services rendered. This is obviously sound as earnings result from the use of assets, earning power is that which gives value to assets. Property devoted to public use constitutes assets and should therefore be the basis of all computations concerning returns. Stock and bonds are liabilities. For the purposes of this inquiry the property accounts were restated, as far as possible, so as to bring them into conformity with the present accounting system prescribed by the Interstate Commerce Commission, and among the most significant facts developed in connection with the anthracite inquiry was that the combined net operating receipts (that is, the balance left from gross receipts after paying operating expenses and taxes) of all the railways serving the Anthracite region, for the year that ended with June 30, 1914, amounted to only 5.06 per cent of the cost of their property devoted to public use. Since the creation of the Commission there have been only nine years in which this ratio has exceeded seven per cent, while in nine years it fell below six per cent, and in two years it was only slightly above four per cent. This rate of return upon property is lower than it ought to be in the general public interest.

The Annual Report for 1913 contains a statement of the conditions which led this Company to participate in the general five per cent advance in freight rates which was then under suspension by the Interstate Commerce Commission. The effort to obtain a partial readjustment of tariff rates, in view of the added cost of producing railway services, has at last been sanctioned, as to some of the changes attempted, by a majority of the Commission. A majority of the Commission at first opposed most of the changes, and an order, cancelling the new tariffs, was issued, over the dissent of two Commissioners, on July 29, 1914. Nevertheless, at that time the Commission said:

"In view of a tendency towards a diminishing net operating income as shown by the facts described we are of opinion that the net operating income of the railroads in official classification territory, taken as a whole, is smaller than is demanded in the interest of both the general public and the railroads; and it is our duty and our purpose to aid, as far as we legally may, in the solution of the problems as to the course that the carriers may pursue to meet the situation." *31 I. C. C., pp. 351-384.*

This proceeding was reopened by an order of the Commission, entered on September 19, 1914, and further hearings were granted, at which the carriers produced testimony covering their operations during the period subsequent to the former closing of the case, on May 29, 1914, and relating to the financial consequences of the European war. Concerning these data, the Commission said:

"These figures serve to emphasize our previous finding of the needs of carriers in official classification territory, taken as a whole, for increased net revenue." *32 I. C. C., pp. 325-327.*

The majority of the Commission concluded that these conditions justified the proposed advances on all freight traffic except (1) rail and lake traffic, (2) bituminous coal and coke, (3) anthracite and iron ore, and (4) rates controlled by unexpired orders of the Commission. The commodities thus excluded form a very substantial part of the traffic carried by The Delaware and Hudson Company. Estimates based on the traffic handled during the year that ended with October, 1914, excluding state traffic to which the action of the Interstate Commerce Commission does not directly apply, show that in 1914, $13,851,634 of a total revenue of $18,941,192 came from the excepted classes, leaving $5,089,558 with reference to which rates have been advanced. Assuming that the increase is exactly five per cent, the additional revenue accruing to this Company would be $254,478. This is equivalent to about one-fourth of one per cent on the total cash invested in its property devoted to public use. A subsequent order of the Commission, in recognition of the relationship of the rates to and from various points and districts, granted permission to increase certain rates a trifle more than five per cent where necessary to preserve the relationships of the existing rate structure. This, however, will not substantially increase the additional revenue produced by the advance. The tariffs providing for the advance on interstate traffic became effective on January 15 and February 23, 1915.

In its opinion of July 29, 1914, rendered in connection with the original order cancelling the proposed advances, the Commission recommended to the carriers certain expedients for increasing net revenues. Effort to apply these suggestions has been made and has in some instances resulted in adverse action by state authorities. So far as they are applicable to this Company, however, it is estimated that, including the increase in the price of mileage tickets from two to two and one-quarter cents per mile and the withdrawal of round-trip passenger rates, already in effect, they can be made to produce approximately $130,000 per annum or about one-eighth of one per cent upon the property of this System devoted to public use.

The Federal valuation of railways in charge of the Interstate Commerce Commission is proceeding slowly and the great difficulties and tremendous expense, both to the Government and to the railways, are becoming increasingly apparent. The estimates given to the Committee on Appropriations of the House of Representatives by the Director of Valuations, in charge of the work of the Commission, indicates a cost to the Government of from $18,000,000 to $21,000,000 and a minimum time for the completion of the task of not less than four years from July 1, 1915. The same authority indicated a cost to the railways greatly in excess of the cost to the Government. He advised the Committee that a particular road "which is poor and cannot afford it, has been obliged to do a great deal of work and is laying out a great deal of money," actually spending, for the purposes of the valuation, at the rate of "one hundred dollars a mile." The estimates given when legislation providing for this work was pending were about one-eighth of the amount which is now admitted as the expense to the Government alone. It is probable that the work would never have been authorized if Congress had been advised that the cost would even approximate the amounts that are now certain to be required. A Presidents' Conference Committee, a Committee of Engineers, and a Committee on Financial History and Accounts have been organized by the railways and are co-operating satisfactorily with the Valuation Board established by the Commission. The latter has completed inventories of four roads, none of them of the largest, but valuations have not yet been placed upon the different units of the property embraced, much less upon any of these railways as an entirety. This Company has found it desirable to undertake an examination of the records of its long existence and a considerable amount of field work in order to protect its interests in the valuation. This work is progressing satisfactorily.

Additions and Betterments.

Renewing and strengthening bridges on the main lines to make them capable of carrying Class E-5 Consolidation Engines, as mentioned in the annual reports for 1912 and 1913, continued through 1914, resulting in charges of $73,929.94 to Additions and Betterments, and of $51,945.42 to Operating Expenses. About ninety per cent of this program was completed, and it will be fully completed in 1915. Strengthening bridges between Saratoga Springs and North Creek, to make them capable of carrying engines of Class E to E-3 inclusive, undertaken in 1913, as mentioned in the report for that year, was completed in 1914. Improving and lengthening the bridge carrying the Troy road and tracks of the United Traction Company over the tracks of this company at Menands, N. Y., to provide increased horizontal and vertical clearances and room for additional main tracks in connection with the reconstruction of the Troy road as a State highway, as mentioned in the report for 1913, was completed in 1914 at a total cost of $74,532.26, of which $31,061.22 was expended during 1914. Of the total cost, $51,950.26 was charged to Additions and Betterments, and $22,582 to Operating Expenses. In connection with the bridge improvement program, it was found necessary to reinforce abutments of Bridge No. 11 at Troy, N. Y.; No. 12 at Voorheesville, N. Y.; No. 42.02 at Barnerville, N. Y.; No. 46.85 at Cobleskill, N. Y.; No. 52.44 at Richmondville, N. Y.; No. 18.64 at Mechanicville, N. Y.; No. 55.28 at Fort Edward, N. Y., and No. 70.13 at Fort Ann, N. Y. There was expended on this work, to December 31, 1914, $62,878.81, of which $43,898.99 was charged to Additions and Betterments, and $18,979.82 to Operating Expenses. The elimination of grade crossing at Bainbridge, N. Y., mentioned in the annual report for 1913, was completed during 1914 at a total cost of $15,669.31, one-half to be borne by The Delaware and Hudson Company, and one-half by the State of New York.

The installation of block signals between Plattsburgh and Rouses Point is in progress, $15,634.88 having been expended during the year. This work will be completed early in 1915. An extensive improvement in the block signal system, consisting of the installation of distant signals at the end of double tracks and for passing tracks leading from single track line, and the extension of overlaps to a minimum distance of 2,000 feet where distant signals are not in use, was undertaken during the year. This was practically complete on December 31, 1914, the expenditures to that date having been $35,514.03, of which $29,950.03 is chargeable to Additions and Betterments and $5,564 to Operating Expenses. A small amount of work remaining to be done on the Champlain Division will be completed early in 1915.

Improvements at Albany, including purchase of additional lands, the erection of general office building and freight terminal, and construction of bulk delivery and freight house tracks, as mentioned in the annual report for 1913, progressed satisfactorily, and will be completed during 1915. To December 31, 1914, $790,026.28 had been expended on these improvements.

Fifteen Class E-5 consolidation locomotives, ten Pacific type Passenger locomotives and seven steel-center-sill, double truck, four wheel cabooses, all paid for from funds accumulated under the First Lien Equipment Trust Indenture, were received during the year.

The program of development of the yards at Carbondale, mentioned in the annual report of 1913, continued during 1914, and $27,543.30 was expended thereon. Construction of tracks to serve the new washery at Providence, Pa., known as Marvine Breaker No. 2, mentioned in the annual report for 1913, continued during the year. There was expended $26,856.33 during 1913, and $16,908.54 during 1914, a total of $43,764.87, all chargeable to Additions and Betterments. The work will be completed in 1915. Addition of four boilers and one blower to the Mechanicville Power Plant, mentioned in the annual report for 1913, was completed in 1914. Increasing the height of the smoke stacks of this power plant by 100 feet, in order to effect fuel economies, was begun and will be completed during 1915. There had been expended to December 31, 1914, $38,185.53, all charged to Additions and Betterments.

The installation of a 50,000-gallon tank at Hudson, Pa., mentioned in the annual report for 1913, was completed during the year. A pumping plant, to furnish an adequate supply of water for the new shops at Colonie, N. Y., was completed early in 1914 at a total cost of $14,256.11, all charged to Additions and Betterments. New and modern track scales were installed at Green Ridge, Pa., during the year to take the place of scales that had become inadequate on account of the increased capacity of freight cars.

The net changes in the property accounts, on account of Additions and Betterments to the Company's railroad during the year (including expenditures on account of items mentioned above) amounted to $1,820,738.87.

Station and yard improvements, including new passenger station at Ticonderoga, N. Y., undertaken during 1913, as mentioned in the report for that year, were completed during 1914. This work was paid for from accumulations under the operating contract with the Ticonderoga Railroad Company.

Construction of the Wilkes-Barre Connecting Railroad, to connect the Pennsylvania Railroad and the lines of this Company, near Wilkes-Barre, mentioned in the annual reports for 1912 and 1913, progressed rapidly during 1914, and it is expected that the line will be opened for operation early in 1915.

ALLIED STEAM RAILWAYS.

The Greenwich and Johnsonville Railway Company shows a decrease in Operating Revenues for the year 1914 of $14,569.85, as compared with the previous year. The Operating Expenses decreased $6,542.42. The Net Income was $20,140.83, a decrease of $6,162.83. A dividend of six per cent for the year ended June 30, 1914, was declared.

The Quebec, Montreal and Southern Railway Company shows a decrease in Operating Revenues of $8,835.17, as compared with the previous year. The Operating Expenses decreased $16,955.83. Income from Hire of Equipment increased $11,514.33. The Net Income, not allowing for interest due The Delaware and Hudson Company, amounted to $149,051.37, an increase of $19,758.62.

The Napierville Junction Railway Company shows a decrease in Operating Revenues of $14,668.78, as compared with the previous year. Operating Expenses show an increase of $11,816.45. Net Income amounted to $24,858.11 or 4.14 per cent on Capital Stock outstanding, a decrease of $28,015.02, compared with the previous year. A dividend of three per cent for the year ended December 31, 1914, was declared. The Freight Revenue decreased $23,019.77, while Passenger Revenue increased $8,080.19. The latter increase was due to the inauguration of through passenger train service over the Napierville Junction Railway between Montreal and points on The Delaware and Hudson. The increase in expenses was due to increased maintenance charges and increased passenger train service. The cost of maintenance, while higher than in the preceding year, was not abnormally high, inasmuch as during the first years of the Company's existence the renewals were naturally relatively small.

ALLIED ELECTRIC RAILWAYS.

Gross Operating Revenues of the United Traction Company decreased $47,271.94; Hudson Valley Railway Company, $43,508.29; Schenectady Railway Company, $89,198.93, and Troy and New England Railway Company $940.36, while those of the Plattsburgh Traction Company increased $1,832.01. Decreases in Net Operating Revenues were as follows: United Traction Company, $201,379.52; Hudson Valley Railway Company, $48,659.08; Schenectady Railway Company, $92,294.20; Troy and New England Railway Company $634.31, and the Plattsburgh Traction Company $713.74.

The business depression, particularly during the latter part of the year, adversely affected the revenues of all the traction companies, while, at the same time, various causes increased cost of operation. The unusually severe weather in the earlier months of the year very greatly increased the cost of removing snow and ice. The United Traction Company's cost of power is steadily increasing, owing to operation of heavy modern steel cars and inability to purchase the additional power as cheaply as that covered by the first contract. Effective July 1, 1914, various operating employees were granted increases in wages. These increases amounted to about $15,000 for the last six months of the year. Similar increases were granted to employees of the Hudson Valley Railway Company, aggregating approximately, $3,000.

Dividends of two per cent for the year 1914 were declared on the Capital Stock of the United Traction Company; six per cent on that of the Schenectady Railway Company; two and one-half per cent on that of the Troy & New England Railway Company, and four per cent on that of the Plattsburgh Traction Company.

The Hudson Valley Railway Company, after years of continued effort, has secured the right to cross Broadway in the Village of Saratoga, which will enable it to install a belt line service in Saratoga and to materially improve the through service between Albany and Glens Falls. A new concrete viaduct has been constructed over the Hudson river, connecting Glens Falls and South Glens Falls. A new bridge over the Barge canal south of Fort Edward has been completed; and the Whitehall bridge in Fort Edward has been raised 2.4 feet, to facilitate traffic on the Barge canal.

The use of heavier cars and the increased frequency of service of the United Traction Company have necessitated the erection of a new substation at the corner of Chapel street and Sheridan avenue, Albany, to centralize the power distribution in that city so that delays to traffic may be avoided. This sub-station will have an ultimate capacity of 9,600 K. W., and be completed in the Spring of 1915 at a total estimated cost of $150,000. The transmission system connected with the Twenty-fifth street sub-station, Watervliet, was enlarged during the year by the installation of an additional set of transmission lines to the Mechanicville power plant, a distance of twelve miles, and 3,102 feet of cable to Congress and River streets, Troy, and 6,892 feet of cable to a connection with the line of the Schenectady Railway Company and the installation of one 600 K. W. rotary converter. There were also installed 10,649 feet of cable on Cohoes road, and 5,015 feet on the Cohoes Belt Line. The feeder on Madison avenue, Albany, was extended 4,789 feet.

All equipment was maintained in an efficient condition, but owing to reduced earnings and heavily increased expenses part of the ordinary painting of cars was deferred, and will be undertaken during the year 1915.

On December 11, 1914, the Public Service Commission, Second District, State of New York, issued an order directing the United Traction Company to make changes in its facilities and services in Albany which, if they can lawfully be required, would necessitate capital expenditures that would involve raising $1,106,580.43 and entail material and continuing additions to operating expenses without being productive of any additional revenue. Among other things, the Company was ordered to purchase forty-two additional cars seating forty passengers each; to provide higher powered snow-fighting equipment; to extend its lines in Arbor Hill and New Scotland road; to extend its underground conduit and feeder system, and to provide itself with a private and exclusive telephone system. The Company was also ordered to provide more frequent service on certain lines. In many respects the changes that were ordered are believed not to be in the ultimate interest of the public, but must impair the ability of the Company permanently to render satisfactory service, and the capital expenditures would be excessively burdensome and unreasonable at this time, especially in view of present financial conditions throughout the country and the decreased patronage of these street car lines. The recent capital expenditures of the United Traction Company should be considered in connection with this order. The following shows such expenditures from January 1, 1907, to November 30, 1914, inclusive, together with the amounts still to be expended upon work now in progress, classified according to the principal items.

Item.	Expended.	To Be Expended.	Total.
Engineering	$9,122.23	.....	$9,122.23
Rights of way	15,186.00	.....	15,186.00
New lines and extensions	142,142.59	.....	142,142.59
Roadway and track	383,882.27	$17,782.91	401,665.18
Paving	265,163.93	48,860.37	314,024.30
Bridges	9,000.00	.....	9,000.00
Distribution system	273,251.98	134,846.49	408,098.47
Signal apparatus	7,434.85	.....	7,434.85
Power plant equipment	49,585.04	1,303.06	50,888.10
Cars and electric car equipment	539,742.92	3,517.60	543,260.52
Buildings and fixtures	10,587.59	.....	10,587.59
Shop machinery and tools	10,324.91	.....	10,324.91
Other additions and betterments	72,552.80	.....	72,552.80
Total	$1,787,977.11	$206,310.43	$1,994,287.54

In addition to the expenditures for paving included in the foregoing, paving requirements of the cities of Albany and Troy, if the present plans are carried out, will make necessary a further expenditure of $166,825.60 by this Company.

The capital expenditures required by the order would not be self-sustaining, but instead would cause additional expenses for maintenance and for other operating purposes, while the increased frequency of service required on some lines would cause added expense without bringing in any additional revenue, and this added service is not justified by the patronage at the present time. After the order was entered, application to the Commission for a rehearing was made and denied, although the Company offered proof of the financial conditions, including the changes brought about by the war, and of other matters, arising subsequent to the hearings in July, that were believed to be relevant and important. The Courts have been appealed to in the matter and proceedings under the order have been stayed pending a decision by the Appellate Division.

As compared with 1907, the rates of wages of the conductors and motormen employed by the United Traction Company show an increase of more than twenty-seven per cent, a result of resort to arbitration in settlement of labor difficulties. The pay of other employees has increased proportionately. The total pay-roll for the year 1914 was about $240,000 higher than it would have been except for these increases.

ALLIED BOAT LINES.

The Operating Revenues of The Champlain Transportation Company show a decrease of $16,263.02, and the Operating Expenses show a decrease of $2,431.34, making a decrease in Net Operating Revenue of $13,831.68 for the year. The Operating Revenues of The Lake George Steamboat Company show a decrease of $2,682.86, and the Operating Expenses show a decrease of $3,571.53 as compared with 1913, making an increase in Net Operating Revenues of $888.67 for the year. As the traffic of the boat lines consists largely of those traveling for pleasure, the Season of 1914 was adversely affected by the unfavorable business conditions throughout the country.

LITIGATION.

In the litigation heretofore reported in connection with the contract under which this Company operates the Ticonderoga Railroad, accounting proceedings are pending before a Referee, in conformity with the recent decision of the Court of Appeals.

The action brought against the Company in 1913 by Katherine S. Weld and others for an accounting of royalties under the Henry B. Rockwell coal lease of 1859, is still pending. A new action for an accounting has been begun by William S. Birdsall and others interested in the royalties payable under the coal lease of James Stott made to this Company in 1890. The suit is still pending. The suit for an accounting under the coal lease of William Miles and others to this Company, made in 1880, which was begun in August, 1913, is in course of settlement.

On December 29, 1914, The Rensselaer & Saratoga Railroad Company brought suit against The Delaware and Hudson Company, involving the interpretation of the lease under which the property of the former is operated by this Company. The suit involves the ownership of 8,000 shares of stock of The Rensselaer & Saratoga Railroad Company now carried as a Treasury asset of this Company. The matter is proceeding in regular course and the General Counsel is very hopeful of a decision favorable to this Company.

The Rensselaer & Saratoga Railroad Company claims that under its contract with The Delaware and Hudson Company the latter should pay any income tax which is assessed against the former. The assessment for the ten months ended December 31, 1913, amounted to $6,659.77, of which $533.33 was erroneously assessed, leaving $6,126.44 to be paid. The lower court has decided a suit brought to test this question unfavorably to this Company but appeal was taken and is now pending in the Appellate Division.

GENERAL REMARKS.

On July 1, 1914, the Workmen's Compensation law became effective in the State of New York. It provides for death benefits and compensation to employees during disability due to injuries received in their employment. The extent to which this Company's railway traffic is interstate renders it unlikely that it will be materially affected. Suitable provision has been made by the allied traction lines, hotels and other companies affected, whereby they have become self-insurers, as provided under the Act, having made the required deposits with the Commission as a guarantee of compliance with the Act.

Public attention cannot be too forcibly directed to the increasing difficulties under which the most solvent railways must compete for the capital necessary for their continued development to keep pace with the forward strides of general industry. So far as this competition is with States and Municipalities, it has recently become more intense by reason of the advancing rates offered and the freedom of such investments from the Federal income tax and the inquisitorial features attending its enforcement while, so far as it is with manufacturing or industrial corporations, the same effect has sprung from the longer establishment and enhanced stability of the issuing corporations. The public offerings of State and Municipal bonds, exclusive of those taken for the sinking fund of New York City, increased from $143,590,868 in 1902 to $383,150,828 in 1912, and the aggregate annual issue of such bonds paying four per cent or higher increased during the same period from less than $60,000,000 to substantially $380,000,000. Not only do these issues compete with those of railways for the share of the limited investment fund required by the latter, but the augmented governmental activities that they suggest, tend to increase the general burdens of taxation, of which so disproportionately large a share is invariably imposed upon the railways. It is not surprising, therefore, that from 1902 to 1914, the annual taxes paid by American railways increased from $54,465,437 to $157,371,100. Many, however, may not have realized that in 1914 the various taxing authorities demanded and collected $38.26 out of every $100.00 which the railways had left out of their operating gross receipts after the payment of wages, other operating expenses and interest on indebtedness, as against $15.92 out of every $100.00 in 1902, or that in the later year the railways paid $2.39 in taxes for every dollar which they paid twelve years earlier. Especially in view of the drain upon the World's resources that is attending the great European war and that is likely to continue long after that war has closed, these facts ought to receive earnest thought. They indicate a great necessity and a great opportunity for unselfish, unprejudiced and constructive statesmanship.

The vote of 135 to 68 in the Pennsylvania House in favor of the repeal of the state extra crew law is as significant in its way as was the overwhelming referendum vote of the people of Missouri for the repeal of similar legislation. It is one among many indications that public sentiment is running very strongly against legislation imposing unnecessary restrictions and expenses on railways. The change in public sentiment regarding regulation of railways which has occurred within the last two years is so great as to be almost astonishing. The train crew law in Missouri was killed by publicity. The railways told the facts and the people did the rest. The vote in the Pennsylvania House also was a result of publicity. The railways told the facts and the law-makers and public responded in the only way that rational people could. The great change in public sentiment which the votes in Missouri and in the Pennsylvania House reflect has itself been effected by publicity. The leaders of the railways decided some years ago that as publicity had proved such an effective means for destroying abuses in the railway business, it probably would be an equally effective means for stopping unjust attacks on the roads and protecting them in their rights. This view is being fully justified. The campaigns of publicity which the railways have conducted have both secured the repeal of a little bad legislation and have prevented the enactment of a lot of it. The more the facts about both railway management and railway regulation are dragged out and exposed to the sunlight the less bad management and the less bad regulation there will be. The railways know that abuses in management have not been able to stand publicity and if they keep on using it they will find that crooked regulators and crooked regulation are just as incapable of standing it.

Pennsylvania Extra Crew Legislation

The earnings of the steam railways of the United States for the fiscal year ended June 30, 1914, resulted in a total operating revenue of over $3,000,000,000, only about $217,000,000 of which was paid out in dividends, while over $250,000,000 was paid for locomotive fuel, this item representing about 25 per cent of the total cost of conducting transportation. Moreover, the cost of fuel for locomotives is increasing each year to such an extent that almost every important railway is taking active steps to educate its employees along the lines of fuel economy. Much has been accomplished by means of improved appliances on locomotives in obtaining a greater percentage of useful work from each pound of coal burned, but the burning of coal on grates has been continued because no one has seemed able to perfect a better method. It has long been recognized that the ideal method of burning coal, and the one which produces practically perfect combustion, is that of burning it in suspension in a pulverized form. A solid cubic inch of coal exposes only six square inches for the liberation of heat, while in powdered form, a cubic inch of coal exposes from 20 sq. ft. to 25 sq. ft., making possible a much more uniform production of gas. Until recently no experimental work has resulted in a practical application of this method to the production of steam, but experiments conducted during the past year have proved highly successful in using pulverized coal in locomotive fireboxes under difficult operating conditions. An outline of this work and its results will be found elsewhere in this issue. The possibilities of making use, in pulverized form, of the low grade coals in the West which now have to be passed over as unsatisfactory for locomotive use, will be readily recognized, as well as those of using dust, screenings, slack and culm which accumulate from all mining operations. The successful use of pulverized fuel in locomotive fireboxes should open the way for a marked reduction in expenditures for fuel on railways.

Pulverized Fuel for Locomotives

The Interstate Commerce Commission in the industrial railways case and again in the five per cent case indicated to the railways that it believed they were rendering at terminals many free services which, because they were free, worked unfair discriminations in favor of those who received them. It said that the railways should make reasonable charges for these services both to remove the discriminations and to secure needed increases in their net earnings. In an attempt to conform to the views of the commission the eastern railways filed tariffs fixing rates for the spotting of cars, and both eastern and western railways filed tariffs imposing charges for trap car service and other similar services for which previously they had not been charging. The shippers naturally attacked these tariffs. Hearings regarding

Difficulties in Charging for "Free Services"

them have been going on before the commission ever since. It is now evident that the case of the railways for the specific tariffs which they filed fixing rates for spotting cars has broken down, and it looks as if their case involving charges for trap car service is going the same way. It has been admitted by the counsel for the eastern lines that the spotting tariffs on file with the commission are discriminatory, and, as a practical matter, unworkable. The hearings have failed to establish or even indicate any fundamental principle which will serve as a guide in determining where special terminal charges should be made or the amounts that should be charged. This is chiefly due to the enormous multiplicity and diversity of the conditions which have been shown to exist at different centers of industry. The varied conditions which exist are the product of years of development of both commercial industries and the transportation industry, and, although a continuance of the practices which have grown up around these conditions may result in some unfair discrimination, it has become only too evident that any attempt to revolutionize the conditions and practices in pursuance of a desire to establish theoretical equity will do far more harm than good. As George Stuart Patterson, of the Pennsylvania Railroad, has suggested, the subject is one which could be more satisfactorily handled by means of informal conferences between the commission and representatives of the railways and the shippers than it can be by means of formal hearings and orders. It seems clear that in any formal order the commission makes it should confine itself to removing palpable discriminations and that any other action it takes should be directed to bringing about conferences between all directly concerned for the purpose of establishing correct fundamental principles around which conditions and practices may develop in future.

PUBLIC REGULATION OF RAILWAY WAGES

THE able paper on public regulation of railway wages which Professor Frank Haigh Dixon of Dartmouth College presented at the last meeting of the American Economic Association points out clearly and forcibly the defects in our present system of dealing with labor controversies on railways. A part of Professor Dixon's paper is published elsewhere in this issue. The three prime shortcomings of our present system indicated by Professor Dixon are, first, that it does not prohibit strikes in advance of investigation of the merits of controversies; second, that it does not provide that investigations or arbitrations shall be conducted by experts; third, that it does not make it necessary for advances in wages resulting from arbitration awards to be considered in the regulation of railway rates.

The remedy for the first of these shortcomings is to reverse the provisions of the Newlands act. Under this law postponement of lockouts and strikes until after investigation of the merits of controversies is entirely voluntary, while obedience to the awards of arbitration boards is compulsory. The law ought to be so changed as to prohibit lockouts or strikes until after investigations of the questions involved by impartial public authorities, and, arbitration having thus, in effect, been made compulsory, obedience to the awards should be made voluntary. The public has a right to insist that there shall be no interruption of railway service until competent representatives of the public have investigated and made public their findings regarding the points in dispute.

In order that investigations or arbitrations may be conducted by impartial experts rather than, as now, by boards composed partly of experts who are partisans and partly by non-partisans who are not experts, there is need, as Professor Dixon indicates, for the appointment by the government of investigators or arbitrators whose tenure of office shall be as permanent as that of members of the Interstate Commerce Commission or of the Interstate Trade Commission. Only by having permanent public officials assigned to this duty will we establish a system of settling wage disputes which will be consistent and just as between the parties directly concerned and which will adequately protect the rights and interests of the public.

Perhaps the best way to establish a direct and equitable relationship between the regulation of rates and the regulation of wages would be to give the latter function to the Interstate Commerce Commission. It is understood that the commission is not anxious to get the job, and this is not at all surprising. But every dollar of railway wages must be paid out of railway rates, and since wages take 45 cents out of every dollar earned it is evident that if changes in wages are not to be fully and frankly recognized in the regulation of rates, the effects on railway net earnings will be very unhappy.

One of the most important wage arbitrations ever conducted, that between the western railways and their engineers and firemen, has just been concluded at Chicago, and the arbitrators are now considering their award. Regardless of what the award may be, it is likely to give an impetus to the discussion of the regulation of railway wages. To those who wish to inform themselves, regarding this important subject Professor Dixon's clear and authoritative paper will be very valuable.

THE NOISE NUISANCE

A PROMINENT eastern railroad, one which has an energetic press agent, recently announced that employees had been notified that the company wished their co-operation in avoiding complaints of noises around sleeping cars at night. Rather mild language. Another superintendent, one on an important western road, suggested, unconsciously, one reason why mild language is so generally used in dealing with the noise nuisance, when he said that, "We must be careful and not positively prohibit the use of the bell or the whistle, as these signals are sometimes absolutely necessary, and the failure to use them may tangle us up in court controversies."

These incidents indicate the difficult nature of this problem. It is difficult because it is not of first importance. Where the noise nuisance is of first importance the question is simple. On the New York Central, for example, between Woodlawn and the Grand Central Terminal, New York City, about 12 miles, four-track, through a thickly settled district, trains pass every few minutes all day; but never a whistle is heard, and very little is heard of the bells. The rule is absolute; no use to be made of these noise-makers except in case of positive imminent danger to life or limb. But on any road, as soon as the engineman is allowed some discretion, trouble begins. The superintendent tries rigid orders, and the plan does not work. He tries keeping silent (himself) and complaints begin to come in. Enginemen prove to have all kinds of defects of judgment; and innumerable investigations produce only partial improvement; and, not deeming the problem a vital one, the superintendent at last gets tired and contents himself with mild language, like that quoted above.

But why should enginemen's deficiencies of judgment be taken for granted? They must be educated, if any progress is to be made, and the only way to educate is by the time-honored but slow processes of all education: deal with individuals, drive each point home before distracting the learner with another, and enforce "review lessons" as many times as may be necessary. We speak of enginemen more particularly, because the whistle, the bell and the pop-valve are the most prominent nuisances; but the procedure is the same, in principle, with all classes of employees.

Is it a common thought that we are doing pretty well already; that further progress would cost more than it would be worth? Surely not, if we reflect for a moment, even superficially. In various other matters, no more important than this, we are not satisfied with a percentage of 99.75; we strive for 100. Why not here? It is true that being awakened in a sleeping car by an outrageous noise at 2 a. m. is not the worst misfortune in the world. One can go to sleep again and wake up at daylight with the spirit of forgiveness toward both the man who made the noise and the employer who tolerates him. But the way to make friends of passengers is to run things so that forgiveness will not have to be exercised very often. Again, a campaign

to secure 100 per cent in repression of unnecessary noise helps powerfully to secure perfection in other things where carefulness is required in small matters. Ticket sellers say that they make fewer mistakes when business is brisk than when passengers come to the window five minutes apart. On the same principle an engineman keeps his mind more alert if he is required to watch out in several different directions simultaneously.

This comment was started by the suggestion that some of our educational methods do not seem to produce wholly satisfactory results. Except in favorable circumstances, circulars and reasoning and suspensions and reprimands all leave much to be desired. In this situation, the most practicable suggestion that we have heard is to replace arguments with facts. The arguments are all well known. They need strengthening, but apparently can be made stronger only by being backed up by more facts.

Why not have printed a full and carefully written record of all noise offenses that have occurred on your division for several months past? Go far enough back to make a long list; then have these facts impressed on the men's memories. The superintendent who feared to prohibit too positively, lest his employees should sound the whistle too little, practically admitted that he could not trust his men's judgment. One way to improve judgment—the present methods having proved unsatisfactory—will be to compel the men to do a lot of thinking on the subject. With enough records—vivid, forcefully expressed records—this can be done.

Aside from enginemen the class most needing attention is the workmen around large stations at night—including express company employees. In most stations, the percentage of good service in this respect already is high. In a large railway station the suppression of all noises is at times impossible. In attempting to give sleeping-car passengers complete quiet we are taking a large contract. But, as already suggested, to strive for perfection in this matter will improve the service in other directions; so the striving is well worth while.

DEVON AND ILFORD

A PROMINENT railway officer remarked recently, in discussing the automatic train-stop problem, that it is a "live question." As a good many things seem to indicate that among the great majority of railroad officers this question is in a somewhat somnolent condition, the remark quoted is of special interest. One reason why in some quarters the question is still a live one is to be found in reports of train accidents like those in Connecticut and in England, given in another column of this issue. Disastrous train accidents have been comparatively infrequent in this country for many months now, and a short-sighted optimist might conclude that to drop the strenuous discussions of former collision days would be entirely justifiable. But any one disposed to take this view should remember two things—that when business is dull the disasters diminish in even larger proportion than does the volume of traffic (indicating an increase later); and, secondly, that however infrequent the spectacular smash-ups which excite the public, the wideawake railroad officer is never deceived, even in the dullest times. To the superintendent who lays his plans for safety, not according to newspaper clamor or the published interviews of congressmen or commissioners, but according to the known errors of locomotive runners (errors which do not become public) the question of securing perfect observance of signals is always a live one; and if the superintendent is a live one, and is on an important and busy road, he finds that this question cannot be separated from the automatic-stop question; automatic stops have already got a respectable standing.

In short, the principal question at issue, both at Devon and Ilford, is the hackneyed one of whether enginemen can be educated to 100 per cent efficiency as lookout men; or, more in detail, whether runners, with the aid of another man on the engine, instructed to act as monitor, can observe all signals with such unerring regularity as to make automatic train-stopping devices unnecessary. And, as a part of this main question, we have a second one, which bothers the great majority of railroad officers, namely, can the men in charge of the maintenance of signals be depended on to keep automatic devices in such perfect condition that they will prove really desirable as an additional safeguard, over and above the minds of the best-trained force of enginemen? In this connection, the term "best-trained" means, of course, the best that may be expected to be found in actual service; not the best that can be theoretically planned for.

We have called these two accidents notable. Devon is notable because the officers of the New Haven road have given very careful attention to the training of enginemen for two years and more. An investigator would be warranted in expecting to find there the best attainable conditions; good men, well trained, with adequate inspection. In view of the excellent records of the principal English lines, Americans expect to find these good conditions prevailing in England at all times. If mistakes occur on these roads, still more may they be expected on the "average" road. On both the New Haven and the Great Eastern we find the system of visual signals faultless; and on both of them the requirement that firemen shall aid in keeping a lookout proved to be worthless, or worse.

This editorial is not written for the purpose of going over the old arguments; the reader who wants those can refer to our files of last summer. The question today is, Is this a live problem? If it is, why does everything move so slowly? The American Railway Association committee seems content to drop automatic stops; to pin its faith on improvement in discipline. Assuming that the art of discipline is so well understood that co-operative study or investigation is unnecessary, the position of the committee, having been accepted by the association, absolves the association from the duty of further action. But suppose the committee is wrong; suppose that some automatic device ought to be thoroughly tried; suppose that the whole question ought to be tried out, to a conclusion, for the general good; is our officer, quoted at the beginning, doing his full duty? The New Haven, the New York Central, the Central of New Jersey, the Erie, the Lackawanna, the Pennsylvania, the Burlington, the Chicago & Eastern Illinois, the Maryland & Pennsylvania, and we don't know how many other roads, are encouraging outside experimenters; but where are the signs of progress? What active interest are the roads themselves taking? The Chicago & Eastern Illinois has the most business-like program; but it has been criticized. And, criticism or no criticism, the apparent indifference of the principal roads to this apparently useful experiment suggests that, as regards the American railroad profession as a whole, the automatic stop question, though perhaps alive, is in great need of clarification.

It is possible, perhaps, to clarify a little by a study of Lieutenant Colonel Von Donop's report; though his conclusion is characterized by the time-honored English mildness and indirection. He shows up the mistake of the Great Eastern in putting audible warnings at home signals—which in most cases is an almost useless expenditure of money—but speaks of the correction of this mistake as merely "desirable," not of pressing importance. The Board-of-Trade inspectors as a body have long since declared unequivocally for automatic stops or cab signals, but the writer of the present report seems to have forgotten that declaration. Again, he asks for an "unmistakable" warning at the distant signal; but that is hardly a correct statement of the point. Runners do not mistake so much as they ignore. "Inescapable" would be a better word. Perhaps the most instructive thing in this British report, for us, is the calm ignoring of the automatic-stop question; if the Englishmen are sound in their position, our live question should be, not discipline vs. automatic stops, but, rather, discipline vs. automatic stops or audible distant warnings.

The questions here suggested may be summed up about like this: Do we want some mechanical or electrical appliance to supplement the best engineman's vigilance? Does this want exist continuously, or only when the public is excited by a disaster? If the need is just as great now as it was in 1913, should not the problem be settled in months instead of being allowed to drag through years?

Letters to the Editor

THE YARDMASTERS' CONVENTION

Seattle, Wash., April 17, 1915.

To the Editor of the Railway Age Gazette:

The second annual convention of the United Yardmasters' Association will be held at Seattle, Wash., from June 15-19, next. We would like to have men from the mechanical, claims and transportation departments of different railroads attend this meeting to point out to us the deficiencies in our work so that we can consider means to remove them.

Other railway organizations such as the Car Service Association, the Master Mechanics' Association, the American Railway Engineering Association, etc., hold meetings and exchange ideas. The mechanical men discuss broken drawbars and damaged car sills, the claim agents talk about the losses to their companies resulting from rough handling of cars, etc. These meetings are excellent and do much good, but they remind one of a temperance lecture telling a Y. M. C. A. audience of the terrible effects of liquor when it was evident that no one listening to the speaker ever took a drink. To a certain extent these associations are doing what the temperance lecturer is doing. Few of them have ever told a switchman that he was doing wrong when he was careless and damaged the car and contents. It has remained for the yardmaster to talk to the engineer and switchman about carelessness. The same applies to the per diem question. The average switchman knows nothing about per diem and cares less. With proper training the roads can save much money without any additional expense. This can best be done by securing the intelligent co-operation of the yard forces.

Representatives from the mechanical and claim departments can do much good by attending this convention and discussing these problems with the members.

John Flaherty,
General Yardmaster, Northern Pacific.

INTERSTATE COMMERCE COMMISSION STATISTICS

Nashville, Tenn.

To the Editor of the Railway Age Gazette:

Beginning with statistics for the year 1911, the Interstate Commerce Commission abandoned the ten territorial groups and substituted three districts, "substantially identical with the three great classification territories," and subdividing the roads into three classes, according to the magnitude of their operations. No one will question the wisdom of this change; but the southern and southeastern roads have good reason to believe that the results shown for "Roads in Class 1, Southern district," do not fairly reflect the conditions surrounding the average or typical southern road, particularly when compared with the results shown for "Class 1, Eastern district."

It is stated in the commission's report that "Each operating carrier is assigned to that district in which the major part of its operations lies, *or with which it seems most closely allied in character*" (italics my own). But there are those who will object to the inclusion of the Norfolk & Western, Chesapeake & Ohio, and Kanawah & Michigan, in the Southern district, on account of their being more analogous to the Trunk lines with regard to traffic density, rate structure, and geographical location, notwithstanding the greater portion of their mileage may be located south of Mason and Dixon's line.

The dividing line between official and southern classification territories is not so clearly defined as to admit of an absolute segregation of roads. However, it is well known that rates between Richmond, Norfolk, and Portsmouth, on the one hand, and points in CFA territory are made by the use of percentages of the New York-Chicago rate, and subject to the official classification. Moreover, this system of rate making applies to and from all of the Ohio river crossings, and is projected into southern territory to Nashville, Tenn., and Memphis. As rates to southern territory are constructed on the river crossings, or Virginia cities combination, there can be but a small proportion of competitive traffic handled by the Chesapeake & Ohio or Norfolk & Western on rates that are not made on the Trunk lines basis and subject to the official classification.

Comparing the gross and net operating revenues, we find the following reported for the year 1912:

	Gross Operating Revenue.	Net Operating Revenue.
Eastern district, class 1	$21,166	$6,294
Norfolk & Western	19,766	6,997
Chesapeake & Ohio	13,152	5,150
Kanawah & Michigan	17,860	6,426
Southern district, class 1	10,235	2,962
*Southern district, class 1	9,376	2,591

Eliminating the Norfolk & Western, Chesapeake & Ohio and Kanawah & Michigan.

The effect of including these lines in the Southern district is most striking when a comparison of the freight density and average receipts per ton, per mile, is made.

It will be helpful in making such a comparison to also consider the former grouping. The present Eastern district comprises old Groups I, II, III, and a part of VI, while the present Southern district comprises old groups IV and V. Group I included the New England states; Group IV, the Virginias and Carolinas; Group V, the rest of the Southern states..

Group or District.	Year.	Tons one mile per mile of road.	Average Receipts per ton, per mile cents.
I	1910	873,877	1.115
II	1910	2,797,011	.641
III	1910	2,020,779	.588
VI	1910	906,835	.751
Eastern, all roads	1912	2,131,165	.647
Southern, class 1	1912	2,326,286	.638
Norfolk & Western*	1912	3,994,718	.424
Chesapeake & Ohio*	1912	2,957,056	.407
Kanawah & Michigan*	1912	3,845,189	.404
IV	1910	1,098,029	.655
V	1910	715,992	.802
Southern, all roads	1912	952,994	.700
Southern, class 1	1912	1,058,531	.684
†Southern, class 1	1912	767,697	.831

*Included in Southern district averages.
†Omitting the Norfolk & Western, Chesapeake & Ohio, and Kanawah & Michigan.

It is at once apparent that the inclusion of these three roads in the Southern district distorts the averages to the extent that they mean little, if anything. It will be noted that although the freight density of the Eastern roads (class 1) was more than twice as great as that of the Southern roads, the average receipts per ton per mile were only 0.46 mills less. Out of 35 roads in class 1, Southern district, only nine had average receipts less than .684, and only 13 had a density of 1,000,000 tons or more. Included in these are the three roads mentioned. These roads, though comprising less than 11 per cent of the mileage, handled more than 35 per cent of the tonnage.

It is true that no grouping can, in the very nature of things, be exact, but a grouping which covers so wide a field as to reduce the results to an average far removed from the actual conditions surrounding the majority of roads included, is, to say the least, not very illuminating.

While on the subject of statistics, I have been wondering why no one has suggested that perhaps the four elaborate tables, published annually by the commission, showing the number, classification and percentages of rolling stock, etc., equipped with air brakes and automatic couplers, have outlived their days of usefulness. Less than one per cent of the total number of engines and cars is not now so equipped, and it is just possible that the percentages will not change much in the next few years. The energy expended in preparing these tables might be conserved to a more beneficial use. For example, I imagine that railway executives, bankers, and others would be glad to have the commission publish tabulated statements, showing by years the amount and character of railway bonds maturing. Such a statement could well include a few recent years, as well as the years to come, with data showing the amounts paid, extended, defaulted, etc. I believe such figures would be of more general interest and value than air brake and coupler statistics.

J. L. Hopkins.

The Success of Main Line Electrification*

A Discussion of Conditions Which Affect It, with Operating Data Dealing with Results on the New Haven

By W. S. Murray

Consulting Engineer, New York, New Haven & Hartford, New Haven, Conn.

The part of the New Haven system that has been electrified constitutes its most important division, extending from New Haven to New York, and on its main line, yards, sidings, and spurs every class of railroad movement is being daily made by electricity. The route mileage electrified is 73 miles, of which 61 is of four tracks and 12 of six tracks, thus giving a total main line mileage, measured in single track, of 316. To this may be added 184 miles of yards, sidings, and spurs, thus making a grand total, measured upon a single-track basis, of 500 miles. It is of interest to note that of the yards electrified one includes 35 miles, the other 25 miles.

Four-Track Tangent Catenary Construction, Showing Anchor Bridge with Sectionalizing Switches Installed on It,

Electric power is supplied from a single station, centrally located, but this will, in a short time, be supplemented by other supplies to be applied at the east and west ends of the electrification zone. There are 100 passenger, freight and switching electric locomotives, and 69 multiple-unit cars. One main electrical shop has been completed, the capacity of which permits the maintenance and repairs of the above-mentioned electric motive power.

To date over $15,000,000 has been expended on this electrical transportation plant. While such a figure represents the cash outlay, there have accrued to its appropriation accounts, during the process of construction, large credits for steam equipment replaced, as, for example, the 150 steam locomotives which have been transferred to other parts of the New Haven system, and the steel bodies of the multiple-unit equipment, which would have been purchased even had not the electrification been undertaken.

Passenger Service.—All passenger service west of Stamford, Conn., is electrically operated. For the winter timetable, excluding Sundays, the schedule calls for 68 trains per day into Grand Central Terminal, two through trains terminating in Harlem River station and the same number of trains out of the Grand Central Terminal and Harlem River, or a total of 140 trains per day. The Harlem River Branch service includes 19 trains each way per day, except Sundays, between New Rochelle and Harlem River. On the New Canaan branch 16 trains are operated each way between Stamford and New Canaan. This makes a total week-day schedule of 210 trains per day. Additional trains in and out of Grand Central Terminal are operated on Saturdays, and extra trains are also run on the Harlem River branch on Sundays.

Of the 70 through trains per day between Grand Central Terminal, or Harlem River, and New Haven, 46 are electrically operated the entire distance, steam locomotives being used between New Haven and Stamford on the remaining 24 trains. Of the 210 trains per day, 114 are hauled by electric locomotives, multiple-unit equipment being used on the remaining 96 trains. There are 48 a.c.-d.c. locomotives used in passenger service. The multiple-unit equipment at the present time comprises four a.c. motor cars, 21 a.c.-d.c. motor cars, and 46 trailers.

The average number of electric train miles per day is about 6,600, of which 1,400 are made by multiple-unit equipment, the remaining being trains hauled by electric locomotives.

The passenger locomotives make an average of 8,200 miles per day, some of the individual locomotive mileage being as high as 450 to 500 miles. Forty-one of the 48 passenger locomotives

*From a paper presented at a joint meeting of the Franklin Institute and the Philadelphia section, American Institute of Electrical Engineers, January 20, 1915.

View in Westchester Yard, Harlem River Branch; the Cross Catenary Span in the Immediate Foreground Serves Ten Tracks

used in a.c.-d.c. service were originally designed to haul trains of 200 tons trailing weight in local service, 250 tons in local express service, and 300 tons for through express service between New York and New Haven. The remaining seven a.c.-d.c. passenger locomotives were originally designed to haul local trains of 350 tons trailing weight or express trains of 800 tons trailing weight at a maximum speed of 45 miles an hour. In actual service these locomotives attain a maximum speed of 55 miles an hour.

The multiple-unit motor cars make an average of 2,100 miles per day. The proportion of trailers to motor cars for a.c.-d.c. equipment averages two trailer cars to one motor car.

Freight Service.—There are 36 alternating current locomotives used in freight service. These are geared locomotives of 1,400 horsepower each and were designed originally to haul a trailing load of 1,500 tons in through service at 35 miles an hour, although they are used at times for heavy passenger service in the a.c. zone during the summer months, when the heating of trains is not required. Some of these a.c. locomotives are used in transfer service between Oak Point and Westchester freight yards on the Harlem River branch, others in way freight and switching service, but the majority are used on through freight trains between Harlem River and Bridgeport or New Haven. Outside of the fast freights, which are usually under 1,500 tons trailing weight, most of the freights are hauled by two locomotives, the trailing tonnage averaging from 2,500 to 3,000 tons, although, as an experiment, tests have been made in using three locomotives with trains of over 200 cars and 4,500 tons trailing weight. About 20 freight trains are hauled daily at the present time by electric locomotives between Harlem River and Bridgeport or New Haven.

Switching.—Electric switchers are used in the three main switching yards on the Harlem River branch, located at Westchester, Oak Point and Harlem River; also at Stamford, Port Chester, New Rochelle, Mt. Vernon and at Van Nest, the latter yard being principally used for storage.

At Oak Point and Harlem River the switchers are used principally for unloading and loading floats and making up trains. One switcher was placed in service in March, 1911, at Stamford, and the remaining 15 have been in operation since September, 1912. They have been highly successful in operation, and their reliability is evidenced by the fact that to date there has only been one case of grounded main motor, although the 16 locomotives have made approximately 50,000 miles each. Some of these locomotives have been at times in continuous service 24 hours a day for 30 days, the only attention received being the renewal of blower or compressor motor brushes, or contact shoe of pantograph trolley at such times as change was made of the operating crew. Four of these electric switchers have been found to do about the same work as six of the steam switchers, which they have displaced.

Our experience to date has taught us that electrification points to three principal places where economy of operation can be secured, and in the order of their importance they may be mentioned as follows: Saving in fuel; saving in motive-power maintenance and repairs; and saving in train miles.

Assets created by electrification, which may at times be controlling factors, as, for example, the reclamation of city terminal property, after the removal of gas and smoke by the elimination of steam locomotives, are of most important consideration. In cases, however, that do not involve large city terminal electrification, the general credits and debits resulting from electrification work may be said to about offset each other, and thus the value of the returns can be based upon the three items first mentioned. If we know the number of freight and passenger train miles in a division proposed for electrification, and the cost of each one of the train miles, today we can say with very little chance of error what the cost of each one of those train miles in freight and passenger service will be when that division is operated by electricity. If we were to duplicate the steam train movement by an electric train movement, a certain economy would be shown, but by reason of the ability to concentrate in single train movements greater tractive efforts and higher speeds, greater individual tonnages can be translated, and thus the third item of economy appears in the reduction of train miles.

Experience with the movement of billions of ton miles in freight, passenger and switching service by electricity has justified the early predictions that one pound of coal burned under the boilers of a central electric power station and converted into electrical energy and transmitted to an electric engine will develop twice the drawbar pull at the same speed as a similar pound of coal burned in the firebox of a steam locomotive; and, second, that the maintenance and repairs on electric locomotives of the straight alternating-current type are on the order of one-half of those required for steam locomotives of equal weight on drivers. It is thus seen that the problem of electrification merely revolves around the question of the density of traffic in which the economies aforesaid can be practiced, and, therefore, the denser the traffic the greater the requisite motive power for its movement, and hence the greater the saving to be effected.

TABLE I

THE NEW YORK, NEW HAVEN AND HARTFORD RAILROAD COMPANY. STATISTICS OF ELECTRICAL OPERATION—NEW YORK AND SHORE LINE DIVISIONS. FOR THE MONTH OF NOVEMBER, 1914, COMPARED WITH THE MONTH OF OCTOBER, 1914.

Cos Cob Power House.

	November		October	
	Total	Per KWH	Total	Per KWH
Coal consumed (tons)	12,439.44	2.78 lbs.	12,280.84	2.75 lbs.

*Revised.

It is perfectly possible to keep the maintenance and repairs of the electric locomotive down to one-half of those of steam under the most favorable conditions of steam maintenance, and in many cases below this figure. On the other hand, due to the peculiar nature of the electric engine, which has not as yet been enough appreciated, it will be only by the most rigorous and careful inspection and conformity to rules of operation that this relation can be maintained. Indeed, if electric engines be treated as has been the custom of treating steam locomotives, then their repairs, instead of costing far less, will cost far more than those of the steam engine.

An inheritance by the New Haven of the old steam locomotive engineers for the operation of their electric engines is a case

where the tail of the dog wags the body. While it is a good argument that these men understand the roadbed and signals better than anyone else, this argument fails when engineers without electrical experience or training can bid in the electric runs, depending upon their seniority and record of service. The condition might be alleviated by one set of men, once in remaining in; but there is a constant change, and it is a long time before the steam locomotive engineer divorces himself from the fact that he is not operating a steam locomotive. During his period of learning how to operate the electric engine he does not suffer, the people do not suffer, but the road suffers, and the locomotive suffers most. Here, therefore, we see the necessity of electrically trained men.

While all of the main line tracks of the New York division are electrified, there still remains in passenger and freight service, as the statistics of electrical operation, and give operating information with reference to:

1. The amount, distribution and cost of electric power generated at Cos Cob station. (Table I.)
2. Statistics and operating costs of electric passenger service.
3. Statistics and operating costs of electric freight service.
4. Statistics covering line and equipment failures.

I would ask those who review these statistics with an analytical eye to bear in mind that they are taken from an electrical plant which, from its inception, has been handicapped both from a construction and operating point of view. The underlying principle applying to the New Haven electrification required that its motive power equipment be designed to operate on both alternating and direct-current power, and that, further, on account of inadequate shop facilities in the past it has been necessary, since

*Revised.

as previously shown, a considerable amount of steam operation, made necessary by the New Haven having had to avoid capital expenditure for power house and motive power equipment. It can be readily understood that a large reduction in operating expense can be effected when the division is placed on a 100 per cent electrical basis.

OPERATING RESULTS

Essentially necessary is a wholesome confidence on the part of railroads undertaking electrification that the result predicted will be attained, and what we are doing on the New Haven today electrically from an operating standpoint could not be better epitomized than by the presentation of one of the last monthly operating reports. They are shown herewith, and are known securing new shop facilities, to make very heavy repairs throughout the entire electric motive power of the road. I have, therefore, to offer this word of caution in analyzing the statistics that are presented, for it is to be noted that the cost of locomotive repairs is high. For example, referring specifically to the table of operating costs of electric passenger engines, Table II, it is to be noted that in the month of October the repairs are recorded as 8.56 cents per locomotive mile, while for November these repairs have increased to 10.61 cents per locomotive mile. At first this would seem to indicate that the new shop facilities were increasing rather than diminishing maintenance costs. This, however, may be explained by the fact that all of the passenger engines have been undergoing general repairs, and invoices for material were passed in greater amounts for November than for October. Many

of the electric locomotives have not received a general overhauling since 1907, and during this time their log sheets of operation show some of the locomotives have made over 350,000 miles.

Showing, however, what can be done with electrical equipment under the care of a better maintenance, I present in Table III monthly costs and mileages for one of these locomotives made since these engines have passed through the shops. Notwithstanding the engines are of the alternating current-direct current type, it is of interest to note that their records so far show an average

cost of under five cents per locomotive mile. It is of particular interest to note that locomotive No. 032, which received its overhaul first, has now operated 93,140 miles at an average cost of 3.6 cents per locomotive mile.

The maintenance figures for the 10 engines first through the shops give a sharp contrast to those in the general table of passenger engine operating costs (Table II) and emphasize the lack of maintenance to which the electric locomotives were subjected in the early days of their operation. Had conditions permitted

Stamford local trains include one train, New Rochelle to Stamford.

our electric passenger engines to be of the straight alternating-current design, in my opinion their average maintenance would not have exceeded four cents per locomotive mile.

During the past six years of electric operation there have been collected some very valuable data with regard to the amount of power required to operate trains of variable tonnage in passenger, freight and switching service. Based on this data, the power required to operate trains under normal or peak conditions of schedule can be calculated with results practically coinciding with the estimates.

By means of wattmeters installed on all locomotives and motor cars it has been possible to record the differences of power required by trains operating under local and express conditions. The long period over which these statistics were kept and power rate constants thus developed has permitted us to abandon an elaborate tabulation and consolidate the information in a more general statement. Of value to those who are interested to follow more closely these results, Tables IV, V and VI will be of assistance. These tables are compiled from the June, 1914, statistics of electric passenger and freight train operation between Woodlawn and points east to New Haven. At that time the overhead system had only recently been completed to New

Haven, and there was but a small percentage of electric service, both as regards passenger and freight between Woodlawn and New Haven. While the tonnage in both passenger and freight service has been greatly increased since that time, these tables, however, may be taken as giving reliable data in connection with the electric train movements recorded. The watt hours per ton mile (abbreviated in tables as W.H.P.T.M.) are secured through meters recording input power to the electric motors. To determine the actual amount of power taken from the contact wire, these figures should be divided by 97 per cent, thus allowing an average loss of 3 per cent for the step-down transformers installed on the electric engines and motive power. As examples of the increments of electric service, since the extension of the electrification to New Haven, while it is to be noted that the total electric passenger ton-miles for June, 1914, were approximately 41,000,000, and that of the freight 9,400,000, the former has now increased to 62,000,000, and the latter to 44,000,000.

Of special interest to the writer with regard to the tables covering electric passenger operation is the variation in watt hours per ton-mile for the various express and local services.

For example, it is to be noted that the power rate for New Haven express trains eastbound is 31.4 watt hours per ton-mile, this rate being increased slightly for trains operating to Stamford; the rate rises quite rapidly for trains operating in local service to Stamford, and continues to rise for local trains operating to Port Chester and New Rochelle respectively. It is, of course, well known that the rate of power supply per ton for express operation is very much lower than that required for local operation, as in the case of the latter the train suffers,

under the conditions of braking, the loss of the kinetic energy stored in it under the conditions of acceleration. The increasing watt hours per ton-mile as shown in the tables are practically proportional to the diminishing distance between train stops. It may also be said that the distance between stops increases progressively east of New York City, and if, for example, suburban territory under consideration for electrification has to be served by train schedule with distances between stations approximately the same as those obtaining on the New Haven Road, the "power rate" constants as shown in these tables will be found to be sufficiently accurate in the study of power necessary to train movement.

In the tabulated statistics covering electric freight operation the point of principal interest is the difference between the rate per ton-mile as indicated in the June tabulation as against those tion of heavy freight trains. It was first thought that when these large train units were placed on the line the power house would be subjected to very heavy drafts of power under conditions of accelerating them. The reverse, however, was found to be the case, and where, previous to the operation of these trains, the power station output curve showed peaks of a fluctuating character, these heavy trains have served to smooth out the curve of power station output. A reasonable explanation of this would seem to rest in the fact that when a number of the heavy trains are under translation, and it becomes necessary to accelerate one from rest, the supply of current necessary to this acceleration, while not reducing the line voltage materially, does so, however, to a point which corresponds to a speed of the trains in translation lower than the speed at which they are actually operating, and thus these heavy trains, by their own mass energy, as in the

Ton miles are based on weight of trailing load.
Percentage of tonnage to rating is found by dividing the total tonnage of trains as they leave Harlem River by the rating of locomotive hauling those trains.
Ton miles per hour is found by dividing ton-miles by the total running time of trains between terminals.
Average speed is found by dividing train-miles by total running time of trains between terminals.

* Revised.

shown under the general tabulation of freight service (Table VII), where it is to be noted that the kilowatt hours for fast and slow freight are, on the average, considerably below 30 watt hours per ton mile, this rate being based upon the tonnage of the trailing load. Allowing for the weight of the electric engine, the watt hours per ton-mile will be reduced to 26, and, as some 200,000,000 ton-miles have been actually recorded by meter registration in freight service, it may be said that 30 watt hours per ton mile on level track is a reliable figure, with slight margin to cover electric freight operation in a combination of fast and slow service; *i.e.*, without stops for trains averaging between 1,500 and 3,000 tons trailing load.

It is of interest at this juncture to point to an interesting experience we have had in connection with the electrical operacase of a flywheel, automatically release a large amount of power, which becomes available for the accelerating train.

The matter of savings to be effected in engine repairs are subject to local conditions, for, while it may be said that steam locomotive repairs, upon an average, may be placed at 10 cents per locomotive mile, on the other hand there may be situations where the railroad has, for example, to use water of severe scaling characteristics and thus run up the cost of repairs excessively.

In the matter of train miles the savings to be effected are dependent upon local conditions, but it can be stated as a general conclusion, based on a very considerable experience, that electric engines of the order of 100 tons on drivers should be maintained at a rate not exceeding five cents per locomotive mile,

and that the coal bill for transportation is cut to at least one-half.

Having determined for any situation what savings can be effected by the substitution of electricity for steam, then, as previously stated, the commercial justification of a change to the new motive power is entirely based upon whether these savings will cover the interest, insurance, depreciation and taxes on the electrical investment necessary.

The motive power feature of electrification, like its other parts, has virtually reached the pound stage. Electric locomotives of approximately 100 tons will, under present conditions of cost of labor and material, vary between 18 cents and 20 cents per pound. This figure is practically irrespective of speed-torque characteristics, a high-speed passenger locomotive and a low-speed switcher not varying greatly in cost upon a pound basis. Multiple-unit cars, now usually built of steel, do not vary greatly in the density of traffic and in the use of a large number of electric engines by which we can save enough money to pay for the capital expenditure necessary to the supply of power to them for the operation of many trains.

In conclusion, I would plead for an especially conservative point of view on the part of the public with regard to electrification. While the savings to be effected under certain conditions of electrification may be considerable, on the other hand the construction investment necessary to these savings may be very great. So many roads in this country have either passed or lowered their dividends that it is hardly necessary to emphasize the fact that only a healthy condition of finance throughout the country will warrant the consideration of electrification, and again I would say that partial electrification, such as that applying to yards only and not main line, while it might prove of

from the above figures, but, if anything, may be quoted as being slightly higher in cost per pound. As a concrete example, I would say that a first-class, high-speed, 100-ton, straight alternating-current electric passenger locomotive, capable of handling a 250-ton trailing load in normal large city suburban service, should cost $40,000. A steam locomotive which would do the same work would probably not cost more than $15,000, but the savings effected due to the greater operating economy of the electric engine would represent a figure of twice or three times the amount invested in the electric engine. Thus we might say that for every electric engine we purchase we would be justified at least in making a capital investment of $40,000 to cover the cost of electric power houses and transmission equipment necessary to supply that electric engine with current. By this reasoning we again approach the answer as to the conditions affecting the success of main line electrification in the fact that it is advantage to a public, might at the same time prove to be a serious and unfair burden for the railroad to carry.

PRUSSIAN STATE RAILWAYS.—In a semi-official communication just issued in Berlin, the communal authorities are warned, in making up their revenue estimates, not to count on receiving any communal income tax from the Prussian state railways on account of lines passing through their districts. The communication says that, while there has recently been some increase in the railway earnings, the falling off in the receipts during the first month of the war was so great as to leave little prospect of a credit balance for the year, and the communes must therefore not count on getting anything from them for the fiscal year 1915.

Public Regulation of Wages of Railway Employees*

Expert Arbitrators Needed; What Is the Base of Reasonable Compensation? Should Arbitration Be Compulsory

By Frank Haigh Dixon
Professor of Economics at Dartmouth College

"The food and clothing of our people, the industries and the general welfare of the nation, cannot be permitted to depend upon the policies and the dictates of any particular group of men, whether employers or employees, nor upon the determination of a group of employers and employees combined. The public utilities of the nation are of such fundamental importance to the whole people that their operation must not be interrupted, and means must be worked out which will guarantee this result."

These concluding words of the arbitrators in the dispute between the locomotive engineers and the railways in 1912 give warning of a situation to which the public has been singularly indifferent. The railway provides a service which is a necessity of the entire people, and the interruption of this service is a national calamity. Wage increases in this industry are usually sooner or later shifted to the shoulders of the people at large in the form of increased rates. The public's interest in railway labor controversies is supreme, and should assert itself far more effectively than it has thus far in the consideration or adoption of any plans for wage regulation.

There are today on the payrolls of the railways of the United States nearly two million men, who receive in wages annually a billion four hundred million dollars. Forty-five per cent of the gross revenues of the carriers is paid out again in wages; and of the total expense of operating all the railways in the country, nearly 65 per cent is chargeable to labor.

This great body of wage earners is by no means homogeneous. Its membership ranges all the way from the alert, intelligent, well-paid engineer down to the shifting class of day laborers engaged in track work. Neither are all classes organized to the same degree of efficiency and power. The bargaining strength of the great mass of track workers amounts to little. Above these, but below the top, is a considerable group of occupations with organizations that are generally affiliated with the American Federation of Labor, such as the wood and metal workers, machinists, signalmen, clerks and station agents. Finally at the top are the four brotherhoods directly engaged in train service. Although these four unions contain not quite a fifth of the whole number of employees, they represent the dominant element in the railway labor world, and it is largely in connection with them that experiments in wage regulation have been tried out in this country.

THE TENDENCY TOWARD STANDARDIZATION

Concerted movements among employees in train service began in 1907, and have grown in frequency until now, except for minor local grievances, they may be said to be well-nigh the only method by which the demands of the brotherhoods are presented. At first the roads resisted, but the brotherhoods became so effective in such cases in securing the same results from the roads successively that they would have obtained from them collectively that the railways gave up the fight, and have for several years conducted their important negotiations as a group. Territorial controversies have now become the rule, and have such strategic advantage for the men that they are not likely to be abandoned. One territory is now matched against another where formerly it was one road against another. The most significant result has been the marked movement toward complete standardization of wages and working conditions throughout the territory involved. The railways have resisted this movement on the ground that differences in physical characteristics of roads, in traffic density, and in ability to pay have made complete standardization inequitable. It has been generally held by arbitrators that a worker is entitled to his hire, that if a road cannot pay a proper wage it must seek relief in an enhancement of its earnings, and that the public will not permit a road to furnish an inferior service through the employment of an inferior grade of men at wages below the prevailing level. This position must be accepted as sound. There is likewise much in the contention of the employees that many of the weaker roads are so interlocked with the more prosperous ones that their inability to pay standard wages is more apparent than real.

Whether or not there is justification also for disregarding differences in physical and traffic characteristics on different roads, which heretofore have been important considerations in the determination of rates of pay, this much is clear: Such disregard is tantamount to unfair discrimination among employees. It is a disregard of the individual in the larger strategic interest of the organization as a whole.

That the brotherhoods have in mind ultimately a national standard of wages and working conditions, there is some evidence, but a national movement will not be inaugurated until it is found to be strategically advantageous. The first duty of the unions while in the midst of a conflict is to win their case, and they use such arguments as are most effective at the moment. The argument for national standardization was urged by the conductors and trainmen because they were trying to raise the eastern wages up to the level of the west. When they reach the west they are very likely to lay stress on the greater cost of living in that territory, and to insist upon a restoration of the previously existing differential in favor of the western area. The result of it all is to raise the lower end of the wage scale and to smooth out many of the differences in working conditions on different roads and in different territories.

A further movement is now in progress to secure the association of all the brotherhoods in one united demand upon the roads. On more than twenty-five railway systems federation of the four brotherhoods is in effect, and on others working agreements exist between two or three of these organizations. Recently the articles of federation of these four unions have been revised to permit co-operation with other organizations whose membership is exclusively employed by railway companies, such as the telegraphers and railway clerks. For a number of years the conductors and the trainmen have co-operated in their wage demands. The present association of the engineers and firemen in a joint movement in the west may well be considered, in the light of earlier unhappy relations, as a fraternization of the lion and the lamb. Faced by this new ideal of a united labor force in an undivided country, the public may well give heed and devote its best thought to a consideration of its own interest in the outcome.

REGULATION UNDER FEDERAL LAW

The first important federal statute which attacked the railway wage problem was the so-called Erdman act enacted in 1898. The statute covered interstate railways and employees engaged in train service. It designated as mediators two federal officials, the Commissioner of Labor and the chairman of the Interstate Commerce Commission. As controversies assumed larger dimensions and the concerted movement became a regular and apparently a permanent method of negotiation, it was realized that a board of three members, in which the decision lay

*From a paper presented before the American Economic Association.

with one man alone, was too small a body to which to entrust issues of such magnitude. This was the motive for replacing the Erdman act in 1913 with the so-called Newlands act. Certain changes in the form of procedure long recognized as needed were also adopted. The Newlands act provides first for mediation by a board of mediation and conciliation consisting of a permanent commissioner and two other government officials. They are given the power not possessed by the former mediators of proffering their services. In case the controversy goes to arbitration, the board may consist of six members rather than three, if the parties prefer—two representing each side and two intermediaries chosen by a majority vote of the four. In case of failure to choose in this manner, the selection is made by the federal mediators.

We have therefore witnessed in this country a series of concerted movements extending over great stretches of territory and covering the period from 1907 to the present time, in which four different methods of settlement have been applied: Mediation under the Erdman act, arbitration under the Erdman act, mediation followed by arbitration under the Newlands act, and arbitration by voluntary agreement outside the statute. Which of these methods, if any, is a panacea for labor troubles on interstate railways? At the outset it may be asserted that the avoidance of labor conflicts is not the sole object or the ultimate goal of wage-regulating legislation, and that the absence of strikes is not a final index of the success of the laws which have been described. It is of course obvious, particularly when the transportation industry is under consideration, that the maintenance of normal operating conditions is an end greatly to be desired. From the standpoint of the general public, which can only occasionally be made to look below the surface, this appears to be the one and only object of all legislation relative to mediation and arbitration. Moreover, although it would be rash to assert that there will never be another railway strike of large proportions, the likelihood of such an outcome of any controversy is growing more and more remote. We have not had a railway strike of any magnitude for twenty years. It is true that the balance of power in the control of wage conditions has passed for the moment from the railways to organized railway labor. It is true that strike votes are always taken, and that these result in entrusting to the grand officers of the brotherhoods the power to call a strike at their discretion. But these polls are in most instances mere devices to strengthen the strategic bargaining power of the organizations. It is always the confident expectation of the grand officers that possession of the power will make its exercise unnecessary.

Prompt adjustment of the instant controversy was the service that the able mediators under the Erdman act, Judge Knapp and Dr. Neill, performed. They succeeded in nearly every mediation which they conducted in reaching an adjustment to which both sides were willing to agree, and today railway managers and employees are unanimous in commending the work of those public servants. They prevented labor conflicts, an outcome which satisfied the public, and they compromised the disputes with such a degree of success that, although neither side was satisfied, both were willing to abide by the result and the employees were contented to delay for a season a renewal of their attack upon the railway "wage fund."

The wisdom of so framing the statute as practically to designate two specific individuals as mediators became evident, as these gentlemen grew more and more familiar with the complex details of the wage schedule and were able to adjust controversies with increasing intelligence. It more than once happened that they were called in to pass on the merits of an existing schedule which they themselves had had a part in constructing. The element of permanence in the mediating body made possible the development of an expert proficiency in the work of adjustment. The weakness of the method was contained in its very nature. It was a mediation and not an arbitration. The function of the mediators was in no real sense to enter into the merits of the controversy.

This policy of seeking an adjustment rather than a judgment on the merits of the issue is well shown in the engineers' and firemen's case of this present year in western territory in which President Wilson intervened. When the employees presented their demands, the railways canceled existing schedules and made counter-demands. To these the employees vigorously objected, insisting that they would give up nothing that they had gained in their years of struggle, and refusing to consider any terms except those which they themselves had proposed. The federal mediators when called in, accepted the point of view of the employees, apparently because they found that there was no other way to avoid a strike. This "compromise" the employees promptly agreed to, contending that they had gone half way in accepting arbitration at all, since they had earlier asserted that they would never again resort to a method which had produced results so unsatisfactory to them. Hence the railways were put in the position before the public of declining the proposal of a federal mediation board which the employees had accepted. They had been out-manœuvered and their capitulation was inevitable even before they made their call at the White House.

It is worthy of note that in no instance has the original demand for a modification of existing schedules come from the railways. Railway managers have apparently felt it wiser to let well enough alone. They have preferred to cut down or readjust their working forces in times of light traffic rather than bring on a struggle by upsetting fundamental conditions. This is partly to be explained by the fact that during most of the period under consideration railways dealt separately with their own employees, and were in a weaker position strategically than now under the plan of concerted movements. Moreover, it is more than probable that increases in wages did not distress them so seriously in the days when the capacity of their plants left some leeway for expanding business, and when there was a more generous margin between income and outgo.

In view of the fact that controversies have always had their origin in a demand from the side of the employees, the verdict even though a compromise has always resulted in giving something to the men. Even if the railways' unwillingness to grant the demands has merit, there is no way of enforcing their claims. Playing a game in which the cards are stacked against them, they must acquiesce in the outcome, which usually whittles down but never rejects the demands of the employees.

As the size of the contesting forces has widened the gap between employer and employee, as the conflicts have become more serious, and as the increasing gravity of the railways' financial condition has made a wage increase a matter of genuine alarm, resort has been taken more commonly to the method of arbitration. This has meant the choice of one, or under the amended statute two, non-partisan arbitrators. Selection has been a task of the greatest difficulty. In almost no case have the representatives of the contestants been able to agree on the independent member or members of the board, and the burdensome duty has fallen on the government mediators.

SHORTCOMINGS OF THE ARBITRATORS

The independent arbitrator, like the juryman, must have no preconceptions. His affiliations with life must be untainted by contact with railways. If he has ever had experience in an arbitration, he is likely to have incurred the displeasure of one side or the other sufficiently to render him unacceptable. But it is obvious that while impartiality and diplomatic skill are necessary, ignorance of the questions at issue is not. A wage schedule is a complex affair and its complexity is growing with the tendency to lay greater stress on working conditions and less on rates of pay. In the conductors' and trainmen's case, for example, the board had to consider the demands of conductors, baggagemen, brakemen and flagmen in passenger, freight and yard service, in local and through service, in electric and steam service; and it had to pass upon questions such as length of the working day, overtime and how computed, compensation for deadheadings, for double-headed trains, and for holding men

away from their home terminals. The representatives of the two factions are experts chosen for their thorough knowledge of the issues and their skill in presenting them. The umpire enters the hearings usually with no acquaintance even with the elementary principles of railway wage schedules. He listens to the highly technical testimony of witnesses—employees and operating officials—and at the conclusion of the hearings he is set upon in conference by the other two so-called arbitrators. His superficial half-knowledge results in inconsistent rulings, and his lack of background leads him to the natural conclusion that there is merit in the contentions of both sides, and that justice lies somewhere between. The unsatisfactory verdict, frequently ambiguous and conflicting in its different provisions, gives opportunity for a further continuance of the struggle on the individual railways that have been parties to the concerted movement. These decisions of arbitration boards lay down no helpful precedents for future action, and have no general educational value. The situation is in no wise improved when two umpires take the place of one. What is needed in the independent arbitrators is not merely a high degree of mentality or diplomatic skill, or profound knowledge of the labor problem in general, but rather a thorough familiarity with conditions of railway labor.

But not alone in the actual awards have the decisions of the boards been unsatisfactory. In many cases the explanations of these decisions have been unimpressive, and the reasoning unacceptable. A careful reading of the decision in the conductors' and trainmen's case leaves one with a lurking suspicion, which it is difficult to dispel, that the board decided first on the amount of increase to be granted and later found a reason therefor. The engineers' board of 1912 discussed at some length the insoluble problem as to what is the basis of a fair wage. They were forced to the conclusion that the science of economics furnished no answer, and that they could only approximate an answer by comparing railway wages for similar service in other parts of the country and wages in other industries of like character.

It becomes clear then that a substitution of arbitration for mediation has lost to the country and to the contestants the expert service of trained mediators. Moreover, because of the method of selection, and the type of men chosen as intermediaries, the arbitration procedure has become largely a formality resulting in compromise verdicts, which as shown by the discussion have not been thus far as satisfactory to either side as were the agreements under the mediation process. We have not therefore obtained either from the mediation method or that of arbitration results of enduring value. Under the policy of mediation we have developed experts in the interpretation of railway wage schedules, but these experts have been debarred by the very nature of their office from considering issues on their merits. Under arbitration, the forms of a judicial hearing have been conscientiously observed, attempts have been made to weigh evidence and to reach just conclusions; but the men upon whom the burden of decision has fallen have not been experts. One of the important consequences of this is that the public, whose agents the independent arbitrators are supposed to be, has been at a disadvantage, and has not been adequately represented.

It must be clear that we need above all things else, for the handling of these great labor disputes, a group of independent persons who have become expert through permanence of tenure. It would be natural to expect that any permanent body of arbitrators would quickly become unacceptable to one side or the other or both. The long continued success of the mediators under the Erdman act was in large part due to the fact that they made no pretense of settling questions on their merits. A settlement after thorough investigation will not usually strike the middle point between the contesting sides. Again it is the fear of the employers that such a board would "get into politics" and of the employees that it would fall into the hands of the employing class.

If such a board of official arbitrators were created and the parties to the contest should refuse to invoke their services, ought they to be compelled to do so? Ought we to attempt to introduce compulsory arbitration? Such a proposal does not at the present time command serious attention. The enthusiasm for it in this country has perceptibly cooled in recent years.

Is compulsory arbitration desirable?

Compulsory arbitration has not realized its early promise in countries where it has been tried. One of the fairest and most sagacious students of the labor problem in the South Seas, Dr. Victor Clark, has reached the conclusion that compulsory arbitration has been successful only among unorganized laborers and that the powerful trade unions have not been prevented from striking when it has been to their interest to do so. Compulsory arbitration succeeded in the early years when the laborers were securing constant increases in their wages, but the ardor of the unions has cooled as the verdicts have become less favorable. It is of interest to note that even in decisions under compulsory arbitration the lure of the compromise is ever present.

As a matter of fact the situation is hopeless, and will remain so, as long as we delude ourselves into thinking that we can under present economic conditions find a basis for wages in any theory of ultimate reasonableness. It may be that we are not merely chasing a will-o-the-wisp when we are hunting for a reasonable wage, but we are at any rate seeking the unattainable. No more in the determination of a wage scale than in the determination of a railway rate is there an exact mathematical formula for reasonableness. So long as the two parties to the dispute are free to dicker undisturbed by outside influences, the conclusions reached will be the resultant of the bargaining skill and brute force of the contending factions; if arbitrators intervene guess-work and compromise will play their part. Moreover, we are dealing here with an industry in which an interruption of service quickly becomes intolerable. Consequently we cannot permit the contestants to settle their differences by employing the customary weapons of labor warfare. So we set up devices under the sanction of law as a substitute for force. As a rule and in the long run these arbitration boards will give to the men what they might if left undisturbed have secured by their own efforts. The public has gained peace but it has not reached any final solution of the wage problem.

No escape from the obstacles with which this question is beset will here be attempted, but it is submitted that the gravity of the situation will be much relieved, and the question far more intelligently handled, if provision is made for a compulsory investigation by non-partisan experts of the issues involved in any controversy, and for the proper presentation of the results. Specifically, the principle of the Canadian Industrial Disputes act should be adopted in this country. This act declares a lockout or a strike to be illegal until the matters in dispute have been investigated by a government board, and pending the investigation conditions are to remain as they were before the dispute arose. The investigating boards are temporary, appointed for the immediate controversy and discharged when their reports have been rendered. They consist of three members, one representing each side and a third chosen as umpire by the two; or, if the two fail to agree, by the minister of labor. However, these boards are not merely for investigation. In fact, their main purpose is to effect a conciliation and avoid a strike. Our experience with the railway labor situation as summarized in this discussion would lead us to expect that a board chosen in the Canadian fashion would not meet the requirements. While in Canada the same man has frequently served as chairman on different boards; there is no requirement that he shall do so. In this country, in the present temper of labor and capital, there is little likelihood that the same man would be acceptable for long. If a new man is chosen each time he lacks the necessary knowledge and expereince.

The need of expert investigators

Those responsible for the investigation and its results should be permanent government officials devoting their time exclusively

to this work. While an investigation is under way, they might very properly be assisted and checked by representatives of the two sides.

The call for expert investigators is so imperative as to require little argument. In the first place the merits of the immediate issues need to be studied by those who possess the necessary qualifications, and all the facts that would be helpful in creating an enlightened public opinion should be disclosed. Mediators and arbitrators, limited as they have been in time, and restricted to issues directly submitted, have in most cases confined themselves to the immediate wage contract. As a consequence one adjustment has been of little or no assistance for the next. It might well be one of the functions of such a body to make the public realize that a reasonable wage is impossible of attainment. We need much enlightenment on such fundamental issues as the relation of wages to cost of living, and to railway operating efficiency. Such questions as the following are demanding intelligent answers: Is there any logical relation between railway wages and railway output? between wages and the capacity and efficiency of the plant? For example, is there any proper connection between a trainman's wages and an increase in trainload? between an engineer's wages and an increase in tractive power? Again, have the risks and responsibilities of trainmen increased or decreased with the introduction of modern operating tools and methods? Is the working life of a trainman shorter than that of his fellow worker in similar industries outside? How does the railway employee's wage compare with that of workers in other highly skilled occupations? Are the brotherhoods receiving wages out of proportion to those of other classes of railway labor? Is there and should there be any relation between railway wages and railway revenue? Is the question of fair wages involved with the questions of fair interest and fair profits?

A group of permanent investigators would develop skill in weighing evidence, would build up a body of valuable precedent, would accumulate an experience that would be enriched constantly with the passing of years. For these labor struggles move in cycles, and the issues that investigators had passed upon would appear again in familiar form as the basis for later demands. Moreover, these men would acquire facility in the presentation of the results of their investigations in terms that the public could understand. It is essential, if public opinion is to be invoked in aid of settlements, that the issues shall be freed of all technicalities and stated in a manner to arouse public interest and stimulate public discussion. The difficulty of such a task is often underestimated.

The success of the investigators in settling disputes during the progress of the investigation would depend upon the personality of the government investigators and their skill in building up a reputation for impartiality. The tendency would of course be for them to become increasingly unpopular as time went on, for their conclusions concerning issues investigated, if of a character to command public confidence, would frequently strike hard at the contentions of one side or the other. But whether these investigators are to be permanently acceptable to the opposing factions is not after all the controlling consideration. These are public questions and it is the public that demands enlightenment.

As already noted, such a plan would forbid strikes or lockouts during the period of investigation. After the results were published, this restraint would be removed. But the likelihood of a labor outbreak following the publication of the results of an investigation would be remote. The very fact that the contestants would be compelled to delay their conflict would have a tendency to develop a spirit of compromise. This is of great psychological import in any impending quarrel. Again, the territory involved is so vast, the leaders of the labor organizations are so mindful of their great responsibilities, the railway managers are so sensitive to public opinion and so watchful of their earnings, that strikes in any event are not at all probable in the future in connection with this class of controversies. Moreover, the probability of a strike is very greatly lessened when the public has once become thoroughly informed on the issues and is prepared to take a hand.

As for the amendment of our existing statutes covering mediation and arbitration, this may, except in details, properly be left until the results of compulsory investigation have been appraised. It has been suggested that the Newlands act should not be confined to employees in train service, but should be extended to include all railway employees; and it has been proposed that there should be some sort of co-ordination between the board of mediation and conciliation and the Interstate Commerce Commission in the matter of increased wages and increased rates. It may be, as has many times been suggested, that the Interstate Commerce Commission will be obliged eventually to give more attention to operating expenses and to take over the regulation of railway wages. It is clear that the commission at present is not disposed to fall in with the suggestion usually made by arbitration boards, and raise rates to compensate for the increased wages that the boards have awarded. That these boards have taken a sound position in insisting that they have no concern with the ability of a road to pay has already been conceded in this discussion. But the fact remains that the margin of railway net revenue is growing constantly narrower, and that the railways are contemplating with much concern the steady increase in wages which they are unable to check and the hardening of rates which they are unable to disturb.

No final solution of so perplexing a problem as that of the relations of capital and labor is to be expected within the near future, even in the field of public service corporations, but we can begin at once to study the whole question in a thoroughgoing fashion and with the use of the most highly developed scientific methods, and thus lay the foundation for a larger participation of the public in the settlement of disputes in which its interest is so fundamental.

ELECTRIC INTERLOCKING AT AULON, TENN

An all-electric interlocking plant has recently been put in service at Aulon, Tenn., at the crossing of the Nashville-Memphis main line of the Nashville, Chattanooga & St. Louis with the Illinois Central's line leading to its new yard in South Memphis, and with the main line of the Louisville & Nashville, all of which are double tracked. The Union, a single track belt line railway, also crosses the L. & N. at this point. The tower is a two-story brick structure. The machine is of the G. R. S. unit-lever type, containing 88 spaces, having 53 working levers operating 61 functions. The power for the plant is furnished by the Memphis Consolidated Gas & Electric Company, at 220-volts, a. c., with a frequency of 60. For the electric lights, both in the tower and in the signals, and for one winding of the track relays, the current is transformed to 110 volts. The track circuits are alternating current, but for the mechanisms and control d. c. is used. Emergency power is supplied by Edison storage battery A-4-H type, consisting of 90 cells of 150 a. h. capacity. This is available for the operation of the interlocking machine and all switch and signal motors, as well as for lighting purposes.

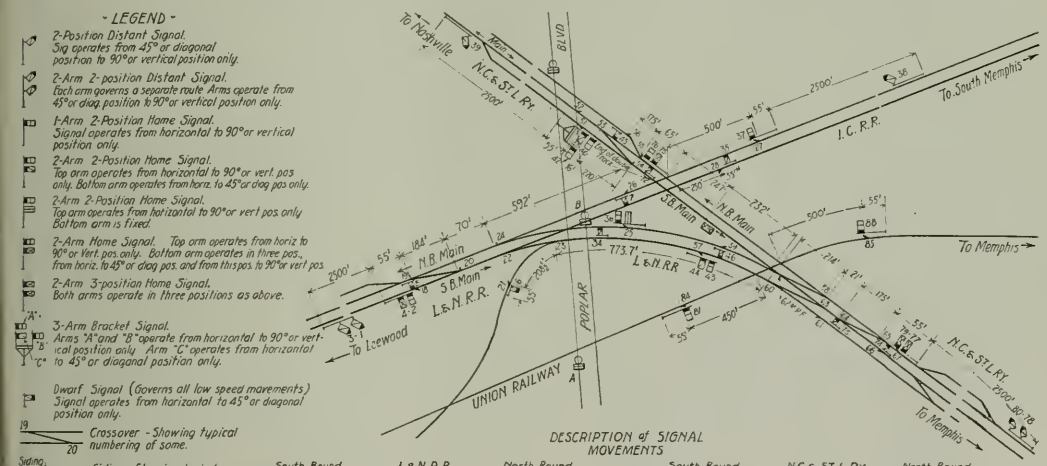
The high signals are G. R. S., model 2-A, with top-post mechanism, mounted on iron posts, working in the upper quadrant. Home signals have three positions wherever there is another home signal in advance; otherwise, they operate in two positions. The home signals are semi-automatic; the 45 to 90 deg. positions being controlled by the track circuits, so that after a train enters a section the signal cannot be cleared by the leverman until the train passes the insulated joint at the end of the track circuit for that section. Distant signals are two-position, operating from 45 deg. to 90 deg., each distant signal being operated by a lever in the tower and also controlled by a circuit breaker on the home signal in advance. The dwarf signals are G. R. S., model 3, solenoid type, working in two po-

sitions, 0 to 45 deg., and are controlled entirely from the tower. On the top of the tower there is a low-voltage electric horn for giving signals to call the attention of switching crews, and also for calling the maintainer when he is needed. The night indications of signals are green for proceed, yellow for caution and red for stop. Derails on the high speed tracks are Morden lifting type and on low-speed tracks of the Hayes type. Both detector circuits and 53-ft. detector bars are used.

Poplar boulevard, which crosses all four railroads, is a street on which there is a dense traffic, many automobiles using it, especially at night. Realizing that the occupants of automobiles might frequently fail to hear the ringing of the ordinary crossing bell, and fail to note the approach of trains, a signal of the Brach type was installed—the "automatic flagman." This gives both a visible and an audible warning. It contains eight stationary electric lamps with red lenses showing on the street in both directions. These lamps are automatically lighted one after the gine to move over the crossing; but since the signals go to stop automatically as soon as the leading end of a train passes them the control wire is looped in multiple through the back contacts of all the track relays in the circuit which include the sections of track crossed by the street; so that the bell continues to ring, through the track relay control, after the signal has gone to stop, and until the train has passed the crossing.

Previous to the installation of this plant, the numerous switches were operated by switchtenders and by trainmen, using hand signals. Six switchtenders were employed regularly, three of whom were operators. Switches were only lined up for through trains. Freight train and switching crews had to throw the switches themselves and also protect their trains by flags, when necessary.

The instructions for trainmen were formulated with special care and were accompanied by large scale charts prepared by the signal engineer of the Nashville, Chattanooga & St. Louis.



Descriptive Chart Prepared for Trainmen; Electric Interlocking at Aulon

other in a manner to give the effect of a swinging red lantern. Above the lights in large lettering, is the sign, "Railroad Crossing," and a large locomotive-type bell, which sounds as trains approach.

The unusual conditions under which the "automatic flagman" and bells were to operate were taken into consideration, and special circuits were designed to meet these conditions. As all the railroad lines cross Poplar boulevard, a proceed indication must be given by a home signal in every case before it is necessary for the automatic flagmen to start operating. The control circuits for the automatic flagmen were therefore looped in multiple through the circuit breakers on all of the home-signal levers which govern a route over the crossing. The contacts on the levers are normally open; that is, when the signals are at stop; and they are closed when the lever is changed to clear a signal. Thus the automatic flagmen would continue to operate only so long as there is a signal clear to permit a train or engine to move over the crossing; but since the signals go to stop automatically as soon as the leading end of a train passes them the control wire is looped in multiple through the back contacts of all the track relays in the circuit which include the sections of track crossed by the street; so that the bell continues to ring, through the track relay control, after the signal has gone to stop, and until the train has passed the crossing.

Previous to the installation of this plant, the numerous switches were operated by switchtenders and by trainmen, using hand signals. Six switchtenders were employed regularly, three of whom were operators. Switches were only lined up for through trains. Freight train and switching crews had to throw the switches themselves and also protect their trains by flags, when necessary.

The instructions for trainmen were formulated with special care and were accompanied by large scale charts prepared by the signal engineer of the Nashville, Chattanooga & St. Louis. This chart, which is illustrated, was posted on the bulletin boards of all the roads several weeks in advance.

The apparatus was furnished and installed by the General Railway Signal Company, under the supervision of G. S. Pflasterer, signal engineer of the Nashville, Chattanooga & St. Louis. The rubber covered wire, of which there is 160,000 ft., was furnished by the Kerite Insulated Wire & Cable Company, New York

---

Railway Extension in Italian North Africa.—The 20-mile railway from Azizia to the foot of the Garian mountains in Tripolitania was opened to public use on January 21, 1915. This is known as the Azizia-Henscir el Abeat division, and in addition to the terminal towns serves stations at Bir Cuca, Laim Aimirat and Cave. The two trains that formerly operated daily in each direction between Tripoli and Azizia, now run to Henscir el Abeat.

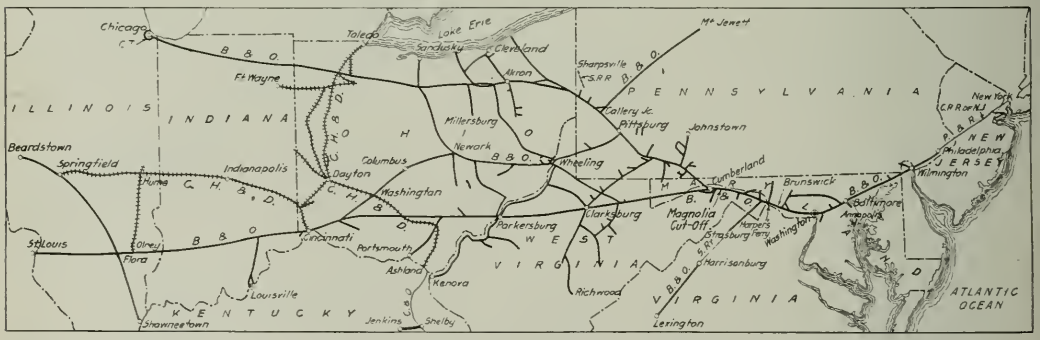
Reasons for Building the B. & O. Magnolia Cut-off*

Low Grade Double Track Line 12 Miles Long Costing $6,000,000 Relieves a Serious Operating Problem

By A. W. Thompson
Third Vice-President, Baltimore & Ohio

During the period of 17 years in which the construction of the original line of the Baltimore & Ohio between Harper's Ferry, W. Va., and Cumberland, Md., was under consideration, many routes were surveyed on both sides of the Potomac river. On account of a lapse in the company's Virginia charter and a provision in the law extending the charter, that the route must lie in the state of Virginia, the company was forced to adopt a line south of the river. This location had other decided advantages, however, as it reached the fertile valleys bordering on the tributaries of the Potomac, avoided interference with the Chesapeake & Ohio canal then far advanced in its construction, and was cheaper than a line north of the river by $2,625,000. The final location of this line was made in September, 1839, and the road opened to Cumberland in November, 1842. On account of the necessity for avoiding heavy construction work a line with heavier grade but shorter than the circuitous route following the river was adopted. The original line included three tunnels, all branch, and ascending a 0.3 per cent grade to the foot of a 20 mile helper grade of 0.75 per cent at a point 8 miles west of Pinkerton on the Connellsville division. The estimates show that it would require approximately $17,755,000 to construct a new line and revise the present one on such a basis. At the summit of the mountain the 1.23 per cent line through Sand Patch tunnel could be replaced by one commencing at Garrett, Pa., having a 0.3 per cent eastbound grade with a tunnel 13,500 ft. long. This revision would cost $4,312,000. These new lines and revisions would permit operation on a 0.3 per cent basis from the Fairmont coal fields eastbound to the summit of the Allegheny mountains with a helper grade of 20 miles.

On the east side of the summit the grade is descending eastbound until the location of the recent Magnolia improvement is reached. At this point the completion of this work provides a 0.1 per cent eastbound grade to Cherry Run, where a 0.3 per cent helper grade has been established eastward to Hedgesville. From



Map of the Baltimore & Ohio System Showing Location of the "Neck" Between Cumberland and Brunswick in Which the Magnolia Cut-Off Improvement Is Located

of which have now been eliminated, the last being a part of the Magnolia cut-off improvement.

HANDLING COAL TO TIDEWATER

In January, 1844, the new road was offered a contract for hauling 175 tons of coal, pig iron and bar iron for 300 days in the year at a rate of 1½ cents per ton mile. From this beginning the semi-bituminous coal trade on the Baltimore & Ohio has grown to 30,000,000 tons a year, the gross revenue from which is 0.4 cents per ton mile. If a new project were considered for handling this traffic from the Maryland, West Virginia and Pennsylvania fields to tidewater, undoubtedly a line with grades against eastbound traffic not exceeding 0.2 per cent could be built over these ridges with a tidewater terminal located at some point on the Potomac river.

During the growth of this business the question of more economical operation has been constantly studied and many surveys have been made covering various lines from the Fairmont, W. Va., region to tidewater. It has been found possible in these surveys to establish an eastbound low grade line beginning at Van Voorhis on the Fairmont, Morgantown & Pittsburgh Hedgesville to Harper's Ferry surveys have been completed which show that for $3,500,000 a low grade line can be constructed, having a maximum eastbound grade of 0.1 per cent. These surveys have been made looking toward the future when it is thought the eastbound tonnage will have grown to such proportions that more economical operation will be necessary and the large expenditures will be justified.

EAST END OF CUMBERLAND DIVISION

The congestion on the 102-mile freight division between Cumberland and Brunswick was serious as early as 1900, and various improvements were considered, including the Magnolia cut-off. Owing principally to the heavy expenditures necessary to add to the track facilities along the Potomac river, however, they were postponed from time to time. At Cumberland, two double-track lines, one from Pittsburgh and Chicago, and the other from Cincinnati and St. Louis, meet and form the main line east. At Patterson Creek, 8.1 miles east of Cumberland, a freight cut-off joins the main line from the Cincinnati-St. Louis line, which eliminates handling this freight through Cumberland. These two double-track lines merge into a three-track road from Patterson Creek to Little Cacapon, 13.9 miles, at which point there is a westbound passing siding. From the latter point to Magnolia, 7.5 miles, there are but two tracks with a westbound siding

*Abstracted from a paper presented before the Engineers' Society of Western Pennsylvania, November 24, and published in the December, 1914, Proceedings. A description of the interesting construction features of this important work was published in the *Railway Age Gazette* of July 17, 1914.

at Magnolia. An additional freight running track is provided from Magnolia to Hansrote, 9.5 miles, at the foot of the helper grade. From Hansrote to Orleans Road, 4.7 miles, there are two tracks on an 0.8 per cent grade, eastbound, against the

follows: 14 per cent fast freight, 84 per cent slow freight, 2 per cent package local. The average daily movement on the east end of the Cumberland division for a 10-day period, ending March 10, 1914, is shown in the following table:

Average Daily Movement—East End Cumberland Division
For Period 10 Days Ended March 10, 1914

ruling movement from Hansrote to the summit at Doe Gully tunnel. From Orleans Road to Cherry Run, 25.3 miles, there are three tracks with a four-track section from Sir John's Run to Hancock, 5.1 miles. At Cherry Run the main line which is double track, ascends an 0.8 per cent grade for a distance of 7 miles to the summit at North Mountain. From Cherry Run to Cumbo there is a low-grade, eastbound double-track freight line, 14 miles long, which passes around North Mountain and joins the main line again at the latter point. From Cumbo to Fawver, 3 miles, there is a double-track line and from Fawver to Opequon, the foot of a helper grade, there are three tracks, the third being the eastbound running track, and an 0.8 per cent ascending grade begins at Opequon, which continues to the summit at Hobbs, 7.3 miles. From this point to Engles, near Harper's Ferry, 5.8 miles, there is a double-track line with an 0.8 per cent descending grade and a westbound third track. From Engles to Weverton, 6.2 miles, there is a double-track line. Brunswick yard, the east end of the freight division, is situated just east of Weverton.

The division is operated for a general grade of 0.3 per cent, eastbound, using helper engines over the two 0.8 per cent grades. With the completion of the Magnolia cut-off, helper engines at Hansrote will be eliminated, which will permit a continuous movement of freight trains between Cumberland and Martinsburg, the part of the road of greatest traffic density. From Martinsburg east over the third summit, the use of helper engines will be continued until the low-grade line between Martinsburg and Harper's Ferry will have been built. The elimination of the 2½-mile helper grade at Hansrote was delayed on account of the very rough country and the circuitous route of the river, pending a decision in regard to a general change which would shorten the line and reduce the curvature in addition to eliminating the helper grade.

The Traffic and Resulting Congestion

A diversified business is handled over this line, the preponderance of which is soft coal. There are three points of interchange with other roads, at Cumberland with the Pennsylvania, the Cumberland & Pennsylvania, the Georges Creek & Cumberland and the Western Maryland, at Cherry Run with the Western Maryland, and at Martinsburg with the Cumberland Valley. At the latter two points, 47 and 71 miles respectively east of Patterson Creek, 43 per cent of the eastbound freight leaves the B. & O. for eastern Pennsylvania and New England delivery, coal being the principal commodity diverted. The Cumberland Valley is also the route of the Central States Despatch.

The greatest density of traffic on the B. & O. system, that is, the number of trains handled as well as the ton miles per mile of road, obtains between Patterson Creek and Martinsburg. There have been handled annually 20,000,000 net tons of freight per mile of road between these points and an average of 15,000,000 net tons per mile of road over the entire freight division between Cumberland and Brunswick. This traffic is divided as

As shown in the table, the heaviest tonnage is handled between Patterson Creek and Cherry Run, the number of trains being approximately the same in each direction. The eastbound gross tonnage amounted to 68.1 per cent of the total, consisting of 97.5 per cent loaded, and 2.5 per cent empty cars, while the westbound freight movement comprised 23.8 per cent loaded and 76.2 per cent empty cars. Of the total cars operated, 97 per cent carried full rated tonnage, which is a very high average. The highest average miles per car per day for the system obtains on this division for two reasons, first, because of the through movement and the large number of cars handled and second, because of the small amount of business originating in this territory.

The most serious congestion in handling this heavy traffic was, of course, on the helper grade between Hansrote and the summit at Doe Gully tunnel. Six or seven eastbound freight trains were always in the vicinity of this helper grade, either moving or waiting for track and on account of the helper engines having to use the westbound track down the grade, the westbound traffic was frequently delayed and the delay to helper engines, in turn, delayed eastbound trains.

Improvement in Operation 1910-1914

The congestion in this portion of the line, referred to as the "neck of the bottle," became so serious in the latter part of 1910 that conditions were given particular study with a view to taking care of the business offered at that time, as well as to provide for increased business. Had a revision of grade and line been worked out and decided upon at that time, and the money appropriated, the completion of the work could not have been accomplished in time to take care of the business offered, as it would have required at least 18 months to two years to complete any scheme presented for the Magnolia cut-off, and from four to six months to get any relief whatever from third track along other portions of the division. It was therefore necessary to do something at once and existing financial conditions demanded exceptional care in making expenditures.

In order to secure immediate results it was decided to order Mikado locomotives for immediate delivery, to construct additional automatic signals, and build third tracks where they could be laid on that portion of the line not affected by the proposed Magnolia cut-off, establish signal indications for the operation of trains, and provide more and better supervision. The Mikado locomotives ordered for this division weigh 284,500 lb., and have 55,000 lb. tractive power with 26.2 per cent greater hauling capacity than the consolidation locomotives previously used. A vigorous campaign was also started for a better carload, a decrease in the number of cars hauled, and an increase in the number of revenue tons per train.

The various passing sidings and freight tracks both east and west of the 17-mile section of road which was to be improved by the Magnolia cut-off, were coupled and extended, thereby securing maximum freight running trackage for a considerable

distance at each end of the proposed improvement. Interlocking towers were placed five miles apart and crossovers constructed between tracks to permit of parallel movements. In this three-track layout, the middle track was equipped with automatic signals to permit movements in both directions and the operation of all trains in this district was placed under signal indication, eliminating train order movements, the third-track system particularly lending itself to increased efficiency because of its flexibility in permitting almost four-track operation. No 16 frogs were installed in crossovers, which, when used, were covered by upper-quadrant, low-speed signal blades. A main-track coaling tipple, ash pits and water facilities were placed at Sir John's Run, half way on the freight run east from Cumberland, which resulted in a reduction in the cost of operation. Additional supervision was secured by placing well-trained men both on the road and in the superintendent's office. Particular attention was given to following the makeup of trains to reduce the number of breaks-in-two to a minimum, and further to see that each train was given its full tonnage rating. Inspectors were also placed in the coal region to see that each car was loaded to its capacity.

During the four years 1910-14 the average carload on this division increased 13.4 per cent, the increase in average capacity of system cars during the same period being 5 tons, or 13.5 per cent. As an indication of the results secured by these measures the following table shows a comparison of operating statistics for this division between the fiscal years 1910 and 1914, indicating a considerably increased volume of business and a marked increase in efficiency:

Operating Statistics

Description	Fiscal years 1910	Fiscal years 1914	Increase or decrease	Per cent
Miles of road	117.00	117.00	.....	....
Miles of main track	344.47	369.73	25.26	7.3

Track Diagram and Profile of the East End of the Cumberland Division Showing Location of the Magnolia Cut-off and Proposed Improvements Between Cumbo and Harper's Ferry

In the four years ended June 30, 1914, the revenue train load increased 51.3 per cent with a decrease in the freight train mileage of 23.4 per cent. The following table shows the decrease in number of trains run in that period and the increase in the net ton mileage:

Comparisons of Car and Ton Miles

Number of freight trains run in 1910	36,082
Number of freight trains run in 1914	28,527
Decrease	7,555
Per cent decrease	20.0
Total freight car miles in 1910	108,438,695
Total freight car miles in 1914	113,743,373
Increase	5,304,678
Per cent increase	4.9
Net ton miles in 1910	1,997,887,181
Net ton miles in 1914	2,316,743,150
Increase	318,855,969
Per cent increase	16.0

A comparison of the freight movements in this territory for 1914 and 1910 is shown in the table on the following page.

Comparison of Freight Movements

	Trains	Per cent Inc. Dec.	Loads	Empties	Total	Per cent Inc. Dec.
Keyser, East 1910	4,749	....	207,207	1,470	208,677	....
Keyser, East 1914	3,964	16.5	246,414	4,638	251,052	20.2

Brunswick, West 1910	9,039	....	118,219	233,956	352,175	....
Brunswick, West 1914	6,307	30.2	107,546	266,770	374,316	6.3
Martinsburg, West 1910	3,412	....	28,160	138,095	166,255	....
Martinsburg, West 1914	2,406	29.4	35,742	154,743	190,485	14.6

These improvements in operation made it possible to take care of a rapidly increasing business, postpone for three years the construction of the Magnolia improvement, thereby saving the interest on a large sum of money that would otherwise have been expended immediately, and to provide additional time for studies of the contemplated line revision.

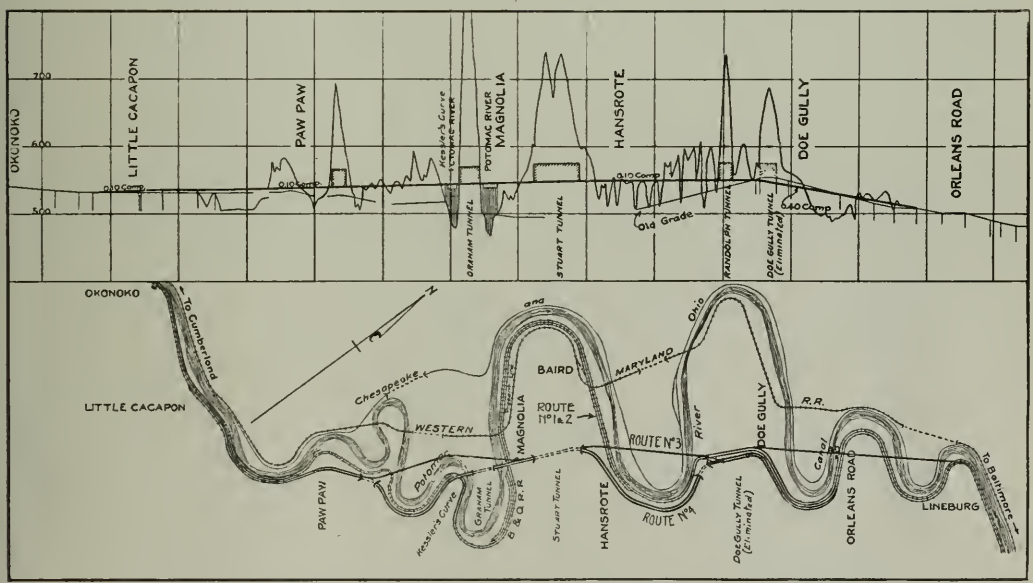
CHANGES IN LINE AND GRADE

The various studies that have been made as to improvements in the operation of the east end of the Cumberland division have shown that it is possible to obtain grades of 0.1 per cent or 0.2 per cent against eastbound traffic which is the loaded and ruling movement, and of 0.15 per cent against westbound traffic with 0.4 per cent helper grades on certain sections. The various studies pointed clearly to the fact that a 0.1 per cent grade is justified as compared with either a 0.2 per cent grade or the present method of operation. This grade would permit a maximum eastbound train load, based on the most economical operation, and the maintenance of a proper balance of power between eastbound and westbound movements. The general proposition to obtain better gradients over the entire division will necessitate the building of a low grade line along the river from Cumbo yard to Harper's Ferry, in addition to the Magnolia cut-off. The former line has been investigated and the recommendation made that any future construction of additional tracks between North Mountain and Harper's Ferry should be along this route.

Before the adopted line of the Magnolia cut-off was located and construction commenced, the studies included locations of both 0.1 per cent and 0.2 per cent lines, as it would be possible to obtain either of these grades on the Cumbo-Harper's Ferry lines. The present 0.3 per cent grade line from Cherry Run to Cumbo will have to be operated with a light helping engine on either 0.1 per cent or 0.2 per cent grades. The completion of the Cumbo-Harper's Ferry lines and the Magnolia cut-off would leave very little additional grade reduction necessary to obtain a 0.1 per cent grade against eastbound movement and a 0.15 per cent grade against westbound traffic, especially if it is considered necessary to revise on that basis only one track for slow freight in each direction.

CONSIDERATIONS IN LOCATING MAGNOLIA CUT-OFF

In taking up the study of the Magnolia cut-off improvement, an investigation covering several years was made of the train movement and tonnage handled, motive power, probable future locomotive tractive power and train loads. The relation of loaded eastbound movement to empty westbound movement being also carefully studied. It was finally decided that an eastbound grade of 0.1 per cent was possible, which would permit the most economical operation, and that a westbound 0.4 per cent grade would take care of the balance of traffic in that direction.



Location of Four Routes Considered for the Magnolia Improvement and Profile of the Adopted Line

The question as to the construction of a new two or four-track line was also given a great amount of study. Four possible propositions were considered; first, a temporary third track alone, the present line retaining the eastbound helper grade; second, two additional tracks along the present line, retaining the helper grade; third, a four-track low grade cut-off abandoning the present line; and, fourth, a two-track eastbound low grade cut-off using the present line for westbound movements. Before the final decision was reached a total of 29 propositions covering various grades and alinements were covered, following practically three routes. These various studies included plans for building the new line in parts over a term of years, and the estimated cost of the lines varied from $1,425,000 to $15,575,000. The following table shows the estimated cost of a few of these

lines; also the annual operating costs, with and without interest, for the present traffic and for double that traffic:

Summary of Cost of Construction and Operation of the Different Lines

Line	Cost of new construction	Number of trains — Present: Annual cost of operation	Present: Annual cost of operation including interest	Double: Annual cost of operation	Double: Annual cost of operation including interest
Present Line and Grade:					
No. 1—Three tracks throughout	$2,235,000	$615,087	$726,837	.....	.....
No. 2—Four tracks throughout	3,375,000	615,087	783,837	$1,230,174	$1,398,924
0.1 per cent *E.B.* — 0.3 per cent *W.B.*					
No. 3—Four tracks throughout	15,575,000	258,724	1,037,474	517,448	1,296,198
0.1 per cent *E.B.* — 0.4 per cent *W.B.*					
No. 4—Two tracks throughout*	6,000,000	284,580	584,580	569,160	869,160

*Two new tracks with present line will make four track line.

The following table shows the saving in distance and curvature for the four principal routes considered:

Statement Showing Saving in Distance and Curvature

Line	Eastbound: Dist. Miles	Eastbound: Saving Miles	Eastbound: Curvature Deg.	Eastbound: Saving Deg.	Westbound: Dist. Miles	Westbound: Saving Miles	Westbound: Curvature Deg.	Westbound: Saving Deg.
No. 1..	20.8	...	2,130	.....	20.8	...	2,130	.....
No. 2..	20.8	...	2,130	.....	20.8	...	2,130	.....
No. 3..	12.5	8.3	495	1,635	12.1	8.7	305	1,825
No. 4..	15.2	5.6	1,380	750	20.8	...	2,130	.....

IMPROVEMENTS EFFECTED BY CUT-OFF

The recommended line No. 4, which was finally adopted and built at an estimated cost of $6,000,000, is a double track line, using the present operated tracks for westbound traffic. This has made it possible to secure a four-track line and derive the benefit from a low grade with the least expenditure. Furthermore, it is believed that the following important characteristics have been secured. First, a minimum grade both eastbound and westbound which will permit the most economical operation; second, a 0.1 per cent grade eastbound, possible over the entire freight division, which will fit in with a general grade revision scheme from the coal fields to tide water; third, a 0.4 per cent grade for westbound business which is practically justified by the probable balance of future traffic; fourth, a four-track system between Little Cacapon and Orleans Road, which will take care of a largely increased volume of business and probably take care of the traffic over the division for a great many years. This section is the first portion of a four-track system, which will gradually be extended from Patterson Creek to Brunswick, a distance of 95 miles.

The Magnolia cut-off was more essential to the development of the Baltimore & Ohio as a system than is shown by the advantages to be gained by economies in operation. In view, however, of the heavy expenditure necessary to provide the additional tracks for the purpose of eliminating congestion that has heretofore existed in the handling of traffic over the east end of the Cumberland division, particularly this 17-mile section, it is reasonable to expect a reduction in the operating costs. Some of the direct savings that may be expected are as follows:

Elimination of Hansrote Helping Station—		
Operation of helping engines	$35,000	
Water station facilities	2,000	
Interlocking tower	3,000	
		$40,000
Overtime account of facilitated movement		20,000
Train mileage, increased tonnage, wages, fuel and supplies, including proportion of locomotives and car repairs	125,000	
Less mileage allowance to crews	20,000	
Total direct saving per annum		$205,000
Total direct saving per month		17,080

The flexibility in operation brought about by the elimination of the cause of congestion will result in a saving equivalent to the cost of operating eight road and two helper engines. It also will avoid bad situations beyond the improved section which will be beneficial in the coal regions where the traffic is assembled, as well as at points of destination, especially tidewater, permitting a quicker movement of traffic over the entire system. Conservatively estimated on the basis of the present business this saving should amount to approximately $500,000 a year.

While it has not been definitely decided, it seems from an operating standpoint that the new line can be better operated by using both new tracks for eastbound freight trains and the present main tracks and third track for east and westbound passenger trains and all westbound freight trains. Although the line is shorter by the new route, this advantage from the standpoint of passenger traffic is offset by the old line having no tunnels and being along the Potomac river for the entire distance. Facilities for handling passenger traffic will, however, be greatly improved by the elimination of the helper stations and the removal of the eastbound fast and slow freight trains from the old line.

WESTERN RATE ADVANCE HEARING

Testimony of the representatives of shippers and of the western state railway commissioners against the proposed advances in freight rates on fresh meats and packinghouse products occupied the hearing before Commissioner Daniels at Chicago this week in the western rate advance case. This is to be followed by testimony on the livestock rates from May 1 to May 5. Testimony on the advances on fruit and vegetable rates and on rice and rice products was heard on April 22, 23 and 24. The testimony on grain and grain products was not completed in the time allotted for it in the schedule on April 21, although several night sessions have been held, and supplemental testimony will be presented on the days allotted for unfinished evidence at the end of the hearing.

One of the witnesses for the shippers of grain and grain products was W. J. Thompson of the United States Department of Agriculture, who introduced exhibits to prove that the farming industry is unprofitable and in too weak a condition to stand the proposed advance of one cent per 100 lb. in the grain rates. He presented figures based upon returns from 273 farms to show that the net return only averaged 3½ per cent on the value of the property used. Under cross-examination by T. J. Norton, general attorney of the Atchison, Topeka & Santa Fe, Mr. Thompson said that he had not taken into consideration the fact that the farmer gets a living for himself and his family, and that he had not included money the farmers receive for butter, eggs and other similar products. Mr. Norton entered objection to the entire testimony as being irrelevant. Commissioner Daniels ruled that the question of whether the shipper was making a profit or a loss had nothing to do with the reasonableness of a freight rate, but said that since the question of returns had been raised he would admit the testimony for what it was worth, although he was not strongly persuaded, he said, that the average farmer keeps cost accounts.

C. W. Hillman and Jean Paul Muller testified as expert accountants for the shippers and the state commissions as to the cost of handling grain traffic. Mr. Hillman presented an extended analysis of the operating revenues and expenses of the Chicago & North Western to show the margin between the cost of moving grain and the revenue received by the railroad per car for the month of November, 1914. He divided the operating revenues and operating expenses of the road between freight and passenger service, and then attempted to separate the expenses of handling the wheat, other grain and grain products traffic. The result was to show that the cost of carrying a car of wheat into Chicago from Sioux City, Iowa, 526 miles,

was $29.41; from Council Bluffs, Iowa, 470 miles, $26.53, and from South Omaha, 478 miles, $26.84. On other grain his figures were $28.44, $25.81 and $26.33, respectively, and on grain products $25.16, $23.53 and $23.91, while he figured the cost from the average station, 399 miles, as $27.26 on wheat, $25.74 on other grain and $24.72 on grain products. The average earning per car, he said, as shown by waybills covering the movement of 33 cars of wheat from 25 typical stations in Minnesota, Nebraska and South Dakota, was $108.29 for an average haul of 406 miles. On other grain, 947 cars, with an average haul of 444 miles, the average earnings per car were $116.13; and 546 cars of grain products traveling an average distance of 438 miles, yielded an average revenue per car of $42.76.

Mr. Muller, who appeared for the National Council of the Farmers' Co-operative Grain Dealers' Association, testified that grain traffic is a more profitable tonnage than the average of all freight traffic, basing his conclusion upon an analysis of the operating revenues and expenses of the Chicago, Rock Island & Pacific; Atchison, Topeka & Santa Fe; Chicago, Burlington & Quincy and Chicago, Milwaukee & St. Paul. On the Rock Island, he said, 21.27 per cent of the total operating expenses could be charged directly to the freight and passenger accounts without the necessity of any allocation. By various methods he charged 67.22 per cent of the total operating expenses to freight traffic. He then divided the freight expenses as between road haul and switching and terminal movements, and by dividing the total road costs by the reported number of loaded freight car miles, with an allowance of 40 per cent for the cost of empty return haul, he obtained a road movement cost per loaded car mile of 6.928 cents. The average haul as determined by an examination of the movement of 3,731 cars through various western states was 359 miles. This multiplied by the road haul cost per mile gave a total average road haul cost on grain and grain products of $24.87 per car. The average unit terminal cost was obtained by dividing the total number of loaded freight car miles by the average distance hauled, adding the relative percentage for empties, and then dividing the results so reached into the total yard and terminal cost. This gave a terminal unit cost of $2.53 per car, or on the basis of four terminal movements per car, two at each end of the haul, a total terminal cost of $10.13 per car, which, added to the road haul cost, gave a total expense of $35 per car, while the average revenue was $58.32 per car. The net operating revenue, he said, is therefore equivalent to a gross profit of 66.66 per cent at an operating ratio of 60.01 per cent as compared with a gross profit of 38.87 per cent on all freight at an operating ratio of 72.01, and a gross profit of 33.74 per cent on all business, both freight and passenger, at an operating ratio of 74.77 per cent. On grain alone, he said, the returns are equivalent to a gross profit of 124.34 per cent at an operating ratio of 44.57 per cent.

By similar methods he apportioned 59.16 per cent of the total operating expenses of the Santa Fe to the freight traffic and arrived at a total road haul cost of $27 per car and a terminal cost of $10.16 per car for grain and grain products. The average revenue for an average haul of 394 miles, as shown by the movement of 11,581 cars, was $72.91 per car. For the St. Paul he found the cost for grain and grain products was $30.70 per car, and the net operating revenue per loaded car of grain and products, he said, was equivalent to 65.28 per cent at an operating ratio of 60.5 per cent as compared with a gross profit of 58.66 per cent on all freight at an operating ratio of 63.03. For the Burlington road he placed the cost per car at $30.56, as compared with an average gross revenue of $71.65 per car, making a gross profit on operating costs of 136 per cent at an operating ratio of 42.37 per cent.

On cross-examination by C. C. Wright, general solicitor of the North Western, Mr. Wright compared Mr. Muller's formula for separation of costs between freight and passenger service with that of Mr. Hillman, and asked Mr. Muller if he agreed with Mr. Hillman. "We never have agreed on anything," said Mr. Muller. He said he had charged to freight all company freight hauled, whether or not used for passenger service, saying that Mr. Hillman's separation of this item into freight and passenger service was impracticable.

Mr. Wright also drew an admission from the witness that in previous cases, as in this one, he had always used his formula on the heavily loaded commodities to show that they stood more than their share of the transportation costs. His contention was that the same formula would not work on the lighter loaded commodities. "If your figures here show that grain is earning too high a rate," he said, "it must necessarily follow that some other commodities are earning too low, must it not?" "That is true," said Mr. Muller.

Mr. Hillman admitted under cross-examination that he had used the gross weight basis in dividing the expenses of the North Western because of a decision of the United States Supreme Court, but he stated that he did not consider it proper in view of his experience as an accountant. Mr. Wright also challenged his calculations as making no allowance for empty car movements. Mr. Hillman insisted that his method of separating costs was better than that used by Mr. Muller.

H. W. Danforth, president of the National Council of Farmers' Co-operative State Associations, also testified in opposition to the advances in grain rates, saying the average return on farms in the corn belt states is only 3 to 3½ per cent.

J. A. O'Brien of Brownsville, Tex.; E. P. Byers of Ft. Worth, Tex.; C. E. Childs of Sioux City, Iowa, and A. A. Mullens of Iago, Tex., testified in opposition to the proposed advances in rates on fruit and vegetables from Texas. The witnesses disagreed as to whether the dealer or the grower would have to pay the advance.

When the hearing on advances of 3½ cents per 100 lb. in the rates on meat and packing house products was taken up on Monday, Mr. Heinemann introduced 82 exhibits, most of which were prepared to show that fresh meats and meat products pay higher freight revenue per car, per ton, and per train mile than the other traffic handled by western railroads. Mr. Heinemann said that the proposed advance from Omaha, St. Joseph and Kansas City to the Mississippi river and points east would total $3,063,694. On fresh meats alone the increase would mean $2,251,203, not including the advances which would be paid on westbound tonnage. He compared rates on meat between the Mississippi and Missouri rivers with the divisions of the transcontinental rates, saying that the latter are far below the danger line, often used by railroad officials, of 15 cents per car mile, and that it looks as if the carriers were trying to make the packers bear the burden created by unremunerative rates on other hauls and other commodities. He also objected to the attempt to increase the cost of one of the prime necessities of life.

"The railroads," said Mr. Heinemann, "have declared that they never intended to increase the rates on packing house products above the charges contemporaneously in effect on fifth class articles. Arkansas is one of the greatest cured meat consuming sections in the United States. Yet an examination of the proposed tariffs shows that to 10 representative points the carriers are planning to put in rates on packing house products from three to 17 cents higher per 100 lb. than fifth class rates.

"The Interstate Commerce Commission, in fixing southwestern cattle rates, established a scale on hogs 114 per cent of the cattle rate; sheep and goats, 125 per cent; packing house products, 139 per cent and fresh meats 168 per cent of the cattle rates. This relationship the carriers in this case would destroy by putting in hog rates 113 per cent of the cattle rate, sheep and goats, 122 per cent; packing house products, 151 per cent and fresh meats, 189 per cent of the cattle rates. This is another graphic illustration of the manner in which the railroads seem to be endeavoring to saddle the heaviest burdens upon the packing industry.

"Not content with seeking to advance our rates on long hauls, the carriers are also endeavoring to boost our charges for interplant movement between our various Missouri river houses. Between Kansas City and St. Joseph we now pay 35.5 cents per

car mile on fresh meats and 24.2 cents on packing house products. Both rates yield considerable in excess of the so-called 'danger mark' of 15 cents. The carriers are also asking permission to cancel a number of carload rates on packing house products between Missouri, Kansas and Iowa points. This would have the effect of advancing those rates all the way from 17.5 to 128 per cent."

NEW CLEARANCE REGULATIONS IN ILLINOIS

Following an investigation of the subject of clearances on railroads as affecting safety of operation, the state Public Utilities Commission of Illinois has just issued regulations specifying the minimum horizontal and vertical clearances which may be established in the construction and reconstruction of any railroad or building adjacent thereto, unless permission has first been given by the commission to deviate therefrom.

Separate regulations are made for steam and electric railroads and for street railways. Only those portions relating to steam railroads are given below.

VERTICAL CLEARANCES

1. Except as hereinafter provided, no through truss bridge shall be constructed in any track, nor shall any bridge or other structure be constructed across any track over which freight or passenger cars are operated, having a vertical clearance less than 22 ft. above the top of rail for a lateral distance of 5 ft. from the center line of track. From a point 5 ft. horizontally distant from the center line of track and 22 ft. above the top of the rail, the clearance lines may extend downward at an angle to points which are 8 ft. 6 in. distant on each side of the center line of the track and 17 ft. above the top of rail.

2. At passenger stations and coach yards where passenger equipment only is handled, vertical clearances may be less than 22 ft.

3. Overhead loading platforms spanning tracks over which freight cars are handled for icing or other loading purposes may have a vertical clearance less than 22 ft., when such platforms or structures are so constructed as to open upward or outward by means of counter weights or other devices, so that such platforms shall furnish the full amount of vertical clearances specified in Rule 1 at times when cars are being switched.

4. Except at passenger terminals and in coach yards where passenger cars only are handled, all awnings and canopies spanning any track or supported at the sides thereof where such track is in an open thoroughfare, must have full vertical clearance as provided for in Rule 1. Canopies and awnings at freight houses adjoining a track not in an open thoroughfare, may be constructed with a minimum vertical clearance of 15 ft. 6 in., provided such obstruction does not extend closer than 5 ft. 6 in. from the center line of track. In every case where there is a canopy or awning at a freight house, the edge of which has a vertical clearance less than 22 ft., a warning sign shall be erected at some suitable place at each end of such canopy or awning, warning the train employees of the insufficient clearance and prohibiting them from riding on the sides of cars while in motion.

5. Where tracks other than thoroughfare tracks serve engine houses, car shops, elevators, warehouses, coal and ore tipples and industrial plants, vertical clearances less than 22 ft. may be used, provided that in no case shall this vertical clearance be less than 17 ft. for a distance of 4 ft. from the center line of track. From a point 4 ft. horizontally distant from the center line of track and 17 ft. above the top rail, the clearance line may extend downward at an angle to a point which is 7 ft. distant from the center line of track and 14 ft. above the top of rail.

6. In all cases where overhead structures span tracks with a vertical clearance less than that provided for in Rule 1, a rule must be issued by the Railroad Company prohibiting trainmen and other employees from occupying the tops of cars while in motion within certain prescribed territorial limits.

HORIZONTAL CLEARANCES

10. Except as hereinafter provided, and at switch turnouts, the distance from the center of any track to the center of an adjoining track shall not be less than 14 ft.

11. The distance from the center of any switching lead which lies adjacent and parallel to any other track (excepting a track of like character) where the switches are not operated mechanically, shall not be less than 18 ft. from center to center of tracks. The distance from center to center of two adjacent switching leads shall not be less than 21 ft.

12. Any two tracks given up wholly to passenger service, lying adjacent and parallel to each other, and leading from the main track into a passenger terminal or coach yard, may be constructed with track centers less than 14 ft., provided the track centers on the opposite sides of any such pair of tracks are not less than 14 ft., or where the face of any building or other structure is not less than 8 ft. 6 in. from the center of the adjacent track.

13. Any two adjoining freight tracks given up to freight loading and unloading purposes, such as tracks at freight houses, private industries, team tracks and like purposes, may be constructed with track centers less than 14 ft., provided the track centers on the opposite sides of any such pair of tracks are not less than 14 ft., or where the face of any building or other structure is not less than 8 ft. 6 in. from the center of adjoining track; provided also that it shall be permissible to construct on one side of any such pair of tracks a high platform for loading and unloading freight at freight houses, not less than 5 ft. 6 in. from the center of adjoining track as hereinafter specified.

14. Except as hereinafter or hereinbefore provided, no track shall be constructed adjacent to any building or other structure, nor shall any signal post, switch stand, building or other structure be constructed adjacent to any track which has a horizontal clearance of less than 8 ft. 6 in. from the center of track, measured at right angles thereto, it being understood that the horizontal clearance of 8 ft. 6 in. shall be maintained in respect to buildings from the level of the top of the rail to a point on the vertical clearance line as herein established. The clearance line for structures other than buildings and low platforms shall extend from a point 4 ft. above the top of rail, downward at an angle to a point 5 ft. 6 in. distant from the center line of track to a point which is level with the top of rail.

15. Platforms for loading and unloading of freight including livestock, the tops of which are approximately level with the floor of freight cars, may be constructed adjacent to only one side of freight tracks which are not in an open thoroughfare at a distance less than 8 ft. 6 in. from the center of track, but not less than 5 ft. 6 in. therefrom; provided, that in every such case, warning signs shall be erected at a suitable location at each end of such platform, calling trainmen's attention to insufficient clearance and prohibiting them from riding on the sides of cars while in motion.

16. Passenger loading platforms, the tops of which are level with the platforms of passenger cars, may be constructed next to tracks which are given up wholly to passenger service, at a distance less than 8 ft. 6 in. from the center line of such tracks, provided the passenger coaches are equipped with platform gates and kept closed while the train is in motion. Passenger loading platforms which do not exceed a height of 4 in. above the top of rail, may be constructed a distance of not less than 4 ft. 6 in. from the center line of track; and platforms which do not exceed a height of 8 in. above top of rail may be constructed a distance not less than 5 ft. 1 in. from the center line of track.

17. The horizontal clearances specified herein shall not apply to mail cranes when the arms of same are in position to support mail sacks for delivery to trains, provided the top arm of such mail crane when in position to support mail sacks for delivery is not above a point which is 6 in. below the lower sill of the engine cab window of the engine pulling the train which is supposed to pick up mail sacks, if such arms when in position to support mail sacks encroach upon the horizontal clearance of 8 ft. 6 in. from the center line of track.

The Use of Pulverized Fuel for Locomotives

An Outline of Results from Tests Extending Over a Year and Recently Concluded; What May Be Expected

The use of pulverized coal for heat-producing purposes is not new, this fuel having been extensively used for many years in cement and metallurgical furnaces, but while experiments have from time to time been conducted with a view to its use in the generation of steam, they were never developed to a practical and commercial conclusion.

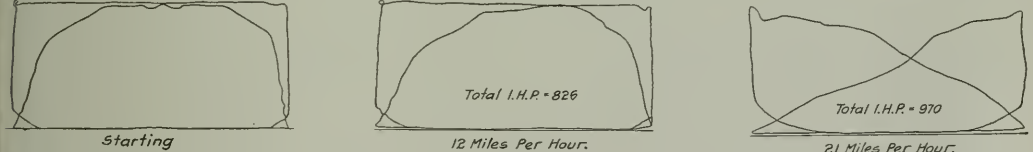
There are many reasons why a successful application of a means of burning pulverized fuel in locomotive fireboxes should be looked upon favorably. Such combustion is smokeless and there are no cinders or sparks thrown from the stack. The first of these items would bring the use of pulverized coal into careful consideration in congested terminal districts where public opinion is forcing the railways towards expensive electrification projects, while the second shows its value in the operation of steam locomotives through forests and other regions where fires are easily set. Furthermore, with the rapid inroads which are being made in the more superior qualities and grades of fuel supply of the United States, and, in fact, of the world, the cost of coal is rapidly increasing. With the application of pulverized coal burning apparatus, use can be made of the dust and refuse from mines as well as peat, petroleum coke, coke brieze lignite and other low grade coals which are under present conditions unsatisfactory for steam production in locomotives.

To produce the best results as regards complete combustion and the least trouble from ash and slag, pulverized coal should contain not more than one per cent moisture and be of a uniform fineness, so that not less than 95 per cent will pass through a 100 mesh and not less than from 80 to 85 per cent through a 200 mesh screen. Coal must, of course, be dried either before grinding it or when burning, this being an item of expense that is necessarily present regardless of whether the coal is burned on grates or in suspension in the powdered form. When coal which is not dry is fed into a furnace the moisture is evaporated, which means that an added quantity of coal must be burned to maintain the temperature, the latter being reduced about 72 deg. F. for each one per cent of moisture entrained. As this cannot be overcome by feeding additional fuel with the same percentage of moisture, the loss of heat is about two per cent for each one per cent of moisture, this loss being further increased when applied to the usable heat above the temperature of the escaping smokebox gases. If the coal is dried before grinding, however, the cost for drying will be almost saved because of the decreased power required for pulverization and also because of the improved combustion resulting from the greater degree of fineness obtained in the dried as compared with the moist coal.

The cost for preparing pulverized coal varies with the cost of the coarse coal and with the moisture content. However, from data obtained during the past 10 years, assuming the cost of the coal at from $1 to $2 a ton, a total cost for preparation will vary from 25 cents to 50 cents in the case of a plant having a capacity of two tons (of 2,000 lb.) per hour to a cost of 10 cents to 20 cents in a plant of a capacity of 25 tons per hour. The amount of fuel required for drying the coal averages from one to two per cent of the coal dried. It will, of course, be necessary in railroad work to equip the existing principal coaling stations with machinery for crushing, grinding, drying and conveying the coal to a suitable storage plant as well as to the locomotive tenders.

The work of developing equipment for burning pulverized coal in steam locomotives has been carried out during the past year and a half and the results have now assumed a final and definite form, so that it is possible to give in what follows a general idea of what has been accomplished. The equipment referred to in this article has been developed by the Locomotive Pulverized Fuel Co., 30 Church street, New York, and while it is not possible to describe it at present in detail, it is expected that a more detailed description of the apparatus will be available at a later date. In order to determine the commercial practicability of the appliances which have been developed, application was made to a ten-wheel locomotive of about 31,000 lb. tractive effort, 200 lb. working steam pressure, 22 in. by 26 in. cylinders, 69 in. diameter driving wheels, 55 sq. ft. of grate area and equipped with a Schmidt superheater.

The experimental work has been carried out on this locomotive almost continuously since early in June, 1914, on a ruling grade from 6½ to 8 miles long and also on a district of 92 miles. Some of the indicator diagrams obtained are shown in one of the illustrations. As originally built the locomotive had an exhaust nozzle 5 in. in diameter, this being approximately 19.6 sq. in. in area. The nozzle used with the pulverized coal apparatus was rectangular, 5½ in. by 8 in., giving an area of 44 sq. in. With the original nozzle the back pressure at speeds of from 15 to 20 miles an hour was from 8 lb. to 11 lb., while with the rectangular nozzle the back pressure at the same speeds was from 1 lb. to 3 lb. The reduction in back pressure much more than compensated for the steam consumption of the turbo-generator as well as for any use made of the steam blower while at the same time increasing the locomotive's capacity and reducing wear and tear on the machinery. The turbo-generator, which is of 10 kw. capacity, is placed at the forward end of the locomotive in front of the smokebox or in any other convenient location, and supplies current for two motors driving the conveying and blowing machinery at the firebox end which carries the coal into the firebox.



Indicator Diagrams Taken on a Locomotive Using Pulverized Coal as Fuel

The smokebox temperatures obtained were from 425 deg. to 490 deg. F., while the corresponding firebox temperatures ranged from 2,600 deg. to 2,850 deg. F. On no occasion did the locomotive stall because of insufficient steam; in fact, the safety valves were open at all times when the engine stalled. The tests were all conducted under the most severe conditions possible, namely, cold weather, low volatile coal, coarse pulverization of the coal, full tonnage rating and in many instances more than full rating.

The tonnage hauled on the maximum ruling grade ranged from the regular summer rating to 15 per cent greater than the summer rating in freezing weather and the locomotive accelerated the train in numerous instances on the ruling grade to speeds of from 20 to 25 miles per hour.

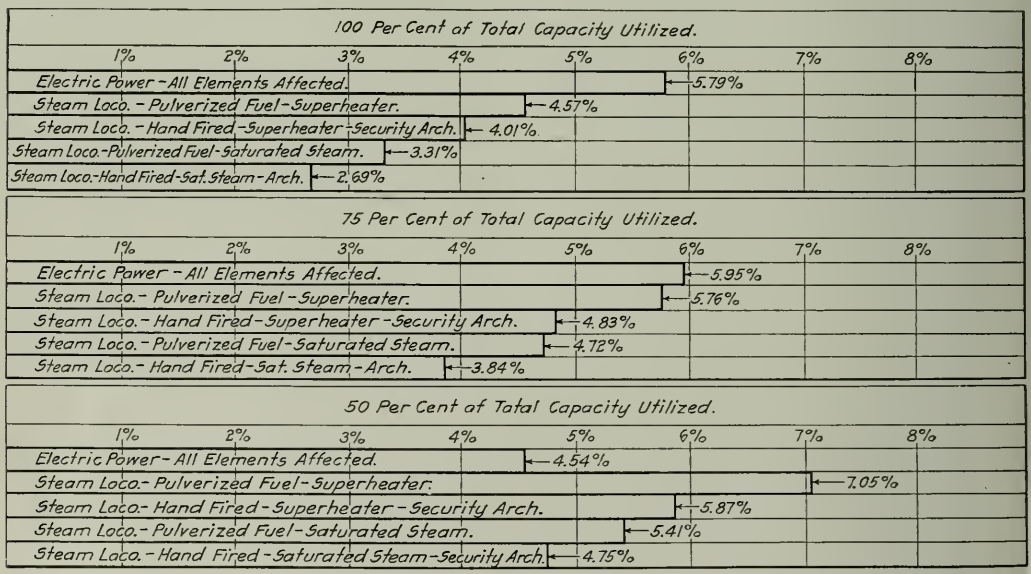
The coal used in these tests was ordinary bituminous coal and contained from 21 to 26 per cent volatile matter and about 15

per cent of non-combustible. When fed at the rate of 2,500 lb. to 4,000 lb. per hour the various smokebox gas analyses showed an average of less than 1 per cent of free oxygen or carbon monoxide and from 11 per cent to 14 per cent of carbon dioxide. The evaporation obtained ranged from 9½ lb. to 12¾ lb. of water per pound of coal from and at 212 deg. F.

The coarsest grade of the coal ran 39.6 per cent through a 200 mesh screen, 20 per cent on a 200 mesh screen and 40.4 per cent on a 100 mesh screen. The finest grade ran 66½ per cent through a 200 mesh screen, 95½ per cent through a 100 mesh screen and 98½ per cent through an 80 mesh screen. According to statements made before the American Society of Mechanical Engineers, the most satisfactory results are obtainable from coal which will run from 80 to 82 per cent through a 200 mesh screen and 95 per cent through a 100 mesh screen. Analyses of the coal used showed that it ranged from .67 per cent moisture, 65.16 per cent fixed carbon, 21.63 per cent volatile matter, and 13.12 per cent ash with 13,671 B.t.u. per lb., to .88 per cent moisture, 25.67 per cent volatile matter, 63.05 per cent fixed carbon and 10.4 per cent ash with 13,912 B.t.u. per lb. In the statements before the American Society of Mechanical Engineers referred to above, 30 per cent volatile matter was generally mentioned as a minimum for the best results. The capacity of each combination conveyor, feeder and mixer ranged from about 250 lb. of coal per hour at the lowest speed of 23 revolutions per minute of the feed screw to about 1,600 lb. of coal per hour at a speed of 133 revolutions per minute, this capacity being susceptible increase or decrease as the demands of the locomotive may require.

The locomotive steamed satisfactorily throughout the tests; in fact, more steam was produced than was required, and there was no smoke. The exhaust steam assumed at times a slightly grayish color, but at no time was there any evidence of dust or ashes, and no cinders or sparks were emitted. There is a saving of from 15 per cent to 25 per cent in coal consumed as compared with ordinary hand firing, but it has so far been impossible to compute this definitely. No change is necessary in the boiler of the locomotive other than to remove all of the smokebox draft appliances and the grate and ashpan equipment. The pulverized coal blowers and controllers are attached to the front of the tender coal space and the coal tanks can be applied to many tenders as at present constructed. This coal container is so arranged as to be usable for either pulverized coal or fuel oil, and the entire equipment can be readily changed without extra cost for burning fuel oil. The ordinary brick arch is used in the firebox and special brick work is used below the arch and mud ring. The refuse runs down into a collection pan below the firebox in the form of a slag which when hardened is of a glassy nature and is very easily broken and falls out when the pan is opened. About 2.5 per cent of the weight of the coal fired when it contains 15 per cent of non-combustible is deposited in the slag pan in the form of concentrated slag as compared with about 15 per cent accumulation in the ashpan when coal is burned on the grates. This is due largely to the slag containing no combustible whatever, whereas ordinary asphan residuum usually contains considerable combustible.

The cost for preparing pulverized coal should, it is believed, be more than offset by the difference in mine cost of the mine refuse and sweepings as well as lignite and other inferior grades of coal, as compared with fuel that must be used when burning on grates. Considerable savings in the matters of inspection, maintenance and operation are also indicated through the complete elimination of grates, ashpans, smokebox netting, handhole plates and spark hoppers, firing tools and squirt hose, as well as trouble due to loss of fuel from the open coal space. There is no soot collection in tubes and terminal and intermediate delays due to cleaning and dumping fires and blowing out tubes are also avoided and the facilities for performing such work are practically eliminated. There being no cinders, cutting of superheater elements, etc., is eliminated. The cost of building fires is also reduced to a minimum, as no special fuel or labor is required for this purpose, it being only necessary to light a piece of oily waste or other similar material to start the fire The fire can be extinguished when the locomotive is on sidings and at terminals, or when drifting, thus saving fuel, and it will restart from the heat of the furnace within an hour without relighting. When building fires, 200 lb. steam pressure



Comparison of Thermal Efficency of Electric and Steam Motive Power, Showing Percentage of Power Delivered at the Rail for 100 Per Cent B. T. U. in the Coal

can be obtained from water at 40 deg. F. in 45 or 50 min. The physical requirements of firing a locomotive are reduced to those of firing with oil while at the same time a more constant firebox temperature and more uniform steam pressure are claimed to be available under varying operating conditions. Relieving the fireman of the arduous physical exertion of hand firing should result in an improved standard of applicants for this position, making it correspondingly easier to develop higher class enginemen.

The following figures should be of interest as bearing on the cost of electrification as compared with that of equipping an average modern type of locomotive for burning pulverized fuel: Cost of a new Consolidation type locomotive of 50,000 lb. tractive effort, equipped with superheater and

(a) for handfiring and burning coal on grates, approximately	$22,000
(b) for burning fuel oil in suspension, approximately	22,750
(c) for mechanically stoking and burning coal on grates, approximately	24,000
(d) for automatically stoking and burning pulverized coal, lignite, peat or fuel oil in suspension, approximately	26,500
(e) cost of electric locomotive, approximately	50,000

Throughout the entire series of tests no trouble whatever was experienced with explosions, no tendency was found for any explosion to take place and there was no blow-back and noise such as occurs where fuel oil is used. In general, the firing of pulverized coal is conducted by means of one of two methods, one being known as the short flame method and the other as the long flame method. In the application to locomotives a combination of the two methods has been employed.

One of the illustrations shows a diagram of the thermal efficiency of electric and steam motive power under different conditions. The top portion of this diagram, in which 100 per cent of the total maximum capacity or load factor is assumed as utilized, is obviously an ideal condition, the condition in which 50 per cent is utilized being more nearly the average for steam road operation. It will be noticed that under these conditions pulverized coal shows up as extremely advantageous. These figures do not consider any emergency power plant or storage battery equipment for electrical operation.

TWO NOTABLE TRAIN ACCIDENTS

A derailment that occurred at Devon, Conn., on the New York, New Haven & Hartford, on March 23, in which an important express train was thrown off the track at a derailing switch, approaching an open drawbridge, and was prevented by a very small margin from falling down a high bank, was due to the engineman believing that he got a clear distant signal"; and coincidently with the report of the details of this accident we have the Board of Trade report from London giving the particulars of the collision which occurred on the Great Eastern, at Ilford, on January 1, from a similar cause. At Devon there was only one personal injury, and that slight; but at Ilford ten passengers were killed. The details of these two accidents will be of interest to readers who look upon the prevention of this class of mistakes as one of the most important problems connected with "safety first."

The train derailed at Devon was the Boston express leaving New York at 4 p. m. and the accident occurred about 5:30. The weather was clear. On sighting the home signal the engineman saw that it was against him and he applied the brakes, reducing speed to about ten miles an hour at the moment he went off the track. The engine and first three cars went over the derail, but all remained upright and the damage was small. There are several fixed spans in the bridge between the shore and the draw so that the train was stopped a considerable distance short of the opening; but the engine rested near the edge of the bank near the abutment. The engineman at fault was a runner of experience, with a good record.

The collision at Ilford occurred at about 8:40 a. m. on a clear day. A suburban passenger train from Gidea Park to London, moving at low speed, through a crossover from the local to the express track, about 300 ft. west of the station, was run into by a train from Clacton to London, coming on at high speed on the express track. It struck the seventh car in the Gidea Park train at somewhere from 25 to 50 miles an hour. Besides the ten passengers killed upwards of 500 passengers notified the company of personal injuries or shock sustained. The signals and switches at the point of collision are controlled by Ilford West Box. Between this and Ilford East Box there is controlled-manual block signaling and there is no question but that the signals were set against the Clacton train. The engineman, Fred P. Bloomfield, has been in the service 23 years, and a runner three years and six months.

The distant signal at which the mistake was made is about 3,300 ft. from the point of collision; and at the East Box home signal, which is 1,350 ft. from the point of collision there is an automatic apparatus for putting torpedoes on the rail when the signal arm goes to stop. Neither the engineman nor anyone on the train admits having heard the torpedoes, but several competent witnesses outside convinced the inspector that the "detonators" acted properly. The engineman's testimony at the hearing was not very clear. He said that he saw the home signal at stop and that he shut off steam, though apparently not promptly; and the inspector concludes that probably the sound of the torpedoes was the first thing that made him realize his danger. Between the distant and the home signal the steam from the engine beat down and this, he says, interfered with his seeing the home signal until close to it. Bloomfield's firemen, George Albert Adams, said that he was engaged in firing when they passed the distant signal, so that he did not see in what position it was.

The inspector (Lieut. Col. P. G. von Donop) devotes considerable space to a discussion as to just where the engineman finally shut off steam, and of the reason why he did not shut off sooner, there being a good view of all the signals; but his interrogatories evidently threw little light on the main question, and he found the collision to be "entirely due to want of care on the part of Bloomfield in noting the position of the signals"; and the final conclusion is: "This collision, which was attended with such sad results and which was mainly due to the fact of the driver not noticing that his distant signal was at danger, points to the desirability of the provision of some arrangement for giving a driver an unmistakable warning as to the position of his distant signal when he passes it. Several railway companies have already made trials of devices designed for this purpose, and on some lines such devices are already in use to a limited extent. The Great Eastern does not, however, appear to have as yet taken any steps toward the provision of any such warning arrangement at their distant signals, though in the neighborhood of London they have provided a large number of emergency detonator machines at their home signals. It is, however, at the distant signal that the warning is especially needed, and in the face of this accident the attention of the company is called to the desirability of this provision."

RESULTS OF OPERATION OF TEXAS CAR EQUALIZATION PLAN

By O. C. Castle
Car Service Agent, Sunset-Central Lines

February 28, 1915, marked the close of the fifth month's operation of the car equalization plan entered into on October 1, 1914, between the International & Great Northern and the Sunset-Central Lines, which was described in the *Railway Age Gazette* of January 15, 1915, page 95, and January 29, page 177.

The object which the originators of this plan had in mind was two-fold: The protection of each road against misuse of its cars by the other party during periods of extreme shortage and increased flexibility of equipment with a reduction in switching expense, through the elimination of cross interchange of empty cars.

While there is no tangible basis on which to estimate the saving in switching expense, there can be no doubt that there has been a considerable saving. Before the agreement was entered

into the average number of cars of each party in use on the line of the other party was slightly in excess of 100. This number rapidly increased until on February 28, the number averaged about 500. For the Sunset-Central, for instance, it is quite obvious that the difference in these averages represents 400 Sunset-Central cars which are allowed to remain on the International & Great Northern tracks until they may be moved to us under load, whereas, under the former practice they were returned empty as soon as possible after being released, crossing on the interchange track an approximately equal number of International & Great Northern cars which we were returning empty. It will be recalled that an earlier report of operations showed how the percentage of empty to total deliveries had been reduced from 68.1 to 28.6.

Respecting the protection of our equipment against abuse, it has not been necessary to invoke that feature of the arrangement, for the reason that there has been almost a continuous surplus of all classes of cars throughout the five months covered by this report. This condition, however, has made it possible to develop that side of the equalization proposition that has to do with keeping the per diem payments approximately equal during the periods of surplus, when neither road is in need of its equipment.

In the absence of any agreement for a common use of cars, or for reciprocal storage of surplus foreign cars, it is the almost universal practice in times of surplus for roads to rid their rails of foreign cars by sending them home empty, at the same time applying their own cars for loading to the very lines whose cars are being returned empty. The excess empty haul caused by this ridiculous practice was estimated by the American Railway Association as amounting to 153,849,432 miles during the month of January, 1908, when the panic of 1907 turned an extreme shortage into a stupendous surplus in less than six weeks. With an equalization plan in operation, however, the only empty interchange of cars is that required to keep the balance approximately equal from day to day, and even this may be dispensed with by extending the plan to provide for the storage, free of per diem, of excess cars not needed by their owners.

The per diem figures for the five months furnish striking evidence of the practicability of the plan from the accounting and financial side. The figures, by months, follow:

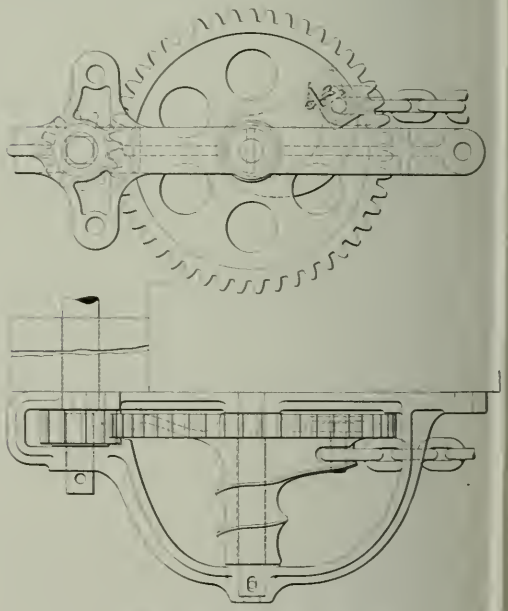
	Per diem paid I. & G. N.	Per diem rec'd from I. & G. N.	Dr.	Cr.
October, 1914.....	3,644.10	3,271.05	373.05	.....
November, 1914.....	5,335.65	5,639.40	.....	303.75
December, 1914.....	6,517.80	6,103.30	414.50	.....
January, 1915.....	6,926.40	7,245.35	.....	318.95
February, 1915.....	6,763.95	7,046.10	.....	282.15
Total	29,187.90	29,305.20	.....	117.30

FREIGHT CAR HAND BRAKE

In the development of the geared hand brake shown in the drawing special attention has been given to the securing of a powerful brake without sacrificing rapidity of action. This device, known as the Peacock freight car brake, consists of a malleable iron frame, a geared drum and shaft, and a pinion secured to the lower end of the brake shaft. The brake is operated by the usual type of shaft, the lower end of which is forged to a square section where it passes through the pinion, a cotter through the end securing it in position. Sufficient clearance is provided through the pinion so that finish is unnecessary and the space between the shaft and the gear readily frees itself from dirt which would tend to collect were a closer fit used.

The drum and gear are cast integral, holes being cored through the web of the gear to lighten it as much as possible and also to prevent the accumulation of dirt on its upper surface. The surface of the drum is formed into a shallow spiral groove, the bottom of which is over two inches in diameter. This eliminates the twisting and cutting of the chain, caused by the small drum usually employed. The upper portion of the drum is so designed that the center line of the chain follows a parabolic curve as the drum revolves, the end of the chain being secured at a point near the rim of the gear. This facilitates taking up the slack without loss of time or sacrifice of leverage when the effective application begins.

The chain is secured to the drum by a bolt in double shear which passes through a slotted hole. When in place the pull of the chain moves the bolt in the slot until its head occupies a pocket on the upper surface of the web from which it cannot be directly removed. A cotter through a lug on the web of the gear prevents the head of the bolt from sliding out of the pocket should the pull on the chain be released. The drum revolves on a straight unfinished bar of cold rolled steel, the lower end of which rests in a pocket in the frame. The drum is bored out with ample clearance and is packed with graphite grease to prevent corrosion when the car is standing out of service. A



Geared Hand Brake for Freight Cars

cotter through the lower end of the bar and the frame prevents it from turning and cutting the frame.

The brake has a gear ratio of 12 to 48, and with a force of 100 lb. exerted at the rim of a 16 in. brake wheel it is claimed to produce over 1,700 lb. pull on the chain. This is more than four times the force exerted on the chain by the usual type of hand brake where the chain is wound on a 1½ in. drum at the lower end of the brake shaft.

To successfully meet the conditions imposed upon a hand brake for freight equipment cars the cost must be low. With this consideration in view the use of finished parts has been avoided as far as possible, the only finished surface in the device being the bore of the drum. As shown in the drawings the frame is designed for application to cars having platform end sills, but the brake may be designed for application to freight cars of any type. It is manufactured by the National Brake Company, Buffalo, N. Y.

Portuguese Railway Fares Increased.—Press despatches report that the Portuguese railway companies have determined to raise fares 10 per cent. owing to the dearness of coal, and that the prices of other commodities, including gas, sugar and bread, have also risen.

General News Department

The anti-tipping bill recently passed by the Minnesota house of representatives has been killed by the senate committee on general legislation.

The House of the Michigan legislature has rejected the bill proposing an increase in passenger fares on railroads in Michigan based on a sliding scale in accordance with their gross earnings. The bill had been passed by the Senate.

The Ohio Public Utilities Commission, by a law just enacted, has the power to suspend proposed advances in transportation rates for 60 days, and puts on the railroads the burden of proving that a proposed increase is reasonably necessary.

The express car on Train No. 1 of the Louisville & Nashville was robbed on the line between Mobile and New Orleans, on the night of April 23, the safe in the express car being blown open. The baggageman was shot and dangerously wounded.

A large number of suits against railroads operating in Illinois have been filed by the state's attorneys of Henry, Warren and Mercer counties, Illinois, to recover fines of $100 each for alleged violation of the law which requires railroads to reimburse shippers for loss of grain in transit.

Col. B. W. Dunn, chief inspector of the Bureau for the Safe Transportation of Explosives and other Dangerous Articles, will give an illustrated lecture on proper methods of packing and handling explosives and other dangerous articles, at the Y. M. C. A. Auditorium, Chicago, on Friday evening, April 30.

The Pennsylvania Railroad in March ran 70,196 passenger trains, and 64,067 of them—91.3 per cent—arrived at their destinations on time. The Pittsburgh Division ran 5,292 trains and 94.5 per cent of them made a perfect record. On the electric line of the West Jersey & Seashore, out of 2,480 trains, 98.2 per cent arrived on time. Three divisions had more than 97 per cent of their trains arrive on time.

In the United States District Court at Toledo, Ohio, April 27, fines aggregating $2,700 were assessed against six railroads. The defendants admitted violations of the hours of service law. The roads fined and the amounts were: Cleveland, Cincinnati, Chicago & St. Louis, $100; Toledo Terminal, $200; Cincinnati, Hamilton & Dayton, $1,600; Michigan Central, $100; Lake Shore & Michigan Southern, $400; Wabash, $375.

The steamships Finland and Kroonland, formerly in the service of the Red Star Line between New York and Antwerp, are now advertised to carry passengers from New York to San Francisco, through the Panama Canal, the first sailing to be Saturday, May 1. The Finland is scheduled to sail on that day, and it is said that 350 first-cabin passengers have already engaged passage.

"Travel Stamps"

Harry I. Miller, chairman of the board of directors of the Buffalo & Susquehanna Railroad, and connected with a number of other railroads, is president of a corporation recently organized in Virginia, and having headquarters at 115 Broadway, New York City, to sell "travel stamps," to be used by merchants or manufacturers to draw trade, using them after the manner in vogue with trading stamps or coupons. The stamps are to be redeemed in certificates good for passenger transportation, railroad, street railroad and steamboat. The name of the corporation is Travel Stamps, Inc., and one of the directors is Newman Erb, president of the Minneapolis & St. Louis and a director in other roads. It is proposed to sell "travel stamps" to retailers and manufacturers of all classes of goods, in four denominations, redeemable for one mile, one-quarter, one-tenth and one-twentieth miles, stamps to be given to purchasers, free, with purchases amounting to five cents and upward. A mile travel stamp, or its equivalent in smaller denominations, will be exchanged for "any or all kinds of first-class passenger transportation, either by boat or rail." The company expects to open offices at important railway terminals for the redemption of stamps. It is proposed in New York City to make a stamp or stamps equivalent to two miles exchangeable for one subway, surface-car or elevated ticket.

To make the stamps practically equivalent to money, an agreement has been entered into with the New York Trust Company to keep on deposit with that institution at all times a sum of money more than sufficient to redeem all stamps outstanding.

New York Excess Crew Law

The "full crew" law of the state of New York remains on the statute books. The bill to repeal it, which was passed by the Senate, was defeated in the Assembly on the last day of the session by a vote of 68 in favor of repeal and 60 against. Seventy-six votes (a majority of the whole Assembly) would have been necessary to carry the repeal.

Extensive Use of the Continuous Home Route Card

The continuous home route card for freight cars, recommended by the Committee of the American Railway Association, which was described in the *Railway Age Gazette* last week, has now been adopted by over 100 roads. From an account printed in the Equipment Register it appears that in addition to the roads named by us last week (page 903) the list includes the following:

Alabama Great Southern	Louisville & Nashville
Ann Arbor	Louisville, Henderson & St. Louis
Atlanta & West Point	Mobile & Ohio
Atlanta, Birmingham & Atlantic	Nashville, Chattanooga & St. Louis
Atlantic Coast Line	New Orleans & North Eastern
Augusta Southern	New Orleans, Mobile & Chicago
Baltimore & Ohio Southwestern	New York, Ontario & Western
Bangor & Aroostook	New York, Philadelphia & Norfolk
Boston & Albany	Norfolk & Western
Boston & Maine	Rutland
Canadian Pacific	St. Louis & San Francisco
Central of Georgia	Southern Pacific
Central Vermont	Southern
Cincinnati, New Orleans & Texas Pacific	Sunset Central Lines
Coal & Coke	Tennessee Central
Cumberland & Pennsylvania	Toledo, Peoria & Western
Cumberland Valley	Toronto, Hamilton & Buffalo
Duluth, South Shore & Atlantic	Vandalia
Georgia	Virginia & Southwestern
Georgia, Florida & Alabama	Western of Alabama
Huntingdon & Broad Top Mountain	Wrightsville & Tennille
Kanawha & Michigan	Yazoo & Mississippi Valley

All except the Atlantic Coast Line will put the new card in use on May 1; the A. C. L. a month later. It was in 1893, at the Car Accountants' convention in Indianapolis, that the continuous home route card was first proposed.

Employees' Clubs on the Lehigh Valley

The employees' club, on the Wyoming division of the Lehigh Valley, now has 300 members. It meets monthly at division headquarters. This is one of a series, the management having encouraged the organization of clubs on every division of the road. Enginemen, firemen, conductors, trainmen, yardmasters, machinists, boiler-makers, engine house foremen, section foremen, track supervisors, agents, clerks and division officers make up its membership. A small membership fee is charged to defray the expenses of the monthly meetings which are held the first Monday night of

each month, when a paper prepared by an employee of the division is read. Among the subjects which have been dealt with are: Car demurrage; the making of a valuable conductor; fuel economy; air brakes; handling of freight at transfers; first aid to the injured; signals; train operation on the Wyoming division; new book of rules; efficient and safe handling of locomotives; freight claims, causes thereof and resultant expense; duties of section foreman and handling of long trains on heavy grades.

At the first annual dinner, held recently at Wilkes-Barre, 218 employees were present. The price of the dinner was two dollars a plate. Including loss of time, the cost to many of the men amounted to from six to twelve dollars each, an indication of the interest being taken by the men in the organization.

Cole-Scoville Truck

In the description of a 2-10-2 type locomotive recently built by the Baldwin Locomotive Works for the Erie, which appeared on page 706 of our March 26 issue, a statement was made to the effect that the locomotive was equipped with the Cole trailing truck. The correct name of this truck, which is of the outside bearing type, with a hinged or floating yoke, is the Cole-Scoville truck.

International Railway Fuel Association

The following is the program of the seventh annual convention of the International Railway Fuel Association, to be held at Hotel La Salle, Chicago, May 17 to 20:

MONDAY, MAY 17

Morning session, 9:30 to 12:30.

Invocation; address by president; address by A. M. Schoyer, vice-president, Pennsylvania Lines West; report of secretary-treasurer; appointment of committee to audit books of secretary-treasurer; appointment of special committees; unfinished business; new business.

Paper: Powdered Coal—Preparation and Use in Locomotive and Stationary Boilers, by W. L. Robinson, supervisor fuel consumption, Baltimore & Ohio.

Afternoon session, 1:30 to 4:30.

Paper: Fuel Conditions in South America, by J. W. Hardy, sales agent, West Kentucky Coal Company.

TUESDAY, MAY 18

Morning session, 9:30 to noon.

Paper: Analysis of Dependent Sequence as a Guide to Fuel Economy, by Harrington Emerson, consulting engineer.

Paper: Smoke Prevention, by E. W. Pratt, superintendent of motive power and machinery, Chicago & North Western.

Afternoon session, 1:30 to 4:30.

Paper: Standardization of Coal Preparation, by H. C. Adams, president Jones & Adams Coal Company.

Report of committee on Fuel Stations, H. J. Slifer, consulting civil engineer, chairman.

WEDNESDAY, MAY 19

Morning session, 9:30 to noon.

Paper: Relation of Mechanical Stokers to the Fuel Problem, by committee on Firing Practice, D. C. Buell, director Railway Educational Bureau, chairman.

Paper: Fuel Oil for Locomotive Use, by G. M. Bean, Pacific Coast representative American Arch Company.

Afternoon session, 1:30 to 4:30.

Paper: Waste of Fuel in Railway Stationary Plants, by Joseph W. Hays, combustion expert.

Report of committee on Storage of Coal.

THURSDAY, MAY 20

Morning session, 9:30 to 1:00.

Reports of standing and special committees on: Drafting Locomotives; Fuel Tests; Fuel Accounting; Constitution and By-Laws; Subjects for Eighth Annual Meeting.

Election of officers.

Balloting for place of meeting, eighth annual convention.

Adjournment.

The Traveling Engineers' Association

The following is the program for the twenty-third annual convention of the Traveling Engineers' Association, to be held in the Hotel Sherman, Chicago, from September 7 to 10:

TUESDAY, SEPTEMBER 7

Morning session: Opening exercises and consideration of subject: What effect does the mechanical placing of fuel in fireboxes and lubricating of locomotives have on cost of operation? W. L. Robinson (B. & O.), chairman.

Afternoon session: Recommended practices for the employment and training of new men for firemen; L. R. Pyle (M., St. P. & S. S. M.), chairman.

WEDNESDAY, SEPTEMBER 8

Morning session: The advantages of the use of superheaters, brick arches and other modern appliances on large engines, especially those of the Mallet type; J. E. Ingling (Erie), chairman.

Afternoon session: How can the road foreman of engines improve the handling of the air brakes on our modern trains? C. M. Kidd (N. & W.), chairman.

Evening: The entire evening will be devoted to examining the exhibits.

THURSDAY, SEPTEMBER 9

Morning session: Difficulties accompanying prevention of dense black smoke and its relation to cost of fuel and locomotive repairs; Martin Whelan (C. C. C. & St. L.), chairman.

Afternoon session: The electro-pneumatic brake; by W. V. Turner (Westinghouse Air Brake Company).

FRIDAY, SEPTEMBER 10

Morning session: The effect of properly designed valve gear on locomotive fuel economy and operating; W. E. Preston (Southern).

Afternoon session: Scientific train loading; tonnage rating; the best method to obtain maximum tonnage haul for the engine over the entire division, taking into consideration the grades at different points on the division; by O. S. Beyer, Jr. (Rock Island).

Election of officers and adjournment.

Engineers' Society of Western Pennsylvania

At the structural section bi-monthly meeting of the Engineers' Society of Western Pennsylvania, to be held in the Society Rooms in the Oliver building, Pittsburgh, Pa., on Tuesday, May 4, a paper will be presented by F. M. McCullough, assistant professor of materials of the Carnegie Institute of Technology, entitled "Local Sands and Gravels as Aggregates in Concrete."

United Yardmasters' Association

The United Yardmasters' Association will hold its second annual convention at Seattle, Wash., on June 15 to 19. A large number of yardmasters from different sections of the United States and Canada have already expressed an intention to be present.

MEETINGS AND CONVENTIONS

The following list gives the names of secretaries, dates of next or regular meetings, and places of meeting of those associations which will meet during the next three months. The full list of meetings and conventions is published only in the first issue of the Railway Age Gazette for each month.

AIR BRAKE ASSOCIATION.—F. M. Nellis, 53 State St., Boston, Mass. Next convention, May 4-7, 1915, Hotel Sherman, Chicago.

AMERICAN ASSOCIATION OF FREIGHT AGENTS.—R. O. Wells, Illinois Central, East St. Louis, Ill. Annual meeting, May 18-21, 1915, Richmond, Va.

AMERICAN RAILWAY ASSOCIATION.—W. F. Allen, 75 Church St., New York. Next session, May 19, 1915, New York.

AMERICAN RAILWAY MASTER MECHANICS' ASSOCIATION.—J. W. Taylor, 1112 Karpen Bldg., Chicago. Annual meeting, June 9-11, 1915, Atlantic City, N. J.

AMERICAN SOCIETY FOR TESTING MATERIALS.—Prof. E. Marburg, University of Pennsylvania, Philadelphia, Pa. Annual meeting, June 22-26, 1915, Hotel Traymore, Atlantic City, N. J.

AMERICAN SOCIETY OF CIVIL ENGINEERS.—Chas. Warren Hunt, 220 W. 57th St., New York. Regular meetings, 1st and 3d Wednesday in month except July and August, 220 W. 57th St., New York.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS.—Calvin W. Rice, 29 W. 39th St., New York. Next spring meeting, June 22-25, 1915, Buffalo, N. Y. Annual meeting, December 7-10, 1915, New York.

ASSOCIATION OF RAILWAY CLAIM AGENTS.—C. W. Egan, B. & O., Baltimore, Md. Annual meeting, May 19, 1915, Galveston, Tex.

Association of Railway Electrical Engineers.—Jos. A. Andreucetti, C. & N. W. Room 411, C. & N. W. Sta., Chicago. Semi-annual meeting with Master Car Builders' and Master Mechanics' Associations. Annual meeting, October, 1915.

Association of Railway Telegraph Superintendents.—P. W. Drew, Soo Line, 112 West Adams St., Chicago. Annual meeting, June 22-25, 1915, Rochester, N. Y.

Association of Transportation and Car Accounting Officers.—G. P. Conrad, 75 Church St., New York. Next meeting, June 22-23, Niagara Falls, N. Y.

Canadian Railway Club.—James Powell, Grand Trunk, P. O. Box 7, St. Lambert (near Montreal), Que. Regular meetings, 2d Tuesday in month, except June, July and August, Windsor Hotel, Montreal, Que.

Car Foremen's Association of Chicago.—Aaron Kline, 841 Lawler Ave., Chicago. Regular meetings, 2d Monday in month, except June, July and August, Hotel La Salle, Chicago.

Central Railway Club.—H. D. Vought, 95 Liberty St., New York. Regular meetings, 2d Friday in January, May, September and November. Annual meeting, 3d Thursday in March, Hotel Statler, Buffalo, N. Y.

Engineers' Society of Western Pennsylvania.—Elmer K. Hiles, 2511 Oliver Bldg., Pittsburgh, Pa. Regular meetings, 1st and 3d Tuesday in month, Pittsburgh.

Freight Claim Association.—Warren P. Taylor, R. F. & P., Richmond, Va. Annual meeting, June 16, 1915, Chicago.

General Superintendents' Association of Chicago.—A. M. Hunter, 321 Grand Central Station, Chicago. Regular meetings, Wednesday, preceding 3d Thursday in month, Room 1856, Transportation Bldg., Chicago.

International Railway Fuel Association.—C. G. Hall, C. & E. I., 922 McCormick Bldg., Chicago. Annual meeting, May 17-20, 1915, Hotel La Salle, Chicago.

Master Boiler Makers' Association.—Harry D. Vought, 95 Liberty St., New York. Annual convention, May 25 to 28, 1915, Chicago, Ill.

Master Car Builders' Association.—J. W. Taylor, 1112 Karpen Bldg., Chicago. Annual meeting, June 14-16, 1915, Atlantic City, N. J.

New England Railroad Club.—W. E. Cade, Jr., 683 Atlantic Ave., Boston, Mass. Regular meetings, 2d Tuesday in month, except June, July, August and September, Boston.

New York Railroad Club.—Harry D. Vought, 95 Liberty St., New York. Regular meetings, 3d Friday in month, except June, July and August, 29 W. 39th St., New York.

Niagara Frontier Car Men's Association.—E. N. Frankenberger, 623 Brisbane Bldg., Buffalo, N. Y. Meetings, 3d Wednesday in month, New York Telephone Bldg., Buffalo, N. Y.

Peoria Association of Railroad Officers.—M. W. Rotchford, 410 Masonic Temple Bldg., Peoria, Ill. Regular meetings, 3d Thursday in month, Jefferson Hotel, Peoria.

Railroad Club of Kansas City.—Claude Manlove, 1008 Walnut St., Kansas City, Mo. Regular meetings, 3d Saturday in month, Kansas City.

Railroad Men's Improvement Society.—J. B. Curran, Erie R. R., 50 Church St., New York. Meetings, alternate Thursdays, October to May, Assembly Rooms of Trunk Line Association, 143 Liberty St., New York.

Railway Club of Pittsburgh.—J. B. Anderson, Room 207, P. R. R. Sta., Pittsburgh, Pa. Regular meetings, 4th Friday in month, except June, July and August, Monongahela House, Pittsburgh.

Railway Electrical Supply Manufacturers' Association.—J. Scribner, 1063 Monadnock Block, Chicago. Meetings with Association of Railway Electrical Engineers.

Railway Signal Association.—C. C. Rosenberg, Myers Bldg., Bethlehem, Pa. Stated meeting, May 26-27, 1915, Hotel Astor, New York. Annual meeting, September 14-17, 1915, Salt Lake City, Utah.

Railway Storekeepers' Association.—J. P. Murphy, N. Y. C. R. R., Box C, Collinwood, Ohio. Annual meeting, May 17-19, 1915, Hotel Sherman, Chicago.

Railway Supply Manufacturers' Association.—J. D. Conway, 2136 Oliver Bldg., Pittsburgh, Pa. Meetings with Master Car Builders and Master Mechanics' Associations.

Railway Telegraph and Telephone Appliance Association.—G. A. Nelson, 50 Church St., New York. Meetings with Association of Railway Telegraph Superintendents.

Richmond Railroad Club.—F. O. Robinson, C. & O., Richmond, Va. Regular meetings, 2d Monday in month, except June, July and August.

St. Louis Railway Club.—B. W. Frauenthal, Union Station, St. Louis, Mo. Regular meetings, 2d Friday in month, except June, July and August, St. Louis.

Salt Lake Transportation Club.—R. E. Rowland, David Keith Bldg., Salt Lake City, Utah. Regular meetings, 1st Saturday of each month, Salt Lake City.

Southern & Southwestern Railway Club.—A. J. Merrill, Grant Bldg., Atlanta, Ga. Regular meetings, 3d Thursday, January, March, May, July, September, November, 10 a. m., Piedmont Hotel, Atlanta.

Toledo Transportation Club.—Harry S. Fox, Toledo, Ohio. Regular meetings, 1st Saturday in month, Boody House, Toledo.

Traffic Club of Chicago.—W. H. Wharton, La Salle Hotel, Chicago.

Traffic Club of Newark.—John J. Kautzmann, P. O. Box 238, Newark, N. J. Regular meetings, 1st Monday in month, except July and August, The Washington, 559 Broad St., Newark.

Traffic Club of New York.—C. A. Swope, 291 Broadway, New York. Regular meetings last Tuesday in month, except June, July and August, Hotel Astor, New York.

Traffic Club of Pittsburgh.—D. L. Wells, Gen. Agt., Erie R. R., 1924 Oliver Bldg., Pittsburgh, Pa. Meetings bi-monthly, Pittsburgh. Annual meetings, 2d Monday in June.

Traffic Club of St. Louis.—A. F. Versen, Mercantile Library Bldg., St. Louis, Mo. Annual meeting in November. Noonday meetings, October to May.

Train Dispatchers' Association of America.—J. F. Mackie, 7122 Stewart Ave., Chicago. Annual meeting, June 15, 1915, Minneapolis, Minn.

Transportation Club of Detroit.—W. R. Hurley, Superintendent's office, N. Y. C. R. R., Detroit, Mich. Meetings monthly, Normandie Hotel, Detroit.

Utah Society of Engineers.—Frank W. Moore, 1111 Newhouse Bldg., Salt Lake City, Utah. Regular meetings, 3d Friday in month, except July and August, Salt Lake City.

Western Canada Railway Club.—L. Kon, Immigration Agent, Grand Trunk Pacific, Winnipeg, Man. Regular meetings, 2d Monday, except June, July and August, Winnipeg.

Western Railway Club.—J. W. Taylor, 1112 Karpen Bldg., Chicago. Regular meetings, 3d Tuesday afternoon in month, except June, July and August, La Salle Hotel, Chicago.

Western Society of Engineers.—J. H. Warder, 1735 Monadnock Block, Chicago. Regular meetings, 1st Monday in month, except January, July and August, Chicago. Extra meetings, except in July and August, generally on other Monday evenings. Annual meetings, 1st Wednesday after 1st Thursday in January, Chicago.

Traffic News

David Harlowe, who recently resigned as a member of the Wisconsin Railroad Commission, has opened an office at 35 Mack block, Milwaukee, Wis., as consulting traffic manager.

The Ann Arbor has filed a suit in the Federal Court at Detroit, asking a permanent injunction restraining the state officers of Michigan from enforcing the law fixing passenger fares in the State at a maximum of two cents a mile.

The Eastern Trunk Lines and their connections, have given notice of a general increase of about two per cent. in the freight rates on wrapping, book and news paper; this in addition to the 5 per cent advance made recently.

The Chesapeake & Ohio has followed the Baltimore & Ohio in asking authority from the state of West Virginia to make a general increase in passenger rates. The present rates, based on two cents a mile, are declared unremunerative, and it is desired to advance all rates to the basis of at least 2½ cents a mile.

The Boston & Albany has announced new passenger rates, to become effective May 1, based on the opinion given by the State Public Service Commission in its recent investigation. From Boston to Worcester, 44 miles, the old rate is one dollar; new, $1.04; Boston to Springfield, 99 miles, old rate, $2.25; new, $2.40; and others in proportion. Some of the rates, for short distances, are advanced one cent.

The war tax on tickets in Canada is as follows: Five cents on every parlor car seat and 10 cents on every sleeping car berth; railway and local steamship tickets 5 cents for each $5 or fraction thereof, according to the value of the ticket; but there is no charge on a ticket costing $1 or less. That on ocean steamship tickets varies according to the value; $10 and under, no tax; $10.01 to $40, $1; $40.01 to $65, $3; $65.01 and up, $5. The tax applies on all tickets reading between or from points in Canada, whether such tickets are sold in Canada or in a foreign country.

Panama Canal Earnings

Up to March 1, 1915, the earnings from tolls on vessels using the Panama Canal, according to the Canal Record, fell short of meeting the expenses of operation and maintenance of the canal by $261,098. From the beginning of the present fiscal year on July 1, 1914, to March 1, 1915, a period of eight months, the total expenditure attributed to operation and maintenance, was $2,595,613. The total earnings from tolls in that period were $2,334,515. In other words, on a business requiring the expenditure of $2,595,000, the government has lost approximately 10 per cent. The operation and maintenance figures include all the diversified expenditures necessary for keeping the canal open and in order and the work of moving vessels through the locks. To such expenditures have been added a pro-rated part of the expenses of the civil government, of the sanitary work and of general administration, which three items have amounted to $574,570 during the period.

Illinois Manufacturers' Association Sees Discrimination in Low Passenger Fares

The directors of the Illinois Manufacturers' Association have addressed a communication to the House Utilities Committee of the Illinois legislature saying: "It is unfair to the shippers of this state to be compelled to pay freight rates based upon an allowance for a deficiency in the transportation of passengers. While it is true that the price of the goods in the end absorbs the freight the fixing of a rate so high that it will take care of a loss in passenger service is not an equal distribution. Fully 50 per cent of the passenger travel is for pleasure, and is not incident to the transaction of business. It should therefore be treated to a large extent as a luxury and placed on a sound

economical basis. A conservative estimate of the amount of money paid by the manufacturers and other shippers of Illinois for railroad freight service is over $1,000,000,000 annually. This amount should not be subjected to increase in order that passengers may be carried below the cost of transportation. It is therefore hoped that the members of the committee will report favorably on the measure authorizing an advance of one-half cent per mile in passenger rates."

Statement of Western Railways on Cummins Amendment

R. B. Scott, of the Chicago, Burlington & Quincy, H. A. Scandrett, of the Union Pacific, and Charles Donnelly, of the Northern Pacific, have filed a statement with the Interstate Commerce Commission, outlining their position as to the effects of the Cummins amendment to the act to regulate commerce, which becomes effective on June 3. The statement is as follows: "At the present time, in the case of property which is transported subject to the rules and conditions of classification there are two lawful rates: First, what is termed a reduced rate, which is applicable when the property is transported subject to all the terms and conditions of the uniform bill of lading, and second, a rate that is 110 per cent. of such reduced rate—this higher basis of rate being applicable when the property is not carried subject to all the terms and conditions of the uniform bill of lading.

"While there may be some question as to whether this or that stipulation contained in the uniform bill of lading is made unlawful by the Cummins act, there is no such question as to certain stipulations, such as those in regard to the presentation of claims. We have, then, this situation: One rate if certain conditions are incorporated in the bill of lading, and a different and a higher rate, if they are omitted.

"In that situation Congress enacts a law which prohibits the carrier and the shipper from agreeing to abide by certain of the terms of the uniform bill of lading. The rate, therefore, which was conditioned on the shipper agreeing to all the provisions of the uniform bill of lading is cancelled by act of Congress. The legal effect is no different than if the carriers cancelled from their tariffs the lower rate.

"In either event, the higher basis of rates remains. It was the lawful basis before the enactment of the Cummins act; it would have been a lawful basis if the carriers had of their own initiative cancelled the lower basis of rates, and it will be none the less a lawful basis after the Cummins act becomes effective."

This statement was filed in reply to a question by Commissioner Clark as to what would be the status under the law without any action by the Commission or by the carriers.

Canada to Cuba

Grand Trunk freight car 30017 has just returned to Canada after a unique itinerary, which began at Chicago last December. From the Grand Trunk it went to the Wabash; to the Chicago, Burlington & Quincy; to Wiggins Ferry; to the Mobile & Ohio; to the Atlantic Coast Line; to the Florida East Coast; a ferry to Havana, where it was photographed as a curiosity; returned to the Florida East Coast; to the Atlantic Coast Line; to the Norfolk & Western; to Wiggins Ferry; to the Terminal Railroad Association, St. Louis; to the Chicago & Eastern Illinois; to the Toledo, St. Louis & Western; to New York, Chicago, St. Louis; to Lehigh Valley; to New York, New Haven & Hartford; to Lehigh Valley, and to the Grand Trunk at Niagara Falls.

All-Steel Trains in South Africa.—Owing to the increasing cost of timber for coach building, the possibility of constructing passenger stock of steel is being considered by the authorities of the Union of South Africa railways, and the chief mechanical engineer has been authorized to order two trains of steel coaches for trial.

Congo Railway Completed.—The railway line from Kabala (Congo) to Lake Tanganyika, on the line of the Great Lakes, which follows the course of the Lukuga, and will unite the Lualaba River to Lake Tanganyika, was laid to kilometre 267—that is to say, to its terminal point—about March 15. This event marks a notable date in the history of the Belgian Congo.

Commission and Court News

INTERSTATE COMMERCE COMMISSION

William Wrigley, Jr., of Chicago, has filed a complaint with the Interstate Commerce Commission against the charges for switching cars on industrial sidings at San Francisco and other Pacific coast terminals.

Hearings will be held by the commission beginning Monday, May 17, on various proposals of the eastern railroads to advance certain freight rates in official classification territory. These include the rates and regulations governing the transportation of beer and non-alcoholic beverages, tobacco, grain, rags and scrap.

The commission has further suspended from May 1 to November 1 tariffs of the New York Central, Pennsylvania, Baltimore & Ohio, Erie, Lehigh Valley and other railroads proposing advances in the charges for handling freight by lighter and float from and to points in New York harbor within and outside the free lighterage limits These rates were originally suspended from January 1.

A hearing will be held before Examiner Mackley at San Francisco on June 22 relative to the ownership and operation of the steamship Great Northern. This is the ship owned by the Great Northern Pacific Steamship Company (controlled by the Great Northern) which after being launched at Philadelphia carried passengers through the Panama Canal, as it was on its way to the Pacific coast, where it is to be used in regular service.

Examiner Kelley of the Interstate Commerce Commission held a hearing at Chicago on April 26, in the matter of the withdrawal of regulations covering the concentration of dairy products, and on April 28, on minimum weights for shipments of packinghouse products, fresh meats and other articles transported in peddler cars. On April 30, Examiner Bell will hold a hearing in the matter of stopping cars in transit to complete loading or partially unload shipments.

Classification of Display Racks

W. & J. Sloane v. Southern Pacific et al. Opinion by the commission:

The commission finds that defendants' rule resulting in the imposition of higher charges on display racks, in less than carload lots, weighing less than 1,000 lb., than for similar racks weighing 1,000 lb. or more, is unreasonable, and awards reparation. (33 I. C. C., 509.)

Lack of Concurrence in Through Rates

E. I. Du Pont De Nemours Powder Company v. Wabash et al. Opinion by the commission:

The Wabash filed and posted a through tariff, naming a through rate of 90 cents a net ton on bituminous mine-run coal in carloads from Springfield and Riverton, Ill., to Mooar, Ia., in which the delivery line, the Chicago, Burlington & Quincy, was not named as a party and had not concurred. Charges were collected on shipments from and to the points named on the basis of the combination of intermediate rates. The commission awards reparation against the carrier which issued the tariff, on the showing that the complainant relied on the through rates published, to its injury. (33 I. C. C., 507.)

Change of Destination—Compensation Therefor

Doran & Company v. Nashville, Chattanooga & St. Louis, et al Opinion by the commission:

The complainants made five shipments of lumber from Chattanooga via the Nashville, Chattanooga & St. Louis to Nashville, thence via the Louisville & Nashville to Cincinnati, the original destination. At that point three cars were reconsigned to Toronto, Ont., and charges were collected at a rate of 28 cents a hundred pounds. On the other two cars, which were reconsigned to London, Ont., charges were collected at a rate of 25 cents. These rates were the sums of the intermediate rates to and from Cincinnati, whereas the joint through rates from

Chattanooga were 22½ cents to London and 23 cents to Toronto. Requests for reconsignment filed with the agents of the railways while the shipments were en route from Chattanooga to Cincinnati were denied on the ground that the tariff did not authorize reconsignment of lumber on the basis of the through rate.

The commission finds that defendant's refusal to allow reconsignment and diversion of lumber on the basis of the through rate from the point of origin to the new destination with a reasonable charge for the extra service performed, where the contents of the car remain unchanged, where the change of destination or route does not involve an out-of-line haul, and request is made in a reasonable time, was unlawful and unreasonable. It is held that the charges collected on the shipments in question were unreasonable to the extent that they exceeded the charges that would have accrued at the joint through rates plus a maximum additional charge of $5 per car for the extra service incident to reconsignment at Cincinnati. Reparation is awarded on that basis. (33 I. C. C., 523.)

Advances in Freight Rates from the East to St. Paul and Minneapolis Disapproved

Minneapolis Civic & Commerce Association et al. v. Algoma Central & Hudson Bay et al. (Rail-Lake-and-Rail Rates to St. Paul). Opinion by the commission:

It is held, that the proposed 90-cent scale of rates from trunk line and central freight association territories to the twin cities has not been justified by the respondents and that the 28-cent scale of differentials in the rates to the twin cities over the rates to Duluth is unduly discriminatory as against the former; that the present 83-cent scale of rates to the twin cities is not unreasonable or unlawfully discriminatory against those communities, nor is the 21-cent scale of differentials over the rates to Duluth unduly preferential of that port as alleged; that for the future any class rates to the twin cities in excess of a 21-cent scale of differentials over the rates to Duluth will be unjustly discriminatory as against the twin cities, and any class rates to the latter communities on a scale of differentials lower than 21 cents, first class, will be unduly discriminatory as against Duluth. A scale of rates, rail-lake-and-rail, from trunk line and central freight association territories to the twin cities based upon a rate of 83 cents, first class, prescribed for the future. Carriers will be expected to bring their commodity rates into harmony with the class rates. (33 I. C. C., 577.)

Rates on High Explosives to Grand Trunk Stations

Opinion by Commissioner Harlan:

Certain of the eastern carriers have proposed to cancel the joint through rates on high explosives from Baltimore, Wilmington and Philadelphia to points in the undeveloped districts of Michigan on the Grand Trunk Western, whereupon there will be left in effect intermediate rates considerably higher than the present rates. Considerable of this traffic to these points moves via various lines to Buffalo, thence through Canada over the Canadian member of the Grand Trunk System, the Grand Trunk Railway of Canada and thence to destination over the Grand Trunk Western, the domestic member of that system. Both the members of the Grand Trunk System for a number of years have joined with the lines east of Buffalo in maintaining through routes and joint rates to these destinations.

It is offered in justification that it is against the policy of the Grand Trunk Railway of Canada to maintain joint through rates on high explosives. The commission believes that it should have jurisdiction over joint rates from one point in the United States through Canada to another point in the United States. It does not at this time wish, however, to make a definite ruling upon questions involving a possible conflict of authority as between the rate regulating bodies of this country and of Canada, without a more ample consideration of the matter. It, therefore, expresses no final conclusion respecting the question of its jurisdiction.

The points in Michigan on the Grand Trunk Western may be reached over reasonably convenient routes lying wholly within the United States, as a number of the carriers operating south of the lakes in United States territory are parties to the tariffs in question. The protestants are entitled to through routes and reasonable joint rates, and the respondents are, therefore, expected to withdraw the cancellation until such routes have been established via the domestic lines at the through rates now in effect. The Grand Trunk Western will be expected to join in all such rates and routes to local points on its rails. (33 I. C. C., 567.)

Rates on Iron Ore from Mines on the Mesabi Range

In re rates, practices, rules and regulations governing the transportation of iron ore. Opinion by Commissioner Meyer:

In this case the commission finds that the present rate of 60 cents a long ton on iron ore from mines on the Mesabi range in Minnesota to vessels at Two Harbors and Duluth, Minn., and Allouez Bay, Wis., is unreasonable and that it should not exceed 55 cents.

The case began in informal proceedings, started in December, 1908, by Leon E. Lum The complaint was later made a formal one. The commission, however, finally decided to institute an investigation regarding the rates, practices, etc., relating to the carriage of iron ore in this territory.

In 1913 the Duluth & Iron Range shipped 1,567,000 tons of ore from the Vermillion range, 8,546,000 tons from the Mesabi range, or a total of 10,113,000 tons from both ranges; the Duluth, Missabe & Northern shipped 12,329,000 tons from the Mesabi range; the Great Northern, 13,154,000 tons from the Mesabi range; the Northern Pacific, 40,000 tons from the Cuyuna range; and the Soo line, 696,000 tons from the Cuyuna range. The following table shows the average annual number of long tons expressed in thousands for five-year periods:

Average for five years ending Dec. 31—	D.&I.R.	D.,M. &N.	G.N.
1911	7,566	11,255	7,168
1912	7,801	10,664	8,477
1913	8,680	11,368	10,395
1914	7,968	9,938	11,181

It was shown, also, that since 1911 the ore tonnage of the Great Northern had been greater than that of any of the other roads, but that it was probable that the Great Northern would have a relatively smaller tonnage after 1914 because of the cancellation of a contract by which the Steel Corporation, through a subsidiary, had agreed to ship certain yearly minimum tonnages over the Great Northern.

The rate on ore from the Vermillion, Mesabi and Cuyuna ranges to the docks at Two Harbors, Duluth, Allouez Bay and Superior is uniformly 60 cents a long ton, regardless of distance. The weighted average haul, obtained by dividing ton-miles by the tons, from the Mesabi range, is 108 miles over the Great Northern, 77 miles over the Missabe and 67 miles over the Iron Range. The average haul from the Vermillion range is 89 miles, and from the Cuyuna range, 112 miles.

The rate of 60 cents was attacked as unreasonable in and of itself. There was no charge of discrimination, except that it was argued that a rate in excess of a reasonable rate would be tantamount to a rebate to the Steel Corporation, which controls the Iron Range and the Missabe. "It is suggested by carriers that the commission is not called upon to enforce the anti-trust act or the commodities clause in this case, but the fact that the Steel Corporation, through a subsidiary, the Oliver Mining Company, is the largest shipper over these roads cannot be ignored. The fact that the same corporation indirectly controls two of the roads and owns the larger portion of the ore shipped over them, demands a strict interpretation of any standard of reasonableness which is adopted, although the right of these roads to earn a fair return upon the property devoted to public use is not questioned."

Detailed cost figures were introduced by both sides. The work of considering these figures was simplified by the position taken by the carriers that the Iron Range and the Missabe were built primarily to carry ore, and that ore was so large a part of their traffic that the non-ore traffic could be regarded as a by-product.

The commission, basing its opinion largely upon the valuations made by the state of Minnesota, believed that no great error would be made in concluding that the fair value of the properties for the purposes of the case were not in excess of $22,130,635 for the Iron Range, and $28,464,955 for the Missabe as of June 30, 1912.

Taking these maximum valuations as an average for the five-year period ending June 30, 1914, the total operating expenses, taxes and capital charges at 7 per cent are estimated as 44.69 cents a long ton for the Iron Range and 42.05 for the Missabe. For the same valuations the results for the five years ending in 1913 are 45.04 cents for the Iron Range and 40.03 for the Missabe. If the valuations submitted by the carriers be substituted the results would be 56.96 cents, 54.88 cents and 54.26 cents for the

years 1912 to 1914 respectively for the Iron Range and 43.15 cents, 42.42 cents and 46.70 cents respectively for the Missabe. It is further held that practically every comparison that can be suggested between the ore lines of the Great Northern and the Iron Range and the Missabe point a very large profits on the ore traffic of the Great Northern, perhaps equal to those on the other two roads, and any rates found reasonable for the Iron Range and Missabe will make this traffic profitable to the Great Northern. The 60 cent rate yields average earnings per gross ton mile for the three roads of 7.098 mills and net earnings 6.338 mills.

The representatives of the road serving the Cuyuna range said that even if no order were entered with respect to them the rates fixed for the Mesabi range would be controlling. The Soo ond Northern Pacific would doubtless be justified in participating in the ore traffic at a considerably less rate than 60 cents.

An order will be entered to the effect that the rates on ore from the Mesabi range should not exceed 55 cents. No order is made with reference to the rates from the Vermillion and Cuyuna ranges. (33 I. C. C., 541.)

Trap Car Service at Chicago

William D. McHugh, attorney for a number of railroads entering Chicago, has filed a brief with the Interstate Commerce Commission on behalf of the carriers in support of the tariffs abolishing free trap car service in Chicago and immediate vicinity, and imposing a charge of four cents per 100 lb. for such service. Mr. McHugh says in the brief, that there are in Chicago over 10,000 industries, all of which ship merchandise. Of these, about 3,000 have private sidings to which, under the present tariffs, the trap car service is available. The present tariffs require that for trap car service there must be loaded a minimum of 6,000 lb. for western, and 10,000 lb. for eastern lines. An exhibit compiled for this case, listing all the trap cars handled on five of the principal railroads in Chicago for the first five days of five representative months of 1914, comprising 1,180 trap cars, shows that this service was rendered to only 71 shippers, and 822 trap cars out of a total of 1,185, were handled for only six shippers. Of the L. C. L. merchandise received and delivered by the railroads in Chicago daily, 1,564 tons is handled by tunnel, 2,636 tons by lighter, 993 tons by trap car, and 6,771 tons by team.

The average number of trap cars moved daily in Chicago is 121, and the average weight of the load is 15,500 lb. Probably because his tonnage is not equal to the minimum requirements, Mr. McHugh says, the ordinary shipper cannot avail himself of this trap car method of relieving himself of the expense of transporting his merchandise to the stations of the railroads. Consequently, the trap car service is, in effect, a privilege accorded only to the large shippers. The 7,000 industries that must transfer their merchandise by team at their own expense, are in competition with those industries for which the carriers provide these free services and are, therefore, compelled to pay an expense from which the large shippers are free.

The purpose of the carriers in filing the tariffs now under investigation, he says, is "to abolish this favoritism and make the uniform rate a rate for transportation from station to station, which is the service rendered to all shippers, and then to provide that if any shipper desires a special service, that of having his merchandise transported between the railroad stations and his warehouse door there shall be a reasonable and fair charge imposed for that special service."

To show that the proposed charge is reasonable, the brief points out that the revenue which would accrue to the carrier for the trap car service on the average load would be $6.20 per car, while under the Lowrey tariff, $6 per car is the minimum charge for switching throughout the Chicago district; and that testimony in this case shows that the cost of the movement of the average trap car amounts to $6.87. Moreover, the average income from the trap car service would not equal the average of the cash outlay in the way of absorptions made by the carriers in the trap car service with the connecting lines. It is also asserted that the testimony shows that the charge of four cents a hundred pounds for trap car service as a substituted service for the teaming is a charge really less than the average teaming cost to the shippers.

STATE COMMISSIONS

The Railway Commission of Canada has adopted an order requiring railways, when they have to refund money on a ticket which has not been used, or has been but partly used, to make payment within 30 days; or, if the ticket reads over two or more lines, then within 60 days.

At the hearing before the Kansas Public Utilities Commission on the application of the Kansas roads for authority to make advances in freight and passenger rates, the Atchison, Topeka & Santa Fe filed a statement showing that it cost that company $1,126,310 during the year 1914, to comply with state and federal laws and regulations affecting railroad operation. The expense was divided as follows: Hours of service laws, $244,636; excess crew laws, $60,862; boiler inspection laws, $226,087; safety appliance laws, $253,506; postal car requirements, $48,180; twenty-eight-hour stock laws, $8,601; semi-monthly pay laws, $7,462; headlight laws, $32,110; specific orders of state commissions, $78,414; other enactments $166,452.

Texas Commissioner Wants Exclusive State Jurisdiction Over Rates

William D. Williams, of the Texas Railroad Commission, has announced his intention of writing to all members of Congress, asking their support for an amendment to the act to regulate commerce to prevent the exercise by the Interstate Commerce Commission of any authority over state rates, such as those involved in the Shreveport rate case. The proposed amendment, which was recommended at the last meeting of the National Association of Railway Commissioners, is as follows:

"And, provided, that nothing in this act, nor the exercise of any authority by the interstate commerce commission by virtue thereof, shall absolve any railroad or other common carrier from obeying any rate, rule, regulation or practice of any state with respect to the transportation of passengers or property, or the receiving, delivery, storage or handling of property, wholly within one state, and not shipped to or from foreign country, to or from state or territory as aforesaid, unless any such common carrier shall have secured the judgment of a court of competent jurisdiction holding such rate, rule, regulation or practice imposed as aforesaid, to be unreasonable."

In a letter to the Texas Congressmen, Commissioner Williams says: "It seems to me obvious that the road which we are now following leads inevitably to the destruction of state regulation and to the very bitterest of commercial wars between the several states. All state-made rates must be reasonable and must under the law, afford a proper return and profit to the railroad company doing the haul. If state rates are made which do this they ought not to be set aside by the courts, or the interstate commerce commission, or by any other authority."

PERSONNEL OF COMMISSIONS

Frank A. Wightman has resigned as a member of the Missouri Public Service Commission to become superintendent of safety of the St. Louis & San Francisco, with headquarters at Springfield, Mo. Eugene J. McQuillen, formerly circuit judge at St. Louis, has been appointed a member of the commission, to succeed Mr. Wightman.

COURT NEWS

The New Jersey Court of Errors and Appeals has sustained the order of the Board of Public Utility Commissioners of that state denying the application of the West Jersey & Seashore to lease its property to the Pennsylvania for 999 years. Chief Justice Gummere, who wrote the opinion, said it was a rightful use of the powers of the legislature to delegate such regulative power to the Utility Commissioners.

In the United States District Court, at Trenton, N. J., April 27, the Lehigh Coal & Navigation Company was in-

dicted, on 30 counts, for accepting illegal rebates from the Central of New Jersey, on shipments of coal from Nesquehoning, Pa., to points in New York and New Jersey. The transactions appear to be the same as those on which the railroad company was found guilty of violation of the law a few weeks ago.

The Baltimore & Ohio has brought suit in Kanawha county, West Virginia, against the attorney general of that state and aginst other state officers, for an injunction to forbid the enforcement of the law of that state limiting passenger fares to the basis of two cents a mile. The Baltimore & Ohio sets forth in its complaint that it is operating its passenger trains in that state at a loss of $9,000 a month. Announcement was made some time ago that fares would be advanced about May 1.

Judge Trieber, of the United States district court at Little Rock, Ark., has granted the application of the Kansas City Southern for authority to make passenger rates in Arkansas on the basis of 3 cents a mile, and freight rates higher than those which had been fixed by the railroad commission of that state. The railroad commission was perpetually enjoined from enforcing either the two-cent passenger rates or the reduced freight rates. A short time ago the court issued a similar injunction applying to the St. Louis & San Francisco.

Change of Destination—Limitation of Liability

A carload of goods and live-stock was shipped from Crescent, Okla., to Hill City, Kan., but the point of destination was changed by order of the shipper at Salina, Kan., to Buffolo Park, Kan. The Kansas Supreme Court holds that the entire transportation was governed by the regulations of interstate commerce, under which a carrier may limit its liability for damages to the reasonable value of the property declared in the shipper's contract.—(Kirby v. Union Pacific (Kan.), 146 Pac., 1183.)

Crossing Accidents—Looking and Listening

The Missouri Court of Appeals holds that a person who passes with a team over as much as 80 feet of the public road, when his view was unobstructed, without looking and listening, is guilty of contributory negligence, as a matter of law, although the defendant was negligent in not sounding the whistle or bell. Prior decisions of the Missouri Supreme Court have held it to be negligence to so pass over clear spaces of less than 30 feet.—(Owens v. St. Louis Southwestern (Mo.), 174 S. W., 116.)

Florida Rules Governing Use of Terminals for Rival

The Supreme Court of Florida holds that Rules 3, 15 and 17, governing the transportation of freight, promulgated by the State railroad commission, do not contemplate that a common carrier, having switching and terminal facilities for its own use, at a particular point, shall be forced, at least without adequate necessity, compensation and protection, to collect and distribute within its own switching limits for a competing line, car loads of freight destined to or arriving from points reached by its line; such carrier having no part of the line haul.—State v. L. & N. (Fla.), 67 So., 875.

Spur Track—Release for Damages by Fire

A contract between a railroad company and the owner of land adjoining its right of way provided for the construction of a spur, partly on the right of way, and partly on the adjacent land, for the material advantage of the parties, but primarily for the benefit of the owner of the land. A clause of the contract indemnified the railroad against loss and damage or expense by fire to cars and contents standing on the siding, and released it, in general terms, from all claims of whatsoever character for damages resulting to the property of the owner of the land, by reason of fire originating from the engines of the railroad. Action was brought against the railroad for the burning of a large quantity of pulp wood, stored around the side track, by the escape of fire from an engine passing on the main line. The West Virginia Supreme Court holds that the clause of the contract released the railroad from damages by fire from locomotives on the main line as well as those on the siding. West Virginia Pulp & Paper Co. v. B. & O. (W. Va.) 84 S. E. 334.

Live Stock Law—Failure to Fence

In a locality where the Texas stock law was in force, making it unnecessary for a railroad to fence against animals, and making it unlawful for a stock owner to permit his cattle to run at large, a railroad, being forbidden under the Texas statutes to permit Johnson grass to go to seed, placed poison on the right of way, which killed cattle trespassing thereon. It was held by the Texas Court of Civil Appeals that the railroad need not foresee that stock might be running at large, nor need it employ guards to prevent cattle trespassing and being poisoned.—(Ft. Worth & R. G. v. Brown (Tex.), 173 S. W., 943.)

Lease for Elevator Space—Exempting Railroad from Liability

A railroad leased ground for a grain elevator, the lessee to assume all risk of damage arising from the movement of cars, or from the operation of the railroad in any respect, whether the result of negligence or otherwise. A freight car got off the track and was pushed through the elevator building. In an action against the railroad to recover for the damage, the Kansas Supreme Court holds that the clause exempting the railroad from liability is not in contravention of public policy, and is valid. (Griffiths Grain Co. v. St. Joseph & G. I. (Kan.), 146 Pac., 1134.)

Excess Crew Law—Construction

The Arkansas Supeme Court holds that the "Full Crew Law" of that State, which provides that it shall not apply to any company whose line is less than 50 miles in length, applies to all railroads whose entire mileage operated is more than 50 miles, whether they have 50 miles within the State or not; that the classification of railroad lines of more than 50 miles in length and lines of less than 50 miles is reasonable and proper, and that it is not an unconstitutional regulation of interstate commerce when applied to a foreign railrood engaged in such commerce.—(Kansas City Southern v. State (Ark.), 174 S. W., 223.)

Liability of Initial Carrier—Live Stock

In an action against the initial carrier for damages to a carload of horses, it was contended by the defendant that the plaintiff should not recover, because his caretaker accompanied the horses and knew exactly where the damages were inflicted, and consequently the Carmack amendment did not apply, in the absence of any difficulty in locating where the injury occurred. The Texas Court of Civil Appeals, however, holds that the act fixes absolute liability on the initial carrier, which is liable, despite the insolvency of the connecting carriers, and the fact that the statute was passed so that shippers who did not accompany their shipment would be able to hold someone liable.—(Texas Mexican v. King (Tex.), 174 S. W., 336.)

Recovery of Undercharge

After repeated interviews and correspondence with the representatives of the Louisville & Nashville, a passenger bought two round-trip tickets from Nashville to Salt Lake City, by way of Chicago and Denver, and to return via Denver, Amarillo, Ft. Worth and Memphis; and paid for each ticket $49.50. This was $29.15 less than the legal rate on each ticket. The passenger could have gone to Salt Lake at the rate which he paid, but over other routes. He was in no way at fault in the matter. He merely told the agent the points to which he wished to go, and that he did not wish to go and return by the same route. The agent fixed the routing and named the fare. The Tennessee state courts gave judgment for the defendant in an action to recover the undercharge; but this has now been reversed by the United States Supreme Court, holding that the rate filed under the Interstate Commerce Act is the only lawful charge, from which there can be no deviation on any pretext. Ignorance or misquotation of rates is not an excuse for paying or charging either less or more than the rate filed. It was not a case of

misrouting. A misstatement or misquotation of the rate over a given route is one thing; misrouting is another. The court held that there was no misrouting, in any proper sense, the route given by the company being that requested by the passenger.—Decided April 5, 1915.

Contracts as to Crossings

The Chicago & North Western agreed that the Milwaukee Northern might maintain its tracks across the C. & N. W. right of way and under its tracks, the M. N. agreeing, in case the N. W. built an additional track, to pay the expense of adjusting the physical situation so as to accommodate the new track. The C. & N. W. built a new track, and in an action on the contract the Wisconsin Supreme Court holds that the contract is binding on the Milwaukee Northern, notwithstanding the statute (1913, § 1797-56), declaring that every crossing, hereafter made, shall be above, below or at grade, as the railroad commission shall determine, and that the commission shall fix the proportion of the expense. The purpose of the statute was merely to promote safety as regards future established crossings—not to deal with existing crossings.—(C. & N. W. v. Milwaukee Northern (Wis.), 151 N. W., 804.)

Hours of Service Act—Emergency

In an action to recover penalties for violation of the hours of service act, by requiring telegraphers in a night and day office to remain on duty for more than 9 hours in 24-hour periods, the answer alleged as a reason for the requirement, that a train despatcher in the office became "abusive, insubordinate and defiant," and it became necessary to dismiss him, because his retention would have endangered the public, and that he was replaced as soon as possible. The Circuit Court of Appeals, Eighth Circuit, holds that this stated a cause of "emergency," within the meaning of the statute, and constituted a defense. The Court said that the danger arising from fatigue is not greater than that arising from disobedience, wilfulness, or malice. (United States v. Denver & R. G., C. C. A., 220 Fed., 293.)

Extra Fares—Powers of Commission

In an action for improper ejectment, the defendant pleaded an order of the Alabama railroad commission authorizing the collection of 15 cents extra from persons boarding the train at ticket stations without tickets. The plaintiff, on a trip where the ticket fare was 13 cents, got on the train without a ticket and was ejected on his refusal to pay the 15 cents additional. The preamble of the commission's order mentioned certain lines, but omitted the defendants'. The order, however, began: "That no railroad in Alabama," indicating that it applied to all railroads in the State. It was held by the Alabama Supreme Court to apply to the defendants' road, as otherwise it would be void for discrimination. The Court held the order to be authorized by Laws 1907, p. 711, giving the commission power to change rates, regardless of Code 1907, § 5563, fixing rates generally.—(Kimbrell v. L. & N. (Ala.), 67 So., 586.)

Georgia Railroad Tax

The roads now operated by the Central of Georgia under lease from the Augusta & Savannah and the Southwestern, were built under special charters, by which the property was not subject to be taxed higher than one-half of 1 per cent upon the annual income. The state controller having sought to tax the whole property to the lessee, the United States Supreme Court holds that only the tax provided for in the charter can be collected. Under the charter the holder of the exclusive privilege of operating thereby granted might obtain its revenue by doing the whole business itself, by letting in others to share a part of it, or by making a lease of the whole. The court considered that no change in the matter of tax exemption could have been expected to follow from the demise of the road, any more than it would have followed from the admission of another carrier to partial rights, or of an individual to carry his own goods. A similar decision was at the same time made in the case of the Georgia Railroad, leased by the Louisville & Nashville and the Atlantic Coast Line.

Railway Officers

Executive, Financial, Legal and Accounting

H. S. Buefcher has been appointed general claim agent for the Texas & Pacific, with headquarters at Dallas, Tex., in place of W. L. Chew, resigned.

E. J. Pearson, first vice-president of the Texas & Pacific, has been elected president of the Trans-Mississippi Terminal Company, with office at New Orleans, La., succeeding E. F. Kearney, resigned.

D. E. Hedges continues as auditor and assistant treasurer of the Tennessee, Alabama & Georgia, with headquarters at Chattanooga, Tenn. It was erroneously stated in our issue of last week that Mr. Hedges had resigned as auditor.

Guy J. Bunting, assistant general auditor of the Chicago, Milwaukee & St. Paul, at Chicago, has been appointed general auditor, with headquarters at Chicago, succeeding B. A. Dousman, who at his own request has been assigned to special duties in Milwaukee as assistant general auditor.

Henry W. Miller, assistant to the president of the Southern Railway at Atlanta, Ga., has been elected vice-president, with headquarters at Atlanta, and the office of first vice-president has been abolished as a mark of respect to the late Col. A. B. Andrews, the only incumbent since the organization of the company.

F. A. Lehman, who has been acting general superintendent of the eastern lines, Western district, of the Atchison, Topeka & Santa Fe, at Newton, Kan., for the past six months, will return to the position of assistant to vice-president, with headquarters at Chicago, on May 1. E. Raymond, who took Mr. Lehman's place temporarily, returns to Newton as general superintendent.

The receivers of the Chicago, Rock Island & Pacific have announced the following appointments: George H. Crosby, vice-president, secretary and treasurer, has been appointed secretary and treasurer; H. M. Sloan, assistant to the president, has been appointed assistant to the receivers; M. L. Bell has been appointed general solicitor, and F. Nay has been appointed controller, all with offices at Chicago. White & Case, of New York, have been appointed general counsel.

Operating

The office of T. W. Evans, general superintendent, Second district of the New York Central, has been removed from Syracuse, N. Y., to Buffalo.

A. C. Ridgway, second vice-president of the Chicago, Rock Island & Pacific, has been appointed chief operating officer for the receivers, with headquarters at Chicago.

F. A. Wightman, who has been a member of the Missouri Public Service Commission, has resigned to become superintendent of safety of the St. Louis & San Francisco, with headquarters at Springfield, Mo.

M. A. Mulligan, general yard inspector at South Bethlehem, Pa., has been appointed acting superintendent of the New York division of the Lehigh Valley, with office at Jersey City, N. J., vice M. C. Roach, deceased.

Traffic

J. E. Gorman, first vice-president of the Chicago, Rock Island & Pacific, has been appointed chief traffic officer for the receivers, with office at Chicago.

Engineering and Rolling Stock

J. A. Shaw, electrical engineer of the Canadian Pacific, at Montreal, Que., has been appointed general electrical engineer, with headquarters at Montreal.

C. W. Van Buren has been appointed general master car builder of the Canadian Pacific, with headquarters at Montreal, Que., in place of R. W. Burnett, resigned.

H. A. Macbeth, division master mechanic of the New York, Chicago & St. Louis at Conneaut, Ohio, has been appointed superintendent of motive power, with headquarters at Cleveland, succeeding E. A. Miller, deceased. T. C. Baldwin has been appointed master mechanic, with headquarters at Conneaut, to succeed Mr. Macbeth.

Purchasing

F. D. Reed, assistant to the vice-president and purchasing agent of the Chicago, Rock Island & Pacific, has been appointed general purchasing agent, with headquarters at Chicago. Mr. Reed was born April 22, 1868, at Fort Dodge, Iowa, and was educated in the public schools of Chicago. He entered railway service September 24, 1884, as wheel inspector of the car department for the Pennsylvania Lines West of Pittsburgh, at Chicago, which position he held until March, 1885, when he became clerk and timekeeper. In September, 1890, he was made chief clerk of the car department and held that position until July, 1895, when he was appointed assistant chief motive power clerk at Fort Wayne, Ind. In February, 1900, he was appointed chief motive power clerk and remained in that capacity until April, 1904. He then entered the service of the Chicago, Rock Island & Pacific as chief motive power clerk at Chicago. In February, 1906, he was made general storekeeper at Silvis, Ill., and held that position until May, 1910, when he was appointed assistant to the vice-president of the purchasing department, at Chicago. On June 1, 1911, he was also appointed purchasing agent of the same road.

F. D. Reed

OBITUARY

Eli A. Miller, superintendent of motive power of the New York, Chicago & St. Louis, with offices at Cleveland, Ohio, died at his home in Cleveland, on April 18, after having been ill with pneumonia since April 7. Mr. Miller was born May 1, 1847, in Washington county, Pa., and was educated in the public schools. He entered railway service in 1865, with the Cleveland & Pittsburgh, and was consecutively laborer and helper until 1866. From 1866 to 1871, he was machinist apprentice and machinist with the Pittsburgh, Cincinnati & St. Louis, at Dennison, Ohio. From 1871 to 1873, he was machinist for the Louisville & Nashville, at Bowling Green, Ky. In 1873, he was made foreman of the Pittsburgh, Cincinnati & St. Louis, and later, in 1880, he was made roundhouse foreman of the same road, at Columbus, Ohio. In 1882, he was appointed master mechanic of the New York, Chicago & St. Louis, at Conneaut, Ohio, which position he held until May 1, 1905, when he was appointed superintendent of motive power of the same road, with office at Cleveland.

E. A. Miller

E. H. Calef, general freight agent of the St. Louis, Iron Mountain & Southern, died on April 21, at his home in St. Louis, Mo., at the age of 48.

Samuel Bancroft, Jr., chairman of the board of directors of the Huntington & Broad Top Mountain Railroad & Coal Company, died on April 22, in a hospital in Philadelphia, Pa., at the age of 75.

John F. Boniger, secretary and treasurer of the Texas-Mexican Railway, died at Laredo, Tex., on April 21, aged 49 years. He had been secretary and treasurer of this company for the past 22 years.

Lieut.-Colonel Lacey R. Johnson, who was appointed general welfare agent of the Canadian Pacific in March of this year, died on April 17, at the age of 60. He had been in the service of the Canadian Pacific since 1882.

William E. Chamberlain, formerly, from July, 1898, to April, 1904, general manager of the New York, New Haven & Hartford, died on April 22, at his home in Brookline, Mass., at the age of 80. At the time of his death Mr. Chamberlain was general manager of the Armstrong Transfer Company.

William H. Bancroft, vice-president of the Oregon Short Line, and first vice-president of the San Pedro, Los Angeles & Salt Lake, died at Salt Lake City, on April 22, of appoplexy. Mr. Bancroft was for several years vice-president and general manager of the Oregon Short Line, but retired from active service on February 1, 1914, retaining the title of vice-president. He was born on October 20, 1840, at Newberg, Ohio, and entered railway service in April, 1856, as telegraph operator and ticket clerk of the Michigan Southern. From 1861 to 1869, he was division operator, clerk and despatcher on the Erie, and from 1869 to 1872, was despatcher, superintendent, clerk and train despatcher on the Kansas Pacific. On October 20, 1872, he was appointed assistant superintendent of the Atchison, Topeka & Santa Fe, and in May, 1875, was appointed superintendent of the St. Louis, Lawrence & Western. For a short period in 1878 he was chief despatcher of the Missouri, Kansas & Texas, and from April, 1878, to July 28, 1886, was superintendent of various divisions of the Denver & Rio Grande. From August 15, 1884, to July 29, 1886, he was also receiver of the Denver & Rio Grande Western. On the latter date he was appointed general superintendent of the Denver & Rio Grande, which position he held until 1890, when he entered the service of the Union Pacific as general superintendent of the Mountain division. This position he held until March, 1897, when he was made vice-president and general manager of the Oregon Short Line. On January 15, 1904, he was made general manager of the Union Pacific. In April, 1904, he returned to the Oregon Short Line as vice-president and general manager, which position he held until February 1, 1914. From November, 1904, to February, 1905, he was also acting general manager of the Southern Pacific. In March, 1905, he was also elected first vice-president of the San Pedro, Los Angeles & Salt Lake, and on November 1, 1906, also president of the Utah Light & Railway Company.

W. H. Bancroft

Equipment and Supplies

CAR BUILDING

The Chicago & North Western, it is reported, may increase its recent inquiry for box cars from 2,000 to 3,000.

The Chicago, Milwaukee & St. Paul has ordered 2,000 freight cars from its West Milwaukee shops and 7 sleeping cars from the Pullman Company.

The Minneapolis, St. Paul & Sault Ste. Marie has ordered 400 40-ton box and 100 40-ton steel automobile cars from the American Car & Foundry Company.

The Pennsylvania Lines West have divided an order for 150 steel underframes, between the Ralston Steel Car Company and the Greenville Steel Car Company.

The Russian Government is reported to have placed an order for 17,100 air brakes with the Westinghouse Air Brake Company. This item has not been confirmed.

IRON AND STEEL

The Chicago, Burlington & Quincy has ordered 2,000 tons of rails from the Illinois Steel Company.

The Chicago Railways Company has ordered 20,000 tons of girder rails from the Lorain Steel Company.

The Buffalo, Rochester & Pittsburgh has ordered 2,000 tons of steel rails from the Carnegie Steel Company.

The Atlantic Coast Line has ordered 6,000 tons of steel rails from the Tennessee Coal, Iron & Railroad Company.

The Kansas City Southern has ordered 6,000 tons of steel rails from the Algoma Steel Corporation, Ltd. These rails are to be rolled under the American Railway Engineering Association specifications, with the nick and break test.

SIGNALING

Block Signals on New York Elevated Lines

The New York State Public Service Commission, First District, is keeping up a pressure on the Interborough Rapid Transit Company, New York City, to completely equip all of the lines operated by it, both subway and elevated, local as well as express tracks, with the most complete automatic block signal protection.

The express tracks in the subway have complete automatic block signal protection, with automatic train stops and with signals and stops at the approach to the stations placed close together for the purpose of regulating the speed of trains which are to stop at the stations. For several years past the company has been extending the use of block signals, including the train stops, on the local tracks, although on these the trains, in most cases, stop about every quarter mile, and the speed consequently is always low. Following a slight collision on the elevated lines, last December, the State Commission called upon the road to present plans for complete signaling of the elevated lines. The president of the company, in his reply, expressed the intention to provide complete signaling equipment on the new express tracks of the elevated lines, now being built, but in regard to the local tracks said that complete signaling would reduce the capacity of the lines; the present practice being to run trains on these lines constantly with speed under control. With this arrangement, trains in the congested hours may be run as close together as is necessary. The Commission, however, is not satisfied with the attitude of the road and has adopted a resolution calling upon the company to make a trial installation on the elevated lines not later than October 1, next; to make a thorough test as soon as practicable, and by June 1, 1916, to be prepared to submit to the Commission all necessary information as to whether such trial system shall be extended throughout the whole of the elevated lines. This resolution evidently contemplates the introduction of "speed control" signaling throughout all the lines.

Supply Trade News

The Carbo Steel Post Company, Chicago, has started construction work on a new plant at Cambridge, Ohio.

The Dearborn Chemical Company, Chicago, has opened an office in Edificio del Banco Anglo Sud-Americano, Buenos Aires, Argentine, in charge of Edward C. Brown.

The B. W. Parsons Co., dealing in railway material and mill supplies, has moved its offices in St. Paul, Minn., from the Pioneer building to 1306 Merchants Bank building.

The C. W. Hunt Company, Inc., manufacturers of coal handling and conveying machinery and small motor trucks, has moved its New York office from 45 Broadway to the eleventh floor of the new building of the Adams Express Company, 61 Broadway.

The Chicago office of the Westinghouse Electric & Manufacturing Company has taken over the sale of Nuttall gears, pinions and trolleys, manufactured by the R. D. Nuttall Company, Pittsburgh, Pa., for the electric railway, mining and industrial fields in the Chicago territory.

The eleventh annual convention of the Associated Advertising Clubs of the World will be held in Chicago, June 20 to 24, in the Auditorium theater. Various departmental meetings will also be held in the Auditorium hotel. One of the features of the convention is to be the educational exhibit of trade and technical publications. A very comprehensive program is planned and many prominent business men will speak. It is expected that over 10,000 men will attend the convention.

The Linde Air Products Company, New York, has purchased a factory site in St. Louis on Forest Park Boulevard, between Sarah street and Boyle avenue; and the work of erecting buildings will be started as soon as plans can be drawn and contracts awarded. The St. Louis plant will be the fourteenth erected by the company, and with its completion Linde oxygen will be distributed from 39 points. In addition to oxygen the Linde Air Products Company also produces nitrogen and other rarer gases contained in the atmosphere.

At the annual meeting of the stockholders of the Joseph Dixon Crucible Company, held in Jersey City, on April 19, the former board of directors was re-elected for the ensuing year. The vote recorded was the largest ever represented at an annual election—19,519 shares out of a possible 20,000. The directors re-elected the following officers: George T. Smith, president; George E. Long, vice-president; J. H. Schermerhorn, treasurer; Harry Dailey, secretary, and Albert Norris, assistant secretary and assistant treasurer.

L. S. Brach Supply Company, New York, is about to move its factory to larger quarters at 129 Sussex avenue, Newark, N. J. An extensive laboratory for the testing of the company's apparatus has been included in the new factory, besides ground space for the erecting of signals for testing before shipment. Included in the products that will be manufactured in the Newark plant are: Brach automatic flagman, arresters, hydrogrounds, recorders, switch devices and concrete products. The Solderall Company, a subsidiary, will also have its products manufactured in this plant.

The report of the United States Steel Corporation and its subsidiary companies for the quarter ended March 31, 1915, shows total net earnings for that period of $12,457,809, and a deficit, after payment of interest and preferred dividends, of $5,389,861. This compares with total net earnings of $10,933,170, and a deficit of $5,606,283 for the previous quarter, and with the total net earnings of $17,994,381, and a deficit, after dividends, of $6,289,644 for the quarter ended March 31, 1914. During the quarter last mentioned, however, the Steel Corporation was paying dividends of 1¼ per cent. on its common stock, while at present no dividends are being paid on that stock.

Railway Construction

Alabama, Tennessee & Northern.—This company is planning to start work soon on the extension projected last year from the present northern terminus at Reform, Ala., north for about 70 miles to a connection with the Illinois Central.

Boston (Mass.) Roads.—Governor Walsh has signed a bill ordering the removal of the elevated structure in Charlestown, and the construction of a subway 1.25 miles long to Sullivan square to replace it.

Chesapeake & Ohio.—Contracts for the construction of 29.8 miles of the Chesapeake & Ohio Northern from a connection with the Chesapeake & Ohio in Kentucky to a connection with the Norfolk & Western near Waverly, Ohio, have been let to W. W. Boxley & Co., Roanoke, Va.; the Rinehart & Dennis Company, Charlottesville, Va.; Winston & Company, Richmond, Va., and the Robert Grace Contracting Company, Pittsburgh, Pa. (April 23, p. 913.)

Chesapeake & Ohio Northern.—See Chesapeake & Ohio.

East & West Coast.—Construction work on the line from Bradentown, Fla., southeast via Manatee, East Manatee, Alsace, Lorraine, St. Claire, Myakka City, East Myakka, Parkton, Pine Level and Belgium to Arcadia, 49.8 miles, has been completed with the exception of the stations and section houses, and the line is to be put in operation on May 1. The maximum grade is 0.5 per cent, and the maximum curvature 2 deg. There is one steel bridge and about three miles of wooden trestle on the line. The company expects to develop a traffic in lumber, naval stores, citrus fruits, livestock, etc. Allen W. Jones, president; W. B. Wilson, vice-president, Bradentown.

Florida Roads.—The Port Commission of Jacksonville, Fla., has given a contract to A. J. Mills, Jax, Fla., to build the connecting railroad and freight yards within the city of Jacksonville. M. Corse, chairman, and F. W. Bruce, chief engineer, Jacksonville. (February 26, p. 389.

Lexington & Eastern.—See Louisville & Nashville.

Louisville & Nashville.—The Lexington & Eastern is building a five-mile spur line up First creek in eastern Kentucky from a connection with the North Fork extension to the lands of the Haley Coal Company.

Louisiana Roads Electric.—A company is being organized to build an electric line from Rayville, La., south to Alto, thence to Egypt, 22 miles. The company expects to develop a traffic in cotton, general freight and passengers and farm products; three stations will be put up on the line. T. J. Coenen, Rayville, is back of the project. (April 16, p. 871.)

Meridian & Memphis.—Construction work on the extension from Union, Miss., west to Sebastopol, about 13 miles, has been suspended, it is said, until the completion of a new survey which may require a change of line. (January 29, p. 211.)

New York Subways.—The New York Public Service Commission, First district, has awarded a contract for the construction of Section No. 2 of Route No. 12 to the Inter-Continental Construction Corporation, the lowest bidder at $2,744,263. This section is a part of the Eastern Parkway subway in the borough of Brooklyn, between Prospect Park Plaza and a point about 600 ft. east of Nostrand avenue. (March 26, p. 720.)

Bids will be opened by the commission on May 18, for the construction of Section No. 2 of Route No. 49, which is that part of the Gravesend avenue elevated railroad in Gravesend avenue and Shell road, between Bay Parkway and Avenue X, in the borough of Brooklyn. The Gravesend avenue elevated railroad will connect the Fourth avenue subway with Coney Island.

Ocilla Southern.—This company has secured trackage rights over the Hawkinsville & Florida Southern from Pope City, Ga., to Hawkinsville, and as soon as the Ocilla Southern extension is completed into Pope City, probably by July next, trains will be operated into Hawkinsville. (March 26, p. 720.)

Ocmulgee Valley.—Work is now under way, it is said, on the line from Lumber City, Ga., southwest to Jacksonville, about 20 miles, and track has been laid on about 10 miles. C. S. Smith, president; J. C. Work, chief engineer, Lumber City. (March 26, p. 720.)

Portland Railway, Light & Power.—It is reported that this company contemplates the construction of a new line from either Cottrell on the Mount Hood line or through Sandy, Ore., for a distance of 18 miles.

Southern New England.—Work is now under way on about 58 miles of the line building from Palmer, Mass., southeast via Brimfield, Fiskdale, Southbridge, Sandersdale, Webster, Douglas, Millville, Woonsocket, R. I., and Pawtucket to Providence, R. I., about 75 miles. John Marsch, Southbridge, Mass., is the contractor. The cost of the work will be about $80,000 a mile. The maximum grade will be 1 per cent compensated and the maximum curvature 6 deg. The work is very difficult, about 60 per cent being rock work. There will be 22 steel and 74 wooden bridges, also one viaduct 1,200 ft. long and 125 ft. high on the line. This company, which was organized by the Grand Trunk, started work in 1912, and early this year petitioned the state legislature of Rhode Island for an extension of time to July, 1917, in which to complete work on the section in Rhode Island. Under the terms of the original charter the section in Rhode Island was to be finished by July, 1915. E. C. Smith, president, J. M. Morrison, chief engineer, St. Albans, Vt. (February 12, p. 289.)

Western Maryland.—This company has arranged for trackage rights over two lines of the Baltimore & Ohio, one from Rockwood, Pa., for about 20 miles into Somerset county and the other from Connellsville, Pa., to Fairmont, W. Va. In each case the Western Maryland will build short spurs to reach coal mines. The construction involved in these spurs, which are now being located, will not exceed eight or ten miles.

West Virginia Roads (Electric).—Work is now under way, it is said, on an electric line for the Princeton Power Company from Princeton, W. Va., southwest to Bluefield, 12 miles. Much of the grading work has been completed and track laying is expected to be started in the near future. S. J. Evans, president, Princeton.

RAILWAY STRUCTURES

Beloit, Wis.—The Rockford & Interurban Railway will build a timber bridge of 55 spans of 16 ft. length over the Rock river near Beloit. The estimated cost is $12,000. Work is to be done by company forces. Creosoted yellow pine will be used. W. S. Hubbard of Rockford, Ill., is the chief engineer.

Chicago, Ill.—The contract for the foundation work for the Pennsylvania Lines' new freight terminal at Chicago, mentioned in last week's issue, was let to the Sumner-Sollitt Company, Chicago.

Lexington, Ky.—The Chesapeake & Ohio has not yet completed plans for new shop buildings at Lexington. A contract has recently been let to the Combs Lumber Company, Lexington, for building a seven-stall roundhouse at Netherland, just outside of Lexington.

New York.—A bridge is to be built over Westchester creek at One Hundred and Seventy-seventh street, in the borough of the Bronx. Detail plans have not yet been completed. The plans will call for a structure to carry double track for the operation of electric street railway cars.

Pittsburgh, Pa.—Plans are being made by Allegheny county officers to build a suspension bridge with a double deck approach viaduct, over the Ohio river at Pittsburgh. The proposed structure will require 15,000 tons of steel, and will carry tracks for the operation of steel railway cars. The cost of the work will be $1,500,000. J. G. Chalfant, county engineer, Pittsburgh, may be addressed.

Reading, Pa.—The Philadelphia & Reading has let contracts for rebuilding a bridge under the Lebanon Valley tracks over Sixth street, Reading, as follows: Masonry and concrete work to Seeds & Derham; structural steel work to the McClintic-Marshall Company, and waterproofing to James Kelly. The new structure will consist of deck-plate girders, covered with solid concrete floor waterproofed, and all exterior girders will be incased in concrete.

Sidney, Ohio.—The Cincinnati, Hamilton & Dayton has asked bids for a new steel bridge at Sidney to be built at an approximate cost of $20,000.

Railway Financial News

Atlantic Coast Line.—J. P. Morgan & Co., the First National Bank and the National City Bank, all of New York, are offering $5,000,000 Atlantic Coast Line general unified mortgage 4½ per cent bonds of June 1, 1914-1964 at 89¼, yielding about 5.10 per cent interest on the investment. These bonds are issued under the mortgage which provides for $200,000,000 of bonds, of which $88,921,685 are reserved to retire underlying liens and of which, including the present issue, there are now $29,951,000 bonds outstanding. The proceeds from the sale of the bonds are to be used to reimburse the company for expenditures for additions and betterments and for refunding underlying debt which has matured and been paid off.

Baltimore & Ohio.—Kuhn, Loeb & Company and Speyer & Company, both of New York, have bought from the Baltimore & Ohio $40,000,000 4½ per cent secured notes, one-half maturing in two years and one-half maturing in three years. This amount embraces the entire authorized issue of such notes. The subscription list for the Baltimore & Ohio 4½ per cent secured gold notes has been closed by Kuhn, Loeb & Company and Speyer & Company, the $40,000,000 notes offered for subscription today having been over-applied for. Offering price was 99½ for the two-year, and 99 for the three-year notes.

Chicago, Rock Island & Pacific.—A minority stockholders' committee has been formed, consisting of N. L. Amster, Warren C. Crane, Alfred J. Keppelmann and Frank W. Bauder, of New York; E. S. Dickerson, of Philadelphia; George G. Prentice, of New Haven; Peter G. Ten Eyck, of Albany; Nathaniel French, of Davenport, Iowa; George W. Smith, of Maine, and Courtlandt Linkroum, of New Jersey.

Delaware, Lackawanna & Western.—Suit has been brought by minority holders of the Morris & Essex against the Delaware, Lackawanna & Western, which leases the Morris & Essex, claiming that $1,500,000 more should have been paid to stockholders in the last 10 years than was paid because of the improper increase in the funded debt of the Morris & Essex. About $10,000,000 of this increase was to reimburse the Lackawanna for expenditures made on the Morris & Essex and charged to the Morris & Essex property account, which expenditures would have been, if made on the Lackawanna itself, charged to expenses.

Erie.—Drexel & Company, of Philadelphia, and the Guaranty Trust Company, New York, are offering $6,000,000 Genesee River Railroad first mortgage 6 per cent sinking fund bonds, due July 1, 1957, at 103¾, yielding about 5.75 per cent. These bonds are secured by a first mortgage on the new Genesee River cut-off of the Erie and are guaranteed principal and interest by the Erie.

Missouri, Kansas & Texas.—Holders of more than 73 per cent of the $19,000,000 outstanding 5 per cent notes due May 1 had up to April 27 agreed to extend their notes at 6 per cent. The time for the deposit of these notes has been extended to May 1. Additional security, consisting of $1,309,000 5 per cent consolidated mortgage bonds of the Missouri, Kansas & Texas, has been deposited with the Central Trust Company as trustee. The company has made no arrangements for the payment of non-assenting notes. Some of the notes—the exact amount can only be estimated—are held abroad and of the notes held in England some have already been mailed for deposit in the United States. Under the British treasury ruling the notes cannot be deposited in England but must be sent to this country if their holders desire to extend them.

Morris & Essex.—See Delaware, Lackawanna & Western.

New York, New Haven & Hartford.—Stockholders on Saturday, April 24, approved the following proposals made by the board of directors:

1. The reduction in the capital stock to $157,117,900, by the cancelation of $22,899,100 stock now in the treasury.

2. The acceptance of amendments to the company's charter to bring it in conformity with recent legislation enacted in Connecticut and in Rhode Island.

3. The authorization of an issue of bonds by the New Haven, as successor to the New York, Providence & Boston, and as successor to the New Haven & Northampton, under mortgages of those companies dated 1892 and 1906, respectively.

Wabash.—Judge Adams, of the federal district court, has signed an order authorizing the sale of the Wabash at an upset price of $21,000,000. The upset price had previously been fixed at $34,000,000.

The reorganization plan has been completed by representatives of the leading security interests in the property. A committee of seven, consisting of an equal number of members from the Wallace protective committee and the Pierce committee of the refunding and extension bonds and a representative of the stockholders' committee, was appointed to proceed immediately with the work of reorganization.

Kuhn, Loeb & Company, New York, have agreed to underwrite the plan, under which it is proposed to raise $27,720,000 of new capital by an assessment of $30 a share on the stock. The holders of the $35,600,240 first refunding and extension 4s will be given for their bonds a new and special preferred stock. Three classes of stock will be issued, common, preferred and the special preferred. Holders of the present common are to receive something more than a half of their holdings in new common with the remainder in new preferred, upon payment of the assessment. Holders of the present preferred are to get more than a half in new preferred and the remainder in new common, upon payment of the assessment.

Western Pacific.—The Wall Street Journal says that there are rumors to the effect that Governor Johnson, of California, has dropped his plan to buy the Western Pacific for California and that these reports are circumstancial and it is believed that the governor, on the advice of his lawyers and experts who went thoroughly into the matter, has decided that the plan is not feasible.

Railway Extension in Argentina.—The firm of Anastasio Lopez y Cia. (San Luis, F. C. P., Argentina) has secured a concession from the province of Mendoza to construct a 71-mile line from General Alvear to San Rafael, province of Mendoza. The concession includes branch lines to Las Malvinas, 25 de Mayo, and Cuadro Nacional, about 30 miles of track in all, and such other branches up to a distance of 6 miles from the main line as may be necessary to connect the system with centers of production needing an outlet. These additional branch lines are estimated at another 30 miles for the present. The region traversed is said to be well irrigated and under intensive cultivation. The system adopted for the new line is that of the so-called economical secondary railway with a 75-centimeter (2.46 ft.) gage. Steam traction will be used at first, but it is planned to electrify later. Work will be commenced in about six months.

German Railway Employees.—According to reports the employees of the Prussian State Railways who are in sympathy with trade unionism have a very real grievance against the government. The railway administration has for a number of years obliged men entering the service to sign a declaration that they would not become members of a trade union or a Socialist society, and would not attend meetings or read newspapers of the kind. On the outbreak of war, these restrictions remained unrelaxed so far as concerned railwaymen employed prior to mobilization, but new employees who have been engaged to take the place of those with the colors have not been compelled to sign the declaration. The result is a most anomalous and unfair position. Socialist and trade union newspapers are now allowed to be sold at the railway bookstalls, and to be sent to men at the front, but the bulk of the railway employees are not permitted to read them, although they can buy these publications at the stations where they are engaged, which they could not do prior to the war. The concession is, of course, due to the government's desire to placate the members of the German Socialist Party. The position is especially resented because about one German railway man in six, or a total of some 100,000, has already been called up for military service. The Minister of Railways has had his attention drawn to the matter in the Reichstag, but has declined to interfere or to discuss the subject, excusing himself on the ground of the "political truce."—*Railway Gazette.*

Wabash Reorganization Plan

The Wabash reorganization plan, outlined in another column in this issue, is drastic, but whether drastic enough or not only time can show. Stockholders are assessed $30 in cash per share and receive new preferred and common stock to a total par value of the amount of stock which they are surrendering in the case of the preferred, and of 95 per cent of the par value of the stock which they are surrendering in the case of the common. The first and extension mortgage bondholders are exchanging a bond for a preferred stock, and while they are receiving, it is true, stock with a par value 20 per cent greater than the face value of the securities which they are surrendering, they are also surrendering coupons calling for interest payments amounting to about 12 per cent and are compelled to underwrite the $30 assessment on the stock under pain of forfeiture of their equities, with the exception of the very small amount which would probably accrue to them as their pro rata share of the selling price under foreclosure of the property. The interest charges of the new company are but $3,183,915, as against present interest charges, all of which, of course, are not being paid, however, of $5,795,278. In the fiscal year ended June 30, 1914, the property earned a sum available for interest payments of $2,680,975, or an amount less by $502,940 than the sum required for interest under the new plan. Under the plan the new company will have funded debt and equipment trust obligations amounting to $26,000 per mile of road. This is conservative, and if rates and operating conditions are such as to permit of a reasonably low operating ratio, the property ought to show a return on at least the first preferred stock, and in time on the second preferred stock. As will be seen, however, rates and operating conditions in 1914 were not such as to permit even the total interest charges on the funded debt to be earned. The main points about the plan which are notable are the large scaling down in fixed charges, the conservatism with which stock is issued against paper equities surrendered, and the fact that no provision is made for any large amount of money to be spent on additions and betterments to the property, the plan providing but for $3,500,000 working capital for the new company after the payment of receivers' certificates, expenses of reorganization, etc. This is not more than the current necessities of a railroad company and does not allow of any capital expenditures.

The Continental Telegraph Alphabet

A telegraph operator on a prominent western road asks us to advocate the use on railroad wires of the Continental alphabet, in place of the Morse. He calls for the change in the interest of "safety first," for, as everyone admits, there is less liability to error in reading. The Morse operator, like the stenographer, is doing a prodigious amount of guessing, every day, and the wonder is that so very, very few wrong guesses go uncorrected. Besides safety, our correspondent makes a strong plea on the ground of convenience and the lessening of the wear on the nerves, an argument which, he says, is backed up by the cable and wireless operators who use the Continental. On principle, we are disposed to endorse our correspondent's view; but the number of operators who cannot be displaced, yet who could not easily perfect themselves in a new language, make the practical question rather confusing. The writer of these lines has been familiar with the Morse alphabet from boyhood, and he would weep to see it displaced. The sound of "Morse" when sent by some of the renowned old-timers is as pleasant to the ear as the classical verses which were committed to memory in the primary school. In an office where the Continental is used he feels as little at home as he would in the parliament of Norway. But "safety first" does have an application here. The Morse alphabet has a record for safety; but with the Continental the attainment of safety is no doubt much easier. Simplicity tends to safety, and the elimination of the spaced letters and the long dash simplifies the work greatly. Again, there is the question of uniformity. The nations of the world are practically agreed on the Continental for international telegraphing. In despatching, the question may not be of the first importance, for it looks as though everybody would soon be using the telephone; but for long distances the dots and dashes still have a great field of usefulness, and "safety first" has an application even in message work. The Continental is already in use on land lines in this country to a considerable extent, notably on long lines of the Postal Company, and its use is said to be increasing.

Proposed Ohio Legislation

A bill has been introduced in the upper house of the Ohio legislature which, if passed and made effective, would reduce the rate on intrastate shipments of coal in Ohio proportionately to the reduction of the rate from Nelsonville to Toledo from $1 to 75 cents. Regardless of the question of the reasonableness of Ohio intrastate coal rates, this particular piece of state legislation is vicious in principle. In 1910 the Ohio railroad commission ordered the Ohio rates reduced proportionately to a reduction of from $1 to 85 cents in this Nelsonville-Toledo rate. An appeal was made to the courts and the case is now being tried by the Supreme Court of Ohio. To attempt to pass a law which would reduce rates by a substantial amount further even than the state commission reduced them, while the highest state court is engaged in determining the reasonableness of the commission-made rates, is about as indefensible as any state regulation of railroads could be. It is pertinent, moreover, to briefly describe the method used by the Ohio commission in arriving at the 85-cent rate. The cost of service was estimated by the commission, and this was taken as 60 per cent of the total cost, the other 40 per cent taking care of fixed charges, taxes, profits, etc.; but when the commission came to determine the cost of service they divided it into two parts—one the cost of haulage, which they found to be 39.02 cents, and one the terminal cost, which they found to be 20 cents. Instead of adding these two together and then adding two-thirds they added two-thirds to the cost of haulage but nothing to the terminal cost, thus arriving at about 85 cents, whereas if they had followed out their own formula and taken the total cost of service at 59.2 cents, which was what they determined it to be, and added two-thirds, the rate would have been 98.386 cents. It will be remembered that the rate which the commission reduced was $1.

AWARD IN ENGINEERS' AND FIREMEN'S ARBITRATION

THE award made in the arbitration of the demands of the engineers and firemen of western railways is published elsewhere in this issue. As to its effect on existing schedules and conditions it is impossible to make any accurate analysis until it has been applied to the actual operating conditions on each road and until it has been determined in what instances the present rules or rates will be retained by the employees in preference to those granted. Under the "saving clause" of the arbitration agreement any changes in rules or working conditions will result in an increased expense to the railroads.

Apparently a greater increase in the payrolls will be brought about through the operation of the new rules than by the direct increases in wage scales granted. The enginemen's brotherhoods have stated that the increases will amount only to about $1,000,000 a year. The general managers' committee has declined to make any premature estimate.

Some advances in pay are given for the smaller engines, both freight and passenger, but most of the money to be paid out on account of the higher wage scales will go to the engineers and firemen in switching service and to the hostlers, who are given a very substantial increase. In the classification of engines according to the weight on drivers as a basis of compensation the board has followed the eastern award to the firemen, and it is difficult to make any comparison with the present rates because the present classifications on western roads are a mixture of the cylinder dimension and the weight basis and vary greatly on the different roads.

As Messrs. Park and Byram observe in their statement filed with the award, benefits will accrue to the men who are most deserving of more pay and better rules, rather than to the men who are now receiving the highest pay and the most liberal rules.

Whether the award will have any tendency toward standardization will depend on the extent to which the men prefer to retain the present schedule provisions, and they will of course prefer those that give them the most money or which they consider most favorable to them in other ways. But as the railroad arbitrators show, any considerable degree of standardization was impossible under a one-sided agreement which permitted standardization only in an upward direction, by making universal the most favorable rules and rates to be found anywhere, and did not afford any opportunity for an equalization by taking away some rule or rate now in effect to replace it with one that could be uniformly applied. Such a standardization was offered the employees in the counter-proposals of the railroads and was refused because the men preferred to stand for their demand for a pyramiding of the most favorable rates of wage to be found in any schedule upon the most favorable rules in existence.

The award of the board shows that the majority fully recognize the interrelation of rates of wages and rules, and as a result the most unreasonable demands of the men were either denied or so modified that they will not have the cumulative effects on other rates or rules which the subtle wording in which they were submitted would have produced. In other instances, the board recognized that while certain conditions might need correction, in most cases they could be properly adjusted only with reference to local conditions or other special circumstances, and not by a hard and fast rule applying to all roads.

EFFECTS OF TRAIN LIMIT LEGISLATION

PRESIDENT EARLING, of the Chicago, Milwaukee & St. Paul, in a recent statement to the Public Utilities Committee of the Illinois House, presented some statistics regarding the expense to which the St. Paul road would be put in Illinois if the train limit bill pending in the legislature should be passed. The bill in question would prohibit freight trains from containing more than 50 cars. All important railways have invested large sums in grade reductions, long passing tracks, large yards, locomotives of large tractive power, etc., to enable them to handle freight in large train loads and secure the operating economies thus attainable. Mr. Earling's statement regarding the effect the proposed legislation would have on the St. Paul is summarized elsewhere. He shows that it would render valueless an investment in Illinois of $4,091,753. A return of 6 per cent on this would be $245,500 annually. Beside rendering this investment valueless the legislation, Mr. Earling shows, would cause an increase in the operating expenses of the St. Paul in Illinois of $441,155. The loss per annum on investments rendered valueless and in increased operating expenses would therefore be $687,000.

The mileage of the St. Paul in Illinois is 415 miles, and therefore its loss per mile would be $1,654. The total railway mileage of the state on June 30, 1913, was 12,013. If the total loss per mile on all the railways would be as great as Mr. Earling estimated it would be on the St. Paul, the proposed legislation would cost the railways of the state almost $20,000,000 a year. This estimate of the total cost in Illinois is, of course, a rough approximation, but it gives a clew to the enormous increased burden that would be put on the railways directly and on the public indirectly.

Limitation of the length of freight trains is advocated in the interest of public safety. Those who are seeking it claim that it would reduce railway accidents. If it would reduce railway accidents to any considerable extent it might be desirable in spite of the increase in expenses it would cause. But as a matter of fact, the proposed reduction of the length of trains would not reduce accidents. It would be certain to increase them. If the length of trains was reduced this would obviously make it necessary to run more trains in order to handle the business. But past experience shows that the

most certain way to increase railway accidents is to increase the number of trains run under any given set of conditions. Furthermore, the statistics show that there is a closer relationship between the number of accidents and the number of freight trains run than there is between the number of accidents and the number of passenger trains run. A careful analysis of the statistics for the period from 1903 to 1914 shows that during this period in 90 per cent of the cases when there was an increase in freight train mileage there was an increase in the number of accidents of all kinds, and when there was a decrease in freight train mileage there was a decrease in accidents of all kinds. The following table gives the freight train miles per year during this period and the number of all classes of persons killed and injured in accidents resulting from the movement of trains.

Casualties to All Persons—Accidents Resulting from Movement of Trains

	Freight train miles	Killed	Injured
1903	526,000,000	9,605	48,361
1904	535,000,000 Inc.	9,801 Inc.	52,916 Inc.
1905	546,000,000 Inc.	9,433 Dec.	55,613 Inc.
1906	594,000,000 Inc.	10,367 Inc.	63,417 Inc.
1907	630,000,000 Inc.	11,474 Inc.	71,630 Inc.
1908	587,000,000 Dec.	9,851 Dec.	64,714 Dec.
1909	568,000,000 Dec.	8,470 Dec.	54,238 Dec.
*1910	635,000,000		
1911	626,000,000 Inc.	9,957 Inc.	70,922 Inc.
1912	612,000,000 Dec.	10,185 Inc.	77,175 Inc.
1913	644,000,000 Inc.	10,550 Inc.	86,688 Inc.
1914	612,000,000 Dec.	9,893 Dec.	79,388 Dec.

*Complete accident statistics for 1910 are not available.

The table shows that in 1905 there was an increase in freight train mileage and a decrease in the total number of persons killed. Again in 1912 there was a decrease in freight train mileage and an increase in the total number killed and the total number injured. In every other instance during this period an increase in freight train mileage was accompanied by an increase in casualties and a decrease in freight train mileage was accompanied by a decrease in casualties.

The proposed legislation is not in the interest of safety. It would be impossible to suggest legislation which would have a more certain tendency to reduce safety. The bill ought to be entitled, "An act to increase the cost of rendering transportation service to the public and to add to the number of people killed and injured on railways."

THE DISTURBANCE OVER THE WESTERN ARBITRATION

THE board which arbitrated the demands of the engineers and firemen of the western railways has made its award, and the representatives of the engineers and firemen are vigorous in their denunciations of it. They criticize the attitude of Arbitrator Charles Nagel, and announce that they will seek a congressional investigation of the action of the Mediation and Conciliation Board in appointing him, and the part he took in the arbitration. They charge that his business and professional affiliations necessarily prejudiced him against the demands of the engineers and firemen, and that his attitude was hostile to them during the hearings.

In order that a fair and rational opinion may be formed regarding this case, its outcome and the complaints of the representatives of organized labor, it is necessary to review the case from the beginning. In October, 1913, the engineers and firemen presented to the railways requests for increases in wages and numerous changes in the rules controlling their conditions of service. The railways, in reply, gave notice of the termination of the existing contracts and made counter proposals. The employees responded by demanding still larger increases of wages and additional improvements in their conditions of service.

The Board of Mediation and Conciliation finally was asked to intervene. After it had made numerous futile proposals, it suggested to the employees that both the demands of the railways and the secondary and additional demands of the employees be dropped and that only the original demands of the employees be arbitrated. The employees having everything to gain and nothing to lose by this plan, accepted it. The railways, having everything to lose and nothing to gain by it, rejected it. The railways were thus put in the position of refusing to arbitrate, although they had first asked for arbitration. When a breach seemed inevitable, President Wilson appealed to the roads in the name of patriotism to accept this one-sided basis to save the country from a great railway strike when its prosperity was imperiled by the war in Europe. Thus put into a hole by the federal board of mediation and pushed still further into it by the President, the railways, practically under duress, agreed to a plan by which they had everything to lose and nothing to gain.

In accordance with the provisions of the Newlands Act the railways and the employees appointed two representatives each on the Board of Arbitration. These four could not agree on the two impartial arbitrators. Judge Peter C. Pritchard and Charles Nagel, formerly secretary of Commerce and Labor, were therefore appointed by the Board of Mediation. Between the time of their appointment and the beginning of the arbitration nine days elapsed. This was ample for both sides to investigate them. As both had national reputations, nothing could have been easier than to have learned all about their antecedents and affiliations. But no objection was made to either of them. The public hearings, the filing of briefs and the arguments took five months. During this time no objection was made to either of them. But after the arbitrators had been conferring some time, and the representatives of the employees knew what the award would be, they began to bombard President Wilson and the Board of Mediation and Conciliation with telegrams charging Mr. Nagel with unfitness because of his business connections, and demanding his removal.

The implication that the Board of Mediation and Conciliation appointed Mr. Nagel in a spirit of hostility to the engineers and firemen will not bear scrutiny in view of the board's previous action in putting the railways in a position where they were forced to accept a basis of arbitration entirely unfavorable to them. Furthermore, the action of the employees in postponing their complaints about Mr. Nagel until they knew what the award would be, convicts them of utterly unfair practice. If there was anything questionable in his affiliations the representatives of labor should have informed themselves about this and made their objections to him before the arbitration began. Messrs. Stone and Carter in a public statement assert, however, that they did not inform themselves on this subject. Why didn't they? Were they not being paid by the engineers and firemen to represent them in all matters bearing on the controversy? Mr. Nagel had been a member of the President's cabinet. He had been for years one of the most prominent men, politically, professionally and in business in St. Louis. Everybody in that city who reads the newspapers, and many persons throughout the country, know him by reputation. And yet Messrs. Stone and Carter say they knew nothing about him and never took the pains to inquire! Messrs. Stone and Carter think they have drawn an indictment of Mr. Nagel. What they have drawn is an indictment either of their own fairness, or of their competency to represent their brotherhoods in matters of importance.

Their avowed failure to inform themselves concerning the arbitrators was on a par with the way they conducted the entire case. They led their followers into making demands so unreasonable that no fair body could have granted any considerable part of them. Such a bad case needed skillful handling—a need accentuated by the fact that the railways had made very elaborate and thorough preparations for the presentation of their side. The representatives of the labor unions met the issue largely by the methods of the pettifogger, the muckraker and the barnstormer. They put into the records the most outrageous misquotations of statements which they attributed to railway officers and railway publications. They agreed at the start that the financial ability of any road to pay reasonable wages was not a factor in the case and then deluged the record with muckraking misrepresentations regarding the alleged financial mismanagement of western railways. It was the bad case of the employees

and the incompetent way it was presented, and not the attitude of the arbitrators, which caused their defeat. The purpose of the disturbance which Messrs. Stone and Carter are now kicking up seems to be to put on Mr. Nagel the odium of a result for which they themselves are responsible.

Since the representatives of the employees want a congressional investigation, the *Railway Age Gazette* hopes that the railways will join them in asking for it. But if there is to be one let us have it go into the entire history of this controversy. Let us also have it go into the entire labor situation on the railways of the United States and the methods which the government should adopt for dealing with them. That situation needs thorough ventilating. The procedure for mediation and arbitration provided by the Newlands Act is not adapted to permanently prevent strikes and lockouts or to get wages and conditions of work put on the right basis. The sooner all the pertinent facts regarding the labor situation on the railways of this country are presented to Congress and it takes action accordingly, the better it will be for the railways and their employees, and especially for the general public.

NEW BOOKS

Proceedings of the Master Tinners', Coppersmiths' & Pipefitters' Association. Compiled and published by W. E. Jones, secretary of the association, Chicago & North Western Railway, Chicago, Ill. 83 pages, 6 in. by 9 in. Bound in paper.

This book is the report of the second annual convention of the American Railroad Master Tinners', Coppersmiths' & Pipefitters' Association, and contains papers on Oxy-Acetylene Welding, Shop Efficiency, Alloys and Their Uses, Tin Roofing vs. Canvas Roofing, and Specialized Training.

The Mechanical World Pocket Diary and Year Book. 298 pages, net, 4 in. by 6 in. Bound in cloth. Published by Emmott & Company, Ltd., Manchester, England. Sold in the United States by The Norman Remington Company, 308 North Charles street, Baltimore, Md. Price 50 cents, postpaid.

This well known book contains a large amount of information covering a wide range of engineering subjects, all of which has been brought up to date in the new edition. Aside from the revision of material which the book formerly contained, a number of new sections have been added including some useful notes on gear cutting, a new section dealing with limit gages and another containing information relative to the strength of flat plates. A large number of tables are given, several of which are included for the first time this year, and many additional illustrations have been introduced. The present edition marks the twenty-eighth year of publication of the Pocket Diary and Year Book, and it has met with much favor because of its moderate price and the concise form in which the subject matter is arranged.

The Mechanical World Electrical Pocket Book. 224 pages, net, 4 in. by 6 in. Bound in cloth. Published by Emmott & Company, Ltd., Manchester, England. Sold in the United States by The Norman Remington Company, 308 North Charles street, Baltimore, Md. Price 50 cents, postpaid.

The electrical pocketbook is a companion volume of the well-known Mechanical World Pocket Diary and Year Book. The 1915 issue has been thoroughly revised and a number of new sections added. The section on electricity on shipboard has been rewritten and considerably extended, while additions have been made to the sections on electricity in coal mines, motor starters and others. A number of sections have been revised and condensed, and as it now stands this little volume contains a large amount of up-to-date information covering the whole range of electrical engineering which should be especially useful to those in charge of electrical plants and machinery. Aside from the engineering information the book contains a number of mathematical tables and also includes a conveniently arranged diary. It is well indexed and its convenient size and low price commends it to those who desire a ready source of general information on electrical subjects.

Letters to the Editor

THE TRAINMASTER AND THE ENGINE-HOUSE FOREMAN

Haileyville, Okla.

To the Editor of the Railway Age Gazette:

The discussions in the *Railway Age Gazette* on the relation between the trainmaster and the engine house foremen cover a broad field and are applicable to other departments as well. The friction alluded to is only the result of lack of harmony prevailing among the employees of the departments and of breadth of mind sufficient to appreciate the other man's duties and responsibilities.

The trainmaster and the chief despatcher are responsible for the movement of trains; the engine house foreman is responsible for the condition of the power to handle the trains. Without good power transportation suffers in the end. The engine house foreman is supposed to send the engines out in such shape that they will make successful trips to the end of the division; to enable him to do this he must have support from the operating department in various ways.

The transportation department should give to the engine house foreman a "sight" report at 7 a. m. and 7 p. m. showing what is moving toward him, together with the individual engine numbers, the names of the enginemen and firemen on the engines, whether they are handling full or light trains, and whether the engines in transit are experiencing any mechanical trouble; at the same time he should be given an approximate call for trains, barring accidents, of course, that will be required for the 12 hours ahead. With the above information at hand the foreman will be in a position to determine fairly well how soon and with what success he can turn the engines. This is not done in many cases, and on some roads not at all, and for that reason we cannot expect too much from the man in charge of the roundhouse or shop. When there is a demand for an engine at a particular hour and the engine house foreman is not ready for it the trouble begins. Then it is that the trainmaster or chief despatcher will in all probability criticize the foreman or will beg him to let the engine go and *we* will take the chances. If the chance is taken and a failure occurs, who gets the worst of it? No one but the transportation department as a train is out on the road with no engine and light mileage will of necessity have to be made to expedite the movement of this train, to say nothing of the delay to the freight; with all of this the engine house foreman will be severely criticized both by the superintendent and master mechanic.

There is no more reason why the transportation department should deal harshly with the mechanical department because an engine cannot be produced just at the time desired than there is for the mechanical department to criticize the transportation men because they do not hurry the power into the terminal. Each has its duties to perform and each should be the judge as to the better way to handle its own matters. I have seen cases where an engine pulled into a terminal and before it had time to reach the roundhouse the trainmaster or chief despatcher would telephone the engine house foreman and say, "Here is the 999, how soon can you get it ready? We want it for an extra east right away." They will keep this up until the patience of the man trying to turn the engine is exhausted. It may be that this engine does not reach the roundhouse promptly, possibly is blocked by a switch engine, or something else occurs which is likely to cause delay in a yard; then when the engine house foreman has put all his energy on the engine and reports it ready to the chief despatcher, a transportation problem, such as incoming trains bunching near the terminal, yardmaster being unable to get the train ready, or similar difficulty prohibits the engine being run at the time wanted. Again, it is customary

to avoid paying time-and-a-half to machinists, boiler makers and other mechanics for overtime; therefore it is necessary to close the work down possibly between 5 and 7 a. m. and 5 and 7 p. m.; if this custom prevails it is known to all that during these hours no work can be done on engines. Then why embarrass the engine house foreman by trying to work out the impossible?

In my experience of several years working with engine house foremen and handling heavy divisions, it has been my aim to work harmoniously with them, giving them all the assistance that I possibly could, and keeping them advised of the situation at all times. I have never found one yet that would not strain a point to help out and do it cheerfully. There is a way to secure the desired results and to maintain a friendly feeling at the same time.

J. L. Coss,
Despatcher, C. R. I. & P.

FACTOR OF ADHESION IN STEAM LOCOMOTIVES

St. Marys, Pa.

To the Editor of the Railway Age Gazette:

The article that appeared in your issue of April 9, 1915, page 778, under the title "Why Use a High Factor of Adhesion in Steam Locomotives," is one that has deserved more consideration from motive power men than it has received, and there is no doubt in the mind of the writer as to the correctness of the stand that the author has taken.

For some years past the reduction of the cost of transportation seems to have been a matter of the greatest consequence. The superheater, mechanical stoker and other appliances are really responsible for the great economic claims made for the Pacific and Mikado types, rather than the locomotives themselves. Consolidation and Mikado type locomotives of the following dimensions been working on the same road on heavy grades with curves as sharp as 12½ deg. for three or four years, and there appears to be very little difference in their performance. While no conclusive records have been kept the coal consumption of the Mikados does not indicate any saving over the Consolidations:

	Consolidation	Mikado
Diameter of boiler	79 in.	79 in.
Grate area	57 sq. ft.	57 sq. ft.
Total heating surface	3,143 sq. ft.	3,682 sq. ft.
Total weight of locomotive	199,850 lb.	226,300 lb.
Weight on drivers	178,950 lb.	179,950 lb.
Cylinders	22 in. by 28 in.	22 in. by 28 in.
Diameter of drivers	51 in.	51 in.
Total weight of locomotive and tender	339,100 lb.	368,600 lb.
Steam pressure	200 lb.	200 lb.
Tractive effort	45,169 lb.	45,169 lb.
Superheater and mechanical stoker	None	None

The writer has been opposed to the building of 4-4-2, 4-6-2 or 2-8-2 types of locomotives for a road on which the conditions would permit the use of the 2-6-0, 2-8-0 or 2-10-0 types, for the reason that considerably more unproductive weight is necessary in an engine having a four-wheel engine truck than in one with a two-wheel truck. The trailer truck is only a source of expense, and the weight resting on it could be put to much better service. Of course, on roads where the curvature is very sharp it may be necessary to use a trailer truck, but where such conditions do not exist the writer can see no good reason why the natural development of the Mogul and Consolidation types should not be utilized. There are Moguls hauling passenger trains and giving excellent service, demonstrating that it is not necessary to use a four wheel engine truck in passenger service.

The primary arguments in favor of the Mikado, are the greater tonnage that it will haul, and a saving in fuel and water. Of course the Mikado shows up better in the various tests and comparisons made, but most of these are anything but fair to the Consolidation, for the reason that the Mikado has invariably been a heavier engine, usually equipped with a superheater, and sometimes with a mechanical stoker or other appliances that the Consolidation did not have. Had the Consolidation and the Mikado been of the same total weight, exclusive of the tender, with the trailer truck weight of the Mikado put on the drivers of the Consolidation, and had the same ratio of adhesive weight to tractive effort used in the Mikado been given to the Consolidation, with the same superheater, mechanical stoker, etc., the results would have been as much in favor of the Consolidation as they now stand against it.

Another argument in favor of the Mikado is that we cannot get sufficient firebox and boiler capacity in the Consolidation type. Let us look into the necessity for the deep firebox first. The Erie Triplex locomotive has not an exceedingly deep firebox; this allows the placing of a 63 in. driving wheel under the firebox, and yet the boiler generates sufficient steam for three sets of large cylinders. It is doubtful if there has been a Mikado built with driving wheels larger than 63 in. In this connection the writer has not thought it impossible, assisted by a mechanical stoker and superheater, to develop a long narrow firebox that would meet the conditions more successfully than the present wide firebox fired by hand. A great many boiler troubles arise from the fireman's being unable to utilize the entire grate area of a firebox containing only 57 sq. ft. on long, hard runs. This is especially true in the summer, when he frequently fires with a bank at the back end to protect himself from the intense heat. Moreover, firemen often become almost exhausted by the time they have completed two-thirds or three-quarters of the trip and allow the fire to become dirty or die next to the tube sheet, leaving the locomotive burn what coal it will to obtain enough steam to get to the terminal. The use of such a long firebox would permit of larger diameter drivers being placed beneath it.

The length of rigid wheel base seems to have been an objection offered for not developing the Consolidation type, but this is no argument when we consider some of the advertising matter that has been put before the public. For example, I quote from two advertisements in the *Railway Age Gazette:* "The Erie locomotive, although it has a rigid wheel base of 22 ft. can traverse curves of 16 deg"; and "the locomotives illustrated are operating on grades of 4 per cent and curves of 16 deg."

Where a road has curves no sharper than 10 deg. in its main line, it is questionable if a 2-8-2 or a 2-10-2 are the proper types of locomotives to build when considered from the point of mechanical efficiency. Let us see if we cannot obtain a rigid wheel base for the 2-8-0 and 2-10-0 types sufficient to provide boiler capacity that will take care of the natural development of these classes for roads not having sharper curves than 10 deg.

To find the middle ordinate for the rigid wheel base of a Mikado, the rigid wheel base of which cannot be far from 17 ft. 6 in., on a 16 deg. curve, using the formulas

$$M = \frac{C^2}{8R} \text{ and } C = \sqrt{M\ 8\ R}$$

In which M = the middle ordinate,
C = the rigid wheel base of the locomotive,
R = the radius of the curve;

we have

$$M = \frac{17.5 \times 17.5}{8 \times 359.26} = .10655 \text{ ft. or } 1.2786 \text{ in.}$$

therefore using .10655 ft. for the middle ordinate of a 10 deg. curve we have,

$$C = \sqrt{.10655 \times 8 \times 573.69} = 22 \text{ ft. } 1\ 3/16 \text{ in.}$$

The 2-10-2, by the same method, would have a rigid wheel base of 28 ft. 1 3/16 in. It will therefore be seen that another pair of driving wheels could be used if the firebox were constructed like that of the Erie Triplex. Taking the dimensions of the Mikado in question, the natural development of this locomotive would have been a 2-10-0, with proportion something like the following:

Total weight of locomotive, exclusive of tender	276,600 lb.
Weight on front engine truck, approximately	26,000 lb.
Weight on driving wheels	250,000 lb.
Cylinders	28 in. by 32 in.
Steam pressure	180 lb.
Tractive effort, approximately	61,000 lb.
Factor of adhesion	4.09

Equipped with superheater and mechanical stoker.

E. F. Given.

Arbitration Award In Enginemen's Wage Controversy

Engineers and Firemen on Western Roads Given Only Slight Increase in Pay and Changes in Working Rules

The board of arbitration appointed under the Newlands law last year to settle the controversy between the western railroads and the engineers' and firemen's brotherhoods on the demands of the enginemen for increases in wages and changes in the rules controlling conditions of service, filed its award in the United States district court at Chicago on April 30. The award grants some comparatively slight increases in pay and a number of rules making changes in working conditions and in the basis for computing compensation, although with many important modifications in the form of the demands as submitted by the men, while some of the rules asked for were denied entirely.

The board of arbitration consisted of J. C. Pritchard, of Asheville, N. C., former judge of the United States circuit court, chairman; Charles Nagel, of St. Louis, former secretary of commerce and labor; H. E. Byram, vice-president of the Chicago, Burlington & Quincy; W. L. Park, vice-president of the Illinois Central; F. A. Burgess, assistant grand chief of the Brotherhood of Locomotive Engineers, and Timothy Shea, assistant president of the Brotherhood of Locomotive Firemen and Enginemen.

The award was signed only by the first four of the arbitrators named. Mr. Burgess and Mr. Shea presented a minority report, protesting against the award as unfair and unsatisfactory. Chairman Pritchard also filed a memorandum saying that in his opinion some of the rates agreed upon are not as high as they should be, but that he had joined with other members of the board in making the award because some of the rules agreed upon accord to the men substantial benefits which should not be denied them. Mr. Park and Mr. Byram also filed a statement that their signatures to the award do not imply approval of it in principle or in detail, saying that the agreement under which the arbitration was held gave no latitude to the board to adjust or reconcile unequal conditions.

The various developments in the controversy and the hearings before the board have been fully reported in previous issues of the *Railway Age Gazette*. The demands of the enginemen were comprised in 16 articles which were submitted to the board. It was estimated by the railroads that if the demands were granted in the form submitted the increase in their payrolls would amount to $41,000,000 a year, or about 51 per cent. The award of the board with a comparison of the demands made by the men on each article, is as follows:

ARTICLE I.—BASIS OF DAY'S WORK AND OVERTIME.

Passenger Service.—The minimum passenger rate for engineers shall be $4.30, and for firemen $2.50; 100 miles, or less, 6 hours and 40 minutes, or less, shall constitute a minimum day's work in all classes of passenger service except as otherwise specified herein; miles made in excess of 100 pro rata.

On short turn-around runs, no single trip of which exceeds 80 miles, including suburban service, overtime shall be paid for all time actually on duty or held for duty in excess of 8 hours (computed on each run from the time required to report for duty to end of that run) within 12 consecutive hours; and also for all time in excess of 12 consecutive hours computed continuously from the time first required to report to final release at end of last run. Time shall be counted as continuous service in all cases where the interval of release from duty at any point does not exceed one hour.

All other passenger overtime shall be computed on the basis of 15 miles per hour from the time required to report for duty until released, and separately for each part of a round trip run. All passenger overtime will be paid for at the rate of 75 cents per hour for engineers and 45 cents for firemen, and will be computed on the minute basis. When employees of any road elect to retain their present overtime basis, no part of this article is to be used in computing or paying passenger overtime.

Freight Service.—The minimum freight rate for engineers and firemen shall be according to class of locomotive, as provided in Article II, for 10 hours, or less, or 100 miles, or less; miles made in excess of 100 pro rata. Overtime in freight service is to be computed on the basis of 10 miles per hour, and paid pro rata on the minute basis.

General.—Road engineers and firemen required to perform a combination of more than one class of road service during the same trip will be paid at the rate and according to the rules governing each class of service for the time or miles engaged in each, but will be paid for the entire trip not less than a minimum day at the highest rate applying for any class of service performed during such trip. Where two or more engines of different weights on drivers are used during a trip or day's work, the highest rate applicable to any engine used should be paid for the entire day or trip.

In the article proposed by the employees it was provided that in passenger service five hours or less should constitute a day's work, and that overtime should be paid for on a basis of 20 miles per hour. In all other service except passenger and switching service, it was provided that overtime should be computed on a basis of 10 miles per hour and paid for at the rate of 15 miles per hour.

ARTICLE II.—RATES OF PAY.

Passenger Service.—The minimum rates of wages per day shall be:

	Engineers	Firemen—Coal	Firemen—Oil
Engines less than 80,000 lb. on drivers	$4.30	$2.50	$2.50
Engines 80,000 lb. and less than 100,000 lb. on drivers	4.30	2.55	2.55
Engines 100,000 lb. and less than 140,000 lb. on drivers	4.40	2.60	2.60
Engines 140,000 lb. and less than 170,000 lb. on drivers	4.40	2.70	2.55
Engines 170,000 lb. and less than 200,000 lb. on drivers	4.45	2.85	2.70
Engines 200,000 lb. and less than 250,000 lb. on drivers	4.45	3.00	2.85
Engines 250,000 lb. and less than 300,000 lb. on drivers	4.65	3.20	3.05
Engines 300,000 lb. and less than 350,000 lb. on drivers	4.80	3.40	3.25
Engines 350,000 lb. and over on drivers	4.80	3.60	3.45
Mallet engines regardless of weights on drivers	5.00	4.00	3.85

Freight Service.—The minimum rates of wages per day shall be:

	Engineers	Firemen—Coal	Firemen—Oil
Engines less than 80,000 lb. on drivers	$4.75	$2.75	$2.75
Engines 80,000 lb. and less than 100,000 lb. on drivers	4.80	2.85	2.75
Engines 100,000 lb. and less than 140,000 lb. on drivers	4.85	3.00	2.85
Engines 140,000 lb. and less than 170,000 lb. on drivers	5.10	3.20	3.05
Engines 170,000 lb. and less than 200,000 lb. on drivers	5.30	3.45	3.30
Engines 200,000 lb. and less than 250,000 lb. on drivers	5.45	3.70	*3.55
Engines 250,000 lb. and less than 300,000 lb. on drivers	5.60	3.80	3.80
Engines 300,000 lb. and over on drivers	5.75	4.00	4.00
Mallet engines less than 275,000 lb. on drivers	6.00	4.00	4.00
Mallet engines 275,000 lb. and over on drivers	6.50	4.25	4.25

*Oil differential not to apply on engines weighing over 215,000 lb. on drivers.

Existing rates of pay per day that are higher than the above minima are hereby awarded.

Work, Wreck, Pusher or Helper, Mine Runs, Circus Trains, and Trains Established for the Exclusive Purpose of Handling Milk.—Through freight rates will apply on all work, wreck, pusher or helper, mine runs, circus trains, and to trains established for the exclusive purpose of handling milk; all according to class of engines; overtime to be computed on minute basis. Through freight rules in this award as to mileage and overtime to apply.

Belt Line or Transfer Service.—The board recognized that in belt line or transfer service the grade of work is clearly different from ordinary switching service, and may, therefore, properly be entitled to higher rate of pay; but the information before the board shows that conditions over the Western territory vary so widely in this service that they are unable to reach an agreement regarding a fair rate for such service. The board, therefore, refers the question of belt line or transfer service back to the engineers and firemen and the managements of the different roads for local settlements, which shall take into consideration the difference between belt line or transfer service and switching service, in fixing the rates of pay.

Grades of 1.8 Per Cent and Over.—The territory in which there exists a differential in rates of pay by reason of gradients has been long established, and we make no change in respect thereto. On railroads where a differential in the rates of pay for engineers and firemen is allowed under schedules in effect October 10, 1913, on account of grades or mountain service, either by excess rates or constructive mileage, such differential shall be maintained in addition to the rates granted by this award.

Narrow-Gage Locomotives.—This request is declined.

Electric Locomotives, Electric Either Multiple Unit or Single, Gasoline or Other Service.—Wherever electric service is installed as a substitute for steam, or is now in operation on any of the railroads parties to this arbitration, or on any of the tracks operated or controlled by any of them as part of their system, the locomotive engineers and firemen shall have the preference for the positions of engineers, or motormen, or helpers on electric locomotives or multiple-unit trains; but this right of the engineers and firemen shall not operate to displace any man operating electric power on any of the railroads parties to this arbitration, on May 1, 1915.

Since the use of electric locomotives or multiple-unit trains upon steam

railways is in so early a stage of development, and there is as yet no approximation to stable conditions, but a wide variation in existing practices, the board find themselves unable, from the evidence before them, to make any uniform rules regulating rates of pay and conditions of service for engineers, or motormen, or helpers employed on such trains. The minimum day's wage of $4.30 for engineers or motormen, and $2.50 for helpers in passenger service, and $4.75 for engineers or motormen, and $2.75 for helpers in freight service is, however, awarded; but the day's work covered by the same, both as regards hours of service and mileage covered, is that which now exists in electric service on the various roads, not that covered under the preceding headings pertaining to "freight and passenger service." This award is without prejudice to existing contracts for such service.

Additional Pay.—Through or irregular freight trains doing work such as loading or unloading freight, stock or company material, switching at stations, spurs, mines, mills, or required to pick up or set out cars, unless cars to be picked up are first out, or cars to be set out are switched together at terminals, or doing any other similar work, shall be paid for same at overtime rates in addition to time or mileage made on the trip.

In the article submitted by the employees the scale for passenger service ranged from $4.50 to $5.60 for engineers and from $2.90 to $3.75 for firemen. In all other classes of service, except passenger and switching service, and Mallet locomotives, the scale ranged from $5 to $6.70 for engineers and $3.25 to $4.50 for firemen. For Mallet type engines they asked rates ranging from $7.50 to $8.25 for engineers and $4.90 to $5.50 for firemen. A separate classification was made for locomotives weighing between 200,000 and 225,000 lb., and between 225,000 and 250,000 lb., while all engines weighing over 250,000 lb., except Mallets, were to be paid the highest rates asked. For divisions where the grade is 1.8 per cent or over, an increase of 10 per cent over valley rates was asked, and for narrow gage locomotives a 5 per cent increase over present rates was asked. For service on electric locomotives the article submitted provided a scale ranging from $4.50 to $5.60 for motormen in passenger service, and of $3.35 for helpers. In other service except passenger and switching the scale provided for rates ranging from $5 to $7 for motormen and $3.75 for helpers. For switching service the article proposed rates ranging from $4.75 to $6 for motormen and $3.10 for helpers.

ARTICLE III.—LOCAL OR WAY FREIGHT.

A minimum of 30 cents per 100 miles, or less, is to be added for local freight service to through freight rates for engineers and firemen, according to class of engine. Miles over 100 to be paid for pro rata.

The employees had asked for an increase of 10 per cent over through freight rates for local or way-freight service, and also for overtime rates in addition to time or mileage made on the trip for through or irregular freight trains doing such work as loading or unloading freight or picking up or setting out cars.

ARTICLE IV.—SWITCHING SERVICE.

Rates of Pay.—The minimum rate of wages per day of 10 hours or less; overtime pro rata on minute basis, shall be:

	Engineers	Firemen
Engines less than 140,000 lb. on drivers	$4.25	$2.70
Engines 140,000 lb. and over on drivers	4.40	2.75
MALLET ENGINES		
Engines 275,000 lb. or less on drivers	5.15	4.00
Engines over 275,000 lb. on drivers	5.40	4.00

Beginning and Ending of Day.—Time to begin when required to report for duty and to end at time engine is placed on designated track or engineer or fireman is released, exclusive of time off for meals.

Meals.—Engineers and firemen in switching service shall be allowed one hour for meals between the hours of 11:30 a. m. and 1:00 p. m., and between the hours of 11:30 p. m. and 1:00 a. m., but if required to work the meal hour or any part thereof, they will be paid for the hour in addition to the minimum day, and be allowed 30 minutes under pay for meals. The time for meals will commence at the time engineer and firemen are released from care of engine. Engineers and firemen will not be required to work longer than 6 hours without being allowed 30 minutes for meals.

Existing rates of pay per day that are higher than the above minima are hereby awarded

The employees had asked for rates ranging from $4.75 to $6 for engineers and $3.10 to $4 for firemen. They also asked that engineers and firemen required to begin service other than between the hours of 6 a. m. and 8 a. m., should be paid two cents an hour in addition. They also asked for overtime at the rate of time and one-half after 10 hours.

ARTICLE V.—BEGINNING AND ENDING OF A DAY.

In all classes of road service, an engineer's or fireman's time will commence at the time he is required to report for duty, and will conclude at the time the engine is placed on the designated track or relieved by hostler at terminal.

The article proposed asked for the payment of 30 minutes as preparatory time in addition to all other time or mileage made on the trip or day, and payment for one hour where rules or schedules require the men to be on duty more than 30 minutes before the time ordered to leave, and when required to be on duty more than one hour, payment for actual time.

ARTICLE VI.—TERMINAL DELAY.

Initial Terminal Delay.—Compensation for initial terminal delay is not allowed beyond that involved in the rule, that pay shall begin in all cases at the time an engineer or fireman is required to report for duty.

Final Terminal Delay.—For freight service final terminal delay shall be computed from the time the engine reaches designated main track switch connection with the yard track.

For passenger service, final terminal delay shall be computed from time train reaches terminal station.

Final terminal delay, after the lapse of 30 minutes, will be paid for the full delay at the end of the trip, at the overtime rate, according to class of engine, on the minute basis. If road overtime has commenced, terminal overtime shall not apply, and road overtime will be paid to point of final relief.

The employees asked payment for initial terminal delay from the time they are called to leave the roundhouse or other point until the departure of trains, and for final terminal delay from the time they arrived at passenger depot or switch leading from main line into yard, until relieved from duty, on the minute basis in addition to time or mileage made on trip.

ARTICLE VII.—AUTOMATIC RELEASE AND TIE-UP.

The request contained in the first paragraph of this article is denied.

Continuous Time.—Engineers and firemen in train service tied up under the law will be paid continuous time from initial point to tie-up point. When they resume duty on continuous trip, they will be paid from tie-up point to terminal on the following basis: For 50 miles or less, or 5 hours or less, 50 miles pay; for more than 50 miles and up to 100 miles or over 5 hours and up to 10 hours, 100 miles pay; over 100 miles or over 10 hours, at schedule rates. It is understood that this does not permit running engines through terminals or around other crews at terminals unless such practice is permitted under the pay schedule.

The rule submitted by the employees provided that engineers and firemen arriving at terminal or end of run are automatically released, and when used again may begin a new day. This paragraph was denied. The continuous time rule provided that engineers and firemen tied up between their terminals will be paid continuous time, no deductions to be made for time tied up.

ARTICLE VIII.—HELD AWAY FROM HOME TERMINALS.

Engineers or firemen in pool freight and in unassigned service held at other than home terminal, will be paid continuous time for all time so held after the expiration of 22 hours from time relieved from previous duty, at the rate per hour paid for the last service performed. If held 14 hours after the expiration of the first 32-hour period, he will be paid continuous time for the next succeeding 10 hours, or until the end of the 24-hour period, and similarly for each 24-hour period thereafter. Should an engineer or fireman be called for duty after pay begins, his time will be computed continuously.

The rule proposed by the employees provided for the payment of continuous time for time held at other than home terminals, including rest period, after the expiration of 15 hours from the time relieved from previous duty, at the rate per hour paid for the last service performed.

ARTICLE IX.—DEADHEADING.

Deadheading on company's business on passenger trains will be paid for the actual mileage at 4.3 cents per mile for engineers, and 2.5 cents per mile for firemen, and for deadheading on other trains at 4.75 cents per mile for engineers and 2.75 cents per mile for firemen; provided, that a minimum day at the above rates will be paid for the deadhead trip if no other service is performed within 24 hours from time called to deadhead. Deadheading resulting from the exercise of seniority rights will not be paid for.

The rule proposed by the employees provided that deadheading on company business should be paid for at the same rate and on the basis as the engineer and fireman on the train.

ARTICLE X.—HOSTLERS.

The minimum pay for hostlers will be $4.20 per day of 12 hours, or less, overtime pro rata. Only roundhouse employees who, in handling engines,

are required to have a knowledge of main line train movements will come under this designation. Engineers and firemen will have preference for positions as hostlers. This will not operate to disqualify those who now hold such positions, nor to prevent same being filled from other classes of employees who may be eligible thereto, who can qualify. All other roundhouse employees handling engines during 25 per cent, or more, of their daily assignment will receive $3 for 12 hours, or less, overtime pro rata. On roads where the right to legislate for hostlers has been conceded by the company to the engineers or firemen, such right as specified in individual schedules shall not be affected by the adoption of this article.

The article submitted by the employees provided that at points where an average of 6 or more locomotives are handled within 12 hours, hostlers shall be maintained; that hostling positions shall be filled from the ranks of the firemen and paid $3.35 per day, and $4.75 per day when required to make main line movements. It was also provided that when main line or road hostlers are paid the same rate as engineers in switching service, such positions shall be filled from the ranks of the engineers.

ARTICLE XI.—EFFICIENCY TESTS.

We recognize the necessity of making efficiency tests, but when such tests are made they should not be conducted under conditions that are hazardous to the employees.

The article submitted provided that the practice of conducting surprise tests by turning switch lights and placing red lights or flags, unaccompanied by torpedoes, beside the tracks, or wiring down automatic signals to proceed position be eliminated.

ARTICLE XII.—ASSISTANCE FOR FIREMEN.

On coal-burning locomotives, either passenger or freight, coal will be shoveled forward at specified points, whenever necessary, or by men riding on locomotives for that purpose, so that it can be reached by firemen from deck of the locomotive. Coal of proper size for firing purposes will be placed on all tenders. It is understood that the committees on individual roads will take up with their respective officers the question of shoveling coal forward on tenders and determine the points where men shall be located to do this work.

The rule is substantially that asked by the employees.

ARTICLE XIII.—TWO FIREMEN.

When a second fireman is deemed necessary on coal-burning locomotives in freight service weighing more than 200,000 lb. on drivers, the matter will be taken up with proper officials of individual railroads by the committee. Failing to reach a settlement, the matter shall be referred to an adjustment commission to be composed of five persons, two of whom are to be chosen by the railroad company, two by the committee, and one to be selected by the four thus chosen, who shall be the chairman of the commission. Should the four men fail to agree on the fifth, then three days after the last of the four have been selected, the fifth man shall be named by the United States Board of Mediation and Conciliation. If, for any reason, the selection of the fifth man cannot be made by the United States Board of Mediation and Conciliation, he shall be named by the United States district judge of the district in which the controversy may have arisen. All expenses incurred in connection with the settlement of such matters shall be borne equally by the two parties to the controversy.

When two firemen are employed on a locomotive as a result of the application of the preceding paragraph, they shall each be paid the rate for the class of engine next below, per Article II of this award.

The employees' rule provided that on coal burning locomotives weighing 185,000 lb. or more, when used in freight service two firemen should be employed.

ARTICLE XIV.—MISCELLANEOUS.

Cleaning of Locomotives.—On railroads where firemen are required to clean locomotives, they shall be relieved of such cleaning.

Setting Up Wedges, Filling Grease Cups, Cleaning Headlights, also Placing Supplies on Locomotives.—Where engineers and firemen are required to set up wedges, fill grease cups, or clean headlights, they shall be relieved of such service at all points where competent roundhouse force is employed. Neither will they be required to place on, or remove tools or supplies from locomotives, fill lubricators, flange oilers, headlights, markers or other lamps at points where roundhouse force or an engine watchman, is employed.

These rules are substantially as requested by the employees.

ARTICLE XV.—OFFICIAL RECORD OF WEIGHTS ON DRIVERS.

For the purpose of officially classifying locomotives, each railroad, party to this arbitration, will keep bulletins at all terminals showing actual weight on drivers of all engines in its service.

This rule is substantially that requested.

ARTICLE XVI.—THROWING SWITCHES AND FLAGGING.

The complexity of the service and the variety of the rules are such that this board does not deem it wise to undertake to formulate a general rule upon [illegible]'s subject at this time.

The rule proposed by the employees provided that engineers and firemen would not be required to throw switches, flag through blocks, or fill water cars.

GENERAL REGULATIONS

In awarding the above rates, rules and conditions it is understood that the engineers or firemen on any railroad may elect to take any daily rate, rule, or condition as herein awarded, but the board denies right of the men to take a part or whole of any rule herein awarded and couple it with a part or whole of any rule in the present schedule and thereby create a new condition not contemplated by the award.

Nothing herein is to be construed to deprive the engineers or firemen on any railroad from retaining their present rules and accepting any daily rate that may be awarded, or retain their present daily rate, and accept any awarded rule. It is further understood that the foregoing does not in any manner conflict with or nullify any part of Article 12 of the arbitration agreement, which reads as follows:

"That any rates of pay, including excess mileage or arbitrary differentials, that are higher, or any rules or conditions of employment contained in individual schedules in effect October 10, 1913, that are more favorable to the employees than the award of said board, shall not be modified or affected by said award."

STATEMENT BY CHAIRMAN

The memorandum filed by Chairman Pritchard is as follows:

"I deem it proper to say that in my opinion the freight rates, as well as the yard rates for firemen and engineers, agreed upon by the board, are not as high as they should be. Nevertheless, the rules as respects weight on drivers, time constituting a day's work, initial and terminal delay and overtime, passenger rates and rules, and other rules, accord to the men substantial benefits which should not be denied them. Therefore, in order that the provisions of the award may be put into effect and the men permitted to enjoy the benefit accruing therefrom, I conceive it to be my duty to join other members of the board in making this award.

"I am satisfied that as respects many of the propositions submitted to us we have approached as near as may be at this time a standardization of many important rules and rates which will, in the future tend to remove many things that have been the cause of innumerable controversies between the railroads and their employees."

STATEMENT OF RAILROAD ARBITRATORS

The statement filed by Arbitrators Park and Byram is as follows:

"That our signatures to the award may not imply approval of it, in principle or in detail, a brief word of explanation seems necessary.

"Any scheme of standardization or approach to it which does not permit of equalization of dissimilar rates and rules, in our opinion, is unsound. The agreement under which the arbitration was held gave no latitude to the board to adjust or reconcile unequal conditions. It was one-sided. It permitted standardization only if upward.

"To such provisions of the award as confer benefits upon men whose present rates and conditions merit adjustment we are in hearty accord; to those who, in our judgment, the testimony showed to have been liberally paid and properly treated, we feel that nothing additional is due, and, in agreeing to changes in their rates and rules and to other conditions of the award, it was only because it was made apparent that these changes were necessary if we were to have an award at all. It appeared to us that for the maintenance of the principle of arbitration for the adjustment of labor disputes, which is the public interest, our duty lay in this direction, even though additional burdens of expense and regulation follow."

MINORITY REPORT OF BROTHERHOOD REPRESENTATIVE

The minority report filed by Messrs. Burgess and Shea, the brotherhood representatives on the board, declared that the decision has not in any manner settled the questions submitted for arbitration and simply postpones any further action on the questions involved for a period of 12 months. It is declared that the board "has substantially disregarded testimony of witnesses for employees relative to the long hours and heavy tonnage trains, and, in fact, all the prevailing conditions in the western country, giving little or no consideration to the exhibits, which in a graphic way clearly set forth the increased productive ef-

ficiency of engineers and firemen, disregarding the evidence contained in numerous reports by railway officials as to the work of firemen on large engines having almost reached the limit of human endurance." It is also asserted that "a great opportunity to bring about industrial peace and the hearty co-operation of the employers and the employees has been lost by the failure of the board to equitably and justly settle the questions involved." The information shown by some of the railroads' exhibits, they say, is calculated to mislead and inaccurately represent the actual facts, for while the wages "in some instances might appear liberal when the aggregate amounts only are considered, close investigation in every case revealed the fact that the engineers and firemen had either run a great number of miles or worked from 13 to 20 hours a day during the month. An attempt to pursue such a method would compel the toiler to work more hours instead of raising the rate per hour."

"The whole theory is so repugnant to us," they say in conclusion, "that we feel it our duty to advise not only all railroad employees, but every organization of labor to seek by every influence to secure the revocation of a law that has the smallest tincture of that principle embodied therein. The unfairness of the award as handed down by a majority of this board compels us to file a dissenting opinion. To do otherwise would tacitly give assent to an award that does not permanently settle any of the questions involved and one that unquestionably will create chaos and ill feeling among all classes of train service employees and particularly engineers and firemen."

Warren S. Stone, grand chief of the Brotherhood of Locomotive Engineers, and W. S. Carter, president of the Brotherhood of Locomotive Firemen and Enginemen, in a statement given to the newspapers said that they had been "grossly deceived in being compelled to submit the case to a jury on which sat not only two railroad officials, but also one alleged neutral arbitrator who has shown by his conduct and demeanor throughout the whole hearing that he was the violent partisan of the railroads." Even before the award was filed they attempted to cast discredit upon it by sending protests to President Wilson and the members of the United States Board of Mediation and Conciliation at Washington, demanding the removal of Mr. Nagel as an arbitrator, on the ground that they had just discovered that he was a trustee of the Adolphus Busch estate of St. Louis, and a director of the Union Trust Company of St. Louis, and of the Northwestern Mutual Life Insurance Company of Milwaukee, all large holders of railroad securities. Messrs. Chambers and Knapp of the Board of Mediation and Conciliation, and later President Wilson, replied asking that the protest be withheld, but it had already been filed with the board of arbitration. After an exchange of telegrams and a conference with the President the Board of Mediation and Conciliation declined to act on the protest, saying that Mr. Nagel's connection with the Busch estate was known to the board before his appointment. It was not recalled that any of the board knew he was a director of the companies named, but a knowledge of that fact would have been favorable rather than otherwise to his appointment. The telegram continued:

> You doubtless had as much information regarding Mr. Nagel's business connections as any member or officer of this board prior to his appointment, and you had ample time to make further inquiries before the organization of the arbitration board and the acceptance of his services, and certainly before the extension of the life of that board, which was the act of yourselves by agreement with the railroad representatives independently of the board of mediation and conciliation.
>
> The foregoing statement is not made for the purpose of escaping any responsibility on the part of any member or officer of this board for Mr. Nagel's appointment, for nothing was known before his appointment nor has been brought to our knowledge since his appointment which in our opinion disqualifies him as an arbitrator, and our confidence in his ability and integrity remains unchanged.

Messrs. Carter and Stone announced that they would not attempt to appeal from the award to the courts, but that they would abide by it for a year. At a meeting in Chicago on Sunday and Monday of the general chairmen of the two organizations to consider the award, resolutions were adopted recommending that the executive officers of the brotherhood endeavor to obtain a congressional investigation of the award and of the appointment of Mr. Nagel.

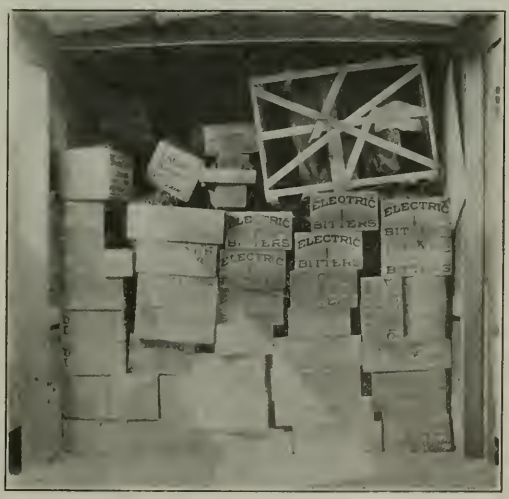
CAREFUL LOADING OF PACKAGE FREIGHT

The Chicago & Alton, at its freight houses in Chicago and St. Louis, has been making some interesting experiments in the loading of package freight with a view to economizing space (and therefore saving cars), and also looking to the reduction of

Bulkhead Used in Chicago & Alton Freight Cars

breakages and a consequent diminution of claims for loss and damage.

O. Ashworth, freight claims inspector, as a result of his study of a large number of damage claims, concluded that better



Twenty-five Ton Load After a Journey of 284 Miles; Bulkhead Removed

stowing in the cars would prevent a good deal of damage, and he suggested the use of bulkheads in the cars to hold packages in place. In the past, merchandise cars have been loaded with only about 12,000 lb. to 20,000 lb., with a view to keeping at the minimum the damage from shifting. In commencing the experiments with bulkheads, it was found that to secure the best results, packages should be loaded to the roof. With each of the two ends—two half cars—nearly filled, loading was stopped and the bulkheads were put up. For these old doors of worn-out box cars were utilized. These were braced with scantlings 2 in. x 4 in., the pieces being attached to the center of the old door by a pivot, and the ends held in place by cleats at the sides of the car. The cost of nails, lumber and labor in applying the bulkheads was trivial, and the same material is used over and over again.

It developed that usually cars could be loaded with 40,000 lb. of freight, while in one instance, a car was loaded with 49,500 lb.

Of 31 cars which were loaded for test purposes, and which contained 12,440 packages, only one turned out other than perfect. In this car one package was found damaged to a trifling amount. Under former methods of loading, and without the protection of bulkheads, damage claims are reported to have averaged three per car, amounting perhaps to $10 a car. Thus in carrying six or seven hundred tons of freight there was an estimated saving of perhaps $700 to $1,000 in the prevention of claims and the saving of the time of 60 cars; or, if there is a surplus of cars, still there is the saving of the unnecessary haulage of 60 cars, and saving of track room at freight houses, etc.

The prevention of damages in transit is, of course, a constant element in the successful carrying on of the freight business in a way to satisfy shippers and consignees.

WHERE THE DELIVERING AGENT FALLS DOWN

By D. C. Davis

Shippers of less than carload freight, of uniform kind or in uniform containers, frequently *mark* one or more packages too many for one consignee and destination and one or more too few packages for another consignee and destination.

These shipments may be sent in ferry cars to a transfer and the receiving clerk may never see them; or they may be loaded into the car by the shipper's drayman at a station and the receiving clerk may never have an opportunity to check the markings with the shipping order; or the receiving clerk may have an opportunity to check the shipment and not notice the errors in marking, being satisfied as long as he counts up the number of packages and finds it corresponds with the number called for on the shipping order. In either case the shipper is furnished with a bill of lading and the railroad's responsibility begins.

The result of such an error would then be something like this: The agent at, say, San Francisco receives six boxes of soap for John Jones, while he holds billing for five boxes only (one over). The agent at Boston receives four boxes of soap for William Smith, while he holds billing for five boxes (one short).

The agent at San Francisco, knowing Jones to be a reliable man, and on the accommodation list, credit good, turns over all the boxes to Jones and puts out a request for correction of billing, which may or may not come along in six months or a year. Anyhow, it is all forgotten and Jones is in a box of soap, innocently or otherwise.

Right here is where the delivering agent falls down. He should never have delivered this package to Jones without presentation of bill of lading, or other proof of ownership.

In the meantime let us look into the Boston situation. William Smith has been billed for five boxes of soap and has only received four boxes. He waits a while and then puts in a claim for the other box. Investigation is made, the goods are found to have been received and checked O. K. at originating point; short at destination, one box; somewhere in between shipping point and destination a box has gone astray or has been stolen. Good checking through transfer stamps may enable the investigator to finally locate where the over package went to. The difficulties of this, however, increase with the distance the two destinations are apart.

Then come up questions of duplicated orders and depreciation in price and quality of goods and before the matter is eventually settled, if it ever is settled, there have elapsed months, perhaps years, and considerable labor, back haulage or corrections of billing, and other things too numerous to mention, to be adjusted.

The decision of the I. C. C., June 23, 1913, that where merchandise is improperly addressed, the shipper making the error must bear the burden of the resulting freight charges and the fact that the correct address was noted on the bill of lading is not material, will go far towards making shippers more careful in marking their shipments properly, but there will always be a large amount of freight improperly addressed as long as shippers hire as shipping clerks boys who do not realize the importance of properly marking every package or clerks who are careless or inattentive to their duties. A good shipping clerk is a valuable asset to any firm.

The writer of this article is in a position where he has observed hundreds and perhaps thousands of errors similar to the above and is convinced that if shippers will instruct their shipping clerks to use extra care in checking the packages with the shipping order or bill of lading, before presenting goods to the railroad for shipment, a great improvement will be made in the overs, shorts and claims.

Furthermore, if the railroad receiving clerks will be careful to check the marks on the packages with the shipping order when received and the delivering agent will deliver only on presentation of bill of lading or other proof of ownership, the marks on the package not being a sufficient proof of ownership, as demonstrated above, a great deal of useless labor, expense and mis-delivery of packages can be avoided.

SAVING WASTE GRAIN

The Rock Island agent at the Silvis (Ill.) transfer, constructed a rat-proof grain bin last fall, holding 25 to 30 bushels of grain, and began systematically to save the grain recovered in the sweeping of empty cars placed at the platform for loading. This was done at practically no expense, as it was necessary to clean the cars before loading and regular employees were utilized in the work. As opportunity offered he also collected any grain spilled from bad order cars in the Silvis yards. This grain was sold from time to time and the receipts turned into the company treasury through the local agent. While this grain was damp and more or less dirty, it made good chicken feed and no difficulty has been found in selling it at $0.80 per hundred pounds. The amount recovered in four months was as follows:

November, 1914	$15.05
December, 1914	71.80
January, 1915	64.10
February, 1915	116.60
Total	$267.55

The Deniliquin Railways of New South Wales.—It is stated that the government of New South Wales contemplates taking over the Deniliquin & Moama Railway line, which forms the connecting link between the first-named town and the Victorian railway system at Echuca. Should this be done and the line be extended further northwards, and should the proposed line from Moulamein to Moama (immediately north of Echuca) be carried through, an enormous area of wheat land will be opened up.

Reclamation of Scrap on the Great Northern

Large Savings Made by Reworking All Wrought Iron Scrap Into Bar Iron at the Company's St. Cloud Mill

The geographical location of a railroad governs to a large extent the practices to be followed in the reclamation of scrap material. Some roads find it to their advantage to concentrate the classifying, reclaiming and salvaging at one principal point on the system, while other roads salvage and reclaim a great amount of material at the various shop points, leaving the classifying to be done at the scrap docks. This latter practice the Great Northern has found it expedient to follow, owing to the number and location of its shops; and its shop men are so trained that but little usable material finds its way to the general scrap docks. Thus it is only necessary to classify the scrap, salvaging

Fig. 1—Scrap Pile at St. Cloud, Minn.; Great Northern

what material is picked up from the road, such as track material, wreckage, etc., which is brought directly to the scrap dock.

The bulk of the scrap is received at St. Cloud, Minn., 75 miles west of St. Paul, where it is sorted and held for shipment to the scrap dealers, with the exception of the wrought iron scrap which is salvaged or worked over into first class bar iron in the rolling mill at that point. On the extreme west end of the system the scrap is classified and sold direct to the mills in that vicinity. By following this plan a large amount of cross hauling of the reclaimed material is eliminated, the stores department is relieved of a large amount of accounting, since the material reclaimed is turned directly into the local stock, and the shops receive direct credit for the amount of material they reclaim.

While the company has met with marked success in operating on this basis the chief point of interest is the reworking of the wrought iron scrap at St. Cloud. At this point the company operates a full fledged rolling mill for this purpose, and since it was started in August, 1913, it has reworked all of the wrought scrap originating on the entire system at a substantial profit. During the year 1914 this mill produced 8,863,835 lb. of bar iron, divided into various classes as follows:

Round iron, common	6,326,865 lb.
Square iron, common	42,780 lb.
Flat iron, common	1,852,635 lb.
Deformed iron, common (for reinforced concrete)	14,505 lb.
Hexagonal iron, refined	91,480 lb.
Round iron, refined	507,407 lb.
Flat iron, refined	28,163 lb.
Total	8,863,835 lb.

This was done at a cost of less than 90 cents per 100 lb., on an average, this figure including the cost of the scrap at current prices and all overhead charges, and it is conservatively estimated that a saving of over 25 per cent has been made on the market price of the iron rolled.

The mill is operated as a distinct unit and is under the direct jurisdiction of the superintendent of motive power in charge of shops. All the work connected with it is done on a contract basis, the standard rolling mill scale being followed consistently. The wrought scrap is sold to the mill by the stores department, as to an entirely independent concern, at the prevailing scrap prices, and the mill sells, as it were, direct to the stores department, charging for the material the cost of production, which includes the scrap cost and all overhead charges. This price is carried in all the general price lists and is changed monthly. As the mill is able to supply the needs of the system there is no confusion with the outside market prices. The work of the mill is done on a shop order basis, the orders being issued by the stores department for a sufficient quantity to warrant the changing of the rolls.

The workmen in the mill are all experienced mill men, it being found quite desirable to obtain them from other mills rather than to attempt to educate the local men to do the work. The force consists of one head roller who has charge of the mill and with whom the contracts are made, two roughers, two stranders, two finishers, one catcher, one hooker-up (these men pass the heated bars through the rolls), two heaters, two helpers, two

Fig. 2.—Wrought Iron Scrap Ready to Be Made Into Piles for Rolling Mill

straighteners, two shear men and four pilers, all of whom are paid out of the contract price.

The scrap as it is received from the system is shown in Fig. 1. It is classified from this pile and delivered to the scrap bins, with the exception of the wrought iron scrap. The rods in good condition and of a diameter generally used at different points, are cut to length, straightened and applied against any orders for such material. The wrought iron scrap which is not thus handled is cut to proper length for piling, sorted and delivered to the piling bench. Fig. 2 shows a pile of the smaller pieces just outside of the mill. As it is required it is shoveled through the window onto the piling bench shown in Fig. 3. Here it is made up into piles varying from 75 lb. to 250 lb. in weight. The flat iron is used for the sides and battens of the piles.

The wrought iron axles are sheared to length as shown in Fig. 4. This iron is rolled into what is known as the refined

iron mentioned in the output table given above. It is used for engine bolts, all rivets except those used in boiler work, and such other material as requires a better grade of iron. The iron made from the piles is known as common iron. The piles are heated in two large oil furnaces of the reverberating type, each having a capacity of 1,900 lb. per heat. These furnaces are located in front of the rolls, one on each side, and each furnace is used in rotation; that is, while one is feeding the rolls the other is heating its charge to the proper rolling heat. The heated piles are carried from the furnace to the mill, a rear view of

Fig. 3—Piling Bench at St. Cloud Rolling Mill

which is shown in Fig 5, by long tongs suspended from an overhead trolley which runs between the two furnaces and the roughing rolls shown on the left in the photograph.

The mill is what is known as a 12-in., three-stand mill, there being three sets of housings. The rolls in the different stands are connected by flexible couplings and the entire mill is driven by a 125-hp. Buckeye engine. The housings of the mill were built by the company and the rolls purchased from the United Engineering & Foundry Company, Pittsburgh, Pa. For the entire work of the plant 44 separate rolls are required. These are maintained in condition by a machinist, a special room being assigned

Fig. 4—Sheared Wrought Iron Axles Which Are to Be Rolled Into Refined Iron Bars

to this purpose (see Fig. 6). The rolls are such that the following sizes of bars may be rolled:

Round iron	½ in. to 1⅞ in.
Square iron	½ in. to 1½ in.
Hexagonal iron	⅞ in. to 1⅜ in.
Flat iron	¼ in. to 1 in. by 2 in.
	⅜ in. to 1 in. by 1½ in.
	⅜ in. to 1 in. by 1¾ in.
	⅜ in. to 1 in. by 2 in.
	⅜ in. to 1 in. by 2½ in.
	⅜ in. to 1 in. by 3 in.
	⅜ in. to 1 in. by 3½ in.
	⅜ in to 1 in. by 4 in.
	½ in. by 1⅞ in.

In addition to this deformed iron is rolled for concrete reinforcing bars. All but the ½-in. round iron is rolled to size in one heat. This is made into billets in order to produce the necessary homogeneity of metal for the small bar.

As the finished bar comes from the rolls it is placed on a hot bed. Bars have been rolled as long as 200 ft. The maximum output made by the mill is 75,000 lb. for one day (a day

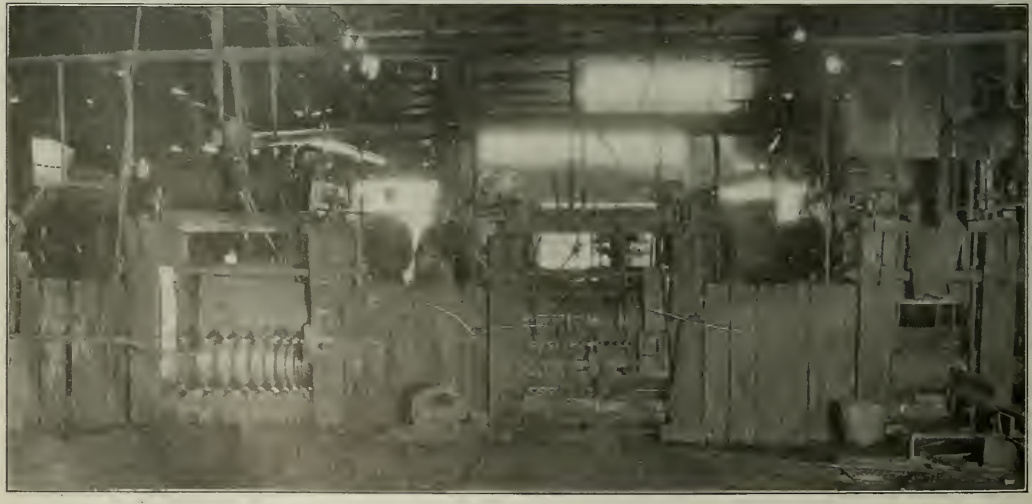


Fig 5 - Rear View of the Rolling Mill; Roughing Rolls on the Left

is governed by the run of the heats) and 1,480,000 lb. for one month. The bars are taken from the hotbed while still hot, passed over a series of large diameter rollers and cut to length, usually 16 ft., on an alligator shear. They are then weighed on track scales and placed in stock as shown in Fig. 7. The refined iron

Fig. 6—Shop for Maintaining the Mill Rolls

is distinguished from the common iron by red paint on the ends. Taken as a whole the mill occupies a space 250 ft. long by about 45 ft. wide.

With all this material collected at this point it has been found expedient to manufacture bolts, rivets and grab irons at St. Cloud for the entire system. During the year 1914 over 1,600,000 bolts were made at an average cost per 100 lb. of $1.20 without nuts, this cost including the cost of the iron as produced by the mill, labor and the necessary overhead expense. In addition to this 322,740 ½-in. carriage bolts were made at an average cost of $1.60 per 100 lb. without nuts. One hundred and seventy-six thousand rivets were also made at an average price of $1.25 per 100 lb. boxed. This latter item alone represents a saving of over 300 per cent. The bolts and rivets under 9 in. in length are made in an automatic Ajax bolt machine which is fed directly from a furnace handling the 16-ft. rods. This machine will produce on an average of 1,500 lb. of rivets per hour and 4,000 bolts. Fig. 8 shows some of the carriage bolts thus made. The bolts over 9 in. in length are made on a continuous motion bolt machine, which will produce 1,200 bolts per hour.

As stated in the first part of this article the local shops do what reclaiming is possible. For instance, a group of machines

Fig. 8—Carriage Bolts Made on Automatic Bolt Machine

is used in the freight car repair shop at St. Cloud for reclaiming the bolts and nuts taken from the cars under repairs. It consists of a four-head threading machine, a small shear and a six-spindle nut tapping machine. Those bolts and nuts that are found suitable for use are placed directly in bins in the shop for immediate use. Those bolts that are slightly damaged are

Fig. 7—Storage Yard for Finished Bar Iron

sheared off, rethreaded and placed directly in the available stock, and the nuts that are badly rusted are tapped and also made available for immediate use. Large quantities of bolts are thus reclaimed with all the otherwise necessary accounting and transshipping eliminated.

In addition to the manufacture of bar iron at St. Cloud the Great Northern makes all of its heavy bar iron from 2 in. up to 12 in. square for the system at its Dale street, St. Paul, Minn., shops under a 4,000 lb. hammer. The scrap is made into piles of 250 lb. and hammered into slabs and held in stock for shop orders for heavy bar iron. This shop slabs 11,000 lb. per day. In cases of emergency the material is worked into driving axles. The company also maintains its brass foundry at this point, where all the brass scrap is received and used. This foundry provides the necessary brass castings for the entire system and has a capacity of 15 tons.

TRAIN ACCIDENTS IN MARCH[1]

The following is a list of the most notable train accidents that occurred on railways of the United States in the month of March, 1915:

Collisions

Date.	Road.	Place.	Kind of Accident.	Kind of train.	Kil'd.	Inj'd.
1.	C. R. I. & P..... C. & N. W.....	Cedar Rapids.	xc	F. & P.	1	8
31.	Cleve. & Pitts.....	E. Liverpool.	rc	P. & F.	0	1

Derailments

Date.	Road.	Place.	Cause of Derailm't.	Kind of train.	Kil'd.	Inj'd.
1.	Southern	Juliette	d. track	P.	1	1
1.	Boston & Maine.....	Pownal.	d. coupler	F.	0	0
4.	Central Vermont.....	Cambridge.	unx	P.	0	7
3.	Georgia	Buckhead	unx	P.	1	1
†5.	Atch. T. & S. F.....	Elsinore.	.....	P.	1	14
14.	Chicago & E. I.....	Shelburn.	unx	P.	1	2
16.	Macon & B.....	Upson, Ga.	unx	P.	0	5
23.	N. Y. N. H. & H....	Devon.	neg	P.	0	1
26.	Baltimore & Ohio....	Meyersdale.	b. wheel	F. & P.	0	4

The trains in collision at Cedar Rapids, Iowa, on the first, were a switching engine of the Chicago, Rock Island & Pacific and a passenger train of the Chicago & North Western, the switcher running into the passenger train, which was standing still. The engineman of the switcher, who was out on the running board, started, as soon as he saw the danger, to go back into the cab, but he was knocked off and killed; and eight other trainmen were slightly injured. The collision was due to the inexperience of the firemen, who was running the engine while the engineman was outside the cab.

The trains in collision near East Liverpool, Ohio, on the 31st, were an eastbound passenger and an eastbound freight, the passenger running into the freight. The caboose and three freight cars were damaged. One employee was injured. The passenger train, running under a permissive block signal, approached the freight, which had been stopped near the station, at uncontrollable speed.

The train derailed at Juliette, Ga., on the first, was southbound passenger No. 6, and the baggage and the express cars were overturned. The baggageman was killed and his helper was injured. There were 50 passengers on the train, none of whom are reported injured. The tender was the first vehicle to leave the track, and it is said that the cause of the derailment was a loose rail.

The train derailed on the Boston & Maine at Pownal, Vt., on the first, was a westbound freight, consisting of two engines and 70 cars. The train, moving about 30 miles an hour, broke apart at the eleventh car from the rear end by the failure of a draw-bar, which became loose in consequence of the loss of nuts from the yoke strap bolt. The separation of the cars caused the application of air brakes in emergency; and this caused such a shock that the fifteenth car from the engine was separated from the sixteenth by the pulling out of its draw-bar. This draw-bar, when it fell to the track, derailed the four following cars. One of the derailed cars struck the passenger station and demolished it, and another in the same way destroyed the freight house.

The train derailed near Buckhead, Ga., on the night of the third, was eastbound passenger No. 4, and four passenger cars were overturned. A freight car on a side track took fire and it, together with the locomotive, were badly damaged by the flames. The fireman was killed and one passenger was injured. In the four cars overturned were about 60 or 70 passengers, yet only one was seriously injured.

The train derailed near Cambridge, Vt., on the fourth, was an eastbound passenger, and two coaches fell down a bank. Four passenger, two employees and an express messenger were injured. The cause of the derailment was not determined.

The train derailed near Elsinore, Cal., on the fifth, was a southbound passenger. The rear coach had its rear truck derailed at a frog, just before reaching the bridge over the San Jacinto river. The truck slewed and pulled the car out of line and it was detached from the car ahead and was overturned, dropping about 17 ft. This car had a steel underframe and was but slightly damaged. One passenger was killed and the conductor and 13 passengers were injured. The train is said to have been running not more than 12 or 15 miles an hour, but the rail, on the curve (of 12 deg.), approaching the bridge was somewhat worn, and the roadbed was soft by reason of a heavy rainfall.

The train derailed at Shelburn, Ind., on the 14th, was the southbound Dixie flyer. The engine and three cars ran off the track and the station building was damaged. The engineman was killed and two trespassers were injured. The cause of the derailment was not discovered.

The train derailed near Upson, Ga., on the 16th, was mixed train No. 6, and one freight car, one mail car, the baggage car and two coaches fell through a trestle bridge 17 ft. to the ground below. The mail clerk and five employees were injured.

The train derailed at Devon, Conn., on the 23rd, was an eastbound express. The engine and first three cars ran off a derailing switch and stopped close to the abutment of the bridge over the Housatonic river. The fireman jumped off and was slightly injured. The train had run past distant and home signals set against it, and went off the derailing switch at about 10 miles an hour. The engineman at fault was a runner of experience, with a good record.

The trains involved in the wreck at Meyersdale, Pa., on the 26th, were an eastbound freight and a westbound passenger. The freight was derailed by the breaking of a wheel, and one car fell against the passenger train, which was passing on the adjacent track. Two passenger cars were badly damaged, and four passengers were injured.

[1]Abbreviations and marks used in Accident List:
rc, Rear collision——bc, Butting collision——xc, Other collisions——b, Broken——d, Defective——unf, Unforeseen obstruction——unx, Unexplained——derail, Open derailing switch——ms, Misplaced switch——acc. obst., Accidental obstruction——malice, Malicious obstruction of track, etc. ——boiler, Explosion of locomotive on road——fire, Cars burned while running——P. or Pass., Passenger train——F. or Ft., Freight train (including empty engines, work trains, etc.)——Asterisk, Wreck wholly or partly destroyed by fire——Dagger, One or more passengers killed.

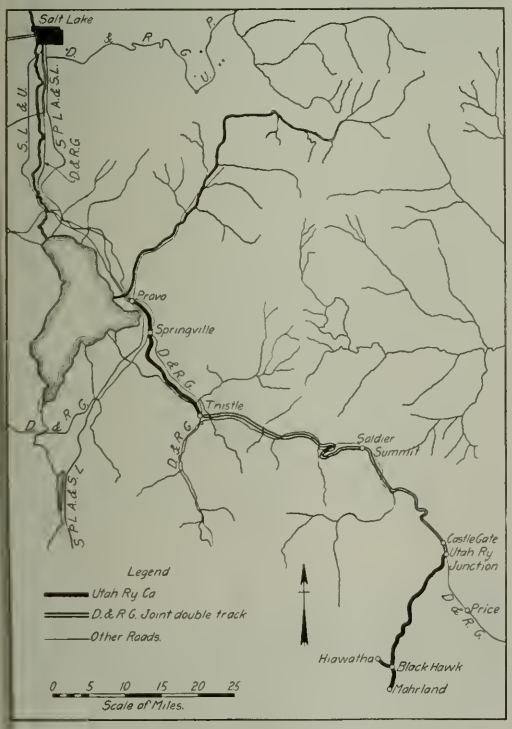
THE NEW FLAGMAN.—No flagman should be put on duty until he has learned the road and passed a satisfactory examination. The conductors should use care in working the new flagman, being careful they go back, carry the necessary signals with them; and to caution them in going back, especially at night, about how far they should go. Unless the new man is cautioned he will likely go back half the distance he should, partly on account of not knowing how far to go, poor judgment of distance at night, and for fear his train will go off and leave him in the woods. While we should never have in our employ a flagman so irresponsible as to make it necessary for the conductor to follow him and see that he does what the conductor tells him to do, yet I know of two cases in the past few years where, if this had not been done, collisions would have occurred.—*E. H. Daniel, in the Railroad Herald.*

Construction of New Line to Reach Utah Coal Fields

Required Movement of 100,000 Cubic Yards Per Mile, Much of Which Disintegrated Badly Upon Exposure

The Utah Railway Company was incorporated on January 24, 1912, as the Utah Coal Railway Company, which name was changed to the Utah Railway Company on May 4, 1912. The purpose of the organization was to construct a standard gage railroad from Provo to the coal fields of Carbon and Emery counties, Utah.

The coal fields to be served are a part of the Book Cliffs coal field, in the western extension of the Uintah coal region in the Rocky mountains, being, for the most part, that portion of this field south of the angle defined by the canyon of the Price river and lying along the easterly escarpment of the Wasatch range which forms the easterly rim of the Salt Lake basin. They are



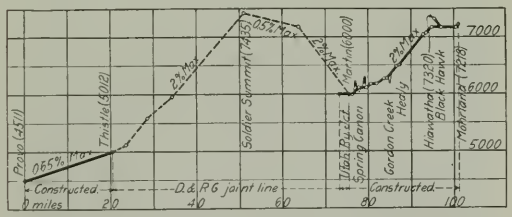
Map of New Line of the Utah Railway Between Provo, Utah, and Mohrland

known locally as the Castle Valley coal fields, Castle Valley being located at the base of the escarpment.

The coal outcrop in this section of the Uintah coal region is in the escarpment and at an elevation of 7,500 to 8,500 ft. above sea level, hence well up on the sides of or near the summit of the more elevated portions of the Wasatch range, making necessary the use of trams or other devices for carrying the coal from the mine openings to the tipples which are usually located near the foot of the escarpment. Coal seams in this section are usually nearly level, and carry little, if any, water.

Coal was being mined at the time of incorporation at Spring Canyon, Hiawatha, Black Hawk and Mohrland, as well as at openings along the Huntington river, capable of producing a large tonnage of a high grade of bituminous coal, for which there was a market. The output of these mines was limited and the marketing irregular by reason of insufficient railroad facilities. Three years previous, a line of railroad had been constructed from Price, Utah, to serve the mines at Hiawatha, Black Hawk and Mohrland, but it had proved inadequate for the requirements.

That portion of the coal field under consideration is cut through by the Price and Huntington rivers, and on account of the Price River canyon, Soldier Summit, Soldier Creek and Spanish Fork canyons being occupied by the Denver & Rio Grande, careful study was given the country for other routes, but Soldier Summit being the lowest summit available it was decided to encounter the difficulties consequent upon its use, as well as the use of canyons leading therefrom, occupied by an existing line of railroad, in preference to adopting a route calling for the crossing of the range by summits of a much greater elevation. In fact, the next lowest summit considered was at an elevation nearly 1,500 ft. greater than that of Soldier Summit, which has an elevation of 7,450 ft. above sea level. After careful study of the country by means of preliminary instrumental surveys it was decided to adopt a maximum grade of 2 per cent compensated for curvature, and a maximum curvature of 8 deg.;



Profile of New Line of Utah Railway and Joint Line with D. & R. G. Over Soldier Summit

all curves having a radius of less than 2,865 ft. being spiraled for a speed of 25 miles per hour.

The country traversed between Provo and Thistle presents no unusual features, about two-thirds of this distance being along and upon a bench of cultivated land said to have been formed by wave action of an ancient lake, while the remaining one-third is in the canyon of the Spanish Fork river alongside the D. & R. G. track and near the bottom of the canyon.

From Utah Railway Junction to Mohrland the line as located is just outside the foot of the abrupt slope from the projecting sandstone-capped promontories or fingers of the escarpment. The country at the foot of the cliff-like escarpment slopes rather abruptly to Castle Valley and at intervals is deeply cut by drainage channels, none of which, with the exception of Gordon Creek show a surface flow, except after storms or during periods of melting snow. Most of these channels show evidence of rushes of water in considerable volume, which, by reason of the steep slope, have moved many boulders which are profusely distributed along the drainage courses. The shale which forms most of the ground surface that is not denuded sandstone, disintegrates under exposure to such an extent that it gullies freely under a flow of water, resulting in an uneven washing and wearing down of the surface, leaving it in the form of heavy corrugations deeply cut by gullies with steep slopes. Many of these gullies have cut down to ledges of sandrock which form the floor of the wash, while at places during storms the water rushes over the outcrop of these ledges forming water falls of considerable

height. To the east and 1,500 to 2,000 ft. below the line can be seen the comparatively level Castle Valley, some six miles distant.

As the surveys progressed and the possibilities of the country developed it was decided to fix the western terminus of that portion of the line to be constructed at that time, at Provo, Utah, in the Utah valley, 48 miles south of Salt Lake where a junction was possible with two steam lines, the Denver & Rio Grande and the San Pedro, Los Angeles & Salt Lake, and one electric line, the Salt Lake & Utah, all of which have direct lines with favorable grades between that point and Salt Lake or Ogden.

In fixing the location of the line between Thistle and Castle Gate traversing the deep, narrow and crooked canyons of Spanish Fork river, Soldier creek and Price river, with the restrictions as to grades and elevation mentioned, care and patience was necessarily exercised. The fact that the D. & R. G. has a through line, double-tracked for a portion of the distance, located for the most part in the bottom of these canyons, was something of an obstacle in addition to the extreme roughness and moun-

Typical Construction Work North of Blackhawk

tainous character of the country traversed, but the interests back of this project at no time lost sight of the desirability of securing a line that could handle economically the traffic of a heavy output from the coal fields to be served.

Grading on this line was begun near Mohrland, the southern terminus, in September, 1912, and near Thistle in November of that year, although at that time the location of the line on several sections had not been fixed and several revisions and modifications were afterwards found desirable. After the location of the entire line had been substantially fixed and construction started at both ends, negotiations were entered into with the D. & R. G. with a view to avoiding, as far as possible, interference with its existing and operated tracks. These negotiations finally developed into an arrangement whereby the D. & R. G. improved its line and completed a second track between Thistle and Helper with favorable grades and curvature, with an arrangement under which this trackage could also be used by the new company. It was also arranged for the D. & R. G. to use jointly the Utah Railway trackage under construction between Provo and Thistle. As this arrangement provided trackage for the Utah Railway Company from Thistle to near Castle Gate, over D. & R. G. property and tracks, no construction was started between these points, construction being confined to that portion of the line between Provo and Thistle, and between Castle Gate (Utah Railway Junction) and Mohrland.

Between Provo and Thistle, 20.7 miles, the line was so constructed as to permit of its being used as an east bound track by the D. & R. G., with a maximum grade rate of 0.65 per cent against east bound traffic, and a maximum curvature of 4 deg.

Looking North from Blackhawk Along the Utah Railway

Where practicable, conforming with the above standards, it was constructed alongside the operated track, which was in part reconstructed and modified to conform therewith. For about one-third of this distance it was necessary to detour from the operated line to a maximum distance of about one mile.

The principal features of interest on this part of the line consisted of changes in the channel of Spanish Fork river and the rectification of the main line and other trackage of the D. & R. G. between these points. The construction of this 20.7 miles was supervised and handled by the D. & R. G. in behalf of the Utah Railway Company, and the track was laid and put in operation as an east bound track for the D. & R. G. August 1, 1914.

Although construction on a connection with the D. & R. G. between Castle Gate and Helper, designated as "Utah Railway Junction," and Mohrland, 26 miles, was commenced at Mohrland in September, 1912, the final location of this portion of the line was not completed until the spring of 1913, when the entire work was placed under construction. This location, although made with care, called for an unusual percentage of curved line,

The Gordon Creek Steel Girder Viaduct on the Utah Railway

about 46 per cent of the total length being curved and over 62 per cent of this curved line being on curves of 6 deg. or over, the total angle in the 26 miles of line being 3,090 deg. 56 min.

On account of the extremely rugged nature of the country, the surface of which consists largely of sandrock and black shale common to the coal formations in this section of the mountains, some heavy and expensive work was necessary to secure a railroad of the type desired. In view of the high cost of grading consequent upon the irregularities of the country, efforts were made to so fix a location as to give a fair balance to the excavations and embankments, as on many sections of the line little or no borrow was to be obtained except by blasting.

Although the shale which constituted a large per cent of the

excavated material had an earthy appearance upon the natural surface, when penetrated it developed a hard, almost rocky nature, quite difficult for drilling and blasting, although upon exposure to the atmosphere, it frequently crumbled rapidly into an earthy form. Large masses of this shale rock taken from the excavation and placed alongside the grade would crumble in a few months to a mound of earthy material, giving little indication of its formidable character to the grading forces, or the expense required for its removal. Swelling of the material removed from an excavation was frequently as much as 50 per cent, yet after a few months' exposure it would slack and shrink to nearly its original bulk. Culverts and other structures placed under embankments of this material were affected by this unstability, in some cases quite unfavorably, as, dependent somewhat upon the manner in which the material was placed, different action would result, the swelling and shrinking sometimes resulting in the movement of certain parts of certain layers of the embankment. In one or two cases where embankments built of this material abutted on solid formations, by reason of this resistance portions of these embankments seemed actually to creep up-hill in their efforts to expand during the swelling period.

As to future permanency of embankments constructed of this unstable material, it is the opinion of those most familiar with its characteristics that the outer portions of these embankments will disintegrate or slack upon exposure to the atmosphere, thereby filling the interstices of the broken material underneath to such an extent that continued slacking will not proceed to a great depth into the embankment, but that the outer surface will in effect be sealed by the slacking of the more exposed portions and that thereupon further disintegration will take place slowly, if at all.

While usually massive and coarse sandstone was encountered, occasional layers were found that might be termed a good grade of building stone. The larger portion of this sandstone seems to partake somewhat of the nature of the shale with which it is associated and it is not unusual to find heavy layers of this sandstone, the surface of which slacks and crumbles quite freely after exposure to the atmosphere for a few months.

The grading of the roadbed for this 26 miles of single track railroad called for the moving of slightly over 2,673,000 cu. yd. exclusive of 1,638 lineal feet of single track tunnels. Of these roadbed quantities about 62 per cent was classified as solid rock, 26 per cent as loose rock and 12 per cent as earth. The tunnels, 615 and 803 feet long, respectively, were both on 8-deg. curves, through rock and shale formations. No water was found in driving these tunnels.

On account of the aridity of the climate, no unusual drainage features were encountered. Only one bridge was required to serve drainage. This was at Gordon creek, which is in a deep gash or gully where crossed by this line. While the normal flow of this stream is not over 20 sec. ft., it is subject to rushes of water from summer storms or cloudbursts which indicate at times 4,000 sec. ft. The bridge or viaduct across this stream has a height of 135 ft. above the creek bed, and a length between back walls of end abutments of 624 ft. The bridge consists of 5 spans of 80 ft., and 1 span of 60 ft., deck plate girders supported by 1 steel bent and 4 steel towers, these towers carrying 40 ft. steel girder tops. The entire bridge is on a 6 deg. curve. Over Spring Canyon creek two 60-ft. deck plate girders were used, this crossing serving for drainage as well as for a branch line of railroad underneath. One temporary wooden bridge 105 ft. long was used over the Southern Utah Railway, the uncertain future of that line of railroad not justifying a permanent structure at the crossing. For mining waterways, rock wall culverts, arch and box type, or beam girders on concrete walls were used, as well as cast iron pipe with rock end walls. The largest arch used was a 16-ft. span with a length of 175 ft.

The roadbed for one foot or more in depth, as was thought necessary, was formed of selected material, which was hauled considerable distances in some cases. Before the track was laid this was brought in by teams, and after track had been laid by trains. While this selected material was in no case first class for the purpose, it served to cover and protect the shale and to a great extent retard or prevent its disintegration, and to form a reasonably firm and somewhat elastic roadbed to shed such moisture as was likely to fall thereon and upon which the track has been successfully maintained at a reasonable cost to date. There being no natural ballast available in this section of the country, no ballast was used, the track being put to line and surface with the roadbed material. It is to be expected the embankments built of shale will continue to settle and shrink, which will in some cases call for raising and resurfacing of the track. Should these settlements cease or become unimportant, ballasting may thereupon seem justified, but it was thought that the use of expensive ballast hauled long distances would not be justified upon these settling embankments so long as the track could be maintained thereon at a reasonable cost without ballast.

The main track was laid with 90-lb. A. R. A. type "A" rail, with Bonanza joints and 18 7 in. by 8 in. 8-ft. ties per 33-ft. rail. Sidings and spurs were laid with 75-lb. rail. Two steel water tanks, each of 50,000 gal. capacity, were erected.

The grading, tunnelling and work connected therewith was done under contract with the Utah Construction Company of Ogden, Utah. The steel bridge material was furnished by the American Bridge Company of New York and erected by Gerrick & Gerrick Company of Seattle, Wash. Track laying and surfacing was done by company forces. H. S. Martin was in charge of construction work under the direction of William Ashton, chief engineer.

WESTERN RATE ADVANCE HEARING

Testimony of protestants against the proposed advances in the rates on livestock occupied the hearing before Commissioner Daniels at Chicago in the western rate advance case throughout most of this week, the testimony on packing house products having been concluded on April 30. This will be followed by some unfinished testimony of protestants, and the hearing is expected to be concluded on May 10.

R. O'Hara, rate expert for Swift & Co., presented 31 exhibits to show that the increases on packing house products should not be allowed. He disputed statements by railroad witnesses regarding the percentage of empty car mileage in the packing house business, saying that for all the roads in the case for the year ending June 30. 1912, the percentage of loaded car mileage was 71.09, and for the year ending June 30, 1914, the loaded mileage for the Swift Refrigerator Line was 55.4 per cent. He said the proposed advances would add $488,747 to the annual transportation charges paid by Swift & Co., that it is extremely doubtful that such an advance could be passed on to the consumer, and that it seems likely that the livestock shipper would have to bear the burden.

W. W. Manker, assistant traffic manager for Armour & Co., presented 29 exhibits, in which an effort was made to show that the rates on packing house products are amply remunerative and pay a much greater revenue per ton mile than the average of other commodities. The present advance, he said, would disturb an adjustment as between the rates on livestock and fresh meats and packing house products which has been approved by the federal courts, and that in the advances proposed there is no uniformity shown. Mr. Manker said that the total amount of freight charges paid by Armour & Co. on materials and supplies used in the operation of its plants was $1,841,899 in 1914, and included in this list of supplies are several commodities on which the rates have been advanced. In addition the increases on fresh meats and packing house products would cost this company, he said, $415,784 a year. He disclaimed knowledge of the capitalization or dividend rate of his company.

C. O. Cornwell, assistant traffic manager of the Cudahy Packing Company, claimed that the proposed rates would be discriminatory and would disturb existing relationships, and said he did not believe the carriers had made a careful and con-

scientious effort to adjust the proposed advances upon any equitable basis, while they would limit the volume of the movement of packing house products in parts of the territory.

A. F. Stryker, secretary and traffic manager of the Live Stock Exchange of South Omaha, based his chief protest on the fact that it was proposed to advance rates out of Omaha 3½ cents, while the Chicago & Alton and the Wabash have contracts with the packers for rates from Kansas City which already give that city an advantage of 5 cents over Omaha, and the proposed rates would increase Omaha's disadvantage to 8½ cents. The difference in rates militates against Omaha, he said, because cattle raisers can obtain better prices in Kansas City on account of the lower rates on the product.

A. B. Caswell, manager of the Milwaukee Tanners' Freight Bureau; J. F. Nicholas of Charles Friend & Co., Chicago, and W. V. Hardie of the Oklahoma City Chamber of Commerce, protested against the proposed advance in the rates on hides.

H. G. Krake, commissioner of the Traffic Bureau of the St. Joseph Commerce Club, protested against the disadvantage under which the St. Joseph market operates in competition with Kansas City, and also against the increase in the rates on hides.

Fred Pettijohn, a cost accountant associated with the Mutual Audit Company of Louisville, submitted an extended analysis of the operating expenses of the Chicago & Alton for the month of October, 1914, to show the cost of transporting meat. Of a total operating expense on the western division for the month of $290,498, he assigned $215,981 to freight and $40,089 to fresh meats and packing house products; whereas the gross revenue received by the Alton on this traffic was $70,583. Out of this he said the road paid switching absorption amounting to $7,658, leaving a net revenue of $62,925. Adding to the operating expense $11,704 to cover hire of equipment and $89.96 as the proportion of train cost on company material, he obtained $51,884 as the total cost chargeable against the packing house traffic; or 6.69 mills per ton-mile against a ton-mile revenue of 11.24 mills. In other words, he said the Alton handled this traffic at an operating ratio of 59.48 per cent, making a profit of 40 per cent. From a similar analysis of the Northwestern traffic and expenses he figured a profit of 36 per cent on a relative smaller volume of tonnage because of the higher rates. Mr. Pettijohn was cross-examined at length by Dr. M. O. Lorenz, statistician for the Interstate Commerce Commission, and by C. C. Wright, general solicitor for the Chicago & North Western, who seriously questioned some of the methods used by the witness in making his calculations.

"By whom are you employed in this case?" asked Mr. Wright. "Clifford Thorne employed me to work up the packers case," replied Mr. Pettijohn.

"Are you employed for and in behalf of all these large packing concerns?" asked Mr. Wright. "I couldn't tell you, Mr. Wright, who all the packers are behind this movement; the check comes through M. Thorne."

Mr. Thorne then stated that the money was given by the packers to pay Mr. Pettijohn and all his assistants. "The attorney for the packers gave the money," he said, "and his name was Luther Walter. I know nothing further."

"The money was contributed by the packers, Armour & Co., Swift & Co., Morris & Co. and Sulzberger & Sons Company," said Mr. Walter.

C. S. Balch, statistician of the Chicago & North Western, testified in rebuttal of the statements made by accountants for the protestants as to the cost of operation. He said that investigation showed that on all the cars moved by the North Western out of South Omaha to Iowa, Illinois and Wisconsin for November, 1914, the earnings, after taking out the switching charges at Chicago and Omaha, equaled only $52.99 per car, and that taking the figure of 10.1 cents per car mile arrived at by the witnesses for the protestants as the cost of hauling each car one mile, it would cost $49.60 to haul a car to Chicago, leaving a net of $3.39 to pay taxes and overhead charges, on an operating ratio of 93.7 per cent.

F. A. Leland, chairman of the Southwestern Tariff Committee, also testified in rebuttal, pointing out objections to the exhibits filed by witnesses for the packers and replying to their objections to the exhibits he had filed in his direct testimony. He also submitted a number of supplementary exhibits.

The first witness on behalf of the protestants against the advances in the rates on live stock was T. W. Tomlinson of Denver, secretary of the American National Livestock Association. He said the proposed advance is an attempt on the part of the carriers to shift the burden of transportation to the interstate shippers, and presented a number of comparisons to show that the present rates, as well as the proposed rates, are much higher than the rates for similar distances under the Illinois, Iowa, Missouri, Kansas and Texas state tariffs. He also said that many of the proposed rates are higher than the rates approved by the Interstate Commerce Commission in the Oklahoma City case. He said that the cost of expedited special service, as claimed by the railroads, is "largely mythical"; that there has been no improvement in the service given live stock traffic within recent years; that on the contrary the time schedules have been lengthened. He also claimed that live stock moves in trains that carry as a rule as much revenue tonnage as the average of all trains, and that the large empty movement of live stock in cars is explained by the fact that there is a surplus of box cars moving westbound, and there is no necessity to load live stock cars as long as that condition exists. "The present rates on live stock are higher than ever before in the history of the industry," he said. "I estimate that shippers of live stock now pay directly or indirectly from 20 to 25 per cent more for marketing their stock than they did 15 or 20 years ago. This increase has been caused by flat advances in the rates themselves, by higher charges for feeding in transit, by the withdrawal of rebates, by the withdrawal of free transportation formerly accorded buyers who wished to go out to pick up stock, and by the change in rates from charges per car to cents per hundred pounds."

C. B. Heinemann, assistant traffic manager for Morris & Company, also testified in opposition to the advances on live stock in southwestern territory. He took the position that the existing basis of rates has been adjusted upon a schedule prescribed by the commission, and that the rates were ample to cover the carriers' necessities. He offered exhibits to show that the carriers had not followed out the commission's suggestion that rates on feeder stock be 75 per cent of the beef cattle rates, and said he believed the scale prescribed by the commission in the Oklahoma City case, if properly observed, would give the carriers all the compensation which they could reasonably expect.

W. W. Manker, assistant traffic manager of Armour & Co., also testified against the proposed increase on live stock in southwestern territory, contending that the rate scale fixed by the Interstate Commerce Commission is higher now than the state rates and that the difference would be increased by an advance.

J. D. Jackson, president of the Cattle Raisers' Association of Texas, testified that the cattle industry is in no position to pay higher transportation charges, and that there has been no material change in the conditions to justify an increase in rates. Similar testimony was given by H. A. Stonebreaker, a member of the executive committee of the American National Livestock Association.

The English Railways and the Government.—The Board of Trade has announced that under a new agreement between the government and the railways which have been taken over under the Act of 1871, 25 per cent of the war bonus granted to railway employees will be borne by the companies. It has also been agreed that in future the compensation payable to the companies by the government during the period of control shall be the sum by which the net receipts of the railways during that period fall short of the aggregate net receipts for the corresponding period of 1913, without any reduction.

The Rivers and Railroads in the United States*

The Considerations That Should Lead to the Development of Railroads Rather Than the Building of Canals

By F. Lavis
Consulting Engineer, New York

The paper on the above subject by Wm. W. Harts (abstracted in the *Railway Age Gazette*, February 5, 1915) calls very timely attention to one of the problems of the economics of transportation which is often misunderstood or entirely ignored. This ignorance or misunderstanding has resulted in the expenditure of a great deal of money without adequate benefit, and not only has this been the case in the past, but it still continues. Our national policies in these matters seem to be too often conceived in a generally haphazard manner, rather than to be founded on sound economic laws, and in the general development of the whole resources of their countries certain European nations seem to be guided by more orderly processes of thought and action than we are. But even in Germany, the greatest exponent of order and system, it is by no means a fact that the development of its waterways has resulted in the attainment of unqualified success in low costs of transportation thereon. It has frequently been assumed that this is the case, but it has been shown† that in Germany, as elsewhere, many of the items which should be included in the cost of water transportation have been omitted. Such success as *has* been attained, however, has been largely due to the fact that the matter of deciding on the projects on which public moneys shall be spent has been generally left to a comparatively small body of men of training and experience in the particular class of work or problems involved, whereas, in the United States, this is generally decided by the votes of the people.

It is probably true that in the development of their waterways some of the European nations have attained a greater measure of success than we have, but in the general realm of transportation, including that by railways, it is undeniable that we have far out-distanced the rest of the world. This success has, generally speaking, been the result of policies formulated by a few men or by small groups who have brought our railroads to the high plane of efficiency on which they rest today. *Rest* is used advisedly, as apparently the initiative which has achieved these results is now held in abeyance by the passing of the control of our transportation systems into the hands of those charged by the state with their regulation and who have not the personal incentive to strive "to make a dollar earn the most interest."

Under our form of government it is inevitable that the final decision in regard to the expenditure of money for public improvements must rest on the approval of the people as a whole, and it is perhaps too much to expect that any large proportion of them can be so educated as to be able to form independent judgments on all matters of this kind.

The State of New York is just about completing a new canalized waterway from the Great Lakes to the navigable waters of the Hudson river at a cost of approximately $130,000,000 or more. The construction of this canal was authorized by vote of the people of the state only a few years ago, and apparently they were influenced by two arguments, both of which are, in the writer's opinion, fallacious. These arguments are: (1) That by providing competition the canal would compel the railroad lines to keep freight rates down, and (2) that the actual cost of transportation would be less by the canal than by railroad.

It does not seem necessary at this time to go into much detail to show how these arguments fail. The theory of competition is scarcely tenable, in view of the almost absolute control of railway rates by both state and federal regulation. The actual cost of transportation by canal is only less when the interest on the investment in the canal and the cost of its administration and maintenance is ignored in calculating it.

Taking into consideration the interest on the investment and the cost of maintenance, amounting to 6.6 mills per ton mile, it has been shown* that the total cost of transportation on the Erie canal is about 8.6 mills per ton per mile, and this for low grade, bulk freight alone, whereas the freight receipts of the New York Central were only 6.2 mills per ton mile for all classes of freight, indicating a considerably lower figure even than this for the low grade bulk freight.

It is also shown that the cost of construction of the old Erie canal was not less than about $165,000 per mile, and the new canal will cost double that, which may be compared with the capitalized value of the New York Central Railroad at about $180,000 per mile.

Prof. Engels, an eminent German authority, has stated† that to improve a German river involved an expense equal to that of building a double track railroad on easy gradients through a mountainous country; that is to say, from $100,000 to $150,000 per mile.

The question of the value of waterways for the purpose of providing competition for the railways is very ably discussed‡ by M. Colson, an eminent French authority, who uses as an illustration a specific case in France where the relations are apparently somewhat similar to those of the New York Central and the Erie canal. The argument is paraphrased to fit this latter, with which we are all familiar. It is argued that if lower rates were the desired object, there is probably no doubt that if the New York Central had been presented with, say, one-half the cost of the barge canal, and half the estimated annual cost of administration and maintenance, it would have been glad to guarantee a freight rate of 2 mills per ton mile (the actual net transportation cost on the canal) on such items of bulk freight as may be expected to pass through the canal during the season the canal is open. The lower rates would thus be secured and the state would have saved many millions of dollars. Probably, however, there would be a great outcry and protest against the subsidizing of a particular railroad to obtain a reduction of rates in a certain local section, without obtaining the same reduction in the rest of the country or state, yet this is really what is done, except that the cheap rates are obtained for a certain small part of the population by spending the money for a canal rather than by giving it to the railroad.

The importance of a study of the questions raised by the author of the paper needs no argument, especially in view of the existing financial and economic crisis. All who have broad knowledge of the newer civilizations, that is, those of North and South America, as well as Africa, Australia, etc., cannot but be impressed with the tremendously large number of important things to be done, and the difficulty of getting money enough to carry out even a small part of them, including often those of considerable merit. The Balkan war

*Abstract of a discussion in the March Proceedings of the American Society of Civil Engineers.

‡Bulletin Int. Ry. Congress, Nov., 1913, p. 958.

and the present European war, so far as their effects have any bearing on the financial situation, are but the culmination of a vast and far-reaching crisis in the affairs of the world produced by the great *demands* for capital for legitimate and urgently required developments of new countries, and the totally inadequate *supply*. It is, therefore, doubly necessary *now* that the greatest care be exercised in selecting for development only those projects which are sound when judged from the broadest economic viewpoint.

So far as concerns the conclusions of Mr. Harts that it is time that we awoke to the wastefulness of much of the expenditure for improvements of rivers and to the desirability of applying the money towards increasing the facilities and depth of water in our ocean ports, the writer is in entire agreement.

The development of our ports must be planned on an adequate basis to take care of a large overseas commerce, and our interior lines of communication must be so developed to carry our products from one part of the country to another at the lowest possible cost per ton mile. In the present state of the art, with possibly a very few exceptions in respect to certain natural deep inland waterways, the railway is the best and cheapest means of inland transportation of which we have knowledge, and unless there is a distinct revolution along lines as yet undreamed of, is likely to remain so for some time to come.

Mr. Harts also referred to the three stages in the economic development of inland water routes, the first before the advent of the railroads when the waterways provided practically the only means of access and communication, and when owing to the rapid growth of the country they were prosperous; the second, the era when the competition of the railroads almost entirely superseded water transport, and the third looking forward to a time when the waterways of this country may be utilized to some such extent as they are in many parts of Europe as almost equal in importance to the railway companies as lines of transportation for low grade freight.

We cannot of course say that this third era will *never* develop in this country, but it seems somewhat improbable, if the development of the art of transportation by railway continues to develop in the future to any such extent as it has in the past. In Europe the railways have never entirely superseded the rivers and canals or offered the effective competition they have in this country, and it must be remembered that a great many of the mercantile and industrial centers of Europe were built up along the water routes and established there long before the advent of the railroads. Of course many of the largest of the modern industrial and manufacturing enterprises have grown up coincidentally with the railways, but the majority of them are but developments from those of an earlier period, built up alongside navigable rivers and canals.

Another point of considerable difference is that in Europe, society and the industries, having been organized before the advent of the railroad as the primary agency of transport, were developed as a number of comparatively small self sustaining groups that is, self-sustaining so far as concerns the necessities of life. In the United States, however, the development of the railway as an efficient and cheap means of transport, reaching all parts of the country, before the development of the principal industries, has enabled these latter to be located where the soil, climate and other conditions were best suited to them, and then to distribute the finished product to the point of consumption.

In the United States the country has been developed by the railways, and while many industrial establishments have been so located as to enjoy the benefits of both rail and water transportation, the railway is always of paramount importance. In spite of some adverse criticism of some details and of some of the figures used, the statement of Mr. James J. Hill that, in comparison with the rates of wages, the cost of freight transportation on the railways of this country is only from one-third to one-quarter as much as in Germany, is undoubtedly substantially correct. Taking into consideration, therefore, the limitations of flexibility of water transportation routes, the necessity that business shall come to them and that they can seldom if ever be carried to the business, the fact that some cargoes, notably coal, deteriorate from wet and dampness, that there are other inherent difficulties in connection with inland water transport, increased hazard, and insurance rates, and considering the efficiency of our railroads, there seems little reason to expect now that there will be any general development of fluvial or canalized inland transportation, unless there is a revolution in methods which are entirely beyond any present expectations, and which, therefore, it is useless to attempt to provide for.

MIKADO AND PACIFIC TYPE LOCOMOTIVES OF MODERATE SIZE

The Baldwin Locomotive Works has recently completed ten Mikado and six Pacific type locomotives for the Nashville, Chattanooga & St. Louis, and although not particularly large for their respective types, the engines are interesting examples of modern motive power.

The Mikado type locomotives exert a maximum tractive effort of 49,400 lb., and with a weight on drivers of 205,000 have a factor of adhesion of 4.15. They are equipped with Schmidt superheaters and Security sectional arches, and are so designed that Standard stokers can be subsequently applied if desired. The firebox throat has a depth of 24 11/32 in., measured from

Mikado Type Locomotive for the Nashville, Chattanooga & St. Louis

the underside of the barrel to the bottom of the mud ring. The tubes are electrically welded into the back tube sheet.

The cylinders are arranged with outside steam pipes, and the steam distribution is controlled by 15-in. piston valves which are set with a lead of 3/16 in. Neither relief nor by-pass valves are used. The valve gear is of the Walschaert type, controlled by the Ragonnet power reversing mechanism. The pistons have cast steel dished bodies with iron bearing shoes cast on, the width of the piston head being 5¼ in.

The locomotives are equipped with Cole long main driving boxes, and with the latest design of Hodges trailing truck, the spring rigging being cross-equalized between the rear driving wheels and the trailing truck. This is accomplished by pinning together, on the center line of the locomotive, two transverse beams, one of which is connected by links with the rear driving springs, while the other is connected with the rear truck equalizer. It is claimed that this construction assists in maintaining a correct weight distribution on both sides of the locomotive when passing over uneven places in the track, and that it also reduces stresses on the frames and equalizing gear.

The Pacific type locomotives are in general similar to the Mikados, although they have smaller cylinders and boilers, and the wheel loads are somewhat lighter. The tractive effort exerted is 33,800 lb., with a ratio of adhesion of 4.25, the weight on the drivers being 143,500 lb. As in the Mikado type, the spring rigging is cross-equalized back of the rear driving wheels. The boiler center line is 9 ft. 6 in. above the rail, which allows room for a furnace throat as deep as that applied to the Mikados. The Schmidt superheater and Security brick arch are used in these engines also.

The tenders of both locomotives are of the Vanderbilt type, carried on Standard forged and rolled steel wheels. The engine truck wheels are steel tired and of the same make.

The tables contain the leading dimensions of both types:

General Data		
Gage	4 ft. 8½ in.	4 ft. 8½ in.
Service	Passenger	Freight
Fuel	Soft coal	Soft coal
Tractive effort	33,800 lb.	49,400 lb.
Weight in working order	219,550 lb.	264,300 lb.
Weight on drivers	143,500 lb.	205,000 lb.
Weight on leading truck	37,400 lb.	20,700 lb.
Weight on trailing truck	38,650 lb.	38,600 lb.
Weight of engine and tender in working order	375,000 lb.	490,000 lb.
Wheel base, driving	13 ft.	15 ft. 9 in.
Wheel base, total	34 ft. 1 in.	34 ft. 4 in.
Wheel base, engine and tender	69 ft. 4 in.	69 ft. 7 in.
Cylinders

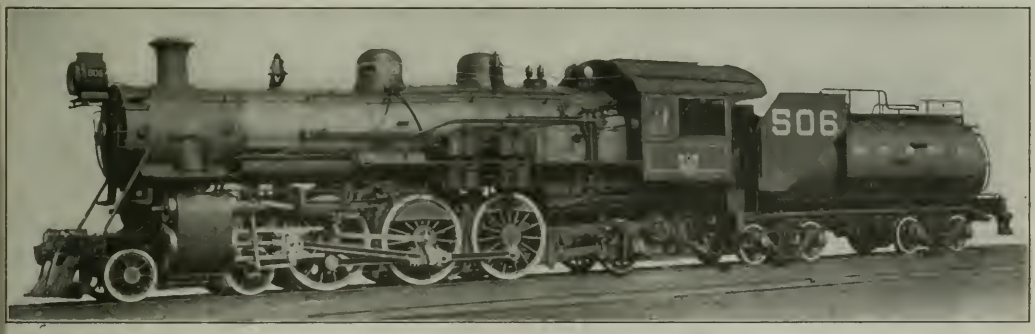
PREMIUMS FOR FREIGHT TRAIN SPEED

On the Cleveland division of the Baltimore & Ohio special credits are awarded to freight train men for making good time. The arrangement applies to both through and local trains. When a crew makes a run between division termini—from Chicago Junction and Cleveland to Holloway, or from Chicago Junction to New Castle—in satisfactory time, all of the members receive credit, and these credits, according to a circular issued by the superintendent, W. C. Lechlider, "will have great influence in clearing up personal records." This arrangement was put in effect at the beginning of the year, and we are informed that for the first three months the results have been found highly satisfactory. The lengths of the runs are 123, 126 and 133 miles. Bulletins were issued after the end of the first month, and at a number of times since, so that the interest in the scheme has been well kept up; and there is hardly a man in the train service on the whole division who has not already been given credit marks for good runs or for making definite suggestions for improvement. A number of men have received enough credit marks to clear their records of certain reprimands.

In through freight train service the number of hours overtime paid for in March was 392, and this was 100 hours less than the number paid for in February. In the overtime statement for March some of the principal items were: Meeting



Nashville, Chattanooga & St. Louis Pacific Type Locomotive

trains 83 hours; taking and leaving cars 57 hours; engine failure 17 hours; trains ahead 16 hours; accidents 7 hours.

There are at this time in service on the Cleveland division about 40 freight train crews.

In a statement for the months of February and March, showing the degree of promptness with which "quick despatch" trains were moved on different divisions of the Baltimore & Ohio, the Cleveland division stands at the head of the list in both months.

THE WABASH REORGANIZATION PLAN

On April 28 the three committees, two representing the first refunding and extension mortgage bonds and one the stockholders, signed the reorganization plan of the Wabash, which provides for the formation of a new company and the raising of $27,720,000 cash to pay off receivers certificates, expenses of the receivership, and furnish working capital for the new company. Kuhn, Loeb & Company, New York, are to form a syndicate to underwrite this reorganization plan.

Under the plan the underlying $62,302,000 bonds will remain undisturbed, interest having been paid on these bonds by the receivers, and the $2,541,000 equipment obligations maturing after December 31, 1915, will remain undisturbed, as will also the debenture mortgage bonds, of which there is but $315,000 outstanding, not controlled by the joint reorganization committees. This makes a total of $65,158,000 undistributed obligations. The new company will issue $46,200,000 5 per cent profit sharing preferred (non-cumulative) stock A; $48,720,000 5 per cent convertible preferred (non-cumulative) stock B; $43,540,000 common stock, and $1,500,000 4 per cent notes due May 1, 1920. This is a total of $139,960,000 new securities, and a grand total of $205,118,000 to be issued or assumed by the new company. The old company had a capitalization of $198,160,000, exclusive of guarantees, floating debt, etc., and before the issue of receivers' certificates or other obligations of the receivers. The present total capitalization of the old company and the obligations incurred by the receivers, excluding, however, undetermined guarantees, is $222,319,377. The total charges, inclusive of receivers' certificates, are at present $5,795,278. Under the reorganization plan the total interest charges would be $3,183,915.

The various classes of securityholders and creditors affected are as follows, exclusive, of course, of the holders of underlying bonds which remain undisturbed:

First Refunding and Extension Mortgage Bondholders.—There is $40,600,000 of these first refunding and extension mortgage bonds outstanding and there is in addition $5,684,000 coupons in default on these bonds. Holders of these bonds under the new plan are to receive payment in cash for their January 1, 1912, interest coupon ($20 per bond, or a total of $812,000) and 120 per cent of the face value of their bonds in new convertible preferred stock B, the total amount being $48,720,000. The price which they pay for this is the surrender of their old bonds and the agreement which they must enter into to underwrite the raising of the needed $27,720,000 cash in the event that the preferred and common stockholders of the old company do not enter into the plan and pay the assessment as provided in the plan. In the event, therefore, that none of the stockholders submitted to the assessment, the first and refunding mortgage bondholder would have to surrender his bond and pay $682.76 per bond in cash, less $20 which he would receive in cash for the coupon due January 1, 1912, making a net cash payment of $662.76, for which he would receive $1,137.93 in new profit sharing preferred stock A, $1,200 in new convertible preferred stock B, and $1,072.41 in new common stock.

Preferred Stockholders.—There is outstanding $39,200,000 of old preferred stock. This stock under the plan is to pay an assessment of $30 per share in cash and give up the old preferred stock certificate with a par value of $100 and receive in exchange $50 par value of new profit sharing preferred stock A, amounting in all to $19,600,000, and $50 in new common stock, amounting in all to $19,600,000.

Common Stockholders.—There is $53,200,000 common stock outstanding on which an assessment of $30 in cash per $100 share is to be paid by the holders thereof and the stock certificates surrendered, and holders are to receive in exchange $50 per share in new profit sharing preferred A stock, a total of $26,600,000, and $45 per share in new common stock, amounting in all to $23,940,000.

Unsecured Creditors.—Creditors of the company are to receive 25 per cent of their claims in new convertible preferred stock B at par and 75 per cent in new common stock at par (the total amount of stock so issuable is not exactly determinable and is not included in any of the total figures for capitalization given above or below).

In the event that the stockholders do not submit to an assessment of $30 per share their equity is apparently wiped out and the burden of reorganization falls on the present holders of the first refunding and extension mortgage bonds. In the event that a part or all of these bondholders do not accept this burden, the only equity which they will have is their pro rata share of the difference between the price which the sale of the property subject to the underlying bonds will bring under foreclosure sale and the sum necessary to pay off the receivers' certificates. The upset price of the property subject to the underlying bonds has been fixed at $21,000,000 by the court and there are $15,950,000 receivers' certificates outstanding beside a judgment for $950,377, known as the Compton judgment. The fact that a syndicate headed by Kuhn, Loeb & Company is to underwrite this plan means that if the stockholders do not pay their assessment, and a part or all of the necessary cash is not raised by the first and extension mortgage bondholders, the underwriting syndicate will raise the cash, paying to dissenting bondholders their proportion of the residue after the sale as mentioned above, and will take the securities which would have been distributed to stockholders and bondholders under the plan had they paid their asessments.

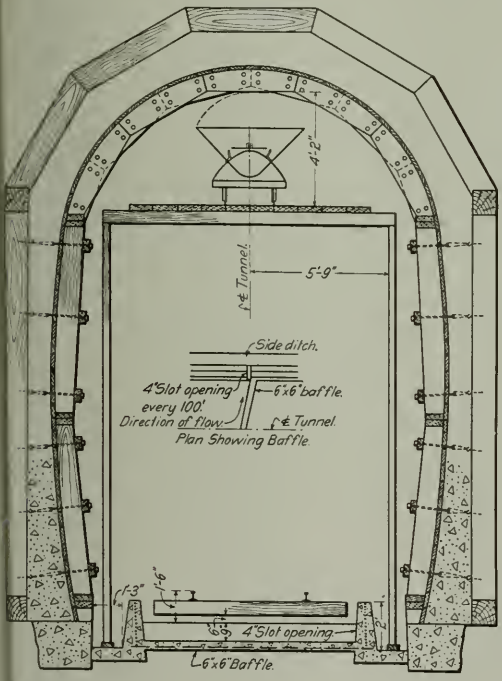
LINING TUNNELS ON THE NEW LEWISTOWN-GREAT FALLS LINE OF THE ST. PAUL

On the extension of the Chicago, Milwaukee & St. Paul from Lewistown, Mont., to Great Falls, described in the *Railway Age Gazette* of April 2, 1915, there are six tunnels aggregating 5,333 ft. in length, all of which are lined with reinforced concrete, except one 250 ft. long. The linings have a minimum overhead thickness of 15 in., and a sidewall thickness of 12 in. The accompanying drawing shows a typical cross section of the lining and the special concrete gutters which were provided to care for the drainage in tunnel No. 1. Tunnels No. 3, 4, 5 and 6 required no special provision for drainage. Wooden forms lined with sheet metal and built in sections 16 ft. long were used. These were wedged up to position at the bottom and after the concrete was poured and set the wedges were removed and rollers substituted to enable the form to be moved to a new position. Each form was allowed to remain in position for 48 hours after the concrete was poured before being moved.

At tunnel No. 1 the concrete plant consisted of three mixers, one being set in front of and above each portal on falsework and one at a shaft, 118 ft. deep, 750 ft. from the west end of the tunnel. The shaft was sunk by the forces which drove the tunnel and was finally lined with concrete for ventilating purposes. Gravel and cement were delivered at the tops of the banks adjacent to the mixers at the portals by wagons and were delivered from these points to the mixers by gravity chutes as required. The mixers discharged the concrete directly into steel dump cars which were operated on a double track placed on a staging. This staging was built as high as possible to permit the operation of trains through the tunnel. The dump cars delivered the concrete to a point opposite the form to be poured and discharged it di-

rectly into that portion of the form below the springing line. For that portion above this the concrete was poured into a shallow box from which it was shoveled into the form. The lagging above the springing line was made in sections about 3 ft. wide, so that it could be removed from the form centers to enable the arched portion of the lining to be placed more readily. The concrete mixer at the shaft discharged into small cars which were lowered in a cage down the shaft to the staging where the concrete was dumped into the delivery cars.

To make sure that all voids adjacent to the segmental timbers were filled it was decided to force cement grout back of the concrete lining. To accomplish this, a plant consisting of a Ransome-Caniff grout mixer, a 40-hp. kerosene burning engine and a 10 in. by 10 in. single-stage air compressor was installed. The grout mixer was mounted on a small push car or set to one side of the track on the ground in the tunnel, as circumstances



Cross Section of Tunnel 1 Showing Side Drains and Method of Placing Concrete Lining

required, and from this the grout was conducted through a 2 in. air hose to 2 in. pipes previously placed in the crown of the arch. The pipes left in the crown of the arch to receive the grout were spaced about 5 ft. center to center and grout was forced into one pipe until it made its appearance at the next pipe but one when the connection of the air hose was made to the next pipe. The air pressure used was 60 lb. to 100 lb., according to the conditions. The plant was operated with five men and an engineer who succeeded in placing 280 batches of 2⅔ cu. ft. of grout each in 10 hours. An average of 230 batches per 10 hours was maintained throughout the five tunnels.

The same general scheme was used for lining all of the other tunnels with some minor differences due to local conditions. Tunnel No. 4, which was affected by an adjacent slide, required retimbering for a distance of 200 ft. at the east end, and to provide against the heavy lateral movement, induced by the slide, the wall timbers when reset were so placed as to provide an additional thickness of concrete of 18 in. In addition to this excavations were made between the wall timbers into which concrete was poured to form stiffener ribs. It was necessary at this tunnel to elevate the gravel for concrete 250 ft., which was accomplished with an inclined industrial track operated by a cable and hoisting engine. The concrete mixing plant at tunnel No. 4 consisted of one mixer mounted at each portal and the mixing of concrete for tunnels No. 3, 5 and 6 was handled with a single mixer at each.

In all of the tunnels excepting tunnel No. 4, which ran 8 cu. yd., the lining averaged 5 cu. yd. per foot of tunnel. At tunnel No. 1, where two 10-hr. shifts were used and three concrete mixers were in operation, as high as 58 ft. of lining was placed in 24 hours, and this rate of progress continued for three weeks toward the end of the work. At the other tunnels, excepting No. 4, 16 ft. of lining was completed every 10 hours with a single shift, and when two shifts were used that rate continued. The average cost of the concrete lining was about $16 per cu. yd.

This work was done by company forces under the general direction of C. F. Loweth, chief engineer, and E. O. Reeder, assistant chief engineer. F. B. Walker was assistant engineer in direct charge of the work.

COST OF TRAIN LIMIT LEGISLATION

A. J. Earling, president of the Chicago, Milwaukee & St. Paul, in a statement at the hearing before the committee on public utilities of the Illinois House of Representatives recently, in reference to proposed train limit legislation, presented a detailed estimate showing that a law limiting the number of cars hauled in one train to 50 would render valueless investments totaling $4,091,753.32, which have been made by his company on its 415 miles of line in the state of Illinois and would involve an increase in freight train miles in the state of 20.08 per cent., equivalent to an additional operating annual cost of $441,155.04. The investments consist of three items: expenditures made for improvements in the line to permit the hauling of heavier trains, the excess cost of locomotives having greater hauling capacity, and the increased cost of freight cars designed to be handled in longer trains.

For the purpose of this estimate the improvements in line only on the Chicago & Council Bluffs division were considered. These improvements are of five kinds: (1) increase in standards of track construction, (2) extensions of yard and passing tracks, (3) strengthening of permanent bridges, (4) increase in size of turntables, engine houses and other facilities, and (5) reduction in grades. Under the first head it was assumed that to haul the present business with lighter engines the same track mileage would be needed, but that the standards could be placed on a basis of 75-lb. rails, lighter fastenings, less ballast and fewer ties. The difference between the cost of the present track structure and the lighter track amounts to $589,950 for the 146 miles of double-track line considered. The estimated cost of yard and side tracks in excess of the lengths required for 50-car trains amounts to $1,056,200. In estimating the value of these extensions the cost of the necessary grading, track structure and right of way was included.

Under present operating conditions all structures are designed for Cooper's E-50 loading. If lighter locomotives hauling 50-car trains were in service, these bridges could be designed to carry not greater than Cooper's E-36 loading. As the ratio of the steel in structures for an E-36 loading and for an E-50 loading is about 0.8, the estimated excess investment is based on 0.2 of the cost of the steel work now in place and 25 per cent of the cost of the substructures, which could be smaller and lighter if they carried lighter structures. The reproduction cost of the present Mississippi river bridge at Savannah is estimated at $331,000 and as the original structure, built in 1880 for a lighter loading, cost approximately $225,000, one-half of the difference, or $53,000, is considered chargeable to the C. & C. B. division in

Illinois, and is included in the estimate of the excess cost of heavy bridges which totals $342,600.

It was assumed that on account of the large equipment now operated, the size of water stations, clinker pits and coaling stations has been increased 25 per cent as compared with the initial construction. The original light equipment required a 56-ft. turntable while at present a 90-ft. one is being used, while during the same time the depth of engine houses has been increased from 70 ft. to 96 ft. It was assumed in making the estimates that the ratio of cost of the engine houses is directly proportional to the length of the stall, the increase amounting therefore to about 30 per cent. In addition to this the present locomotives require more expensive facilities than the earlier light engines, it being assumed that 10 per cent of the cost of these facilities represents the additional investment. The total estimate for the item of buildings is $207,600.

It is a difficult matter to determine the exact investment for grade reductions and changes of line, largely on account of the early cost-keeping methods. The total figure used, $546,150, was obtained from an early estimate by the chief engineer, with allowances for other grade reductions made in changes of line, an estimate of the cost of certain items such as freight on material paid to foreign companies, transportation of men over company lines, engineering and legal expenses, etc., and the expenditures made by the operating department to raise sags, widen banks and cuts.

The excess cost of the locomotives which have been purchased to handle heavier trains, assignable to the state of Illinois on the basis of locomotive mileage, is estimated at $742,011.32. This figure was secured by determining the average cost of all engines purchased between July 1, 1899, and June 30, 1907, and a similar figure for the engines purchased between July 1, 1907, and June 30, 1914. The difference between these figures, amounting to $4,463.32 is taken as the excess paid for each locomotive during the latter period to secure greater power. This rate applied to the number of engines purchased during that time gives the total excess investment for the system, from which the portion chargeable to Illinois is secured.

In order to arrive at the cost of properly equipping freight cars to be handled in long trains, a detailed statement was prepared showing the cost of all freight equipment cars, including cabooses, that have been built with metal draft arms, with steel center sills, and with steel underframes, also cars equipped with friction draft gears, and for each car an estimate was made of the investment which would have been necessary if the car had not been equipped with these improvements. The difference between these figures applied to the total number of cars showed an excess investment of $5,043,541 for the system, of which $607,242 is chargeable to Illinois on the basis of freight car mileage in that state.

The estimated cost of operating additional trains if a 50-car limit bill was passed, was prepared as follows: It was assumed that all cars exceeding 50 in trains operated on the present basis would have to be made up into new trains moving between the same two points daily, except that for each particular run not to exceed 10 cars daily could be absorbed in trains now operating with less than 50 cars or could be held over for the same run the following day. In other words, it was assumed that all of the traffic moving on a particular day would have to move on that same day if this bill was passed. If, for example, four trains running between Chicago and Savannah handled 63 cars each on a certain day, there would, under the new system, necessarily be five trains each with 50 cars, the two additional cars being held over until the following day. If, however, there were four trains run that day between Chicago and Savannah, each with 68 cars, it was assumed that it would be necessary under the proposed law to run six trains that day, five with 50 cars and one with 22 cars. The estimates were prepared on two assumptions; first, that all trains would run between their present destinations with 50 cars and the other that they would be stopped at the state line and there made up into trains of the maximum length which can be hauled on the division. Under these assumptions, it was shown that 416,184 and 292,815 additional train miles, respectively, would be required. On the basis of $1.06 for each additional train mile this would involve an annual additional operating cost of $441,155.04, or $310,383.90, respectively. The first figure representing increase in train mileage is 20.08 per cent of the total train mileage in the state at present.

THE GOLDEN RULE APPLIED TO FREIGHT CLASSIFICATION

The following is taken from The Houghton Line, a trade publication of E. F. Houghton & Co., Philadelphia:

I remember once our sales department came to me and asked me to represent them before the Southern Freight Classification Committee, in a protest against what our folks considered was an unjust classification. I asked for the facts and arguments. They gave them to me. I read them over, and I said: "I don't see any argument in here which would influence me if I were a railroad man."

A railroad man is working for the railroad. It is the railroad's duty to serve the public, but it is every railroad man's duty to remember that the public are also his stockholders. I asked them what argument I could give the railroad that would be worth while from the railroad man's idea. They could furnish me with no such argument, and I refused to appear before the committee.

The next year, when the Classification Committee again met at Atlantic City, our folks came to me with what they supposed was a terrible grievance. We had lost all of our trade because of the unjust classification, and the people who formerly bought from us were buying tallow locally; not that the tallow was better, but it was so much cheaper when you took into consideration the excessive freight charges. And I said to them: "Here is an argument for the railroad.

"The railroad has lost business. They collect no freight on the local tallow at all. They are mutually interested with us in a lower classification. They can benefit their stockholders by such a classification." And forthwith I appeared before the committee at Atlantic City, and the committee being composed of railroad men—good railroad men—wise railroad men—saw the point at once. They didn't detain me 10 minutes, and the request was granted.

But while I was only 10 minutes doing my little turn before the committee, I sat in that committee room pretty nearly three hours waiting for my case to be called, and I was impressed and amazed at the general attitude of every man who had a case before the committee. Each one was protesting against an individual injustice to himself. He wanted the railroad to do something which would enable him as an individual to beat out his competitors, which would be to his personal individual advantage, just as if the railroads existed for the personal advantage of any individual concern. Not one single argument did I hear which presented to these railroad men some advantages for the railroad. It is as if a man would come to you and want to buy goods on which he knew you were going to lose money, merely that he might make more for himself.

And that is the general attitude of the public towards public service corporations in general and railroads in particular.

Women as Railway Porters in England.—The Great Central Railway of England is making experiments to see how far women can be employed as railway porters to set free men of military age. At present two women are being employed at Marylebone in this capacity. The experiment is the result of suggestions from the railway executive committee, and it is expected that other railways will follow the Great Central's example.

General News Department

In Pennsylvania the bill before the legislature to repeal the "full crew law" has been passed by the lower House, and in the Senate has been reported out by the committee, by a vote of seven to six.

The United States civil service commission will receive applications until June 8 for the position of examiner of accounts for the division of valuation of the Interstate Commerce Commission; salary from $2,220 to $3,000 yearly.

A press despatch from Seward, Alaska, reports that on Thursday, April 29, the first spike on the new government railroad was driven by Martha White, who was the first white child born in that region. The engineering commission in charge of the construction of the railroad has issued notices discouraging men looking for work; but very few are to be employed this season.

The new freight terminal of the St. Louis Southwestern, situated at the foot of East Fifth street, Fort Worth, Tex., was opened on May 1. The office building is two stories high and 40 ft. square, and is built of reinforced concrete and brick. The freight warehouse is 420 ft. long, has three scales, has creosoted plank flooring and 27 receiving and delivering doors. The entire building is under tile roofing.

Dr. F. H. Newell, consulting engineer of the United States Reclamation Service, has been appointed professor of civil engineering at the University of Illinois, effective May 1, succeeding Prof. Ira O. Baker, who has resigned after 40 years of service. Prof. Baker tendered his resignation over a year ago, but has held the position pending the selection of a successor. He will probably continue to be connected with the department.

Special Train to Atlantic City Mechanical Conventions

The Pennsylvania Lines have announced that for the accommodation of those who will attend the conventions of the Master Mechanics' and Master Car Builders' Associations at Atlantic City next month, a special train will be provided, leaving Chicago at 5:30 p. m. on Monday, June 7, and arriving at Atlantic City about 5 p. m. the following day. The summer tourist fare will be $31.15 for the round trip, tickets good to return within 30 days, with an extra fare of $4.

Air Brake Law More Rigid

In the United States Circuit Court of Appeals at Richmond, Va., May 4, the judges affirmed unanimously a decision of the District Court, holding it unlawful for a railroad to require the use of hand brakes to control the speed of trains while on the road; that is to say, presumably, at all places where the law requires the train to be equipped with air brakes in condition for use. The contention of the road was that, with long trains on descending grades, the use of the hand brakes, to supplement the air brakes, was necessary to safety. The court held, in substance, that excepting in extraordinary emergency the use of the hand brakes in such a situation is contrary to the air-brake law.

National Transcontinental Road to Be Opened

The Canadian Government announces that in consequence of the declination of the Grand Trunk Pacific Railway to take a lease of the new government railroad, the government itself will at once proceed to put the line in operation from Moncton, N. B., to Winnipeg, Man. At the same time the government will take over and operate the Lake Superior division of the Grand Trunk Pacific, which is the branch of the National extending to Fort William. The officers of the government railway system, now operating the Intercolonial, will take charge of the operations on the new line. Between Winnipeg and Fort William, where the Grand Trunk Pacific has been running trains for some months, the employees will be taken into the government service. It appears that trains have been run, by or in behalf of the contractors on about 300 miles of the line east and west of Cochrane. Cochrane is at the junction of the Temiskaming & Northern Ontario, about 500 miles north of Toronto. The government has for several months been running trains three times a week on the National between Moncton and Levis, opposite Quebec, about 466 miles.

Railroad Laws in New Jersey

In New Jersey, as in New York, the interests opposed to the repeal of the excess crew law succeeded in preventing repeal. Mr. Stevens, of Cape May, had introduced two bills, one to repeal the law now on the statute books, and the other to specifically give authority to the public utility commissioners to decide as to the number of men required on trains; but neither bill ever came up for discussion.

Other railroad legislation played but a small part in the sessions of the legislature. There are six new statutes bearing on railroad interests, but none of them is of great importance.

Governor Fielder vetoed the Pierce grade crossing bill, which passed both houses, a comprehensive law being already on the statute books. This existing law leaves the elimination of grade crossings entirely in the hands of the Board of Public Utility Commissioners. The Pierce bill proposed the elimination of one crossing annually for each thirty miles of railroad. No attempt was made in the Senate to pass the Pierce bill over the veto.

The new laws this year are:

Chapter 350, authorizing first class cities to operate connecting railroads.

Chapter 402, providing for a penalty of $1,000 for railroads refusing to honor passes held by State officers.

Chapter 401 allows a new railroad to take over a line already in existence.

Chapter 57 defines the powers of railroads and municipalities in the adjustment of costs for grade crossing changes.

Chapter 408 gives free passes to members of new boards created this year.

Chapter 404 regulates the construction of physical connections between railroads, the Utilities Commission being clothed with power to require the establishment of connections.

Opening of the Van Buren Bridge

The new bridge of the Van Buren Bridge Company across the St. John river, connecting the Bangor & Aroostook Railroad in Maine with the International Railway in New Brunswick, was opened on May 1 in the presence of a large number of visitors, including officers of New England and Canadian railroads and members of the American Congress and the Canadian Parliament. This bridge, a riveted lattice, consisting of five spans, each 160 ft. long, was begun only last September, and a large part of the work has been done while the temperature was around zero, and at times much lower. To build the concrete piers under these conditions, housings were used around each pier, and by using steam pipes and salamanders, the concrete was successfully made in spite of the low temperatures. The cantilever method of erection was used, thus avoiding risk of interruption of the work by the breaking up of the ice in the river.

The president of the Van Buren Bridge Company is P. R. Todd, president of the Bangor & Aroostook Railroad; consulting engineer, W. J. Wilgus, of New York City; resident engineer, T. A. Lang. The railroad of the Van Buren Bridge Company is 1.2 miles long, Van Buren, Me., to St. Leonards, N. B. On the Canadian side it crosses the National Transcontinental and a branch of the Canadian Pacific, a single interlocking plant (electric) serving for both of these crossings.

By the opening of this route the all-rail distance from a large part of New Brunswick and Quebec to Southern New England is shortened about 200 miles.

The contractors for the substructure were: Cyr Brothers, of

Waterville, Maine, and for the bridge, the Dominion Bridge Company, Limited, of Montreal. Hill & Hammond, of Woodstock, N. B., were contractors for the roadbed, track-laying, ballasting, fencing, and telephone line, and the General Railway Signal Company of Canada, Limited, of Montreal, for the interlocking plant.

Industrial Relations Commission at Washington

The Federal Industrial Relations Commission resumed hearings in Washington, D. C., on May 4. The inquiry opened with H. B. Perham, president of the Order of Railway Telegraphers, as the first witness, who declared that the Pennsylvania Railroad oppressed its employees. He was followed by Robert T. Lincoln, chairman of the board of directors of the Pullman Company, who was questioned regarding conditions of employment of porters and conductors.

Mr. Perham said that the only organizations of employees recognized by the Pennsylvania were those of the engineers, firemen, conductors and brakemen.

"It has discriminated," he said, "against the railroad telegraphers who belong to the organization by discharging them, and denying them promotion. It has pursued the same tactics against the organized shopmen and broke up the organization of the clerks by discharging all those who would not withdraw from the unions."

Foremen and minor officials had bluntly informed men that they were discharged "because of their labor activity," though there was some technical charge assigned for their dismissal.

The road's police system, he said, cost about $800,000 a year. He gave instances of alleged espionage and arrests of union men, and charged that the strike in May, 1911, was precipitated when officers of the company sought to compel 1,000 employees to withdraw from labor unions. He said that the Voluntary Relief Association of the railroad company was not voluntary. Employees, in joining, signed an agreement to forfeit all their accumulation of premiums if they went out of the service of the company. Last year, he said, 4,141 employees, who had thus paid $3,707,080, left the employ of the company and lost all they had paid in.

Mr. Lincoln's testimony in large measure covered the same ground as that covered in the hearings at Chicago and reported in the *Railway Age Gazette* April 9, page 786. Asked if he thought the salary of $27.50 now paid a negro porter as a minimum is enough to maintain his family in comfort and decency, he replied, "Absolutely not." The Pullman Company, he said, was not opposed to organized labor, provided it permitted the company to engage men outside the union. The way for men to negotiate with employers about wages or working conditions, in his opinion, was to appoint committees to interview officers. Asked if he thought paying porters $60 a month and posting notices in all cars requesting that tipping be abolished would have any effect, Mr. Lincoln said he thought tipping would continue.

Mr. Lincoln said that the Pullman Company employed from 6,000 to 6,500 porters. There were 45 district superintendents, and these places were filled from the ranks of the conductors.

The chairman of the commission asked Mr. Lincoln if it were true that the employees had made complaints of their condition and treatment and that their petitions never reached the board of directors. Mr. Lincoln said he thought "it would be rather hard to get the board together for such a purpose."

Mr. Lincoln said that the custom of paying tips was not a nice one. "But it is an old custom and one to which the colored race is accustomed. The public seems to be fond of it. The little services a porter can do seem to justify the tip."

"Do you know that there is a widespread criticism of your company on account of it?" asked Mr. Walsh.

"No, I never heard of such a suggestion," replied Mr. Lincoln.

Asked about losses of linen and the system of penalties to restrain this loss, Mr. Lincoln said that two-thirds of the whole number of employees of the company were paid the good service bonus last year, so that not many could have been punished for loss of linen. The fines for linen lost amounted to $60,000 last year, but the actual losses were far greater than that. Men were not fined a month's salary for their delinquencies and no men had been discharged, as had been reported, for trying to organize unions.

Mr. Lincoln described the relief association maintained by the employees, and said that the Pullman Company underwrote the mutual assessment plan of death payments. The company had no direct plan for relief of employees in sickness or in case of accident.

Solicitor Daniels of the Pullman Company testified concerning legal matters. Where a Pullman employee was hurt in a railroad accident, a suit at law against the operating company was the regular course pursued. He told of a Pullman employee who got a judgment against the Pennsylvania Railroad recently for $14,000 for injury in an accident.

"And we had to pay the judgment," added Mr. Daniels. The Pullman Company is forced by many of its contracts to settle all such judgments for injury by accidents. "The strongs roads," said Mr. Daniels, "compel us to do this and the weak ones can't."

On Wednesday, W. W. Atterbury, vice-president of the Pennsylvania Railroad, testified at length. He presented a prepared statement which explained the policy of the road and rehearsed at length the dealings of the company with the telegraphers' brotherhood and with the federal mediation board in 1909 and 1912; he replied in detail to charges of unfairness to organized labor. He said that the company did not oppose organization of its employees, but did insist upon the "open shop" principle and opposed unions with affiliations which might bring on sympathetic strikes

"We would welcome closer relations with our employees," said Mr Atterbury, "if it could be brought about under proper auspices. We would more than welcome an organization of all Pennsylvania Railroad employees among themselves without entangling outside alliances. Such an organization undoubtedly would be good for the railroad, and anything that is good for the railroad is good for the employees. Our position is identical with that of the federal government respecting the postal railway employees. The government forbids these employees joining an organization that might call them out of their work through sympathy."

"Is the question asked whether a man is a member of a union?"

"No. We never ask the question in employing a man unless he begins to bother us. We are acting on the defensive and not the offensive."

"Is the relation between labor and the employer getting better?"

"I should say so. In the last ten years there has developed a new code. It is different from that of twenty years ago. In the Pennsylvania Railroad all of us come up from the ranks. We are one big family, and we try to avoid outside interference with our affairs. I should be very much surprised if we ever see a great railroad strike again. Industrial conditions are getting better. Labor and employer are closer in touch."

Mr. Atterbury said he was not opposed to many features of the Canadian arbitration law which requires the giving of 30 days' notice before a strike can be declared, and allows the government to present both sides of the dispute.

Concerning the manner in which the railroad kept in touch with sentiment among its men, Mr. Atterbury said:

"Confidential investigators, in no way connected with the railroad's police department, are employed to ascertain and report the conduct and sentiment of employees and the movements, actions and plans of labor leaders and organizers. These men are not empowered to make arrests.

"Labor leaders, with control of the workmen through membership in labor organizations, can cause employees to leave their work, resulting in a strike and interfering with train operations, without giving any previous warning. As the railroad company has the responsibility of maintaining adequate train service and is subject to fines by the government for delays to the mails, it must keep itself informed of the movements of labor agitators. It is necessary that trained men be employed to conduct these investigations.

"Confidential investigators are also employed to identify themselves as employees in various departments to secure correct information as to any efforts of labor organizers among employees which tend to destroy the harmony and friendly feeling which for many years have generally existed between this company and its employees. Investigators are also employed to learn the grievances, if any, of the employees which have been reported to labor organizations for adjustment, in order that such satisfactory settlement as conditions will permit may be made, and to keep the officers fully informed of conditions which they

should know, to permit them properly to manage the property. . . .

"We know what is going on. There are volunteers who give us information. There are about 400 in the police department, and we are prepared for anything that might happen. We do not leave anything undone to keep our trains running that is legal and lawful."

In answering the question whether it was possible for the state to give police protection Mr. Atterbury said:

"In theory, yes, but in practice, no. There is so much opposition to the state protecting corporations that we have found it necessary to look after protection for ourselves.

"We have the finest body of men in the United States in Pennsylvania, the state constabulary. Yet every labor organization is bitterly opposed to its enlargement. It is a dream of the millennium to expect police protection from the states, with all the different political winds blowing through the legislature. If the states should properly protect us it would be an ideal situation. We ought not to attend to the police duty of the states, but we are forced to do it."

American Society for Testing Materials

The eighteenth annual meeting of the American Society for Testing Materials will be held at the Hotel Traymore, Atlantic City, N. J., June 22 to 26.

At the first session meeting, on Tuesday, June 22, at 11 a. m., opening business will be conducted and reports will be received from the committees on Standard Specifications for Coal, and on Standard Specifications for Coke.

At the second session, on Tuesday, at 3 p. m., reports will be received from the committees on Standard Specifications for Wrought Iron; Standard Specifications for Cast Iron and Finished Castings; Corrosion of Iron and Steel, and Standard Tests of Insulating Materials.

The subjects assigned for the remaining sessions are as follows:

Third, Tuesday, June 22, 8 p. m., Non-Ferrous Metals.

Fourth, Wednesday, June 23, 10 a. m., Steel.

Fifth, Wednesday, June 23, 8 p. m., Heat Treatment of Steel.

Sixth, Thursday, June 24, 10 a. m., Testing Apparatus. Among the four papers to be presented at this session will be one by C. D. Young, engineer of tests, of the Pennsylvania Railroad, entitled: The New Physical and Chemical Laboratory of the Pennsylvania Railroad at Altoona.

Seventh, Thursday, June 24, 3 p. m., Cement and Concrete.

Eighth, Friday, June 25, 10 a. m., Ceramics, Gypsum and Lime.

Ninth, Friday, June 25, 3 p. m., Preservative Coatings and Lubricants.

Tenth, Saturday, June 26, 10 a. m., Road Materials, Timber and Rubber.

Recreation periods are provided for Wednesday afternoon and Friday evening, and a smoker is announced for Thursday evening. Special rates have been secured in the hotel for the members of the society and their guests. In addition to the reports of the standing committees and the presentation of monographs on the special subjects, the convention will consider four proposed amendments to the by-laws affecting membership and the adoption of standards.

Air Brake Convention

The twenty-second annual convention of the Air Brake Association was held at the Hotel Sherman, Chicago, May 4 to 7, L. H. Albers, New York Central Lines, presiding. The convention was opened with prayer by Rev. Martin J. Magor. Robert Quayle, general superintendent of motive power and car department, Chicago & North Western, welcomed the association to the city with an inspiring address, calling particular attention to the opportunities of the air brake men in assisting their respective roads in performing their service to the public. He complimented the association on the work it has done to improve conditions in train operation and clearly pointed out the importance of the work of the air brake expert.

President Albers in his address laid particular stress on the standardization of air brake equipment and economical practices in the operation and maintenance of the air brake, believing that if more care was exerted in the cleaning of triple valves, more time could be given between the periodic cleaning which would show a substantial saving.

During the opening exercises W. J. Hatch, the retiring president, was presented with the past president's badge, and S. J. Kidder was given a loving cup as a token of the honor and esteem in which he was held by the association. A letter was also read to the association from F. W. Brazier, superintendent of rolling stock, New York Central Lines, who was invited to address the association, but was unable to be present.

The secretary reported a total membership of 1,119 members and a cash balance in the treasury of $427.91, as of May 1, 1915. A complete report of the convention will be published in next week's issue.

The following is a list of exhibitors at the convention:

American Steel Foundries, Chicago.—Brake beams. Represented by W. E. Fowler, Jr., and P. O. Johnson.

Ashton Valve Company, The, Boston, Mass.—Gages, testers, wheel press recorders and valves. Represented by J. W. Motherwell, H. O. Fettinger and J. F. Gettrust.

Barco Brass & Joint Company, Chicago.—Barco flexible joints, metallic car connections. Represented by F. N. Bard, C. L. Mellor and L. W. Millar.

Crane Company, Chicago. Air brake fittings. Represented by Frank D. Finn, F. W. Venton and John Jordan.

Detroit Lubricator Company, Detroit, Mich.—Lubricators. Represented by A. D. Homard and A. G. Machesney.

Dixon Crucible Company, Joseph, Jersey City, N. J.—Flake graphite. Represented by Mr. Snyder.

Garlock Packing Company, Palmyra, N. Y.—Fiber packing. Represented by T. P. Dunham and J. P. Landreth.

Green, Tweed & Co., New York.—"Palmetto" packing. Represented by F. M. Thomson and V. B. Nickerson.

Johns-Manville Company, H. W., New York.—Packing expander rings and slack adjuster. Represented by J. E. Meek, G. Christenson and P. C. Jacobs.

N. Y. & N. J. Lubricant Company, New York.—Non-fluid oil, brake cylinder lubricant, N. F. O. triple valve lubricant. Represented by J. H. Bennis and F. E. Sparks.

American Railway Association

General Secretary W. F. Allen announces that the spring meeting of the American Railway Association will be held at The Biltmore, Madison and Vanderbilt avenues, Forty-third and Forty-fourth streets, New York City, on Wednesday, May 19, beginning at 11 a. m. Reports will be presented by the committees on transportation, on maintenance, on relations between railroads, on the safe transportation of explosives and other dangerous articles, on electrical working and on legal and traffic relations. The election of a second vice-president will take place at this meeting, and also of members of several committees.

American Association of Railway Surgeons

At the annual meeting of the American Association of Railway Surgeons held in Chicago on Monday, Dr. J. P. Kasper, chief surgeon of the Atchison, Topeka & Santa Fe at Topeka, Kan., was elected president; Dr. J. M. Burke, of Petersburg, Va., was elected vice-president, and Dr. L. J. Mitchell, of Chicago, was re-elected secretary and treasurer.

Association of American Railway Accounting Officers

R. A. White, general auditor of the New York Central Railroad, has been elected president of the Association of American Railway Accounting Officers, and L. A. Robinson, comptroller of the Chicago & North Western, first vice-president; J. A. Taylor, comptroller of the Central of New Jersey, second vice-president, and E. R. Woodson, secretary, have been re-elected.

Central Railway Club

At the regular meeting of the Central Railway Club to be held at the Statler Hotel, Buffalo, N. Y., on Friday, May 14, S. S. Riegel, mechanical engineer of the Delaware, Lackawanna & Western, will present a paper entitled: The Locomotive of Recent Developments.

New England Railroad Club

At the regular meeting of the New England Railroad Club to be held at the New American House, Boston, Mass., on Tuesday, May 11, Henry Cave, president of the Cave Welding Company, will present a paper on Recent Developments in the Oxy-Acetylene Process, which will be illustrated with stereopticon views.

The American Society of Mechanical Engineers

At the meeting of the American Society of Mechanical Engineers to be held at the Engineering Societies building in New York, on Tuesday, May 11, a paper will be presented by John Calder, entitled Metal Spray Processes in Engineering and art.

MEETINGS AND CONVENTIONS

The following list gives names of secretaries, dates of next or regular meetings, and places of meeting.

Air Brake Association.—F. M. Nellis, 53 State St., Boston, Mass.

American Association of Demurrage Officers.—F. A. Pontious, 455 Grand Central Station, Chicago. Next meeting, July 21, 1915, Milwaukee, Wis.

American Association of Dining Car Superintendents.—H. C. Boardman, D. L. & W., Hoboken, N. J. Next meeting, October 21-23, 1915, Boston, Mass.

American Association of Freight Agents.—R. O. Wells, Illinois Central, East St. Louis, Ill. Annual meeting, May 18-21, 1915, Richmond, Va.

American Association of Passenger Traffic Officers.—W. C. Hope, C. R. R. of N. J., 143 Liberty St., New York.

American Association of Railroad Superintendents.—E. H. Harman, Room 101, Union Station, St. Louis, Mo. Next meeting, August 19-20, 1915, San Francisco, Cal.

American Electric Railway Association.—E. B. Burritt, 29 W. 39th St., New York. Annual convention, October 4-8, 1915, San Francisco, Cal.

American Electric Railway Manufacturers' Association.—H. G. McConnaughy, 165 Broadway, New York. Meetings with American Electric Railway Association.

American Railroad Master Tinners, Coppersmiths and Pipefitters' Association.—W. E. Jones, C. & N. W., 3814 Fulton St., Chicago. Annual meeting, July 13-16, 1915, Hotel Sherman, Chicago.

American Railway Association.—W. F. Allen, 75 Church St., New York. Next session, May 19, 1915, New York.

American Railway Bridge and Building Association.—C. A. Lichty, C. & N. W., Chicago. Next convention, October 19-21, 1915, Detroit, Mich.

American Railway Engineering Association.—E. H. Fritch, 900 S. Michigan Ave., Chicago. Next convention, March 21-23, 1916, Chicago.

American Railway Master Mechanics' Association.—J. W. Taylor, 1112 Karpen Bldg., Chicago Annual meeting, June 9-11, 1915, Atlantic City, N. J.

American Railway Tool Foremen's Association.—Owen D. Kinsey, Illinois Central, Chicago. Annual meeting, July 19-21, 1915, Hotel Sherman, Chicago.

American Society for Testing Materials.—Prof. E. Marburg, University of Pennsylvania, Philadelphia, Pa. Annual meeting, June 22-26, 1915, Hotel Traymore, Atlantic City, N. J.

American Society of Civil Engineers.—Chas. Warren Hunt, 220 W. 57th St., New York, Regular meetings, 1st and 3d Wednesday in month, except July and August, 220 W. 57th St., New York.

American Society of Mechanical Engineers.—Calvin W. Rice, 29 W. 39th St., New York. Next spring meeting, June 22-25, 1915, Buffalo, N. Y. Annual meeting, December 7-10, 1915, New York.

American Wood Preservers' Association.—F. J. Angier, Supt. Timber Preservation, B. & O., Mt. Royal Sta., Baltimore, Md. Next convention, January 18-20, 1916, Chicago.

Association of American Railway Accounting Officers.—E. R. Woodson, 1300 Pennsylvania Ave., N. W., Washington, D. C.

Association of Manufacturers of Chilled Car Wheels.—George W. Lyndon, 1214 McCormick Bldg., Chicago. Annual meeting, 2d Tuesday in October, 1915, New York.

Association of Railway Claim Agents.—C. W. Egan, B. & O., Baltimore, Md.

Association of Railway Electrical Engineers.—Jos. A. Andreucetti, C. & N. W., Room 411, C. & N. W. Sta., Chicago. Semi-annual meeting with Master Car Builders' and Master Mechanics' Associations. Annual meeting, October, 1915.

Association of Railway Telegraph Superintendents.—P. W. Drew, Soo Line, 112 West Adams St., Chicago. Annual meeting, June 22-25, 1915, Rochester, N. Y.

Association of Transportation and Car Accounting Officers.—G. P. Conard, 75 Church St., New York. Next meeting, June 22-23, Niagara Falls, N. Y.

Bridge and Building Supply Men's Association.—L. D. Mitchell, Detroit Graphite Co., Chicago, Ill. Meetings with American Railway Bridge and Building Association.

Canadian Railway Club.—James Powell, Grand Trunk, P. O. Box 7, St. Lambert (near Montreal), Que. Regular meetings, 2d Tuesday in month, except June, July and August, Windsor Hotel, Montreal, Que.

Canadian Society of Civil Engineers.—Clement H. McLeod, 176 Mansfield St., Montreal, Que. Regular meetings, 1st Thursday in October, November, December, February, March and April. Annual meeting, January, Montreal.

Car Foremen's Association of Chicago.—Aaron Kline, 841 Lawlor Ave., Chicago. Regular meetings, 2d Monday in month, except June, July and August, Hotel La Salle, Chicago.

Central Railway Club.—H. D. Vought, 95 Liberty St., New York. Regular meetings, 2d Friday in January, May, September and November. Annual meeting, 2d Thursday in March, Hotel Statler, Buffalo, N. Y.

Engineers' Society of Western Pennsylvania.—Elmer K. Hiles, 2511 Oliver Bldg., Pittsburgh, Pa. Regular meetings, 1st and 3d Tuesday, Pittsburgh.

Freight Claim Association.—Warren P. Taylor, Traffic Manager, R. F. & P., Richmond, Va. Annual meeting, June 16, 1915, Chicago.

General Superintendents' Association of Chicago.—A. M. Hunter, 321 Grand Central Station, Chicago. Regular meetings, Wednesday, preceding 3d Tuesday in month, Room 1856, Transportation Bldg., Chicago.

International Railway Fuel Association.—C. G. Hall, C. & E. I., 922 McCormick Bldg., Chicago. Annual meeting, May 17-20, 1915, Hotel La Salle, Chicago.

International Railway General Foremen's Association.—Wm. Hall, 1126 W. Broadway, Winona, Minn. Next convention, July 13-16, 1915, Sherman House, Chicago.

International Railroad Master Blacksmiths' Association.—A. L. Woodworth, C. H. & D., Lima, Ohio. Annual meeting, August 17, 1915, Philadelphia, Pa.

Maintenance of Way and Master Painters' Association of the United States and Canada.—T. I. Goodwin, C. R. I. & P., Eldon, Mo. Next meeting, October 19-21, 1915, St. Louis, Mo.

Master Boiler Makers' Association.—Harry D. Vought, 95 Liberty St., New York. Annual convention, May 25 to 28, 1915, Hotel Sherman, Chicago, Ill.

Master Car and Locomotive Painters' Association of the United States and Canada.—A. P. Dane, B. & M., Reading, Mass. Next convention, September 14-16, 1915, Detroit, Mich.

Master Car Builders' Association.—J. W. Taylor, 1112 Karpen Bldg., Chicago. Annual meeting, June 14-16, 1915, Atlantic City, N. J.

National Railway Appliances Association.—Bruce V. Crandall, 537 So. Dearborn St., Chicago. Next convention, March, 1916, Chicago.

New England Railroad Club.—W. E. Cade, Jr., 683 Atlantic Ave., Boston, Mass. Regular meetings, 2d Tuesday in month, except June, July, August and September, Boston.

New York Railroad Club.—Harry D. Vought, 95 Liberty St., New York. Regular meetings, 3d Friday in month, except June, July and August, 29 W. 39th St., New York.

Niagara Frontier Car Men's Association.—E. N. Frankenberger, 623 Brisbane Bldg., Buffalo, N. Y. Meetings 3d Wednesday in month, New York Telephone Bldg., Buffalo, N. Y.

Peoria Association of Railroad Offices.—M. W. Rotchford, 410 Masonic Temple Bldg., Peoria, Ill. Regular meetings, 3d Thursday in month, Jefferson Hotel, Peoria.

Railroad Club of Kansas City.—Claude Manlove, 1008 Walnut St., Kansas City, Mo. Regular meetings, 3d Saturday in month, Kansas City.

Railroad Men's Improvement Society.—J. B. Curran, Erie R. R., 50 Church St., New York. Meetings, alternate Thursdays, October to May. Assembly Rooms of Trunk Line Association, 143 Liberty St., New York.

Railway Business Association.—Frank W. Noxon, 30 Church St., New York. Annual meeting, Decemher, 1915, Waldorf-Astoria Hotel, New York.

Railway Club of Pittsburgh.—J. E. Anderson, Room 207, P. R. R. Sta., Pittsburgh, Pa. Regular meetings, 4th Friday in month, except June, July and August, Monongahela House, Pittsburgh.

Railway Electrical Supply Manufacturers' Association.—J. Scribner, 1063 Menadnock Block, Chicago. Meetings with Association of Railway Electrical Engineers.

Railway Fire Protection Association.—C. B. Edwards, Fire Ins. Agt., Mobile & Ohio, Mobile, Ala. Next meeting, October 5-7, 1915, Chicago.

Railway Signal Association.—C. C. Rosenberg, Myers Bldg., Bethlehem, Pa. Stated meeting, May 26-27, 1915, Hotel Astor, New York. Annual meeting, September 14-17, 1915, Salt Lake City, Utah.

Railway Storekeepers' Association.—J. P. Murphy, N. Y. C. R. R., Box C, Collinwood, Ohio. Annual meeting, May 17-19, 1915, Hotel Sherman, Chicago.

Railway Supply Manufacturers' Association.—J. D. Conway, 2136 Oliver Bldg., Pittsburgh, Pa. Meetings with Master Car Builders and Master Mechanics' Associations.

Railway Telegraph and Telephone Appliance Association.—G. A. Nelson, 50 Church St., New York. Meetings with Association of Railway Telegraph Superintendents.

Richmond Railroad Club.—F. O. Robinson, C. & O., Richmond, Va. Regular meetings, 2d Monday in month, except June, July and August.

Roadmasters' and Maintenance of Way Association.—L. C. Ryan, C. & N. W., Sterling, Ill. Annual meeting, September 14-16, 1915, Chicago.

St. Louis Railway Club.—B. W. Frauenthal, Union Station, St. Louis, Mo. Regular meetings, 2d Friday in month, except June, July and August, St. Louis.

Salt Lake Transportation Club.—R. E. Rowland, David Keith Bldg., Salt Lake City, Utah. Regular meetings, 1st Saturday of each month, Salt Lake City.

Signal Appliance Association.—F. W. Edmunds, 3868 Park Ave., New York. Meeting with annual convention Railway Signal Association.

Society of Railway Financial Officers.—Carl Nyquist, C. R. I. & P., 1134 La Salle St. Sta., Chicago. Annual meeting, September, 1915.

Southern Association of Car Service Officers.—E. W. Sandwich, A. & W. P. R. R., Atlanta, Ga. Next meeting, July 15, 1915, Atlanta. Annual meeting, January, 1916.

Southern & Southwestern Railway Club.—A. J. Merrill, Grant Bldg., Atlanta, Ga. Regular meetings, 3d Thursday, January, March, May, July, September, November, 10 A. M., Piedmont Hotel, Atlanta.

Toledo Transportation Club.—Harry S. Fox, Toledo, Ohio. Regular meetings, 1st Saturday in month, Boody House, Toledo.

Track Supply Association.—W. C. Kidd, Ramapo Iron Works, Hillburn, N. Y. Meetings with Roadmasters' and Maintenance of Way Association.

Traffic Club of Chicago.—W. H. Wharton, La Salle Hotel, Chicago.

Traffic Club of Newark.—John J. Kautzmann, P. O. Box 238, Newark, N. J. Regular meetings, 1st Monday in month, except July and August, The Washington, 559 Broad St., Newark.

Traffic Club of New York.—C. A. Swope, 291 Broadway, New York. Regular meetings last Tuesday in month, except June, July and August, Hotel Astor, New York.

Traffic Club of Pittsburgh.—D. L. Wells, Genl. Agt., Erie R. R., 1924 Oliver Bldg., Pittsburgh, Pa. Meetings bi-monthly, Pittsburgh. Annual meeting, 2d Monday in June.

Traffic Club of St. Louis.—A. P. Versen, Mercantile Library Bldgs., St. Louis, Mo. Annual meeting in November. Noonday meetings October to May.

Train Dispatchers' Association of America.—J. F. Mackie, 7122 Stewart Ave., Chicago. Annual meeting June 15, 1915, Minneapolis, Minn.

Transportation Club of Detroit.—W. R. Hurley, Superintendent's office, N. Y. C. R. R., Detroit, Mich. Meetings monthly, Normandie Hotel, Detroit.

Traveling Engineers' Association.—W. O. Thompson, N. Y. C. R. R., East Buffalo, N. Y. Annual meeting, September 7-10, 1915, Chicago.

Utah Society of Engineers.—Frank W. Moore, 1111 Newhouse Bldg., Salt Lake City, Utah. Regular meetings, 3d Friday in month, except July and August, Salt Lake City.

Western Canada Railway Club.—L. Kon, Immigration Agent, Grand Trunk Pacific, Winnipeg, Man. Regular meetings, 2d Monday, except June, July and August, Winnipeg.

Western Railway Club.—J. W. Taylor, 1112 Karpen Bldg., Chicago. Regular meetings, 3d Tuesday in month, except June, July and August, Karpen Bldg., Chicago.

Western Society of Engineers.—J. H. Warder, 1735 Monadnock Block, Chicago. Regular meetings, 1st Monday in month, except January, July and August, Chicago. Extra meetings, except in July and August, generally on other Monday evenings. Annual meeting, 1st Wednesday after 1st Thursday in January, Chicago.

REVENUES AND EXPENSES OF RAILWAYS

MONTH OF FEBRUARY, 1915

Name of road.	Average mileage operated during period.	Operating revenues: Freight.	Passenger.	Total, inc. misc.	Operating expenses: Maintenance: Way and structures.	Of equipment.	Traffic.	Transportation.	Miscellaneous.	General.	Total.	Net operating revenue (or deficit).	Railway tax accruals.	Operating income (or loss).	Increase (or decr.) comp. with last year.

Traffic News

The Louisville & Nashville has asked state authority to advance passenger fares on all branch lines in Alabama from 2½ cents a mile to three cents.

Vigorous protests have been filed by newspapers against the increase in freight rates on paper, announced last week, to take effect May 27, in Official Classification territory.

The Chicago, Milwaukee & St. Paul has made arrangements to operate 125 special trains to California and the North Pacific coast for conventions and meetings of various organizations between May 1 and September 5.

The Cape Cod Canal, connecting Buzzards and Cape Cod bays, Massachusetts, announces that rates for passage through the canal have been reduced. Vessels drawing 18 ft. of water may now pass through the canal. The company has added to its tariff a schedule of rates for towing sailing vessels through the canal.

The Baltimore & Ohio on May 1 advanced passenger rates in West Virginia to the basis of 2½ cents a mile, attaching to each ticket a conditional rebate coupon, saving the passenger from loss in case the railroad commission should be able to carry out its purpose to forbid the discontinuance of the two-cent rate.

The railroads carrying grain from Buffalo to the Atlantic Seaboard have filed new tariffs reducing from ten days to five days the time allowed for free storage of grain in the elevators at Buffalo. This storage allowance is an element in the rate of transportation from Buffalo to the seaboard and shippers are expected to protest against the change.

The post office department has filed with the Interstate Commerce Commission a complaint that railroad freight charges on stamped envelopes from Dayton, Ohio, are unreasonably high as compared with rates on similar goods sent by ordinary shippers. Stamped envelopes are charged first-class, and other envelopes and paper, it is alleged, are carried at third-class and fifth-class.

The nominating committee of the Traffic Club of Pittsburgh has nominated the following candidates for the various offices of the club to be voted upon at the June meeting: President, William H. Sproull; first vice-presidents, T. W. Bennett, Ralph W. Cooke and W. E. Whitemore; second vice-presidents, Charles B. Ellis, Edwin C. Jepson and John F. Lent; secretary, P. L. Wells, and treasurer, James T. Meison.

The southeastern railways have notified the Interstate Commerce Commission that they have prepared an amended classification providing that after June 3 freight rates will be increased 10 per cent, unless shippers accept the railroads' bill of lading; but this change is understood to be based on a new form of bill of lading, the terms of which have not been made public. The carriers are considering changes in rules which, evidently, are designed to provide for increased rates where the liability of the carrier is increased by the Cummins law, while retaining those conditions, printed in the bill-of-lading form, which are not affected by this law.

The Merchants' Association, New York City, reports that the freight sent from New York to Pacific coast ports through the Panama Canal during the first eight months of business amounted in value to $41,202,591, which is 90 per cent of the value of all freight moving through the canal from the Atlantic to the Pacific. Three companies are now operating a regular steamship service through the canal, and since the beginning of January a vessel has left New York on an average of every three days. The passenger steamships of the International Mercantile Marine Company, which have been put on the route between New York and San Francisco, as announced in the *Railway Age Gazette*, April 30, p. 945, are to sail fortnightly. Of the freight shipped from New York during the last eight months, more than nine-tenths started from some point outside of New York City; and some of it came from as far west as Davenport, Iowa, and Sheboygan, Wis. Among the commodities carried have been starch from Iowa, beer from St. Louis and Milwaukee, cotton goods from North Carolina and flour from Minneapolis.

Commission and Court News

INTERSTATE COMMERCE COMMISSION

The hearing before the commission on proposed advances in western passenger fares set for May 17, has been postponed to July 6, at the request of the western state railway commissions.

The commission has suspended from May 1 to August 29 a proposed increase of 30 cents a ton in the rate on bituminous coal from Chicago to Redwing, Minn., and intermediate points on the Chicago Great Western, applicable on traffic originating at mines in Kentucky.

The commission has suspended tariffs of the Louisville & Nashville and the Cincinnati, New Orleans & Texas Pacific proposing to cancel the present joint through rates on bituminous coal in carloads from the Kanawha district of West Virginia to points in Kentucky.

The commission has suspended a tariff of the Chicago & North Western proposing changes in the rules governing the eastern shipment of wool. This tariff provides for the withdrawal of the commodity rate of 86 cents a 100 lb. on wool in carloads from Belle Fouche and other points in South Dakota to Winona, Minn., destined to Buffalo, Pittsburgh and other eastern termini.

A hearing on the tariffs filed by the railroads canceling the privilege of stopping freight trains for loading and unloading in transit was held before Examiner Bell of the commission on April 30. James Webster, assistant freight traffic manager of the New York Central Lines, testified for the eastern lines and W. A. Poteet, chairman of the Trans-Missouri Freight Bureau, testified on behalf of the western lines.

Jurisdiction Over Urban Electric Lines

Opinion by the commission:

Electric railways, other than street passenger railways, participating in the interstate movement of persons or property are in this case held subject to the requirements of the commission relative to the filing of reports of finances and operations and accidents. Railway companies which provide both street-car or other intrastate service and interstate service should, however, restrict the scope of their monthly reports of accidents so as to include only accidents resulting from the operation of cars engaged in the transportation of passengers and property in interstate commerce. (33 I. C. C., 536.)

Fourth Section Applications in Rates on Grain to Jackson and Meridian, Miss.

Opinion by the commission:

The carriers are authorized to continue rates on grain and grain products from Omaha, Neb., St. Louis, Mo., and Ohio river crossings to Jackson and Meridian, Miss., on the basis of combination on Vicksburg, Miss., lower than rates concurrently applicable on like traffic to intermediate points.

Authority to continue rates between Vicksburg, Miss., and stations on the Alabama & Vicksburg applying on grain and grain products, that result in higher charges on grain and grain products from Omaha, St. Louis and Ohio river crossings to intermediate points than to Jackson and Meridian are, however, denied. (33 I. C. C., 613.)

Rates on Toasted Wheat Biscuit

Kellogg Toasted Corn Flake Company v. Atchison, Topeka & Santa Fe et al. Opinion by the commission:

The rates charged by defendants for the interstate transportation of toasted wheat biscuit and toasted wheat krumbles in carloads in western trunk line and southwestern territories are found to be discrimatory in that they exceed the rates on cream of wheat, Post tavern porridge and like uncooked cereal foods in carloads between the same points. The commodities are of substantially the same value; the transportation conditions are sub-

stantially similar, and both classes are rated the same in the official, southern and western classifications, different ratings being maintained only in the territory in controversy by special commodity tariffs and exceptions to the classifications. (33 I. C. C., 534.)

Rates on Paper From New England Points to New York

Opinion by the commission:

Paper in less than carloads is rated third class in the official classification. Respondents, the Boston & Maine, the Boston & Albany and the New York, New Haven & Hartford, publish less than carload commodity rates from producing points on their lines in New England to New York and New York delivery points lower than third class. In the tariffs under consideration it is proposed to cancel these commodity rates leaving the class rates in effect. The Boston & Maine has since proposed a scale of rates higher than the present rates, but somewhat lower than the rates under consideration. It is found that these rates and the rates proposed by the Boston & Albany and the New Haven in the suspended tariffs are justified. (33 I. C. C., 609.)

Joint Rates With the Chicago, Ottawa & Peoria

Chicago, Ottawa & Peoria v. Chicago & North Western et al. Opinion by Commissioner Harlan:

The complainants operate an electric railway in Illinois from Princeton in an easterly direction through Peru, La Salle, Ottawa and Morris to Joliet, with branch lines southward from Ottawa to Streator and northward from Hicks Junction to Ladd. It is a part of the Illinois Traction system, although it has no physical connection with that system and already has joint rates on interstate traffic with some of the trunk lines. In this proceeding it asks that the defendants be required to establish through routes and joint rates on all interstate traffic between points on defendants' lines and points on its own rails. The commission finds that there is no public necessity for the routes and rates asked for, as the shippers and receivers of freight at all the towns reached by the electric railway now have joint rates over steam roads to all points reached by such roads, at as low rates, and with as efficient service as would result from the establishment of the through routes and joint rates asked. (33 I. C. C., 573.)

Lumber Transit Privileges at Buffalo

Buffalo Lumber Exchange and Buffalo Chamber of Commerce v. Alabama Central et al. Opinion by Commissioner McChord:

The commission finds that the carriers have not justified proposed increased rates on hardwood lumber from southern points, stopped in transit at Buffalo, and reconsigned to points east, northeast and southeast thereof. It was shown that these proposed increased rates were largely the result of a dispute between the carriers as to divisions.

The rates, regulations and practices of the southern carriers applying on this traffic were not found unreasonable or discriminatory, except as to the rule published by Morgan's Louisiana & Texas providing for the application of combination rates on shipments routed over certain lines, which was found unreasonable. (33 I. C. C., 601.)

Proportional Rates on Grain Products From Omaha to Destinations South of the Ohio

Opinion by Commissioner Clements:

The Illinois Central has proposed to increase the rates on grain products from Omaha to destinations local to its lines in the Mississippi valley in order to bring them in harmony with the general rate adjustment as between Omaha, Kansas City and St. Louis, primary grain markets. No change is proposed in the grain products' rates to Mississippi river points, or to competitive points on the Illinois Central.

The commission finds that the carrier has justified the increases in the rates from Omaha to the destinations here involved south of Montgomery, Miss. It has not, however, justified increases in the rates to stations north of Elton, Miss., nor the full increases to destinations south of and including Elton, to and including Montgomery. Maximum rates to these stations are prescribed for flour, coarse grain products and oatmeal. (33 I. C. C., 621.)

Joint Rates With the Campbell's Creek Railroad

Campbell's Creek Coal Company v. Ann Arbor et al. Opinion by Commissioner Meyer:

The commission in its original findings in this case held that the Kanawha & Michigan discriminated against the Campbell's Creek Railroad in that it awarded main-line or Kanawha district rates on coal from points on the Kanawha & West Virginia and the Coal & Coke, while it did not award such rates to points on the Campbell's Creek. The carrier was directed to eliminate this discrimination, either by cancelling the main-line rates from points on the Coal & Coke and the Kanawha & West Virginia, or by establishing these rates as joint rates with the Campbell's Creek. The Kanawha & Michigan elected to cancel the main line rates with the Coal & Coke and the Kanawha & West Virginia.

The commission now holds that main-line or district rates applying from points on the Coal & Coke and the Kanawha & West Virginia should be continued, and that through routes and joint rates should be established from points on the Campbell's Creek. Such rates should not exceed the main line or distinct rates applying from points on the other two roads. (33 I. C. C., 558.)

STATE COMMISSIONS

The New York State Public Service Commission, Second district, has suspended, until July 1, proposed increases in commutation passenger fares on the Long Island Railroad.

The railroads have completed their testimony before the Kansas Public Utilities Commission on their petition for authority to increase passenger fares, and the commission has adjourned to a date to be fixed later, when the commercial travelers, who are opposing the advance, will be given an opportunity to be heard.

PERSONNEL OF COMMISSIONS

Clinton White, a member of the Massachusetts Public Service Commission and of its predecessor, the Railroad Commission, for many years, announces that on May 17 he is going to retire, that being the day on which he will reach the age of 70.

COURT NEWS

The Supreme Court of Missouri has authorized 11 railroads in that state to file briefs in the case instituted by the attorney general of the state against the Chicago & Alton to recover excess charges collected while the freight and passenger rate laws were in litigation. The circuit court of Saline county decided this case in favor of the railroad, holding that the attorney general could not recover the charges on behalf of the state or unnamed shippers.

In the Supreme Court of the United States the government has won its suit against the Erie Railroad to recover penalties for violation of the safety appliance laws in the movement of freight trains between Jersey City, N. J. and Weehawken, about two miles. The road had claimed that the movement of trains in question was essentially a yard or switching movement; but the court finds that, by reasonable interpretation, these should be called main line movements. The lower court is ordered to grant a new trial, two decisions, those of the district court and of the circuit court of appeals, having been in favor of the road. This decision settles in favor of the government a similar suit against the Chicago, Burlington & Quincy, relating to movements in Kansas City.

Right of Way—Abandonment

The conveyance of a strip of land to a railroad company for a right of way, "to have and to hold the same for and so long as the same is used for railroad purposes," is held by the Minnesota Supreme Court to convey an easement only, and not the absolute fee-simple title. An easement so held may be lost by abandonment. In the present instance a track of the Duluth Transfer, owned by the Northern Pacific, had been taken up by the latter, and for ten years no use had been made of the right of way for any purpose. It was held that there was an intentional abandonment of the right of way. Norton v. Duluth Transfer (Minn.), 151 N. W., 907.

Duty to Keep Ticket Office Open

Railroad companies in Kentucky are required by statute to keep their ticket offices open at least 30 minutes immediately preceding the schedule time of departure of passenger trains. A passenger without a ticket boarded a train at a station where there was a ticket office. The train was about seven minutes late. The ticket office had been kept open until about seven minutes after the schedule time of departure, when the agent left the office to attend to outside duties. The passenger arrived at the station after schedule time. It was held by the Kentucky Court of Appeals that he might be required to pay the extra flat charge of 10 cents, the statute having been complied with. Ponder v. Lexington & Eastern (Ky.), 174 S. W., 786.

Derailing Devices—Unreasonable Order

The Litchfield & M. allowed an electric road to cross its line under an agreement that the latter was to construct and maintain a derailing device, and L. & M. trains always to have precedence. An order of the Illinois Railroad and Warehouse Commission, reversing the obligations and rights under the agreement, required the electric road, running about 40 trains a day, to install interlocking, at a cost of $4,200, gave it equal rights of crossing, and required the L. & M., running four or five trains a day, to assume the expense of operating the interlocking and to stop its trains, when necessary, at an expense of $1.08 for a loaded train and 83 cents for a train not loaded. The Illinois Supreme Court holds the order to be unreasonable; and that a fair apportionment of the cost of operation would require each road to bear the expense in proportion to the number of times which each used the crossing. Railroad and Warehouse Commission v. Litchfield & M. (Ill.), 108 N. E., 347.

Establishment of Stations—Reasonableness of Order

The Railroad Commissioners of Florida having issued an order requiring the Florida East Coast to establish and maintain an agency station at Mims, the Florida Supreme Court holds that the duty of a railroad company to provide fit and suitable roadbeds and tracks and rolling stock may be distinguished from the duty to provide stations along its line. The one is an essentially higher and more important duty than the other. In the latter case the fact that the performance of the duty will be unremunerative may be considered. In the present case it appeared that the road is operated at a loss, that its stockholders receive no dividends, that there is no sinking fund, that its income is not sufficient to pay the interest on its bonds, and that ample accommodation for the business received existed at Mims. It was held that if these facts were true the order was unreasonable, and the railroad company was entitled to an opportunity to prove them. No evidence having been taken, the order was subject to be set aside. State v. Florida East Coast (Fla.), 67 So., 906.

Taxation—Intangible Elements of Value

The Supreme Court of the State of Washington upholds as valid and constitutional the assessment, for 1913, of the Northern Pacific's operating property within the state, as a unit, at $126,000,000, including an added item of $12,290,000 on account of density of traffic and volume of business along its line, the nature of the country through which its line ran, the facilities for transacting railroad business owned by private individuals, such as warehouses and docks, the proximity of extensive coal mines enabling it to obtain coal at reduced cost, regardless of its ownership, the resources of the country adjacent to its line, and the density of population and development of the tributary territory, considered as intangible elements affecting the value of its operating property.

It was also held that, in the absence of any willful fraudulent acts charged against either the state board of tax commissioners making the assessment or the state board of equalization adopting it, or any charge that such boards refused to hear evidence as to value or acted arbitrarily, the assessment, where the difference between the assessed value and the actual value was as small as 10 per cent, would not be interfered with by the court purely on the ground that it was excessive, and because of a radical change in conditions resulting in large decrease in net earnings of the property and a permanent impairment of its value. Northern Pacific v. State (Wash.), 147 Pac., 45.

Railway Officers

Executive, Financial, Legal and Accounting

Alden B. Muller has been appointed secretary and treasurer of the Texas-Mexican, with office at Laredo, Tex., succeeding John F. Boniger, deceased.

William Gerig, vice-president, general manager, treasurer and chief engineer of the Pacific & Eastern at Medford, Ore., has resigned to take a position in connection with the work on the union depot at St. Paul.

G. J. Bunting, whose appointment as general auditor of the Chicago, Milwaukee & St. Paul, with headquarters at Chicago, has already been announced, was born July 14, 1881, at Portsmouth, Va., and was educated in the common and high schools. After his graduation from high school he completed his education under private tutorage. In 1900 he was made general accountant of the Cashie & Chowan road in North Carolina and later held positions with two large public accounting agencies, the Audit Company of New York and the Indiana Audit Company. In May, 1909, he was appointed examiner of accounts for the Interstate Commerce Commission and remained in that position until July 15, 1911, when he was appointed general accountant for the Chicago, Milwaukee & St. Paul at Chicago. On March 15, 1913, he was appointed assistant general auditor of the road, from which position he is now promoted.

G. J. Bunting

Walter Platt Cooke, whose election as president of the New Orleans Great Northern, with headquatrers at Buffalo, N. Y., has already been announced in these columns, was born on April 28, 1869, at Buffalo, N. Y. He was educated in the public and high schools of his native town, and in 1891 graduated from Cornell University. He engaged in the practice of law in Buffalo, and is a member of the firm of Kenefick, Cooke, Mitchell & Bass. Mr. Cooke is an executor of the Frank H. Goodyear estate, and has been in charge of the estate for several years. Mr. Goodyear was one of the founders of the Great Southern Lumber Company, and his estate owns a large interest in that company as well as in the stock of the New Orleans Great Northern Railroad. Mr. Cooke has been chairman of the executive committee for four years of the Great Southern Lumber Company and of the New Orleans Great Northern Railroad, and for over a year has been first vice-president and general counsel of the railroad company.

W. P. Cooke

J. R. Stephens, chief engineer of the Missouri Pacific and the St. Louis, Iron Mountain & Southern, has been appointed assistant to the president, with headquarters at St. Louis, succeeding A. Robertson, promoted.

E. N. Renfrew, auditor of agencies of the New York, New Haven & Hartford, the Central New England and the New England Steamship Company at New Haven, Conn., has been appointed auditor of miscellaneous receipts, with office at New Haven. He will have charge of all miscellaneous revenue and will also continue to perform the duties of auditor of agencies.

L. R. Wood, whose appointment as auditor of the Oregon Short Line, with headquarters at Salt Lake City, Utah, has already been announced, was born November 20, 1875, at Denison, Iowa, and was educated in the common, high and business schools. He entered railway service February 10, 1899, in the traffic department of the Fremont, Elkhorn & Missouri Valley. From February 20, 1900, to July 1, 1905, he was stenographer to the auditor of disbursements of the Union Pacific, and from July 1, 1905, to January 1, 1910, he was general clerk in the general auditor's office of the Union Pacific-Southern Pacific system. In January, 1910, he was made assistant chief clerk to the vice-president and controller of the same road, and held that position until March 1, 1912, when he was made chief clerk to the auditor of the Oregon Short Line. On April 11, 1914, he was appointed assistant auditor of the Oregan Short Line, from which position he is now promoted.

Henry Watkins Miller, whose election as vice-president of the Southern Railway, with headquarters at Atlanta, Ga., has already been announced in these columns, was born on August 8, 1868, at Raleigh, N. C., and was educated in the public and private schools of his native city. In October, 1885, he entered the service of the Richmond & Danville as loading clerk at the Raleigh freight house and as relief telegraph operator. He was advanced to billing clerk and then chief clerk at this station, and later became rate clerk in the division freight office. In September, 1888, he left the traffic department to become chief clerk and secretary to the third vice-president of the same road, becoming secretary to the second vice-president on the organization of the Southern Railway, and from 1894 to December, 1901, was secretary to the first vice-president. He was then appointed assistant to the first vice-president, and in December, 1910, was appointed assistant to president, which position he held at the time of his recent election as vice-president of the same road as above noted. He has also served as secretary of various subsidiary lines of the Southern Railway, and has recently been elected vice-president of the Danville & Western; Blue Ridge Railway; Augusta Southern; Tallulah Falls, and the Hartwell Railway Company. He is also president of the Kentucky & Indiana Terminal Railroad Company, and of the Durham Union Station.

H. W. Miller

Operating

A. L. Christiansen has been appointed superintendent of car service of the Elgin, Joliet & Eastern, with office at Joliet, Ill.

J. L. Marquette, trainmaster of the Western division of the Chicago & Alton, has been appointed assistant superintendent, with headquatrers at Slater, Mo.

F. M. Metcalfe has been appointed to be in charge of the bureau of efficiency of the Northern Pacific, with headquarters at St. Paul, succeeding Charles T. Banks, resigned.

Traffic

John Redding, contracting agent of the Wabash at Toledo, Ohio, has been promoted to commercial agent, with headquarters at Toledo.

John S. Campbell has been appointed district agent of the Pennsylvania Lines and Union Line at Portland, Ore., succeeding F. N. Kollock, retired under the pension system.

A. S. Edmonds, general agent of the Missouri Pacific-Iron Mountain System, at Philadelphia, has been appointed traffic manager of the Chesapeake Steamship Company, of Baltimore.

E. M. Meagher, chief clerk in the office of the general freight and passenger agent of the Buffalo & Susquehanna, at Buffalo, N. Y., has been appointed acting general freight and passenger agent, with headquarters at Buffalo.

J. F. Blumensteil, division freight agent of the Detroit, Toledo & Ironton at Springfield, Ohio, has resigned to engage in other business. H. A. Fidler, assistant general freight agent at Ironton, Ohio, has been transferred to Springfield.

Horace Emerson has been appointed commercial agent of the Atlantic Coast Line, with headquarters at Sumter, S. C. E. M. Finch, commercial agent at Montgomery, Ala., has been appointed commercial agent, at Ocala, Fla., vice H. H. Brand, deceased, and the position of commercial agent at Montgomery has been abolished. Pendleton Goodall, commercial agent at Cincinnati, Ohio, has been appointed commercial agent at St. Louis, Mo., vice C. H. Trimble, deceased, and E. H. Smith succeeds Mr. Goodall.

J. M. Johnson, vice-president in charge of traffic of the Missouri Pacific-Iron Mountain System and the Denver & Rio Grande, has moved his headquarters from St. Louis to Chicago. W. A. Rambach, assistant to the vice-president, with headquarters in Chicago, has been appointed assistant freight traffic manager in charge of rates, etc., with headquarters at St. Louis. J. N. Githens, assistant to the vice-president, has been appointed assistant freight traffic manager in charge of solicitation, with headquarters in St. Louis. W. I. Jones, assistant to the vice-president, has been promoted to general freight agent of the Iron Mountain, to succeed E. H. Calef, deceased. C. C. P. Rausch, assistant-general freight agent at St. Louis, has been promoted to general freight agent. His duties will consist of appearing before the different railroad commissions and such other work as may be assigned him. D. R. Lincoln, assistant-general freight agent, with headquarters in Kansas City, has been transferred to St. Louis, with the same title, but with increased duties and responsibilities. W. H. Alexander, assistant-general freight agent at St. Louis, has been transferred to Kansas City to take up the work formerly performed by Mr Lincoln.

Engineering and Rolling Stock

W. H. Winterrowd, mechanical engineer of the Canadian Pacific at Montreal, Que., has been appointed assistant to the chief mechanical engineer, with headquarters at Montreal.

E. A. Hadley, assistant engineer of the Missouri Pacific and the St. Louis, Iron Mountain & Southern, has been appointed chief engineer, with headquarters at St. Louis, succeeding J. R Stephens, promoted.

O. E. Selby, engineer of bridges and structures of the Cleveland, Cincinnati, Chicago & St. Louis and the Peoria & Eastern at Cincinnati, Ohio, has been appointed principal assistant engineer, and J. B. Hunley succeeds Mr. Selby.

Harry A. Macbeth, who has been appointed superintendent of motive power of the New York, Chicago & St. Louis, with headquarters at Cleveland, Ohio, succeeding E. A. Miller, deceased, was born on September 23, 1867, at Wellsville, Ohio. He was educated in the common and high schools and entered railway service in October, 1883, with the New York, Chicago & St. Louis. He was machinist apprentice from 1884 until 1887, machinist from 1887 to 1891, gang foreman from 1891 to 1898, when he was appointed general foreman. This position he held until 1905, when he was appointed master mechanic, and he has served in that capacity for the last 10 years, recently with headquarters at

Conneaut, Ohio, from which position he is now promoted to superintendent of motive power.

Charles W. Van Buren, who has been appointed general master car builder of the Canadian Pacific, with headquarters at Montreal, Que., as has already been announced in these columns, was born on October 18, 1867, in Rensselaer county, N. Y. He went to the common schools until he was 16 years old, and for a year attended night school in New York City. In 1889 he began railway work on the New York Central & Hudson River. He was a carpenter at the West Albany shops until 1891, when he was made foreman, and two years later he was put in charge of car department work on the Adirondack division at Herkimer, N. Y. In 1896 he was transferred to Utica in charge of car department work on the Adirondack and the Mohawk divisions of the New York Central & Hudson River and the West Shore. He entered the service of the Canadian Pacific in July, 1905, as general car inspector on the lines east of Port Arthur. The following year he was appointed division car foreman of the Eastern division, remaining in that position until July, 1909, and then served as master car builder of the eastern lines of the same road, with headquarters at Montreal, until May, 1911. He then went to the Union Stock Yard & Transit Company, Chicago, as assistant general superintendent, remaining with that company until January, 1915, when he was appointed general foreman of the Milwaukee Refrigerator Transit & Car Company, at Milwaukee, Wis., which position he held until his recent appointment as general master car builder of the Canadian Pacific, as above noted.

Purchasing

E. J. Urtel, chief clerk in the president's office of the Buffalo & Susquehanna, at Buffalo, N. Y., has been appointed purchasing agent, with headquarters at Buffalo.

OBITUARY

Union B. Hunt, former chairman of the railroad commission of Indiana, died at Indianapolis on May 3.

E. H. Calef, general freight agent of the St. Louis, Iron Mountain & Southern, whose death on April 21, at his home in St. Louis, Mo., was briefly noted in these columns last week, was born in St. Louis in 1867. His entire railway career was on the Missouri Pacific-Iron Mountain system. He began railway work in January, 1884, as a messenger in the freight claim department and later became traveling freight agent in the Indian Territory and other fields. In 1899 he was appointed commercial agent at Sedalia, Mo., and in March, 1905, was appointed division freight agent of the Iron Mountain at Little Rock, Ark. In September, 1908, he was made assistant general freight agent, with headquarters at St. Louis, and on June 1, 1913, he was appointed general freight agent of that road, with office at St. Louis.

E. H. Calef

The Railways of Belgium.—It is reported from Brussels that the Germans have not only repaired almost all the railways in Belgium which were damaged through the war, but that they are also engaged on the construction of a new line from Aix-la-Chapelle via Visé-Glons to Brussels, avoiding Liége and the awkward curve of Ans. The railway on completion will considerably reduce the length of the connection between Germany and Brussels, Ghent, Antwerp and the coast.

Equipment and Supplies

LOCOMOTIVE BUILDING

The Western Maryland is in the market for 10 locomotives.

The Chicago Great Western is asking for bids on 5 switching locomotives.

The French Government has issued specifications for 100 large locomotives.

The Cuba Railroad has ordered 10 ten-wheel type locomotives from the American Locomotive Company.

The Pennsylvania Railroad has given its Juniata shops authority to proceed with the construction of 50 superheater Mikado type (L-1-s) locomotives.

CAR BUILDING

The Cold Blast Transportation Company is in the market for 300 refrigerator cars.

The Atchison, Topeka & Santa Fe is said to be intending to build or buy a hospital car.

The Pittsburgh Steel Company has ordered 10 hopper cars from the Standard Steel Car Company

The Contractors' Service Company, New York, is in the market for 45 50,000 to 60,000-lb. capacity, steel underframe flat cars not less than 32 feet long.

The Western Maryland, reported in the *Railway Age Gazette* of April 16 as contemplating the purchase of a number of passenger cars, is about to issue inquiries for these cars and for 1,000 coal cars.

The Ponca Refining Company, reported in the *Railway Age Gazette* of April 16, as having ordered 100 tank cars from the American Car & Foundry Company, has now increased that order to 120 tank cars.

The New York Municipal has ordered 100 steel subway cars from the American Car & Foundry Company. These cars are in addition to the 200 ordered in the latter part of 1914 and will be of the same type.

The Pennsylvania Equipment Company is in the market for 100 or 150 40-ft., 80,000 to 100,000 lb. capacity flat cars, 1 second-hand combination passenger and baggage car and 2 combination passenger, mail and baggage cars.

The Central Locomotive & Car Works is reported to be asking bids on trucks, castings and forgings for 1,000 freight cars, said to be in preparation for building 1,000 cars for the Minneapolis & St. Louis. This item has not been confirmed.

The Russian Government is understood to have closed or to be about to close contracts with the Pressed Steel Car Company for railroad equipment variously estimated to be worth from $10,000,000 to $40,000,000. The contracts are said to include from 10,000 to 17,500 all-steel freight cars.

IRON AND STEEL

The Illinois Central is in the market for 2,000 tons of angle bars.

The Boston & Maine is asking bids on about 1,000 tons of steel.

The Norfolk Southern is inquiring for 1,500 tons of steel rails.

The Lehigh & New England is receiving bids on 300 tons of bridge material.

The Southern has ordered 1,575 tons of steel rail from the Pennsylvania Steel Company.

The Minneapolis & St. Louis has ordered 5,000 tons of rails from the Illinois Steel Company.

The New York, New Haven & Hartford is inquiring for about 200 tons of steel bridge material.

The Chicago, Indianapolis & Louisville has ordered 3,000 tons of rails from the Illinois Steel Company.

The Pittsburgh & Lake Erie is reported to have ordered 5,700 tons of rails from the Carnegie Steel Company.

The New York Central is asking for bids on 300 tons of shapes for three bridges to be constructed at Jersey City.

The Chicago, Milwaukee & St. Paul has ordered 119 tons of steel rods from the Minneapolis Steel & Machinery Company.

The Dallas Union Terminal has ordered 215 tons of steel tor train sheds at Dallas, Tex., from the American Bridge Company.

The Central of New Jersey is asking for bids on 500 tons of fabricating steel for a bridge to be constructed in eastern Pennsylvania.

The Cincinnati, Hamilton & Dayton has asked for bids on three steel bridges for immediate delivery to cost approximately $200,000.

The Texas & Pacific has ordered 273 tons of steel for a railroad crossing for the Dallas Terminal, Dallas, Tex., from the American Bridge Company.

The Wisconsin & Northern has ordered 134 tons of steel for a 261-foot deck plate girder viaduct at Gresham, Wis., from the Wisconsin Bridge & Iron Company.

The Atchison, Topeka & Santa Fe has ordered 230 tons of steel for two 100-foot turntables, one at Amarillo, Tex., and one at Wellington, Kan., from the American Bridge Company.

The Russian Government is said to have issued inquiries in this country for bridge steel and rails to the value of $100,000,000. Negotiations are nearing completion with the Lackawanna Steel Company, whereby that company will supply 20,000 tons of rails.

The Government Railways of the Union of South Africa, reported in the *Railway Age Gazette* of April 16 as having ordered 30,000 tons of rails from the Dominion Iron & Steel Company, have ordered 35,000 tons from that company. They are also reported to have ordered 35,000 tons from the Algoma Steel Corporation, Ltd.

MACHINERY AND TOOLS

The Chesapeake & Ohio is in the market for a planer and a vertical turret lathe.

The Waterloo, Cedar Rapids & Northern will spend $300,000 during the next three months for equipment for its power plant at Waterloo, Iowa.

The Minneapolis, St. Paul, Rochester & Dubuque Electric Traction is asking bids through the J. G. White & Co., Inc., for 11 machine tools to be installed in its shops at Minneapolis.

The Alaska Engineering Commission has awarded to the Browning Company, Cleveland, Ohio, a contract for a locomotive crane to be used on the construction of the new Alaska railroad.

The Seaboard Air Line has ordered about $50,000 worth of machine tools to replace tools damaged in the recent fire at the Portsmouth, Va., shops. Work on the rebuilding of these shops has been commenced and it is expected that more machine tools will be purchased later.

The Missouri, Oklahoma & Gulf is inquiring through the Arnold Company of Chicago for five lathes, five grinders, three boring mills, two drills, two presses, a planer, a universal milling machine, a portable crane and hoist, a portable valve facing machine, portable valve setting rollers, a triple-head bolt cutter, a pipe-cutting and threading machine, a draw cut shaper, a bar shear, six portable vises, a 3,300-lb. steam hammer, a forging machine and bulldozer, 2-in. bolt header and forging machine, a pressure blower, a case-hardening and spring furnace, a 500-lb. belt-driven hammer, 12-ft. bending rolls and a 12-ft. flanging clamp.

Supply Trade News

The Baldwin Locomotive Works is reported to be negotiating for a large contract for war material.

Edward A. Hill, retired manufacturer of railway supplies, died April 29, at the home of John C. King in Chicago.

S. F. Klohs, mechanical engineer and draftsman, has moved his office from the Monadnock block, Chicago, to room 1309, Great Northern building.

John H. Lloyd, formerly assistant to the president of the Morgan Engineering Company, Alliance, Ohio, died recently in that city at the age of 56 years.

J. R. Wills, for eight years supervisor of signals of the Oregon Short Line at Ogden, Utah, has joined the sales force of the National Carbon Company, Cleveland, Ohio.

The Cast Steel Locomotive Ashpan Company, St. Louis, Mo., has been incorporated with a capital stock of $40,000 by H. M. Pflager, Arthur W. Morey and Fred W. Dieckmann.

H. S. Collette, secretary of J. G. White & Co., Inc., and the J. G. White Engineering Corporation, New York, has resigned from these companies and expects to reside permanently in California.

The Edgar Allen American Manganese Steel Company, Chicago, has changed its name to the American Manganese Steel Company. This company has foundries at Chicago Heights, Ill., and New Castle, Del.

The Louisville & Nashville has recently awarded a contract to the Roberts & Schaefer Company, Chicago, for the equipment of a large 500-ton, four-track reinforced concrete coaling station, for installation at Lexington, Ky.

It is reported that the Franklin, Pa., plants of the Chicago Pneumatic Tool Company will soon be put in operation day and night on an order for shells estimated up to 300,000 received from the Bethlehem Steel Corporation.

On and after May 1, the New York offices and show rooms of The Dahlstrom Metallic Door Company, Jamestown, N. Y., will be located on the fifth floor of the Consolidated Gas Company's building, 130 East Fifteenth street.

John H. Hall, 2 Rector street, New York City, has discontinued his practice as consulting engineer and has entered the employment of the Taylor-Wharton Iron & Steel Company, High Bridge, N. J., as metallurgical engineer.

The Pittsburgh Steel Car Company, Pittsburgh, Pa., has been incorporated at Dover, Del., with a capital of $100,000; and will manufacture and deal in steel railroad cars. The incorporators are Norman P. Coffin, Herbert E. Latter, Wilmington, Del., and Clement M. Enger, Elkton, Md.

In recognition of his services to the engineering profession, the Japanese government through its Department of Education has conferred upon J. A. L. Waddell, consulting engineer of Kansas City, Mo., the degree of Hakushi (Doctor of Engineering, the highest scholastic honor in its gift).

The Western Electric Company has recently shipped three boat loads of telephone poles to Greece. The shipment was made in 45 carloads from the concentration yard at Toledo, Ohio, and consisted of 15,000 4-in. top, 20 ft., and 2,000 5-in. top, 25 ft. Northern Cedar poles of first quality. The Greek Government will use the poles in extending present telephone facilities.

The Union Signal Construction Company, Pittsburgh, Pa., has been incorporated at Dover, Del., with a capital stock of $10,000, to manufacture, buy, sell and deal in all kinds of railroad supplies, including signal apparatus. W. D. Uptegraff, Pittsburgh, Pa.; T. W. Siemon and T. S. Grubbs, Edgewood, Pa., are the incorporators. Messrs. Uptegraff and Siemon are officers of the Union Switch & Signal Company.

The Westinghouse Electric & Manufacturing Company has received an order having an aggregate value of $27,500,000 from the British government for 1,000,000 rifles at $27.50 each. The con-

tract was placed through J. P. Morgan & Co. and it is understood that the rifles are being ordered for Russia. It is further reported that there is also an additional order for the same amount; and if the latter report be also true the total orders for rifles will total $55,000,000. The company has been working for some time on some smaller orders for shrapnel. The rifles are not to be made in the company's own plants, but in shops secured with that object in view. The plants will thus not be interfered with, but will be prepared to work on domestic orders for electrical equipment.

In the *Railway Age Gazette* of April 23 it was reported that the American Locomotive Company was supposed to have closed contracts with the Russian government for shrapnel aggregating $65,000,000 in value. Later reports have made it evident that the only company which has received orders for shrapnel from the Russian government is the Canadian Car & Foundry Company. That company closed a contract some time ago for approximately $83,000,000 worth of such material. The contract calls for more than 5,000,000 loaded shrapnel shells, the shot and shells to be shipped separately, and a considerable portion of it has been sublet to American and Canadian companies. The American Locomotive Company has, however, received an order for $68,000,000 worth of unloaded shrapnel shells; but this order has been received from Great Britain rather than from Russia. The company plans to fill about one-half the order at its Richmond and Dunkirk plants and has already purchased a large amount of the special machinery which will be required. The remainder of the order will be filled by the New York Air Brake Company and the Westinghouse Air Brake Company; and it is understood that the latter will divide a part of its share with the Union Switch & Signal Company.

Westinghouse Electric & Manufacturing Company

The directors of the Westinghouse Electric & Manufacturing Company at their meeting on Wednesday issued the following statement: "The company will not require additional capital for its present volume of business or for any increase expected in the near future. It has made adequate provision, without borrowing, for the execution of the large orders recently received from foreign governments. On the other hand, in case of the radical increase in business which may come with good times, the company would be handicapped in securing additional capital by the following restriction of the trust indenture under which its convertible bonds were issued, viz., the Electric Company will not issue additional stock and title to preference or priority over its assenting stock, nor distribute any capital stock by way of stock dividends, nor issue any capital stock at a price more than 10 per cent below the market price of the stock of the same class at the time the new stock is offered for subscription or sale.

"In order that the company may be in a position when the time comes, to raise additional capital by the sale of stock the following tentative plan has been approved. It is proposed to ask the bondholders to consent to the elimination of the above provision, and in consideration therefor to reduce the price at which common stock—formerly called assenting—may be issued for the bonds upon conversion from 200, the price now fixed by the agreement, to par for the balance of the present calendar year and thereafter 110.

"As an incident to this plan, in case it becomes operative, either common stock to the amount required for conversion under the proposed modification, or new bonds convertible into common stock at the reduced price, would be offered to the stockholders for pro rata subscription at 105, and to the extent that stocks or bonds are sold upon that basis the proceeds would be used in retiring present bonds at redemption price.

"Accordingly under the proposed plan bondholders would receive either (a) cash at the redemption price of 105 and accrued interest, or (b) par in new bonds convertible into common stock at the reduced price, or (c) part cash and part new bonds.

"An agreement providing for this plan is in course of preparation under which the Guaranty Trust Company will be depositary and Kuhn, Loeb & Company managers. It will rest with the managers to determine whether and when the plan shall become operative. A circular announcing the plan in its definite form will be issued shortly."

Railway Construction

Beaumont, Liberty & Houston Traction.—Organized in Texas to build an interurban line from Houston, Tex., east to Beaumont, about 81 miles, also to build from Houston, southwest to Richmond, about 30 miles. E. Kennedy, Houston, and associates are back of the project.

California Southern.—This company has awarded a contract to the Blythe Construction Company, Los Angeles, Cal., for the construction of a new 41-mile railroad from Blythe Junction and Blythe to the lower Palo Verde valley. Grading has been started on the 10-mile branch between Blythe Junction and Blythe. The company intends to buy rolling and motive power in about 90 days. J. M. Neeland, Los Angeles, Cal., is president, and G. W. Rice, Blythe Junction, Riverside county, Cal., is chief engineer.

Canadian Roads.—Construction work, except ballasting on a section of about ten miles, has been finished on the line building from a point on the Grand Trunk Pacific to Indian Bay for the Greater Winnipeg Water District. This line, which is part of the improvements being carried out to provide a water supply for the city of Winnipeg, Man., from Shoal Lake, is expected to be open for operation soon, to carry contractors' supplies and necessary materials for aqueduct construction. A total of 102 miles of track, including spurs and sidings has been laid. S. H. Reynolds is chairman of the commissioners, Winnipeg, Man. (February 27, p. 451.)

Chicago, Rock Island & Pacific.—This company has resumed track elevation at Chicago, Ill., between Seventy-ninth and Eighty-seventh streets.

Cumberland Northern.—Surveys are now being made and bids will be asked for in about 30 days, to build from a connection with the Louisville & Nashville at Barbourville, Ky., north via either Fighting creek or Little Richland creek to the headquarters of Collins fork, and along Goose creek and south fork of Kentucky river to Manchester, about 25 miles. There will be a number of small bridges on the line. An extension is projected north about 30 miles to Beattyville, but this extension will not be built this year. The company expects to develop a traffic in coal, lumber, livestock and general merchandise. C. F. Heidrick, president; M. Posey, locating engineer, Barbourville. (See Kentucky Roads, April 23, p. 914.)

Hampden Railroad.—Governor Walsh has allowed to become law without his signature the bill passed by the Massachusetts legislature extending to July 1, 1918, the time within which this company shall locate and complete its proposed branch lines to Holyoke and Chicopee Falls.

Hiawassee Valley.—Work is now under way by the Wright-Johnstone Contracting Company, Andrews, N. C., on the section from Andrews southwest via Peach Tree to Hayesville, 25 miles. The grading work is about 75 per cent finished. It is expected that the line will be leased and that the lessee will furnish the rails and the rolling stock. The company was organized in 1913, to build a 35-mile line from Andrews, N. C., southwest via Peach Tree to Hiawassee, 35 miles. O. L. Anderson, president, and F. Cloud, chief engineer. H. S. Kinnebrew, Andrews, N. C., is in charge of the work. (October 31, p. 818.)

Midland Railway.—Application has been made for a charter in Georgia by this company, with a capital of $1,000,000, it is said, to build a line from Savannah, northwest to Milledgeville, about 150 miles, also to build branch lines to other points. W. M. Exley, W. H. Webb, L. M. Mikel, K. I. Helmey and C. A. Johnson of Effingham county; J. A. Davis of Burke county, and H. O. Burman of Chatham county, are said to be interested.

Texas Roads.—Plans are being made to build a line from Lamesa, Tex., south to Midland, about 55 miles. Residents of Midland have been asked to raise a bonus of $250,000 in aid of the project. T. J. O'Donnell, Sweetwater, and W. L. Carwile, Dallas, are the promoters.

Wyoming-Montana.—This company has been incorporated at Sheridan, Wyo., with a capital stock of $2,000,000 and proposes

to construct a railroad from Sheridan, Wyo., to Beaver Hills and Big Horn. George Forsyth, Olaf Nelson and D. P. B. Marshall are the incorporators.

RAILWAY STRUCTURES

Beacon, N. Y.—The New York Central has given a contract to John Thatcher & Sons, Brooklyn, N. Y., for building a new passenger station at Beacon, to include a main building 49 ft. by 65 ft., and a baggage room 31 ft. by 42 ft. The contract calls for the construction of the station superstructure and wooden platforms and canopies. The sub-structure is already in place. The new station will be of red brick construction on a rough face concrete base up to the window sills, and the exterior brick walls will be of rough texture. The roof over the main building will be of red tile, and on extensions of slag. The subway now in place will connect the passenger station with inter-track platforms.

Buffalo, N. Y.—The Lehigh Valley has awarded to J. Henry Miller, Incorporated, Baltimore, Md., the first contract for construction work in connection with the new freight and passenger terminal to be built at Buffalo. This contract covers some of the important building work in connection with the new freight and passenger stations proper and, with the incidental work attached to it, will amount to $750,000. The passenger station, which will be built of Indiana limestone, will face main street, extending from Quay to Scott streets. A tunnel will extend under Washington street, in the rear, reaching the head house, platforms and tracks. The site for the passenger station proper has already been cleared. The freight terminal will be located south and east of Scott and Washington streets, and this site also is being prepared for the beginning of construction work.

Bids are wanted, May 15, by Edward B. Guthrie, chief engineer of the Buffalo Grade Crossing Commission, Buffalo, for the excavation and masonry work for two bridges at Lord and Smith streets, where the streets are to be carried under the Pennsylvania Railroad tracks. The superstructures are to be built by the Pennsylvania Railroad. Bids for the masonry and steel for a bridge over the Pennsylvania Railroad at Bailey avenue will probably be received about two weeks later. In addition the Lehigh Valley and the Delaware, Lackawanna & Western will build bridges in connection with the other Bailey avenue work.

Chicago, Ill.—The New York, Chicago & St. Louis has awarded a contract to the Pennsylvania Steel Company for a bridge of 5 spans over the Illinois Central tracks at Seventy-ninth street, Chicago, to be completed November 1, 1915. This bridge comprises about 2,000 tons of steel and completes the grade elimination work of this company under the 1909 ordinance.

The contract for the foundation work for the Pennsylvania Lines' new freight terminal at Chicago was let to the Glones-Sinek Company, Chicago, instead of to the Sumner-Sollitt Company, as was previously reported in these columns. (April 30, p. 955.)

The Union Station Company has asked for bids for the construction of sewers and retaining and curb walls in connection with the work on the new Union Station.

Matawan, N. J.—Bids will be asked for about June 15 by the Board of Chosen Freeholders, Matawan, for a Strauss bascule trunnion bridge to be built over Matawan creek, at a cost of about $40,000. The new structure will carry tracks for the operation of the Jersey Central Traction Company's cars, and this company will pay one-half of the cost of the new bridge.

Philadelphia, Pa.—A bill has been introduced in the Pennsylvania legislature calling for an appropriation of $15,000, to make plans and select the site of a bridge, to be built over the Delaware river, between the cities of Philadelphia and Camden, N. J. It is understood that the proposed structure, which is to be known as the William Penn Memorial Bridge, will carry tracks for the operation of street railway cars.

Portsmouth, Va.—An officer of the Seaboard Air Line writes regarding the report that contracts have been let to build a temporary shop building at Portsmouth; that the company has arranged for a temporary cover on a portion of the burnt shop area, but no decision has yet been reached for the construction of a permanent building.

Railway Financial News

Chicago, Rock Island & Pacific.—The Sheldon proxy committee, which voted for the election of W. Emlen Roosevelt, Charles Hayden and William J. Matheson as directors at the last annual meeting, has issued a circular, which says in part: "Now that the court has taken possession of the property, the committee deems it essential to stockholders that they should be free to adopt for their protection other agencies with fuller powers. The committee, therefore, surrenders all rights granted to it and especially the right to vote at the regular annual meeting next October." The committee says that it was not informed that the railway company was to be put in the hands of a receiver.

A committee has been formed to protect the interests of the holders of the $20,000,000 20-year 5 per cent debentures. This committee is composed of Seward Prosser, president of the Bankers' Trust Company; E. K. Boisot, A. Barton Hepburn, Edwin G. Merrill and James Speyer.

Kansas City, Mexico & Orient.—William Volker has filed a petition asking for the appointment of a receiver for the Kansas City, Mexico & Orient, claiming that the reorganization committee and the United States & Mexican Trust Company are not carrying out the terms under which the road was reorganized.

Missouri, Kansas & Texas.—About 90 per cent of the $19,000,000 notes due May 1 have been deposited for extension.

Pennsylvania Railroad.—Kuhn, Loeb & Co., New York, have bought from the Pennsylvania $65,000,000 general mortgage 4½ per cent bonds. It is understood that the offering price to the public will be between 98 and 98½. The proceeds from the sale will be used along with the proceeds of the $49,000,000 first mortgage bonds recently sold to pay at maturity the $86,827,000 3½ per cent convertible bonds due October 1.

Wabash.—An abstract of the reorganization plan and editorial comments thereon are published elsewhere in this issue.

Railway in Argentina Leased.—The Compañia General de Ferrocarriles de la Provincia de Buenos Aires has contracted a seven year lease of the 25-mile section of the Rosario to Mendoza Railway, running from Rosario to Fuentes.

Economics of Electric Signal Operation.—Density of traffic enters into the question of the selection of the type of apparatus for block and interlocking signals. Where traffic is very dense, quick operation of the signals is desirable in order that trains may follow each other without having to wait for a signal to clear. In such situations also, it is usually out of the question to distribute storage batteries easily, and consequently, if they are used they must be stationary and be charged over a line from a central point. This method quickly becomes uneconomical when low voltages are desirable, or necessary, owing to the large loss of energy in transmission, for the potential cannot be higher than that needed to charge the batteries. With alternating current the potential may be made as high as desired, and the transmission losses cut down. Yet even under very unfavorable conditions stationary storage battery may be the most desirable means of operating a signal system. This is especially true where reliability, at a reasonable cost, is chiefly to be desired. The storage battery may be made of such capacity that it will operate the system for any given time without the necessity for recharging, so that should the line fail, there would be no interruption of signal operation. This is not possible with alternating current apparatus. Storage batteries occupy less space than primary batteries of the same capacity, and need less attention in the way of renewals. It is not necessary, except at rare intervals, to transport heavy supplies to be used in storage battery maintenance, whereas this must be done every time a primary battery is renewed. Storage batteries, however, need the attention of the maintainer every time they are charged, and this occurs much more frequently than the renewal of primary battery.—*W. H. Arkenburgh.*

Reclaiming Scrap Material

A railroad officer who had made a tour of inspection of the scrap reclaiming plants on various roads, when asked what impressed him the most, replied that the greatest benefit he had received was in learning what not to do. The reclaiming of scrap is a problem which requires the most careful study. What may be profitable for one road to reclaim may not be profitable for another. An enthusiast, and there are such men handling the reclamation of scrap, must be very careful not to be "penny wise and pound foolish." There are vast opportunities for making money in doing this work and there is also an excellent opportunity to overdo it. The overhead charges, as in no other class of work, must be carefully watched. An able and intelligent supervisor who can devote his entire time to the study of this problem will earn his salary many times over. It is a purely business proposition and it should be run on a business basis. It must be handled in the main for profit only, and in this respect it is different from the general run of railway shops where output is generally the controlling factor. The Railway Storekeepers' Association has been making a careful study of this subject and the report at its convention next week will be looked forward to with a great deal of interest.

Weaknesses of Railroad Advertising

We publish elsewhere parts of an interesting paper by Edward Hungerford on "Railroad Advertising," Mr. Hungerford criticizes the organization and methods used by railways generally in handling their advertising. On the whole his criticisms are justified. On most railways the advertising department is a mere appendage of the passenger department, and its chief function is to exploit the passenger service. Neither its location in the passenger department nor the use of practically all of its appropriation for exploiting passenger service is sound. There are numerous purposes besides that of exploiting the passenger service for which advertising could be effectively used, and if this were done the business of the railways and their relations to the public would be improved. The railways have a great deal more freight traffic than passenger traffic and their freight service is relatively profitable, while their passenger service is relatively unprofitable. Why spend so much money in advertising the least profitable part of the business and so little in advertising the most profitable part? Within recent months railways in various parts of the country have used advertising extensively to present to the public facts regarding the inadequacy of their earnings and the unreasonableness of certain kinds of legislation, such as that for the limitation of the length of freight trains and for unnecessary men in train crews. There can be no doubt that this advertising has tended to create a more intelligent and fair public sentiment regarding railway matters. There are so many good uses that can be made of advertising that it is a pity its principles and possibilities are so little understood in the railway business.

Battle of the Cost Accountants

It is perfectly easy to ascertain what it costs to render any particular railway service. At least, so we have been told for years by a certain class of professional critics of railways. The reason, according to these people, why the roads have not developed a system of cost accounting as a basis for making rates is that they have wanted to surround the traffic manager's job with an atmosphere of mystery in which he could work his will at the expense of his customers. But when self-confessed "experts" employed by the packers and other shippers and their willing coadjutors, the western state railroad commissions, attempt to analyze the costs of handling different kinds of traffic, the results of their calculations seem to depend entirely on what they want to prove. Four cost accountants, three of whom were employed by the state commissions and the shippers, and one by the Interstate Commerce Commission, testified before Commissioner Daniels at Chicago recently, and each of them succeeded in establishing an entirely different cost of handling each of the commodities regarding the rates on which they testified. Each of these "experts" also succeeded, of course, in showing that the methods used by each of the other "experts" in arriving at his results were entirely wrong. If this had been a battle between cost accountants employed by the railways on one side and the shippers and their humble servants, the state commissions, on the other, it might have been understandable, but the inability of even one side to get its "experts" to come anywhere near agreeing shows the stage of development that railway

cost accounting is still in. As long as "experts" of this class continue to thus disagree it is to be feared rates must perforce continue to be based on the unscientific and despised principle of "what the traffic will bear." This fiasco shows how much easier it often is to fulminate against those who act on unscientific principles than it is to formulate scientific principles for them to act on.

THE STUDENT IN THE RAILWAY BUSINESS

A LARGE majority of the higher officers of American railways have risen from the ranks without the advantage of college education and training. In many cases they have not even gone through high school. There is, in consequence, a widespread impression that the knowledge and mental discipline which can be obtained by study is of no advantage, or may really be disadvantageous to one who seeks to rise in railway service. No impression could be more entirely wrong or more adapted to be harmful to the ambitious young men in the service. There is no better educated class of men in the United States than the higher officers of our railways, and a large part of the education of the most "practical" of them has been derived from the study of the literature of their business. This needs to be emphasized for the good of the young men in the service and for the good of the roads themselves, for the need of the roads for officers who know both all that can be learned about their business from practical experience and all that can be learned about it by study, constantly exceeds the supply.

In the first place, the number of college men who have made successes in the railway service is large in proportion to the number of college men who have entered it. Among the college men who within very recent years have been brought prominently before the public by their promotions to positions of great importance are Howard Elliott, who left the presidency of the Northern Pacific to become chairman of the New Haven; Fairfax Harrison, president of the Southern; Julius Kruttschnitt, chairman of the Southern Pacific, and Hale Holden, president of the Burlington. A college training is far from being a drawback in a railway career. It is a great help.

In the second place, there is hardly a high officer of an American railway who has risen without a college training who has not, nevertheless, been a student all his life. It is a great mistake to assume that the "self-made" leaders of the industry have learned all they know in their daily work. The greatest of all this class, James J. Hill, studied at a small academy but never went to college. But Mr. Hill did not quit studying when he left the academy. He is one of the most widely read men in any line of business or professional work in America. To mention other high railway officers who, without college training, have nevertheless become highly educated, would be invidious, because to mention some would be to discriminate against many others equally deserving of mention. The president of one of the large eastern lines, who started railway work as a track laborer and a fireman, says that the turning point in his career was reached when he read Wellington's work on "Economics of Railway Location." The detailed information, the scientific principles and the broad outlook of this book taught him there were many things he could learn from the printed page which he could not learn elsewhere, and from that time he has been a tireless reader of the literature of transportation and of the broad field of economics and industry.

The president of a large western railway not only reads almost everything published on the problems of transportation and industry, but buys and gives as Christmas presents each year to the officers of his road the best recent book he can find on these problems. He seeks thereby to cultivate the same studious habit among his subordinates which he has found valuable to himself. The chairman of another large western road subscribes to all of the economic journals and has them sent to his home address. The president of another great western trunk line is an omnivorous reader not only of books and magazine articles relating to railway and business matters, but also of newspaper clippings, and those who come in contact with him are often astonished at the completeness of his knowledge of everything that the press is saying about railways. A few days ago the presidents of three great railways met by chance. Their railways are all in the same territory. One might have expected that their conversation would have turned to the railway situation in their section. On the contrary, one of them, who carries as heavy responsibilities as any business man in the United States, opened the conversation with the question, "Have you seen Prof. Ripley's new book on 'Railroads'?"

The illustrations given are not exceptions to the rule; they are illustrations of the rule. If one could ascertain the amount and breadth of the study done by the officers of each rank in the railway business he would find that on the average the presidents are the hardest and broadest students of all.

It is not a mere coincidence that the higher officers of the railways usually are not only among the most practical men in the business, but also among the most studious. Broadly speaking, there are only two ways in which people learn. One is by experience and the other is by study, and the one is as indispensable as the other. The experience of others, if properly understood and utilized, is as valuable as one's own experience, and study of books, magazines, convention reports and so on, is the best means to get a broad knowledge of the experience of others in such concentrated form as to make it serviceable. The man who attempts to do an important class of work without appropriate previous experience will usually make a failure of it, however much he may have studied. But the man who relies entirely on his own experience as a means of preparation for higher duties will with almost equal certainty make a mediocre success or a complete failure. A book, or an article, may be written, or a paper edited by a so-called "theorist," but if he is skillful in bringing together the results of the experience of practical men, a reading of his writings will be helpful to the most practical.

Every once in a while you hear a man say that he "hasn't time" to read the literature of his profession. In 99 cases out of 100 such a man will never be promoted to a high position, and if he is will make a failure in it. It is not a coincidence that as a class the presidents of the railways are the hardest and broadest students in the business, because in most cases those who are presidents owe their promotions to the fact that they early learned the necessity of adding to the knowledge derived from their own comparatively narrow experience, the knowledge of the experience of others that can be gained only by broad reading and study. They do not study because they are presidents; but they are presidents largely because they have studied!

ENGINE MAINTENANCE AND FAILURES

THE cost per engine-mile of locomotive maintenance and the mileage per engine failure give the best indications of the economy of the operation of the mechanical department of a railroad. For several reasons, however, these items should not be used to compare the efficiency of the operation of mechanical departments of different roads. In the first place, the operating conditions will to a large extent affect the performance of the mechanical department, bad water, heavy grades and poor track having material effect on the condition of the power. Also, the class of power and the facilities provided for its maintenance will be a large determining factor. The best way to use these figures is to compare one year with another, making a careful analysis of them with a view of correcting the weak points. This will require a thorough study of the conditions on each individual road and will undoubtedly show where profitable investments may be made.

An excellent example of what has been accomplished by following this practice may be found on the Minneapolis, St. Paul & Sault Ste. Marie. The cost of locomotive maintenance per locomotive mile for the year 1914 on the Soo Line proper, that is,

excluding the Chicago division—the old Wisconsin Central—was 8.55 cents, with an average mileage per engine failure of 49,925 miles. Within the past nine years this road has increased its mileage per boiler failure from 9,250 miles in 1906 to 848,720 miles in 1914, notwithstanding the fact that a large part of the territory over which it operates has very bad water. The Chicago division, during 1914, operated at a cost of 5.87 cents per locomotive mile with a record of 50,608 miles per engine failure and 1,872,000 miles per boiler failure. This division, however, has good water. The year before this road, the Chicago division (Wisconsin Central), was taken over by the Minneapolis, St. Paul & Sault Ste. Marie (1908) it was operated with 550 engine failures. In 1914 the total number of failures was 105. In this case the mechanical department has been materially assisted by the introduction of modern power. The Soo Line, taken as a whole, made the best showing of any road owning over 75 locomotives in the matter of boiler defects reported by the Federal Bureau of Locomotive Boiler Inspection, having only 46 locomotives reported as defective out of 529 owned and 313 inspected, with none ordered out of service.

Attention is called to this performance to illustrate what can be done by carefully and effectively studying the problem of locomotive maintenance. The officers attribute their success to perfecting the organization and insisting on careful maintenance and rigid inspection.

NEW BOOKS

Railway Statistics of the United States for the Year Ending June 30, 1914. By Slason Thompson, director of the Bureau of Railway News and Statistics. 140 pages, 5½ in. by 8¼ in. Bound in paper. Published by the author at Chicago.

This is the eleventh edition of Mr. Thompson's annual volume of railway statistics, which is valuable because of the promptness with which it is issued, and because of the interesting character of the classes of information which it includes, such as the comparison with foreign roads and other facts not given in the publications of the Interstate Commerce Commission. The statistics of the essential features of railway construction, maintenance and operation are compiled from annual returns identical with those made to the Interstate Commerce Commission from 446 roads operating 245,894 miles of line, representing nearly 97 per cent of the mileage and fully 98 per cent of the total traffic of the railways in the United States. For previous years comparisons are made with the official figures of the Interstate Commerce Commission.

The railway statistics of the United States are given under the headings of mileage, equipment, employees and their compensation, capitalization, cost of construction, ownership, public service, earnings and expenses, taxes, damages and injuries, accidents and receiverships. The statistics of foreign railways cover 21 countries. An introductory chapter compares the railway progress in the two decades, 1894 to 1904, and 1904 to 1914, and also gives a very interesting analysis of the present situation of the American railways and their relation to government regulation. After showing the reduction in rates, and increases and expenses for the last 10 year period, however, Mr. Thompson shows that there is a brighter side to the railway situation in a number of signs that mark the tempering of the popular mind toward the transportation industry. In this connection he shows that numerically considered there was a practical balance between the number of decisions rendered by the Interstate Commerce Commission during the year for and against the carriers. While there were 111 decisions dismissing complaints there were 112 decisions making reductions or allowing reparation, and 56 decisions permitting advances and 55 denying advances; also the percentage of decisions dismissing complaints, 49.8 per cent, is larger than for any year since the bureau began its analysis of decisions in 1909, and the percentage of decisions awarding reparation or reducing rates, 50.2 per cent, is the smallest for any year. Mr. Thompson points out, however, that the decisions permitting advances are the only ones affording permanent relief to the railways.

Letters to the Editor

A VICE-PRESIDENT IN CHARGE OF LABOR

Wilmington, N. C.

To the Editor of the Railway Age Gazette:

Railroad labor contracts are unlike anything pertaining to similar contracts in other industries. The farmers, the merchant and the manufacturer employ at a fixed rate per unit of time or output, making it necessary only to keep a record of the hours employed or the number of pieces manufactured in order to decide questions arising under the contracts in force. Also, in most cases labor employed by these classes of employers can be closely supervised. On a railroad the conditions are quite different. Labor is widely scattered, often entirely removed from those in charge, and the contracts are based not only on time and piece, but on combinations of both, resulting in such an intricate system that no one but a decided specialist is competent to pass intelligently on questions which arise.

Every railroad man who has anything to do with the supervision of transportation labor knows that a large part of his time is taken up by the adjustment and settlement of matters arising from misunderstandings or from ignorance of the company's labor agreements. In one case which came to the writer's notice a general manager estimated that 60 to 70 per cent of his time during a period of half a year was taken up in handling grievances with brotherhood committees.

So, then, a situation exists of which the unfortunate part is this: That the time of transportation and general officers which ought to be given to matters concerning the economical movement of trains, is given over in large part to the settlement of labor disputes, to the detriment of transportation matters as a whole. Nor can the situation be solved by having at hand subordinates well versed in pay schedule matters, for the reason that the men are generally unwilling to accept a settlement which goes against them until it has been reviewed by the highest officer to whom they can appeal.

This gives rise to the question, "Why not a vice-president in charge of labor?" A man of the proper temperament and a thorough understanding of the questions involved, it seems to the writer, could be of incalculable value to the present American railroad organization.

We have in our present organization men whose sole duty is to see that materials are obtained at the lowest possible cost consistent with good quality. It is a further duty of these men to see that such materials are used with the greatest economy possible. Why, then, is it not imperative, now that wage schedules and the entire relation of the company to its employees has become complex, to have a trained officer handle such relations, with a view to obtaining as much as possible for the money expended as is consistent with service and safety? Also, to see that the labor employed, even as the material purchased by the supply department, is used with the greatest economy; which, in the case of labor, is the same as saying developed to its highest efficiency. In 1913, the Bureau of Railway Economics tells us, the railways of the United States expended 2.16 billions of dollars for operation; of this 63.4 per cent was for labor and 36.6 per cent for material, a ratio of nearly 2 to 1. If, then, we have created a special department to care for material, why not organize a department to look after the purchase of labor, which we buy in so much larger quantities, and to develop it to its highest capability?

On a road having a vice-president in charge of labor any grievances arising among trainmen, shopmen or other employees, after being passed on once by the subordinate officer directly in charge, to the dissatisfaction of the man or men affected, would be immediately referred to this vice-president. He would proceed to meet the men and his ability and authority would enable

him to settle all matters which are adjustable; and this with a minimum of lost time, correspondence and friction. Some will object that questions will still be appealed to the president or higher. This is true, but on the other hand a vast deal of intermediate correspondence and delay, if not actual friction, will be eliminated, and it is believed that the right man in such a position could and would decide matters in such a way that the president need waste but little time in rallying to his support.

The office could be made a broad one, to the great benefit of the whole organization. For instance, besides the mere handling of disputes, this vice-president would be advised of every decision made by any lower officer in regard to labor differences. Classifying these he would be able to advise with the officer by whom the decision was made, and often, by the prevention of a repetition of some decision, avoid the establishment of a dangerous precedent.

His would be the one department charged with the keeping of a complete record of each employee as to: (*a*) date of employment; (*b*) rate of pay; (*c*) promotions; (*d*) discipline.

The heads of the relief and pension departments could, not unnaturally, be brought under his supervision. The fact of his having complete records of all employees would make this desirable, and the keeping of relief or pension records of an employee on the same card or in the same envelope with his service record would avoid duplication of work.

A vice-president with the duties suggested would find his time fully occupied. By taking over duties now performed by other men he would give those men more time to devote to strictly transportation work. This would result in a money saving far exceeding the cost of any salary which could justifiably be paid to such an officer. For, if a general manager, a general superintendent, or any transportation officer, because of press of his "labor" work, fails to properly supervise train loading, the accumulation of foreign cars, etc., he can in a short time cause a money loss which will many times exceed any possible cost of creating and maintaining such an office as is here outlined.

J. Lowell White.

WAGES OF ENGINEERS AND FIREMEN

Fort Worth, Tex.

To the Editor of the Railway Age Gazette:

In the award of the board of arbitration, in the controversy between the western railroads and the engineers and firemen, the minority report of members Burgess and Shea contains some wild assumptions and assertions that indicate they are bad losers, to say the least. The minority practically intimates that if the next demand is not granted, the two organizations will strike; they say that "this award settles nothing"; they refer to immense surplus earnings and dividends, also concealed assets, and demand increased wages as a share in these sums, disregarding the law of supply and demand for labor or any consideration of the value of the work, asking the same wages for oil-burning engines and mechanical stokers as for shovel-fired big engines.

If surplus earnings and dividends justify corresponding increases in wages, will the engineers and firemen work for less wages on the Wabash, Western Pacific, Frisco, Rock Island or other roads where there were deficits? Certainly not, the work is only worth its value.

They say that in 1914 the western railroads paid $43,000,000 in dividends on fictitious stock. In looking over the list of roads, parties to this arbitration, after you eliminate the roads that failed to pay any dividends, if you capitalize this $43,000,000 at 4.3 per cent, you have one billion for value of fictitious stock. Such assertions are reckless and vicious, and should be carefully and publicly denied and actual facts compiled and published.

They practically insist that there will be no peace until all their demands are granted. By their position they make it necessary and advisable to meet their demands with a stern refusal.

Employees in other departments need consideration, especially those that are unorganized.

The average earnings of enginemen are now about as high as the work is worth, even admitting it is hazardous, and the hazard can be reduced by spending more money on tracks and signals, although their vocation is far safer now than it was a few years ago, engines ride easier and hours are shorter.

The writer concedes that they should be well paid, even better paid than other classes of employees, but the time has now come for them to be content with their lot, under present conditions.

Avery Turner.
Receiver, St. Louis, San Francisco & Texas.

THE USE OF A HIGH FACTOR OF ADHESION

Chicago, Ill.

To the Editor of the Railway Age Gazette:

Referring to the inquiry "Why Use a High Factor of Adhesion in Steam Locomotives" on page 778 of the issue of April 9, I would suggest for your correspondent's consideration that the fact that it is customary to reduce the thickness of driving tires from 3½ in. to 1¾ in. by turning, and to bore out the cylinders to a diameter at least ½ in. greater than the new diameter, may throw some light on the adoption of a factor of adhesion which he considers unnecessarily high.

C. E. Miller.

Toronto, Ont.

To the Editor of the Railway Age Gazette:

This subject, referred to on page 778 of the issue of April 9, was recently a matter of much concern on this road and at that time was thoroughly discussed by our mechanical department officers.

Speaking generally, it would appear that practically all new locomotives have been equipped with superheaters, brick arches and other appliances which tend to greatly increase the sustained capacity of the boiler. In superheater engines the steam is to some extent wire drawn in the superheater, hence the pressure at the beginning of the stroke may not be as high as in saturated steam engines, while, owing to the superheater, the mean effective pressure will be higher, thus insuring an appreciable reduction in slipping, which may be taken advantage of in the design of superheater engines. We have been operating superheater engines for more than five years, and the most successful freight engine we have was designed with a factor of adhesion slightly less than 4.5. We do not feel that this should be exceeded, at least for our requirements. Our Pacific type passenger locomotives have a factor of 4.3, with a boiler pressure of 170 lb.

It is difficult to discuss the subject without reference to some specific service, as we have found that where slow heavy freight service is concerned it is possible to reduce the factor to 4.1 and even less by increasing the boiler pressure. This practice has given excellent results. Many freight engines have been built with a factor as low as this, but when the tractive effort is greater than 25 per cent of the weight on driving wheels, there must be an abnormally good rail condition in order to realize the full power, which even then cannot be done unless a low speed is maintained.

It has been our practice to design locomotives for 170 lb. boiler pressure (the boilers being calculated for 200 lb. pressure), using a moderate factor of adhesion; this allows for increasing the boiler pressure and thus increasing the ratio between tractive effort and weight on driving wheels.

L. K. Sillcox,
Assistant Mechanical Engineer, Canadian Northern.

Badges for Welsh Railway Employees.—The Cardiff Railway Company has just issued to all members of its staff of military age, who are desirous of enlisting, but cannot be spared from the service of the company, a tastefully designed badge, indicating the fact that the wearer is engaged in important war work at home.

Aspects of the Financial Problem of the Railways*

Consideration of the Effect Which the Federal Reserve Act Will Have on Needs of Railways for New Capital

By H. P. Willis
Secretary of the Federal Reserve Board

The most fundamental fact in the present railway situation is, I believe, the demand for new capital. For reasons which are known to all and require no detailed discussion from me, the amount of capital invested in new transportation enterprises during the past few years has been insufficient. The mileage of the country has been increased only from 207,977 miles in 1903 to 249,802 miles in 1913. The railroads of the country, considering the difficulties under which they have had to work, have done well in maintaining their investment in plant equipment and facilities generally. It would be wrong, however, to believe that they have kept pace with the advancing development of the country in other directions. What the reason for this relative backwardness is, I shall not attempt to inquire in detail at the present time. Certainly the ten years last past have not been an encouraging time for railroads, nor have they been years during which the investor either was, or could be expected to be, eager and willing to put his funds into transportation enterprises.

Now suddenly a new factor has been added. A struggle of unprecedented violence has broken out in Europe, with the result of destroying enormous quantities of fixed and circulating capital. This destruction of capital has affected every department and branch of enterprise, and will continue to do so from now until the close of the struggle in which nearly all of Europe is engaged. Various estimates have been made from more or less trustworthy sources with reference to the actual destruction of wealth in the course of this world conflict. I do not believe that any of these estimates can be even approximately accurate. Yet we can, with entire safety, recognize that very vast losses are being inflicted upon the world from three sources—the actual physical destruction of forms of capital, the withdrawal of productive workers from employment, and the actual loss of these workers and their productive power in consequence of death on the battlefield or from injuries or disease. Much of these losses of capital is of a kind which cannot be measured in terms of money, and much of it can not be estimated or accurately stated.

What we do know is that when the close of the war shall have been reached, however it may turn out, there will be a very great demand for capital to be used in the upbuilding of industries and in the restoration of those objects of use and production which have been so widely and so ruthlessly destroyed. The natural effect of this shortage of capital will be an increase in the rate of interest, with corresponding competition among those who wish to use capital for the purpose of carrying on business. This demand for capital will be a demand for long-term investment funds, not for money. However it may be masked by temporary circumstances, it will be a real thing involving the readjustment of supply and demand of the means of production. Such readjustment can be had only through an adaptation of methods of production and alteration of the prices charged for the use of the capital in question.

I know that there are some thinkers who believe that, owing to depression there will be a period in which demands for capital will be slack, and the rates of interest low. Whatever temporary force there may be in such a view as applied to short periods, it cannot, in the nature of the case, hold over the long-term operations involved in the process of restoring and rebuilding the business of the world. To restore the lost shipping, to replace railway lines, to rebuild factories and generally to put the world where it was before the opening of the struggle as regards productive facilities, with be the labor of a long period. While this is proceeding, other enterprises throughout the world will have to bear their share of the burden. They cannot, if they would, escape the fact that the new capital they need is urgently desired by others who would be willing to pay for it at high prices.

Thus, the railways, which are among the greatest borrowers of capital in every country, must, in the nature of the case, in common with other industries, find themselves hampered and crippled by anything which stands in the way of their obtaining the resources they require. They are confronted by a peculiar problem because of the practice which has arisen in recent years of financing their necessities in no inconsiderable degree on a short-term basis. We do not exaggerate, therefore, when we say that the capital problem of the railways was serious before the war, that it had been made particularly serious by the practice of short-term borrowing, and that the war itself has now placed the roads in an unprecedented position.

THE FEDERAL RESERVE ACT

While the situation is thus one which presents difficulties worthy of the attention of the best financiers, in so far as the acquisition of capital is concerned, there is a second factor in the situation that deserves very careful consideration, both from the standpoint of what it will do to influence conditions, and of what it will not do. This is the change that has come about in our banking system. Little more than a year ago congress passed the Federal Reserve Act. This act provides for the creation of banks of rediscount whose function it is to make banking resources fluid, and by that means to render capital active in a degree never heretofore possible. I do not exaggerate in the least when I say that this act holds out the greatest promise to business enterprise that has been offered to it for many years.

If the business community contents itself with simply continuing its present methods of operation, it will derive great advantage from the law. It will find (1) that local banks will be able, by rediscounting the paper of local enterprises, to provide the funds needed by such enterprises in their commercial transactions; (2) that there will be no such wide fluctuations of interest rates either geographically or from season to season as now exist; (3) that there will be no necessity of emergency measures to safeguard the country from the possible results of financial panic or stringency. Credit will be more simply available, cheaper, and more equitably open to all.

Not the least of all the advantages to the business man will be found in the provisions with respect to bank examinations, since through these, it may be hoped, many operations which have been open to criticism in the past will be clearly detected and corrected before they have had time to impair the vitality of institutions which might otherwise have continued sound and solvent. This is equivalent to saying that, under the new law, credit, even if there be no change in business methods, will be cheaper and more evenly diffused

*From an address before the fifth annual banquet of the Railroad Men's Improvement Society, New York, February 6, 1915.

as well as more steady and more certainly to be counted upon by those who do business by acceptable methods. But the community will not gain the greatest advantage from the measure if it adheres merely to established types of operation. The new act provides for the creation of a thorough discount market, such as has existed for many years in every European country. This means that every merchant of established local credit may in the future count upon a free sale for his paper throughout the reserve district in which he is situated, and to a somewhat lesser degree generally throughout the country.

The rediscount principle, when fully worked out, taken in connection with the use of the acceptance system, limited though it be to foreign trade transactions, will enable the sound, even though small, manufacturer or trader to get the advantage of the best rates of commercial credit that prevail anywhere within his region of the country. If there is capital to spare—unemployed and seeking occupation—he may expect that, through the general sale of bills under the new system, such capital will be available for the purchase of his paper, and will be so employed. By the judicious use of the acceptance privilege, now for the first time given to national banks, the local bank will be enabled to facilitate the movement of goods into and out of the country, and will at once make the utmost of its own capital, and at the same time enable its clients to gain the widest employment for their resources. The net result of these various influences should be (1) considerable reduction in average rates of interest on commercial paper throughout the United States; (2) very great reductions in the rates in certain sections remote from commercial centres; (3) stability and certainty in distribution of credit; (4) creation of new and more convenient types of paper.

SHORT TIME FINANCING

But while the act will be of enormous advantage to the business world, and through it to every productive, agricultural and industrial enterprise, it is not well for any thinker on the subject to mislead himself into the belief that such legislation will do the impossible. The Federal Reserve Act is not a measure which has to do with long term investment of capital, and those who look to it as a direct means of relief for manufacturing enterprises, like those who look to it as a means of providing agricultural resources, must inevitably be disappointed. Their disappointment will be based not upon the lack of results, but upon the fact that these results will be different, and will be exhibited in a way at variance with that which they had expected. It is worth while for me, therefore, to explain with some care, the relation of the Federal Reserve act to this question of longer term borrowing.

Much has been said of the effect of the Federal Reserve Act in furnishing an elastic currency, and in converting good commercial paper into immediate means of payment through rediscount operations. It was natural that the first attention of the public should be centered upon this subject, since it, above all others, has for many years past seemed to constitute the crux of banking operation. I would not for an instant minimize the importance of what has thus been done; indeed, I regard it as the fundamental purpose of the act. There is, however, much to be said of the effect of the Federal Reserve Act in other directions. One of these neglected phases of the subject relates to the influence of the new law in bringing about a readjustment of the rates of interest upon paper of varying maturities. The Federal Reserve Act specifically limits the paper which is rediscountable by member banks, as well as that which is purchasable in the open market, to notes and bills running not over 90 days, except in those cases where the paper is drawn to finance agricultural transactions, when the limit is extended to six months.

The act, however, wisely gave to the banks the power of regulating rates of discount on a different basis for shorter and for longer term paper; and to the Federal Reserve Board the power to approve such varying rates. It, moreover, permitted a variation of rates as between different sections of the country, so that both a time and a geographical variation were sanctioned. This was an important advance as compared with previous plans for the reformation of the banking system. Under the older plans it had been intended to create a rate of discount which would be uniform throughout the country; while such plans usually contemplated the rediscount only of very short term paper. The Federal Reserve Act was more carefully adjusted to conditions in that it recognized that much of the business of the United States is done on a relatively long period of credit; and that the fact that this period of credit is longer in some cases than in others, in no sense means that the paper is not liquid, and that it is practically certain to be redeemed at maturity, notwithstanding that the maturity is postponed.

The effect of the Federal Reserve Act, then, is to establish a series of maturities, some longer and some shorter, and to permit the placing of different rates of discount on these maturities. This is an idea of great importance. It is not a novel idea, because every well managed bank of large capital and great scope of operation endeavors to apply this policy. But it is of greater importance than ever before for the reason that the Federal reserve banks, owing to their ability to discriminate carefully between different classes of paper, will be able to make effective the discrimination they introduce into the rates applicable to different maturities of commercial paper. Inasmuch as they stand ready to take very short term paper in very large amounts at an unusually low rate of discount, they tend to emphasize the desirability of making obligations run for as short periods as practicable, since, the longer an obligation runs, the higher the rate of interest to be paid on it.

In other words, the Federal reserve banks are rendering to the commercial community the useful service of emphasizing the time element as compared with the mere element of safety in commercial paper. They will place a premium upon good short term commercial paper, and they will tend, so far as practicable, to discourage the financing of long term obligations through commercial capital except in those cases where the borrower is able to pay a relatively high rate of interest because of special conditions under which his product moves to market. The theory upon which the whole act is based, indeed, tends to place stress upon the view that very long term obligations, no matter how safe they may be, cannot be financed through the commercial banks at low rates, and that they are not as appropriate a medium for investment of funds as are the much shorter term maturities already referred to.

THE RAILROADS AND THE BANKS

The principle thus recognized has a most important bearing upon the conditions under which many enterprises are financed. It is true that within recent years railroads and other industrial enterprises have turned in many cases to the banks for the purpose of getting accommodation, and the banks have financed them upon the basis of short term notes, such notes running one, two, three or more years. That these notes have borne relatively high rates of interest has been a natural, not to say inevitable, incident in the situation; and the roads have been obliged to bear the brunt of the resulting expense. In other words, they have placed themselves in the position of long term commercial borrowers at banks. Under the new system they will be no more favorably situated than under the old; indeed, the fact that they are borrowing practically on the basis of long term commercial borrowers, will be emphasized.

The commercial banks will inevitably find themselves more and more inclined to keep their assets invested in paper

and obligations which do not exceed the maturities mentioned in the Federal Reserve Act; or if, for purposes of investment they place a part of their funds in long term obligations, they will take this step simply for the sake of convenience. They will be inclined to discourage the carrying of borrowers who are really seeking for additional capital; and they will tend more and more to convert their holdings of such borrowers' paper into short term commercial paper. They will tend more and more to adopt this policy as time goes on, and as the supply of commercial paper in new forms makes it more adequate to the needs of the situation. The carrying of such short term obligations will, therefore, tend to drift more and more into the hands of purely investment bankers, and they will need to establish a regular and steady flow of the securities into the hands of the public. Within recent years many banking institutions have become large investors in notes running from one to five years. The safety of the obligations is doubtless assured, but they are not strictly banking investments.

The direct inference from what I have said is a thought which has often been suggested within the past year or two in well informed quarters, but which has never been emphasized so positively as today. This is that above all things else it is imperative to facilitate the funding of railway obligations into long term securities, and to place these securities in the hands of the public. What the railroads seek to obtain through the issue of securities is capital for extending their equipment and mileage, and for generally enlarging their investments in fixed forms. The railroad is not in the position of a commercial borrower; and the obligations which take the form of bonds or three year notes, have no such relation to current services and payment therefor, as is the case with paper issued by commercial firms, corporations or individuals. It has long been a familiar fact that the best rates of interest and the most favorable terms were obtained by giving to railroad securities a reasonably long maturity; and it has been equally obvious that the credit of railroads was best safeguarded and the stability of their funded indebtedness was most strongly assured when the securities were widely distributed, and their bonds held by actual bona fide investors who bought them because they sought a safe means of investment for their funds, and intended to hold them because of the income producing power of the securities.

From all standpoints, then, and for all reasons, it is most urgent that the commercial banks of the country should be enabled to relieve themselves of the load of short term obligations representing investments in fixed capital, which they are now carrying. It is not possible to state the amount of such securities which appear among the assets of the banks, national, State and private, but it is large. This sum of values held by banks does not represent commercial banking operations, and will no doubt be gradually eliminated from the banks' assets and added to individual assets. It should not, in so large a measure, at least, continue to figure as a part of the commercial banking resources of the nation. To bring about this change does not imply any reflection on railroad credit; but, on the contrary, must be the outgrowth and most marked success of an effort to strengthen it.

THE PUBLIC AND RAILROAD SECURITIES

How can the public be induced to take up these securities, thus relieving the banks of the necessity of carrying railroad and similar securities, and to hold them firmly and permanently that they may constitute an indefinite investment in the railroads of the country, and may enable the roads to get the advantage of reasonable rates of interest at the same time that they are given the knowledge that they will not be disturbed by any necessity of refinancing themselves at short intervals? The answer to this question can be furnished by making the securities of railways more attractive to, and more popular with investors, and consequently by producing a stronger and more continuous demand for them.

Many persons seem to suppose that the placing of the securities with the public in the way I have indicated necessarily means the raising of interest thereon. This by no means follows. The small investor does not seek a high rate of interest so much as absolute security. He feels absolutely secure when he finds that the railroad which has issued the bonds he buys is earning a revenue sufficient to take care of the interest upon its obligations. In proportion as this revenue is adequate, the safety of the investment is assured; in proportion as safety is assured, rates of interest decline; in proportion as rates decline, the life of the investment can be lengthened. The situation is the exact reverse of that existing with respect to commercial paper, inasmuch as the rate of interest is primarily a matter of safety and long life; whereas in commercial paper the rate is the outgrowth of prompt maturity and certainty of liquidation. Certainty of liquidation is analogous to safety of investment, but far from being identical with it. There is nothing to be gained and much to be lost from attempting to identify the two factors. They should be sharply differentiated from one another; and it should be recognized that conditions which control rates of interest on commercial loans are far from being the same as those which control rates of interest on capital investment.

I have thus described to you some of the fundamental principles of the Federal Reserve Act in its relation to a phase of the banking problem which has received relatively little discussion. I have not attempted to indicate what is the relation of the new banking system to the question of interest rates on long term loans, and yet I think I should, perhaps, say a few words on that point. It should be understood that while, as I have attempted to explain, there is no necessary connection between the rates on short term obligations and notes or bonds running over a period of years, there is, nevertheless, an important relationship between the amount of capital or financial energy required to carry on the banking system of the country and the amount of such energy required for the support of long term operations.

The Federal Reserve Act is essentially a means of economizing the country's gold supply and its credit resources. When fully developed, the act may be expected to set free a considerable amount of capital which has heretofore been needed to carry on short term operations. That is to say, by reason of the fact that short term operations have been provided for on a smaller basis of outlay than in the past, a considerable amount of capital employed in financing these operations will be set free, and will thereby be enabled to go into the long term or investment field.

In so far as this release of capital is effective, it will tend to improve conditions in the general money market, and to lower rates of interest prevailing there. It will, moreover, do an even more important thing than this. By helping to make the line of division between short term and long term undertakings clear-cut and well defined, it will relieve the long term borrower of many incursions into his general field of capital investment from which he now suffers. The effect should be a decidedly more stable and probably a lower rate of interest than would be established without this factor. This in itself will be of very great value to the legitimate borrower who may wish to place securities on the market.

Both of these factors are, however, of that slowly working and conservative kind that figures but little in current discussions of such subjects, and that receives only passing attention from the casual student. They will require a considerable period for their complete development, and when they have been fully applied it will still remain true that the financial problem of the long term investor is essentially dependent upon the demand and supply of capital and in its prac-

tical working out, upon the question what he can offer to the public.

In the case of the railway this becomes a serious matter. As a result of the legislation, with which we are all familiar, intended to control transportation rates, our railroads have become far more stereotyped in practice than formerly. They do not venture to reduce a rate in the hope of stimulating business because they recognize that once reduced, a rate can only with great difficulty be advanced. The railways, whatever the stabilizing influence affecting the rate of interest may be, will, therefore, always have to meet the question whether they can provide the actual net resources that are necessary to take care of their fixed obligations. Undoubtedly the recent advances granted by the Interstate Commerce Commission will be of some service. But will the railroads be permitted to retain those advances? Will public opinion allow the roads to keep for themselves the fruits of these higher rates? Will organizations of employees regard the rates as only a basis for increased wage demands to be taken from the roads as soon as they can by arbitration or other methods, succeed in absorbing them?

A QUESTION OF EDUCATION

This is not a financial problem, it is a question of popular attitude and education. But the problem is financial in this sense: Up to date the railroads have been too largely dependent upon banking institutions for the financing of their obligations. The time has come when the public must be induced and expected to take over these obligations and to carry them as investments. If they cannot or will not do this, then the financial problem of the railroads is truly a serious one. It is undoubtedly a fact that the railways of the country, in order to introduce the technical improvements in their financial situation of which I have spoken, must be able to furnish the basis of all long term credit—a safe surplus of revenue over expense, applicable to the payment of interest. This they cannot do unless they are enabled to earn satisfactory revenue from freight and passengers, thereby providing for meeting their obligations, and giving the holder of such obligations meantime, the confidence that his funds are in safe hands.

Something has been done in this direction by the recent 5 per cent rate decision of the Interstate Commerce Commission. This decision, however, is of more importance in what it suggests than in what it accomplishes. The basis for it is manifestly found in the statement that the railroads are recognized as having distinct and ascertainable needs, and to be authorized to collect sufficient revenue for the services they render to compensate the holders of their securities for the use of the funds intrusted to the carriers themselves. There has been an unmistakable turn in public opinion with regard to this subject. So long as the roads were regarded as possessing unlimited resources, practically indestructible by any kind of legislation or exactions, there was little hope of establishing a business basis for the acquisition of railroad capital.

It is only when the railroad is recognized as being a public utility both as regards the claim on the public and as regards its obligations, that a just balance between service and income can be developed. Such a balance it must now be the effort of the country to obtain. How can it accomplish the result? First of all, the dictates of the situation call for the development of a theory of railroad rates which will result in giving to the carriers a return upon all capital legitimately invested by them. Regulation cannot work in one direction only; it must operate to the advantage of the railways as much as to their disadvantage. It is traditionally a poor rule that will work only one way; and in this case, efficient service to the community dictates that the laborer shall be considered worthy of his hire. If railroads cannot tax the public according to their own will, as we all today, I think, agree that they should not, then the public cannot afford to tax the railroads to such an extent as to destroy the capital of those who have legitimately invested. Neither can the railroads be expected to go on extending their facilities and increasing their services to the public unless they are guaranteed at least that minimum rate of living wage which is demanded by laborers in the interest of society.

It may be an unpopular saying, but nevertheless a true one, that the wages of capital must be paid quite as regularly and quite as fully as those of labor, if capital is to continue to perform its functions in the community. Those who save and invest capital, will not continue to do so if their savings and investments are so affected as to yield them no return. The great mass of the public appreciates the problem and sympathizes with the difficulties of those enterprises in which they are themselves interested much more strongly than in those which are to them only an abstraction. This is true of the railways. There has undoubtedly been a large advance within recent years in the distribution of both stock and bonds of the carriers among the public at large. But rapid as this progress has been it has not yet been rapid enough to meet the requirements of the case. It has not gone far enough to solve the difficulties of the situation. It has not reached the real root of the difficulty.

Too much railroad capital has been derived from the banks and financial institutions, and has been carried by them as part of their investments. Too much railroad capital has been obtained through the sale of shares and bonds under conditions that have not resulted in attracting the real ultimate holder. It is necessary to get the shares and obligations of the railroads into the hands of the mass of the public, and to make the people really and in fact proprietors of the transportation lines. This measure is called for urgently from the financial standpoint for the reasons which I have thus set forth. It is, however, called for much more urgently from the social standpoint. The carriers are public utilities. And this character is not one-sided but must be considered from every aspect. The roads should be public in the sense that they appeal to and depend upon public support as well as in the sense that they must render public service and must meet the requirements of the community for accommodation. When in this sense the railroads have been popularized with the community, a two-fold benefit will result. The banks and investment institutions of the country will be relieved of the necessity of carrying long term investments when they should be devoting their funds entirely to the development of commerce and business, while on the other hand the people who are holders of the securities, will recognize the claims of those who look to the railroads for earnings, as well as to those who look to them for accommodation.

When this result shall have been attained, and in proportion as it shall have been attained, the so-called rate problem will have disappeared. The public will no longer look upon the railway as an incubus, and will begin to regard it as a business partner. It will no longer feel that every dollar paid into a railroad treasury is a dollar deducted from the community's wellbeing, but it will recognize the same mutuality of benefit in dealing with the carrier as is recognized in local communities where men deal with others because they expect those others to deal with them in return.

PUBLIC WORKS IN QUEBEC.—Sir Lomer Gouin, Premier of Quebec province, says that the provincial government continues to subsidize the construction of steel highway bridges. Some 260 bridges have already been put into service, and 56 are now under construction. This has entailed an expenditure, since 1908, of about $700,000. Since 1912 the government has abolished 11 toll bridges and 6 railroad-and-highway grade crossings, at a cost of about $1,400,000.

The Pennsylvania Improvements Through Piqua, Ohio

The Work Includes a New Station and Second Track on Revised Grade, Eliminating Eight Street Grade Crossings

The improvement work recently completed by the Pittsburgh, Cincinnati, Chicago & St. Louis on a six-mile section of line on the Indianapolis division, extending through Piqua, Ohio, 73 miles west of Columbus, is unusually comprehensive, as it effects important economies in the handling of a heavy through traffic, increases the permanency of construction on this section and adds greatly to the facilities for handling both freight and passenger business in a town of 13,000 inhabitants.

EXTENT OF THE IMPROVEMENTS

The operating conditions of the engine district from Columbus to Bradford, 84 miles, are improved by the addition of a second track in the only remaining single-track section in that district, and the reduction of grade from a maximum of 1 per cent uncompensated to 0.7 per cent compensated, the ruling grade on the division. The standard of construction is raised by the widening and thorough drainage of two long cuts, the replacement of an old low level bridge over the Great Miami river and the construction of steel concrete subways over all streets. In addition to the advantages enjoyed by the town as well as the railway in the separation of grades at streets, a new passenger station has been provided, the freight station has been enlarged, and the local freight yard and industry tracks improved. The railway has met the entire expense of the improvement, including damages to personal property.

This six-mile section forms a part of the main line of the Pan Handle from Pittsburgh to Chicago, and also of the line from Columbus to Indianapolis, which forms part of an alternate route from Pittsburgh to St. Louis. The westbound traffic consists largely of coal from the Pittsburgh division and the Norfolk & Western at Columbus and the eastbound business includes meat, merchandise and stock from Chicago and the west and empty coal cars. The average train movement is about 85 trains per day.

In addition to the Pennsylvania trains, the old single track line handled the passenger and local freight trains of the Cincinnati, Hamilton & Dayton between the connection of the Piqua & Troy Branch just west of the passenger station and the Cincinnati, Hamilton & Dayton junction, about a mile east of the station. Under the old arrangement these trains in order to reach the center of Piqua used the Piqua & Troy Branch and the Pennsylvania between Troy and Piqua Junction instead of the C. H. & D. main line on the east side of the Miami river. These movements increased the total for that portion of the Pennsylvania's line to about 97. This operating arrangement had to be terminated when the Pennsylvania tracks were elevated through Piqua on account of the inability of the C. H. & D. to secure ordinances from the city for the elevation of its branch line tracks up to the Pennsylvania connection. A new station was therefore built near the junction and all C. H. & D. through trains now use its main line.

The tonnage rating on the Columbus-Bradford district was limited to 1,700 tons in both directions by the old grade through Piqua and on account of delays in this single-track section it frequently required 16 hours for the run with a full tonnage train. As soon as the first track on the new grade was put in service it was possible to add 200 tons to this rating and cut the running time for westbound traffic and later, similar economies were effected for eastbound traffic when the second track was put on the new level.

All construction work has been handled without interference to traffic. To facilitate the work through town the center line was shifted to the north an average of about 32 ft. The improvements involved the handling of 460,000 cu. yd. of grading; the placing of 40,000 cu. yd. of concrete in bridge substructures, retaining walls, etc.; the erection of three arch culverts, a five-span deck plate girder structure over the Great Miami river and solid floor bridges over eight streets; and the laying, ballasting and surfacing of about 20 miles of new main, side and yard tracks.

GRADING

By laying a continuous 0.7 per cent compensated grade line from the ends of the improvement down to the river crossing, the cuts at both ends were deepened enough to furnish the necessary material for filling across the valley on the higher level. When the plans were made it was expected that the C. H. & D. would elevate its branch line, and on this basis the quantities of excavation and embankment were balanced, allowing 10 per cent for waste. On account of the change in plans, about 20,000 yd. from the west cut intended for the C. H. & D. connection was used to widen the fill for yard tracks.

The cuts are about 7,000 and 9,000 ft. long, respectively, and were lowered a maximum of about 9 ft. They were widened to carry three tracks in order to allow the excavation to be handled without interference to traffic and to provide for a future additional track. The roadway section in these cuts provides for a distance of 17 ft. from the center line of the outside track to the toe of the slope. The banks were sodded during the first season's work, but this did not prove entirely satisfactory on account of the height of the slopes which exceeded 25 ft. in many cases. Where the banks showed any indications of being wet, trenches 2 ft. deep were dug vertically or diagonally down the slope and filled with riprap stone to provide an open drain to the side ditches. These bank drains have been very successful in keeping the slopes in good condition.

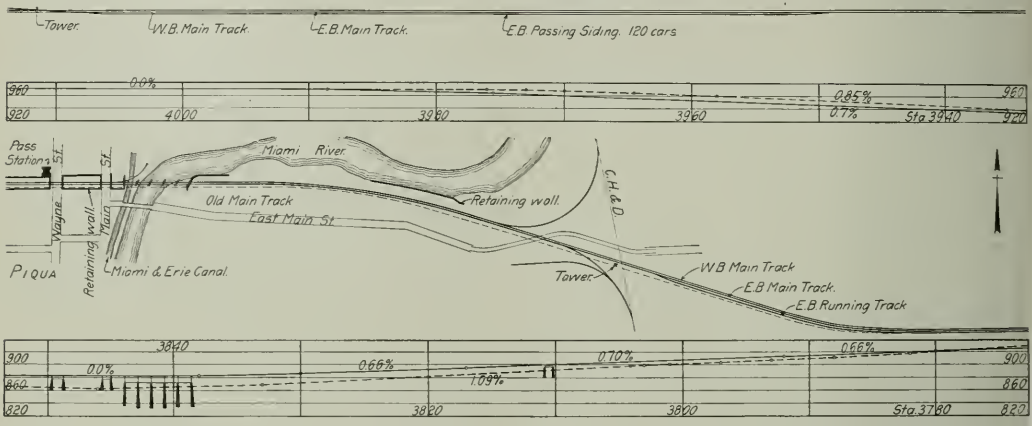
Tile drains 6 in. to 18 in. in diameter were laid in one side ditch in each cut and a similar line of 6 in. to 12 in. tile in the other ditch. Bell end vitrified pipe was used for these drains laid with 1-in. open joints and covered with cinders or loose stones. Catch basins were provided at intervals of about 800 ft. These drains lead to open riprapped ditches. The effect of one of the large drains was clearly shown in the east cut, which had a width of only 9 ft. from the center line of tracks to toe of slope. After one-half of the new cut was finished the side drain was laid, with the result that a temporary cinder ballasted track in that cut was easily kept in condition and the remaining half was noticeably drier when it was excavated. The slopes were finished and the ditches dug by an American ditcher.

The new double-track fill is about 2½ miles long, with a maximum height near the river of about 19 ft. The standard top width is 37 ft., providing a shoulder of 12 ft. from center of track. The material handled was mostly clay, requiring an allowance of 10 per cent for shrinkage on the shoulders. A speed limit of 10 miles per hour was enforced on the new fill and 20 miles an hour was allowed after it became thoroughly compacted. The main track is laid with 100-lb. rail on oak ties with four rail anchors per rail. The roadbed is surfaced with 6 to 8 in. of cinders on which 12 in. of gravel ballast is placed.

The excavation was made almost entirely by two Marion steam shovels, models 60 and 70, and the material was handled by a standard gage and a narrow gage outfit. The grading was planned to avoid the necessity of hauling the material across the old river bridge on account of the interference to traffic that would have resulted. Some trestle was driven west of the river between the street crossings, but the lighter fill on both sides and the big fill adjacent to the river on the east side were made by spreading and raising tracks. Some very good records were made in handling this filling material by keeping the dump in good condition and anticipating as far as possible, other causes

of delay. The standard gage outfit of two 10-car trains with an average haul of about 1½ miles handled an average of 1,200 yd. per day for eight months, working a single shift. The best month's record was about 41,000 cu. yd. The 15-yd. Western dump cars were used in this outfit, averaging 12 to 13 cu. yd. loaded. The narrow gage outfit, using 20-ton dinkies and 3-yd. cars, of the new bridge. The piers are skewed about 30 deg. to bring them in line with the current.

The excavation for the piers was made by two McMyler cranes, one with a 1-yd. orange peel bucket and the other with a 1-yd. clam shell bucket. The footing piles under the east abutment and the three easterly piers were driven by one of the cranes



Plan and Profile of New Two-Track Line on Revised Grade Through Piqua, Ohio

handled as high as 1,300 yd. per day, 17,000 yd. in two weeks, and 30,000 yd. in one month. Three trains of 15 cars each were used in this outfit, the haul being about two miles.

BRIDGES AND RETAINING WALLS

The new river bridge replaces a through truss structure on stone piers and abutments built in 1888. The two river spans, each 138 ft. long, and the approach deck girder span over the Miami and Erie canal, did not provide a sufficient waterway for the floods to which the river is subject and the new bridge was accordingly increased in length to five 105-ft. deck plate girder spans. The danger from floods is further decreased by the raised grade, the old tracks being only about 5 ft. above high

High Water at the Old Miami River Bridge in the Spring Floods of 1913 Showing Piers in Place for the New Structure

water. Prior to the disastrous floods in the spring of 1913, the river channel was changed at the curve above the bridge and the bank protected by levees on the north side and a retaining wall 300 ft. long on the south side connecting to the east abutment with suspended leads in which a No. 2 Vulcan steam hammer was operated. The west pier and the west abutment are founded on limestone, which is only 2 ft. below low water at the pier site, although it dips so rapidly to the east that it was not reached by 15-ft. piles at the next pier. The piers were built in coffer-dams with steel forms above the footings. The maximum height is 47 ft. Three 85-lb. rails were provided in the nose of each pier as ice breakers.

The concrete in the east abutment and the three easterly piers

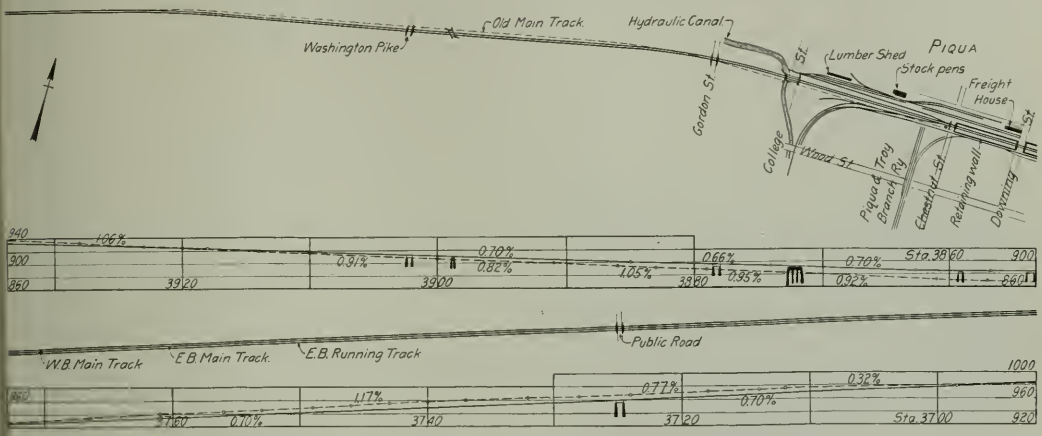
The New Miami River Bridge

was placed from a mixer plant about 60 ft. east of the abutment. The sand and stone were dumped through a trestle in the old line which had been driven to replace a section of the old fill adjacent to the new abutment and piers. From the storage bins under this trestle, the proper proportions of the materials were loaded into an automatic dumping car which was hauled up to the ½-yd. Ransome mixer. The concrete was handled to the forms in buckets by the locomotive crane. The west pier and the west abutment were placed from a portable plant which was also used

for a large part of the retaining walls and subway abutments through town.

The six existing streets and highways crossing the line within the limits of this improvement were carried under the elevated tracks in subways and similar provision was made near the west end of the work for two new streets which it is expected will

It was necessary in only one case to depress the street grade, and in this instance the tracks were carried on a temporary trestle, while the excavation for the street was made with a Thew shovel to an approach grade of 4 per cent. This required the handling of 16,000 yd. of material. A total of 4,700 ft. of retaining wall was built, the longest continuous wall being along



Plan and Profile of New Two-Track Line on Revised Grade Through Piqua, Ohio

be opened. With one exception, these structures consist of concrete abutments and steel columns on the curb lines supporting steel trough decks filled with concrete. The exception is a three-span arch bridge over a street and a canal from which the city takes its water supply. The possibility of adding third and fourth tracks later was considered in designing all subways, either by building the abutments wide enough to carry the additional tracks or by providing for an extension of the substructure. The over-

Three-Span Arch Bridge Over College Street and a Small Canal

head clearance under these subways is 13 ft. at four streets, 15 ft. at three streets, and 17 ft. at the other streets.

The maximum street width is 66 ft., and with one exception the crossings are practically at right angles. The longest trough span is 44 ft. A line of 10-in. clay tile is laid in each trough and in some of the deeper ones, two lines are used in order to save concrete and reduce the dead load. A 3-in. layer of concrete was placed first, on which the tiles were laid, the concrete being tamped solidly around them. The top of the troughs were covered with concrete to a minimum depth of 2 in., and the upper surface of this concrete was waterproofed, four processes being used, namely; Sarco, Johns Manville, Barrett and Erhart. The edges of the trough decks were finished with concrete copings. The arch bridge has three spans of 37 ft. 6 in. each, the arch rings being five-centered. The concrete is reinforced with Clinton wire mesh. The fill over the haunches was made with cinders.

the south bank of the river east of the bridge where a 300-ft. wall containing 6,000 yd. of concrete was placed.

A large part of the walls and subway abutments through town were placed with a mixing plant operating on a 10-ft. gage-track between the walls as shown in one of the accompanying illustrations. This plant was equipped with a storage bin for sand and stone above the 1 yd. Ransome mixer and a 40-ft. tower in which the concrete was elevated for chuting to place. The boiler, hoisting engine and mixer engine, were located on the opposite end of the car from the tower, serving as a counterweight. The sand and stone were handled direct from gondola cars alongside to the storage bins over the mixer by a locomotive crane which was also used to place bags of cement on the charging platform, handle the sections of wall forms and excavate for the footings under the walls. The plant could be moved eas-

Portable Mixer Outfit Used in Placing Concrete Retaining Walls, and the Derrick Car Used to Handle Material from Cars to Hopper Bins

ily to keep the length of chute at a minimum. This plant placed as much as 150 yd. of concrete in a single shift and averaged 35 yd. of concrete and 25 yd. of excavation every working day for the entire season. The plant was operated by a crew of 8 to 10 men with a labor charge of about $35 per day.

A stationary mixer plant was used during the winter for some of the walls. The storage bins were provided with steam coils

and the plant was well housed in to allow work to be carried on in cold weather. About 2,200 yd. of concrete was placed during one month with this plant.

PASSENGER STATION

The new passenger station is a brick structure on concrete foundations with stone trim and tile roof. It is located on an important street near the center of town with its floor level about 3 ft. above the sidewalk grade. A wide terrace across the

A View Through the Town During the Construction of the Retaining Walls, Showing Sectional Forms and Derrick Car for Handling Material

front of the building connects with a passage under the track from which two stairways lead up to the platforms at track level. Additional stairways are provided at the streets on both sides of the one on which the station is located and a carriage drive approaches the rear of the station building from the opposite street.

In addition to the main waiting room the building contains

New Pennsylvania Passenger Station at Piqua, Ohio

a women's room, men's room, ticket office, baggage room and express room. A basement is provided for the furnace and coal room, and a baggage and express elevator connects the station and track levels. The floor in the waiting room is of terrazzo, the walls of brick and the arch ceiling of plaster. The building is provided with electric light and steam heat throughout. The track platforms are 20 ft. wide, of brick on a concrete base with concrete curb. Steel frame shelter sheds and a small shelter house are provided on each platform.

This improvement has been carried out under the general direction of W. C. Cushing, chief engineer, maintenance of way, and B. V. Sommerville, principal assistant engineer, Pennsylvania Lines West, Southwest System. F. H. Watts was division engineer at the beginning of the work and was later succeeded by G. R. Barry. Mr. Watts was charged with the preparation of plans and the close supervision of the construction till promoted and succeeded by Mr. Barry. E. H. May was engineer in charge. H. E. Culbertson & Co., Cleveland, Ohio, had the general contract and handled the grading. The construction of the river bridge and most of the retaining walls and subway abutments was let to the McKelvy-Hine Company, Pittsburgh, Pa.; the concrete arch and the remaining concrete work was contracted to the Hezlep Sinclair Company, Cleveland, Ohio; the steel in the river bridge and the subways was erected by the Ketler-Elliott Company, Chicago, and the sloping, ditching and track work was handled by company forces. F. L. Packard, architect, Columbus, Ohio, designed the new station, and George B. Hicks, Springfield, Ohio, had the contract for the construction of the building.

SAFETY AND SHORT TRAINS*

By Marcus A. Dow

General Safety Agent, New York Central Lines.

This bill to limit the length of trains to a maximum of 50 cars per train, has been presented and its passage urged as a measure of safety, it being the contention of the gentlemen favoring the measure that shortening the length of trains will lessen the chances of accident and reduce the number of injuries. To persons unfamiliar with the details of personal injury work and the prevention of accidents as undertaken by the railroads of today, this argument may appear reasonable, but before accepting it as a conclusion it is essential to consider a number of important facts.

In the first place, the fact must be admitted, even by those the least informed, that safety in reality rests not upon whether there are a few cars more or less in a given train, but upon the way in which that train and others on the same road are handled and operated. There is not now, nor has there ever been a well fortified argument for, nor a sincere demand to shorten the length of trains to increase safety. The Interstate Commerce Commission in all of its exhaustive studies and reports has never pointed out a single case where the number of cars in a train, nor the number of men on a train, nor the number of engines hauling a train was a factor contributing to or causing an accident.

As a matter of fact, if the proposition were fairly considered, it would seem reasonable, if not probable, that the passage of the so-called "short-train" bill will tend to increase the risk of injury rather than decrease it. The density of traffic as measured by the number of trains to handle and get safely over the road, will increase with the shortening of the train, resulting in a greater chance of confusion and increasing the chance of error. This feature, of course, becomes more important on roads where the traffic is heaviest and density of traffic is already a problem requiring the most skillful attention of expert operating men. To suddenly require all roads to multiply the number of trains they must handle without a corresponding increase in trackage and other facilities would necessarily result in confusion and increased hazard.

Much stress has been laid by the supporters of this bill upon the great sacrifice of life and limb on the railroads of this country. Admitting freely that there are far too many persons

*From an argument made by Mr. Dow before the Public Utilities Committee of the Illinois house on Monday, May 10. This committee has since taken unfavorable action on the bill.

injured on our railroads and that many of the accidents resulting in injury can and should be avoided, I wish to point out how these accidents can be prevented and what steps are being taken to prevent them. For years there has been a nation-wide agitation in behalf of greater safeguards for employees of railroads, other industries and the general public. In every state there has been a veritable epidemic of legislation with a view of protecting the workingman from possible injury. Safety devices of every description have been installed, rules formulated, regulations adopted and mechanical safeguards invented and applied until it would seem that accidents never could happen. But, the disquieting feature of the situation has been that up to a year ago in spite of these extraordinary precautions taken to insure immunity from harm, accidents resulting in injuries increased steadily, and the very laws that were made to lessen accidents actually seemed to foster them. It remained for the officials of the railroads and other great industries to discover where the real trouble lay. The conclusion was reached that with all the laws that might be passed and safety devices that might be installed, there would be no successful reduction in accidents until there had been enlisted the co-operation of those in whose interest these precautions were being taken.

In other words, it was found that the human element was knocking all the carefully laid plans of well meaning legislators into a cocked hat, and with this fact in mind there has been launched within the past few years what has universally been called a "Safety First" campaign, and practically every railroad in the United States is now vigorously conducting such a campaign, regardless of the expense incurred thereby. On the New York Central Lines during the year 1912 only 9.65 per cent of all injury cases were due to defective equipment, tools or appliances, the balance being due to fault of injured man or another employee, or else unavoidable. This statement speaks for itself, and supports the contention that the making of laws and installing safeguards is not the solution of the accident prevention problem. Rather does it depend on the extent to which the employees co-operate in an effort to eliminate practices and conditions which are unsafe and which lie within their own power to correct.

I wish to refer to some of the advertising matter that has been sent out by supporters of this "short-train" bill, and call your attention to some things contained therein which will undoubtedly mislead you if you are not acquainted with all the facts. A post card which was mailed broadcast to citizens of this state, as well as to members of this legislature, decries the fact that 593.359 people were killed and injured on the railroads of this country in the three years from June 30, 1911, to June 30, 1914, and particular stress is placed on the fact that 31,851 of those injuries resulted fatally. They do not attempt to further enlighten you by telling you, truthfully, that 16,463 of these persons killed, or more than 51 per cent were trespassers who voluntarily and needlessly risked their lives by going upon the railroad tracks where they had no right to be. Neither do they attempt to explain that 12 per cent of those killed were travelers-on-the-highway killed on grade crossings, or other outside persons, and that only 30 per cent of all those killed were employees of the railroad on duty, while only 3 per cent of the killed were passengers. They point accusingly to the fact that in three years there were 593,359 persons killed and injured on railroads in the country, leading you to believe that railroad work is the most hazardous of all occupations—and that a railroad is a veritable industrial slaughter house, whereas in truth railroad casualties form only a small part of the total industrial accidents annually, conservative statistics of large insurance and casualty companies indicating that more than 30,000 persons in all industrial occupations are killed and more than 2,000,000 injured every year.

These figures do not include other than industrial accidents, such as those occurring in the city streets, etc. The coroner's record for the city of New York indicates that during the year 1913, a total of 5,750 persons met violent death in the borough of Manhattan alone, of which 402 were in street accidents, 867 were due to falling out of windows, down stairways, off from scaffolds, etc., and 215 due to accidental drowning.

Interstate Commerce Commission figures indicate that during the year ended June 30, 1913, on all the railroads of the country there were 181 passengers killed in train accidents, while during that period there were 1,018,283,000 passengers carried, so that there was one passenger killed in a train accident for every 5,625,873 carried, regardless of the distance they were carried. In the city of Chicago alone during 1913 there were 372 persons killed in the city streets by being struck or run over by some moving street vehicle. Chicago has a population of approximately 2,500,000. Therefore, as against 372 inhabitants of Chicago killed in her streets by moving vehicles, and hundreds more of her citizens killed in various other ways in a single year, the railroads of the country transported more than twice as many passengers as Chicago has inhabitants before one was killed in a train accident.

The proponents of this bill have insistently intimated that the railroads almost without exception have accidents every year resulting in fatal injuries to passengers, the statement having been made that it is questionable if any railroad except the New York Central went through last year without killing a passenger. During the year 1913 there were in the United States steam railroads of 299 operating companies, with a mileage of 120,901 miles on which there was not a passenger killed in a train accident, although there were more than four hundred million passengers carried by these roads.

Interstate Commerce Commission figures also indicate that in the year ended June 30, 1913, there were 557 employees killed in train accidents. During that same period the railroads transported 300,558,334,000 tons of freight one mile, with an average of 14.31 tons of freight per car or 210,033,776 loaded cars one mile, so that one employee was killed in a train accident for every 37,708,039 loaded cars moved one mile. And what does this indicate—simply this, that for every hundred loaded cars operated a distance of 377,080 miles one employee was killed, and this, mind you, does not take into consideration the vast number of empty cars handled at the same time. In other words, one railroad employee was killed in a train accident for each hundred loaded cars transported a distance equal to 15 times around the world, or as far as from the earth to the moon and half way back.

Another fact in connection with these figures indicating 593,359 persons injured and killed on the railroads in three years which must not be overlooked, is that the majority of these injuries were of a more or less trivial character. We know that a little over 31,000 of the cases, resulted fatally, of which 51 per cent were trespassers. Of the injuries every case is included where the employee lost more than three days from work, and injuries were reported as such which often consisted of only a bruise or scratch of the hand, or some other minor injury. An examination of the New York Central records of injuries for a year indicates that only one out of every 227 employees injured was permanently disabled.

Less than 10 per cent of all railroad injury cases are due to collisions and derailments, and even the majority of these are in accidents which could only be prevented by greater care on the part of human beings involved in the accidents. The Interstate Commerce Commission employs expert investigators, who make investigations into the causes of wrecks on railroads throughout the country. These investigations are exhaustive and often weeks, and even months are consumed enquiring into every detail of a single train accident. During the 12 years, 1902-1914, the commission investigated directly, through its own agents, 1,570 train accidents, of which only 218, or 14 per cent were caused by defective track, equipment or appliances, and 15 per cent were due to bad weather, outside agencies, unknown causes or unavoidable, while 1,120 or 71 per cent of the train accidents investigated by the commission in the 12 years were found to have been due to the fault of a member of the train crew, a

despatcher, operator or some other employee. The human element! It can never be effaced by all the safety appliances that can ever be invented and applied, nor by all the laws and regulations that can ever be passed and enforced.

On the New York Central the average number of cars per train increased 3.11 cars in 1914 over 1913, notwithstanding which fact there was a decrease in every class of accident. There was a decrease of 73 per cent in trainmen killed and 39 per cent in trainmen injured; of trainmen in yards a decrease of 33 per cent killed and 42 per cent injured; of yard trainmen killed a decrease of 19 per cent and injured 39 per cent. While a part of this decrease was brought about by safety educational work, it is partly attributable to the fact that with an increase in the average number of cars per train, there was a decrease of 18 per cent in the number of trains run. In 1914 there was on all the railroads a decrease in all classes of injuries in train accidents, and it is known that the length of trains did not decrease in that period, but rather did it increase, while the number of trains operated on the roads in general decreased thereby decreasing the hazard.

The contention is made that with a shorter train there would be a better opportunity for the crew to make inspection of the running gear, brake rigging, etc., while stopping at points en route. In the first place, it should be clearly understood that on virtually every railroad today trains are made up in terminals by a yard crew, are inspected before leaving by car inspectors located at the terminal, and then turned over to a road crew, which latter crew has nothing to do with the train until it is made up, inspected and ready to leave the terminal. As far as the more lengthy trains are concerned, the only stops made are as a rule to take water or at meeting points. Little or no switching is done en route so that cars are not handled roughly. The longer trains must necessarily travel at slower speed than the shorter ones, so that possibility of accident to the long train is decreased thereby. As far as making inspections en route, as every crew is required to do when stops are made, this rule is expected to be lived up to and crews must take the time to do the inspecting work required of them and the length of the train, no matter whether long or short, has never been nor can it be given as an excuse for non-compliance with this rule. As to any contention that accidents would result from drawheads pulling out on longer trains, while it is true that drawheads do pull out occasionally, it is an occurrence not confined to long trains and the truth of the matter is when they do pull out it is usually when the train is starting, and at a time when no accident would occur.

To suddenly increase the employees to the number that would be necessary to man the many additional trains the passage of this law would require, would mean another element of increased hazard instead of a decrease in hazards, because every green man that is employed is an experiment at the best.

PIECE WORK IN THE FREIGHT OFFICE

In the freight office of the Chicago, Rock Island & Pacific at Burr Oak (Chicago) the clerks who make waybills and those who examine claims have for the last twelve months been making waybills on typewriters. They have been paid at the rate of ninety cents a hundred items for making waybills and seven cents each for attending to claims for overcharges and damage; and the agent, J. W. Lawhead, in the Rock Island Employees' Magazine for May, gives the results of the year's experience.

Previous to May 1, 1914, waybills were made with pen and ink, each clerk receiving $75 a month and usually about $10 additional for overtime. Three claim investigators received $70 a month, these men helping the bill clerks in the afternoon and being helped by them in the morning. The billers usually got through their work about 9 p. m. Eight Remington machines were put in service in April, but before beginning the year (May 1) it was found that seven would be enough; and on May 16 the billing force was reduced to six men. The office handles 2,000 claims a month and bills out 50,000 items. This work now costs an average of $590 a month, which is $200 less than the former cost, two claim investigators having been taken off at the beginning of the new arrangement. A revising clerk goes over all of the waybills for errors before they are sent out; another man—clerk to the bill department—sorts the tally sheets when they come from the loaders, and still another is the extension clerk, who using a comptometer, puts on each tally, before it goes to the bill clerk, the amount of freight charges for that item. The office force was changed around so that these new positions involved no new expense.

The bill clerks come on duty at 9 a. m., about an hour later than formerly, and usually finish about 6:30 p. m. In the twelfth month, April, 1915, out of 29,638 items billed, the six clerks had made 165 errors, all of which, except six, were caught by the revising clerk. This averages one error to each 175 items. If a clerk's errors amount to more than one in 200 he is subjected to a slight penalty, and has his name posted on a bulletin. Making less than one in 200 in a month he is given a clear record for that month. In March two men made clear records, one having billed 12,580 shipments and the other 12,741, with errors numbering 42 and 62 respectively. The woman with the comptometer makes an average of 2,199 calculations daily, figuring all pre-payments twice. During March she was caught in only eight errors. Mr. Lawhead recommends the comptometer also for other work in the freight office. He has two of them in use.

INCREASING THE AVERAGE DAILY CAR MILEAGE ON THE GREAT WESTERN

During the past year the Chicago Great Western has been giving careful attention to the elimination of delays to cars, with the result that the average mileage per car per day has been materially increased. The following comparison by months with the similar performance one year ago shows the average increase to be from 24 to 27.7 miles, or 15 per cent.

Month	Average per car per day 1913-14	1914-15
April	26.3	28.7
May	26.2	29.1
June	24.8	27.5
July	21.8	26.0
August	21.9	27.6
September	23.0	27.8
October	23.0	28.8
November	23.8	28.0
December	24.7	27.6
January	24.1	27.5
February	24.7	25.7
Average	24.0	27.7

This improvement has resulted largely from three causes. While the road has not been extravagant in the use of power and has taken engines out of service as the traffic has decreased, it has maintained in service a sufficient number of locomotives at all times to handle the traffic promptly and to prevent any delays because of lack of motive power.

A second reason contributing to this result is the 12-hour telegraphic daily reports sent to the general manager by each superintendent at 9:00 a. m. and 4:00 p. m. These reports show the conditions at each terminal in the morning and evening, giving the number of cars on hand awaiting movement in each direction with causes for any delays.

A third measure is the close supervision of cars at all stations by the superintendent of car service who keeps informed regarding conditions at each station on the line and the reasons for any delays in cars at those points. The results of this continuous supervision and attention to this phase of operation by the general manager, the superintendent of car service and other operating officers, show the possibilities in this field.

Tests of Exhaust Ventilators on Passenger Trains

Results of Experimental Work Carried Out During Past Winter; Effects of Position of the Car in the Train

By George L. Fowler
Consulting Mechanical Engineer, New York

During the past winter an investigation was conducted to determine the operative efficiency of the Standard exhaust ventilators used on the passenger equipment cars of the New York Central. Prior to this the only data available as to their operation was that obtained in laboratory experiments conducted by the makers, the Standard Heat & Ventilation Company of New York, to determine the ratio existing between the velocity of the wind blowing over the ventilator and the volume of air that would be exhausted by the action of the ventilator. This data will be referred to later.

The Standard exhaust ventilator is pressed from sheet steel and its general outside appearance is that of a quadrilateral pyramid with one side removed. Its base, which is open, is bolted to a side opening in the deck of the car. Its bottom is the side removed and the shape is such that when air is moving past it, either parallel to the center line of the car or at an angle thereto, an induced current is produced, flowing out at the open side. As this opening communicates directly with the interior of the car, through the base, this induced current is supplied by the air within the car and the exhaustion of this air follows, coupled with the ventilation of the car itself.

The purposes of the investigation were to ascertain the quantity of air removed from the car per hour, under the ordinary conditions of service; the rate of the exhaust removal of air at various speeds, so as to obtain the percentage of efficiency as compared with the results of laboratory investigation, which latter may be regarded as the theoretical or highest efficiency; the effect of wind direction; the effect of the location of the ventilator on the car, or the car in the train; the movement of the air currents within the car; the variation in barometric pressure within and without the car, and the amount of air delivered at the breathing zone.

The car selected for the purpose was a standard steel passenger coach of the New York Central lines. It was 69 ft. 4 in. long inside and had a seating capacity for 84 passengers and a cubic content of about 5,160 cu. ft. The car was fitted with twenty Standard exhaust ventilators, ten on each side, alternating with plain perforated metal deck opening screens of which there were eleven on each side. Both deck and exhaust openings could be closed by a Cheeny deck sash. The deck openings measured 28½ in. by 8¾ in. The exhaust openings were trapezoidal in form and had a free opening of 54½ sq. in., or .378 sq. ft., which was reduced by the dial of the anemometer placed in front of them to .359 sq. ft. No screen or netting was used with them.

INSTRUMENTS

For the purposes of the investigation the car was equipped with a vane anemometer, registering to 100,000 ft. of air flow, placed in front of each of four of the exhaust openings on each side. There was one at each end exhaust, with the other two spaced equally between, which made one for each third ventilator.

A cup anemometer of the regulation government type, was placed on the center of the roof of the car deck on the outside. It was arranged to make and break an electrical circuit for each one-tenth of a mile of the flow of the wind. This electrical circuit was arranged to operate a telegraph sounder by which a signal was given for each one-tenth of a mile of flow of air over the roof of the car.

A Boyer speed recorder was attached to one of the axles of the car, and the wire to the indicator was led up into the car. This made it possible to observe the speed at any instant and also retain a graphical record of the speed of the whole run.

A wind vane of standard government dimensions was placed on the center of the deck roof, in line with the cup anemometer, but at the other end of the car. The stem from this vane extended down into the car and had attached to it a pointer rotating over a dial, thus indicating at all times the angle at which the wind was blowing against the car, as a resultant of its own normal motion and that of the car.

A clock was arranged to make and break an electrical circuit at two-minute intervals. This was connected with a bell which sounded a signal for the taking of readings.

The apparatus used for the determination of the variation in barometric pressure, inside and outside the car, consisted of a wooden box, measuring 7 in. by 7 in. by 8¼ in. In each of five of the six sides of this box, eight holes were bored. These were each 5/16 in. in diameter and were widely scattered over the sides. In the sixth side a hole was bored large enough to admit the insertion of a rubber tube having a bore ⅜ in. in diameter. One end of the tube thus communicated freely with the interior of the box, while the other end was attached to one leg of a U-tube, which was half filled with colored water. The box was bolted to a board which replaced one of the deck opening screens. The small holes opened to the outside air and the rubber tube led down to the U-tube within the car, one leg of which was open to the air inside the car. It was thought that the air entering the box through the small holes, and under the influence of the pressure, would have its velocity greatly reduced by the relative sectional area of the box to that of the holes; that it would be so essentially calm as to produce no effect either for exhaust or pressure at the end of the tube, and that the barometric pressure within would be that of the external air, uninfluenced by the motion of the car. The areas were to each other as about 80 to 1, so that air entering the box at the highest recorded wind velocity, even though unchecked by passing through a rough hole 5/16 in. in diameter and 1 in. long would move through at a rate of less than one mile an hour.

MOVEMENT

The car, so equipped, was handled on regular passenger trains for one round trip between Albany and Buffalo; two round trips between Albany and Syracuse, and one round trip between Albany and Weehawken, a total distance of 1,466 miles. With one exception the trains were express. Between Albany and Buffalo six intermediate stops were made westbound, and sixteen eastbound. Between Albany and Syracuse there were fifteen westbound and twelve eastbound. Between Albany and Weehawken, there were thirty-four southbound and ten northbound.

OBSERVATIONS

Readings at two-minute intervals were made of the speed of the train, the velocity of the wind relative to the car and the direction of the wind relative to the car. At fifteen-minute intervals readings were taken of the anemometers in the exhaust openings, and at intervals between these readings observations were made of the rate at which air moved through the exhaust openings. The readings for these observations were taken at 15 and 30 seconds intervals, the time and speed of the train being also noted. From the time at which the observations were made it was possible, by means of the two-

minute readings, to determine the velocity of the wind relative to the car.

AMOUNT OF AIR REMOVED PER HOUR

The amount of air removed from the car per hour was determined by the regular readings of the anemometers placed in the exhaust openings. The individual readings were widely scattered, but, when grouped and gathered under averages of speeds increasing by increments of five miles an hour, they were found to increase with the speed, and show, as would be expected, that the amount of air removed varied with the speed. The amount of air removed from the car under observation, in the eight runs involved, averaged 296,699 cu. ft. for each of the eight ventilators to which anemometers were attached. If this total is divided by the number of hours that the car was under observation, which was 41, we have an average removal of 7,236 cu. ft. of air per ventilator per hour. This covers all speeds and conditions of operation from standing still to 76 miles an hour. The average speed of all the trains between terminals was 35.7 miles per hour, elapsed time.

The rate of the removal of the air through the exhaust ventilators was obtained by taking readings of an anemometer, placed at one of the openings of an exhaust ventilator, at such short intervals of time, and in connection with the actual speed of the train at the instant, that it was possible to determine the actual rate at which the air was removed at different speeds of train and wind. During the whole period of these investigations, there was little or no wind stirring. The result was that wind velocity relative to the car corresponded very closely to that of the car itself.

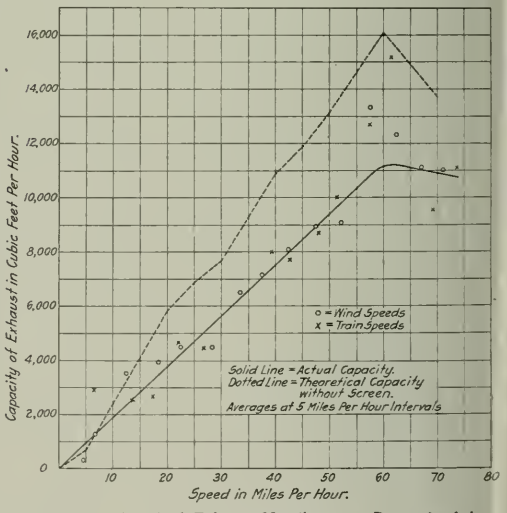
The readings referred to were taken at intervals of 15 or 30 seconds, and at speeds that ranged from zero to 75½ miles an hour for the speed of the train, and from zero to 72 miles an hour for the speed of the wind relative to the car. There were 201 of these observations, and they have been grouped together in five-mile intervals of speed and plotted in the accompanying diagram, under the average speeds. The anemometer readings, thus obtained have been taken to indicate the rate of flow of air through the ventilator at the several observed speeds, and this has been considered to have been uniform throughout the whole area of the exhaust opening. This is warranted by the results of laboratory investigations, in which it was found that, when the direction of the wind currents was parallel or nearly parallel to the center line of the car, the rate of exhaust flow was uniform over the whole area of the ventilator opening. This diagram shows a general progressive increase in ventilator capacity on a straight line up to 60 miles an hour of train and wind speed. In this case, the train and wind speeds being so nearly the same, it is impossible to differentiate between them in the construction of the median line.

For the purposes of comparison the diagram of the ventilator capacities obtained in the laboratory is plotted with those obtained in service. In the case of the laboratory investigation the capacities given are those obtained with the air moving parallel to the center line of the car, and it is interesting to note that there was a steady increase of capacity directly as the speed up to 60 miles an hour, followed by an immediate falling off as that speed was exceeded.

Owing to the absence of wind during the tests the direction of the resultant wind relative to the car indicated only a slight deflection. The average for all of the runs was but 9.35 deg., and it was near this point that the vane stood for most of the time. For this reason it is fair to compare the ventilator capacities obtained in practice with those of the laboratory, as is done on the diagram. If a comparison is made of the relative capacity of the ventilator under the two conditions, it will be found that up to a speed of 60 miles an hour the efficiency in service was about 70.5 per cent of the theoretical capacity of the ventilator, as measured by the laboratory experiments.

For the purpose of making a practical application of these results, let us take the figures already set forth as an example of what was done on the eight runs under consideration. In these we have an average performance per ventilator of removing 7,236 cu. ft. of air, and that at an average speed of 35.7 miles an hour, and under widely varying conditions from standing still to a speed of 76 miles an hour. According to the diagram each ventilator should remove about 6,700 cu. ft. of air per hour. The actual performances through a wide range of conditions check very closely, therefore, with those obtained from a detailed study of an individual ventilator. As the line of the diagram is straight from 0 to 60 miles an hour, the capacity of the ventilator varies directly with the speed, and may be obtained by multiplying the latter by 188.

Again, if we take the average speed of the train during elapsed time from the start to the last reading of the anemometers, and credit each anemometer for the removal of an amount of air corresponding to the elapsed time and the average speed of the train in accordance with the diagrams presented, it will be found that, according to that diagram, each ventilator should have removed 282,797 cu. ft. of air. Comparing the two, we find the average actually removed was 4.9 per cent more than that calculated with the diagram as a base. Hence the diagram



Capacity of Standard Exhaust Ventilator as Determined by Laboratory and Service Tests

may be assumed to represent the conservative capacity of the ventilator, as this small percentage of variation is well with that allowable.

EFFECT OF LOCATION

During the course of the investigations the car was placed in different positions, from being next to the engine to seventh in the train. It will be readily understood that the data available from so small a number of runs is too meager to make definite conclusions possible; but what there is indicates that the location of the car in the train does have an effect on the operation of the exhaust ventilators. In order to determine this it was necessary to consider both the amount of air exhausted and the speed of the train. In this I have taken the total amount of air exhausted and prorated it among the eight ventilators that were fitted with anemometers. This gives the average rate of operation for the car.

According to the diagram the amount of air exhausted varies directly with the speed, so that by dividing the average amount of air exhausted by the average speed of the train a quotient

will be obtained that may be called the base unit of the operation of one ventilator for the particular run under consideration. If we take the averages of all readings and plot them in accordance with the location of the car in the train we find that there is a slow falling away in total capacity as the car is moved back from the engine; until for the seventh car, it is about 14 per cent less than for the first.

The effect of ventilator location on the car is also noticeable. By taking the ventilators, fitted with anemometers in pairs, as they were opposite each other, and averaging each pair for the several trips, it appears that, going back from the front, there is a steady fall in efficiency from the first to the third, with a rise for the fourth.

This indicates that the ventilators at the forward end of the car are most efficient, and that there is a falling off in efficiency at the middle of the car and a rise again towards the rear.

MOVEMENT OF AIR CURRENTS WITHIN THE CAR

Careful observations were made of the movement of the air currents within the car. This was done by means of smoke produced at the points at which it was desired to make observations. The doors and windows of the car fitted closely in their frames. At the cracks of the doors there was never sufficient air movement to operate an anemometer, though a coolness could always be detected. Also in the body of the car below the seven-foot line above the floor, no air currents of sufficient intensity to operate an anemometer could be detected at any time. The anemometer explorations were, therefore, all made in the deck space.

When the car was running at 60 miles an hour, an anemometer placed at the back end of the deck opening, which was 5 ft. 6 in. from the end of the car, showed air velocities of from 180 to 575 ft. per minute when the opening was at the front end. One-quarter of the way across the deck and opposite the opening they were still higher, and when the anemometer was placed close to the ceiling, they ran from 735 to 976 ft. per minute. Out at the middle of the deck, still close to the roof, they fell to from 250 to 440 ft. per minute. As the exhaust was approached on the opposite side of the car, three-quarters of the way across, the velocities increased again to from 600 to 680 ft. per minute. Dropping down into the car they ranged from 700 to 835 ft. per minute, even as low as the deck sill, but no movement of the anemometer could be obtained below the line of the parcel rack. This will give an idea of the velocities at which the air entered the car.

Studies of smoke movement showed that, when produced in the deck, it did not come down into the body of the car, but swept along towards the nearest exhaust ventilator and was carried out. When produced below the line of the deck sill it was quickly dissipated, but slowly came down into the car and then took an upward movement towards the ventilators. When produced in the body of the car in the breathing zone, it started at once for the deck, was nearly dissipated when it reached the sash of the ventilators and was then carried out with great rapidity.

On the run from Albany to Weehawken and return, observations were made as to tunnel conditions and effect. It is the practice of the road to close all of the deck openings and, at times, all of the exhaust ventilators, when passing through tunnels, of which there are three of some length. These are known as the West Point, Haverstraw and Weehawken tunnels. There is a fourth and shorter one at Rondout creek, but the locomotive is out of this before the rear of the train has entered.

In the runs under consideration all deck openings and all of the exhaust ventilators to which anemometers were applied, were left open. Immediately upon entering the tunnels, large volumes of dense black smoke rolled in at the front deck openings. The smoke swept back along the roof of the deck and out at the exhausts. None of it came down into the body of the car and none of it was perceptible to the senses, even to those immediately beneath, when it was so dense overhead as to obscure the head lining. This was true not only of the experimental car, but also in the regular working coach occupied by passengers, whose ventilation was regulated to accord with that used in the experimental car itself.

The runs from Albany to Weehawken, on the West Shore, were made with the twofold object of obtaining data as to the action of the ventilators in tunnels and when running alongside a high bank with a free and clear space on the other side of the car. These conditions obtained on the West Shore, where, for long distances, the track is laid along the bank of the river with high, steep banks on the west and the open river on the east.

It was suggested that, under these conditions, it might be possible that eddy currents, created by the normal wind and the movement of the car close to the bank, might be of such a character as to cause the exhausts to act as intakes. Nothing of the kind could be detected. The ventilators invariably performed their true functions as exhausters of the air within the car, whether running in the open, through tunnels or close to a side bank.

BAROMETRIC PRESSURE INSIDE AND OUTSIDE THE CAR

Under all ordinary working conditions, there was no perceptible difference in the height of the water in the two legs of the U-tube. But, with all deck openings closed, and the 20 exhaust ventilators, with which the car was equipped, open, there was a rise of level on the car side of the U-tube of 1/16 in. when the car was running at a speed of 53 miles an hour, and the wind velocity over the roof was about 54¼ miles an hour, thus showing that, under these conditions, the ventilators were capable of producing a partial vacuum in the car.

AMOUNT OF AIR DELIVERED TO THE BREATHING ZONE

Attention has already been directed to the fact that the circulation of air through the car, under all conditions of service, was of too quiet and gentle a character to be measured or detected by the delicate anemometers used. That there was a circulation, constant and persistent, is shown by the observations of smoke movements. The means adopted to determine the efficacy and efficiency of this movement was that of taking samples of air from the breathing zone of working cars occupied by passengers. These samples were afterwards analyzed for their content of carbon dioxide.

The method is generally known as that of Pettenkofer and "consists in estimating the vitiation of the atmosphere by determinating the amount of carbon dioxide that it contains, and from this computing the amount of air supplied for ventilation."

For the purposes of calculation it was assumed that each passenger would excrete .6 cu. ft. of carbon dioxide per hour, and that the incoming fresh air was diluted with 4 parts in 10,000 of carbon dioxide. The calculation is, then, simply that of estimating the amount of such air that would have to be supplied, for the time and number of passengers concerned, to produce an atmosphere containing the amount of vitiation indicated by the analysis of the samples taken.

The method of collecting the samples was as follows: Two ordinary cautery bulbs were used for pumping the air into the receiving bottles. The admission valves of the two bulbs were held close together and at arm's length from the operator who squeezed them. Their delivery pipes led to the bottom of two clean 8-oz. white-glass bottles. The bulbs themselves had a capacity of about 4 oz. This method insured the delivery of the samples of air to the bottom of the bottle and the forcing of the previous contents out at the neck. In accordance with the practice and recommendations of the Bureau of Mines the bulbs were squeezed at least fifty times in the collection of each sample. The use of two bulbs delivering to two separate bottles was merely to secure two samples as nearly identical as possible for check analyses in case of doubt or accident.

The samples were collected by walking slowly along the aisle

of a working car. Immediately after the collection of the samples the necks of the bottles were closed by the insertion of soft rubber stoppers of the best quality obtainable, and, at the end of the run, these were in turn sealed by dipping in a melted mixture of beeswax and turpentine. Every possible effort was thus made to insure the samples being truly representative of the average condition of the air in the car at the time they were taken. They were all obtained from cars in regular service and the positions of the ventilator openings were recorded.

While the special car was in service, the working coach next to it in the train was used to obtain the air samples, and its ventilators were arranged in the same manner as those of the special car, the only difference between the two being the location of the two cars in the train and its effect on the operation of the ventilators. The effects of this have, necessarily, been neglected.

In a report to the Master Car Builders' Association, in 1908, a committee placed the amount of fresh air that should be supplied for the ventilation of a passenger car at 1,000 cu. ft. per passenger per hour. The results of these tests show that this amount was exceeded in every instance, and that this was accomplished without producing strong air currents or drafts in the breathing zone.

CONCLUSIONS

The conclusions to be drawn from this investigation are that:

One Standard exhaust ventilator will supply sufficient air to the breathing zone to meet the requirements of four passengers on the basis of 1,000 cu. ft. per passenger per hour. Its capacity varies directly as the speed of the train up to 60 miles an hour. The actual capacity in cubic feet per hour equals the speed of the train in miles per hour multiplied by 188. This actual capacity may be taken to be about 70 per cent of the theoretical rating.

The location of the car in the train has an effect on the efficiency of the exhaust ventilator. Speaking generally, the nearer the car to the engine the higher the efficiency. There is probably no mathematical ratio determinable for this.

The location of the ventilator on the car has an effect on its efficiency. The ventilators near the ends of the car have a higher capacity than those at the center, and those at the front have a greater capacity than those at the rear.

No perceptible drafts are created by the Standard exhaust ventilators below the tops of the windows. There is a gentle movement of the air down into the body of the car, and up to the deck in a complex system of currents, that cannot be differentiated.

Smoke or noxious vapors entering the car at the deck openings do not come down into the body of the car, but are drawn out through the exhaust ventilators.

High banks, cuts or tunnels have no effect on the action of the Standard ventilator.

It is not necessary to close the ventilators when passing through tunnels.

The heating of the car near the floor is successfully accomplished.

Women Operate German Railways.—A report received in Paris from Basle says that all the employees on the Berlin Underground Railway are now women. Women are also employed on suburban lines, where they are to be seen cleaning the cars, and even working with the picks and shovels.

Motive Power of the South African Railways.—The total number of locomotives in use on the Union of South Africa Railways at the end of 1913 was 1,458, of which 1,428 were of the standard 3 ft. 6 in. gage and the remainder of 2 ft. gage. The average tractive effort of 75 per cent was 21,626 lb., and the number of locomotives of a tractive effort of over 30,000 lb. was 216. Many of the engines on the books are of an obsolete type, and are gradually being withdrawn from service.

RAILROAD ADVERTISING*

By Edward Hungerford
Advertising Manager, Wells, Fargo & Co.

Advertising was born—50 or more years ago—as a mere incident of the work of the general ticket agent. When that brisk officer rose a bit above the mere details of ticket selling and became general passenger agent, he still carried advertising with him as one of the smaller details of his work—a work to be actually executed by some underpaid office boy or clerk and executed after the fashion of nearly all underpaid work.

The only advertising on the part of the railroads at that time was for passenger traffic. It was rough stuff, bombastic, not logical, not even seeking to be logical. For as far as straight-from-the-shoulder advertising for traffic, or even for a public understanding of their problems was concerned—there was no such thing for the railroads. The railroads advertised "Shortest Route," "Best Route," "Most Popular Route," and, though people went and in many cases found that they were not the shortest, the best or the most popular route, what mattered it? The newspapers had been thrown a little money, and for a little time they would be quiet in their criticisms. And there were some railroads which boasted that they did not have to advertise in the newspapers or the magazines at all. One line said that its advertising appropriations went into the gay stripings of its cars and locomotives—and was quite wrong. Another put its advertising money into its service and was quite largely right—of which more in a moment. Those who put their appropriations into white paper and black ink rarely did it right. A real advertising manager around a railroad office would have been treated as a rarely humorous appendage.

Such conditions could not last, of course. The railroads themselves were the first to discover that their advertising policies were wrong. The discovery came a long time before the finding of the remedy.

It was not so very long after the close of the Civil War that the railroad lines began to multiply in the unpeopled Southwest and the Northwest. Of the possibilities of those rich and undeveloped territories no one with imagination or intelligence might doubt. All they needed for their development—and the enrichment of the railroads that had been built to serve them—was population. In the absence of any other intelligent or organized immigration force the railroads took up the work themselves.

Then it was that advertising came into its first real respect in the railroad offices of the land. It took advertising in the seventies and the eighties, even into the nineties and up to today, to build the fat farms and the fine towns, the budding cities that one sees from the car window as today he crosses Minnesota, the Dakotas, Montana, Oklahoma and West Texas. That advertising was often poor—as our advertising standards of today go—but it was thorough and generous. The results that followed it were astonishing. The response was immediate. The railroads saw that response and invested more advertising funds. The response was increased proportionately. There are counties, metropolitan cities—with trolley systems and country clubs and taxicabs and tango palaces—whole developed states in our land that are young enough to say, and say with truth, that they were builded upon the policy of American advertising.

This has also been the history of the development of western Canada by the advertising of your own railroads. Only you have had two benefits which were denied to the railroads of the United States a generation or so before. You have had the benefit of experience and you have advertised in a day when advertising has begun to come into its own.

One might expect that any profession—you may call it a policy if that suits you better—that had accomplished so much for the railroads would today have a larger recognition than has yet been given it. You might fairly expect that the man who headed

*From a paper presented before the Canadian Railway Club at Montreal, Can., on March 9, 1915.

t upon any great system would be a member of the intimate councils that govern it. Yet, unfortunately, the reverse is the more apt to be true. And no matter how advertising on the railroad has progressed, I think that I am fair in saying that the advertising manager on the railroad has not been permitted to make a similar progress. His position and his progress are hardly to be compared with those of his brethren who occupy similar posts in the staff of great manufacturing and merchandising enterprises. Those men are given every opportunity to perfect and to strengthen themselves, are recognized as the right hand members of the organization. They are "managers" in the full sense of the word. No one dares to doubt their final decision in matters affecting their branch of the conduct of the business. Neither does a railroad executive doubt the decision of the man who is handling the law business of his system—he does not even assume to criticize the contracts which this man may draw up. He does not change the structural plans for bridges or the detailed profile for a projected line across new country.

Does he do as much for the advertising manager?

You know yourselves that the times are far too few when he ever sees an advertising manager. The smart executive has many thoughts and many suggestions on advertising. Most quick-witted and alert men have—and most of their thoughts and suggestions are very good indeed. He may have, and probably does have, more than a little pride in the advertising of his road. But, in many cases, he probably has little more than a head-nodding acquaintance with the advertising manager of his line. That poor soul is "down" in the organization. He works "up" to the president through two or three intermediate executives who may or may not have any intimate knowledge or liking for advertising and who almost certainly will have widely divergent ideas as to its practical application. Frequently he has the exquisite torture of seeing his best publicity ideas so twisted and so changed before they receive the final stamp of approval from the "big chief" and go out into the world to attempt their missions, that he would not know himself these children of his own brain.

Now here is a condition not absolutely prevalent upon the North American continent, but unquestionably dominating far too many of our railroads and preventing them from gaining the fullest advantages from advertising and publicity of every sort. Before we consider the remedy let us give attention to one or two possible causes for this condition. A railroad executive, big-hearted and shrewd-headed, offers what he thinks is a good reason:

"The reason we are willing to defer to the general counsel and do not often assume to criticize him in because we realize that he is a trained man. The points he makes are the result of his specialized education and his experience. Our advertising agent is a very different sort. His book education ceased before he was done in the high school. He has come up with us in the railroad—all the way from office boy. Can you expect us to defer to his judgment or to accept it as something infallible?"

This begins to look as if we had a very definite cause formulating itself. Without losing sight of this point let us turn around and see it from the other angle—from that of the man who is handling the advertising for that very road. He is equally frank.

"Perhaps the old man is right," he admits. "I am willing to admit that one of the main troubles in advertising the railroad is in its advertising man himself. As a rule he has not been selected because of experience or ability—a good many times he has been secretary to some 'big wig' in the traffic department and the advertising job is given him because it was necessary to proffer some slight promotion to a man who has been faithful in the company's service. And eventually he will quit the advertising job. He will be too big for it—the truth is that it will be too big for him—and so he will go and another will come—leaving the whole job to be done over once again.

"The truth of the matter is that a big railroad is just like a big manufacturing concern; its operating end is the manufacturing department, while its traffic end corresponds with the sales department of a factory. One of the weaknesses of the railroad situation today is that some of its leading figures claim that the business is different from any other. There may be minor differences, but in my opinion there is a strong similarity between railroading and manufacturing.

"Yet because of this very feeling that railroading is fundamentally different from other businesses, its advertising is too frequently permitted to also become different. It is not looked upon by these men as a force that may be brought to create traffic—and this despite some of the things that I have told you already tonight—'but as merely a cut and dried, or hit and miss method of making announcements as to train service, excursion rates and the like.'

"Merchandising, like advertising, is a specialized business and requires specialized training and education. And is it to be wondered that a man who has had no special training toward the diplomatic handling of the public has little or no appreciation of the real place of advertising in the progressive business organization? And those having in charge the traffic department of a railroad should be—first of all—good sales managers. Rate clerks can be hired just as easily as an advertising manager can hire a copy writer."

Here then is the case as put by one actual advertising man. And whether we subscribe to it in full or not I think that we all can agree that he has struck at both the cause and the result in far too many railroad advertising departments today. And I do not think, myself, that there is any great problem involved in finding the solution—particularly not when we keep steadily in mind all the while what advertising has done for the railroad, how it has made trains like the International Limited, the Imperial and the Twentieth Century household words, how it has upbuilded whole townships, and counties, and states, and provinces, and so in turn upbuilded the welfare of the railroad.

Just as the legal department of the railroad is its defensive wing, so should the advertising department be its offensive. The advertising manager should sit alongside the general manager and the traffic manager, the counsel and the controller. He should be freed from the detail and left to plan the publicity of the railroad, in its every phase. It should not be alone his work to write time-tables or scurry immigrants out to new localities, to see reporters or to attempt to steal fast freights from his nearest competitor. His work should combine these things and then reach to a far higher plane, the meeting and gauging and shaping of public sentiment of which more in a moment.

The advertising manager of the railroad should be trained—he should train himself if you please—as carefully as that general counsel has trained himself. He should not himself expect to be bidden to sit at the family table without being made ready for the feast. There are plenty of educational forces that stand ready to help him make himself a better man not only for the railroad for which he works, but for the satisfaction of his own peace of mind as well. He should be not only a student of advertising and the things that pertain to advertising, but he should also be a student of changing conditions; he should be what we sometimes call a publicist.

For no matter how intelligently and successfully our railroads may have advertised for immigrants and for passenger traffic of every sort and condition I do not believe that they yet have used paper and ink to the greatest advantage to fight the most of their battles for public sentiment, in repelling the attacks of unjust legislators and commissions. They have rarely used these implements with greatest intelligence. As a rule, if they have advertised for public sentiment through newspaper advertisements, it has been an eleventh-hour measure adopted in a great crisis.

The railroads of the state of New York—splendid advertisers

for passenger traffic each one of them—united in such an eleventh-hour appeal throughout the newspapers of the state against the so-called full-crew bill, which was then before the governor of the state—a bill which would add more than $2,000,000 to their costs of operation. The "ad." was generous in proportions, but the governor laughed at it and signed the bill. He was a shrewd enough molder of public opinion to know that the railroads had thrown away their money.

On the other hand, what a different result might have been written if the railroads steadily and persistently, whether under legislative fire or in times of seeming calm, had told their story quietly and interestingly through the newspapers of the state. It would not have cost them anything like $2,000,000 a year to have brought an intelligent public sentiment to their aid. What it would have cost would have been the expenditure of thought and careful planning by one man in authority—a man trained for just such an emergency as this, plus a most moderate cash outlay for newspaper space, would have produced a campaign that quickly would have ended the "full-crew" menace in New York. In fact, this very sort of a campaign has just been waged by the railroads of Missouri against the "full-crew bill," which had also come into being in that state. Despite the fact that the bill had passed and had become operative as a law a shrewd and deliberate advertising campaign, conducted at a most reasonable cost to the railroad, succeeded in repealing it by popular vote at an election called for that purpose. And it is gratifying to see that the railroads of the United States working toward the repeal of the full-crew bills in some other states, as well as a general increase in their passenger rates are not relying upon the charity or the good nature of the newspapers for free space for the presentment of their case, but are paying for regular advertising for the shrewd, deliberate, forceful statement of their very good arguments. Three days ago the various roads operating in New Jersey, the Central of New Jersey, the Lackawanna, the Pennsylvania, the Lehigh Valley and the Erie, began a campaign in the newspapers, looking to the repeal of the full-crew bill. A similar newspaper campaign is to be carried on in New York. If the campaign in New Jersey is successful, and also against an impending measure to restrict the length of freight trains. The railroads responded to the full-crew bill by running longer freight trains. The labor unions in their turn provided a bill limiting the trains to half a mile in length. The roads are going to fight this. Personally, I am deeply interested in this matter, and I feel that if, instead of waiting for this to take place, they had had an executive, or semi-executive officer; such as the general counsel, the general manager or the chief engineer, a man, who, week in and week out, and month in and month out, had adequately told their story, and shown what it meant to the community in a straightforward and forceful manner, they would be more successful.

Perhaps they have studied the splendid results obtained by a policy of advertising of the telephone companies, a splendid example of the use of advertising of the highest type by a public utility. Perhaps they have read the printed record of the individual campaign waged by the trolley company of Toledo, or those of various traction and lighting utilities which have handled such problems and handled them intelligently.

But they could not have been handled intelligently, or successfully, by some man buried at an inferior desk of a department. They must have been handled by men who were executives, with executive work and executive opportunity—men who were paid and well paid too, to plan in the large ways that the railroad must approach not only its individual patrons, but the entire public upon the printed page. Success of this sort rarely comes in large measure except to men and institutions who go out to meet her in a large way.

To make a brief résumé—we have seen the railroads advertising for emigration, and the advertising responding magnificently to that test. The roads have used advertising also for creating passenger traffic, and I am not so sure but that they might also use it to create freight traffic, but that is open to discussion and to question. But we have not yet seen the railroads taking hold of these great questions of public policy and grasping them with the strength that some other businesses have shown. I imagine this is due to one thing, this very thing I have talked of this evening—that the advertising manager of the railroad has not compelled himself to be recognized by an executive of the railroad organization.

FEDERAL VALUATION PROGRAM

Thomas W. Hulme, general secretary of the Presidents' Conference Committee on Valuation, has issued a circular announcing that the plans of the Interstate Commerce Commission contemplate that valuation work will be commenced on the following lines between July 1, 1915, and June 30, 1917. This program is liable to change and is herein stated for the general information of all interested. Each carrier may expect to receive at least three months and possibly six months' official notice from the director of valuation of the government's intention to commence work on its line.

Eastern District

July 1, 1915, to July 1, 1916

Boston & Maine (complete the work); Boston & Albany; New Haven System, 1,000 miles; Pennsylvania Railroad, 1,500 miles; Central of New Jersey; Pittsburgh & Lake Erie; Bessemer & Lake Erie; Richmond, Fredericksburg & Potomac; Canadian Pacific (in Vermont and Maine); Central Vermont; Grand Trunk (Sherbrooke, Que., to Portland, Me.); Virginian.

July 1, 1916, to July 1, 1917

New Haven System (uncompleted balance); Pennsylvania Railroad; Bangor & Aroostook; Maine Central; Philadelphia & Reading; Buffalo, Rochester & Pittsburgh; Delaware & Hudson; Rutland; Ulster & Delaware; New York, Ontario & Western; Long Island.

Southern District

July 1, 1915, to July 1, 1916

Central of Georgia; Mobile & Ohio; Southern (Eastern half of System); Cleveland, Cincinnati, Chicago & St. Louis; Georgia; Charleston & Western Carolina; Chicago, Indianapolis & Louisville; Nashville, Chattanooga & St. Louis; Pennsylvania Lines West.

July 1, 1916, to July 1, 1917

Southern; Florida East Coast; Pennsylvania Lines West; Atlantic Coast Line.

Central District

July 1, 1915, Ann Arbor; August 1, 1915, Toledo, St. Louis & Western; August 1, 1915, Chicago, Terre Haute & Southeastern; October 15, 1915, Chicago, Milwaukee & Gary; December, 1915, New Orleans Great Northern; December, 1915, Gulf & Ship Island; December, 1915, Texas & Pacific; March, 1916, Minneapolis & St. Louis; April, 1916, Chicago Great Western; May, 1916, Green Bay & Western; July 1, 1916, Duluth, South Shore & Atlantic; November 1, 1916, Texas & Pacific; December, 1916, Louisiana & Arkansas; December, 1916, New Orleans & Northeastern; December, 1916, Louisiana Railway & Navigation Company; April 1917, Michigan Central; April, 1917, Chicago & North Western.

Western District

July 1, 1915, Santa Fe Lines East; October 1, 1916, Missouri Pacific System; October 1, 1916, Texas & Pacific.

Pacific District

July 1, 1915, to July 1, 1916

Great Northern, 3,300 miles; Chicago, Milwaukee & St. Paul (West of Mobridge, S. D.), 1,600 miles; Gallatin Valley; Idaho & Washington Northern; Spokane & British Columbia; Wenatchee Valley & Northern; White Sulphur Springs & Yellowstone Park; Atchison, Topeka & Santa Fe (Coast Lines, California), 1,200 miles; Southern Pacific—Pacific System (New Mexico, Arizona and California), 1,500 miles; Arizona Eastern; Ray & Gila Valley; San Diego & Arizona; San Diego & South Eastern; Twin Buttes; Holton Inter-Urban; Tonopah & Tidewater; Las Vegas & Tonopah; Bullfrog Goldfield; Tonopah & Goldfield.

July 1, 1916, to July 1, 1917

Great Northern (Western District to complete), 2,100 miles, (Pacific District to complete), 500 miles; Chicago, Milwaukee & St. Paul (Pacific District to complete), 350 miles; Spokane, Portland & Seattle; Oregon-Washington Railroad & Navigation Company; El Paso & Southwestern System; Arizona & New Mexico; Atchison, Topeka & Santa Fe (Lines in New Mexico), 1,300 miles; Southern Pacific (Pacific System), 1,000 miles; Miscellaneous Short Lines.

Annual Convention of the Air Brake Association

Moisture in Compressed Air Apparatus and Yard Plants; Operative Freight Brakes; Pneumatic Signals

The twenty-second annual convention of the Air Brake Association was held in Chicago, May 4 to 7, as noted in the *Railway Age Gazette* for May 7, page 983. A report of the convention follows:

PRESIDENT'S ADDRESS

President Albers called attention to the lack of standardization of brake equipment for passenger cars, and suggested that a committee, composed of air brake men from both the Air Brake Association and the Master Car Builders' Association, could by careful study do much to relieve this situation. The L. N. equipment which replaced the old P. M. equipment on the heavier cars, has not given entirely satisfactory results, trouble being experienced with slid-flat wheels, hot wheels and burned brake heads, caused by "stuck brakes." On the New York Central lines it has been found necessary to operate this equipment with its graduated release feature eliminated, which made it necessary to lose two of the features for which this valve was designed, namely, quick recharge and high emergency brake cylinder pressure. The double P. M. and L. N. brake equipment have also caused trouble from "stuck brakes." The new P. C. equipment provided a temporary relief from the troubles experienced with the original valves, but Mr. Albers stated, the complexity of this equipment rendered it difficult to locate immediately and definitely defects which arose in train service. His suggestion was to have a committee work towards a simple standard valve which would be capable of being applied to all but the lighter classes of cars.

Mr. Albers also called attention to the necessity of economy in the maintenance of air brake equipment, with full consideration for safety. On the New York Central, east of Buffalo, tests have been in progress for a period of 18 months, on 18 dining cars, and to this date 16 cars are still in actual service, with an aggregate mileage of 2,321,136 miles, without once having received any attention or lubrication, except that originally applied. None of these cars have given any detention on account of the air brake equipment, nor has any valve been removed except for tests. If the cleaning period, instead of being three months as at present, was extended to four months, the annual saving to a road having 1,000 P. C. equipment cars would amount to approximately $1,640, and if the period was extended to six months the saving would be approximately $3,280. With the P. M. or L. N. type of equipment this saving would be $420 and $840, respectively.

100 PER CENT OPERATIVE BRAKES IN FREIGHT SERVICE

The committee report on this subject was presented by G. H. Wood, Atchison, Topeka & Santa Fe. An abstract of this report follows:

The general opinion is that an operative brake is one in which the piston moves out of the brake cylinder far enough to close the leakage groove, and not more than 10 in. when a full service brake application is made from at least a 70-lb. brake pipe pressure, and remains so until the usual inspection is made, and releases properly in the usual methods resorted to in making ordinary terminal tests; the only other requirement is that the foundation brake gear be connected throughout to bring the shoes to the wheels. The second consideration is the question of what constitutes 100 per cent operative brakes. Our opinion in this respect contemplates each brake in a train be operative as above stated and so connected that they may all be operated from the locomotive. This will constitute 100 per cent operative and meet all the requirements but one, namely, efficiency. The highest efficiency required to meet general conditions is that the train may be controlled by the engineer without the assistance of trainmen with the ordinary hand brake.

Unfortunately, while the requirements of efficiency reduce the difficulty of providing an operative brake, they also result in ability to control trains with a low individual brake efficiency throughout the train or a small percentage of brakes operative for service requirements, while certain other conditions automatically increase the necessary efficiency and number of operative brakes, and the greater the number of cars involved, the more pronounced are these results.

At many terminals we have no provision to charge trains and make inspection in the train yard until the engine is placed on the train. The introduction of the yard pressure lines where the train is made up sufficiently in advance of leaving time, would give an opportunity to make the brake inspection and correct many defects before the engine was placed on the train for departure.

Any one point on a large system attempting to run 100 per cent operative brakes would be immediately confronted with a prohibitive number of cars with inoperative brakes and a congestion that would cause serious delays resulting in this particular point being criticised for tying up traffic. Relief for this particular terminal could only be brought about by allowing inoperative brakes to proceed, or by increasing the amount of the brake work done at the terminals on either side. It can readily be seen that any one railroad attempting to run 100 per cent operative brakes would be placed in almost the same position as the terminal above mentioned, and the same rule in regard to relief would apply between the railroads involved.

The difficulty of establishing the practice of cleaning brakes on cars in trains at large terminals where the tracks extend over a large territory is expensive, as it is hard to get men and material to the cars and men are idle a large part of their time. But again we find that at many small terminals where very little switching is done on the train outside of changing engines and cabooses and where the repair track is close to the train yard, that air brake repairs can be made in trains successfully and economically, as the men in this case can be used on the repair tracks when no trains are in the yard. Yard air lines at these terminals are necessary to test out work of this kind and additional time allowed to trains in terminals to give the car men an opportunity to do the work before, or after, the train is switched. Yard train testing devices must also be provided at terminals in order that cars arriving in trains with brakes "cut out" may be tested to ascertain what, if anything, is wrong, and to test work on the brakes after it is completed.

After the facilities and materials are provided, then comes the proposition of procuring men who are competent and reliable to do the work or men who can be educated in a reasonable length of time. The better supervision we have, the less trouble we have from this source. One of the conditions we find it hard to overcome is the careless manner in which some of the air brake work is done.

We also find trainmen cutting out the brakes that do not release as soon as the others in the train, not waiting until the brake pipe pressure has been raised high enough to release the brakes having the best packing leathers. We find men who have a hobby of keeping the caboose brake cut out, being afraid of sliding the wheels, and others who will cut out cars and bleed them in order to make a switch quickly at some other point. We find enginemen who will cut out tender brakes because the triple does not release promptly or because they are afraid of the hangers breaking, and others who will insist on having the piston travel let out beyond the limit on cars, claiming that the brakes drag—this particularly with small engines. Cars are found with the brake "cut out," and on testing out nothing is found wrong, except that the retainer is turned up, and others with nothing but

a leak at the triple valve union, requiring only a turn of a wrench to stop it. All of these things work against the percentage of operative brakes and are irregularities against which a crusade would have to be waged on every division of every railroad concerned. Some form of defect card must be adopted to be applied by the man cutting a brake out on the road, showing who cut it out and for what reason.

A system must be inaugurated to catch the disabled brakes as soon as practicable after the defect becomes apparent. With this in view, what might be called "dead lines" should be designated at reasonable distances over the road—terminals where facilities are the best, as 100 per cent points where no brakes that are inoperative are allowed to pass, regardless of lading. At all terminals where there are facilities, dead freight loads and empty cars with inoperative brakes should be caught and repaired. All cars on repair tracks should have their brakes carefully tested, and if the cleaning date is over nine months old on home cars, the brakes should be cleaned. This would avoid the necessity of putting the car on the repair track again in so short a time, and when it might possibly contain an important load.

If we wait until the trains are made up in the yard to make inspections we will have delays and bad cars, but if we require the men on all incoming trains to have the train fully charged and then make the required application of brakes before cutting off, the air brake inspection can be made at the time of usual train inspection, and any cars "bad ordered" can be switched out in the usual switching time.

The question arises as to what is to be gained by increasing the number of operative brakes. One reason is to provide a wider margin of safety by the ability to stop in a shorter distance in cases of emergency. The reason more frequently encountered, however, is the resultant reduction of slack action in long trains, which contributes largely to troubles arising from break-in-twos.

Discussion.—F. B. Farmer, of the Westinghouse Air Brake Company, strongly recommended the employment of general car brake inspectors, whose duty it would be to instruct and demonstrate to the cleaners of the freight car air brake equipment how they should do their work, and to check them in their work, thus relieving the car foremen, who in very many instances are not sufficiently familiar with air brake work. He spoke strongly in favor of the incoming tests of the car brakes. This will eliminate a lot of trouble and delay that would otherwise be caused when the brakes are found defective on the outgoing tests. He called attention to the tendency for some of the comparatively level roads to absolutely neglect the maintenance of the retaining valves. This causes a great deal of trouble for roads operating in the mountainous districts, and greatly interferes with the expeditious transportation. In speaking of the "dead line," as described in the report, he stated that at one point on a large road that operated this dead line system, 75 per cent of the brakes cleaned had not run over nine months, showing that this work is not always done as carefully as it should be. Lack of knowledge and hurried work have been a great factor in the improper maintenance of brakes, and many times are the basis for charges of dishonesty in doing the work.

Some roads are having good success with "carding" freight cars with inoperative brakes, permitting them to go to the next terminal. The train men have also been instructed to place "defect cards" on the cars as they become inoperative on the line, and also on those cars that are picked up en route. Considerable educating has to be done to get the men to do this, and only by the assistance of the transportation officials can it be satisfactorily accomplished.

Walter V. Turner, chief engineer of the Westinghouse Air Brake Company, encouraged the members to do all in their power to influence their superiors to give them the proper facilities for keeping the brakes in good condition. Absolute persistence and nerve in carrying out what they believe to be absolutely necessary in the maintenance of brakes is required to get the right results.

ELIMINATION OF MOISTURE FROM YARD TESTING PLANTS

Mark Purcell, Northern Pacific, chairman of the committee on this subject, presented a description of the air cooling plant of the New York Central at the Mott Haven yards in New York City. This plant was installed for the purpose of eliminating the moisture from the compressed air before it was distributed throughout the yards and thus prevent freezing of the air lines, and insure dry air being supplied to the equipment in the yards. The compressors feeding these yards have a capacity of 2,500 cu. ft. of free air per minute. The cooling plant was built on the basis of 3.2 running feet of ¾-in. pipe per cubic foot of free air consumed by the compressor. It is divided into 48 sections, each section having two headers, and 18 pieces of the ¾-in. extra heavy galvanized pipe about 112 in. long. The upper headers are 6 in. in diameter and the lower ones 8 in. in diameter, both being made of extra heavy wrought iron. The 48 sections are arranged in two groups of 24 each, and are so arranged that all the piping is accessible, and sufficient space is provided for the circulation of the atmosphere around the cooling pipes. The air is first received from the compressor into two large storage reservoirs, 4½ ft. in diameter by 11 ft. high. The plant is so arranged that the air may be delivered direct from these reservoirs to the yard or direct through the cooling plant. A roof has been erected over the plant to protect it from the snow in winter and the hot sun in the summer. The plant gives satisfactory service, and from numerous tests made throughout the yard it has been ascertained that it will deliver dry air under all conditions.

Discussion.—Those roads that have not such an elaborate cooling system have found that very good results can be obtained by placing drain reservoirs in the yard piping to catch the moisture as it becomes condensed in the pipes, these reservoirs to be drained twice a day. It was also pointed out that the compressor should have its intake located outside the building where it could obtain as cold air as possible.

The discussion also developed into the consideration of the accumulation of moisture in the air on the locomotive. Briefly summarized, it was believed that sufficient radiating surface should be provided between the compressor and the brake valve, and where possible two main reservoirs were recommended, one of which to be used as a drain for the air system. On large Mallet locomotives it was found expedient to use three main reservoirs. It was also shown that where the compressor or the storage capacity was not great enough to provide the necessary air for operating the train, and where such air was, of necessity, taken directly from the pump without having time to cool, considerable trouble was experienced with moisture in the train line. It was also pointed out that very good results could be obtained by leaving all drain cocks open on the engine and tender during the time the engine is in the roundhouse. In some cases the centrifugal dirt collectors have been found to be of advantage as drains for the train line.

OPERATION OF THE PNEUMATIC SIGNAL DEVICE

The committee report on this subject was presented by L. N. Armstrong, Pennsylvania Railroad, who said in part: Possibly the largest factor in the correct operation of the signal device is maintenance. This is particularly true of the amount of leakage allowed in the signal line. Excessive leakage will destroy the confidence of the crew in the signal system. In order to get the best results the location of the pipe and hose should be as recommended by the M. C. B. Association. In endeavoring to improve the operation of the pneumatic signal system it is necessary to first ascertain the conditions under which the signal is operated. Tests should be made with a recording gage attached to the signal line on the rear car of a train by which can be determined the pressure carried in the signal line, all reductions in this pressure, whether made by pulling the cord or by the hose coupling leaking when passing over crossovers, switches, etc.; and the time required to recharge the line after reductions have been made. It has been found necessary for the train men to make the reductions at the car discharge valve of not less than one second

duration, and pause between the reductions from two to three seconds, or approximately three times as long as the time of reduction. On the longer trains it is necessary to increase this time interval between the blasts. It is believed that the electro-pneumatic signal, which does not have the limitations of the present pneumatic signal, will eventually be adopted. A steam train thus equipped has been in regular service during the past year, covering 180 miles a day with good results.

The construction of the signal valve is such that very careful workmanship is required in order to have the correct clearance between the valve stem and its bushings. The manufacturers have investigated the permissible leakage for signal valves with various sized orifices venting to the atmosphere. Valves which have passed the standard tests using no orifice, passed also when the leakage was six pounds per minute. The results of these tests show that in order to affect the signal valve operation at all, leakage must be excessive and above the amount which should be permitted in service. The committee report also included the method of testing signal valves as used by the Central Railroad of New Jersey at the Elizabethport shops.

Discussion.—The consensus of opinion as to the pneumatic signal was that in its present state it is not an absolutely reliable device. On long trains considerable trouble is experienced with leakage. Where trains are over 18 or 20 cars long, it was believed expedient to increase the signal train line pressure to 60 lb., and on such trains in giving signals from the last car the valve should be held open longer and greater intervals should be allowed between the blasts than on short trains. It was believed that the electro-pneumatic signal system would be of much more value and would give the necessary reliability that should be required in a signal system between the locomotive and cars. Greater care should also be taken in the proper maintenance of the present pneumatic system. Mr. Armstrong, in closing his paper, stated that electric energy sufficient to operate an electro-pneumatic system could be obtained from dry cells or from the electric lighting system on the cars or locomotive.

OTHER BUSINESS

A committee report was also presented on hand brakes for heavy passenger cars in which the need for more efficient hand brakes for heavy passenger equipment cars was shown. This is not to enable the train crew to stop a train at high speed, but rather to enable the switching crew to properly control the cars in yard movement. The present equipment is only good for holding the cars after they have once been stopped. The subject was continued to report at the next convention.

The customary report on Recommended Practices was also presented.

During the convention an afternoon was given to the air brake appliance supply men, who talked to the members concerning their products. On Thursday afternoon the association was addressed by Walter V. Turner, of the Westinghouse Air Brake Company; N. A. Campbell, of the New York Air Brake Company, and J. R. Snyder, of the Pittsburgh Air Brake Company. Mr. Turner spoke of the developments during the past year, and told how the New York subway had increased its capacity by the adoption of the electro-pneumatic brake. Mr. Campbell gave an illustrated talk on the New York electro-pneumatic air brake. Mr. Snyder gave an illustrated talk on the new air brake equipment furnished by his company, laying particular stress on the "No-kicker" attachment.

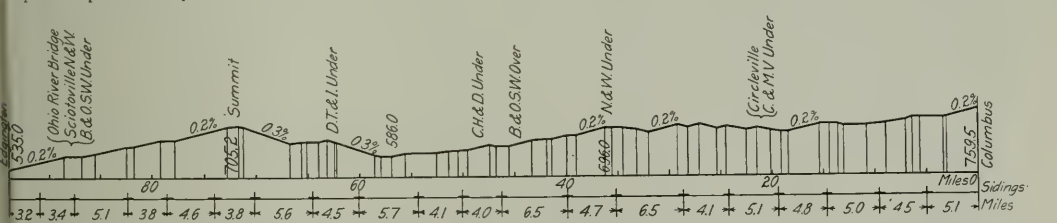
The association was also addressed by E. H. De Groot, Jr., superintendent of transportation, Chicago & Eastern Illinois, and M. H. Haig, mechanical engineer, Atchison, Topeka & Santa Fe.

The following officers were elected for the ensuing year: President, J. T. Slattery, Denver & Rio Grande; first vice-president, T. W. Dow, Erie Railroad; second vice-president, C. H. Weaver, New York Central lines west of Buffalo; third vice-president, C. W. Martin, Pennsylvania Railroad; secretary, F. M. Nellis, Westinghouse Air Brake Company; treasurer, Otto Best, Nathan Manufacturing Company. The executive committee is as follows: T. F. Lyons, New York Central lines west of Buffalo; J. F Barry, New York, Ontario & Western; L. P. Stretter, Illinois Central; Mark Purcell, Northern Pacific; G. H. Wood, Atchison, Topeka & Santa Fe.

It was voted to hold the next annual convention at Atlanta, Ga., on May 2 to 5, inclusive.

NEW LINE OF THE CHESAPEAKE & OHIO NORTHERN

Contracts have been let for the grading and masonry work on 29.8 miles of the Chesapeake & Ohio Northern from Edgington, Ky., to a point near Waverly, Ohio, as mentioned from time to time in our news columns, and the contractors are now moving in and installing their equipment. This company, as a subsidiary of the Chesapeake & Ohio Lines, was organized to build a road from Columbus, Ohio, to Edgington to connect the Hocking Valley with the main line of the Chesapeake & Ohio, but the difficulty of securing funds at a reasonable rate of interest at the present time has made it inadvisable to undertake the construction of the entire mileage for the present. It is planned to connect with the Norfolk & Western near Waverly temporarily and to secure trackage rights over that company's lines into Columbus.



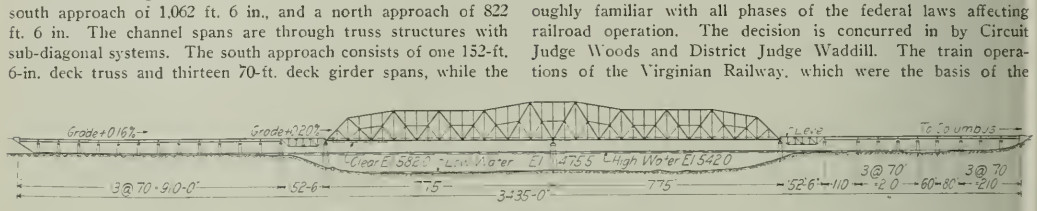
Condensed Profile of the Chesapeake & Ohio Northern, Showing the Entire Line Between Edgington, Ky., and Columbus, Ohio

Starting at Edgington on the south bank of the Ohio river, the new line will swing to the north crossing the river just east of Sciotoville, Ohio, also crossing the Norfolk & Western and the Baltimore & Ohio Southwestern near this point. The temporary connection with the Norfolk & Western is made just south of Waverly on the east bank of the Scioto river, this stream being crossed by the existing line at Waverly and again at Chillicothe. The proposed route then follows the eastern bank of the river for the entire distance to its connection with the Hocking Valley just south of Columbus. It will cross the Detroit, Toledo & Ironton near Waverly, the Cincinnati, Hamilton & Dayton, the Baltimore & Ohio Southwestern, and the Norfolk & Western near Chillicothe, and the Cincinnati & Muskingum Valley at Circleville, the grades at all of these crossings being separated. The maximum grade will be 0.2 per cent compensated northbound and 0.3 per cent southbound.

The construction of the first section of the new line will require the excavation of approximately 3,000,000 cu. yd. of earth and 500,000 cu. yd. of rock, or an average of 120,000 cu. yd. per mile. About 52,000 cu. yd. of concrete, 500,000 lb. of reinforcing

steel, 40,000,000 lin. ft. of timber piling, 700 tons of cast iron pipe and 2,000 tons of structural steel will be required The line will be laid with 90-lb rail and creosoted ties on crushed limestone ballast

The bridge over the Ohio river is the most important piece of work on the line, the substructure of this bridge being now about one-half completed. The structure has a total length of 3,435 ft., consisting of two main channel spans of 775 ft. each, a south approach of 1,062 ft. 6 in., and a north approach of 822 ft. 6 in. The channel spans are through truss structures with sub-diagonal systems. The south approach consists of one 152-ft. 6-in. deck truss and thirteen 70-ft. deck girder spans, while the



Elevation of the New Ohio River Bridge of the Chesapeake & Ohio Northern, Near Sciotoville, Ohio

north approach includes a 152-ft. 6-in. deck truss span and deck girder spans of various lengths from 60 ft. to 110 ft. A clearance of 40 ft. above high water is provided, the variation between low and high water at this point being about 66½ ft. The substructure of the bridge consists of concrete piers and abutments. The alinement is on a tangent across the river and the north approach, with a 1 deg. 15 min. curve on the south approach.

The next most important structure on the line is the crossing of the Little Scioto river about two miles north of Sciotoville. This structure has a total length of 1,080 ft., and consists of eight steel towers and one rocker bent supporting 40-ft. tower girders and 80-ft. intermediate girders. The maximum height at the stream is about 100 ft. In addition to this there will be numerous plain and reinforced concrete arch and box culverts and highway structures of various designs. The small drainage openings will be cast iron pipe with concrete headwalls.

The grading and masonry contracts were awarded to W. W. Boxley & Co., Roanoke, Va., the Rinehart & Dennis Company, Charlotteville, Va., Winston & Company, Richmond, Va., and Robert Grace Contracting Company, Pittsburgh, Pa. The substructure of the Ohio river bridge is being built by the Dravo Contracting Company, Pittsburgh, Pa., and the superstructure is contracted to the McClintick-Marshall Company, Pittsburgh, Pa. This line is being built under the direction of M. J. Caples, vice-president, and William Michel, chief engineer. The Ohio river bridge is being built under the supervision of Gustav Lindenthal, consulting engineer, New York City.

Pullman Service on English Railway Withdrawn.—With a view to economizing coal, all the Pullman cars running on the London, Brighton & South Coast, except those on the "Southern Belle," were recently withdrawn.

HAND BRAKES OUTLAWED

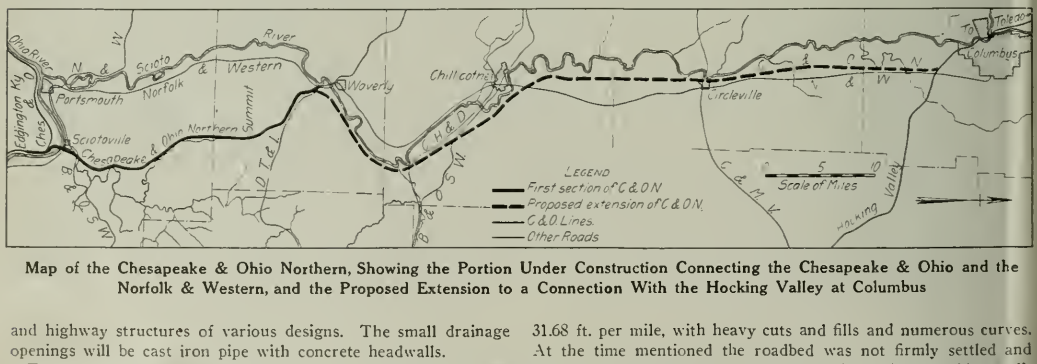
The decision of the United States Circuit Court of Appeals, Fourth Circuit, at Richmond, Va., May 4, briefly reported in our last issue, page 981, holding that the use of hand brakes to control the speed of trains in ordinary service is illegal, was written by Judge Martin A. Knapp, who was for years chairman of the Interstate Commerce Commission and who is thoroughly familiar with all phases of the federal laws affecting railroad operation. The decision is concurred in by Circuit Judge Woods and District Judge Waddill. The train operations of the Virginian Railway, which were the basis of the prosecution by the government, took place in July, 1912. The final arguments before the Circuit Court of Appeals were made November 30 last. The decision confirms that of the District Court at Lynchburg.

Judge Knapp's decision is in substance as follows:

The Virginian Railway was constructed primarily for the transportation of coal at low cost, and unusual expense was incurred to secure favorable grades and permit trains of great length. It appears to be a common practice to operate trains of 100 cars, each carrying approximately 54 tons. These trains are said to exceed in tonnage, if not in number of cars, the trains in ordinary use on any other road in the country.

From Goodview to Huddleston, Va., 13 miles, there is a descending grade to the east, which is the direction of the loaded movement, varying from nearly level to a maximum of 31.68 ft. per mile, with heavy cuts and fills and numerous curves. At the time mentioned the roadbed was not firmly settled and more or less trouble was experienced from the unstable condition of the fills and the sliding of earth and rocks in the cuts. On this account trains were limited by order to a speed of 5 miles an hour at one point and 10 miles an hour at other points. It was found, however, that these very long trains could not be operated safely, at the slow rate of speed required on this grade, when air brakes only were used for their control. This was because air brakes could not be applied with needed effect, if at all, without exerting a pressure which would stop the train, or, if released before the train came to a standstill, would cause such a jerking and surging of the train as to break the train apart; and accidents of this kind were of frequent occurrence. To avoid this danger the company decided upon the use of hand brakes, and accordingly, in May, 1912, promulgated the following order:

"In order to avoid breaking knuckles, pins and couplers in eastbound 100-car trains coming down the six-tenths grade between Goodview Tunnel



Map of the Chesapeake & Ohio Northern, Showing the Portion Under Construction Connecting the Chesapeake & Ohio and the Norfolk & Western, and the Proposed Extension to a Connection With the Hocking Valley at Columbus

and Huddleston, these trains will be held with hand-brakes and the independent engine brake.

"As a general proposition hand-brakes should be set about as follows: Goodview Tunnel to Westgate, 15 brakes; Westgate to Moneta, about 5 brakes; Moneta to Huddleston, about 20 brakes.

"If these brakes do not hold the train sufficiently, additional hand-brakes will be set up, or the independent engine brake used.

"The automatic air brakes will be used if it is seen that the hand-brakes are not holding properly, to make a quick stop on account of being flagged, or in other cases of emergency."

Trains were operated under this order and substantially according to its requirements.

It appears to be conceded that trains of a smaller number of cars could be safely operated on this section of road, even at the slow rate of speed stated, by using only the air brakes and the locomotive power brake. Just how many cars could be handled without the use of hand-brakes is not altogether certain, but apparently there was no difficulty with trains of 50 cars, or even more than that number. In short, the alleged necessity for requiring hand-brakes to be used resulted wholly from the extreme length of the trains, coupled with the low rate of speed at which they were moved.

Was the use of hand-brakes under such circumstances a violation of the federal statute? The original act, approved March 2, 1893, provides that ". . . it shall be unlawful . . . to run any train . . . that has not a sufficient number of cars in it so equipped with power or train brakes that the engineer on the locomotive can control its speed without requiring brakemen to use the common hand-brake for that purpose." The later amendment of 1903 includes this provision:

"That whenever, as provided in said act, any train is operated with power or train brakes, not less than 50 per centum of the cars in such train shall have their brakes used and operated by the engineer of the locomotive drawing such train." [Later modified to 85 per cent.]

The question asked above must be answered in the affirmative. In our judgment the legislation here considered manifests the plain intention of Congress to require the control of trains in ordinary line movement by the train brakes prescribed, and to make unlawful the use of hand-brakes for that purpose. True, the use of hand-brakes is not in express terms prohibited, but this is the necessary implication of the language used and it admits of no other reasonable construction. It was the evident purpose of the train brake provision to prevent the danger resulting from the operation of hand-brakes on the tops of cars in moving trains. In Erie R. R. Co. vs. U. S., 197 Fed., 287, the court took occasion to say that the purpose of the act "was to compel railroads to equip trains in interstate transit with air brakes, thereby contributing not only to the safety of passengers and crews, but saving brakemen, as far as possible, from the dangers incurred in manipulating hand-brakes."

The whole argument of plaintiff in error rests upon the proposition that, since the statute requires that all cars be equipped with hand-brakes, and does not expressly forbid their use for controlling the speed of trains, there is left to "the judgment or discretion of the men operating the trains the decision as to when and under what circumstances the power brake should be used, and as to when and under what circumstances the hand-brake should be used." It is obvious that such a construction would practically nullify the train brake requirement and take all effective meaning from the provision which makes it unlawful to run "any train" unless the locomotives and cars are so equipped that the engineer can control its speed "without requiring the brakemen to use the common hand-brake for that purpose." The contention must be rejected as clearly unsound. It is impossible to believe that the Congress compelled the equipment of locomotives and cars with the appliances specified in the act, for the declared purpose of doing away with the dangerous operation of hand-brakes, and then left it to the carriers themselves to decide when and under what circumstances those appliances should be used.

On the contrary, we deem it beyond doubt that the duty imposed by the provision here considered is mandatory and absolute. There is no express or implied qualification, which in any way relates to the question at issue, and it is not for the courts to introduce an exception which the Congress did not see fit to make. The peculiar and unusual conditions which existed on this section of defendant's road cannot be permitted to excuse an avoidance of the positive requirements of the act. Moreover, those conditions disclose no emergency or extraordinary difficulty. They simply show that the defendant, for the sake of convenience or economy, deliberately ordered the use of hand-brakes in the daily and customary operation of its trains. The justification set up is that trains of 100 cars cannot be moved on this stretch of track, at the slow speed of 10 miles an hour or less, and kept under safe control with the use only of the prescribed power brake. But those operating conditions, which occasioned the need of hand-brakes, are evidently of defendant's own creation. All it has to do to comply with the law is to make up trains of such smaller number of cars as can be safely and properly handled without resorting to the use of hand-brakes. In short, the mandate of the Congress is disregarded in this instance not because compliance involves any physical difficulty which is inherent or practically serious, but merely because it involves some increase of expense. It is too plain for argument that no such reason can serve to condone disobedience to the command of the statute. . . . We are of opinion that the case was correctly decided in the court below and the judgment will therefore be affirmed.

WESTERN RATE ADVANCE CASE

The hearing before Commissioner Daniels at Chicago in the western freight rate advance case, which was expected to have been concluded on Monday of this week, was extended to permit the introduction of unfinished testimony both by representatives of the protestants and the railroads, after it had been announced from Washington that the hearing on the proposed increases in passenger fares on the western roads originally set for May 17, would be postponed until July 6, at the request of the western state railway commissioners.

Testimony of the protestants against the advances in rates on livestock was completed on May 5. A large number of stock raisers from Iowa, members of the Corn Belt Meat Producers' Association, protested against any advance in the rates on livestock on the ground that the business of feeding stock for the market is no longer profitable, but is carried on in the interest of conservation of soil fertility, and therefore is a vital benefit to the agricultural welfare of the country. The farmers also testified that the service given livestock shipments has not improved in recent years, but that schedules in many cases have been lengthened, and they also objected to the accommodation furnished to caretakers of livestock. S. M. Corrie, president of the Corn Belt Meat Producers' Association, said that instead of trying to burden an industry in a critical condition it would be to the interest of the railroads to aid in fostering and building up the livestock business, not only as a means of replenishing the meat supply, but also as the most effective agent in renewing the fertility of the soil. Henry C. Wallace, editor of a farm paper, also urged special encouragement of the industry, saying that the transportation of livestock should be treated by the railroads as the grocer treats sugar, as a staple upon which no profit is expected.

T. W. Tomlinson presented some statistical testimony on behalf of the American National Livestock Association, the Cattle Raisers' Association of Texas and the National Wool Growers' Association. Later Mr. Tomlinson presented a vigorous protest against the introduction of testimony by C. W. Hillman, a cost accountant, put on the stand by the western state commissioners to testify as to the cost of handling livestock. Mr. Tomlinson said he believed Mr. Hillman's exhibits were full of errors and did not reflect correctly the earnings, profit or cost of livestock

traffic. The objection was overruled by Commissioner Daniels on the ground that it questioned the weight and not the admissibility of the evidence.

The subject of cost accounting was given a new prominence in the case when F. H. Millard, formerly connected with the Wisconsin Railroad Commission, and now specially employed by the Interstate Commerce Commission, was put on the stand as a witness for the commission to testify to a cost analysis he had applied to most of the commodities affected by the proposed advances in this case for the Chicago & North Western and the Rock Island Lines. Witnesses for the shippers had previously introduced cost figures for grain, packing house products and livestock, based on conflicting theories which had been objected to by the railways as being full of inconsistencies and errors. Mr. Millard's method, which has been used by the Wisconsin Railroad Commission, attempted to apportion the cost of transporting various commodities and then added a proportion of the return on the property investment based on the value of the commodity. The application of this system to the principal commodities involved in the case on the two roads for the average haul of each commodity resulted in figures higher in almost every instance than the actual earnings of the railroads under the present rates. Rates made on the basis here deduced, he said, would add about $6,500,000 to the revenues of the Rock Island system on carload business, allowing a 7 per cent net return on the value of the property; and about $1,817,000 to the carload revenues of the North Western.

Mr. Millard presented an exhibit outlining his system, with an express disclaimer that the figures presented are necessarily determinative upon the testimony introduced in this case. The method was based on the assumption that the value of the commodities affords a basis for distributing the reasonable return above the cost and that a given commodity is expected to pay above cost a return of 4 per cent plus an additional 1 per cent for each $10 of value per ton, considering the transportation for an entire year. A table showed that for articles with a value of $2 or less per ton, there should be a return equal to 4 per cent on the property devoted to the hauling of that commodity. For commodities valued at from $2 to $5 a ton the return would be 4½ per cent; from $5 to $10, 5 per cent; $10 to $15, 5½ per cent and from $15 to $25, 6 per cent. From this point 1 per cent was added for every $10 of additional value per ton to a maximum of 25 per cent on a value of $205 and over per ton. He said he had checked his method by applying it to all carload business on the Chicago & North Western, adding the present revenue on less than carload business, obtaining a return on the book value of about 6½ per cent.

Mr. Millard first separated freight and passenger expenses, using the basis used in the exhibit filed by L. E. Wettling, accountant for the carriers in this case, except that loss and damage to freight were excluded from the computation of unit costs and the actual amount paid was included in computing the theoretical rate for particular commodities, and 2 per cent of the total freight operating expenses were credited to the freight service, and the same percentage to passenger service to care for the net amount of traffic carried by freight trains for passenger service over the amount of traffic carried by passenger trains for the freight service. Taxes, joint facilities and miscellaneous rents were divided between freight and passenger on the basis of the percentage of operating expenses, and actual amounts were used for hire of equipment. He then separated the road haul expenses and terminal expenses, assigning the road haul expenses to the various commodities on the basis of gross ton miles, including the load, tare and the proper proportion of the empty haul of cars for each commodity. Terminal expenses were assigned to the commodities, one-third on the basis of gross tons handled and two-thirds on the number of cars handled. He then made a mathematical computation of the cost of handling various commodities on the gross ton-mile basis, and computed theoretical rates in cents per hundred pounds for distances up to 1,200 miles, for various net loads. The additional percentages for net return were computed on the value of the property apportioned between the commodities on the basis of ton miles.

According to this method he calculated that coal rates should provide a net return of 4½ per cent; hay 6 per cent; grain 7 per cent; grain products 8 per cent; fruits and vegetables 7 per cent; livestock 19 per cent and packing house products 25 per cent. Witnesses for the packers had asserted that the value of the commodities should not be taken into consideration in fixing rates, except as it affects the liability.

He then presented tables giving the actual cost, including operating expenses, taxes, hire of equipment, joint facilities and miscellaneous rents and his theoretical rates made by adding the percentage of return for distances up to 1,200 miles on each commodity, with figures showing the average haul for each commodity and the actual revenue per ton mile received by the carriers. For the average haul his theoretical rates in cents per ton per mile compare with the actual rates on the two roads, as follows:

Commodity	Rock Island		C. & N. W.	
	Theoretical	Actual	Theoretical	Actual
Grain	.676	.650	.607	.745
Grain products	.827	.561	.725	.448
Hay	1.044	.937	.939	.978
Fruits and vegetables	.940	.759	.931	.809
Live stock	1.921	1.388	1.516	1.313
Packing house products	1.714	.966	1.594	.975
Bituminous coal	.708	.592	.610	.524
Coke	.695	.504	.712	.578

Mr. Millard was subjected to a vigorous cross-examination by representatives of the western state commissioners and by attorneys for the shippers. C. C. Wright, general solicitor of the Chicago & North Western, confined his cross-examination to an effort to elicit as much detail as possible regarding the various methods of computation used. On cross-examination Mr. Millard said that the gross ton-mile basis of computing costs was far more correct than the car-mile basis or the net ton-mile basis which had been used by witnesses for the protestants, saying that the car-mile basis neglects the effect of the loading per car, while the net ton-mile basis neglects the weight of the car. He said that for the Rock Island Lines he had apportioned 62.46 per cent of the total expenses to freight and for the North Western 66.55 per cent, and that he had divided the property account between freight and passengers on the basis of an adjusted division of operating expenses. Asked whether he would advance rates to correspond with changes in price, he said that this should be done only at long intervals; that it was not necessary to allow for temporary fluctuations.

Testimony introduced by W. J. Lauck on behalf of the western state commissioners, brought forth a vigorous objection by Commissioner Daniels that time was being wasted with irrelevant testimony. Mr. Lauck, who had been one of the principal witnesses for the engineers' and firemen's brotherhoods in the recent arbitration proceedings, was put on the stand to introduce similar testimony purporting to show the increased productive efficiency of railway employees and the past history of land grants and stock issues of the western roads, arguing that high expenses of railway operation have been more than offset by the productive efficiency of labor and a resulting great increase in the economical operation of the railroads. At one point Commissioner Daniels ordered one of his statements struck out of the record as being mere surmise. "Has he not the right to give his opinion?" asked one of the attorneys for the shippers. "No, he has not the right," replied Commissioner Daniels, "to give us a lot of superfluous surmise which has no more to do with the reasonableness and justice of these rates than 100,000 other facts which might be taken out of the Encyclopedia Britannica. I am very considerably irritated that the commission is being held here simply to kill time which is allotted to you gentlemen for putting in evidence bearing upon the justice and reasonableness of these rates, or their injustice and unreasonableness if that be so."

U. G. Powell, rate expert of the Nebraska Railroad Commission, introduced some additional exhibits giving figures on prop-

erty investment, income accounts, operating revenues, expenses and taxes of the western railways. He presented tables for 10 roads to show that the average ratio of net income to property investment for 25 years was 5.86 per cent in the northwest, while for the southwest the average was 3.76 per cent. Dr. M. O. Lorenz, statistician for the commission, brought out on cross-examination that his figures showed a gain in rate of return for a long period of years, but a reduction in recent years. The witness ascribed this to increases in the various property accounts.

M. A. Chambers, an accountant for protesting shippers, took the stand to criticize some of the exhibits introduced by L. E. Wettling for the railways on the ground that certain railroads had been omitted. On cross-examination Mr. Wright showed that with the exception of the Great Northern, Northern Pacific and Union Pacific, which lie mostly outside of the territory affected by the advance, all of the roads were unimportant, many in the hands of receivers, and some of them so small that witness said he could not find them on the map.

W. W. Manker, assistant traffic manager of Armour & Company, testified in opposition to the proposed advances in rates on fertilizer from Gulf ports to the central Mississippi valley.

On Monday, J. Pease Norton, a bond expert, testifying for the western state commissioners, presented an exhibit of 137 pages containing a series of tables of bond yields to show that the credit of the railways, as measured by the yield which the public is willing to accept on their securities, has been improving in comparison with government and municipal bonds and public utility and industrial securities. "The true test of the effect of the general financial situation," he said, "would be the pure money rate on long term securities were that figure obtainable. The next best test is the closest approach we have to the pure money rate, represented by government securities and the bonds of the highest class of municipalities. If the yield upon the bond of a company engaged in private business increases faster than the pure money rate, then that is evidence that the credit of the company has declined. If the yield has increased in a less proportion than the pure money rate, then that shows that the credit of the company is on a better plane."

To represent the closest possible approximation to the pure money rate he took the government securities of England, France, Germany and the United States, and the municipal bonds of the 20 largest cities of the United States, and then made comparisons with the yield on railroad bonds for the period 1900 to 1914, showing that the yields had increased as follows:

	1900	1914	Per cent increase
Governments	2.83	3.33	17.7
20 cities	3.2	4.2	31.3
Western roads	3.9	4.4	12.8
Southwestern roads	4.7	5.1	8.5
100 railroad bonds	4.3	4.8	11.5

During the same period Mr. Norton said the pure money rate approximation had increased from 3 to 3.25 per cent and the yield on all the bonds for which he had made computations had advanced 31 per cent.

Comparing railway bonds with industrial and public utility bonds, he said that 13 railways in the western district having revenues of $1,000,000 or more, have issued 4 per cent bonds since 1910, while out of 124 bond issues of public utility companies since 1910 only 6 were at 4 per cent and one of these was guaranteed by the Southern Pacific. But two issues out of 103 by industrial companies having gross revenues of $1,000,000 or more, were at 4 per cent and both issues were guaranteed by railroads. Out of a list of 235 public utility and industrial bonds quoted on the New York exchange, one was a 3½ per cent issue, 21 were 4 per cent, 1 was 4.4 per cent, 17, 4½ per cent, 135, 5 per cent, 58, 6 per cent and 2, 7 per cent.

The shippers' advocates concluded their testimony on Wednesday afternoon, the 12th. The railroads then put on the stand a few witnesses to rebut testimony given by shippers, and it was expected that the hearing would be finished on Thursday.

SAFETY FIRST WORK ON THE SOUTHERN PACIFIC*

By W. H. Whalen,
Division Superintendent, Southern Pacific.

The Pacific system's safety record for five years shows a passenger movement equal to *eight billions* of passengers carried one mile, and without a single passenger fatally injured in a train accident. . . .

To attain the desired safety, the employees of the different divisions of the system have formed themselves into working organizations, known as safety committees. We meet once a month on each division, at which time we sit one or two days considering the different accidents that have occurred during the month, and studying their causes. We also consider suggestions made by the various employees, the number of these suggestions running as high as 220 in some months. Last month we had 125. Each suggestion is weighed carefully and recommendations are made to carry out those considered practicable; some are laid before the management for consideration. To put these suggestions into effect, our company has spent for the year ending June 30, 1914, $42,000, with pending expenditures of $85,000. As a result of one of these suggestions, this company built a subway at the Los Angeles shops, costing $7,000, that employees might go to and from their work under the tracks, rather than crossing over them and experiencing danger from passing trains. In addition, this company has spent $156,000 a year for special officers to assist in controlling the trespassing feature; $150,000 in eliminating grade crossings; $44,000 in protecting 112 additional crossings with alarm devices; $230,000 in providing crossing protection, and $17,000 in installing 40 wigwag signals at crossings; which, with the money expended in carrying out safety suggestions, amounts to $724,000. This is not all, as our signal construction and reconstruction during the past year amounted to $246,400, and their maintenance and operation $417,200, making our total investment in block signals $3,485,000. Eleven additional interlocking plants were installed during the past year at a cost of $160,000. Our fire protecting equipment is valued at $510,000 and the report of the Interstate Commerce Commission for the year 1914 shows that the Southern Pacific excelled all other lines in the United States in miles of road protected by the automatic block system employing electric track circuits.

Forty-one per cent of all of our passenger cars are of all-steel construction, the balance being steel underframe and wooden cars. Only steel cars have been ordered since 1906. Thirteen per cent of all our freight cars are steel, and 53 per cent have steel underframes. During the past year, 1,224 shop machines and tools were furnished with protecting guards and devices, and 1,906 have been so equipped during the past two years.

Our clubs for employees represent an investment of $400,000; their annual maintenance and operation costs $18,000, and approximately $1,000,000 is expended in our hospital system, with an annual maintenance expense amounting to $300,000. The Harriman Research Laboratory was instituted at an expense of $60,000.

The creditable performance in handling passengers shown by the company's records is not traceable alone to this outlay of money, but is due also to the fact that those passengers were entrusted to a thoroughly trained corps of employees who have been trained to think and act in common and in accordance with the standard code of rules. Numerous surprise tests are made by officers of the company, that we may know that the rules are being observed. It requires great effort and self-denial on the part of officers to make the surprise tests, as the work is generally done in the night.

*From an address presented at a number of schools in Southern California.

General News Department

The House Committee on Public Utilities of the Illinois legislature has voted not to report the bill to limit the length of freight trains to 50 cars.

The Wheeling & Lake Erie, on the trains leaving Cleveland for Wheeling at 9 a. m., and Wheeling for Cleveland at 5:05 p. m., runs buffet dining cars on which both the cooks and the waiters are women.

The railroad commission of California has issued an order authorizing the Colusa & Lake Railroad, operating between Colusa and Sites, Cal., to discontinue operation. Passenger trains were discontinued on August 5, 1914.

At a meeting of the local chairmen of the Brotherhood of Locomotive Engineers and the Brotherhood of Locomotive Firemen and Enginemen, held in Chicago last week, to consider the award of the board of arbitration in their recent controversy with the western railroads, a vote was taken in favor of joining with other organizations in the movement for an eight-hour day.

The Bangor & Aroostook, according to a notice from President Percy R. Todd, is to operate, as agent, the line of the Van Buren Bridge Company, and the jurisdiction of all officers of the B. & A. is extended over the property of the bridge company, as of May 1. The opening of the Van Buren bridge, between Maine and New Brunswick was noticed in the *Railway Age Gazette*, May 7.

The special committee on the Relations of Railway Operation to Legislation, has issued a bulletin showing that on January 1 last there were in service in the United States 12,900 all-steel and 5,700 steel underframe passenger cars, and 43,512 wooden cars. Of the passenger cars acquired by the roads in 1914, 74 per cent were all steel; and of 956 cars under construction January 1, only three were of wood. Seventy-five per cent were all-steel.

The attorney general announces at Washington that he will appeal to the Supreme Court of the United States in the cases of William Skinner and James S. Elton, directors of the New York, New Haven & Hartford, who, on appeal to the district court in New York, were held to be immune from the criminal prosecution which has been begun by the attorney general, because they had testified before the Interstate Commerce Commission in its inquiry relative to the doings of the road.

The headquarters and general offices of the Texas State Railroad have been moved from Rusk to Palestine, Tex. A roundhouse, a coal chute and car sheds are being built to take care of the business at this place. A consolidation is being effected whereby the different lines owned by the state of Texas will be under one management, with headquarters at Palestine. The construction of an extension of the road from Palestine through Corsicana to Dallas, is under consideration by the legislature and the state officers.

The "Travel Stamps" Corporation, noticed in the *Railway Age Gazette* of April 30, page 945, appears to have a nearby competitor before it is started, almost. Boston newspapers contain the advertisement of the New England Trade-Travel Company, 59 Temple Place, which offers "Free travel by train, trolley or steamship—Any place—Any time." The reader is exhorted to deal with the liberal and progressive merchants who give trade travel coupons; but the advertisement gives no names of any such merchants. The reader is asked to speak to his dealer about the plan and to write to the New England Trade Travel Company giving names of favorite department stores, grocers, etc.

Pennsylvania Full Crew Law Repeal

The bill before the Pennsylvania legislature repealing the "full crew" law of 1911 and giving specific authority to the Public Service Commission to regulate the number of men to be employed on trains was passed by the Senate on Monday evening last by a vote of 33 to 16, or about the same proportion between ayes and noes as prevailed in the House when the bill was passed a few weeks ago.

Governor Brumbaugh, during the campaign last autumn, wrote a letter in which he said that he was opposed to any change in the full crew law unless such change should be shown to be in favor of the working people; and this statement has led to much speculation as to whether the governor will sign the present bill. He is expected to give public hearings before taking action.

Not Often Met With?

[From a circular to agents, issued by R. T. Walker, Superintendent, Sunset-Central Lines, Houston, Tex.]

Recently one of our agents was called upon by a patron to see if arrangements could be made to have a ticket placed at a station on a foreign line to be used by a lady in coming to the station at which the request was made. It was then 9:30 p. m. and the ticket was to be used on a train leaving at 4 o'clock the next morning; but the agent immediately took the matter in hand and in a few minutes not only had the ticket placed but had the lady notified it was there for her.

The patron, making a handsome acknowledgment of the said accommodation, added:

"It is not often you meet with such agreeable, courteous gentlemen in charge of railroad offices. . . . I have thought several times since this incident occurred, how much of the unreasonable prejudice that exists in the mind of the public against the railroads would be removed if all employees were of the same type as this agent. . . ."

Moncton to Winnipeg

Reports from Ottawa say that the officers of the Canadian government railways, who have been instructed to establish train service on the National Transcontinental, from Quebec westward, are planning only to run, at least for the present, a train each way, twice a week. The purpose is simply to give the best practicable accommodation to the settlers along the line. The number of trains will be increased if there shall be sufficient demand.

Fifteen locomotives have already been taken across the river, at Quebec, for use on the new line. Between Moncton, N. B., and Levis, Que., 466 miles, where the government has been operating the road since last autumn, a train is run each way three times a week; Moncton to Edmundston Tuesday, Thursday and Saturday; Edmundston to Levis Monday, Wednesday and Friday, with return trips on alternate days.

On that portion of the new road from Winnipeg eastward to Graham, and thence southward to Fort William, where the Grand Trunk Pacific has been operating the line under a temporary lease, a similar arrangement has been in effect. A train runs from Winnipeg to Graham, 252 miles, on Monday, Wednesday and Friday; Graham to Fort William, 196 miles, Tuesday, Thursday and Saturday, the return trips being made on alternate days.

On some parts of the Grand Trunk Pacific economy in coal and wages is carried still farther than this. For example, from Young, Sask., to Hoey, 83 miles, there is a regular train for passengers only once a week; Young to Hoey on Monday, Hoey to Young on Tuesday.

Summary of Revenues and Expenses of Steam Roads

The Bureau of Railway Economics' summary of revenues and expenses and comments thereon for February, 1915, are as follows:

The net operating income of the railways of the United States for February increased $52 per mile, or 44.3 per cent, as compared with February, 1914; but February, 1914, was an abnormally poor month, net operating income per mile being 44.0 per cent less than in February, 1913. The increase shown this month, which only partially overcomes the considerable decrease in the same item a year ago, is the result of radical reductions in operating expenses.

Total operating revenues amounted to $205,112,212, a decrease from 1914 of $1,961,957. Operating expenses were $155,031,302, a decrease of $13,966,146. Net operating revenue amounted to $50,080,910, an increase of $12,004,189. Taxes amounted to $10,995,903, a decrease of $296,011. This left $39,028,155 for net operating income, available for rentals, interest on bonds, appropriations for improvements and new construction, and dividends. Operating revenues per mile of line averaged $897, a decrease of 1.9 per cent; operating expenses per mile averaged $678, a decrease of 9.1 per cent; net operating revenue per mile averaged $219, an increase of 30.3 per cent; while taxes per mile were $48, a decrease of 3.5 per cent. Net operating income per mile was $171, an increase of 44.3 per cent. Railways operating 228,678 miles of line are covered by this summary, or about 90 per cent of the steam railway mileage in the United States.

Total operating revenues of the eastern railways per mile of line increased less than one-tenth of 1 per cent as compared with February, 1914, operating expenses decreased 10.2 per cent, net operating revenue increased 81.8 per cent, taxes decreased 3.3 per cent, and operating income increased 158.9 per cent. Even this considerable increase over 1914 failed to bring operating income per mile up to the level of 1913, 1912, or 1911.

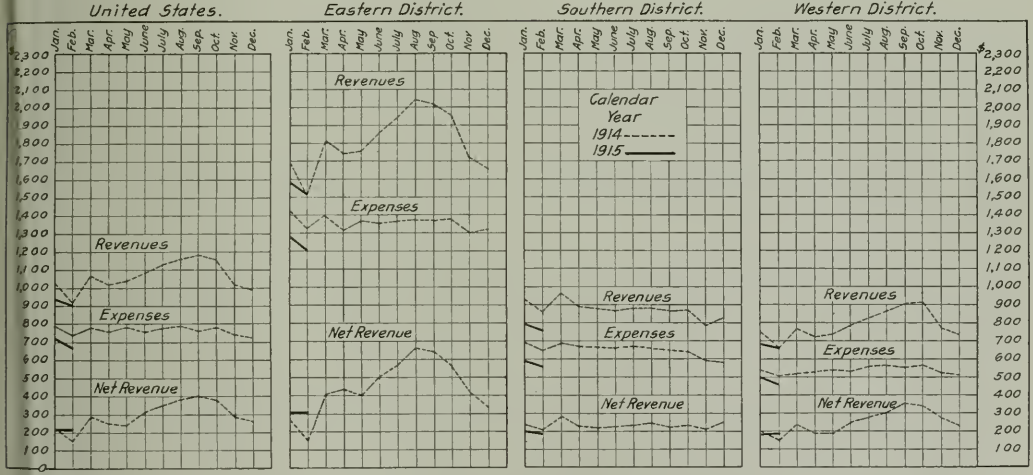
Total operating revenues of the southern railways per mile decreased 10.4 per cent, operating expenses decreased 11.6 per cent, net operating revenue decreased 6.7 per cent, taxes decreased 6.6 per cent, and operating income decreased 6.9 per cent.

Total operating revenues of the western railways per mile increased less than one-tenth of 1 per cent, operating expenses decreased 6.4 per cent, net operating revenue increased 21.0 per cent, taxes decreased 2.5 per cent, and operating income increased 28.8 per cent.

The eight months of the current fiscal year show a decrease in total operating revenues per mile of line of 7.9 per cent as compared with the corresponding period of the preceding year, a decrease in net operating expenses per mile of 9.7 per cent, and a decrease in net operating revenue per mile of 3.2 per cent.

This net operating revenue per mile increased 3.7 per cent in the east, decreased 17.8 per cent in the south, and decreased 3.7 per cent in the west.

February operating income per mile was 44.3 per cent greater in 1915 than in 1914, 19.6 per cent less than in 1913, 18.1 per cent less than in 1912, and 5.8 per cent less than in 1911.



Monthly Revenues and Expenses Per Mile of Line in 1914 and 1915

May Meeting of the Railway Signal Association

The Railway Signal Association will hold its stated May meeting on Wednesday and Thursday, May 26 and 27, at the Hotel Astor, New York City. The board of direction will meet on the 25th. Committee III, on Power Interlocking, will submit revised specifications for electro-pneumatic interlocking, for fiber conduit and for incandescent electric lamps. Committee V, Manual Block, will submit rules for (1) care of dry battery; (2) maintenance of dry cells; (3) maintenance of gravity cells; (4) maintenance of caustic soda cells.

Committee VI, Standard Designs, will submit eight drawings—four revisions and four new ones. Committee X, Storage Battery and Charging Equipment, will submit as information specifications for nickel-iron alkaline storage battery. A report on the cost of electrical energy for a charging line will also be submitted, which will include the cost of types of apparatus for furnishing power, as follows: (1) Motor generator set. (2) Mercury-arc rectifier. (3) Gasolene engine generating set. (4) Gas engine generating set. (5) Steam engine generating set. The special committee on Lightning Protection will submit specifications for air-gap lightning arresters, vacuum-gap lightning arresters, and choke coils for use with lightning arresters. The special committee on Electrical Testing will submit a preliminary report on electrical instruments and various methods of testing.

After the adjournment of the meeting, May 26, the members of the Railway Signal Association will be the guests of the Signal Appliance Association, on a boat trip to West Point. Arrangements have been made to secure the steamer Grand Republic. After reviewing the dress parade, at the Military Academy, the party will have dinner on the boat; and there will be dancing in the evening.

Railway Storekeepers' Association

The twelfth annual convention of the Railway Storekeepers' Association will be held in the Hotel Sherman, Chicago, May 17 to 19. At the meeting committee reports will be presented on the following subjects:

Reclamation—D. C. Curtis (C. B. & Q.), chairman.

Recommended Practices—D. D. Cain (S. A. L.), chairman.

Accounting—P. J. Shaughnessy (Erie), chairman.

Piece Work—W. W. Eldridge (C. B. & Q.), chairman.

Standardization of Tinware—W. F. Jones (N. Y. C.), chairman.

Stationery—E. J. McVeigh (G. T. R.), chairman.

Uniform Grading and Inspection of Lumber—J. H. Waterman (C. B. & Q.), chairman.

Scrap and Scrap Classification—W. Davidson (I. C.), chairman.

Membership—W. D. Stokes (C. of G.), chairman.

Standard Buildings and Structures—L. G. Arnold (A. T. & S. F.), chairman.

Book of Standard Rules—J. G. Stuart (C. B. & Q.), chairman.

Marking of Couplers and Parts—A. J. Kroha (C. M. & St. P.), chairman.

Papers will also be presented on: Handling of Signal Material, and Accounting for Second Hand Serviceable Material.

National Association of Corporation Schools

The third annual convention of the National Association of Corporation Schools will be held at the Hotel Bancroft, Worcester, Mass., June 7 to 11 inclusive. The convention is held in Worcester this year as the result of an invitation tendered at last year's convention by three of Worcester's leading industrial concerns—the Norton Co., the Norton Grinding Co. and the American Steel & Wire Co.

The National Association of Corporation Schools was founded January 24, 1913, and its first meeting was held in New York University, New York. The functions of the association were designated as follows: to develop the efficiency of the individual employee; to increase efficiency in industry; and to influence courses of established educational institutions more favorably toward industry. The first annual convention of the association was held at Dayton, Ohio, September 16, 1913, and the second annual convention at the home of the Curtis Publishing Company, Philadelphia, Pa.

June Conventions Exhibits

Secretary J. D. Conway, of the Railway Supply Manufacturers' Association, has a most favorable report to make of the prospects for the coming exhibition at Atlantic City during the meetings of the American Railway Master Mechanics' and the Master Car Builders' Associations, June 9-17. To date over 200 exhibitors have made arrangements for exhibits, and the average space occupied by each one has increased over 16 per cent as compared with 1914. While the number of exhibitors is somewhat smaller than last year, applications are being received daily, and it looks now as if the exhibit would be almost as extensive as that of last year, despite the business depression which has existed during the past year. More new exhibitors will appear than for a number of years.

The Railway Club of Pittsburgh

At the regular meeting of The Railway Club of Pittsburgh, to be held at the Monogahela House, Pittsburgh, Pa., on Friday, May 28, E. M. Herr, president of the Westinghouse Electric & Manufacturing Company will present a paper entitled "Notes on Some Important Lines of Electrical Power Development."

New York Railroad Club

At the regular monthly meeting of the New York Railroad Club, to be held in the Engineering Societies building, New York, on May 21, a paper will be presented by Gustav Lindenthal, consulting engineer, entitled: Qualities of Good Steel Rails.

MEETINGS AND CONVENTIONS

The following list gives the names of secretaries, dates of next or regular meetings, and places of meeting of those associations which will meet during the next three months. The full list of meetings and conventions is published only in the first issue of the Railway Age Gazette for each month.

American Association of Demurrage Officers.—F. A. Pontious, 455 Grand Central Station, Chicago. Next meeting, July 21, 1915, Milwaukee, Wis.

American Association of Freight Agents.—R. O. Wells, Illinois Central, East St. Louis, Ill. Annual meeting, May 18-21, 1915, Richmond, Va.

American Railroad Master Tinners, Coppersmiths and Pipefitters' Association.—W. E. Jones, C. & N. W., 3814 Fulton St., Chicago. Annual meeting, July 13-16, 1915, Hotel Sherman, Chicago.

American Railway Association.—W. F. Allen, 75 Church St., New York. Next session, May 19, 1915, New York.

American Railway Master Mechanics' Association.—J. W. Taylor, 1112 Karpen Bldg., Chicago. Annual meeting, June 9-11, 1915, Atlantic City, N. J.

American Railway Tool Foremen's Association.—Owen D. Kinsey, Illinois Central, Chicago. Annual meeting, July 19-21, 1915, Hotel Sherman, Chicago.

American Society for Testing Materials.—Prof. E. Marburg, University of Pennsylvania, Philadelphia, Pa. Annual meeting, June 22-26, 1915, Hotel Traymore, Atlantic City, N. J.

American Society of Civil Engineers.—Chas. Warren Hunt, 220 W. 57th St., New York. Regular meetings, 1st and 3d Wednesday in month, except July and August, 220 W. 57th St., New York.

American Society of Mechanical Engineers.—Calvin W. Rice, 29 W. 39th St., New York. Next spring meeting, June 22-25, 1915, Buffalo, N. Y. Annual meeting, December 7-10, 1915, New York.

Association of Railway Claim Agents.—C. W. Egan, B. & O., Baltimore, Md. Annual meeting, May 19, 1915, Galveston, Tex.

Association of Railway Electrical Engineers.—Jos. A. Andreucetti, C. & N. W., Room 411, C. & N. W. Sta., Chicago. Semi-annual meeting with Master Car Builders' and Master Mechanics' Associations. Annual meeting, October, 1915.

Association of Railway Telegraph Superintendents.—P. W. Drew, Soo Line, 112 West Adams St., Chicago. Annual meeting, June 22-25, 1915, Rochester, N. Y.

Association of Transportation and Car Accounting Officers.—G. P. Conrad, 75 Church St., New York. Next meeting, June 22-23, Niagara Falls, N. Y.

Canadian Railway Club.—James Powell, Grand Trunk, P. O. Box 7, St. Lambert (near Montreal), Que. Regular meetings, 2d Tuesday in month, except June, July and August, Windsor Hotel, Montreal, Que.

Car Foremen's Association of Chicago.—Aaron Kline, 841 Lawler Ave., Chicago. Regular meetings, 2d Monday in month, except June, July and August, Hotel La Salle, Chicago.

Central Railway Club.—H. D. Vought, 95 Liberty St., New York. Regular meetings, 2d Friday in January, May, September and November. Annual meeting, 2d Thursday in March, Hotel Statler, Buffalo, N. Y.

Engineers' Society of Western Pennsylvania.—Elmer K. Hiles, 2511 Oliver Bldg., Pittsburgh, Pa. Regular meetings, 1st and 3d Tuesday in month, Pittsburgh.

Freight Claim Association.—Warren P. Taylor, R. F. & P., Richmond, Va. Annual meeting, June 16, 1915, Chicago.

General Superintendents' Association of Chicago.—A. M. Hunter, 321 Grand Central Station, Chicago. Regular meetings, Wednesday, preceding 3d Thursday in month, Room 1856, Transportation Bldg., Chicago.

International Railway Fuel Association.—C. G. Hall, C. & E. I., 922 McCormick Bldg., Chicago. Annual meeting, May 17-20, 1915, Hotel La Salle, Chicago.

International Railway General Foremen's Association.—Wm. Hall, 1126 W. Broadway, Winona, Minn. Next convention, July 13-16, 1915, Sherman House, Chicago.

Master Boiler Makers' Association.—Harry D. Vought, 95 Liberty St., New York. Annual convention, May 25 to 28, 1915, Chicago, Ill.

Master Car Builders' Association.—J. W. Taylor, 1112 Karpen Bldg., Chicago. Annual meeting, June 14-16, 1915, Atlantic City, N. J.

New England Railroad Club.—W. E. Cade, Jr., 683 Atlantic Ave., Boston, Mass. Regular meetings, 2d Tuesday in month, except June, July, August and September, Boston.

New York Railroad Club.—Harry D. Vought, 95 Liberty St., New York. Regular meetings, 3d Friday in month, except June, July and August, 29 W. 39th St., New York.

Niagara Frontier Car Men's Association.—E. N. Frankenberger, 623 Brisbane Bldg., Buffalo, N. Y. Meetings, 3d Wednesday in month, New York Telephone Bldg., Buffalo, N. Y.

Peoria Association of Railroad Officers.—M. W. Rotchford, 410 Masonic Temple Bldg., Peoria, Ill. Regular meetings, 3d Thursday in month, Jefferson Hotel, Peoria.

Railroad Club of Kansas City.—Claude Manlove, 1008 Walnut St., Kansas City, Mo. Regular meetings, 3d Saturday in month, Kansas City.

Railroad Men's Improvement Society.—J. B. Curran, Erie R. R., 50 Church St., New York. Meetings, alternate Thursdays, October to May, Assembly Rooms of Trunk Line Association, 143 Liberty St., New York.

Railway Club of Pittsburgh.—J. B. Anderson, Room 207, P. R. R. Sta., Pittsburgh, Pa. Regular meetings, 4th Friday in month, except June, July and August, Monongahela House, Pittsburgh.

Railway Electrical Supply Manufacturers' Association.—J. Scribner, 1063 Monadnock Block, Chicago. Meetings with Association of Railway Electrical Engineers.

Railway Signal Association.—C. C. Rosenberg, Myers Bldg., Bethlehem, Pa. Stated meeting, May 26-27, 1915, Hotel Astor, New York. Annual meeting, September 14-17, 1915, Salt Lake City, Utah.

Railway Storekeepers' Association.—J. P. Murphy, N. Y. C. R. R., Box C, Collinwood, Ohio. Annual meeting, May 17-19, 1915, Hotel Sherman, Chicago.

Railway Supply Manufacturers' Association.—J. D. Conway, 2136 Oliver Bldg., Pittsburgh, Pa. Meetings with Master Car Builders and Master Mechanics' Associations.

Railway Telegraph and Telephone Appliance Association.—G. A. Nelson, 50 Church St., New York. Meetings with Association of Railway Telegraph Superintendents.

Richmond Railroad Club.—F. O. Robinson, C. & O., Richmond, Va. Regular meetings, 2d Monday in month, except June, July and August.

St. Louis Railway Club.—B. W. Frauenthal, Union Station, St. Louis, Mo. Regular meetings, 2d Friday in month, except June, July and August, St. Louis.

Salt Lake Transportation Club.—R. E. Rowland, David Keith Bldg., Salt Lake City, Utah. Regular meetings, 1st Saturday of each month, Salt Lake City.

Southern Association of Car Service Officers.—E. W. Sandwich, A. & W. P. R. R., Atlanta, Ga. Next meeting, July 15, 1915, Atlanta. Annual meeting, January, 1916.

Southern & Southwestern Railway Club.—A. J. Merrill, Grant Bldg., Atlanta, Ga. Regular meetings, 3d Thursday, January, March, May, July, September, November, 10 a. m., Piedmont Hotel, Atlanta.

Traffic Club of Chicago.—W. H. Wharton, La Salle Hotel, Chicago.

Traffic Club of Newark.—John J. Kautzmann, P. O. Box 238, Newark, N. J. Regular meetings, 1st Monday in month, except July and August, The Washington, 559 Broad St., Newark.

Traffic Club of New York.—C. A. Swope, 291 Broadway, New York. Regular meetings last Tuesday in month, except June, July and August, Hotel Astor, New York.

Train Dispatchers' Association of America.—J. F. Mackie, 7122 Stewart Ave., Chicago. Annual meeting, June 15, 1915, Minneapolis, Minn.

Transportation Club of Detroit.—W. R. Hurley, Superintendent's office, N. Y. C. R. R., Detroit, Mich. Meetings monthly. Normandie Hotel, Detroit.

Utah Society of Engineers.—Frank W. Moore, 1111 Newhouse Bldg., Salt Lake City, Utah. Regular meetings, 3d Friday in month, except July and August, Salt Lake City.

Western Canada Railway Club.—L. Kon, Immigration Agent, Grand Trunk Pacific, Winnipeg, Man. Regular meetings, 2d Monday, except June, July and August, Winnipeg.

Western Railway Club.—J. W. Taylor, 1112 Karpen Bldg., Chicago. Regular meetings, 3d Tuesday afternoon in month, except June, July and August, La Salle Hotel, Chicago.

Western Society of Engineers.—J. H. Warder, 1735 Monadnock Block, Chicago. Regular meetings, 1st Monday in month, except January, July and August, Chicago. Extra meetings, except in July and August, generally on other Monday evenings. Annual meetings, 1st Wednesday after 1st Thursday in January, Chicago.

REVENUES AND EXPENSES OF RAILWAYS

MONTH OF MARCH, 1915

Name of road.	Average mileage operated during period.	Operating revenues			Operating expenses						Net operating revenue (or deficit).	Railway tax accruals.	Operating income (or loss).	Increase (or decr.) comp. with last year.
		Freight.	Passenger.	Total, inc. misc.	Maintenance: Way and structures.	Maintenance: Of equipment.	Traffic.	Trans-portation.	Miscel-laneous.	General.	Total.

Traffic News

The House of the Ohio legislature has passed a bill repealing the maximum freight rate law of that state.

The Chesapeake & Ohio and the Southern have reduced their rates on pig iron, for export, from furnaces in Virginia to Newport News, and Norfolk, Va., from $1.52½ to $1 per ton.

The public utilities committee of the House of the Illinois legislature has reported out, without recommendation, the bill to increase the legal maximum passenger fare in Illinois from 2 to 2½ cents a mile.

The Grand Trunk has announced that after May 16 it will cease to run suburban passenger trains between Chicago and Blue Island, Ill., 20 miles, and Harvey, 23 miles. It will run two suburban trains in each direction between Chicago and Valparaiso, Ind., 56 miles, instead of six in each direction as now.

The attorney general of West Virginia has secured an injunction in the Kanawha Circuit Court against the Baltimore & Ohio restraining it from collecting 2½ cents a mile for passenger fares, and the company has discontinued the sale of tickets at that rate, which was begun May 1, a conditional rebate check being given with each ticket.

The Grand Trunk Pacific announces the arrival at Winnipeg of a carload of wheat from the Peace River country in northern Alberta. This region is about 250 miles north of Edmonton and 500 miles north of the United States boundary. The wheat reached Edmonton over the Edmonton, Dunvegan & British Columbia, a new road extending north from Edmonton about 200 miles and then westward.

Car Surpluses and Shortages

The American Railway Association's Committee on Relations Between Railroads, Arthur Hale, chairman, has issued statistical statement No. 4, giving a summary of freight car surpluses and shortages for May 1, 1915, with comparisons.

The total surplus on May 1, 1915, was 290,819, on April 1, 1915, 327,441, and on May 1, 1914, 230,533.

The surplus for April 1, 1915, shown above, includes figures reported since the issue of statistical statement No. 3 (published in the *Railway Age Gazette* of April 16, p. 865.)

The decreases in surplus under April 1, 1915, are chiefly in Groups 2, 3 and 4 (East and Central East), except box cars. There is an increase in the surplus of box cars chiefly in Group 9 (Central South) and Group 11 (Canada).

The total shortage on May 1, 1915, was 1,192; on April 1, 1915, 357, and on May 1, 1914, 1,654.

The figures by classes of cars follow:

Classes	Surplus	Shortage
Box	100,751	288
Flat	16,669	134
Coal and gondola	119,545	130
Other	53,854	640
Total	290,819	1,192

The Cummins Amendment

Western railroads have filed with the Interstate Commerce Commission a supplement to the Western Classification to make it conform to the Cummins amendment. The supplement includes a note which says: "Ratings on livestock vary according to the valuation stated by shippers, and if carriers have no means of determining values of livestock when tendered for transportation shippers will be required to declare in writing the valuation at time and place of shipment. Where shippers refuse to declare value and to execute the livestock contract, animals will not be accepted for transportation." This is followed by maximum valuations on the various classes of livestock, with a provision that where the valuation declared by shippers exceeds the values mentioned, an addition of 3 per cent will be made to the rate for each 50 per cent or fraction thereof, of additional declared value.

Commission and Court News

INTERSTATE COMMERCE COMMISSION

The Interstate Commerce Commission has issued a conference ruling that on and after August 1, the commission will not consider on the informal docket any application for authority to waive collection of undercharges on shipments delivered subsequent to July 31. A circular has been issued in which the commission says that in cases where tariffs have erroneously been fixed at too high a figure or have been grossly and palpably unreasonable and the full tariff charges have not been collected, it has been the practice of the commission on the informal docket to authorize the carriers concerned to waive the collection of undercharges. It appears, however, that the concession thus granted has been "much abused and overworked both by carriers and shippers." Numerous instances have come to the attention of the commission in which shippers frequently refused to pay charges when they believed them to be unreasonable and the carriers acquiesced in that course of action, hoping the commission would later authorize them to waive collection. Also, the commission says, just prior to proposed reductions in rates shipments have been solicited and made upon the understanding that the full tariff charges will not be collected, and that the carrier will apply to the commission for authority to waive collection. Such practices, the commission says, are unlawful and work serious discrimination.

Initial Carrier Liable for Increase Charges Resulting from Re-routing Without Instructions

Fred S. Morse Lumber Company v. Louisville & Nashville et al. Opinion by the commission:

A carload of yellow-pine lumber originating at Sanford, Ala., on the Louisville & Nashville was consigned to Middletown, N. Y., routed via the Erie Railroad. On account of floods the initial carrier, without instructions from the owner, forwarded the shipment over another route at a higher rate. The commission finds that the initial carrier had no legal right to divert the shipment involved from the route specified in the bill of lading, and that, therefore, it is liable for the resulting increase in charges. Reparation awarded. (33 I. C. C., 571.)

Commutation Tickets

Wellesley W. Gage v. Erie. Opinion by the commission:

Complainant purchased from defendant a fifty-trip family ticket good between Ridgewood, N. J., and New York. The tariff authority for the ticket contained the following provision:

> This class of ticket under conditions of its contract is valid for passage for one year from date of passage, except where otherwise noted, and good only for transportation of the person whose name appears thereon and members of his immediate family and servants therein. The expression "immediate family" applies to those not only living with, but entirely dependent upon, the person whose name appears on face of ticket.

The commission finds that the carrier acted correctly when it refused to honor the ticket when presented by the son-in-law who lived with, but was not dependent upon, complainant. Complaint dismissed. (33 I. C. C., 593.)

Oregon-Washington's Ownership of Boats on Willamette and Columbia Rivers

Opinion by Commissioner Clark:

Upon application of the Oregon-Washington the provisions of section 5 of the act to regulate commerce, as amended by section 11 of the Panama Canal act, for an extension of time beyond July 1, 1914, during which petitioner may continue to operate boats on the Willamette and Columbia rivers, Lake Coeur d'Alene, and the Snake river; the commission holds that the Oregon-Washington does or may compete with its boats in their operations on the Willamette and Columbia rivers, Lake Coeur d'Alene, and the Snake river within the meaning of the act, but that the operation of these boats is in the interest of the public and of advantage to the convenience and commerce of the people; that their continued operation by petitioner will neither exclude, prevent, nor reduce competition on the routes by water, and that

the application should be granted. The rates, fares, schedules and regulations of these boats governing traffic subject to the act, moved by them, must henceforth be filed with the commission. (33 I. C. C., 658.)

Ownership of Steamboat Line Between Carrabelle and Apalachicola, Fla.

Opinion by Commissioner Meyer:

The Georgia, Florida & Alabama asks that it be allowed to continue to own and operate a steamboat between Carrabelle and Apalachicola, Fla. The commission finds that so long as their respective operations remain as at present, the boat line is but an extension of the rail line and the rail line does not, or may not, compete for traffic with the boat line within the meaning of the act. Petitioner's continued ownership and operation of the rail line and boat line is not, and will not be, in violation of section 5 of the act to regulate commerce, as amended by the Panama Canal act. (33 I. C. C., 630.)

STATE COMMISSIONS

A meeting of representatives of the National Association of Railway Commissioners was held at Chicago on Wednesday to consider what part the state commissioners shall take at the valuation conference before the Interstate Commerce Commission, Division of Valuation, at Washington on May 27.

The railroad commission of Louisiana has issued an order prohibiting the railroads of that state from requiring notice of claims for damage to freight to be filed within four months; the commission declares that the carriers must obey the law of the state allowing two years from the date of shipment in which to file such claims.

COURT NEWS

The Supreme Court of the United States, in an opinion handed down last Monday, decides against the Interstate Commerce Commission in its suit to compel F. W. Ellis, general manager of the Armour Car Line, to answer questions and produce papers relative to alleged unreasonable allowances paid by railroads for the use of Armour's cars.

The Chicago, Rock Island & Pacific, the St. Louis, Iron Mountain & Southern and the St. Louis Southwestern have filed a petition in the United States district court at Little Rock, Ark., asking an order to restrain the Arkansas Railroad Commission from enforcing the state two-cent passenger fare law. The court recently issued an injunction restraining the enforcement of the law as to the St. Louis & San Francisco. The petition will be argued on May 28.

Presentation of Freight Claim—Burden of Proof

In an action for injury to livestock the bill of lading stipulated that claim must be presented within 30 days. The Washington Supreme Court holds that the burden of proof of presentation of the claim rests on the plaintiff. The presentation of claim was an affirmative fact peculiarly within the knowledge of the plaintiff, especially when applied to a shipment accompanied by an agent of the shipper. Moreover, it would ordinarily be an easier matter for the shipper to prove that such a claim had been presented than for the railroad to prove the negative thereof. Henry v. Chicago, M. & P. S. (Wash.) 147 Pac. 425.

Private Siding—Obligation to Furnish Cars

A railroad company contracted with a lumber company for the construction and maintenance of a spur track for the exclusive benefit of the lumber company. Subsequently the lumber company bought the timber on a tract of land to be delivered on board cars on the spur track. In an action by the seller of the timber against the railroad company for refusal to furnish cars at the spur, the Texas Court of Civil Appeals holds that the company was under no contract obligation to the plaintiff to furnish cars or to receive freight from him. The contract between the road and the lumber company was not made for the plaintiff's benefit, and he was an entire stranger thereto. And, under the rule that railroads are only required by law to furnish cars at stations provided for the service of the public, or where the railroads are in the habit of accepting freight from any person offering it for transportation, the defendant was under no obligation to plaintiff at the spur. It was a private track, and, even if the road owed the plaintiff the duty to furnish cars, it had no notice of the contract between him and the lumber company and no knowledge of the facts which would make the damages claimed the probable result of its failure to furnish cars. Beaumont, S. L. & W. v. Moore (Tex.) 174 S. W., 844.

Liability of Initial Carrier—Surrender of Bill of Lading

Goods were shipped under a bill of lading requiring surrender of the original before delivery to the consignee. The shipment was delivered by the terminal carrier upon the consignee's written order without surrender of the bill. Following the ruling of the Supreme Court of the United States in Atlantic Coast Line v. Riverside Mills, 219 U. S. 186, the Michigan Supreme Court holds, in an action by the shipper against the initial carrier, that section 7 of the interstate commerce act covers such a claim, and that the initial carrier is liable. Thomas v. Blair, receiver of Pere Marquette (Mich.), 151 N. W., 1,041.

Diversion of Water—Unexpected Injury

In a building adjacent to the railroad right of way, there were stored 50 odd barrels of lime. The ditch and culvert along the right of way were sufficient to carry away surface waters ordinarily collected in the ditch, but an exceptionally heavy rainfall caused the water to be set back, and to reach the lime, causing a fire which destroyed the buildings. In an action against the company, it was held by the New York Appellate Division that it was not guilty of actionable negligence in maintaining the ditch and culvert, and was not liable for the fire. The injury was not of such a nature as a reasonably prudent man would anticipate. Snook v. New York Central, 152 N. Y. Supp., 564.

Crossing Accident—Contributory Negligence

A boy of 12 years was riding on a baker's wagon, which was driven over a crossing with such gross carelessness on the part of the driver that a collision occurred, resulting in the boy's death. In an action therefor it was held by the Maine Supreme Court that no recovery could be had, not on the ground of imputed negligence of the driver, a doctrine which does not obtain in Maine, but because of the boy's own want of due care. He was a bright and intelligent boy, familiar with the crossing and its approaches, and knew it to be a place of danger, and yet he approached the crossing without taking the slightest precaution, either by looking or listening. Crosby v. Maine Cent. (Me.) 93 Atl., 744.

Power to Condemn Waters

The Pennsylvania Supreme Court holds that a railroad company, chartered under the general railroad laws of the state, cannot, in the exercise of its right of eminent domain, condemn for the use of its engines or other corporate purpose the water of a stream over which it has built its roadbed on a right of way acquired by condemnation, its statutory authority being limited to the appropriation of land and material for the location and construction of the roadway. Connellsville & S. L. v. Marketon Hotel Company (Pa.), 93 Atl., 635.

Duty Toward Trespassers on Tracks

The Kentucky Court of Appeals holds that proof that an engineer looked ahead when several hundred feet from a trespasser will warrant a judgment against the railroad for the man's death on the theory that he was seen and the engineer failed to use reasonable care to avoid injury. If the engineer did see the traveler at this point, he might, in the exercise of ordinary care, have concluded that in proper time the man would have left the track, especially as the conditions were such that he could do so quickly and safely. Willis v. L. & N. (Ky.), 175 S. W., 18.

Liability of Initial Carrier—Non Delivery

A consignor, upon learning that his interstate shipment had not been accepted by the consignee and had not been delivered, directed the initial carrier to have the goods returned at once, and then himself took up the matter with the final carrier, making no further application to the initial carrier. The New York Supreme Court, Appellate Division, holds that the initial carrier

was not liable for damages for the final carrier's failure to return the goods to the consignor; any "injury or damage" in such case not being within section 20 of the Interstate Commerce Act, imposing liability on the initial carrier for damage or injury by connecting carrier, nor within section 1 of that act, defining "transportation," as used in section 20, to include services in connection with the receipt, delivery and transfer in transit. Wien v. N. Y. Cent. (N. Y.), 152 N. Y. Supp., 154..

Conductor Not Subject to Telephone-Operator's Hours

The United States Circuit Court of Appeals, Fifth circuit, in the case of the government against the Florida East Coast Railway, appealed from the District Court for the Southern District of Florida, holds that a conductor who is required to stop at stations and by the use of the telephone to report, transmit, receive, or deliver train orders pertaining to his train is not embraced within the terms of the proviso limiting the hours of service of operators to 9 or 13 hours; and, therefore, may be required to remain on duty for 16 hours in a 24-hour period. The decision was by District Judge Maxey, with whom sat Pardee and Walker, circuit judges. Judge Walker dissented.

Conductor E. M. Little, on January 10, 1914, at and between the offices of New Smyrna and Fort Pierce was on duty from 7 a. m. to 11 p. m., and used a telephone in defendant's office at Quay and Lyrata and transmitted or received orders.

After quoting the law Judge Maxey says: The purpose of the proviso was to prescribe shorter hours for work for operators whose primary and principal duities require them to operate telegraphic instruments and telephones, etc. . . . Such employees must perform their duties at a fixed place. It is evident that the intention of the law is that such employees must have a fixed place for work, and at such place they should not be required or permitted to work a longer time than the number of hours prescribed. If the proviso be construed to include a conductor, what number of hours, it may be asked, shall he be permitted to work during the 24-hour period? Shall it be 16, 13, or 9 hours? Having regard for the language of the proviso, it will be scarcely possible to give a satisfactory reply to the question—a difficulty which affords additional ground for holding that as to such employee the proviso is altogether inapplicable.

It seems to us that it would plainly violate accepted canons for construing statutes to include in the proviso a train conductor, having no fixed place for work except on a moving train, and who, under section 2, may be required or permitted to work 16 hours. His primary and chief duty requires him to look after his train, and stopping at a station to transmit or receive an order affecting his immediate train is a mere incidental service which can not operate to classify him as a telegraph or telephone operator or train despatcher. The contention of counsel for the government is that train conductors are included in the words of the proviso, "or other employee," who by the use of the telegraph or telephone despatches, reports, etc. We have endeavored to show that it was not the intention of the lawmakers to so include them. But for another reason the construction insisted upon by the government is thought to be erroneous. The words "or other employee" evidently refer to employees charged with duties similar to those performed by telegraph operators and train despatchers, in accordance with the following recognized rule for the construction of statutes: "In the enumeration of particulars, general and comprehensive terms are sometimes used in the construction of which reason and good sense require that if you would not violate the intention of the writer their meaning must be restricted to things of a like nature and description with the particulars among which they are found." (3 Words & Phrases, 2328.)

This proviso of section 2 of the "hours-of-service act" was construed by the Circuit Court of Appeals for the Eighth circuit in Missouri Pacific v. United States, 211 Fed., pages 893-897. At page 897 it was said by the court:

> As the word "employee" in the proviso of section 2 includes "operator" and "train despatcher," the conclusion here is irresistible that Congress intended by the use of the words "other employees" to mean an employee engaged primarily in the same class of service as would be performed by an operator or train despatcher.

In our construction of the statute we have steadily kept in view the beneficent purpose of the law. If we have construed it properly, the Congress may enact such further legislation as may be deemed best for the public interests.

Railway Officers

Executive, Financial, Legal and Accounting

W. G. Davidson has been appointed treasurer of the Pacific & Eastern with office at Portland, Ore., succeeding William Gerig, resigned.

F. S. Forest has been appointed secretary of the central committee of safety of the Oregon-Washington Railroad & Navigation Company, with headquarters at Portland, Oregon.

M. F. Harden has been appointed cost accountant of the Central of Georgia, with office at Savannah, Ga. It will be his duty, in co-operation with other departments, to prepare, study and interpret statistics of cost and performance.

George H. Smith, whose appointment as general attorney of the Oregon Short Line and general attorney for Utah for the Union Pacific, with headquarters at Salt Lake City, has already been announced, was born in 1874, and was educated in the public schools of Utah. He was graduated from the law department of the University of Michigan in June, 1899. He entered railway service on July 1, 1899, as law clerk in the law department of the Oregon Short Line, and was appointed assistant attorney on January 1, 1900. In 1905 he was appointed assistant attorney for Utah for the Union Pacific and the Southern Pacific. From the spring of 1905 until March 15, 1915, he was also assistant general atorney for the Utah Light & Railway Company.

G. H. Smith

E. E. Calvin, vice-president and general manager of the Oregon Short Line, has been elected also first vice-president of the San Pedro, Los Angeles & Salt Lake, with headquarters at Salt Lake City, Utah, succeeding W. H. Bancroft, deceased.

Operating

George Johnson has been appointed superintendent of the Pacific & Eastern, with headquarters at Midford, Ore.

George W. Jett has been appointed superintendent of telegraph of the Norfolk & Western, with office at Roanoke, Va., vice W. C. Walstrum, deceased.

Paul McKay has been appointed assistant superintendent of the Portland division of the Spokane, Portland & Seattle, with headquarters at Portland, Ore.

C. A. Hawkins has been appointed superintendent in charge of traffic and operation of the Nezperce & Idaho and the Lewiston, Nezperce & Eastern, with headquarters at Lewiston, Idaho, succeeding W. A. Pease, resigned to engage in other business.

Traffic

M. E. Ward has been appointed commercial agent of the Ft. Smith & Western, with headquarters at Ft. Smith, Ark.

John G. Elgin, city passenger agent of the Baltimore & Ohio, at Louisville, Ky., has been appointed district passenger agent, with headquarters at Louisville, succeeding R. S. Brown, deceased.

James T. Neison has been appointed general agent of the Missouri Pacific-Iron Mountain System, with headquarters at Philadelphia, Pa., succeeding A. S. Edmunds, resigned to engage

in other business. The position of commercial agent at Pittsburgh, Pa., has been abolished.

G. M. Bowman, traveling agent of the Chicago, Milwaukee & St. Paul, has been appointed commercial agent at Cincinnati, Ohio, succeeding E. H. Spence, who has been transferred to Pittsburgh, Pa.

C. C. P Kausch, who has been appointed general freight agent of the Missouri Pacific-Iron Mountain System, with headquarters at St. Louis, was born September 24, 1872, at St. Louis, Mo., and was educated in the public schools. He entered railway service July 1, 1888, as office boy for the Missouri Pacific, and was subsequently rate clerk, tariff clerk, chief tariff clerk and chief clerk of the general freight office. On March 1, 1907, he was appointed assistant general freight agent of the road from which position he is now promoted.

W. I. Jones, whose appointment as general freight agent of the St. Louis, Iron Mountain & Southern, with headquarters at St. Louis, has already been announced, began railway work in 1886 as a locomotive fireman on the Iron Mountain. He was employed in that capacity until October, 1888, when he was transferred to the local office of the Missouri Pacific and after remaining there about 15 months went to the traffic department. He left railway work in May, 1891, returning in March, 1901, as chief clerk to the assistant general freight agent of the Missouri Pacific. In November, 1906, he was promoted to commercial agent at Monroe, La., returning to the general office as chief clerk to the freight traffic manager on November 1, 1907. Mr. Jones was made assistant general freight agent in December, 1910, and on August 1, 1913, he was appointed assistant to the general traffic manager of the same road. In March, 1914, he was appointed assistant to the vice-president.

W. I. Jones

W. H. Tayloe, whose appointment as passenger traffic manager of the Southern Railway with headquarters at Washington, D. C., has already been announced in these columns, began railway work in May, 1886, as a clerk in the ticket auditor's office of the Chesapeake & Ohio, at Richmond, Va. From October, 1886, to July, 1889, he served on various roads in the South as stenographer, and in August, 1889, was appointed stenographer and rate clerk to the general passenger agent of the Richmond & Danville, at Birmingham, Ala. From May, 1890, to August of the following year he was traveling passenger agent, and then to October, 1891, was chief clerk to assistant general passenger agent of the same road. He was then consecutively traveling passenger agent at New York, chief clerk to assistant general passenger agent at Savannah, Ga., and at Washington, D. C., of the same road, and later for about four years was district passenger agent of the same road and its successor, the Southern, at Atlanta, Ga. In August, 1896, he was appointed district passenger agent of the Southern Railway at Norfolk, Va., and from February, 1897, to December, 1900, was assistant general passenger agent at Louisville, Ky., when he was transferred in the same capacity to Atlanta, Ga. In May, 1904, he was promoted to general passenger agent of the same road at Washington, D. C. Then, from August, 1909, to December 31, 1912, he was general agent of the freight and passenger departments of the Southern Railway at Denver, Colo. On January 1, 1913, he was appointed traffic manager of the Chesapeake Steamship Company, with office at Baltimore, Md., which position he held at the time of his recent appointment as passenger traffic manager of the Southern Railway, as above noted.

Engineering and Rolling Stock

Frank A. Merrill, acting engineer maintenance of way of the Boston & Maine at Boston, Mass., has been appointed engineer maintenance of way.

William Brandt has been appointed general foreman of the shops of the New York, Chicago & St. Louis, at Conneaut, Ohio, succeeding T. C. Baldwin, promoted.

W. C. Sealy has been appointed master mechanic of the Ontario lines of the Grand Trunk, with headquarters at Toronto, Ont., in place of J. Markey, deceased.

E. A. Hadley, whose appointment as chief engineer of the Missouri Pacific-Iron Mountain System, with headquarters at St. Louis, Mo., has already been announced in these columns, was born in Lowell, Mass., in 1879, and was educated in the common and high schools, graduating from the Lowell high school in 1897. From 1897 to 1901, he was apprenticed to Smith & Brooks, civil engineers, Lowell, Mass., and there secured a combined course of engineering study and practice. In 1901 he entered the employ of the Boston & Maine, and was subsequently draftsman, assistant engineer and resident engineer until 1910. On June 1, 1910, he was appointed to the position of engineer of design of the Missouri Pacific. During the past 18 months he has been engaged on special engineering investigations for the president's office under the title of assistant engineer.

E. A. Hadley

O. E. Selby, whose appointment as principal assistant engineer of the Cleveland, Cincinnati, Chicago & St. Louis, with office at Cincinnati, Ohio, has already been announced, was born on March 9, 1869. He was educated in the common and high schools and the State University of Iowa. He entered railway service in 1887 as leveler and draftsman for the Chicago, Burlington & Northern. He was subsequently connected with the Illinois Valley & Northern and the Houston Central Arkansas & Northern until 1890, when he became resident engineer on the construction of the Louisville & Jeffersonville bridge over the Ohio river at Louisville, Ky. He remained in that position until 1899, when he was appointed assistant engineer of the Cleveland, Cincinnati, Chicago & St. Louis. In 1905 he was appointed bridge engineer and later engineer of bridges and structures, from which position he is now promoted.

O. E. Selby

C. L. P. Russel, assistant supervisor of the Pennsylvania Railroad at Middletown, Pa., has been appointed supervisor of Division No. 31, with office at Cresson, vice W. B. Groff, Jr., transferred, and S. H. Kuhn, supervisor at Olean, N. Y., has been ap-

pointed supervisor of Division No. 28, with office at Norristown, vice E. J. Ayars, transferred.

G. E. Ellis, signal engineer of the Kansas City Terminal, has been appointed service signal engineer for the Interstate Commerce Commission, with headquarters at Washington, D. C.

Tom Windle, formerly master mechanic of the International & Great Northern at Palestine, Tex., has been appointed master mechanic of the Denver & Salt Lake, with headquarters at Tabernash, Colo.

Henry Bartlett, mechanical superintendent of the Boston & Maine at Boston, Mass., has been appointed chief mechanical engineer, reporting to the president. He will have general supervision over matters connected with motive power and other equipment in so far as may be necessary to preserve the standards and systems of the railroad and to secure adherence thereto. All plans and specifications for locomotives and other equipment will be prepared by him and approved by the general manager. The construction of new equipment will be supervised by him and he will perform such other duties in connection with motive power and equipment as may be assigned to him by the president. Charles H. Wiggin, superintendent of motive power at Boston, will report to the general manager. He will have charge of all locomotives and car shops, engine houses and appurtenances, and of the maintenance, repair, and inspection of locomotives and other equipment. The master mechanics, superintendents of shops, electrical superintendent, general car inspector, general air brake inspector and the general piece work inspector will report to him.

OBITUARY

W. C. Walstrum, superintendent of telegraph of the Norfolk & Western at Roanoke, Va., died on May 8, at the age of 60.

P. P. Mirtz, assistant engineer, mechanical department, of the New York Central, died suddenly on May 11, at his home in New York.

O. S. Cockey, general agent of the freight department of the Grand Trunk at New York, died on May 9, at White Sulphur Springs, W. Va.

Charles H. Bronson, formerly from April, 1890, to 1904, auditor of the Pittsburgh & Lake Erie, died on May 3, at Cleveland, Ohio, at the age of 70.

William Pond Harris, formerly until 1898, superintendent of the Plant System, now a part of the Atlantic Coast Line, died on April 24, at his home in Johnson City, Tenn., at the age of 69. He began railway work in the operating department, and served consecutively on the Delaware, Lackawanna & Western; then as superintendent of the Chesapeake & Ohio; the Louisville & Nashville; Baltimore & Ohio; Atchison Topeka & Santa Fe; Charleston, Cincinnati & Chicago, now a part of the Carolina, Clinchfield & Ohio and the Plant System, until 1898, and since that time he had been out of railway work.

Fuel Supplies on the Swedish Railways.—The Swedish state railways are reported to have recently contracted for 200,000 tons of German coal briquettes and 72,000 tons of German coke. A mixture of the two is to be used as a locomotive fuel on some lines. The price is considerably less than that of English coal.

Efforts Made by English Railways to Release Men for the Colors.—Further action by the railway companies, in order to release men for the army or to allow them to be employed on munitions, is likely to be shortly put into force. No men of military age and physique are now taken on, and where their services can be utilized without disadvantage, women are drafted into the service instead. With a view to reducing clerical labor and thereby release clerks eligible for military service, it is proposed to have all parcels and freight sent prepaid, and so reduce bookkeeping work. The practice in force on many railways of prepaying parcels charges by stamps will possibly be universally adopted. Parcels and freight will probably be collected and delivered by the same cartage service, and thereby save men, horses and drays, and a further economy in this direction is possible by further curtailing the hours when goods are received.

Equipment and Supplies

LOCOMOTIVE BUILDING

The Fort Worth & Denver City has ordered 10 superheater oil-burning, Mikado type locomotives from the Baldwin Locomotive Works.

The Boston & Albany has given the American Locomotive Company an order to convert 10 Consolidation type locomotives to Mikado type.

The Serbian Government is reported to have ordered about $50,000 worth of small locomotive parts from the American Locomotive Company.

The Western Maryland reported in the *Railway Age Gazette* of May 7 as being in the market for 10 locomotives, has issued inquiries for 15 Mallet type locomotives.

The French Government, which was reported in the *Railway Age Gazette* of last week as having issued specifications for 100 large locomotives, is also in the market for 25 or 50 locomotives for the Paris-Orleans line.

The Cuba Railroad, reported in the *Railway Age Gazette* of last week as having ordered 10 ten-wheel type locomotives from the American Locomotive Company, has ordered 15 locomotives from that company. As this order is in addition to another recent order for 15 locomotives, this makes a total of 30 locomotives.

CAR BUILDING

The Virginian has ordered 500 steel underframes from the Greenville Steel Car Company.

The Chicago, Rock Island & Pacific has issued inquiries for 5,000 40-ft., 40-ton all-steel box cars.

The Norfolk & Western is inquiring for 10 70-ft. coaches, 12 70-ft. combination baggage and express cars and 2 70-ft. postal cars.

The Chicago & North Western has ordered 2,000 steel underframe box cars from the Western Steel Car & Foundry Company.

The Bingham & Garfield is in the market for 50 60-ton Clark extension side dump ore cars for use by the Utah Copper Company.

The Toronto, Hamilton & Buffalo has ordered 10 steel underframe and steel frame stock cars from the National Steel Car Company.

The Chicago Elevated Railways have ordered 122 all-steel motor cars from the Cincinnati Car Company. These cars will be equipped with Baldwin trucks.

The Chicago, Milwaukee & St. Paul is reported to be contemplating asking prices on 2,000 cars in addition to the 2,000 it plans to build in its own shops. This item has not been confirmed.

The Fort Worth & Denver City has ordered 1,200 40-ft., 40-ton steel center sill box cars, 300 40-ft., 40-ton steel center sill stock cars, and 200 100,000-lb. capacity, steel gondola coal cars from the Haskell & Barker Car Company.

The Department of Commerce has ordered one all-steel fish-distributing railway car from the Harlan & Hollingsworth Corporation, for use in connection with the work of the Bureau of Fisheries. The car will be fully equipped for movement on fast passenger trains.

The Interborough Rapid Transit has issued inquiries for 974 trucks. The order which this company recently placed with the Pullman Company for 478 subway car bodies has been approved by the New York Public Service Commission, First district.

The Russian Government has ordered 2,000 steel underframe box cars from the Eastern Car Company, New Glasgow, N. S., and 2,000 from the Canadian Car & Foundry Company. It has also ordered 20,000 steel axles from the Cambria Steel Company, and is reported to have placed 8,000 cars with the Pullman Company and 2,000 cars with the Seattle Car & Foundry Company. The negotiations for a large order for cars with the Pressed Steel Car Company, are reported as not yet completed.

IRON AND STEEL

The Havana Central has ordered 1,000 tons of rails from the Maryland Steel Company.

The Chicago, Rock Island & Pacific has ordered 10,000 tons of rails from the Illinois Steel Company.

The Atchison, Topeka & Santa Fe has ordered 2,700 tons of steel for oil tanks from the Kennicott Company, Chicago.

The Chicago, Burlington & Quincy has ordered 1,353 tons of steel for various bridges from the Fort Pitt Bridge Company.

The Chicago, Milwaukee & St. Paul is in the market for 32,000 tons of steel to cover construction of freight cars at its Milwaukee shops.

The Russian Government has issued inquiries for 6,000 to 8,000 tons of railroad spikes to be made to Canadian Pacific standards. It is supposed that these will be used in connection with the double tracking of the Trans-Siberian now under way.

MACHINERY AND TOOLS

The Pennsylvania Railroad is in the market for a 25-ton gantry crane.

The Pressed Steel Car Company is inquiring for a number of machine tools.

The Baltimore & Ohio is in the market for a 60-ft. electric gantry crane, for Georgetown, D. C.

The Delaware, Lackawanna & Western has ordered a vertical milling machine and a 36-in. swinging lathe.

The Lehigh & New England is in the market for a 35-ton double-trolley and a 10-ton single-trolley electric traveling crane and for a number of machine tools for the new shops at Pen Argyle.

Russo-Bulgarian Railway.—It is reported that two Russian delegates have arrived in Sofia with the object of concluding an agreement with the Bulgarian Railway Administration, with a view to establishing direct railway communication between Salonika and Russia.

Wages of Employees of the London Tubes.—It is specially to the credit of the London underground electric railway companies that they have agreed to grant to their employees the same advances of wages as have been conceded to meet war conditions of living expenses by the railway companies of the country generally. It must be borne in mind that the tube railway companies, while suffering from disadvantages arising from the state of war, do not share in the advantages arising from the government guarantee to make up net revenue to that accruing before the war began. As the tube railways have no physical junctions with any of the main lines of the country, they are not represented on the Railway Clearing House, and so they did not come within the scope of the government guarantee. They have no goods traffic, their capitalization is necessarily high, and the dividends on ordinary stock—where they exist at all—are low. Yet they have generously come into line with British railways generally, and the war bonus, to be retrospective from the middle of February, is to be paid to many men besides those embraced in the conciliation scheme. While there is a prospect that part at least of the war bonus wages will be repaid by the government to British railway companies generally, it appears doubtful whether this will be the case in regard to the tube companies. Gratitude is rather a scarce sentiment as from employed to employer, but there surely ought to be some feeling of that sort on the part of the underground railwaymen.—*Railway Gazette.*

Supply Trade News

Charles W. Sherburne, founder of Sherburne & Company, Boston, Mass., died on May 6.

The Van Dorn Iron Works, Cleveland, Ohio, has increased its capital stock from $150,000 to $350,000.

D. J. Normoyle has been appointed manager of the Philadelphia office of the Niles-Bement-Pond Company, Inc.

The Vulcanite Portland Cement Company about May 1 will move into new offices at 8 West Fortieth street, New York.

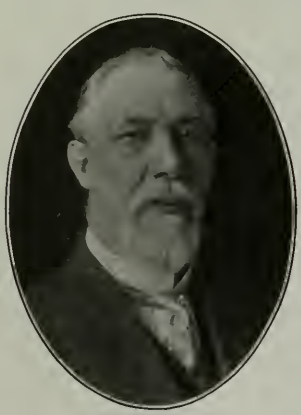
The Taylor Wharton Iron & Steel Company, Philadelphia, Pa., is working on an order for shrapnel shells at its Tioga plant.

The Western Electric Company has moved its Kansas City distributing house into a new warehouse at 608-610 Wyandotte street.

Joseph F. Dixon, Jr., foreign sales manager of the Allis-Chalmers Company, died at his home in Brooklyn, N. Y., on April 30.

The Pyrene Manufacturing Company has moved its head offices in New York to the Vanderbilt Concourse building, 52 Vanderbilt avenue.

George T. Reiss, vice-president of the Niles Tool Works Company, and a director of the Niles-Bement-Pond Company, died at his home in Hamilton, Ohio, on May 5. Mr. Reiss had been in the employ of the Niles Tool Works Company continuously since 1878. He was born in Cincinnati, December 6, 1849. In 1877 he went to Hamilton. He was first employed there as a draftsman, but in 1878 he was given the position of master machinist with the Niles Tool Works Company, and placed in charge of the company's engineering department. He was subsequently chief mechanical engineer and later superintendent of the drafting department. Eventually, he became vice-president of the company and a director of the Niles-Bement-Pond Company. He was an inventor of considerable importance and held a position of prominence in the affairs of the city in which he made his home.



G. T. Reiss

The Brown & Sharpe Manufacturing Company has recently awarded a contract for the construction of a two-story addition to its plant at Providence, R. I.

Charles A. Billings has resigned as manager of the Brooklyn plant of the American Bridge Company, and will devote his entire time to personal interests.

J. W. White, formerly of the Union Switch & Signal Company, has resigned to become special representative of the Electric Cable Company, Bridgeport, Conn.

Charles Spalding, representative of the Gisholt Machine Company, Madison, Wis., in Chicago territory, has transferred his headquarters from the Chicago office to Detroit.

A. W. De Revere has been appointed district sales manager of the Terry Steam Turbine Company, Hartford, Conn., in charge of offices at 524 Monadnock block, Chicago.

The Baldwin Locomotive Works, which is reported to have received a contract for war material, has awarded a contract for

the construction of a large building to be erected adjoining the Eddystone plant.

Paul B. Liebermann, formerly assistant chief engineer of the Sprague Electric Works of the General Electric Company, has become associated with the Hyatt Roller Bearing Company as engineer of tests.

Alfred P. Stewart, who last year purchased a controlling interest in the L. A. Green Equipment Company, steel railroad supplies, announces that he will continue the business under his own name, with offices at 202 Oliver building, Pittsburgh, Pa.

The item in the *Railway Age Gazette* of April 9, page 808, announcing the appointment of a new manager of the Boston branch of Manning, Maxwell & Moore, Inc., incorrectly gave the name of the new branch manager as J. S. Wright. The name given should have been Jos. Wainwright.

Fred A. Geier, president of the Cincinnati Milling Machine Company, Cincinnati, has purchased the interest of Larz Anderson in the Cincinnati Shaper Company and the Cincinnati Gear Cutting Machine Company, Cincinnati. P. G. March will continue as president, and the business will be extended.

E. E. Winship, formerly manager of the Cincinnati branch of Manning, Maxwell & Moore, Inc., has been appointed manager of the Cleveland branch, effective May 1. C. H. Overkamp, formerly of the Conover-Overkamp Machine Tool Company, Dayton, Ohio, has been made manager of the Cincinnati office.

The Davis Manufacturing Company, Milwaukee, Wis., manufacturer of gasoline motors, has closed a contract with the Railway Engineering & Equipment Company, Indianapolis, Ind., for the construction of motors, trucks and underframes for the entire output of railway coaches of the latter company for a period of five years.

P. H. Biggs, sales manager of the Cleveland territory of Manning, Maxwell & Moore, has resigned from that position and has taken an office in the Schofield building, Cleveland, Ohio, under the name of the P. H. Biggs Machinery Company. He will handle machine tools and hydraulic machinery, and represent a limited number of manufacturers in the northern Ohio territory.

The Whiting Foundry Equipment Company, Harvey, Ill., has taken over the foundry equipment business of the Central Iron Works, Quincy, Ill., thereby adding to its line the dust arresters and water cinder mills formerly manufactured by that company. The Whiting Company has retained one of the engineers of the Central Iron Works. It will also be prepared to furnish repairs for Central Iron Works equipment.

The Pittsburgh Steel Car Company recently organized by Pittsburgh capital is planning to erect a plant at Greenville, Pa., which will provide for a capacity of 7,500 steel cars a year. The officers of the company are W. A. Scott, Jr., president; H. B. Scott and L. A. Meyran, vice-presidents; H. W. Best, treasurer; George W. Ramby, secretary, and E. B. Caughey, office manager. The offices are at 512 Ferguson building, Pittsburgh.

The Westinghouse Air Brake Company, in order to fill the portion of the ammunition order recently awarded it by the American Locomotive Company, has erected at its works at Wilmerding, Pa., two temporary buildings, one 65 ft. by 175 ft., and the other 65 ft. by 500 ft., and may also erect other buildings. The necessary machinery is being installed, and it is reported that the company has bought all of the machine tools it will require to fill the order. The company expects to complete the contract in 14 months.

The Pacific Great Eastern Equipment Company has been incorporated with a capital of $3,000,000 and office in Vancouver, B. C., to purchase, hire or manufacture railway cars, locomotives or other rolling stock, deal in rails, contractors' equipment, appliances and tools and to sell or hire the same to railway companies and contractors. The provisional directors are: P. Welch, E. F. White, E. W. Kaufmann, A. H. Sperry and D. C. Pennington, Vancouver, B. C., all of whom are associated with the Pacific Great Eastern Railway.

The Reading-Bayonne Steel Casting Company has recently sold its Bayonne, N. J., plant to the Bayonne Steel Casting Company, and its Reading, Pa., plant to the Reading Steel Casting Company. The Bayonne Steel Casting Company has elected officers as follows: William D. Sargent, president and treasurer, and A. J. Passino, secretary. H. K. Pollard has been appointed sales manager, and Charles Lidstone, superintendent. The officers of the Reading Steel Casting Company are: J. Turner Moore, president; M. G. Moore, vice-president; H. M. Doty, secretary and treasurer; M. G. Moore is also sales manager, and J. Douglas Genger, superintendent. The Reading-Bayonne Steel Casting Company was a combination of these two companies organized about December, 1911.

The Westinghouse Electric & Manufacturing Company which, as noted in last week's issue, page 992, has received a large order for rifles from the British government, has practically completed negotiations for the purchase of the plant and business of the J. Stevens Arms & Tool Company of Chicopee Falls, Mass., and the plants of the Stevens-Duryea Company in Chicopee Falls and East Springfield. The company plans to fill the order at these plants. L. A. Osborne, vice-president of the company, will be in executive charge of the work, and Walter L. Clark, recently vice-president of the Niles-Bement-Pond Company, will be manager of the combined plants in charge of operations. The corporate and commercial identity of the J. Stevens Arms & Tool Company will be retained, and its usual line of rifles will be manufactured. When the war order rush is over the other plants will probably be devoted to the manufacture of the usual line of Westinghouse products.

TRADE PUBLICATIONS

Water Softeners.—The Kennicott Company is the subject of a 29-page booklet prepared by Elbert Hubbard. The booklet is written in a breezy style and will be found of considerable interest.

Door Hangers.—Catalog No. 12, recently received from the Richards-Wilcox Manufacturing Co., Aurora, Ill., illustrates in detail the line of door hangers, grindstones and hardware specialties produced by this company. The book is thoroughly illustrated and contains 296 pages, including an index.

Arc Welders.—The subject of bulletin 1915A, from the Welding Materials Company, Inc., 114 Liberty street, New York, is variable voltage welders. The subject of electric arch welding is dealt with at some length, and a number of illustrations are given, showing its application to locomotive and car work.

Nut Tapping Machines.—Tapper Talks, Nos. 1 and 2 have recently been issued by the National Machinery Company, Tiffin, Ohio, and deal with the National automatic nut tappers which operate on the bent cap principle. Illustrations of the machine at work are included and data given as to the advantages claimed.

Insulating Brick.—Good Furnaces Made Better is the subject of the booklet issued by the Armstrong Cork Company, Pittsburgh, Pa., and dealing with the Nonpareil insulating brick for furnaces and ovens. Illustrations and descriptive matter are included concerning the application of this type of brick for various furnaces.

Valves.—The 1915 catalog, No. 18, from the Golden-Anderson Valve Specialty Company, Pittsburgh, Pa., contains 140 pages, giving in considerable detail descriptive and illustrating matter concerning the various valves manufactured by this company. The valves include a large variety of types for both steam and water service.

Power Plant Oil Filters.—Bulletin No. 10, issued by The Richardson-Phenix Company, Milwaukee, Wis., is devoted to the Peterson power plant oil filter and accessory apparatus for central oiling systems. A large number of half-tone and line engravings are included, and considerable information is given concerning oil filtration.

Cranes.—Book No. 107, issued by the Industrial Works, Bay City, Mich., illustrates and describes the various crane equipments which this company manufactures. These cranes include wrecking cranes, pile drivers, locomotive cranes, lifting magnets, etc. A section is also devoted to other products, such as pillar and transfer cranes, rail saws, transfer tables and wrecking tools. The book contains 88 pages and an insert containing illustrations of a partial set of Industrial wrecking tools. The printing and illustrations are excellent, a high grade of paper being used.

Railway Construction

Alabama Roads.—The Cedar Lake Mill Company, Brewton, Ala., is building a railroad to Brooklyn, it is said, and has decided to extend the line east to Andalusia, about 21 miles.

British Columbia & White River.—An extension of time in which to build this line has been granted by the Canadian parliament. The projected route is from Bear Creek, a tributary of the Chilkat river in British Columbia, to White river, thence to the boundary between Yukon territory and Alaska. C. M. Marpole, G. E. MacDonald, G. E. Wilson, A. McDonnell and Ironside are the provisional directors. (February 26, p. 389.)

Calgary & Fernie.—The Canadian parliament has granted an extension of time in which to build this projected line from Calgary, Alta., southwest to Fernie, B. C. J. R. Lawreym, S. S. Monaham, Victoria, B. C., and A. Mutz, Fernie, are interested. (January 2, p. 50.)

Canadian Western.—An extension of time has been granted to this company in which to build from the International boundary in Alberta via Pincher creek, Cowley and along Old Man river valley to the Livingstone mountains, thence to Calgary, Alta., also to build a branch line west to Michel, B. C. The company was incorporated in 1909, and the provisional directors included J. S. Hough, A. S. Kildall, L. L. Metcalfe and O. L. Boynton, Winnipeg, Man. Hough, Campbell & Ferguson, Winnipeg, are solicitors for applicants.

Charlotte Harbor & Northern.—This company is planning to build an extension, it is said, from Ridgewood, Fla., east to Bartow, four miles, for which surveys are now being made.

Chicago, Milwaukee & St. Paul.—This company has resumed track elevation on its Wilson avenue extension at Chicago, Ill.

Entwistle & Alberta Southern.—Incorporated in Canada to build from a point on the Grand Trunk Pacific, at Entwistle, Alta., south to the Saskatchewan river, about 60 miles. The provisional directors include C. L. Hervey, D. A. O'Meara, Montreal, Que.; T. A. Burgess, L. A. Cote and R. H. Pringle, Ottawa, Ont. (March 12, p. 493.)

Florida Roads (Electric).—Plans are being made, it is said, to build an electric line from Lynn Haven, Fla., south to Panama City, also to other places. Richard Tillis, Montgomery, Ala., is said to be interested.

Glengarry & Stormont.—It is expected that this line will be open for operation about June 1, from St. Polycarpe, Que., on the Canadian Pacific, southwest to Cornwall, Ont., 28 miles. The Canadian Pacific will operate the line.

Gulf, Colorado & Santa Fe.—This company will spend about $300,000 laying heavier rail and fastenings, and about $25,000 for new turn tables at Gainesville and Fort Worth, Tex. F. Merritt, Galveston, Tex., is chief engineer.

Indianapolis Union Railway.—This company has been empowered to issue $4,000,000 in bonds for track elevation work which will eliminate grade crossings by the construction of subways at 11 streets where its track system contains from 2 to 15 tracks. The work will consist of bridges over streets on concrete abutments with earth filling between streets. It will require the rebuilding of the train sheds at the Indianapolis Union station, where there will be 12 through tracks at an elevation of about 15 ft. above street grade. The former grade will be occupied by the baggage rooms, express rooms, etc. The elevation through train sheds will be accomplished entirely on steel structure.

Kanawha, Glen Jean & Eastern.—This company, which operates an 8-mile line from Glen Jean, W. Va., to Tamroy, has under consideration the question of building a two-mile extension.

Kettle Valley Lines.—The Canadian parliament has granted to this company an extension of time in which to build the following branch lines: From Penticton, B. C., to the International boundary at Osoyoos lake; from Summer creek via Allison or Princeton to the junction of Granite creek with the Tulameen river; from One Mile creek to the Copper mountain and Voigt mining camps, 15 miles southwest of Princeton; from Vernon, southerly via Kelowna to Penticton; also to build from a point on the line to be built from Summer creek northerly to Otter Summit, about 30 miles south of Merritt; from near Tulameen for about 50 miles up the Tulameen river valley, from Grand Forks for 50 miles up the north fork of the Kettle river; from Midway to Hedley, and from Penticton to Nicola. (January 29, p. 211.)

Lake Erie & Northern.—The question of carrying out the electrification of the completed section of this line is now under consideration. The company is building between Galt, Ont., and Port Dover via Paris, Brantford and Waterford, 51 miles, and the line has been leased to the Canadian Pacific. The contractors at work from Brantford south to Port Dover expect to complete the work this year, and if the Brantford-Galt section is electrified the southern section will be operated by the same motive power. Martin N. Todd, president, Galt, Ont.

Mississippi Roads.—Surveys are now being made, it is said, to build a railway from Yazoo City, Miss., east to Carthage, about 60 miles, and the Yazoo City Council has voted $50,000 in aid of the project. Walter C. Murphy, Chicago, Ill., is back of the project, and R. H. Douthat, secretary of the Yazoo Commercial Club, is said to be interested.

Mount Airy & Eastern.—Contracts will be let at once, to build a 3-mile extension in Patrick county, Virginia, and an additional extension of three miles is to be built later. The company now operates a 19-mile line from Mt. Airy, N. C., northeast to Kibler, Va. The principal commodities to be carried on the extensions are logs, lumber and farm products.

New York, Westchester & Boston.—An officer writes regarding the report that the Westchester Northern is to be built in the near future from White Plains, N. Y., northeast to Danbury, Conn., that no definite plans at the present time have been made for the construction of that line.

Ohio Roads.—The city council of Youngstown, Ohio, has authorized an issue of $800,000 of bonds to pay the city's share of the cost of a separation of grades of the city streets and the tracks of the Erie, the Lake Shore & Michigan Southern, the Pennsylvania Company and the Baltimore & Ohio at four different crossings. In all cases the streets will go over the tracks. At one crossing the tracks of the Erie will be depressed. In all other cases the railroad tracks will remain at the present grades. The elevation will consist of steel structures with masonry abutments, and the cost of the work will be divided between the city, the railroad companies and a traction company. Work will be done by contract and the cost is estimated at about $3,500,000.

Petersburg & James River (Electric).—Plans have been made by this company to build an electric line from Petersburg, Va., northeast to City Point, 10 miles. The grading work will be light and there will be very few curves; four small bridges are to be built and one sub-station on the line. J. Walter Long, president; B. R. Walters, secretary and treasurer, 801 Real Estate Trust building Washington, D. C.; J. H. Starkey, chief engineer, Rockville, Md.

Red River & Gulf Terminal.—Incorporated in Texas with $75,000 capital and office at Longview, Tex. The plans call for building a line from the northern terminus of the Port Bolivar Iron Ore line of the Gulf, Colorado & Santa Fe north through Marion and Cass counties, thence northwest through Morris and Red River counties, Texas, to a point on Red river southeast of Hugo, Okla., about 85 miles. G. A. Bodenheim, T. C. Morgan, R. M. Kelly, L. L. Featherstone, all of Longview, J. Bradfield and R. N. Taylor, Daingerfield, and W. D. Myers, Houston, are interested.

Richmond & Eastern.—Incorporated in Virginia to build from Richmond, Va., east to Ft. Lee, about five miles. J. C. Robertson, K. T. Crawley and C. B. Anderson, Richmond, are incorporators.

Roby & Northern.—Incorporated in Texas with $10,000 capital to build from Roby, in Fisher county, Texas, north to North Roby, about five miles. The headquarters of the company are at Roby. C. L. White, president; L. C. Eastland, vice-president, both of Hillsboro, and J. C. McWhirter, secretary, Roby, Texas.

Salt Lake & Utah.—This company has awarded a contract to

W. M. Smith, Salt Lake City, for the grading on an extension from Provo, Utah, to Springville, 6.5 miles; this work was started on May 1. The track laying will be done by company forces. There will be one 45-ft. trestle.

Toronto Suburban (Electric)—Grading work on the line building from Toronto, Ont., west to Guelph, 42 miles, is now under way on the section from the Humber river to Islington. The western section of the roadbed was constructed last year and rails and ties are now being laid. A new bridge is being built over the Humber river. (December 11, p. 1107.)

Westchester Northern.—See New York, Westchester & Boston.

RAILWAY STRUCTURES

Birmingham, Ala.—An ordinance is being prepared providing for the construction of a new bridge at Twenty-first street, to replace the present structure. The railroads will be required to build the new structure.

Cincinnati, O.—The Cincinnati, New Orleans & Texas Pacific intends to rebuild its bridge across the Ohio river at Cincinnati. Plans are not sufficiently advanced at present to give definite information.

Hempstead, Tex.—The Sunset-Central lines will build a new bridge over the Brazos river to replace one washed out by floods.

Lowell, Mass.—The city of Lowell will build a bridge to have two spans each 150 ft. long over the Merrimac river at Pawtucket Falls, Lowell. The new structure is to cost $80,000, and it will carry tracks for the operation of cars of the Bay State Street Railway Company.

Monett, Mo.—The St. Louis & San Francisco will build a new depot to replace one destroyed by fire.

Morgantown, W. Va.—The Buckhannon & Northern has given a contract to the Crossan Construction Company, Brownsville, Pa., for the excavation of about 15,000 cu. yd. This is part of the work on a new terminal at Morgantown for the Buckhannon & Northern. No contracts for the buildings or tracks have yet been let.

Nashville, Tenn.—Plans are being made by the Freeland-Klyce Engineering Company, Nashville, for a bridge to be built by Davidson county over the Cumberland river at Hydes Ferry. It is expected that the bridge will be designed to carry double track for the operation of electric cars.

Raleigh, N. C.—The Norfolk Southern is putting up a small shed at the Raleigh yards for the protection of workmen in placing steel underframes on cars. The building will be 40 ft. by 60 ft. The company has also provided additional tracks for handling about 75 cars at one time. The cost of the work will be about $5,000.

St. Paul, Minn.—The Chicago & North Western is asking for bids on channel changes, levee walls, sewer extensions and riprapping in connection with the new union station at St. Paul.

Saratoga Springs, N. Y.—Work is now under way putting up a new passenger station, to be of steel, iron and brick construction, for the Hudson Valley Railway Company, at Broadway and Congress street, Saratoga Springs. The station proper will be 72 ft. long and 20 ft. wide; it is expected that the improvements will cost about $40,000.

South Richmond, Va.—In connection with new terminal facilities for the Southern Railway at South Richmond, a contract has been awarded to Alsop & Pierce, Newport News, Va., for the construction of a new oil house to cost $6,975.

Tillsonburg, Ont.—The Grand Trunk is building with its own forces a small station at Tillsonburg.

Men of English Railways with the Colors.—Up to February 26 a total of 12,233 men, or 14.1 per cent, of the staff of the London & North-Western Railway had joined the colors, and up to March 15, 1,058 had met with casualties, of whom 126 had been killed or drowned in action and 45 had died of their wounds. There were 67 missing and 137 were prisoners of war.

Railway Financial News

Baltimore & Ohio.—The Maryland Public Service Commission has approved the issue by the Baltimore & Ohio of $40,000,000 4½ per cent short term notes, of the proceeds of which $35,000,000 will be used to retire notes maturing June 1, and the remainder for expenditures on property account.

Delaware & Hudson.—A statement was made at the annual meeting which took place this week that about $26,000,000 had been put into the property [apparently it was not specified whether it was the railroad property or coal properties] which had never been capitalized, and which did not appear on the balance sheet.

Delaware, Lackawanna & Western.—A committee representing stockholders of the Morris & Essex, which is leased to the Delaware, Lackawanna & Western, has been formed, consisting of P. L. Hoadley, president of the American Insurance Company, Newark, N. J.; Edward Milligan, president of the Phoenix Insurance Company, Hartford, Conn.; George C. Van Tuyl, Jr., president of the Metropolitan Trust Company, New York, and W. N. Williams, vice-president of the Aetna Insurance Company, Hartford, Conn. This committee asks for the deposit of stock and the granting of proxies to be filed with the Metropolitan Trust Company, New York, and in the request for proxies says that it is of the opinion that the additional dividend of 1 per cent annually provided for in the lease should not only have been paid by the Lackawanna to the stockholders of the Morris & Essex for some years past, but should also be properly payable in the future. Legal proceedings have been begun by the committee to enforce this view.

Michigan Central.—H. E. Anderson has been elected a director, succeeding to the vacancy caused by the resignation some time ago of James Stillman.

Morris & Essex.—See Delaware, Lackawanna & Western.

Nashville, Chattanooga & St. Louis.—A. G. Candler has been elected a director to fill a vacancy.

Traffic Through the Panama and Suez Canals.—The following comparative table gives the number of vessels using the Panama and Suez canals for the months of August, September, October, November and December:

	Panama		Suez	
	No.	Net tonnage	No.	Gross tonnage
August	24	106,288	250	1,402,864
September	57	322,038	323	1,721,195
October	84	420,357	479	2,635,446
November	92	448,801	370	2,635,446
December	99	439,915	397	2,451,424

The Belgian Railways.—The Belgian lines have now been completely taken over by the German war office, and only Germans are employed, even the old porters not being allowed at the stations. To obtain a ticket it is necessary to have a special pass from the military police headquarters and before obtaining this permit the applicant has to state not only where he is going, but for what reason and for how long. All these facts are duly noted down on the pass. Only German coinage is accepted in payment for a ticket, Belgian money being refused. Civilian passengers are only permitted to travel in third-class cars, for which, however, they pay first-class fares. Second-class cars and the so-called first-class cars (some of these are only known as "reserved," the first-class proper having vanished in Belgium a few years ago save on international trains) are labelled to show that they are exclusively reserved for military passengers. Before the traveler reaches the station he is searched by soldiers and the train itself is reached by walking a quarter of a mile or so from the station. The carriages are neither lighted nor heated, and passengers are forbidden to look out of windows when crossing bridges for fear they be shot by sentries. To add to the pleasures of travel, a 10-mile journey may necessitate two or three changes, with a wait of several hours on each occasion.

Freight Car Maintenance

"The freight equipment is in the worst condition it has been for years," according to a statement made by F. C. Schultz, chief joint interchange inspector at Chicago, the largest interchange terminal in the world. As 10,000,000 cars per year are handled at this point the condition there is indicative of the conditions over the entire country. It is a well known fact that the railway shop forces have been greatly reduced during the past year on account of the general depression in business, and this undoubtedly is the reason why the equipment is in such poor condition. However, there is a limit to which this retrenchment can be carried before it becomes a source of excessive future expense. Every road that has found it necessary to make such retrenchments should carefully watch for this limit with the idea in mind that every dollar saved for dividends this year may mean a sacrifice of two dollars next year. The shop forces should now be augmented in order that the summer and fall business may be properly handled. Lack of equipment means loss of revenue and the lack of equipment in proper condition means a loss of revenue and an increase in loss and damage claims.

Decrease in Railway Legislation

Although the legislatures in the states that have two-cent fare laws have shown no disposition to come to the aid of the railways by restoring a part of the reduction in rates made by the passage of such laws, it is evident that there has been a marked tendency on the part of legislators this year to recognize that restrictive and oppressive legislation has gone about far enough. The Special Committee on Relations of Railway Operation to Legislation has just issued a report calling attention to the fact that the amendment to the boiler inspection act was the only law relating to operation passed during the Congress which adjourned on March 4. It also notes that of 1005 bills relating to railway operation introduced in 43 state legislatures up to May 1, only 94 have been enacted into laws, most of which deal with relatively unimportant features of operation. Of the 43 legislatures that have been in session 31 have already adjourned and the others are expected to conclude their sessions shortly. In 1914, with 14 legislatures in session, 236 bills relating to railway operation were introduced and 27 were passed, but for purposes of comparison it is necessary to go back to 1913, when the legislatures of 42 states were in session. In that year, 1,395 bills of the character under discussion were introduced and 230 were passed. There is probably a greater contrast between the characters of the laws passed than between their numbers. In 1913, for example, there were 14 extra crew laws enacted. In 1915 51 bills were introduced relating to the number of men to be employed in train or switching crews, none of which has been passed, and most of the bills which would have added greatly to the expenses of the railways, including the train limit bills, have thus far failed of enactment.

Costly Government Construction in Canada

The results of government construction of the National Transcontinental Railway in Canada will not be hailed by advocates of government ownership of railways as an argument for the adoption of that policy in this country. The line was originally built with the expectation that it would be leased to and operated by the Grand Trunk Pacific. But because of the enormous amount of expense which the government incurred in building it the Grand Trunk Pacific has decided that it cannot afford to lease it and has refused to take it over for operation. It has become necessary, therefore, for the government itself to assume the burden of operating it; and this it began to do on May 1. Since the Grand Trunk Pacific decided it could not operate the line profitably, it is not reasonable to expect that the government will be able to do so, in view of the heavy losses it has regularly suffered from its operation of the Intercolonial. The story of the National

Transcontinental is instructive. Parts of it have been told from time to time in these columns; but it will bear bringing up to date. The construction of the line was turned over to a government commission in 1904. It was to be 1,804 miles long, and the official estimate of its cost made by the minister of finance was $61,415,000. The road was to be leased to the Grand Trunk Pacific, which, after 1922, was to pay for its use a rental of three per cent of its cost. Up to September 30, 1911, however, the line had cost $109,000,000 and the latest estimate of its total cost was $173,000,000, or nearly three times the original estimate. The Grand Trunk Pacific would have been willing to have leased it if it had cost approximately the amount originally estimated; but it was not willing to pay a rental three times as great as it originally expected to. Much is said by advocates of government ownership about the advantages to be derived from the use of the government's credit in raising capital for railway development. But if, as has proved to be the case in Canada, a government will spend three times as much per mile to build a railway as would be spent by a private company, its ability to borrow money at a low rate will fall far short of offsetting the disadvantage resulting from its incompetence and wastefulness in expending the money raised.

TRAIN ACCIDENTS IN APRIL

FOR the month of April our list of train accidents has but two items. Except for these we have seen no report of any collision or derailment in the United States, which was of enough importance to bring it within the "prominent" class from which we make up our record. April is a month in which a light record is always to be expected, but this is the first time in 43 years, or since these records have been kept, that this paper has not printed a monthly train-accident record including at least a half dozen items of considerable importance.

This, of course, does not mean that there were not many accidents last month. The government records, to be compiled a month hence, undoubtedly will show, judging by past years, a list of collisions and derailments involving a loss of somewhere around a half million dollars and a total of many scores of employees injured, with the usual proportion of fatal injuries. But April is the month in which the notable accidents are always at their lowest ebb. The April records of the last 20 years contain only three train accidents of what may be called the first magnitude; Martins Creek, N. J., 1911, twelve persons killed; Bartlett, N. D., 1907, five killed, and Buffalo, Kan., 1903, eleven killed. In the last named case, a rear collision, all of the victims were employees.

In April, 1914, six persons were killed in an electric car, and this year there was an electric-car disaster in Detroit, but these are not included in the train-accident record.

Prior to the establishment of the government accident records, in 1901, the *Railroad Gazette* kept a more complete record, putting into it not only the "prominent" cases, but all train accidents, of which information could be gathered, where any person was killed, or where many were injured, or where the money loss was very large. April had the same peculiarity then. For the first six of the last 20 years (years 1896-1901) the reports of passengers killed in April stood as follows:

Passengers Killed in Train Accidents

	April	Average per month for the whole year		April	Average per month for the whole year
1896	6	10.7	1899	2	9.4
1897	2	5.0	1900	3	9.4
1898	0	4.0	1901	0	..

The only explanation of April's peculiarity that is discernible is to be found in the combination of favorable weather, moderate volume of traffic, and a minimum of inexperienced trainmen. A lessening of the volume of traffic and the number of trains run both reduces the chance of accident and causes an improvement in the quality of the service by forcing the dismissal of some of the men, the newest and presumably least efficient men being, of course, the first to go.

An examination of the April records for the past few years serves to make prominent another fact; the fact that the number of collisions is falling off a good deal faster than the number of derailments. This appears also in the Interstate Commerce Commission bulletins. In the early days of the government accident records the quarterly statements of collisions and of derailments, when measured by the money loss, were generally somewhere near equal, but now they are usually very unequal.

In a matter involving so many uncertain factors, precise comparisons are hardly worth while; but the reasons for this change are quite clear in at least two respects, namely, the extension of the use of the block system (and of air-brakes) in preventing collisions, and the increase in the size and weight of freight cars and engines, and in speeds of freight trains, in enhancing the cost of derailments. The difference between the latest records and those of ten years ago may be seen in the double-column table. The most instructive comparisons are those between the items of cost—columns 4, 7 and 10. "Cost" does not include payments for freight damaged or for personal injuries, and therefore gives no adequate idea of the total losses due to train accidents; but for purposes of comparison, one year with another, these partial figures are even better than the totals would be, for, no doubt, the fluctuations are not so great. Train mileage cannot be compared, satisfactorily, as the figures for 1914 have not yet been published. The showing for improved safety of life and limb is even better than the figures indicate, for in the earlier years the number of casualties does not include trespassers, whereas in the later years it does. And the increase in the volume of traffic is greater than appears, as shown by the footnote. Column B, which is included in column A, is shown separately because, with slight exceptions, it is only the collisions in column B which are susceptible of prevention by the block system. This column, therefore, throws most light on the decrease in collisions as a result of the increase of the use of the block system.

In spite of the uncertainty due to the numerous indeterminate factors, the facts given in this ten-year comparison afford ground for marked satisfaction. For example, take 1904 and 1914. Though the cost item under the head of derailments in-

Collisions and Derailments in the United States; Data Concerning Cost, 1902-1905 and 1910-1914

Twelve months ending June 30	Freight ton mileage (Millions)	A All collisions			B Rear and butting collisions			C Derailments		
		Number	Cost	No. killed	Number	Cost	No. killed	Number	Cost	No. killed

1905	186,463	6,224	4,849,054	608	2,200	2,914,918	456	5,371	4,862,602	456
1904	174,522	6,436	5,190,918	630	2,664	3,379,445	475	4,855	4,192,159	388
1903	173,221	6,167	5,615,746	...	.....	.....	...	4,476	3,981,231	...
1902	157,289	5,042	4,285,683	...	.....	.....	...	3,633	3,359,723	...

*Small roads (Class 3) not included.

creased over 70 per cent, with an increase of traffic of 65 per cent, the number of persons killed decreased 18 per cent. The cause of the increase in cost of derailments has already been suggested. While from 1904 to 1914 the derailment costs were thus increased, collisions costs fell off 27 per cent, and the killed in collisions from 630 to 287, or no less than 54 per cent.

That the decrease in the number and seriousness of train accidents has been more rapid during the past twelve months than in earlier years, is a matter of common knowledge, a principal cause being the falling off in the volume of traffic. The smallness of the totals, with the small proportion of collisions, as compared with derailments, may be seen in the following table:

Number of Prominent Train Accidents Reported

	Collisions	Derailments		Collisions	Derailments
1915 March	2	9	1914 August	4	6
1915 February	5	9	1914 July	2	6
1915 January	2	14	1914 June	3	11
1914 December	3	8	1914 May	2	11
1914 November	5	8	1914 April	1	8
1914 October	3	8			
1914 September	0	7	Total, 12 months...	32	105

These, it is to be remembered, are only the prominent accidents, published in the newspapers. From a statistical standpoint the items may be only straws; but straws show which way the wind blows.

THE COMMISSION ON RELATIONS BETWEEN RAILWAYS AND WATERWAYS

THE Interstate Commerce Commission, in an opinion by Commissioner McChord, has given the most rigorous possible interpretation and application of the part of the Panama Canal act relating to the ownership of boat lines by railways. The law provides that it shall be unlawful for any railway to control or have any interest in any common carrier by water operating through the canal or elsewhere, with which the controlling railway does or may compete. This provision is qualified by another to the effect that if the Interstate Commerce Commission believes that any existing service by water other than through the canal is being operated in the interests of the public, and that an extension of the time during which it is under the control of a railway will not "exclude, prevent, or reduce competition on the route by water," the commission may extend indefinitely the period during which such service by water may continue to be operated. In the administration of these provisions, the commission has ordered all the eastern railways to dispose of their interests in boat lines on the Great Lakes.

Some of these railways, such as the Pennsylvania, the Erie, and the New York Central, own railway lines to Chicago paralleling the lakes on which the water carriers in which they are interested operate. The rails of others, such as the Lehigh Valley and the Delaware, Lackawanna & Western, terminate at Buffalo and therefore connect with, but do not parallel, the lakes and the routes of the lake carriers. Doubtless in requiring the former class of railways to give up their boat lines the commission is but giving effect to the spirit and intent of the law. But the commission holds that the railways which end at Buffalo as well as those whose rails extend to Chicago, must give up their interests in the water lines.

The terms of the law make it plain that Congress never intended that any railway should be required to dispose of its holdings in any water carrier with which it did not and could not compete. The language used makes it especially clear that Congress never intended this with respect to railways having interests in boat lines on the Great Lakes and other inland waterways. How, then, does the commission reach the conclusion that railways which end where the service on the Great Lakes begins may and should be required to dispose of their holdings in lake lines? These railways have through rates and through routing arrangements in connection with railway lines operating between Buffalo and Chicago. The commission finds that by means of these through traffic arrangements with connecting railways, the Lehigh Valley and the Lackawanna are competing with their own boat lines, and it is on this theory that it bases its conclusion that their ownership of interests in boat lines is contrary to the law and to the public welfare.

In spite of the commission's labored and metaphysical reasoning, it is hard for persons not gifted with its powers of ratiocination to see how a railway which begins at New York and ends at Buffalo can compete with a boat line which begins at Buffalo and ends at Chicago. Common sense suggests that the competing with the boat line between Buffalo and Chicago must be done by some other railway, and common sense sometimes, although not always, has weight with the courts. The courts may also consider the fact that under the act to regulate commerce, the railways from New York to Buffalo may be required to make reasonable through rates and routes in connection with railways from Buffalo to Chicago, and that the commission is the body which is empowered to enforce this regulation.

If all the eastern railways except those terminating at the eastern end of the lakes were required to dispose of their boat lines, there would be an increase of competition between the water carriers themselves and between them and the railways. A large majority of the lake lines would then be owned by industrial corporations and independent companies. The fact that some boat lines were owned by eastern railways terminating at Buffalo would not, it would seem, affect the competitive situation materially, if at all. If, at the most, it would affect it only to a slight extent, and nevertheless it can be held that the ownership of some boat lines by railways terminating at Buffalo, is against the public welfare, this can be only on the ground that the public welfare requires absolutely unrestricted competition of the water lines against the railways. As a matter of fact, this seems to be the very position the commission takes. It descants on the beauties of water transportation and the desirability of competition of waterways with railways in the rhetoric of an orator at a river and harbor congress. It says:

> On a water course, where the boats and boat lines are free from domination or control by the railroads, and *where they are left to survive as their merit and the ingenuity of their owners makes possible*, there will be, and always is, a healthy rivalry and striving between such boat lines themselves and with paralleling railroads for all suitable and available traffic. There is competition. This rivalry manifests itself in several ways... *The rates charged fluctuate according to economic principles*, and the shipper enjoys invariably, as a result, lower charges for the transportation routed over such waterways and thereby reaps a return from the "nation's highway."

These statements—the italics in which are ours—cannot be supported by evidence. Seldom or never are boat lines on inland waterways "left to survive as their merit and the ingenuity of their owners makes possible." They are usually subsidized by government appropriations for the development of the waterways they use. As to the statement regarding, "healthy rivalry and striving between such boat lines themselves, and with paralleling railroads," there almost always are agreements between rival boat lines to limit competition between themselves, and the restrictions which the Interstate Commerce act imposes on the railways prevents "healthy rivalry and striving" between water carriers and paralleling railways. Even with all the governmental aid and protection given water carriers it is not a fact that they are usually able to compete effectively with railways. The Mississippi is a deep waterway between Memphis and New Orleans. The carriers on that river are not dominated by railways; yet hardly a ton of freight moves by water between the terminals at Memphis and New Orleans. Less extreme examples could be cited all over the United States. The evidence all shows that the inland water carriers of the United States, excepting perhaps on the Great Lakes, cannot be made able to compete with the paralleling railroads even by government expenditures which cover a large part of the cost of handling the water traffic; and it is very questionable if independent water carriers on the lakes can hold as much of the traffic as has been held by the boat lines which have been controlled by the railways.

As to the statement that "the rates charged (by the water carriers) fluctuate according to economic principles," it would

be interesting to know whether the commission means by this to indorse the way in which rates by water commonly are made. The "economic principle" on which they usually are based is that of "charging what the traffic will bear." Sometimes they are high and sometimes they are low. They may be low for one shipper and high for another shipper of the same commodity, moving on the same boat. The one shipper may get a rebate and the other may not. If the "economic principles" observed in making rates by water are right, why should not the railways be allowed to make rates according to the same principles? Why should the railroads be prohibited from discriminating unfairly between different shippers, required to give notice of changes in their rates, and have advances in their rates made subject to suspension by the commission? If on economic principles the water lines should be encouraged to compete with the railways by making rates in this manner, why should severe restrictions be imposed on the way in which railways may make rates to meet water competition?

It is somewhat surprising to find the commission assuming in the opinion in this case, the same attitude of a mother to water transportation and a stepmother to rail transportation which is assumed by Congress and a large part of the public—and that not the most intelligent or least prejudiced and disinterested part of the public. Perhaps in doing this the commission is merely reflecting and carrying out what it understands to be the will of Congress and the public. But have we not a right to expect an expert body charged with the duty of regulating both rail and water transportation to reason and act on better information and sounder principles than the legislative body and the public which have delegated certain functions to it on the assumption that the exercise of those functions requires expert knowledge and judgment?

NEW BOOKS

Railroad Speed Tables and Time Cord Constructor. By Otto Holstein, P. O. Box 1216, San Antonio, Tex. A thin pocket book, 3¾ in. by 8¼ in. Bound in pasteboard. Published by the author. Price $1.

This is a hand book for use in correcting time tables. It is much like Fleming's, which was issued in 1885 and Beaver's, which was issued in 1913 and was noticed in these columns January 30, 1914. The tables give even miles from 1 to 100, and rates of speed from one mile to 60 miles an hour. A separate chapter gives the rate of speed in miles per hour of a train running one mile in any period of time (stated in even seconds) from 30 seconds to 10 minutes 59 seconds.

Who Built the Panama Canal? By W. Leon Pepperman, chief of office of administration of the Second Isthmian Commission. Size 5½ in. by 8 in., 419 pages, 27 illustrations. Bound in cloth. Published by E. P. Dutton & Co., 681 Fifth avenue, New York City. Price $2.

Any book on the Panama Canal is of particular interest at the present time. Four separate administrations have shared in the construction of this canal; the French, the Army and Navy, the Railway and the Goethals. Each had its particular function and contributed to the ultimate success of the undertaking. This book pays particular attention to the third or railway regime. In the earlier chapters it outlines the conditions existing when the railway men took charge in 1905 and the difficulties confronting the new administration. The major portion of the book is devoted to the accomplishments of the two succeeding years under the administration of T. P. Shonts, chairman, and John F. Stevens, chief engineer of the Isthmian Commission.

At the time of his appointment Mr. Shonts was president of the Toledo, St. Louis & Western Railroad, and Mr. Stevens had just resigned the vice-presidency of the Rock Island. W. G. Bierd, now president of the Chicago & Alton, resigned as assistant general manager of the Rock Island to become general superintendent of the Panama Railroad. J. G. Sullivan, now chief engineer of the Canadian Pacific, was first assistant to Mr. Stevens. David W. Ross resigned as superintendent of transportation of the Illinois Central to assume charge of the purchasing department of the canal. E. J. Williams, now treasurer of the McCord Company, resigned as paymaster of the Chicago & North Western to become disbursing officer on the isthmus. E. S. Benson, general auditor of the Oregon Railway & Navigation Company, and Walter G. Tubby, general storekeeper of the Great Northern, resigned to accept similar positions at Panama.

At the time the railway men took hold the problems of sanitation and organization were of at least equal importance with those of engineering, and the solution of the two former had to precede the latter. Mr. Pepperman describes the methods adopted to secure these desired results, paying particular attention to the problem of organization. By eliminating the customary governmental red tape and introducing railway methods, Mr. Pepperman relates how Mr. Williams saved the United States approximately $750,000. On another page he describes how Mr. Bierd saved $8,000,000 by improvements in the methods of handling excavation, etc. Considerable space is given to a discussion of the incidents concerning the resignation of John F. Wallace as chief engineer, as well as to the solution of the labor problem, the choosing of the lock type of canal and the function of the Panama Railroad. The book concludes with a description of Panama as it existed at the close of the railway regime in 1907, a short history of the Panama revolution and a discussion of the value of the canal itself.

There has been a great deal written and published within recent months regarding the building of the canal. The conclusion which would naturally be drawn from most of this literature is that practically the entire credit for its successful construction should be given to Colonel Goethals and his administration. In fact, this conclusion has been drawn and used as a basis for many arguments in favor of government ownership and management of railways and other similar governmental activities. However, Colonel Goethals himself has publicly acknowledged the debt which the nation owes to Mr. Shonts, and the other railway men with whom the latter surrounded himself when he was in charge of the work. The organization which the railway regime built up and the methods which it introduced, Colonel Goethals apparently concedes, were necessary for the subsequent prosecution of the undertaking. For example, it was during the railway regime that yellow fever was driven from Panama, and without this accomplished no organization could have carried the project to completion.

There can be no question about the vitally important part which the railway regime played in creating the conditions, developing the organization and adopting the methods necessary to the success of the task, and Mr. Pepperman has rendered a distinct public service in both telling the reasons why the army and navy regime, which preceded the railway regime, had made so little progress, and why the railway regime was able to make so much progress in so short a time. The army and navy regime tried to use the customary government methods, and it was not until the railway men came in and brushed those methods aside and substituted railway methods, that the dirt really began to fly.

But while Mr. Pepperman has rendered a public service in setting forth the importance of what the railway men did, many well informed persons are likely to think that he minimizes too much the importance of what was done by John F. Wallace when he was chief engineer, and by Colonel Goethals and his staff. There still remained after Mr. Shonts and his associates had left, a big task requiring administrative ability of a high order, and while the work which the railway men did was necessary in order to prepare the way for later achievements, still, those who are disposed to give due credit to all concerned will not withhold from Colonel Goethals the glory of having performed his part in a way commanding respect and admiration.

The point is that there is glory enough for all, and that that belonging to the railway men need not be minimized in order to give to Colonel Goethals all that belongs to him, or vice versa.

Mr. Pepperman's book is well illustrated with pen and ink drawings by J. Pennell.

Railway Storekeepers' Association Convention

Reports on Scrap and Scrap Classification, Recommended Practices, Reclamation Work, Accounting, Piece Work

The twelfth annual convention of the Railway Storekeepers' Association was held at the Hotel Sherman, Chicago, May 17-20. The association was welcomed to the city by Mayor Wm. H. Thompson and an address was made by E. D. Sewall, vice-president, Chicago, Milwaukee & St. Paul. Mr. Sewall referred to some remarks he had heard which included the statement, "I have no sympathy with the railroads in their present predicament; they brought it on themselves and should get out the best way they can." In his opinion the railways have never received the consideration to which they are entitled. He touched on the attitude of politicians and sensational publications regarding capitalization and defended the practices commonly employed in obtaining capital. Ninety per cent of the present complaints are based on conditions of many years ago.

G. G. Allen, general storekeeper of the Chicago, Milwaukee & St. Paul and president of the association, said in his address that the association had prospered during the past year, 105 new members having been added, 20 of whom were from roads not previously represented. Referring to storekeeping practices, he emphasized the value of well-equipped storehouses in promoting economy, and advocated the employment of supply cars on roads whose location and physical condition lent themselves to such a practice.

The secretary-treasurer reported a total membership of 823, and $546 cash on hand.

SCRAP AND SCRAP CLASSIFICATION

The real meaning of the word scrap is not fully understood by the average railroad employee. To most people scrap implies something useless, without value and to be disposed of only by being cast away. The fact that an article has been cast off does not imply in any way that it is without value for some other purpose. The economical handling of scrap in all of its phases is one of the most important items in railroad operation.

The cost of handling scrap should be considered carefully, as duplicate handling is very expensive. There are some kinds of scrap having such small market value that, if handled through one or two operations at scrap yards or on line of road, the actual cost of handling is greater than the amount realized from the sale of the scrap. On the other hand, with certain kinds of scrap one handling or operation, such as sorting out pieces of certain size or length, or cutting a few bolts and rivets, will result in a saving of several dollars per ton when the scrap is placed on the market.

Scrap should be picked up by section gangs daily and assembled at points designated, such as tool houses, etc. After it is assembled at these points it should be loaded at intervals suitable to conditions.

In loading scrap, rails and frogs should be loaded separately from track scrap, if possible. Mechanical scrap picked up off the right of way and in yards should be loaded separately; serviceable roadway material should be separated and transferred from time to time, instead of ordering new material.

Mechanical scrap should be forwarded to the nearest mechanical shops or supply yard for reclaiming. After reclaimed material has been removed, the car should be loaded to capacity with other scrap and forwarded to the place designated as a general scrap or supply yard, for making ready for the market.

In the handling of scrap, important features to consider are the equipment and back haul. The selection of equipment should be made from cars used for rough freight handling; consideration should also be given to the loading of scrap in open or closed cars to suit conditions at the general supply or scrap yard.

Another feature that should be followed up very closely is the loading of equipment to full tonnage. Oftentimes scrap is forwarded long distances with light load, whereas it could be started out with a light load and all scrap picked up until reaching general headquarters, by which time, if properly handled, the car would have its full tonnage.

Special care should be given to the switching of cars in and around scrap yards with a view of curtailing unnecessary switching. It is necessary that cars loaded ready for weighing be pulled out at certain intervals in order to save switching and as many cars as possible should be handled at this particular time, with the understanding, of course, that other cars will be set immediately for reloading. Scrap should not be loaded in foreign cars unless this is absolutely necessary, and in case it is loaded in foreign cars, the scrap yard foreman should give these preference in order to release the cars promptly.

[The committee suggested the special preparation of certain specified items of scrap not covered in the scrap specification, in order to obtain a better price, the understanding being that this will not change the present scrap classification.]

The report is signed by W. Davidson (chairman), Ill. Cent.; W. A. Linn, C. M. & St. P.; A. L. Tucker, C. & N. W.; H. E. Rouse, C. G. W.; J. F. Rothschild, C. B. & Q.; F. A. Bushnell, G. N., and H. Scatchard, N. & W.

Discussion.—Several members did not approve the addition of a classification for miscellaneous mixed scrap; others believed it necessary in order to provide for small roads without means of classifying and preparing scrap. Reference to the separation of high speed steel scrap brought out the fact that most roads do not have any to sell, a great many welding the small pieces on soft steel and thus using them up. Several members were of the opinion that scrap should be sold direct to the consumer and that the scrap dealer be eliminated. It was decided not to adopt the mixed and miscellanous scrap classification.

RECLAMATION OF MATERIAL

The committee finds that a great deal has been accomplished in the reclaiming of material and also that there is much more to do than has been done. The work needs much systematizing, intelligent supervision, more efficient methods and machinery, and more education of the users of material as well as the reclaimers. There is a vast amount of money tied up in material in store stock under the supervision of the storekeepers, as well as money spent for purchases, which we are responsible for. How much can we reduce purchases and the amount of money tied up in stock material by more efficient reclamation, is the problem which we, as storekeepers, must solve.

The committee believes both purchases and stocks can be reduced materially by reclamation work. The reclamation of material should be under the supervision of the store department for the following reasons:

(1) The store department supervisors are already trained for the work.

(2) The assembling of reclaimed material, its classification, disbursement and accounting is directly in line with good storekeeping.

(3) Centralization of all discarded, second hand, obsolete and scrap material at designated scrap yards under the store department has been found by actual experience to be the best method. The handling of reclaimed material is store department work, as it already has the organization to re-

claim that which is fit to use for the purpose originally intended and can easily supervise the work necessary to make reclaimed material into any shape desired. The store department knows what material cannot be reclaimed for any use and will quickly turn this into money to the best advantage.

(4) The store department has adequate records, showing amount of material used and knows how much of each kind of material to reclaim and will prevent big losses by reclaiming more material than is needed. The store department will also prevent working over material that is not needed.

(5) The store department is in constant touch with the markets and knows at all times the different costs of all articles.

(6) The store department is not only interested in the use of material, but is interested in its abuse. Reclaiming material often shows where there has been abuse, and the store department is in the best position to stop abuse, as it is vitally interested, being measured by the purchases which the abuse increases.

(7) The store department labor force and handy men can do the work cheaper than any other department, as it is necessary for the other departments to do reclamation work in connection with their regular work, which requires high paid mechanics and skilled labor.

There can be no set rules or regulations to cover reclamation work, as the conditions vary so much that each individual case will have to be decided upon its merits. The committee finds, after careful investigation, that the railroads should build and equip efficient reclamation plants (these to be worked up gradually as the needs demand) to handle a large part of the reclamation work, if the best results are to be obtained.

The geographical location of the road, location of shops, scrap market, traffic tide, etc., should govern the location of a reclamation plant and scrap dock. It should be such as to save back haul of scrap, and at the same time give a minimum haul for reclaimed material and be a good distributing point. Of course, the present location of the scrap dock, size of shops using reclaimed material, land, tracks and buildings obtainable for reclamation work will have to be large governing factors in the location, as well as the size of the appropriation obtainable for this work.

Care must be exercised to see that the plant is so located that there will be room for future growth.

The size of the plant, of course, will govern the organization. The committee recommends that the reclamation plant and scrap dock be under one general foreman, whose rate of pay should be from $100 to $150 per month, to whom should report the foreman of rolling mills; foreman of scrap dock (rate of pay $70 to $90 per month); leaders (about one for every six laborers), 17 cents to 35 cents per hour; clerks; piece work inspectors; handy men for operating machines and doing special work (15 cents to 30 cents per hour), and laborers (at labor rates).

The leaders or gang foremen should be carefully selected and trained in their duties. By having leaders it only makes it necessary for the foreman to educate them and hold them responsible for work under their supervision, and then they in turn can educate the men.

The number of clerks and the rate of pay will depend on the size of the plant and work necessary to be done.

Handy men or operators should be used in reclamation plant instead of mechanics and journeymen. Much of the work of the reclamation plant is a growth of that formerly done on the scrap dock. Practically all of the work requires but one operation.

All work in the reclamation plant and on the scrap dock should be done piece work and all day work eliminated.

The size of the plant will depend on the size of the road, the number of plants on that road and the location and space available. The plant should be large enough to prevent congestion and so it can be arranged to handle material at the minimum cost. It is a mistake to build a plant, or any part of one, without a complete, comprehensive plan. Many of our reclamation plants are poorly laid out.

The machinery, tools, etc., will have to be selected to meet individual needs as well as the appropriation available. Second hand machinery and tools can often be used to good advantage, but in most cases discarded machinery and tools have outlived their usefulness and are expensive at any price.

[A list of machinery, tools, etc., for a fully equipped reclamation plant was here included in the report. The costs given were for a guide only.]

The cost of reclaiming is the governing factor as to whether material should be reclaimed or not. In arriving at this cost all the factors should be taken into consideration; cost of handling, cost of actual work of reclaiming, interest, depreciation, etc., on the facilities which it is necessary to install to reclaim material and life of the material after it is reclaimed as compared with new articles. In many cases in reclaiming material we deceive ourselves by not taking all of the factors into consideration. What is possible to reclaim at a profit on one road is not on another, but there are a large number of items that it pays to reclaim on all railroads. In starting reclamation work, such articles should be reclaimed as valves, bolts, brakebeams, couplers, bolsters (welded with oxyacetylene), bar-iron, etc., and then work into the other items as fast as facilities can be installed to reclaim them at a profit.

Material should be classified in accordance with the Railway Storekeepers' Association classification of material, and should be carried in these classifications as recommended in the Book of Rules and distributed and handled similar to store stock. Material should be shipped direct from the reclamation plant wherever practicable; local conditions and shipping facilities, of course, will govern.

The cost of the plant will depend entirely on its size and the amount of work necessary to fit it for the work required. Wherever buildings are obtainable that are suitable for the work they should be used. However, railroads often lose sight of the savings that might be effected by having a plant built and arranged so that the cost of the work will be reduced to the lowest possible limit. The difference in cost of operation of a plant properly laid out and constructed and equipped with labor-saving devices, and one poorly laid out with inefficient equipment, will often pay for the improved plant in less than a year.

One of the strongest arguments against a reclamation plant is that there should be no need for one. It is claimed by many that material should not be allowed to get where it is necessary to reclaim it, and that by proper supervision and use of material there is no reason for a reclamation plant. However, the experience of railroads shows conclusively there is a need for one.

Prevention requires the education of the users of the material by the men in charge, and by the store department. The storekeeper must watch issues of material and call attention to all cases where the old material should have been repaired and used, return old material for new and have old material repaired locally where it pays to do so, and where it does not, send it to the reclamation plant.

Educate the users as to the value in dollars and cents of the material they are using. One of the principal causes of misuse and waste of material is ignorance of its value in dollars and cents. While there are many people in large corporations who do not care for the waste they cause, the larger percentage by far of the employees cause waste through habit and ignorance of values. Object lessons well presented are one of the best ways to educate the users of material. A good method to prevent its being necessary to reclaim material is to make it hard occasionally to obtain, thus forcing the user to help himself.

The change in patterns and designs on account of increases in size and other causes is a big factor in the waste of material, and great care should be exercised before any change.

It is necessary to reclaim a large amount of material and work it over into something else on account of not having had proper care to preserve it. A little paint on steel and finished surfaces is often the cheapest reclamation work that can be done. Material in store stock, as well as charged out material of this kind, should be given the necessary attention to preserve it. It is not good practice to store cut nuts or material with finished surfaces in places exposed to the weather.

It does not pay to reclaim material at the point of origin where it involves extra handling or expense. However, where material can be reclaimed at the point of origin at less cost than at a reclamation plant, and where it can be repaired and distributed at the same cost as at a reclamation plant, it should be done. But there is danger of duplicating work and hidden expense in reclaiming material at the point of origin.

As a rule scrap wharf facilities, as the term suggests, fall heir to what is left in the shop yard in the way of facilities. Wharves, buildings and storage bins for such purposes are usually the result of improvised and temporary structures. Many times the facilities are not only inadequate, but expensive to operate; still their general revision is delayed or prevented by the large outlay to change the plant as a whole, and for the reason that the very first preparations, which perhaps were necessary to meet an emergency, grew piecemeal until they precluded the re-arrangement for greater economy except at considerable cost. Often times unsuitable buildings have been gradually built up with which inadequate facilities the local foremen are badly hampered in their work of handling, inspecting and assorting materials for re-use, repairs or sale.

The scrap dock should be organized so it will have adequate supervision for reclaiming material, and the men sorting scrap thoroughly instructed as to what material should be saved for the reclamation plant. The supervision should constantly inspect the sorting to see that no material is being sold for scrap that can be reclaimed. The profit or loss in reclaiming material is often determined by the handling. One good way to educate is to have a sample or exhibition place where samples or the material to be reclaimed can be seen by the men doing the work, and when mistakes are made, their attention should be called to them and the exhibit also. It has also been found economical to have a schedule so arranged that shop foremen and heads of various departments are permitted to take their turn at the wharf in the supervision of the work generally.

The physical handling will depend on local conditions. This, however, is a very important item in the reclamation of material, for as a rule, excessive handling of reclaimed material will soon eat up the profit of reclamation. It should be an absolute rule that no scrap material of any kind be sold as such until it has been carefully inspected and all reclaimable material removed. Where material reclaimed can be used without any labor, it should be sent to the shipping room or proper storage room and thus eliminate all handling.

Records of car numbers and points from which material comes should be kept so that when material is put in the scrap that should not have been, the matter can be taken up with parties at fault. The scrap dock should be so designed that the reclamation plant will be located to reduce the handling of the material to a minimum. Where this is impossible under present conditions, a comprehensive plan should be drawn up, showing the ideal conditions desired, and then work the scrap dock over a little at a time until the desired arrangement is obtained.

All material reclaimed should be inspected by a competent person to see that it is in condition to meet the requirements of its use. The foreman on the scrap dock can pass on this for the material shipped direct from the dock to the work, and the foreman or sub-foreman of the reclamation plant should do so for the material from the reclamation plant. Suitable testing machines should be provided for testing certain materials and gaging them to see that they will meet the requirements. There is much to be said for and against the practice of painting and marking material reclaimed. The committee feels that, generally speaking, material reclaimed should be painted, dipped or rattled.

[Detailed instructions and forms for handling the accounting for scrap and reclaimed material at a reclamation plant were here included in the report.]

The committee finds it impossible to make up a general statement of the saving made by the reclamation of material that would be applicable to all roads, or even to two or more roads, as conditions are so different. The saving will have to be worked up to suit individual needs for each item reclaimed. [Lists were given as a guide and to show what is being done at the present time on some of roads.]

The committee finds that the moral effect caused by reclaiming material saves many thousands of dollars. The man interested in the welfare of the company, by seeing the vast amount of material reclaimed, exercises much more care in the use of material and finds ways of using it that are cheaper than sending it to the reclamation plant.

The user of material who is careless and indifferent is checked very closely by a reclamation plant, as each individual item can be definitely traced and places the responsibility on the one that caused the loss of the cost of reclamation, thus all users of material are kept keyed up, which prevents material being discarded unless it is justified.

The report is signed by D. C. Curtis (chairman), C. B. & Q.; D. D. Cain, S. A. L.; H. S. Burr, Erie; H. Scatchard, N. & W.; R. K. Graham, A. T. & S. F.; C. H. Rost, C. R. I. & P.; J. H. McMillan, N. Y. C., and H. G. Cook, S. P.

In presenting the report, the chairman of the committee regretted that the committee was unable to include details of the Great Northern rolling mill plant, but referred to the description in the *Railway Age Gazette*, May 7, 1915, page 967.

Lantern slides were used by the committee in presenting its report.

Discussion.—In the discussion which followed the figure of 45 cents per cord for making old ties into engine lighting wood was questioned. The chairman explained that this figure did not cover the cost of picking up the ties on the road. Considerable stress was laid on the possibilities of reclaiming track material, particularly frogs and switches. More critical attention must be given to the subject of reclamation, as many roads are now reclaiming material which should not be reclaimed and some that never should have been scrapped.

ACCOUNTING FOR SECOND HAND SERVICEABLE MATERIAL

By C. H. Samson

Assistant Auditor, Chicago, Burlington & Quincy, Chicago, Ill.

With full appreciation of the highly important part it takes in the purchase of material, there is yet reason to believe that in nothing does a store department render greater service to the company it serves than in judicious and persistent efforts to avoid purchases.

Storekeeping is many-sided and only by developing all sides in their just relation and proportions to each other will the store department as a whole take and maintain its proper place in the railroad organization. Its primary object is to secure the most economical care and use of material and in that work, accounting, in its usual acceptation, though secondary and complementary, has an important part in that it puts the results of the care and use into record form, which is of value in proportion, as it truly reflects the physical conditions and transactions.

Accounting for released material is somewhat different from other phases of material accounting in that it can be absolutely controlled in both the debit and credit, as the values are essentially arbitrary. The main consideration under such conditions is the use of values that will best harmonize with the values fixed by purchase and will be the most natural to apply. The commercial theory and practice in the handling of second hand material cannot be properly applied

to railroad accounting as the railroad is its own best customer and there is neither profit nor sense in "robbing Peter to pay Paul," which is practically the case when one account or department is allowed to take advantage of another.

Material returned to store stock is naturally divisible into three classes for which fixed bases of value can be established:

1. Usable in its present form; value, same as corresponding new material.

2. Needing repairs to make it usable; value, a fixed percentage of corresponding new material when released and full value when repaired.

3. Scrap, not fit for use or repairable; value, fixed prices according to kind.

Considering these classes in the order named, as the physical condition of released material, whether salvage or unused, fixes the class to which it should belong, it is entirely practicable for store department men to determine when an article is usable and to account for it at its proper value, without any supplementary description of its condition, as the fact that it is issued for use is evidence enough. On the other hand, if usable second hand material is handled on a percentage basis, more or less distortion of the material account will surely follow. When received, any desired percentage can be readily applied, as there is no question then as to the fact that it is second hand, but in the issue the distinction must be made on the appearance of the article, and often by the average man under working conditions. However appealing the method may be in theory, and it looks good, in practice it is both unsafe and unnecessary.

As material in stock is issued at its stock value, regardless of the current market price, so should uniformity in value of second hand material be maintained, regardless of its particular use, with only such self-descriptive exceptions as are expedient on account of values and accounts involved, and they are surprisingly few.

As material needing repairs becomes usable when repaired, it naturally follows that its value, when released, should be the usable, or new value, less a percentage allowed for repairs. Before it is repaired, it is not available for issue and therefore cannot be charged to the material class from which the repaired article will be issued. The two conditions can be satisfactorily met by charging the released value and cost of repairs to a material class designated as scrap and crediting that class at usable value, as scrap can readily absorb, in its adjustment, all differences caused by the varying cost of repairs. The greater part of scrap ordinarily is sold, so that the actual value is determined by the market, but so far as the accounting is concerned the values can and should be fixed, subject to adjustment when the sales are made.

In the three sub-divisions, released material touches many phases of storekeeping and for its efficient handling and accounting demands the closest co-operation in the physical and accounting work. An effective working plan, therefore, must not only meet the various complications with definite rules, but must have rules that fit the working conditions at the physical end.

RECOMMENDED PRACTICE

The committee, instead of presenting additional recommendations, feels that it is desirable at this time to call attention to the recommended practices already made by the association. Correspondence with about 50 railroads, relative to the recommended practice, shows that on the whole great improvement in the economical handling of material could be made, provided many recommended practices as outlined by the association were actually put in use by the different roads.

Due to the different methods of handling and accounting, it is impossible at the present time to make a proper comparison of the efficiency of the stores department on the various roads. The greatest fault is with the storekeepers themselves, in not forcefully bringing these practices to the attention of their own roads, and calling attention to concealed expenses in handling material.

To properly compare the work of the stores department, we must have a common basis of arriving at the store expense, and a system of accounting which will not conceal or wrongly distribute the cost of handling material. It would appear that under the present rules of the Interstate Commerce Commission the cost of handling at least could be compared, but such is not the case. Store expense on many roads covers only the storekeepers' pay roll, practically all other expenses being charged to operating accounts. Many storekeepers do not do their own accounting. Storekeepers who actually do all the work that they should do and handle their organization properly are put in a false light by other storekeepers who only do part of the work and are only charged with a portion of the cost of handling and accounting for material.

It should be the duty of the auditing department to see that all the expenses of handling and accounting for material, no matter by what department performed, is charged to the proper account.

Attention was called to the report presented at the convention of 1914 by the accounting committee, and a paper in connection therewith; and the report of the committee on the book of rules, presented at the same convention. These two reports are so complete that the committee recommends that the association urge each member to submit them to their respective roads for adoption. The following in particular appears to be absolutely necessary to the efficient and economical handling of store department work:

The general storekeeper should have entire charge of all material belonging to the company, which is not actually in use, regardless of location. All unapplied material, new, second-hand or scrap, should be carried in his accounts and under his jurisdiction.

The accounting for all material in stock, necessary charges and distributions, including the making of vouchers, should be handled by the storekeeper and charged to store expense.

In order to arrive at honest comparisons, all labor expenses by other departments in handling material should be charged to the proper account—Material Store Expense. This will do more than anything else in placing the store department on a proper foundation.

The handling of scrap material and the sorting and reclamation of it is not properly a material store expense item and each department should stand the labor cost of the initial delivery to the store department. All labor expended by the store department in unloading, sorting, preparing for sale and loading should be charged to the value of the scrap as carried in the scrap class or account. The cost of reclamation should be charged to the article reclaimed as far as possible by the use of reclamation orders.

A classified statement of material received, issued and on hand should be made so that proper attention could be given to the different classes of material.

Disbursements should include only material actually used or disposed of; transfers between stores are not disbursements; labor in maintenance or construction of equipment should be excluded from material disbursements; material in course of manufacture, including labor expended, should be included as material stocks; temporary tracks and material suspense in connection with them should be excluded.

The importance of store delivery is not understood or appreciated on many of our railroads; consequently, it is not in general use.

While a majority of railroads operate supply cars, the greatest efficiency as regards their usefulness has not been reached. On many roads this car or cars simply distribute oil and a few light supplies. The supply car or train is the connecting link between the storehouse and the user of the material on the road, and should be the one great factor in

properly handling and delivering on the ground all material, tools and stationery required for all departments and at the same time pick up all scrap and surplus material and bring it to the storehouse.

The report is signed by D. D. Cain (chairman), S. A. L.; A. M. Gage, L. E. & W.; Clarence Foster, N. Y. C.; L. O. Genest, C. P.; J. J. Opheim, G. N.; W. A. Miller, Southern; H. C. Cook, S. P.; J. R. Mulroy, Pullman Co., and H. S. Burr, Erie.

PIECE WORK

Previous papers and committee reports have fully outlined the advantages to be derived from the piece work system; have shown how to install and maintain the system; provided forms for records, and have also given a few concrete examples of economies which can be effected. There has seemed lacking, however, information as to the compilation and phraseology of the schedules, and this feature the committee has endeavored to cover in this report on a limited scale.

In making up a piece work schedule it should first be properly classified. The scrap dock employees would not be interested in schedules for handling lumber, nor does the ice house force care anything about schedules for handling rail and track material; hence it is recommended that the schedule be compiled in sections so that each shop or yard can be furnished that portion of the schedule which affects the work it has in hand.

It is not expected that the classification given will suit all cases, but should be modified to cover conditions as they exist in each individual case. The classification of the schedule is as follows:

Concrete products—manufacturing and handling; ice; lumber, switch ties, piling, poles and posts; miscellaneous storehouse material; rail and track material; scrap and reclamation material; signal material; tools and machinery; track ties and tie treating chemicals.

Schedules under the various classified headings should be arranged in numerical and alphabetical order. The heading "Miscellaneous Storehouse Material" may be sub-divided to suit conditions. One alphabetical index should cover the complete schedule.

[Examples were included in the report showing the method used in preparing the schedules.]

The following instructions should constitute a preface to each copy of the schedule.

All work unless otherwise specified is to be done by hand. Derrick prices and machine work includes all work, fixing tackle and machinery and doing the necessary switching, as well as transferring from previous jobs unless otherwise specified.

Loading includes getting material from the storage place, placing in the car, and properly blocking it for shipment unless otherwise specified.

Unloading includes taking from the car to the storage place, inspecting, taking out culls and properly piling or placing in racks or bins, unless otherwise specified.

Prices per "job" or per "trip" for derrick or hand work are to be paid only when it requires the extra switching or trips for the work. They are not to be paid when it does not require extra switching or trip and when the work can be done in connection with other work.

Rubble car prices include all handling of car to and from work, unless otherwise specified.

The report is signed by W. W. Eldridge (chairman), C. B. & Q.; B. W. Griffith, N. Y. C.; Geo. Holmes, M. C.; W. H. Thorn, C. St. P. M. & O.; F. J. McMahon, N. Y. C.; J. A. Stewart, N. Y., O. & W., and W. E. Brownell, Lack. Steel Company.

Discussion.—It developed that only a few roads are using piecework in the stores department, but that these few are well satisfied with the results which are being obtained. The Chicago & North Western finds a considerable increase in the work accomplished, and no neglect of inspection. More supervision is needed with piecework. Rates should not be cut when a man's earnings increase.

ACCOUNTING—MATERIAL STORE EXPENSES

In recommending rules governing the accounting for material store expenses, the committee sets forth the principal and general expenses which are concerned and connected with store department operations. In the purchasing department, material store expenses are chargeable with the pay of general and local purchasing officers and their assistants and employees of the purchasing department; also, their traveling, office and other expenses incurred in purchasing material and supplies. The two exceptions are amounts expended for purchasing stationery, which are chargeable to stationery store expenses; and pay and expenses of officers and employees engaged in purchasing a single class of material or supplies, such as ties or fuel, which are chargeable directly to the cost of that material or supply.

[Similar analyses of the charges against material store expenses are given for storekeeping, inspection, switching service, motive power and car departments, maintenance of way department, construction department, handling supplies for, and products from, company industries, handling rail and ties, handling ice, handling bridge material, signal material, structural steel, etc., shipped direct to jobs, handling scrap, and accounting.]

In the application and distribution of material store expenses, percentage rates, representing material store expenses, should be assessed according to the issues. The percentage should remain in effect until conditions may warrant a change, which may be made monthly or otherwise during the fiscal year.

Material store expenses are chargeable on the value of material issued for construction and additions and betterments, as well as for operating expenses; they are not chargeable in connection with transfers of material and supplies as between stores and stock accounts.

Material store expenses are chargeable on the value of the gross issues from stock, regardless of the value of scrap and second hand material released and received in exchange; they are chargeable on the value of the material issued to the shops for the manufacture of goods on store department orders and are also chargeable on the value of all shop manufactured goods issued from store stocks. Material store expenses should be assessed on the value of material and supplies sold from store department stocks.

A ledger account entitled Material Store Expenses should be established, for the specific and exclusive purpose of providing a suspense account through which to clear all debits and credits appertaining to the operation of the store department. This account should be credited with the amounts accruing from the application of the percentage for material store expenses to the value of goods issued. The balance in the account, if debit, would represent undistributed expenses due to the prescribed percentages being insufficient to clear the account; if credit, due to the prescribed percentage being greater than the percentages that would have cleared the account.

The account should be cleared in June account of each year by using for the prescribed percentages the rates of per cents that the actual expenses bear to the actual total material issues for the month.

Stationery store expenses should be handled separately from, but similarly to material store expenses.

The report is signed by P. J. Shaughnessy (chairman), Erie; E. L. Fries, U. P.; H. H. Laughton, Southern; E. E. McCracken, B. & L. E.; D. A. Williams, B. & O.; Chas. I. Davis, D., L. & W., and J. W. Camp, B. & M.

Discussion.—The discussion centered largely on the charging of expenses for the handling of scrap. In this respect the report

conflicted with the reports on Recommended Practices and Reclaiming Material, and was finally amended to agree with them.

STATIONERY

Stationery is material and supplies. The cash values of such supplies is about 4 per cent of all other supplies, with the exception of fuel, rails and ties. Owing to the nature of the material, and the comparatively small unit value, the percentage of cost in buying, handling and accounting is much higher than in the case of other material.

In the handling of stationery, there is the same lack of uniformity of methods prevailing as is the case in the handling of other material. On some roads these supplies are handled by a special department, under a stationery agent; on others, by the general stores. On some roads the stationery supplies are charged out in detail as issued, while on others no detail charge is made, but the total cost is apportioned to the various departments on a percentage basis. There are also many different methods of handling the requisitions on which the stationery is issued.

When stationery is handled by a separate organization, under a stationery agent, the head of the organization is usually the buyer, or purchasing agent for the material, as well as the storekeeper. The one strong point in favor of the separate organization is that it is complete in itself, and there would seem to be a good prospect of eliminating much of the correspondence and referring back and forth that would take place if the stock were maintained by one department, and the buying done by another.

On the other hand, the committee finds many weak spots. In the first place, the organization, to be efficient, must be complete in its ordering, receiving, storing, distributing and accounting for, and this means the maximum of cost. Then the head of the organization, being the buyer, or purchasing agent, is so taken up with the buying that the more important end, the distribution, is neglected by him, this work being largely delegated to members of his staff, who are rarely men of wide railway knowledge. One reason for this is that executives seem to have the idea that the handling of stationery, because it is largely paper, pens and pencils, is boys' work, and we should pay boys' wages. Boys can be used in this work to an extent, but supervision must then be better than ordinary, which has not been found to be the case in separate stationery organizations.

The weak spot in the handling of the stationery supplies by the stores department is that the buying may then be done by a purchasing agent removed from the stores, and much unnecessary correspondence and referring back and forth is entailed.

The strong points in favor of the handling of stationery by the stores department are: An organization for the handling of supplies and material, ordering, receiving, storing, distributing and accounting for. The receiving clerk or clerks of this organization can receive stationery at less additional cost than can a department created for that purpose alone; the porters who handle general supplies can handle stationery supplies at less additional cost than can porters who are maintained for that purpose alone; the distributing force which distributes general supplies can distribute stationery supplies in addition to general supplies at less cost than a force maintained for that purpose alone; the accountants who handle accounts for general supplies can handle the additional accounts for stationery at less cost than can accountants maintained for that purpose alone. All of these men having wider general training than would men handling stationery only, should do the work better.

The committee finds it impossible to make a fixed rule that an ordinary railway should carry so many dollars worth of stationery stock per mile of road operated, because of a lack of uniformity in practice. The figures that mean one thing on one road, mean an entirely different thing on another road. For instance, on one road the stationery stock figures cover the folders, tariffs, tickets, adding machines, typewriters, advertising matter and the postage stamps, while on another road they cover some of these, and on others, none of them.

However, leaving out the items mentioned above, any road having stationery stock that goes beyond ten dollars per mile of road, counting double track as single main line, and counting main line only, would do well to look into the matter.

The conclusions arrived at are:

(1) That the handling of the stationery should be done in connection with the general stores.

(2) That stationery should be charged out in detail, the same as other material and supplies.

(3) That while the receiving, accounting and shipping facilities of the stores be made use of in the handling of stationery supplies, the stationery should be a department by itself within the stores, to the extent that the stationer devote his whole time to stationery matters, and that he be the stationery buyer. In no case should the general storekeeper be called on to do the buying.

The stationery organization should be a part of the regular store organization under the general storekeeper, the staff to consist of the stationer, stenographer and stock room man, with the necessary help to handle the stock, according to the size of the road. Requisitions for purchase of stock supplies should be made up by the stock man, checked by the stationer and approved by the general storekeeper for purchase.

The stationery stock room should be of ample size and laid out in sections; a section to accommodate the forms belonging to each department, and a miscellaneous section to care for forms and supplies common to all departments. There should be a catalog of stationery made up in cheap form, so that it could be renewed at small expense, and a copy of this catalog placed in each office. The catalog should be made up to correspond to the stock room.

Each department should have its own series of numbers and symbols. Thus, the motive power department would be given 1 to 200, and its forms would bear its number and letter, thus—F. 160 M.P. Miscellaneous should have its own number and letter M. Each section should be marked with a small sign, as "Motive Power 1 to 200," and the pigeon holes, or shelves, numbered for the forms placed in them. In addition to the shelving for forms there should be, of course, a sufficient number of cupboards and drawers to hold the other material and supplies. The one thing absolutely necessary about a storeroom is that it be big enough.

In each department of the catalog there should be blank spaces for new forms. The stock man should have a copy of the catalog always on his desk. As a new form is gotten out, he should write it in its proper place, and as an old one is discarded, he should strike it out. This working copy should go to the printer, and from it the new issue should be struck. If this occurred too often, notice of a new form could be sent out, and each office could enter it in writing in its copy. If this was done on a fully organized road, a new issue of the catalog would be needed only once in five years.

The requisitions for supplies of stationery should be approved by the head of the office requiring them, and sent direct to the general storekeeper, and from him to the stationer to be filled. The real checking of the requisitions should be made by the man filling the requisitions. Requisitions from agents should go direct to the storekeeper without approval by superintendents or others.

A carefully prepared list of all stations and offices should be kept in the storekeepers' and stationers' offices. This list should show the number of employees in each office, and any other particulars that might be a guide to men filling requisitions. Stationery supplies should be delivered by supply cars as far as possible.

At stocktaking, the stationery supplies in all offices should be carefully checked, and all surplus or dead stock returned to the stores. It is at stocktaking time that the careless and extravagant man is located.

Requisitions for new forms should be special, accompanied

by a full description of the form and an explanation of why it is required. Multiplicity of forms is a great evil, and additions to the number should be most carefully watched. This should be part of the duty of the stationer. Under this plan he will be relieved of such duties as accounting and distributing, and he should devote his whole time, apart from buying, to the study of standardization and uniformity of blanks, as well as grades and weights of stock.

The report is signed by E. J. McVeigh (chairman), G. T.; C. H. Rost, C. R. I. & P.; R. C. Crosby, Wabash; O. T. Burleigh, B. R. & P.; N. C. Foss, Ann Arbor, and R. A. Weston, N. Y., N. H. & H.

Discussion.—There was considerable difference of opinion as to whether this department should come under the storekeeper or not. One member stated that he had found economy in sending the stationery out in small packages rather than by the supply car.

SUBSTITUTES FOR EXPENSIVE LUMBER

By W. H. Clifton

Lumber Agent, Baltimore & Ohio, Baltimore, Md.

As in other lines of industry, there are certain practices which are followed in the use of lumber in railroad shop and building work today, which have been unchanged for many years, regardless of the decrease in the supply and increase in the cost of the lumber used, or the fact that other kinds of lumber, equally well adapted to the purpose, are more easily and cheaply obtained. This condition seems to be due largely to a lack of knowledge of the characteristics of materials, other than the ones which have always been used for certain purposes.

There are many occasions when 1 in. by 12 in. by 16 ft. white pine of good grade is ordered when 1 in. by 8 in. by 12 ft. to 16 ft. yellow pine, cypress, spruce or even hemlock of a lower grade would answer equally well for the purpose, and would cost considerably less. White pine for pattern work is frequently ordered to be 12 in. and over in width, when, if ordered 8 in. and over with a limit on the percentage of widths under 12 in. acceptable, the lumber would cost less, and the widths under 12 in. will usually be found, piece for piece, to be of better quality than the wide stock.

Not very long ago, while passing through a cabinet shop in a railroad mill, I observed a large number of boxes or trays of a peculiar design in the course of manufacture. The boxes were being made from clear yellow poplar and were heavily ironed, and, I think, were mounted on small truck wheels. Upon inquiry, I was informed that they were to be used as tool boxes by machinists and car repair men for keeping together their wrenches and tools, and for moving them from one job to another. Now, when those trays were finished, they were beautiful to look upon, the bright yellow of the heart poplar standing out in contrast to the black iron branches, but the first time a car man threw his 18 in. wrench or his iron jack lever against the side or end of one of those boxes, an abrasion would appear in the soft surface of the wood in which one might lay a finger, and in a very short time the body and partitions of the box would be gone. Yellow pine or oak would have been a more durable material, and would have cost approximately 50 per cent less than the poplar, but the force in that shop knew little about yellow pine, except that it was more difficult to work, being harder in texture, and, I believe, they considered oak too heavy; but they did know poplar and white pine and no doubt figured that, if it was good enough for cab panels and coach siding, it was good enough for the tool boxes.

The storekeeper did not use those tool boxes, but he supplied the stock to make them, and, perhaps, accepted the boxes in his stock and issued them. He is interested to the extent that, when the practice of using such expensive material for ordinary purposes is discontinued, he will have to carry less of it in stock and his stock balance will drop proportionately.

Noting, about a year ago, that a certain shop was ordering very frequently 1 in. by 16 ft. No. 2 white pine barn boards, inquiry was made as to the purpose for which they were used. Among other things, it was learned that quite a large quantity of the boards were being ripped to 2 in. and 3 in. strips and shipped out on the line for staying explosives in shipments and for stripping powder cars. Hemlock and chestnut cut to the desired size is now being purchased for this use at a cost of $18 to $20 per thousand feet. The white pine cost $27 to $32 per thousand feet. Old car siding and other waste material is also being used.

On two occasions, at different shops, it has been found that track shims were being made from new white oak purchased for gondola flooring, and, while it must be admitted that the shims were excellent and the size of the flooring was well adapted to the method of manufacture, little progress was being made toward economy, which would have been possible by cutting up odds and ends and obsolete sizes of material, of which there was a considerable quantity available at both shops.

The cases mentioned are not exceptions, and are not peculiar to any one shop or railroad. Similar cases can, no doubt, be found to exist on many roads. The condition is the result of practices in effect when high grade lumber was cheap and plentiful.

A remedy is not hard to find or difficult to administer. Usually a little educating of the consuming forces in the possibilities of substituting, with a view of economy, brings the desired result, for the average mechanic on a railroad is not averse to saving money for the company if some one will show him how to do it and co-operate with him in accomplishing the desired result.

Some of the railroads have already gone quite extensively into the substitution of cheaper and more plentiful lumber. The Chicago, Milwaukee & St. Paul has found Douglas fir of suitable grades at a price ranging from $26 to $30 per thousand feet, and Washington cedar at $30 to $37 per thousand feet, to be excellent substitutes in many cases for soft yellow poplar at $65 to $90 per thousand feet. Both fir and cedar can be obtained in any width and thickness desired and can be satisfactorily kiln dried. While this company still uses yellow poplar for outside siding and interior finish on passenger cars, it has been able to cut the consumption of poplar to about 35 per cent of the quantity formerly used. It has also been found that clear red birch is an excellent substitute for mahogany for seat arms, etc., and at a considerable saving in cost.

The Baltimore & Ohio has very recently taken up the question of substituting red or gulf cypress for purposes for which soft yellow poplar has been used. For all purposes in which substitution has been made it answers equally as well as poplar, and, in some cases, it is superior to poplar for the purpose.

The following comparison of the approximate prices of first and second clear soft yellow poplar and the same grade of red or gulf cypress will give some idea of the saving which will be effected:

Approximate Prices, F. O. B. Cars, Cincinnati, Ohio

First and Second Clear Soft Yellow Poplar		First and Second Clear Red or Gulf Cypress	
Thickness	Price	Thickness	Price
1 in.	$50.00	1 in.	$43.00
1¼ in.	55.00	1¼ in.	43.50
1½ in.	52.50	1½ in.	43.00
2 in.	55.00	2 in.	46.00
2½ in.	60.00	2½ in.	56.50
3 in.	65.00	3 in.	57.50
4 in.	68.00	4 in.	62.50

The specifications of the Baltimore & Ohio call for poplar 7 in. and over in width and 8 ft. to 16 ft. long; shipments must average 12 in. or over in width and 50 per cent of the boards must be 16 ft. long; only 10 per cent of 8 ft. and 10 ft. boards are admitted. The cypress can be purchased the same way.

It was formerly the practice on this road to use poplar for blocking in between the framing of baggage, mail and express cars to provide a soft absorbent surface to which glue is applied in putting on the outside sheathing. After a trial,

it was found that a sound wormy grade of chestnut, kiln dried, could be used for this purpose with as good results as obtained from poplar. The chestnut cost approximately $20 per thousand feet; the poplar cost $55 per thousand feet.

Of course, steel is rapidly taking the place of lumber in car and locomotive work, and the possibilities of substitutions of cheaper woods in that class of work will grow constantly less, but there is on most railroads still a large amount of wooden equipment, which will be rebuilt and kept in service for years to come.

OTHER BUSINESS

J. H. Waterman, superintendent of timber preservation of the Chicago, Burlington & Quincy, presented a paper in which he suggested that the storekeeper should examine critically all requisitions and substitute cheaper material if it was just as satisfactory.

The above covers the proceedings for Monday and Tuesday of this week. The remaining sessions will be reported in next week's issue of the *Railway Age Gazette*.

A report on the Uniform Grading and Inspection of Lumber was presented on Tuesday, an abstract of which will also appear in next week's issue.

SOUTHERN PACIFIC EMPLOYEES GIVEN PRIZES FOR SOLICITATION OF TRAFFIC

The Southern Pacific has recently awarded cash prizes to 24 of its employees on the Pacific system in the contest for the personal solicitation of traffic between May 1, 1912, and December 31, 1914. The contest was open to every employee of the company except those traffic representatives and agents whose regular duty it is to solicit traffic.

Prizes of $25, $20 and $15 were awarded on each of seven divisions and in the general offices, and in addition special prizes of $25 each were given to R. W. Dodd, rate clerk in the general freight department, and H. E. Landerkin, rate clerk in the general passenger department, whose records were considered worthy of special consideration since their duties had not placed them in contact with the public. Each of the 10 divisions on the system was constituted a group and two groups were made up of the general offices at San Francisco, Portland and Los Angeles. Prizes were offered to each group to be based on a system of credit units, and it was necessary for contestants to obtain at least 50 credits to qualify. Failure to do so accounted for the fact that no award was made in four of the groups. In the plan of credit rating 40 credits were allowed for each carload shipment secured by unaided effort for transcontinental shipment and 20 credits for other shipments. Twenty credits were allowed for transcontinental carloads reported and secured with the assistance of a traffic department solicitor and 10 credits for other shipments. Five credits were allowed for each carload prospect reported but not secured. Half as many credits were allowed for l. c. l. shipments. Forty credits were allowed for transcontinental passengers secured by unaided efforts and 10 for each other passenger secured by unaided effort. For each passenger reported and secured with the assistance of a traffic department solicitor, 20 credits were awarded for transcontinental passengers and 5 for other passengers. For each transcontinental passenger reported but not secured 5 credits were allowed. Special credits were allowed for large party movements, such as conventions, etc.

A similar contest is now in effect to close on June 30, 1915. Personal solicitation cards are furnished to the employees on request and when a prospective shipper or traveler is obtained the employee forwards the card properly filled out to the nearest district freight and passenger agent. The latter then calls on the prospect and closes the canvass, returning the card to the general office with a notation on it as to what business resulted.

RAILWAYS MUST ABANDON CONTROL OF BOAT LINES ON THE GREAT LAKES

The following is an abstract of the Interstate Commerce Commission's decision, written by Chairman McChord, in the case entitled "Lake Line Applications Under Panama Canal Act" (33 I. C. C., 699), refusing the petition of the rail carriers to retain control of their boat lines on the Great Lakes.

The several lines concerned are as follows: The Anchor line, the Erie & Western Transportation Company, is owned by the Pennsylvania and operates 12 vessels serving Buffalo, Erie, Cleveland, Detroit, Mackinac Island, Milwaukee, Chicago, Sault Ste. Marie, Marquette, Hancock, Houghton, Superior and Duluth. The Mutual Transit Company, owned by the Mutual Terminal Company, which in turn is owned jointly by the Lehigh Valley, the Erie, the Lackawanna and the New York Central, operates 12 vessels serving Buffalo, Fairport, Cleveland, Gladstone, Green Bay, Duluth, Houghton, Hubble, Fort William, Port Arthur and Westport. The Lehigh Valley Transportation Company is owned by the Lehigh Valley and connects with it at Buffalo. The Western Transit Company, owned by the New York Central, operates from Buffalo to Chicago and other Lake Michigan and Lake Superior ports. The Rutland Transit Company, owned by the Rutland Railroad, which in turn is controlled by the New York Central, runs boats between Ogdensburg, N. Y., and Milwaukee and Chicago. The Canada Atlantic Transit Company, owned by the Grand Trunk, operates three steamers between Depot Harbor on Georgian Bay and Chicago and Milwaukee. The Erie Railroad lake line, operated by the Erie, operates between Buffalo and Fairport and Milwaukee, Chicago and Manitowoc.

The commission finds that there is or may be competition for traffic between the vessels and the railroads interested in them within the meaning of the Panama Canal amendment.

There are no cases where any two ports are served in common by the boats and by the paralleling rails of the particular owning railroad entity. In the case of the Pennsylvania, the New York Central, the Erie and the Grand Trunk, however, the railroad entity owning the boats or the interest therein also owns, or has an interest in, other railroad entities whose paralleling rails do serve ports in common with the boats. The interest existing between the several portions of each of these systems and the several boat lines in which it is a stockholder is the kind of interest which the act was intended to reach.

The Lehigh Valley and the Lackawanna are each parties to through all-rail routes and joint rates to all the ports served by their boats. They are members of various fast freight lines, and are also interested in the Lake Line Association organization, the records of which indicate that its function is to insure a "proper" management of the boat lines from the viewpoint of the railroads. While the two roads may not directly compete with their boat lines, their membership in this association or participation in any like understanding places them in a position inimical to the best interests of their boat lines. Placed in such an attitude these roads, through the agency of other roads, with which they are "partners," become the competitors of their own boat lines. What is here said with special reference to the Lehigh Valley and the Lackawanna also applies to the other roads.

That the existence of paralleling through all-rail routes, which the petitioning railroad forms a part of, brings an application under this amendment within its provisions, seems clear when the amendment is considered in its application to the railroad interest in boats using the Panama canal. Neither at the time the amendment became a law, nor now, is there any transcontinental rail line owned or operated by a single railroad or system of railroads in the United States.

The words of the law are as follows:

If the Interstate Commerce Commission shall be of the opinion that any such existing specified service by water other than through the Panama Canal is being operated in the interest of the public and is of advantage to the convenience and commerce of the people, and that such extension will neither exclude, prevent, nor reduce competition on the route by water

under consideration, the Interstate Commerce Commission may, by order, extend the time during which such service by water may continue to be operated beyond July 1, 1914.

The commission finds that it is not in the interest of the public that the rail carriers should continue their control over the lake lines.

It is the opinion of the commission that the purpose of the Panama Canal Act is to preserve to the common interest of the people free and unfettered the "water roadbed" via the Panama canal, and with respect to waters "elsewhere" to restore all the water routes of the country to the same condition of freedom from domination that would reduce their usefulness as a natural means of transportation. Congress has decreed that there shall be a restoration of conditions which prevailed when railroads had no interest in and exercised no control over the boat lines plying the country's water routes. That the legislation might not be arbitrary certain provisions were made so that in given instances which form exceptions to the usual experiences in cases of joint ownership such ownership may be continued. It is not found that the cases at issue constitute such exceptions.

The petitioners have contended that the control of the lake lines by the rail carriers results in responsibility and regularity of the service They allege that the joint ownership results in greater economies, particularly from the standpoint of terminals. They note that certain of the boat lines are being operated at a loss and that only the greater financial strength of the owning railroads enables them to operate.

The commission agrees that no doubt under joint operation certain economies can be effected, but that these economies have not manifested themselves in a reduced lake-and-rail transportation cost to the public. On the contrary there have been advances. These successive advances have had the effect not only of preventing an increase in lake line tonnage, but in diverting from the lake routes to the all-rail lines, part of the tonnage which formerly moved on the lakes. Furthermore there is much reason to believe that the very purpose of these advances in lake and rail rates was to divert tonnage to the all-rail lines. As a direct result, the boats have operated with small cargoes, although their operating expenses were almost as great as if they had been fully loaded. This has in turn resulted in a high operating cost per unit of freight. The commission believes that this policy fully explains the lake line deficit and that such facts make clear that whatever economies might be realized by joint ownership are offset by the waste resulting from the unfair use of vessel tonnage in the interest of the owning railroads. The railroad control of these boat lines cannot be said to be in the public interest when the policy of these railroads has been by an artificial rate structure to deprive the public of the natural benefits that would flow from a free use of this waterway.

There are no instances where the boat lines have actively competed for traffic with one another or with the paralleling railroads under the regime of joint operation. Under independent operation each of the lines, in order to survive, will become a competitor of every other boat line and of the paralleling railroads, and the result of such operation will be reflected in the character of service furnished and in the rates. There will be a considerable advantage, moreover, in that these various boat lines, when independently operated, will be able to make through routes and joint rates with the boats which will be operated on the Erie canal barge lines.

These boat lines under the control of the petitioning railroads have been first a sword and then a shield. When these roads succeeded in gaining control of the boat lines which had been in competition with paralleling rails in which they were interested, and later effected their combination through the Lake Line Association, by which they were able to and did drive all independent boats from the through lake-and-rail transportation, they thereby destroyed the possibility of competition with their railroads other than such competition as they were of a mind to permit. Having disposed of real competition via the lakes, these boats are now held as a shield against possible competition of new independents. Since the railroads are able to operate their boat lines at a loss where there is now no competition from independent lines, it is manifest that they could and would operate at a further loss in a rate war against independents. The large financial resources of the owning railroads make it impossible for an independent to engage in a rate war with a boat line so financed.

The commission from a consideration of the above facts denies the petition of the carriers to retain control of the boat lines, effective, December 1, 1915, and an order has been made to that effect.

FRANCE SAVED BY HER RAILROAD MEN

By Walter S. Hiatt*

One of the big achievements of the war in Europe has been the handling of the transportation situation by the railroads. One general has called it "a war of railroads" because of the vast role played by them in getting troops, provisions and munitions. to the front and on time, the victory being with the army that gets first to a critical point. The often quoted remark of Napoleon, "an army is as strong as its feet," has been adapted to read: "An army is as strong as its railroads."

Every railroad man today knows that Germany has been able to keep up a remarkable fight on her two frontiers by her government owned military railroad system which enables her to shunt the same troops back and forth from one frontier to the other. It is not known that the French railroads have rendered an equally great service in France and at the same time, with the exception of the first two weeks of the war, practically continued on their regular schedule for civil passengers and commercial freight. And all this wonderful work has been done without any noteworthy accident, and it has been done with a constant rerouting of large numbers of troops and war material to meet new battle conditions on a front 940 kilometres (584 miles) long, from the English channel to the Swiss frontier. It has been done with a decrease of rolling stock, in the face of an ever-decreasing coal supply, and always with the same or a smaller number of railroad men.

During the critical period from August 1 to 20 last, no less than 1,800,000 soldiers were gotten to the front, and each of these soldiers was handled three times, so that in reality 5,400,000 troops were delivered at the required points. While these troops were being moved, while possibly 5,000,000 of the civil population was also traveling, while two armies were being hurried into Alsace and Lorraine to begin a double campaign to turn the German army heading for Belgium, on August 3 a special train was provided to conduct the German ambassador, M. de Schoen. to Berlin. No, there was no panic among the railroad employees, there was no breakdown of the French railroad system.

When I got off a ship at Bordeaux lately, the service of which ship, as of all other ships and of all steamship companies, had been seriously interfered with because of the war on land, I expected all sorts of difficulties in riding to Paris, such as slow and dirty trains, frequent side-tracking to permit troop or hospital trains to pass. Right at the very dock, however, I found a railroad agent, as at any American port, ready to sell me a ticket, to assure me that the trains were making fast time, and to check my baggage, both my trunks and that part which I sent by the slow and cheaper method known as "la petite vitesse." At the station I noted a great many soldiers, a huge number of hospital automobiles for the wounded, and a large number of civilian travelers. The usual ticket-taker stood at the platform entrance, with a brassard on his arm to indicate that he was under military service. Beside him stood two red-trousered soldiers with their guns bayonetted to check the coming and going of all travelers, both civil and military. The man who carried my baggage wore the sleeve brassard. He, too, was in the military service.

I was surprised that I could take my choice during the day of no less than four fast trains to Paris, any one of which would

*Our special European correspondent.

make the run in the usual eight to nine hours. Yet when I entered my train, before it pulled out, I counted no less than three long hospital trains pulling in, within the space of a couple of minutes each, and each filled with wounded troops, the men sitting or lying, according to the nature of their wounds. Had I been a blind man, the only sign of the war would have been the wet cushion which I happened to sit on. It was stained red with blood from some wound that had broken. Doubtless the car in which I was to ride had but lately come in with some of the wounded and had been made up into the fast passenger train after a hasty cleaning.

I was surprised at what I saw because I had just finished reading a new book telling how the railroad system of France had broken down, and right from the beginning of the war. So well posted a man as C. W. Barron, of Boston, who wrote this book on the financial aspects of the war, stated that last August the railroad men of France were actually taken from their regular posts of duty and mobilized by regiments, and that but for the motor-busses of the Paris street passenger service carrying troops to meet the Germans, Paris would have been taken. While Mr. Barron's book is otherwise full of good information, in this respect it is incorrect. The statement is in line with many made by persons possessed with the bogy of German efficiency.

Already in France the extraordinary service rendered by the railroads is acknowledged, and in time, I am informed, certain of them—the privately owned—will be decorated with the Legion of Honor cross. In France there are six large railroad systems, two controlled by the state, and four by private companies, the latter comprising 30,000 of the 36,000 miles of single track; on these latter has fallen the brunt of war transportation, because of their geographical positions. It is true that these railroads were not fully prepared for war on such a scale—nobody on earth was fully prepared for that matter—and it is to their credit that they have met bravely and efficiently these unusual conditions, just as do our own railroad men in time of flood or wreck.

It is not denied that the motor car and the motor-bus have and still are rendering a large service. However, it borders on the ridiculous to imagine for a moment that the tremendous transportation work of a railroad has been or can be done by such means. When the truth is told about the way the French troops were launched against the Germans, that resulted in the battle of the Marne, it will be found that it was not so much the few thousands of men hauled in the motor-busses out of Paris but the men of the army of General Manoury that routed the Germans. This army was hastily concentrated at Reims, thanks to the railroads, and so rapidly collected that the German spy and information system did not know of its existence.

I am not judging railroad efficiency of the early part of the war by what I saw in my travels through France lately or of what I saw at the big Paris terminals, where the trains are now moving as quietly and smoothly as in peace times. Not only old railroad men but disinterested travelers during that mobilization period of early August tell me the work was inspiring. Consider the conditions. Every day, beginning with July 26, when the war cloud began to blacken, tourists began to rush to and fro, some to seaports, some inland to their homes, and each day their panic grew. During this first week the trains were doubled, then tripled. No less than 500,000 extra passengers came to or passed through Paris, the railway center of France, and no less than 200,000 of the foreign population left Paris. On July 31 the older soldiers of the reserve army, then as now assigned to the guarding of roads and railroads, began to arrive at railroad depots and add to the crowds. The next day at 5 o'clock all the railroads, which had so far done their work as civil instruments, came under military law.

Did the railroad men lose their heads when this mobilization was declared? When hundreds of thousands of troops began to move from every city and town and farm of France to their appointed place to join their regiments, when other hundreds of thousands of civilians began to fly hither and thither, the railroad men quietly put on their brassards and continued at work.

An old lady who was at that hour struggling on the crowded Paris platform of the Paris-Lyons-Mediterranean, waiting to get a train for Toulon in the far south, and there say goodbye to her son joining his regiment, lately told me she saw the railroad men moving huge trucks of rifles along the platform, going about their business through that excited crowd in the matter-of-fact way of railroad men in emergency the world over. Yet these men had perhaps been without sleep for several nights. It is true that it took this lady sixty hours to reach Toulon instead of the usual sixteen, but she got there. The wonder is that any civilian trains were permitted. As it was they were only sidetracked while the military trains passed, moving at an average rate of forty miles an hour.

One of the amazing feats of the railroad men was the changing, over-night, of the time tables on every one of the six systems. These time tables were changed to a new schedule accommodating from 140 to 160 trains a day. Every station master was notified by telegraph when trains were due at his station. No less than 200,000 messages of this import were sent in a single day.

During twenty long, hot, murderous days, ten thousand trains were kept in motion throughout France. Happily, not all of these trains moved towards the frontier at the same time. Yet, to the complexity of the general forward movement was added that of first carrying the men to their regimental depot. Neither a regiment nor a division is moved all in a piece, like an excursion party. A soldier living in Paris may have to go first to some relatively distant station in the country where he joins his regiment, is armed and equipped, and then moved with his regiment to the headquarters of its army corps in another place; and finally the army corps is moved to a point on a main line and thence to some place at the front, either in the north or the east. A man working in Reims may have to join his regiment at Toulouse in the south, thence to a military camp, and finally to Verdun in the east. What these 10,000 trains began to do in August they have been doing ever since, for the other millions of newly recruited men, or for the shifting of armies to new battle regions.

One must have seen the handling of an army corps to get an idea of what work these inoffensive-looking French trains have accomplished and still are accomplishing. Let railroad officers who have sweated over a 100-car circus movement consider that any heavy movement of troops is made by army corps, and that an army corps consists of no less than 39,000 men, all told; and that to boot there are cannon, horses, kitchen equipment, engineers' equipment, wagons, aeroplanes, ammunition boxes, provisions—enough things to make the moving of a train-load of wild animals seem tame in comparison.

It takes two trains of fifty cars each to transport the men of an infantry regiment. This regiment is subdivided into three battalions of 1,000 men each, and each battalion into four companies. The military end of the affair is easy. Get your cars there and the soldiers, company by company, hop in quickly, without any confusion. Your cars for the infantry regiments are easily gotten rid of. But you need an extra hundred cars to carry nothing but the immediate infantry equipment—mitrailleuse guns, regiment wagons and odds and ends of baggage,

Then you need another extra twenty trains for the artillery of this army corps. Only one cannon can be set on a flat-car, including its limber. About fifty cars are necessary for each regiment's cannon. Next there must be cars for the horses that drag the cannon, cars for the artillerymen, and for all the other equipment that goes with cannon.

If the cavalry regiments travel with the army corps, the job is still worse, as no less than 6 trains of cars are necessary for one cavalry regiment. Add to these trains the ones required by the commissary, the hospitals, the heavy artillery, the trench diggers, the bridge builders, and no less than 70 trains of fifty cars, or about fifty big circuses, are necessary to move an army corps. And the French railroads, if you please, had to move no less than 42 army corps in twenty days.

Commission's Findings Relative to the Cummins Law

That Full Liability is Demanded by the Statute Does Not Allow the Carriers to Increase Their Rates

Following is an abstract of the Interstate Commerce Commission's finding relative to the Cummins amendment, the language of the commission being preserved in so far as possible.

For many years, if not, indeed, from the origin of railroad transportation in this country, common carriers have sought in various ways to limit their common-law liability. One method was by a so called release, executed by shipper and carrier, and intended to be effective whether the loss or damage was due to negligence of the carrier or to other causes.

The Carmack amendment of June 29, 1906 made the initial carrier responsible for the safety of goods through to destination. Since that time, beginning in 1913 with *Adams Express Company v. Croninger*, 226 U. S., 491, the United States Supreme Court has decided in a number of cases, that where the shipper has his choice of two rates, the higher carrying unlimited carrier's liability, and in "a fair, just, and reasonable agreement," declares that the value of his shipment is a certain sum and thereby secures a reduced rate, he is bound by that declaration.

The Cummins amendment (an abstract of which was given in the *Railway Age Gazette* of March 12, page 482) was approved March 4.

The Official Classification provides different rates and forms of bills of lading to be used at the election of the shipper, so that the consignor may have the option of shipping subject to the terms of the uniform bill of lading, or under a receipt by which the carrier accepts unconditional liability. Under this rule property is carried at the normal tariff rates if shipped subject to all the conditions of the uniform bill of lading. Property carried not subject to all these conditions is taken at the carrier's liability, but at a rate 10 per cent higher. The Western classification also contains provisions substantially similar. The Southern classification contains a similar rule, and also provides that the rates on livestock will apply when the declared value does not exceed certain values therein stated and that for each increase of 100 per cent or fraction thereof in the declared value there will be an increase of 20 per cent in the rate.

It is plain that the purpose of this law is, except as otherwise provided, to invalidate all limitations of carrier's liability for loss, damage, or injury to property transported caused by the initial carrier or by another carrier which may participate in transporting it. The law does not specifically say that attempts so to limit the carrier's liability shall not be resorted to, but it declares them to be invalid and unlawful.

The official classification roads have announced the purpose of making certain changes in their bill of lading, but as to rates are still considering the question. They say that the law will impose upon them liabilities not heretofore borne and reserve the right to assert a claim for some increase in rates on account thereof.

The southern lines at first announced their intention of making changes in their rate schedules which would exempt from any immediate increases in rates, certain important heavy commodities said to constitute about 70 per cent of their traffic, and of increasing the rates on the remainder 5 per cent. The commission notes in this connection that it has no right to assume that the proper compensation for the additional risk would be 5 per cent of the rates upon 30 per cent of the carrier's traffic, or that it would be any given per cent upon all the traffic. With regard to shipments of livestock the southern carriers have announced their intention of making an increase of 5 per cent in the rate for each increase of 100 per cent or fraction thereof in the declared value. With reference to the other rates they have later proposed to continue their present rates in effect. Property carried, not subject to the terms and conditions of the carrier's bill of lading will be at carrier's liability, and property so carried will be subject to rates 10 per cent higher than those shown in the tariffs.

The western roads take a position substantially like that of the Official Classification roads. They admit that a 10 per cent increase can not be justified and have no desire to take advantage of a technical opportunity to mulct the shipping public.

It appears that prior to 1913 the limited liability provisions were very generally disregarded in the settlement of loss and damage claims, especially in western territory. To a very large extent at least, despite the limitations of liability, full value was quite generally recognized. After the Supreme Court decided the Croninger case, in 1913, the provisions of the contracts and rate schedules in this and other particulars were recognized as lawfully binding upon carriers and shippers alike, and the policy followed was correspondingly changed. In 1913 the policy was generally adopted, therefore, of endeavoring to enforce the limited liability provisions, but no change was made in the rates. It is now argued that inasmuch as no reduction in rates was made when the limited liability provisions were established, or when they were sustained as lawful by the Supreme Court, there is no justification for an increase in rates now that the liability conditions are restored to substantially what they were prior to 1906.

The uniform bill of lading contains a provision that claims for loss or damage must be presented to the carrier within four months, but until the Croninger case no effort was made to enforce that provision. After the decision the carriers took the position that this provision was in the bill of lading, the terms of the bill of lading were in the rate schedules, and that, therefore, it was unlawful to depart from that requirement. This created a general controversy which was considered by the commission in its report *In the Matter of Bills of Lading*, 29 I. C. C., 417.

The Cummins amendment makes it unlawful for the carrier to fix a period for giving notice of claims shorter than 90 days, for the filing of claims shorter than four months, and for the institution of suits shorter than two years. The law does not indicate the time or date from which these several periods of time shall be computed. . . . It will be necessary for the carriers to determine what periods of time they will fix for the giving notice of claims, the filing of claims, and the institution of suits. It is desirable that the rules be uniform for all the carriers of the country.

It is to be remembered that the Cummins amendment is not a separate statute, but is an amendment to the act. It must, therefore, be construed as a part of, and in connection with other portions of, the act, and in such a way as to give effect to the whole statute. . . .

The more important points which seem to be surrounded with the most doubt and upon which opinions so far expressed most sharply conflict, are:

If no changes are made in existing shipping contracts and rate schedules, will the higher rates provided therein automatically become lawfully applicable upon the date upon which the amendment takes effect? . . . It is contrary to all canons of construction to hold that an act of Congress produces a result not intended by Congress unless the express language of the act compels such a construction. There is nothing in the expressed terms of this act or in the history of this legislation that shows any intent to affect in any degree the existing rates. The legislation is aimed at specified contracts and declares them to be unlawful. The lawful rates on file at this time, therefore, are the rates providing for the limited liability. The Cummins amendment, by

making contracts limiting liability for loss caused by the carriers unlawful, does not destroy these rates, but they remain in effect and are lawfully applicable; for the 10 per cent increased rates are merely additional and can not stand in and of themselves.

Applying correct rules of interpretation, the Cummins amendment does not automatically bring into effect the increased rates named in the classifications. . . .

May the carriers lawfully provide in their tariffs and rate schedules that their liability shall be for the full value of the property at the time and place of shipment?

The loss or damage must, apparently, be either as of the time and place of shipment, time and place of loss or damage, or time and place of destination. Where rates are lawfully dependent upon declared values, the property and the rates are classified according to the character of the property, of which the value of the property may constitute an element, and such classification is necessarily as of the time and place of shipment. It is therefore believed that the liability of the carrier may be limited to the full value of the property so classified and established as of the time and place of shipment.

Does the amendment apply to export and import shipments to and from foreign countries not adjacent to the United States?

This must be answered in the negative. . . .

In the proviso, "that if the goods are hidden from view by wrapping, boxing, or other means, and the carrier is not notified as to the character of the goods," what is the proper interpretation to be placed upon the words "and the carrier is not notified as to the character of the goods"?

There is no inhibition as to the limitation of the liability of a carrier for losses not caused by it or a succeding carrier to which the property may be delivered. The amendment has expressly reapplied the limitation of the prior act with respect to loss or damage caused by the carriers chargeable therewith. It follows, therefore, that the interpretation applied to the act before it was amended is equally applicable to the amendment in so far as the latter affects the right of a carrier to establish rates conditional upon the shipper's assumption of the entire risk of loss attributable to causes beyond the carrier's control. From this it follows that under the amendment a contract or a tariff may lawfully limit to a reasonable maximum the liability of a carrier for losses which it does not cause. It follows further that the rates provided by such tariff may be proportionate to the risk assumed.

This provision of the statute as to goods concealed from view and of the character of which the carrier is not advised clearly prescribes the right of carriers under the direction or approval of the commission to provide for a graduation of rates in accordance with the declared value of the property transported. The liability provided by the rates so established by the commission is applicable no less to instances of loss or damage chargeable to the negligence of the carrier than to those occasioned by causes beyond the carrier's control. But the carriers may not contract to limit their liability for loss, damage, or injury caused by them to property the character of which is manifested by the shipment itself or otherwise disclosed.

In this connection it has been suggested that the carrier might provide that in the event the shipper refused to declare the value the higher rates would apply. This suggestion can not be approved. If the rate is lawfully conditioned upon the value as declared by the shipper, it is as much the shipper's duty to declare the true value of the shipment, as it is his duty to declare the name of a commodity tendered for shipment as to which there are no different rates.

It is important to keep in mind that the carriers are not prohibited from making different rates dependent upon the value of different grades of a given commodity; that, except as covered by the Cummins amendment, including approval of the rates by the commission, the carrier is subject to all of the liabilities imposed by that amendment; and that if, in any instance, the shipper declares the value to be less than the true value in order to get a lower rate than that to which he would otherwise be entitled, he violates, and is subject to the penalty prescribed in, section 10 of the act. The carrier would also be subject to the same penalty in such a case if, having knowledge that the value represented is not the true value, it nevertheless accepts the shipper's representation as to value for the purpose of applying the rate.

Do the terms of the Cummins amendment apply to the transportation of baggage?

This must apparently be answered in the affirmative. Transportation of baggage is a part of the contract for transportation of the passenger. The carriers have always limited their liability for loss of or damage to baggage. The baggage check is the carrier's receipt for the baggage. The conditions attached to the carrier's liability are stated in the fare schedules and on passage tickets of contract form. All ordinary personal or sample baggage is hidden from view by boxing, wrapping, or other means, and the amended law seems clearly to recognize the carrier's right to fix conditions and terms applicable to the transportation of baggage dependent upon the value as declared by the person offering the baggage for transportation.

The necessity for revision of the bills of lading, livestock contracts, and other similar contracts of carriage, as well as of certain parts of the carriers' classifications and rate schedules, is manifest. Bills of lading and shipping contracts can and ought to be at once amended by eliminating obviously unlawful and invalid provisions. Such action will obviate for the immediate future numerous controversies that otherwise would probably arise. Proper analysis should be made of the classifications and tariffs to bring them into harmony with the amended law.

Such changes in classifications and rate schedules can not be made upon statutory notice and become effective contemporaneously with the new law. Permission is therefore hereby given to carriers to make effective on June 2, 1915, upon not less than three days' notice, amendments to the classifications and rate schedules which eliminate provisions or rules that are in conflict with the terms of the new law, provided no such amendment has the effect of increasing any rate or charge for services.

If it shall be made to appear that, with regard to any commodity or commodities, the existing rates do not afford the carriers proper compensation, it could hardly be denied that the rates on such commodities might properly be increased in a sufficient amount to properly compensate the carriers for their added risk and liability. Where rates are lawfully based upon declared values the difference in rates should be no more than fairly and reasonably represents the added insurance. It does not appear that this amendment to the act affords justification for any increase in rates on commodities in general. As has been said, the carrier may not lawfully impose unreasonable rates upon one commodity in order to compensate it for risk or liabilities incurred in connection with the transportation of another commodity, and it is not to be forgotten that the liabilities here considered are only those for loss, damage, or injury to the property caused by a carrier or its agents or employees; in other words, the loss, damage, or injury resulting from the neglect or omissions of a carrier or its agents.

The commission has been conducting an investigation with regard to bills of lading. Further hearings in that proceeding may be necessary in the light of the Cummins amendment. In that connection matters that have been informally presented and urged in this informal proceeding may be presented in a formal way, supported by testimony, and a determination can there be reached on questions as to which the commission now has no information upon which it could base a lawful order. What is attempted here is simply to indicate the impressions gained from the experience had in the past and from the suggestions informally presented by those who are vitally interested in the effect of the Cummins amendment, and the course to be pursued for the immediate future in the light thereof. All of the questions herein discussed are, of course, subject to judicial inter-

pretation, and the views indicated herein might be somewhat changed in the light of more complete information supported by competent evidence.

The classification, tariffs, receipt and other forms used by the express companies have been prescribed by order of the commission. The new law, of course, applies to them as well as to other carriers. They have presented suggested changes in their rules and forms which will be disposed of by a supplemental order in the *Express case*.

INSTRUCTION IN STATION SERVICE ON THE CHICAGO & ALTON

The passenger department of the Chicago & Alton Railroad has recently inaugurated a plan for instructing its station agents in the care and handling of tariffs, the manner in which passenger fares are made from the different stations, particularly in connection with the sale of interline tickets and the routing of such tickets, the care and handling and the issuance of tickets, and more uniform methods of conducting station office matters, such as keeping and filing station records, care and handling of baggage, baggage records, checks, etc., and the advertising and solicitation of passenger traffic.

In order that all agencies on the line should be thoroughly schooled and instructed in these matters the passenger traffic manager, George J. Charlton, recently arranged to send the chief clerk in his office, the chief rate clerk, the assistant to the general baggage agent, the auditor of passenger accounts and the general claim agent, together with the general agent and the division passenger agent of each division, on a trip over the line to meet the agents and give them complete and thorough instructions in all matters pertaining to their station work.

These men were provided with one of the road's official cars, and also a cafe car with a large observation room. Meetings were held in the observation room, and the safe end of the car was used to furnish meals, not only to the instruction party but to the agents in attendance at the meetings. Meetings were held at Dwight, Bloomington, Springfield and Roodhouse, Ill., and Mexico and Higginsville, Mo., and the agents from all stations within 50 miles from those cities were required to be present and in the car on the side track by 10 o'clock in the morning of the day on which the meeting was held. This plan made it possible for the agents to get to the meeting and to leave again in time to return home the same night.

It took just one week to cover the entire line of the road in a thorough manner, and the results of the first trip appeared so satisfactory to the officers that the trip will probably be made an annual affair. The party from the general offices took with them the necessary material in the way of rate sheets, time cards, folders, tickets, checks, maps and everything necessary to completely illustrate the various matters, which were discussed in informal lectures followed by a general questioning on both sides The agents and the principal ticket sellers at each station were given a chance to meet those with whom they are in frequent correspondence on passenger matters and to gain a clear understanding as to the necessity for many little things which have been required of them and which, perhaps, have appeared unimportant in the eyes of the agents.

The agents were most enthusiastic regarding the plan. They asked numerous questions and the representatives of the general office were given an opportunity for a better appreciation of various small difficulties and inconveniences under which many of the agents were working, thus paving the way for a little more sympathy between the department and its agencies, and more good fellowship and team work all around, and it is believed that the better understanding between the department and its agencies alone will be a big benefit to all concerned. A complete record was kept of each meeting and Mr. Charlton has received a number of letters from the agents thanking him for the opportunity presented and speaking highly of the expected results from the meeting.

PRIVATE CAR LINES NOT COMMON CARRIERS

The decision of the Supreme Court of the United States in the appeal of F. W. Ellis, general manager of the Armour Car Lines, against giving testimony concerning the doings of his company before the Interstate Commerce Commission, was reported briefly in the *Railway Age Gazette*, May 14, page 1027. The opinion is by Mr. Justice Holmes, and the decree of the district court, requiring Ellis to answer certain questions, is "reversed without prejudice." Certain questions in a long list are not disapproved.

The investigation begun by the Interstate Commerce Commission had to do with allowances paid for the use of private cars and the practices governing the handling and icing of such cars; minimum carload weights, etc. The decision is substantially as follows:

The Armour Car Lines is a New Jersey corporation that owns, manufactures and maintains refrigerator, tank and box cars, and that lets these cars to the railroads or to shippers. It also owns and operates icing stations on various lines of railway, and from these ices and re-ices the cars, when set by the railroads at the icing plant, by filling the bunkers from the top, after which the railroads remove the cars. The railroads pay a certain rate per ton, and charge the shipper according to tariffs on file with the commission. Finally it furnishes cars for the shipment of perishable fruits, etc., and keeps them iced, the railroads paying for the same. It has no control over motive power or over the movement of the cars that it furnishes as above, and in short, notwithstanding some argument to the contrary, is not a common carrier subject to the act. It is true that the definition of transportation in section one of the act includes such instrumentalities as the Armour Car Lines lets to the railroads. But the definition is a preliminary to a requirement that the carriers shall furnish them upon reasonable request, not that the owners and builders shall be regarded as carriers, contrary to the truth. The control of the commission over private cars, etc., is to be effected by its control over the railroads that are subject to the act. The railroads may be made answerable for what they hire from the Armour Car Lines, if they would not be otherwise, but that does not affect the nature of the Armour Car Lines itself. The petition of the Interstate Commerce Commission to compel an answer to its questions hardly goes on any such ground.

The ground of the petition is that it became the duty of the commission to ascertain whether Armour & Company, a corporation, was controlling Armour Car Lines and using it as a device to obtain concessions from the published rates of transportation, and whether Armour Car Lines was receiving for its refrigerating services unreasonable compensation that enured to the benefit of Armour & Company, all in violation of sections 1, 2, 3 and 15 of the act.

If the price paid to the Armour Car Lines was made the cover for a rebate to Armour & Company, or if better cars were given to Armour & Company than to others, or if, in short, the act was violated, the railroads are responsible, on proof of the fact. But the only relation that is subject to the commission is that between the railroads and the shippers. It does not matter to the responsibility of the roads whether they own or simply control the facilities, or whether they pay a greater or less price to their lessor. It was argued that the commission might look into the profits and losses of the Armour Car Lines (one of the matters inquired about), in order to avoid fixing allowances to it at a confiscatory rate. But the commission fixes nothing as to the Armour Car Lines except under section 15 in the event of which we shall speak.

The appellant's refusal to answer the series of questions put was not based upon any objection to giving much of the information sought, but on the ground that the counsel who put them avowed that they were the beginning of an attempt to go into the whole business of the Armour Car Lines—a fishing expedition into the affairs of a stranger for the chance that

something discreditable might turn up. This was beyond the powers of the commission. The Armour Car Lines not being subject to regulation by the commission its position was simply that of a witness interested in but a stranger to the inquiry, and the commission could not enlarge its powers by making the company a party to the proceedings and serving it with notice. Therefore the matter to be considered here, subject to the qualification that we are about to state, is how far an ordinary witness could be required to answer the several questions that are before the court.

It is to be observed that not every advantage that may enure to a shipper as the result of the position of his plant, his ownership or his wealth is a preference. But the intervening corporation may be a means by which an owner of property transported indirectly renders the services in question, and in that event its charges are subject to the commission by section 15. The supposed unreasonable charge may be used as a device to attain the forbidden end and therefore reasonable latitude should be allowed to see if any such device is used. But still until the Armour Car Lines is shown to be merely the tool of Armour & Company it has the general immunities that we have stated. With the foregoing general principles in view we proceed to dispose of the questions asked.

The questions concerning interlocking officers and relations between Armour Car Lines, Armour & Company and Fowler Packing Company, questions 1, 2, 3 and 7, should be answered. The only objection was on account of the general intent avowed as we have stated. So also questions 4, 5, 6, concerning the acquirement of cars previously owned by Armour & Company and Armour Packing Company, making the second group. Also questions 8, 9, 12 and 13, as to contracts of Armour Car Lines with Armour & Company and Colorado Packing Company for furnishing cars and icing service. The next group, so far as the questions concern the ownership, manufacture and repair of cars, Nos. 10, 11, 14, 16, 17 and 19, need not be answered, except 11 "where are the cars of Armour Car Lines repaired when not repaired in shops of railroads?" The last two groups concern matters into which the commission was not authorized to inquire. The fifth, questions 15, 20, 21, 25, 26, 27 and 28, called for statements showing profit and loss, credits and debits to income, etc., so far as the same related to transportation as defined in the act; and the sixth, Nos. 22, 23 and 24, for statements showing the amount invested in each icing plant and the detailed results of the operation of each, amount invested in each, cost per ton of ice at the source of supply, etc., all matters belonging to the private business of the Armour Car Lines and not open, if our interpretation of the law is correct. Our decision, however, must be without prejudice to the possibility that the case may be brought within section 15 by evidence to the effect stated above.

The decree of the District Court is reversed without prejudice.

Mr. Justice Day, while not differing from the general views taken by the court, is of the opinion that the nature of the inquiry under section 15 made it proper that all the questions should be answered.

RAILWAY DEVELOPMENT ASSOCIATION

The annual meeting of the Railway Development Association was held on May 11, 12 and 13 at St. Paul, Minn. The program included the following papers, many of which were followed by a general discussion: "Intensive Farming in the Irrigated District," by Dr. H. H. Harrington, St. Louis, Brownsville & Mexico; "Intensive Farming in the Drainage Belt," by B. E. Rice, Norfolk Southern; "Corn Growing in the Northwest," by D. E. Willard, Northern Pacific; "Immigration," by S. A. Hughes, Frisco Lines; "Why the Department of Railroad Development Work?" by M. V. Richards, Southern; "Colonization vs. Speculation and Exploitation," by C. L. Seagraves, Atchison, Topeka & Santa Fe; "Science and the Soil," by Prof. Henry G. Bell; "Relation of Live-Stock to Agriculture," by Prof. Thomas Shaw, Great Northern; "The Railroad Industrial Agent," by George Bonnell, Chicago & North Western; "The County Demonstration Agent as a Factor in Railway Development Work," by D. C. Welty, St. Louis, Iron Mountain & Southern; "The Value of Immigration to the Railways," by H. W. Byerly, Northern Pacific; "Erection of Buildings, Platforms, Coal Bins or Other Facilities by Railroad Companies," by John C. Emig, Cleveland, Cincinnati, Chicago & St. Louis; "Co-operating With Farmers," by G. E. Cassel, Norfolk & Western; "The Railways in the Settlement and Development of the Northwest," by E. C. Leedy, Great Northern; "A Better Agriculture," by R. F. Murray, Northern Pacific; "Northwest Immigration," by Wm. H. Killen, Minneapolis, St. Paul & Sault Ste. Marie; "Wealth in an Aggregation of Small Things," by Austin Gallagher, Western Maryland; "What Are the Prerogatives of the Industrial Agent?" by D. E. A. Schubert, Norfolk & Western; "The Field of the Agricultural Commissioner," by T. A. Haverstad, Minneapolis, St. Paul & Sault Ste. Marie; "Industrial Development," by Geo. E. Bates, Delaware & Hudson; "Conservation of Agriculture for the Northwest," by F. R. Crane, Great Northern; "Conditions Affecting Industrial Efficiency," by Grant Williams, Chicago, Milwaukee & St. Paul; "Service of the Development Man," by Rutledge Smith, Tennessee Central.

An informal banquet was held on Tuesday evening at the Hotel St. Paul. Allen D. Albert presided as toastmaster, and the speakers included Governor W. S. Hammond of Minnesota, Ex-Governor A. O. Eberhardt, and Prof. A. F. Woods, who spoke on the subject of "Agricultural Education Work." Officers for the ensuing year were elected as follows: President, John C. Emig, industrial agent, Cleveland, Cincinnati, Chicago & St. Louis; vice-president, L. J. Bricker, general immigration agent, Northern Pacific; secretary, H. O. Hartzell, assistant general industrial agent, Baltimore & Ohio Railroad; treasurer, D. E. King of the Missouri Pacific. It was decided to hold the next meeting of the association in New York in November.

INSPECTION OF LOCOMOTIVES AND TENDERS

The Special Committee on Relations of Railway Operation to Legislation has issued Bulletin No. 66, which shows the attitude of the roads regarding the rules and regulations in connection with the new federal law affecting the government inspection of locomotives and tenders. An abstract of the bulletin follows:

Replies to Circular 69 received indicate a very clear preference on the part of the roads, as is evidenced by the replies to the following questions:

Question	Answer Roads replying	
	Yes	No
1. Should the rules and regulations for the inspection of locomotive and tender be filed by the roads individually?	9	135
2. Should they be filed, if possible, by agreement between the roads?	103	37
3. Should a conference be sought with the Government representatives for the purpose of formulating a standard code?	131	22
6. Should the rules and regulations be confined, so far as possible, to inspection solely?	148	1

Roads operating 171,705 miles have authorized this committee to represent them in these negotiations. Roads operating 22,966 miles, while not specifically delegating this committee to represent them, have promised co-operation and have named representatives. Replies have not been received from roads operating 26,297 miles.

The committee will, therefore, undertake these negotiations with the government on the understanding that should any radical differences of opinion develop as between the roads which it is authorized to represent and those which will deal with the subject individually, it will report the fact with a suggestion for further procedure.

The negotiations will be undertaken by the Conference Com-

mittee of Mechanical Officers, which consists of the following gentlemen:

C. E. Fuller.....S. M. P. & M.....Union Pacific (Chairman).
A. W. Gibbs.....Ch. Mech. Engr....Pennsylvania.
F. H. Clark.....G. S. M. P.....Baltimore & Ohio.
D. R. MacBain....S. M. P.....New York Central.
R. E. Smith.....G. S. M. P.....Atlantic Coast Line.

The following gentlemen will be asked to act with this Committee of Conference in order to provide for the widest representation:

H. T. Bentley.....S. M. P. & M.....C. & N. W.
F. F. Gaines.....S. M. P.....Central of Georgia.
John Purcell .....Asst. to V. P.....A. T. & S. F.
W. H. V. Rosing..Spec. Engr. .....St. L. & S. F.
C. B. Young.....Mech. Engr. .....C. B. & Q.

It is understood that the chief inspector of locomotive boilers desires co-operation in the formulation of the rules and instructions necessary under the act. In view of this fact it is strongly recommended that the railroads do *not* file with the chief inspector any rules or instructions of their own until further advised by circular.

STATISTICS OF EXPRESS COMPANIES FOR 1914

The Interstate Commerce Commission has issued a report on the statistics of express companies in the United States compiled from returns made by the companies for the year ended June 30, 1914. This is the sixth report in the series and covers statistics of the 11 important companies. The total mileage covered in the operations of the express companies as of June 30, 1914, was 305,690, as compared with 301,621 for 1913. This includes coastwise, river and lake mileage, but does not include ocean mileage or any mileage in foreign countries except Canada and Mexico. The steam road mileage was 256,183; electric line mileage 7,680; steamboat line mileage 40,929 and the stage line mileage 896. The total express mileage increased 4,069 miles in 1914, as compared with 1913. The mileage on steam roads increased 4,357 miles. The greatest total mileage shown is that for Wells, Fargo & Company, 99,017, of which 63,692 was steam road mileage. Of the companies listed, eight show increases during the year in mileage covered, two showed decreases and one, the Globe Express Company, shows the same number of miles for 1914 as for 1913. In the steam road mileage the largest increase was that of the Canadian Express Company, 2,551 miles, practically all of which represents the extension of service over the line of the Grand Trunk Pacific.

Tables are given in the report showing mileage by states and territories for 1914 and 1913, cost of real property and equipment, inventory value of equipment owned, income account and profit and loss account, analysis of operating revenues, analysis of operating expenses, general balance sheet statement and statement of financial paper issued during the years 1914 and 1913.

The total cost of real property and equipment for 1914 is given as $33,994,114, of which $16,446,268 represents real estate, buildings and fixtures, of which $6,708,172 represents vehicles, $3,849,554 horses, and $4,470,759, office equipment. The cost of cars is stated at $603,786. The total inventory value of equipment is given as $12,652,618, whereas in 1913 it was $13,555,714.

The income account and profit and loss account for the two years, showing a decrease of nearly $10,000,000 in gross receipts and of over $4,000,000 in net operating revenue, is as follows:

INCOME AND PROFIT AND LOSS ACCOUNT

Income Account	1914	1913
Operating income:		
Gross receipts from operation	$158,891,326.67	$168,880,923.13
Express privileges—Dr.	79,906,078.38	83,872,497.17
Operating revenues	$78,985,248.29	$85,008,425.96
Operating expenses	77,221,993.81	79,215,707.71
Net operating revenue	$1,763,254.48	$5,792,718.25
Outside operations:		
Revenues	$428,155.25	$310,201.37
Expenses	462,041.80	370,133.67
Net revenue from outside operations	*$33,886.55*	*$59,932.30*
Total net revenue	$1,729,367.93	$5,732,785.95
Taxes accrued	1,491,698.62	1,379,258.40
Operating income	$237,669.31	$4,353,527.55
Other income	4,531,740.46	5,563,792.18
Gross income	$4,769,409.77	$9,917,319.73
Deductions from gross income:		
Separately operated properties—Loss	$66,674.39	$14,009.79
Interest accrued on funded debt	784,371.97	801,578.75
Other interest	237,235.21	157,644.92
Other deductions	181,406.95	333,196.87
Total deductions	$1,269,688.52	$1,306,430.33
Net corporate income	$3,499,721.25	$8,610,889.40
Disposition of net corporate income:		
Dividends from current income	2,986,250.24	4,679,823.44
Appropriations for other reserves	.....	6,594.72
Balance to profit and loss	$513,471.01	$3,924,471.24
Profit and Loss Account		
Credit balance on June 30, previous year	$60,165,377.81	$61,955,552.88
Credit balance brought forward from income account	513,471.01	3,924,471.24
Additions for year	985,279.17	161,910.04
Deductions for year	31,453,815.91	3,704,500.29
Dividends declared out of surplus	2,577,683.46	3,172,056.06
Balance, credit, carried to balance sheet	$27,632,628.62	$60,165,377.81

It is stated in a footnote that the decrease of $32,532,749 in the credit balance carried from profit and loss account to the balance sheet, aside from the effect of the decrease of over $4,000,000 in net operating revenue, is substantially represented in special charges to the profit and loss account of the Adams and American companies. The Adams company during the year fixed its capital stock at the sum of $12,000,000, and the specific liability for capital stock was included for the first time in 1914 balance sheets of the company. The charges made by the American Express Company are adjustment of book value of securities owned by company, $3,077,930 and distribution to share holders of Wells, Fargo & Company stock held by company of $9,000,000.

TRAIN ACCIDENTS IN APRIL

The list of notable train accidents occurring in the United States in the month of April (made up by us, as usual, from reports found in the daily papers) is so short that a tabular statement is not necessary. One collision and one derailment, as noted below, are all that we have found which may properly be classed as "notable," and, so far as casualties are concerned, even these are relatively unimportant.

On the Atlantic Coast Line near Tarboro, North Carolina, on the twenty-fourth, northbound passenger No. 42 collided with a southbound freight. Both engines were slightly damaged and three passengers and the Pullman conductor were slightly injured. The freight had encroached on the road-right of the passenger train without proper flag protection.

On the Missouri, Kansas & Texas near Higbee, Mo., on the 29th a northbound passenger train was derailed and three cars were damaged. Three passengers were injured, but not seriously. The train was moving at about 35 miles an hour, and the derailment is believed to have been due to a soft spot in the track, on the inside of a curve, due to heavy rain.

Electric car accident.—At Detroit, Mich., on the 14th a street car was run into by a switching freight, at a crossing, and 15 persons were killed and 20 injured. This accident was reported in the *Railway Age Gazette* of April 16.

BUSINESS AT VLADIVOSTOK.—There has been a great increase recently in imports to Vladivostok for transmission to Siberia and Russia over the Trans-Siberian, says an Ashai despatch, especially in those from America. Four or five steamers of 4,000 to 5,000 tons are constantly in harbor awaiting their turn to discharge cargo. The cargo congesting the landing place is rapidly increasing, and the warehouses recently built to store wheat for export have been leased by the custom house. The Chinese Eastern has been doing all in its power to provide freight cars, but is unable to meet the increasing requirements. American cotton forms the bulk of the goods imported. Already 100,000 bales have arrived and 300,000 are on their way to Vladivostok.

International Railway Fuel Association Convention

Powdered Coal for Locomotives; Fuel Stations and Coal Storage Methods; and Smoke Prevention in Chicago

The seventh annual convention of the International Railway Fuel Association was held in the La Salle Hotel, Chicago, May 17 to 20, D. R. MacBain, superintendent motive power and rolling stock, presiding. The convention was opened with prayer by Rev. John W. Nicely.

PRESIDENT'S ADDRESS

Mr. MacBain said in part: "I am a great believer in the educational phase of the question of fuel. To render efficient service economically in any particular line, familiarity with its details is essential, and this is the more particularly true, perhaps, in the case of the man who actually handles the coal between the locomotive tender and the firebox. For fuel might be purchased with the utmost skill, receive the best attention as to grade and preparation by the railroad company's inspectors, be carefully passed from the coaling plant to the tender and then might be subjected to the grossest kind of misuse and extravagance. The firemen need practical instruction on the road, the more they get the better, and the more efficient and economical will be their services. With this practice in vogue, I am positive that the salaries of the instructors will appear as assets, doubled and trebled, on the auditors' books."

ADDRESS BY MR. SCHOYER

A. M. Schoyer, resident vice-president, Pennsylvania Lines West, made a most interesting address after commenting on the very creditable work of the fuel association. In his address, he said in part:

"It seems to me that one of the burning questions of the day, from a railroad standpoint, is what shall the railroads do either to offset the continuing demand for increased wages or to get the relation of employer and employee on a sounder basis, where right will be considered, instead of might or expediency.

"Three remedies have been suggested—first, government ownership of railroads. I hope that should this country ever adopt government ownership, that I may be out of the railroad business before it is done. The party and administration which are in power when the railroads are once taken over by the government will probably remain in power thereafter as long as they want to. With over two million men working for the railroads and with ten million women and children dependent upon them, any administration having the appointive power can have a force of practically five million railroad votes in hand at all times. Woe to the time and country when any one party or man can have such unlimited power. With ward politicians acting as general managers, state politicians handling the policy, national politicians handling the finances and labor leaders handling the labor questions, there would be no need of arbitration for the wages would be increased upon the asking. There would be no strikes for there would be nothing to strike about. It has always seemed to me that the reduction of interest argument is not at all sound. The government's ability to borrow at a cheap rate of interest is due to the confidence which people have in its ability to pay. With the railroads in the hands of the government, with rates probably continually being decreased, in order to favor special lines of voters, and with wages being increased to favor special lines of labor unions, with incompetent supervision of details the growing deficits would have to be raised by taxation, and it is quite certain to my mind that the result of such losing operations would be that the credit of the government would suffer and rates of interest go higher and higher. I shall, therefore, lay aside the thought of government ownership settling the relations of the men and the railroads.

"The second solution, which has been suggested, is that if the law should provide and the Interstate Commerce Commission should authorize that whenever railroads must through arbitration increase the wages of the employees in any branch of service they be also authorized to increase their freight rates automatically. If an arbitration should give the men an increase of wages of 6 per cent, then the railroads should be authorized to increase freight rates, say 3 per cent. How long the farmer would stand this I do not know; probably once. How long the public generally would stand it I do not know. They might stand it twice. But such a law would soon become so unpopular and would be so burdensome that we might readily expect it to be changed by unanimous consent in a very short time. Therefore, I do not believe that this would solve the question, except for a very short period of time.

"With very great diffidence I bring forward a third solution, compulsory arbitration. Not arbitration as under the Canadian law, which is not entirely compulsory; not arbitration as under the American law, which is entirely optional; not arbitration as exists in any country today; but a law which would compel employer and employee to submit their differences to a court of arbitration, after having done all they could together to solve them.

"I think the court should be constituted by the appointment of three, five or the required number of judges by the President, with the required approval of the United States Senate and of the chief justice of the Supreme Court; the judges to hold office for 10 years, to receive a large and adequate salary, to be removable only for malfeasance in office, and with the approval of the President, the Senate and the chief justice of the Supreme Court. The law should provide that the man should be of adequate ability in the minds of those who appoint him; that he should not have been a railroad officer nor a member of a labor union for five years prior to his appointment. The law should require that no lockout or strike should occur hereafter on railroads, but that when the employers and employees have exhausted their means of getting together they should unitedly refer the matter to the court of arbitration. The decision of the court should be binding; not to be appealed from, except as to errors of law appearing on the record.

"No doubt such a court would be crude at the start. The judges would not know the railroad business nor would they be acquainted with labor difficulties, but, being absolutely free from all politics, political influences, or financial embarrassment, they would, as all men do under similar circumstances, become more and more fair and enlightened and conservative as the time went by.

"Such a law, would, of course, meet with tremendous storms of protest from the employees. It would take from them their liberty to strike, but the law should provide that no requirement of the law should interfere with rights of the men as individuals to leave the employment of the railroads at their own volition. It would meet with indignant protest from the railroad companies, who would feel that it took away from them the right to settle their own questions, both of a financial and disciplinary nature, but the law should provide that nothing in the law should prevent the railroad companies from discharging individual men for cause.

"If these objections could be overcome, and if the law could be passed, it seems to me that its effect would be to stop the unreasonable demands from going to the limit of persecution. Neither the employers nor the employees would be willing to go to the limit of submitting matters to this court unless they were assured of the justice of their positions, and, in the course of time, labor and capital, as applied to the railroads, would find their own relations."

POWDERED COAL*

By W. L. Robinson
Supervisor of Fuel Consumption, Baltimore & Ohio

Coal in a finely divided or powdered state represents the most advanced method for producing perfect combustion, thereby making it possible to more nearly obtain the full heat value of the fuel than by any other known means. While a cubic inch of solid coal exposes only 6 sq. in. for absorption and liberation of heat, a cubic inch of powdered coal exposes from 20 to 25 sq. ft., which enables the more uniform gas production from the volatile matter in the coal and the more prompt and perfect intermingling of gas and air, thereby improving combustion and reducing smoke. Furthermore, there is no cooling of the fire by heavy intermittent charges of fresh coal, and consequent production of lost heat, as is the case with hand or stoker firing on grates.

The mechanical production of coal by machine undercutting and shearing and by powder mining has materially affected the grade of coal produced, by increasing the percentage of dust and slack, which in some instances is as high as from 45 to 55 per cent of the total mine output. The generally recognized waste, unsalable or otherwise low-value coal mine products, such as culm, slack, mine sweepings and dust, all of which are suitable for converting into the powdered form, represent practically the same acreage and mining cost per ton as the commercial grades. Moreover, by powder mining and mechanically exhausting coal in a fine state suitable for powdering, out of shallow, faulty, inferior quality and otherwise undesirable abandoned operations, much fuel that is now going to waste could be advantageously mined and utilized. Furthermore the annually increasing expense to produce the inferior qualities and grades of coal in the mining operations, now make it essential that the railways utilize as much as possible of the inferior grades and qualities of local fuel supply available, in order to conserve the better mine output for commercial revenue tonnage in the domestic and foreign trade.

In general, powdered coal, to give the best results as regards complete combustion and the least trouble as regards ash and slag, should contain not more than 1 per cent moisture, and be of a uniform fineness, so that not less than 95 per cent will pass through a 100-mesh, and not less than 85 per cent through a 200-mesh, and not less than 70 per cent through a 300-mesh screen. The cost for preparing powdered coal will vary with the cost for the raw coal and its moisture content. However, a general average from available data covering periods of the past five to ten years at cement and metallurgical plants will enable the following conservative estimate, assuming the cost of the raw coal at from $1 to $2 per short ton, and that it will require crushing and have a moisture content of from 5 to 10 per cent, when placed in the dryer.

Capacity of plant in short tons per hour	Average total cost for preparation per short ton
2	From 25 to 50 cents
3	From 20 to 45 cents
4	From 16 to 40 cents
5	From 14 to 35 cents
10	From 12 to 30 cents
25	From 10 to 20 cents

The fuel required for drying the coal will average from 1 to 2 per cent of the coal dried. The distribution of the total cost may be approximately stated as:

Fuel for drying	10 per cent
Power for operation	30 per cent
Labor	30 per cent
Maintenance and supplies	25 per cent
Interest, taxes, insurance and depreciation	5 per cent
Total	100 per cent

The cost for preparing powdered coal should be more than offset by the ability to utilize the cheaper grades of fuel.

Finely divided coal dust gives off gas at normal atmospheric temperature, but any pulverized coal coarser than that which will pass through a number 100-mesh screen is liable to explosion only when distilled by the heat or compression of a primary ignition. The finer than what will pass through a number 100-mesh screen carries no danger unless combined in a dry state, in floating suspension in nearly still air and mixed with the requisite amount of oxygen at the requisite temperature to produce "chemical tension" or primary ignition.

Powdered coal may be burned by either of two generally defined methods: The first, or long-flame method, constitutes a progressive burning of the coal. This combustion is accomplished by projecting the primary air which carries the fuel into the furnace with high velocity, the additional air (about 75 per cent) required for combustion being blown or induced into the furnace from other sources. The second, or short-flame method, has been the latest development. This process involves a flame of relatively short travel, and consists of admitting the entire air supply needed for combustion into the furnace with the fuel at low velocity. In the application of powdered coal to a New York Central locomotive, a combination of the long and short-flame methods has been used.

But very little descriptive data as regards the equipment that is essential for burning powdered coal in locomotives has been obtained. However, it may be stated that the principal requirements are: An enclosed fuel container; means for conveying the fuel to the feeders; means for commingling the fuel with air at the time of and after feeding; supplying the proper amount of air to produce a combustible mixture at the time the fuel and air finally enter the furnace; a suitable refractory-material furnace in the firebox; means for disposing of the slag; means for producing the proper draft through the furnace and the boiler; means for harmonizing the draft and the combustion; suitable power for operating the fuel and air feeding mechanism, and an automatic and hand control of the fuel and air regulation.

It is understood that the developed equipment for burning pulverized fuel can be readily applied to all existing modern types of steam locomotives without any changes in the bo except to install arch brick supporting tubes, where fireboxes are not now equipped, and to remove the grates, ashpan and smokebox draft appliances. There is no equipment in the cab except the automatic hand control, which is placed in a position convenient to the fireman. The enclosed fuel container is suitable for either powdered coal or fuel oil, and either kind of fuel can be used by merely changing the feeding equipment. The total weight of the equipment applied will about equal that of the equipment removed.

The information pertaining to the operation of powdered coal burning equipment is also vague. It is understood, however, that for firing up a locomotive, the necessary draft through the boiler is obtained by means of the usual stack steam blower, after which a piece of lighted waste is placed in the fuel and air conduit leading to the firebox, and one of the fuel feeders is started.

SOME BENEFITS TO BE DERIVED FROM ITS USE

With powdered coal the tendency toward the more uniform, intense and sustained firebox temperature, as well as the automatic, continuous stoking of the fuel and the burning in suspension; feeding of practically dry fuel to the furnace; reduction in the clogging and leakage of flues and the reduction in the various heat losses, should all tend to maintain the boiler capacity at its maximum effectiveness under varying operating conditions.

Through the burning of powdered coal in suspension, the necessity for over or under-feeding fuel to grates or retorts is eliminated, and as there are no grate fires to require cleaning, it enables the establishing of the most economical length of locomotive run for the train service to be performed, and the reduction of engine house terminals. As locomotives burning oil are being regularly and successfully operated on runs from 300 to 450 miles each way, the same should be entirely feasible when burning powdered coal.

The use of bituminous coal in a powdered form seems to be the logical solution of the smoke, cinder and spark questions

*See also article on "The Use of Pulverized Fuel for Locomotives," published in the *Railway Age Gazette* of April 30, page 941.—[Editor.]

at engine houses, terminals and on the road, and one that should greatly reduce the loss of heat and fuel cost resulting from imperfect combustion in existing and future steam locomotives.

The elimination of ash pans, grates, smokebox, diaphragm, baffles and nettings substantially reduces the retardation of the products of combustion through the boiler.

With powdered coal, the fuel is supplied to an enclosed, air-tight container on the tender (suitable for either powdered or liquid fuel), prepared to uniform fineness and thoroughly dried, so that when fed to the furnace it immediately produces effective heat. Furthermore, the coal is not touched by hand or shovel from mine car to furnace and there is no loss by pilfering, dropping from the tender container, gangways, through holes in deck, or by firemen shoveling undesirable fuel off the tender on right-of-way.

When powdered fuel is used, the refractory-material furnace retains its heat and prevents the chilling of the firebox and flues, even though the supply of fuel may be cut off and therefore reduces the liability of firebox leakage.

When being worked at from one-half to maximum boiler horse power capacity, a locomotive boiler equipped with a superheater will range from 65 to 55 per cent boiler efficiency, this being representative of the best grate fire practice. Taking into consideration the effect of burning powdered coal in suspension on the various heat losses enumerated, it is most conservative to place the saving to be effected at 25 per cent of the coal fired, actual performance to date having shown as high as from 30 to 40 per cent saving.

The time required for building, cleaning or dumping fires at terminals and cleaning flues and smokeboxes on steam locomotives represents a large percentage of the maximum non-productive delay to power, and is directly responsible for much road and yard crew and shop labor expense. With powdered coal there are no grate fires to clean; the extremely fine nature of the ash and absence of cinders causes practically no accumulation in the flues or smokebox.

As the sulphurous and other poisonous gases resulting from combustion tend to precipitate with the liquid ash into slag, the poisonous and suffocating effect of the products of combustion emitted from the stack is materially reduced.

The use of powdered coal (due to absence of cinders, sparks, ashes, etc.), would reduce cementing of ballast and lack of drainage of roadway, burned out ties and the cost for forking ballast.

As the larger locomotives now frequently require the feeding of from 4,000 to 10,000 lb. of coal per hour to produce their rated hauling capacity, the effectiveness of the boiler is dependent largely on the intelligence and physical qualifications of the fireman. However, with powdered coal and automatic mechanical mixing of the fuel and air and its combustion in suspension, no manual labor is required, and the human element is practically eliminated.

Discussion.—The members participated freely in the discussion, there being some skepticism as to the ultimate outcome of the use of powdered coal. E. H. Stroud, of E. H. Stroud & Company, stated that the coal must be powdered to the correct fineness and that it must be uniformly fine if the best results are to be obtained.

Complete combustion must be obtained to prevent the formation of cinder slag and if the furnace is correctly designed there should be no trouble with the accumulation of slag on the flues. The air and the fuel passed through the burner should be definitely measured, and to accomplish this he strongly recommended that the air necessary for the complete combustion of the powdered fuel be admitted only through the burner. Where air is used to separate the fine from the coarse particles in the process of pulverizing—a coal with 10 per cent. moisture will be reduced to 7 or 8 per cent .moisture. He also recommended a lazy flame, stating that in stationary plants this would give a temperature that could be regulated from 1,800 to 3,600 degs. F. In this same service savings as high as 50 per cent. in fuel of a low price have been made. He gave estimates of 15 cents per ton as the cost for pulverizing fuel at the rate of 5 tons per hour and 4 to 5 cents per ton for drying the coal. From his experience he found that a draft of only ⅜ in. (water column) was required. He recommended a coal with not less than 25 per cent. volatile.

Joseph Harrington, of the Powdered Coal Engineering & Equipment Company, called attention to the effect the use of powdered coal on locomotives would have in postponing the necessity of electrification at large terminals such as Chicago, and spoke to some extent on the large field this type of fuel offers to the railroads.

J. E. Muhlfeld, president of the Locomotive Pulverized Fuel Company, presented a written discussion, in which he confirmed the conclusions derived from Mr. Robinson's paper. He showed that if the powdered coal equipment was applied to all types of locomotives an annual saving of millions of dollars could be made in the cost of fuel to the railways.

Other speakers who have had experience in the use of powdered coal spoke strongly in its favor, and all called attention to the necessity of having the powdered fuel dry, the maximum moisture being placed at 2 per cent.

Mr. Robinson stated in his closure that tests have shown that only 15 lb. of dust was found in the locomotive frontend after a test of two weeks and that evaporation of 8½ to 12 lb., from and at 212 deg., had been obtained.

FUEL CONDITIONS IN SOUTH AMERICA

By James W. Hardy

Sales Agent, West Kentucky Coal Company, New Orleans, La.

Chile, under normal conditions, uses about 3,000,000 metric tons of coal annually; about one-half of this amount comes from foreign countries and the other half is produced at home. In addition during the year 1913 they used 230,845 tons of oil. The physical characteristics of the coal are about the same as Illinois or Oklahoma coal, but considerably lighter, and they use more of it to do the same work than they do of either Welsh or Australian coal. Local coal is sold for considerably less than foreign coal on account of its lightness and preparation. The prices paid for railway coal by the Chilean government for the past eleven years range from $4.44 to $7.28 (in our gold) per short ton, and the average was $5.62 per short ton for all coal. Their specifications were drawn up in such a way that they practically exclude North American coal. They place a limit of $2.11 (Chilean) per 1,000,000 calories (based on kilograms of fuel). This would mean a price of $4.86 per short ton for coal running 12,800 B. t. u. per pound. In addition to this 5 per cent moisture, 15 per cent ash and 2 per cent sulphur was the maximum and a further limitation of 15 per cent screenings through a ½-in. bar screen, set at an angle of 45 deg.

They have used briquettes to some extent in Chile until the European war started, and prefer them to coal and pay about 10 per cent more for them. They prefer to handle them, and so do the ship people prefer them as freight, as they can be loaded and unloaded more rapidly and with less waste.

Peru is not developing her fuel supply to the same extent or as rapidly as Chile and uses much less coal than Chile. The coal mined in Peru is of such inferior grade that its use was discontinued on locomotives; it clinkered badly and ran over 20 per cent ash, fusing at a very low temperature. The Peruvian steamship line uses oil altogether.

Freight rates to South American ports are cheaper from Australia than they are from the United States. Coal is placed on ships at $2.50 per metric ton and taken across in sailing vessels at from $4.30 to $5 per ton freight charges, English coals at $1 to $1.50 higher. The freight cost to get North American coal down there is considerably more than this. The toll through the Panama canal is $1.20 per 100 cu. ft. of carrying capacity, so it costs about 60 cents per ton to get coal through the canal. The best ocean freight rate to the west coast would be between $5

and $6 per ton. The rates have a wide range of fluctuation; they go largely on the theory of "charge all the traffic will stand" and this very feature is a grave danger in getting tied up in contracts for fuel deliveries to those countries.

I only wish the people in the United States, who are clamoring so vigorously, loudly and persistently for government ownership, could see and ride on the government railways of Chile. I am sure they would then be glad and contented to allow things on the railways of the United States to be handled and operated as at present and with, at least, their moral support. The railway between Valparaiso and Santiago is a 66-in. gage track, poorly kept up, coaches dirty and badly in need of paint and varnish, freight cars in a dilapidated condition, coupled with hooks and chains the same as the safety chains between our engines and tenders. No air brakes or safety appliances, not even grab irons. The engines are all much cleaner than they are in the United States. Engineers (drivers as they call them) receive $2.25 to $2.50, and firemen $1.40 to $1.90 per day on a basis of our money. The position of engineer or fireman is not thought much of and their responsibilities are not recognized as they are with us; their social position does not compare with ours in any way.

Their standard shovels were quite a curiosity. The blade is 18 in. long, 6 in. wide, 2 in. deep and has a handle 53 in. long with a little knob on the end. These shovels hold 7 to 9 lb. and are very inconvenient to handle. The fire doors are very small and are left open nearly all of the time. There is a deflector just above the door on the inside set at an angle of about 30 deg., which throws the currents of cold air down on top of the fire, so there is apparently no bad effect on the flues from leaving the door open. They never shake the grates because they are all stationary. They put the coal in about as it burns, and it is astonishing to see how little is in their fireboxes at the end of the run. The freight cars are 10 to 15 tons capacity, although there are some of 30 tons capacity; the smaller size being the favorite. The road is lined with scrap; thousands of dollars' worth being eaten up by the rust. They charge you as much for the baggage as they do for the passenger in some places. The passengers are divided into two classes and they pay according to class; their comforts are about in proportion to the classification.

The Peruvian Corporation Company of London, England, controls nearly all the railways of Peru; they are government owned and were operated by the government for years, but the operation was so faulty and expensive that it nearly bankrupted the country. The service was so poor and uncertain that they were finally taken over by the above corporation to operate for a period of eighty years, and under the able management of such men as J. H. Feehan, who is a native of the United States, they are being placed on a safe basis and are beginning to pay and improve.

The Oraya Railway or Peruvian Central runs out of Lima and crosses the Andes mountains at an elevation of 15,665 ft. above sea level. This is one of the most wonderful pieces of railway engineering and the highest railway in the world. In going 106 miles the main line rises steadily from sea level with an average grade of about 4 per cent, clinging to or boring through solid rock almost the entire distance, to its highest point at Ticlio. There are 65 tunnels, 67 bridges, many of them perfect marvels of construction. Sixteen switch backs are located at various points where the steepness of the mountain permits of no other means of ascent. They have 65 locomotives, both English and American oil burners.

We in the United States have no idea how the cataclysm in Europe has affected South American countries. Train service is reduced in many places to a passenger train per week; shops are working two days per week with reduced forces; thousands of people are out of employment and in destitution.

There have been numerous articles in the newspapers about the great possibilities of our walking away with *all* of the South American trade. We need educating in these matters more than do the people in South America. To do business extensively with South America we must establish banking facilities with them. We must extend long credits, six months to a year at least; we must teach them the American dollar instead of the English pound. We must find a home for their exports; their regular markets are now closed and, as their revenue is largely from exports, how can they buy or pay, unless they can borrow or sell? Representatives must go down there and live; learn the language, customs and habits of the people, their needs and requirements and cater to them. Make things the way they want them instead of trying to convert them to our standards, and then sell at reasonable profits. Of the total tonnage imported by Argentina, Brazil, Chile and Uruguay, only 5.17 per cent comes from the United States.

ANALYSIS OF DEPENDENT SEQUENCE AS A GUIDE TO FUEL ECONOMIES

By Harrington Emerson

The Emerson Company, Efficiency Engineers, New York

With a good steam engine, a good furnace and a good boiler, a horsepower can be produced from one pound to a pound and a half of coal. The steamers of the Inch Line have long records of one pound per 1 hp. The Lusitania, with all her auxiliaries, uses about 1.5 lb. The indicated horsepower generated by all the locomotives of the country when pulling trains, divided into the total fuel, amounts to between 4 and 6 lb. I intend to speak of those attainable ameliorations in our locomotive practice as might reduce the 6 to 4, the 4 possibly to 3.

To bring about attainable reductions, there are three essentials: Complete knowledge of what is taking place from mine to ash pit; an organization that is capable of taking hold of the subject; an organization that is competent to solve the problems.

The first step towards the solution of the problem is to set down what we do know of all the steps from mine to ash pit. It will be found that there are some sixty different, distinct steps and that they form what is technically called a dependent sequence. Unlike the links of a chain, which are in dependent sequence, the use of coal is one in which any loss that occurs in the first term is carried on into the second, the losses in the second link or term are carried on into the third link, and we find suddenly that we have frittered away all the strength there was.

Dependent Sequences in Coal Use in Locomotive Operation

Sequences					
1 to 23	23	A	Administrative inefficiencies	51	per cent
24 to 32	9	B	Shrinks in quantity between purchase and use	92	per cent
33 to 45	13	C	Wastes due to poor design	69	per cent
46 to 52	7	D	Wastes due to poor firing	71	per cent
53 to 58	6	E	Wastes due to poor running	88	per cent
	58			20	per cent

Probably in no case do all the possible losses occur cumulating on any single road, but probably on every road there are at least 30 different kinds of losses. As to each of the fifty-eight a separate analysis would be desirable, an analysis that each must make for himself. I shall content myself with a few indications and a very elementary estimate of the loss that may be occurring.

A.—Administrative Losses.—These far exceed all others, but it is the fireman and engineer who get the most blame.

1—Eff. 99.5 per cent. Buying too much coal. Coal costs money and money carries interest. For a road spending $6,000,000 for coal at $1 a ton the difference between a two months' supply and a two weeks' supply amounts annually to $45,000 a year, or the loss from this source might amount to 0.5 per cent.

2—Eff. 96 per cent. Paying too much. This is much more serious. Coal contains B. t. u's, and this is all that makes it valuable. Wise buying might secure 5 per cent more B. t. u's for the same money. This has proved feasible in industrial plants and on railroads as to other items than coal.

3—Eff. 95 per cent. Buying wrong kind of coal (clinkering, coking, etc.). Certain coals containing 60 per cent of B. t. u's of another coal or—The type of coal may make a very great difference. Wisdom as to this matter might make a difference of 5 per cent.

4—Eff. 94 per cent. Unnecessary transportation. Probably $0.60 a ton

is added to cost of coal on long roads by transportation charges, of which $0.06 might be saved by wise routing.

5—Eff. 98 per cent. Unnecessary handling expenses, loading and unloading, detention of cars, etc.

6—Eff. 90 per cent. Wrong sizing of coal. A. G. Kinyon, a recognized authority, estimates the difference between properly sized coal and usual run at 10 per cent.

7—Eff. 98 per cent. Loss in value of coal due to weathering. In some coals this is very great, as much as 10 per cent in a year. It might be conservatively estimated at 2 per cent.

8—Eff. 99.7 per cent. Moisture in coal. Even if the coal absorbs 5 per cent of moisure the loss is small, about one-third of one per cent.

9—Eff. 99 per cent. Bad water conditions, indirectly affecting coal consumption. Our experience has been that when water was very bad, coal consumption for similar trains and locomotives is higher.

10—Eff. 95 per cent. Scale on tubes and other fire surfaces. F. W. Foltz, fuel supervisor of the Missouri Pacific, stated that the fuel losses due to this cause were enormous. They undoubtedly might be far worse than the 5 per cent allowed.

11—Eff. 99.7 per cent. Leaks from boiler.

12—Eff. 99 per cent. Broken grates. Causing excess of air and waste of coal before being burned.

13—Eff. 97 per cent. Use of cold water and frequent changes. On a road using 6,000,000 tons, this loss probably amounts to $200,000 a year.

14-15-16-17—Eff. 85 per cent. Terminal and roundhouse losses. Mr. Foltz's estimate of terminal and roundhouse losses is 15 to 30 per cent of total fuel bill.

18—Eff. 98 per cent. Detentions on side tracks.

19—Eff. 99 per cent. Short sidings and other unnecessary see-sawing of trains.

20—Eff. 99 per cent. Uneconomical grades. It is very easy to lose money on a grade in order to try to save it on coal. There are, however, sags and fills that have altered original grade that if corrected would favorably affect all operation, including coal.

21—Eff. 98 per cent. Uneconomical loading.

22—Eff. 98 per cent. Wrong assignment of power.

23—Eff. 98 per cent. Unscientific time schedules. Based on distance rather than grades.

If all these inefficiencies should occur on the same road, only one as high as 10 per cent, many of them less than 1 per cent, the end result would be under 51 per cent.

B.—Shrinks in Quantity Between Purchase and Use.—The locomotive is generally charged with coal purchased, not with coal used. These losses are partly due to dishonesty and partly due to carelessness.

24—Eff. 99 per cent. Incorrect mine weights (dishonesty).

25—Eff. 99.5 per cent. Incorrect car weights (carelessness). A car, owing to mud, etc., is more apt to be more than stenciled weight. The extra weight is paid for as coal.

26—Eff. 98 per cent. Biased weigher.

27-28-29-30—Eff. 97.5 per cent. Loss in transit (coal that drops off or is thrown off, loss in loading tenders, loss from tenders). These losses, although small, are like a continuous leak. One railroad supervisor told me that the loss on commercial coal in transit was 2.5 per cent. It is not less for company coal.

31—Eff. 99 per cent. Diversion from coal in transit. I knew a flouring mill which operated for a year on stolen coal, whole car loads being diverted, after being weighed and charged to coal bunkers.

32—Eff. 99 per cent. There are other diversions, as when coal from bunkers is used for office and roundhouse fires, etc., coal used perhaps for company but not used on locomotives. These dishonesties and semi-dishonesties amount perhaps to as much as 2 per cent. The end result is about 92 per cent.

C.—Waste Due to Poor Design.—The best stationary steam engines use about one pound of coal per 1 hp. The ordinary commercial steam engines use from 3 lb. to 20 lb. The conditions under which a locomotive operates are extraordinarily difficult. The power installation is mounted on wheels, the machinery must be rugged rather than accurately finished. Every element of standard operation varies from minute to minute. The fuel, the water, the load varies. It is, therefore, inevitable that severe losses occur from poor design. In good stationary practice 80 per cent of the heat in the coal passes into the water. In locomotive practice very rarely as much as 50 per cent. There is, therefore, a shrink of about 30 per cent in coal efficiency to be charged to design and conditions of operation. Two-fifths of this might possibly be eliminated and if distributed might be apportioned as follows:

33—Eff. 99 per cent. Design of firebox.

34—Eff. 98 per cent. Size of firebox.

35—Eff. 95 per cent. Diameter and length of tubes.

36—Eff. 95 per cent. Front end design. In an English test 375 hp. out of 2,000 was used in creating draft. M. C. M. Hatch, superintendent fuel service, D. L. & W., states that only 19 per cent of front end vacuum pump is effective at fire.

37—Eff. 98 per cent. Poor ash pan design. Air openings should be 14 per cent of grate openings and about 100 per cent of tube opening area.

38—Eff. 98 per cent. Grate openings.

39—Eff. 95 per cent. Radiation.

40—Eff. 95 per cent. Economies due to compounding do not become manifest unless the pressure exceeds 180 lb. Can he estimated at 5 per cent.

41—Eff. 95 per cent. Economies due to superheat.

42—Eff. 98 per cent. Preventable friction in machinery, valves, pistons, rods, bearings.

43—Eff. 99 per cent. Wheels of different diameter, as either ahead or slightly shifted from middle line.

44—Eff. 99 per cent. The difference in economy between high and low steam pressure is discernible.

45—Eff. 99 per cent. Direction of draft through locomotive. End result is about 69 per cent.

D.—Wastes Due to Poor Firing.

46—Eff. 99.5 per cent. Building fires. The loss is relatively great, but on the aggregate, small.

47—Eff. 95 per cent. Smoke and sparks. Too little air. M. C. M. Hatch states that at 2,000 lb. coal fired per hour, the coal loss in sparks is 1.5 per cent; at 7,000 lb. it is 12 per cent. To put the loss in smoke and sparks at 5 per cent is conservative.

48—Eff. 80 per cent. Too much air. This is an invisible but serious loss. Assume 50 lb. excess of air for each pound of coal, the air heated 800 deg. Can lose 0.0686 B. t. u. per lb. per degree. For 800 deg. 54.88 B. t. u's. For 50 lb. excess air this gives 2,744 B. t. u's, or about 20 per cent of the heat units in very good coal. The loss might therefore be 20 per cent.

49—Eff. 98 per cent. Popping and plume—too high pressure.

50—Eff. 99 per cent. Too low pressure. The lower the pressure the less the efficiency of the steam engine.

51—Eff. 99 per cent. Cleaning fires wastefully.

52—Eff. 98 per cent. Dumping fires.

E.—Waste Due to Poor Running.—This paper is on a theory and on a method and does not assume to give any proof of the actual losses, which may be more or less than estimated. Undoubtedly losses exist due to poor running, for I have seen letters from firemen narrating the excessive work put on them, and the coal wasted by bad running.

53—Eff. 99.5 per cent. Slipping drivers (harder on the drivers and rails than on the coal pits).

54—Eff. 98 per cent. Full stroke. A train might very easily waste time at a station and the engineer try to make it up by extra steam on the road.

55—Eff. 99 per cent. Throttling in combination with full stroke results in greater steam consumption.

56—Eff. 95 per cent. Dynamometer car tests show variation in horsepower and constant speed when constant horsepower and variable speed is more economical.

57—Eff. 98 per cent. Unwise acceleration. A great consumption of power to gain a few seconds in time.

58—Eff. 98 per cent. Unnecessary braking. This is the opposite of unnecessary acceleration, but is worse, since it destroys not only stored energy but also brake shoes, driver and truck tires and abrades the rails. End result—88 per cent.

If we take the combined efficiency of the engineer and fireman, it appears to be 62.5 per cent or almost two-thirds. But a test made on a switch locomotive reported in Erie Employes' Magazine showed that current consumption of coal was reduced 65 per cent by care, not 33 per cent. Tests have been made both as to passenger and freight runs, which show actual consumptions under dynamometer-car records amounting to only one-third of usually charged consumption. On such runs, wastes due to poor design and to interest charges, to paying too much, to unnecessary transportation and to unnecessary handling expenses, are not eliminated, nor losses due to weathering.

Eliminating these we would have the following major sequences:

A	Administrative inefficiencies	60 per cent
B	Shrinks in quantity	92 per cent
D	Poor firing	71 per cent
E	Poor running	88 per cent
	End result	34.5 per cent

This sequence in its end result of 20 per cent to 35 per cent checks up well with the special tests made, checks up well with the difference between coal actually required for horsepower

generated and the coal charged to the locomotive fuel account.

To correct the cumulative result in dependent sequence of a number of small evils there should be reliable, immediate and adequate records available from mine to ash pit; an organization capable of handling the problems, and an organization competent to solve the problems.

Railroad locomotive practice is defective as to all these conditions. The records are unreliable, deferred and inadequate. Railroads are very slowly outgrowing the belief that a line officer also necessarily possesses staff competence. The fuel problem is a bigger one than records and a specialized organization. These are the tools wherewith results can be obtained, but before we use tools we must have an organization able to use them, an organization competent to expand and supplement the present cramped type.

Discussion.—The paper was well received, the members approving of the broad basis on which it was written. The subject of fuel economies is of so vital importance that all of the higher railroad officers should take an active interest in it. While the mechanical department is directly interested in the consumption of fuel, there are a great number of ways in which the other departments can assist substantially in saving fuel. For this reason it is believed that more decisive action should be taken by the officers in order that the necessary authority be given for a comprehensive and effective fuel economy campaign. Several members demonstrated as to how the transportation department could be of material assistance. On some roads transportation officers have been included on the fuel committees with excellent results, but there still seems to be a feeling that the general officers do not give the fuel problem the attention which it deserves. Tests have shown that large savings may be made in fuel consumption by providing more supervision on the locomotives. It was believed that if the division superintendents were kept accurately posted as to the actual units of fuel consumed more direct benefits would result.

SMOKE PREVENTION

By E. W. Pratt

Assistant Superintendent Motive Power and Machinery, Chicago & North Western

In 1912 and 1913 elaborate tests were made on the locomotive testing plant of the Pennsylvania Railroad at Altoona, Pa., and a complete report made in 1913 to the American Railway Master Mechanics' Association, with recommendations covering the application of steam-air jets, quick-action blower valves, etc. Since that time practically every locomotive operating in the city of Chicago has been equipped with such apparatus and it has been conclusively proven that soft coal burning locomotives may thereby be kept comparatively free from smoke if the engine crew be given and observe proper instructions at all times.

The smoke inspection bureau of the city of Chicago has accepted these devices as standards and recommends them to those inquiring. This bureau consists of the city smoke inspector, two assistants, ten mechanical engineers and nine deputy observers, covering not only the railroads but the entire city. The expense to the city is about $39,000 per year. The railroads in Chicago have a total of 54 smoke inspectors representing an annual expenditure of about $65,000. A railroad smoke inspectors' bureau, under the direction of a sub-committee of the General Managers' Association of Chicago, has been formed. This is composed of the chief smoke inspectors of all railroads in the city and holds its meetings bi-weekly, inviting thereto all railroad men interested in smoke prevention.

The railroad inspectors are required to report all engines they observe emitting dense smoke on a duplicate post card printed with the form shown herewith. One part of the card is mailed to the joint smoke inspection bureau through the U. S. mails, and the other is sent to the proper officer of the violating road through the railway mails. The bureau makes bi-weekly summaries of the reports for the different roads showing the number of reports filed, the number of locomotives operated in Chicago, the percentage of locomotives reported, the average density of the cases reported and the number of reports made by the inspectors of each railroad. These reports are for the private use of the railroads and are not furnished the city. However, the work of the railroad bureau is heartily approved by the city authorities and has been productive of greater co-operation between the various railroads, so much so that the smoke reading made by the city the year following its inception was over 50 per cent lower.

At the present time all city inspectors are instructed to each read locomotive smoke for a total of two hours each day. This to be done in one period or in several periods of 15 minutes or more. These inspectors being assigned to various districts in the city make it certain that the railroad observations will not be confined to any one locality. From these observations the city issues monthly and semi-annual reports. All readings are made in accordance with the Ringlemann method of determining smoke density and the *engine minute* is the unit employed. It should be understood that the city smoke bureau construes one minute of No. 3, 4 or 5 smoke as a violation of the law.

JOINT SMOKE INSPECTION BUREAU
OF RAILROADS OPERATING IN CHICAGO

Date _____ 191__

Inspector _____

of _____ R. R. noted following cases of dense smoke emission on above date:

ROAD	ENG. NO	TIME		DENSITY NO.	LOCATION	REMARKS
		FROM	TO			

Postal Card Form for Smoke Inspector's Report

An *engine minute* covers the observation of one locomotive during the entire minute. During this minute 14 seconds or less is not counted; 15 to 44 seconds is counted as one-half minute; 45 to 74 seconds is reported as a full engine minute. One-half minute of No. 3 density is 1.5. One-half minute of No. 1 density is 0.5, etc. The per cent smoke density is obtained by multiplying the smoke units by twenty (each Ringlemann unit being 20 per cent) and dividing the product by the total engine minutes.

In order that the city inspectors shall read the smoke density correctly, applicants for these positions pass through a probationary period during which time, under the direction of an experienced inspector, they make thousands of smoke readings with a full size Ringlemann chart set up 50 ft. from them in the direction of the stack under observation. These men are under civil service and their standing is based largely on their ability to correctly read smoke density. The members of the Railroad Smoke Inspectors' Association and the city inspectors frequently have joint classes in the reading of smoke density in order that uniformity may be obtained in the case of independent individual observations.

One of the encouraging features of this plan is that it has so fully met with the approval of the city smoke bureau that the latter has voluntarily opened all their record books to members of the railroad bureau, and the reduction in the per cent of density of railroad smoke during the past two years has been remarkable. It is as follows:

1912	10.74 per cent
1913	6.06 per cent
*1914	7.41 per cent

*The figure for 1914 was made up from the Summer reading of 1914 (by old method) and the reading for September, October and November, 1914 (by new method). This figure would be lower but for the change in method.

STANDARDIZATION OF COAL PREPARATION

By H. C. Adams
President, Jones & Adams Coal Company

The present method of screening has caused no end of trouble in marketing the coal, and various losses to the producer. There is never a time in the year when a market can be found to fit the various sizes that are now being made. This results in large quantities of coal being put on the market for any price the customer is willing to pay. It displaces the size the consumer would ordinarily use and which the operator wants him to use, and destroys any profit that might be secured.

No way has been found to store unmerchantable sizes of coal at the mines in large quantities, as this would mean storage for every size produced at times. During the summer months 6-in. lump is made in great quantities in excess of the demand, and frequently sells at mine run prices, or less. In the fall and winter other sizes are made in excess of demand, so to store coal at the mine it would mean to make room for half a dozen sizes, and the operators have not the room or capital to do this.

The railroads at times have their tracks crowded with deadloads of coal of various sizes, for which there is no market, when this same equipment could be used to advantage in other directions.

Approximately 100 tons of mine run coal, as it is prepared today in Central Illinois, will screen out about as follows:

6-in. lump and larger	30 per cent
6-in. by 1¼-in. egg	35 per cent
1¼-in. screenings	35 per cent

If an operator today has an order for 300 tons of 6-in. lump coal, it is necessary to dig about 1,000 tons of mine run to get it, which gives about 700 tons of coal that he may or may not have a market for.

If all coal preparation was standardized so that the lump coal would be made over an inch and a quarter screen, and the operator had an order for 300 tons of lump, he would only produce, on the same basis of figuring 450 tons. Of this amount of coal, only 150 tons would be 1¼-in. screenings, and in most cases would be easier to sell than the first mentioned separation.

The benefits of standardization are numerous: It would reduce the output to a point where the mine would get running time that would greatly reduce the cost. A great many cars that are now constantly tied up with unsalable sizes would be released and could be used for any other purpose. The operator would not be producing two or three tons of sizes that he has no market for in order to get a ton of the size coal he wants. The railroads for their fuel could use either inch-and-a-quarter lump or mine run, as they deem best, and either of these sizes could be produced in quantities required at all times, for the reason that no unsalable sizes would be produced in order to supply railroad coal. The railways are and should be interested in any move that will benefit the operator. A very large percentage of the freight of some of the roads is coal, and when coal cannot find a market, or perhaps finds an unprofitable market, the railway is sure to feel the effect in the lessened prosperity of the operator and his inability to seek broader markets.

Discussion.—The railways must co-operate with the mine operators if a standardization of fuel is to be obtained. It was shown that by doing this in one case the sizes produced by one operator were reduced from 22 to 6, the railways using coal which the operators found it difficult to market.

FUEL STATIONS

The committee deemed it advisable to consider three separate and distinct sub-divisions of the subject as follows: Plant storage for reloading through the medium of cars; plant storage for direct issue to plant, and central storage for distribution to miscellaneous plants. The committee suggests the use of a locomotive crane with a clamshell or similar device for unloading and reloading storage coal, where the amount to be stored is less than 5,000 tons and where the daily issues are small enough to permit of its use.

A cheap method of unloading cars is to use a trestle from which the coal can be automatically dumped. Such a plant could be located adjacent to the coaling station, if the space is not too restricted and the track arrangements permit. Another method is to erect a timber trestle adjacent to the track on which locomotives are coaled and grates cleaned, provided with a runway for a locomotive crane equipped with a clamshell or grab bucket. A plank wall or barrier should be placed along the side of the trestle contiguous to the storage pile, to prevent the coal from accumulating under the trestle. A strip of land about 60 feet wide, and varying in length in proportion to the capacity of the pile would be required for storage. The plan provides for a capacity of 28 tons per lineal foot of coal pile. The coal will be delivered to the coal-receiving track (on the outside of the engine track) in gondola cars of practically any type, from which it will be removed and transferred to the storage pile by the locomotive crane. If desired, this plant may be used for coaling engines either from cars on the receiving track or from the storage pile. It is not considered advisable to use this plant as a locomotive coaling station at terminals where a large number of engines are coaled.

From somewhat meager figures available it is estimated that with these plans coal can be stored from cars, or reloaded from storage at about 2½ cents per ton.

All new mechanical plants should be so designed as to provide a storage adjunct to permit of unloading coal into the receiving hopper, from which it may be distributed, either to the plant direct, or to a storage pile when business is dull and there is a surplus of road cars and of coal. The plant must be so designed as to permit of the recovery and issuing of the coal from the storage pile through the plant without the use of road cars.

The locomotive crane may be used to good advantage for taking care of ground storage in connection with a mechanical coaling station. This plan has been adopted by the Louisville & Nashville, at three places, where large mechanical coaling stations of reinforced concrete and steel construction are being erected. The receiving hopper is enlarged at the back to form a pit of sufficient size to accommodate the grab bucket of the crane. The crane is located on a circular track back of this hopper, this track centering on the hopper. Coal is dumped into the hopper from the receiving track, and handled to storage by the crane. In reclaiming from the storage pile, coal is picked up by the crane and discharged into the hopper, from which it is handled to the overhead coal pocket in the usual manner. For the most economical operation, such a crane should be electrically operated. Such a plant is estimated to cost $23,000 and has a capacity of 22,000 tons.

With the bridge type, the receiving hopper pit is constructed practically the same as for the locomotive crane. This type lends itself to a much larger storage pile and greater handling capacity than the locomotive crane, but it is, of course, more expensive. The inner trucks of the bridge run on a circular track and are held in position by an arm extending to a central swivel point. The outer trucks also travel on a circular track, the center of the circle being the swivel point above referred to. Coal dumped into the pit at the side of the receiving hopper of the coaling station, is picked up by the grab bucket on the bridge, and placed in storage. A swivel bridge of latest design can be contracted for complete above the rails, for from $25,000 for 100 ft. span, up to $50,000 for 250 ft. span, and handling from 100 to 300 tons of coal per hour.

The cable and drag scraper method has been adopted by the Southern Railway, the Canadian Northern, and others. The storage pile is located directly back of the receiving hopper of the coaling station on a large elliptical area. The coal is dumped into the hopper and conveyed to the top of the coal pocket by the usual mechanical means. Instead, however, of dumping into the coal pocket, the coal is deflected into a chute which carries it out into the storage area. The coal is then spread over this area by means of a drag scraper operated from a drum in a tower over the hopper. Located at intervals

around the storage area are pulling poles to which are attached snatch blocks for the endless cable. This method has the advantage of low first cost and low cost of operation, but causes a great degradation to the coal.

The cableway excavator method contemplates having the storage pile between the receiving hopper and the coal pocket, and is particularly well adapted to a storage of 2,000 or 3,000 tons. A mast is provided at the coal pocket of sufficient height to enable the drag bucket to dump into the bin. Directly behind the receiving hopper, anchorages are provided for the main cable. The hopper is so constructed that the drag bucket may scrape toward the coal bin over a sloping concrete floor. In reclaiming, the coal is picked up by the drag bucket, and deposited directly into the coal pocket, ready for locomotives. This is a very economical system, and has the advantage of not requiring additional machinery for the coaling station. It also lends itself very readily to "under-water" storage.

A central storage plant should provide for the storage of from 100,000 to 500,000 tons, and each plant should be as elastic as possible. It should be located at some convenient central distributing point. It should be as near permanent in its construction as possible, and be so designed and constructed that it could be protected at all times without much expense for maintenance, operation and care. It is believed that a modern plant, answering all practical purposes, can be installed for 100,000 tons of coal for an outlay of from $30,000 upward.

[The committee included in its report a description of the coal storage plants at the Panama Canal as representative of the latest practice, the matter being taken from the annual report of the Isthmian Canal Commission for the year ending June 30, 1914.—Editor.]

WEIGHING AND MEASURING DEVICES AT FUEL STATIONS

The committee recognizes the absolute necessity for having correct efficiency performance records of individual locomotives and enginemen, and believes that the railroads and their executives are prepared to spend certain moneys for proper auditing, but that they desire more reliable results and want to know the actual facts as to what their locomotives and enginemen are doing. Fuel accounting should be considered from two separate and distinct standpoints: That of value and that of quantity. The individual coal plant, locomotive and enginemen should be charged with that which it or he receives, and credited with that which it or he issues and uses. No adjustments of any character should be included in the published statements showing individual performances. It is deemed advisable to suggest the adoption of some reliable automatic means of weighing and measuring, and devices that might be cheaply installed, operated and maintained; not only on new plants being installed, but also that might be applied to plants that are in operation. The committee suggests that this subject be again referred to them, believing that additional methods of establishing an automatic and reliable record of the actual amount of coal issued by each plant to each locomotive and each engineman will be on the market during the coming year.

The report is signed by H. J. Slifer, chairman (Cons. Eng.); E. A. Averill (Standard Stoker Company); E. E. Barrett (Roberts & Schaefer Company); W. E. Dunham (C. & N. W.); H. B. Brown (I. C.); G. W. Freeland (Williams White & Co.); W. L. Krausch (C. B. & Q.); R. A. Ogle (Ogle Construction Company); D. J. Madden (Erie), and J. L. Rippey.

This covers the proceedings for the first two days of the convention—Monday and Tuesday of this week. A report of the remaining sessions will appear in next week's issue of the *Railway Age Gazette.*

Railway Extension in Argentina.—It is reported that a bill authorizing the construction of a branch line from Santa Fe to Puerto Reconquista will be introduced in the next session of the legislature of the Province of Santa Fe. Railway extension work at the present time is practically paralyzed and even if the line is authorized, some time must necessarily elapse before work on it can be started.

WESTERN RATE ADVANCE CASE

The hearing at Chicago in the Western rate advance case, presided over by Commissioner Daniels and Examiner Watkins of the Interstate Commerce Commission, was concluded on May 13, with the introduction of several rebuttal witnesses on behalf of the railways. The protestants had concluded their case the day before. First briefs are to be filed by June 10 and reply briefs by June 20, and oral arguments are to be held at Washington beginning on June 22. The hearing was begun in Chicago on March 4, and has been held daily. During the past month or so many night sessions have been held. The printed record in the case has run to nearly 15,000 pages, while the number of exhibits presented on both sides was 1,060. During the hearing 140 witnesses were heard, 55 appearing for the carriers and 85 for the protestants.

The rebuttal testimony of the railroads included statements by representatives of the Union Pacific, Great Northern and Northern Pacific to show that their companies would receive only very slight increases in revenue from the proposed advances, which are confined mainly to Western Trunk Lines and Southwestern Tariff Committee territory. These were introduced in reply to the contention which has been raised by the protestants throughout the hearing, that the statistical exhibits introduced by the railways were not representative because these roads had taken no part in the case. L. R. Capron, assistant general freight agent of the Northern Pacific, stated that the Northern Pacific's revenues would be increased about $3,000 a year by the advances on coal and about $2,000 by the advances on grain.

E. H. Hawley, of the freight traffic department of the Union Pacific, said that his company would receive approximately $8,000 increased revenue from the advances on hay from Kansas and Nebraska to points east of the Missouri river; that it is slightly interested in the livestock advances but the greater part of its traffic on livestock stops at the Missouri river and is not affected. A telegram was presented from the Great Northern saying the increase in revenue which that company would receive from the advances is only about $20,000 a year. The witnesses testified that while some of the rates would be advanced on some traffic originating on their lines, the advances usually do not apply to their portion of the haul.

Clifford Thorne, of the Iowa commission, contended that these roads should be included because they are interested in a general movement of western roads to advance rates, and are interested in the tariffs eliminating certain "free services" which were originally included in this case but have been transferred to separate dockets. Mr. Capron and Mr. Hawley said that the increases in revenue which their roads would receive from these tariffs were very small. At the request of Luther M. Walter, representing Morris & Co. and other packers, Commissioner Daniels finally made a ruling directing the Great Northern, Northern Pacific and Union Pacific to file division sheets covering the tariffs included in the commission's suspension order.

Just before adjournment Mr. Thorne made a request that the commission allow the introduction as evidence of a large number of exhibits compiled by W. J. Lauck to show the "prosperity" of the roads, and used by him in the recent arbitration proceeding on the engineers' and firemen's wage demands, in which he appeared as statistician for the brotherhoods. Mr. Thorne said that it had been intended to ask for permission to file the entire set of exhibits, comprising about 4,000 pages and representing a cost of $100,000, but as the commissioner had indicated during Mr. Lauck's testimony that he considered a large amount of this material irrelevant, he had decided to ask to file only a selected number of the exhibits. Commissioner Daniels ruled that they could not be introduced.

E. B. Boyd, chairman of the Western Trunk Line Committee, introduced some exhibits in reply to criticisms which had been made by witnesses for the protestants on his original exhibits and to correct some figures in the record on the amount of grain traffic involved in the case. He said that A. E. Helm, of the Kansas commission, in trying to show how many tons of grain

the railways transported from Kansas had included over 6,000,000 tons of corn cobs, by multiplying 30,000,000 bu. of corn by 70 lb., instead of using 56 lb. per bushel for shelled corn, which is the form in which corn is shipped. He said the protestants had used figures showing the total production of grain in various states, which includes a large amount of grain not shipped out of the state.

F. S. Hollands, assistant general freight agent of the Chicago Great Western, testified regarding rates on hogs in Minnesota and Iowa; Conrad Spens, assistant freight traffic manager of the Chicago, Burlington & Quincy, testified in reply to statements by protesting witnesses that the advance on livestock to Chicago would change the routing of the traffic, and F. P. Eyman, assistant freight traffic manager of the Chicago & North Western, explained that rates from Chicago to Wisconsin on livestock had not been advanced on account of the competition with Milwaukee, since the rate from Milwaukee to Wisconsin points is a state rate and cannot be advanced in the present case. N. D. Ballantine, assistant to second vice-president of the Chicago, Rock Island & Pacific, testified regarding the handling of livestock traffic, saying that the railroads' contention that the livestock traffic reduces the efficiency of train operation had been proved by exhibits of the shippers themselves.

J. Pease Norton, bond expert, was placed on the stand as a witness for the state commissions to testify to some additional exhibits showing the yields on various classes of bond issues for the purpose of showing that the credit of railway companies is improving in relation to that of governments and industrial and public utility companies. He presented a compilation for a large number of bonds showing the net proceeds. M. O. Lorenz, statistician for the Interstate Commerce Commission, contended on cross-examination that the list of railways selected by Mr. Norton was unrepresentative, since with only one exception, they have been consistent dividend payers, and their bond prices therefore would not correctly reflect a decline in credit since 1910. Dr. Lorenz also showed that the increase in the proportion of bonds to stock indicated that some factor was at work which affected the credit of the railroads adversely. Mr. Norton attributed the decline in the price of bonds partly to the increase in the production of gold, saying that the bondholder knows his principal when repaid will purchase fewer commodities and naturally wishes a higher rate of interest. Doctor Lorenz asked if this rise in prices would not have some relation to railway rates. Mr. Wright, on cross-examination, showed that improvements in the character and value of a road making the bonded indebtedness a small proportion of the value would have an influence on the price of the bonds, and also that many of the railroad bonds were seasoned securities, whereas the industrial issues were new. He said the comparison of a stable, seasoned security with newer and unsettled issues was worthless. "Ought not the rate of return of the railroad to go up if the itnerest and commodity prices have gone up following the increase in gold production?" asked Mr. Wright. The witness claimed that earlier railway rates were too high, so that no increase was necessary.

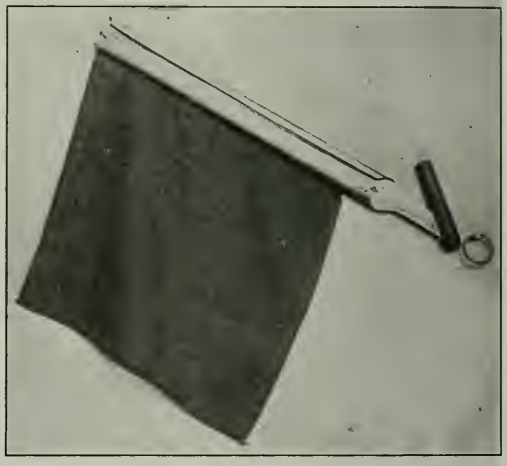
A. N. Bean, an examiner of accounts for the Interstate Commerce Commission, testified as a witness for the commission to present the results of inquiries which had been addressed to the railways, asking an explanation of the increase in operating ratio. He had made a compilation of the replies, showing that the principal causes named by the railroads were increased wages, increased cost of fuel, increased price of ties, larger expenditures for maintenance of road and equipment, increases in taxes, more numerous requirements of state and federal statutes, decreases in revenues with reductions in rates and the introduction of depreciation charges.

Railroad Construction in Portugal.—The government of Portugal has authorized by presidential decree the Administrative Council of the State Railways to spend about $300,000 for the immediate construction of branch lines from Condomil and Ermezinde to Leixoes.

A FLAG AND TORPEDO HOLDER

The illustration shows a flagstaff which has been designed as a convenient holder for torpedoes, doing away with the present methods of carrying them in a sack with a draw string, or of twisting the lead straps around the flag and stick. By this device they can be taken from the container without removing gloves in cold weather. There is also no chance of losing the torpedoes.

The staff is made of galvanized sheet iron, bent as shown, the handle being split into two parts and connected near the ring. The part of the handle on one side is fastened by two bolts, while the portion of the handle on the side shown in the illustration is pivoted by one of these bolts. The staff is corrugated



Combined Flag and Torpedo Holder

its full length to give stiffness. When it is desired to put torpedoes into the staff, the handle is moved on the pivot to the position shown and the torpedoes are inserted in the slot, which will hold 12. The handle is then turned down on the pivot until it occupies its normal position, at which point it acts as a lock and prevents the torpedoes from coming out. The handle is also locked by the corrugation. At the top of the flagstaff the two corners are bent over to prevent the torpedoes being removed at that end.

The flag is fastened by a rod run through the hem, the lower end of the rod passing under the stationary half of the handle and the top end being bent and passing through a hole in the body of the container. A cotter key fastens it in place. This torpedo holder was designed and patented by W. J. Strohm, Moline, Kan.

Higher Rates between Scotland and Ireland.—The cross-Channel shipping companies having recently intimated an increase in their rates for the sea portion of the journey between Scotland and Ireland, the five chief Scottish railways (Caledonian, Glasgow & South-Western, Great North of Scotland, Highland and North British), have given notice of an increase of 1s. 3d. (30 cents), a ton in their rates on merchandise between stations on their lines and ports and stations in Ireland. Live stock rates between certain Scottish stations and the ports of Belfast, Larne, Newry and Dundalk are also to be increased to the extent of the increase in sea transit charges, which is 1s. (24 cents), per head for horses, 6d. (12 cents), per head for cattle, and 3d. (6 cents), per head for sheep, lambs and pigs. Similar notices applying in the reverse direction have been issued by some of the Irish railway companies. The increases are effective June 1.

Maintenance of Way Section

In the April maintenance of way section we devoted considerable space to the renewal of ties. In this issue are found similar articles relative to the relaying of rail. We plan to continue these timely discussions in the June maintenance of way section, in which we will discuss particularly, the ballasting of tracks. We invite contributions on important phases of this subject, including the kinds of ballast best adapted for lines of different densities of traffic, the organization of forces, the relative merits of heavy and light raises, the classes of labor best suited for work in ballast gangs, etc.

Handling Ballasting Work

The Lehigh Valley has laid 160,000 tons of rail during the past five years without spacing ties. The statement by G. L. Moore, in an article on another page describing the methods of laying rail on this road, that "we have yet to find the first case of damaged rail by reason of not spacing joint ties, but have been able to greatly improve our track by diverting the labor so employed in former years to the more important work of improving the surface and line and renewing the ties," is therefore significant and of special interest. This practice is gaining ground on a number of other roads, including the Pittsburgh & Lake Erie, the St. Paul and the Illinois Central. While care must be used in the adoption of this method, the results secured on the roads which have given it extensive trial, commend it for serious consideration on main line tracks which are normally maintained to a high standard and on which, therefore, the track is not allowed at any time to get badly out of line and surface.

Laying Rail Without Spacing Ties

The president of one large railway was led to favor the adoption of ballasted floors on bridges on his lines largely because of the greater sense of security they give to the lay passenger. Another railway officer refuses to allow the high viaducts on his road to be referred to in advertising literature, even though they are excellent examples of engineering design, because of the sense of danger they may create in the mind of the prospective passenger. As outlined elsewhere in this issue, the Pennsylvania and the Lackawanna regularly call their landscape architects into consultation in the design of their passenger stations and the surrounding grounds, even at small outlying points, to harmonize the design with the particular location. Several eastern roads plant flowers systematically about the station grounds each spring, even to the extent of transferring flowers from the hothouses to these various points by special work trains. The Canadian Pacific organized several large extra gangs last fall to cut off all the brush to the right of way fences on the western mountain divisions. These examples illustrate the importance attached to appearances by many railway officers and the expenditures they are willing to make to secure these more or less intangible results. The lesson should not be lost on maintenance of way men, for it is of special significance to them as custodians of the company's property. While many roads have given close attention to the systematic policing of the entire right of way, others have largely neglected it. It costs little or nothing for a bridge crew to burn or otherwise remove the pile heads and odd pieces of timber lying about a job after they have completed their work, or for a concrete gang to level off the small amount of gravel which may be left after the completion of their work. Likewise, it requires little time for the section crew to pile and burn the ties removed from the track and to carefully collect and store the scrap at some obscure point about the section house. A certain amount of debris is necessary about a railway. It is not, however, necessary to display it as prominently as is frequently done. The difference between attention to and neglect of this subject is frequently the difference between a favorable and unfavorable impression on the part of the traveling public.

The Value of Appearances

Normally the relaying of rail should be actively under way at this season. This year, however, the work is being seriously delayed. In the first place, the ordering of rails has been seriously retarded, as occurred last year, when only one-half as much tonnage of new rails was laid as in 1913. While some roads, such as the Burlington, the Santa Fe and the North Western, ordered their usual tonnage early this spring, many are still delaying placing the orders for their requirements, one of the most prominent being the Pennsylvania, which is now reported to be in the market for over 125,000 tons. With the large number of rail orders still to be placed, it is evident that the work of relaying the rail in the track will be seriously delayed this year. This introduces a special problem and opportunity for maintenance of way officers. Because of the ample supply of labor available it will be possible to secure gangs of relatively higher efficiency than in previous years. With the reduced amount of work under way it will also be possible for the supervising officers to give more attention to the details of their work. This will permit the organization of more efficient forces and should result in handling the work more economically.

The Relaying of Rail

CHANGING EXPENSE INTO REVENUE

THE article entitled, "Income from the Maintenance of Way Department" in another column in which the writer describes the methods by which one supervisor has created an annual income of over $10,000 from the sale of materials, most of which were previously considered only a cause of expense, opens the way for study in a field to which comparatively little attention has been paid. As stated in this article the maintenance of way department is primarily a spending organization, and attention has been directed almost entirely towards making these expenditures as economically as possible. This is as it should be from the very nature of this department. But this does not necessarily mean the exclusion of other problems with which the maintenance of way department is in most intimate contact, the solution of which may result to the benefit of the company.

Up to a few years ago all materials unfit for further use in their present condition were sent to a central point and sold in bulk as scrap. Gradually it was found that the sorting of this scrap into various grades enabled higher prices to be realized. This soon led to the establishment of scrap reclaiming plants on a number of the roads at which much of the scrap material was reclaimed for further service by repairing it or converting it into other materials. This development, however, applies only to materials with a generally accepted scrap value. The disposition of other materials such as ties and cinders, released by the railroads in large quantities, has been regarded as a necessary cause of expense, notwithstanding the fact that in certain isolated localities there was a considerable demand for these materials. The supervisor referred to has developed the latent market for these materials by calling their advantages to the attention of possible purchasers and by letting it be known that they were

for sale. In this way he is only following out the practice of many successful manufacturing institutions whose profits come largely if not entirely from the sale of the by-products. The steel mills formerly were glad to give their slag to the railroads if they would haul it away. Finding that the railroads were glad to secure it, several mills are now able to sell it to the roads at a few dollars per car. The fact that a plan such as is outlined in the article referred to must be worked out carefully and with proper supervision to prevent abuses creeping in should not deter the proper officers from giving it careful consideration, for a sufficient number of savings such as this may mean the difference between unprofitable and profitable operation.

LABOR SAVING APPLIANCES

RAILWAYS have been slow in many cases to adopt labor saving devices. This has been particularly true in the maintenance of way department, which has lagged behind other departments, and especially behind the construction department, with which it is closely associated. On construction work the station man of a generation ago with his shovel and wheelbarrow has been replaced almost universally with the grading machine, the steam shovel and the dump car, while the track laying machine has largely replaced hand work on new lines. But one still finds maintenance of way work being done almost entirely by manual labor, aided by a few simple tools, as the tamping bar and the pick.

The reason for this is not apparent at first glance. Twenty-eight per cent of all railway employees are in the maintenance of way department, more than those engaged in the maintenance of equipment, the traffic department and the general offices combined, while nearly 60 per cent of all expenditures for maintenance of way and structures go for labor. This very high proportion of labor cost in the maintenance of way department would indicate that there is a great field for the adoption of mechanical appliances here. The relatively small amount of attention given to this subject, may therefore, probably be considered to be the result of neglect and of preconceived ideas regarding the narrowness of the opportunity rather than from an actual lack of a field.

The best indication of what may be done in this line is a statement of the results actually being secured in certain specific instances where special study has been given not only to the use of mechanical appliances in general, but to means whereby these appliances may be used to the best advantage. Such an instance is the description of the results secured in handling rail out on the line by the use of locomotive cranes, ditchers and derricks on the Lehigh Valley, described in another column. Not only is the picking up of nearly 11 track miles of rail in one day an unusual record, but the manner in which the equipment is regularly handled to secure this result at a cost of only 18 to 23 cents per ton is most unusual. This is only one of many details of maintenance of way work to which power equipment can be applied with corresponding savings. The motor car carrying a power unit provides an opportunity for the use of a wide variety of auxiliary equipment, such as rail drills, tie tampers, portable rail saws, etc. These experiments deserve the hearty support and sympathetic co-operation of maintenance of way men, not only for the results they may produce directly but because of the further improvements to which they may lead. It is the experience of railway supply manufacturers that many railway men are prone to give an adverse opinion regarding a labor saving device without giving it a trial. It is fully as much to the interest of the railroads as the manufacturers for labor saving devices to come into universal use as rapidly as possible, and the quickest way to develop such devices is to experiment with them. There is no more productive field for the reduction of maintenance of way expenditures today than in the replacement of manual labor with mechanical power. Human labor is almost invariably the more expensive.

While a shortage of labor is not to be expected this year, it is only a question of time until this condition will exist, as it does at regular intervals. At such times, when labor cannot be secured at any cost, the value of power equipment cannot be measured solely by its savings. During a season such as this when the indications are that only a moderate amount of work will be carried on, there is more opportunity to study, experiment with and develop new devices than in busy seasons when everyone is working under pressure. This subject should, therefore, receive careful attention this year.

NEW BOOKS

Plain and Reinforced Concrete Arches. By J. Melan, professor of bridge design at the German Technical School at Prague. Translated from the German by D. B. Steinman, professor of civil engineering at the University of Idaho. Size 6 in. by 9 in., 161 pages, 43 illustrations, bound in cloth. Published by John Wiley & Sons, Inc., New York City. Price $2.

The increasing use of concrete arches by railways makes any discussion of the design of such structures of interest to many engineers, and the prominent part which Professor Melan has taken in the development of arch design will serve to introduce his work to many. The book discusses briefly the fundamental arch principles and the stresses existing in an arch and then develops various analytic and graphic methods of analyzing and designing hingeless, one-hinged, two-hinged and three-hinged arches. Other chapters consider the effects of temperature, the displacement of abutments, non-vertical loads, etc. The last chapter covers a method of calculating the stresses in an arch by means of a chart, the use of which is illustrated by numerical examples. In making the translation from the German the notation has been modified and a preliminary index showing all symbols used is inserted for the guidance of the reader. In its diction and phraseology the book bears little evidence of its foreign origin.

Railroad Field Manual for Civil Engineers. By William G. Raymond, professor of civil engineering and dean of the College of Applied Science, State University of Iowa. Size 4¾ in. by 7 in., 405 pages, 31 figures, 83 tables. Bound in leather. Published by John Wiley & Sons, Inc., New York City. Price $3.

The most striking feature of Raymond's Field Manual, just issued, is the use of decimal divisions of degrees in the tables in preference to the more common system of minutes and seconds. The author's reasons for this departure from ordinary practice are stated quite fully in the preface and are based on the convenience in laying out curves with a vernier graduated to read hundredths of degrees and the elimination of the necessity for transposing minutes and seconds to decimals, or vice versa in the solution of curve problems. Instrument makers quote a price of about $20 for changing the verniers of an old instrument and make no difference in the cost of new instruments with such verniers. About 50 engineers, including chief engineers of railroads, independent practising engineers and railroad engineering professors were practically unanimous in their opinion as to the desirability of such a change. It is pointed out that the adoption of the decimal division of the degree does not change the unit, as was the case in the attempted change to the metric system, but is comparable rather with the adoption of the decimal division of the foot in surveying work which is now very general. An endeavor has been made, however, to make the book applicable in case any individual user does not desire to change the system of dividing the degree.

The book is intended primarily for field use and five-place tables have been adopted as representing the greatest degree of precision warranted. The book includes tables and explanatory statements covering curves, the ten-chord spiral, logarithms and trigonometric functions, location tables, construction tables, turnouts and crossovers, azimuth, latitude and time, tables for metric curves, the adjustment of instruments, and miscellaneous tables.

The Design and Construction of Small Stations

Resume of Current Practice on Several Roads in the Selection of Materials and the Arrangement of Facilities

It is estimated that the railways of the United States maintain 85,000 passenger or combination passenger and freight stations, and that fully 80,000 of these are buildings costing $25,000 or less. From these and similar estimates it can be shown that the total value of the small stations is at least equal to that of the large stations and that the annual cost of replacing buildings in the two groups also is roughly the same. Disclaiming any high degree of accuracy for these estimates, they are still sufficient to show the importance of a class of construction which is too often given slight consideration. A $1,000,000 terminal has in its design and construction far more to inspire the architect and engineer and to interest the executive officer than an equal expenditure in assorted sizes of small stations, but the opportunities for effecting economies through careful study of the requirements are at least as great in the latter case as in the former, since such an expenditure might cover 200 buildings located in as many communities of widely differing characteristics. There has been a marked tendency in recent years to provide better station buildings at all points and the number of roads that allow their property to remain the most unsightly spots in the communities they serve is fast decreasing. A number of factors are responsible in varying degrees for this movement. In some cases, competition, local demands, or the authority of a state commission have made necessary heavy expenditures for new stations, but the underlying reason in general is the growing spirit of cooperation between the public and the railroads which is resulting on one side in an increased desire to see the roads fairly treated and on the other side in more active efforts to give the people satisfactory service in every respect.

A Brick and Stucco Building on the Rock Island

The scale by which to measure the suitability of a passenger station to the needs of a community is extremely hard to fix. The revenue from ticket sales is an index of the passenger business originating at a given point, but it might be misleading as a guide to the kind of a station needed, for some towns producing relatively little passenger traffic are good sources of freight revenue, and therefore a somewhat disproportionate expenditure for passenger facilities may be justified by the increased freight traffic resulting from the more cordial relations set up with the people. On the other hand, a rough mining or manufacturing town which would produce more passenger and freight business than a suburban or rural community of equal size might be adequately served by a less expensive building. The amount of transfer business must also be considered for at some stations at junctions or crossings the amount of either passenger or freight traffic originating may be insignificant, but the fact that such a station must be used by a large number of through passengers when changing trains, makes it essential for the repu-

A Small Station on the Santa Fe in the Southwest

tation of the road that comfortable and commodious quarters be provided.

These facts emphasize the necessity for careful study of the nature of each problem to insure the wisest investment in stations, and such studies should preferably be made jointly by representatives of the operating, traffic and enginering departments. On some roads standard designs are used for the very small buildings, and if, on investigation of the community, the old facilities, and the probable requirements, one of the standards is found suitable, there is, of course, no necessity for drawing a new plan for that building. The evident advantages of standard structures are offset, however, in the minds of many railway men by the monotonous appearance of similar buildings recurring frequently along the line and the tendency if standards are followed

to adopt one of these in preference to a special design much better adapted to the local requirements.

A station which fully meets the needs must provide adequate and convenient facilities for the sale of tickets, checking, handling and storing of baggage, receiving, delivering and storing of express and in combination stations, of freight; must contain public rooms of ample dimensions in which are installed all the commonly recognized provisions for the comfort and convenience of the road's patrons; and must have a pleasing appearance inside and out, the latter requirement covering also the surrounding grounds. Considered as an investment, all of these requirements must be met in a building that will have the lowest possible first cost consistent with long life and low maintenance charges. In an endeavor to co-ordinate the experience of various roads in the solution of such problems, a study has been made of the practice on eight typical roads where considerable attention

A Brick Station on the Burlington Showing a Limited Use of Stucco

has been given to the matter and the following discussion presents the variations in details of design and construction with the reasons for each arrangement or material where possible.

ARRANGEMENT

For the smallest villages and towns it is customary to provide a combination freight and passenger station. Such a building, as shown in one of the floor plans reproduced herewith, may have only a waiting room, a ticket office and a freight room, which also serves for baggage and express, or a separate baggage room and toilet rooms may be added. In somewhat larger towns separate freight and passenger facilities are warranted. In a station for passenger traffic only, a main waiting room, women's retiring room, men's smoking room, toilets, ticket office and baggage room are usually included, although some roads frequently use two separate main waiting rooms where the traffic warrants, or in communities with a large number of foreigners or a rough population, and this arrangement is of course necessary in many of the southern states where the law requires separate quarters for white and colored passengers. Two waiting rooms, however, cut up the plan more than a single main waiting room and they are less easily heated. A train order room must frequently be provided in small stations. Particularly for suburban towns, it is not uncommon to include in the plan a loggia or pavilion, adjacent to a drive, or at one end of the building where exceptionally large crowds can find shelter.

The size of the building and the arrangement of rooms must in general be decided on to meet the local requirements. The stations of the class referred to, are usually 20 to 25 ft. wide on the Lehigh Valley, the width being governed by the width of right of way and the necessity for providing a drive behind the building. On the Lackawanna 24 ft. is the maximum width of building and other roads have similar rules. Frame buildings are set back 21 ft. 6 in. from the center of track on the Chicago, Rock Island & Pacific, and brick buildings 30 ft. to 36 ft., while on the Lackawanna 16 ft. platforms have been built, but a greater width is preferred. Where possible, room is provided by this road for flower beds or shrubbery between the station and the tracks. The New York Central usually allows 27 ft. between the building and the center of track, using a canopy over the platform at important stations.

For small stations handling passenger traffic only, the American Railway Engineering Association Manual recommends the following ratios of floor area in the various rooms. General waiting room, 41 per cent; baggage and express room, 26 per cent; ticket office, 15 per cent; women's room, 10 per cent, and toilets, 8 per cent. Typical minimum waiting room sizes are 12 ft. by 20 ft. for the smallest type of station on the Lehigh Valley and 22 ft. by 32 ft. for a brick station on the Rock Island. The smallest ticket offices used vary from 10 ft. by 14 ft. on the Burlington and 8 ft. by 20 ft. on the Lehigh Valley, to 12 ft. by 16 ft. on the New York Central and the Pennsylvania. A preferred size on several roads is 18 ft. by 18 ft., or 18 ft. by 22 ft. The minimum sizes hardly provide room for the telegraph desk, ticket case, tariff file, letter press, etc., which an agent at such a station requires.

At combination stations, the Lackawanna usually has an elevated platform outside the building for handling freight to cars on the siding. The New York Central frequently provides separate baggage and express rooms, and when a single room serves for both, an end door is preferred to prevent the baggage and empty trucks from accumulating on the platform. A raised platform is provided within and without the building and a platform or beam scale may be installed. In many places a partition in the baggage room separates a small space for valuables or for checking parcels. On the Pennsylvania and the Lehigh Valley, the entrance to the men's toilet is from the outside of the building in order to keep some travel out of the waiting room. On the other hand, the New York Central, the Lackawanna, the Rock Island, the Santa Fe and the Burlington, arrange toilets so that both will open inside the buildings to prevent many loafers from using them so readily. The New York Central usually provides for a vestibule between each toilet room and the waiting room if no smoking or retiring rooms are included and on most roads an effort is made to locate the doors out of the line of vision.

WALLS AND ROOFS

The use of frame structures, formerly quite common, is being more and more restricted to new towns, temporary quarters, and permanent buildings only in the smallest villages and towns. The Lehigh Valley has not built a frame station since 1906, and the

A Brick Station on the Burlington with Long Canopies at Either End

Lackawanna does not use frame for any permanent construction in such buildings. The New York Central has recently built a frame combination freight and passenger station costing $16,000, but the more ordinary buildings of this type cost $5,000 to $6,000. This road occasionally uses broad clapboards on its stations, but it is expected to limit the use of frame construction in the future to the canopies between the buildings and the track. The Rock Island builds 80 standard types of frame stations, the maximum size being 24 ft. by 104 ft., costing about $3,500. The Santa Fe builds small frame stations 16 ft. by 40 ft., to 24 ft. by 65 ft. and 24 ft. by 80 ft., costing about $1,200, $2,200 and $3,000, respectively. These structures are located on new lines and they usually re-

main for their natural life, although if the town develops a better station is provided. Frame stations are very seldom built for replacing existing structures. The Burlington builds a number of standard frame combination stations from 18 ft. by 38 ft., up to 24 ft. by 82 ft., costing from $1,500 to $2,950, or $2.20 and $1.50 per sq. ft. of floor area respectively.

The most usual wall construction for permanent stations of medium sizes is of brick or stucco, although concrete, brick veneer, terra cotta and natural stone, are all used to a limited extent. Brick stations are built by most roads at a cost of $3 to $5 per sq. ft. in sizes from 1,000 to 3,000 sq. ft., and are almost universally satisfactory. An impervious vitrified brick is frequently preferred, although some of the rough textile product is coming into use. The dark colors are ordinarily selected with a trimming of natural stone, terra cotta or concrete. The Lackawanna has tried a construction of two 4-in. brick walls with a 2-in. air space between them. In this connection, however, the insulation of the walls is generally considered relatively unimportant for the heating must be proportioned for an excessive window and door area.

Stucco has been widely used and in most cases has given satisfaction, particularly for the upper portion of the buildings. The objection to stucco below the window sills is that it is easily damaged by trucks, wagons, etc. The Lehigh Valley also finds difficulty in the streaking and discoloring of the stucco. On this road a building with hollow tile walls stuccoed costs from $3.35 to $4 per sq. ft. in sizes from 1,000

A Brick and Stone Suburban Station on the Burlington Which Is Showing a Long Life and Low Maintenance Cost

to 2,000 sq. ft. The New York Central does not use stucco below the window course but finds it satisfactory above that level either on frame or hollow tile construction, particularly when the lower part is of brick. The former is of course cheaper. The Lackawanna has used stucco over tile walls but has eliminated this type of construction on the basis of maintenance and appearance. The Pennsylvania frequently uses brick with a stuccoed surface, finding it little more expensive than tile. The Rock Island has built a number of tile and stucco buildings with brick below the windows at about the same cost as an all-brick station. The Santa Fe uses a stuccoed wall down to the foundation, placing guards where necessary to prevent trucks from damaging the surface. These buildings cost about $3.50 per sq. ft. The Burlington builds a 24-ft. by 82-ft. station with frame walls, stuccoed, at a cost of about $3,000 not including heating, lighting or fixtures, and a similar building with tile walls is estimated to cost about $4,000. This road has successfully stuccoed one old frame station.

The Lackawanna uses some concrete buildings, and the New York Central has used concrete up to the window sill course, the cost usually being about the same as for brick. On the latter road the surface is pebbled, brushed or rubbed and the corners chamfered or rounded. In some cases a special face mixture may be poured and brushed out after the forms are removed. The Lackawanna prefers a bush-hammered or bull-pointed surface. In addition to the cost, the chief objections to concrete for station buildings are the difficulty of accurately lining thin, high walls and the extra care required to secure a pleasing appearance of the surface. Brick veneered walls have been used to a limited degree. The Lackawanna places the brick facing on a tile wall and the Burlington finds the average cost for a 24 ft. by 82 ft. combination building without fixtures to be about $4,000. A special type of building used by the Lackawanna in one case is the cream mat glazed terra cotta station shown in one of the accompanying illustrations. Natural stone is ordinarily used only where it can be secured economically near the site and the cost of course varies widely with local conditions.

The very large majority of small stations have a pitched

A New York Central Station with Concrete Base Course and Wooden Clapboards Above

roof with wide overhanging eaves. Plain roof lines are much to be preferred in reducing the maintenance on the building but for architectural effects gables and broken lines are frequently introduced. The most widely used and most satisfactory roofing materials for stations of medium size are tile and slate. The A. R. E. A. Manual recommends these materials for slopes of 6 in. per foot or over and ready or prepared roofing for very small or temporary buildings. The difference in quality between

A Concrete and Stucco Building on the New York Central

various grades of slate and tile makes it difficult to compare accurately either their costs or serviceability. The best grade of slate when properly specified is considered expensive by some roads but its service is not questioned. The principal objection to the average slate roof is that it breaks easily from jars and some roads, as the Lackawanna, limit its use to cheaper stations. A good grade of impervious tile is reported by several roads to cost little more than the average slate and when properly laid on a waterproof paper, gives very good satisfaction. In laying tar paper roofs the Lehigh Valley has

found it necessary to use half round or oval molding over the laps to prevent wrinkling. Gravel and composition roofs, tar paper and asbestos shingles, metal and tin are all used to a limited extent on various roads. Under certain local conditions, all of these materials have advantages.

Opinion is divided as to the best type of gutter, the Pennsylvania favoring a standing gutter while the Rock Island, Lehigh Valley, the New York Central and other roads prefer a hanging gutter. The hanging gutter is usually considered to be easier to repair, the Rock Island using a sheet lead flashing under the tiles to allow repairs to be made without damage to the roof. Gutters and flashings are usually of copper, galvanized iron or a pure ingot iron, while gutters of wood are also frequently used.

A Glazed Terra Cotta Station on the Lackawanna

INTERIOR WALLS AND FLOORS.

Partitions in small stations are usually built of brick, hollow tile or timber studs, the latter being the least desirable but also the least expensive. The lower portions of the walls in the public rooms are commonly wainscoted to a height varying from 5 to 9 ft. Wood is used for this purpose to some extent on the New York Central, the Lackawanna and the Buffalo, Rochester & Pittsburgh. The Lehigh Valley and the Lackawanna use tile extensively, and the Rock Island prefers an impervious brick. In dark rooms a light gray enameled brick is used and in light rooms a dark brick. This construction is found better and cheaper than a good paneled oak wainscot. The Burlington and the Lehigh Valley use some enameled brick. The Santa Fe in general prefers a chair rail to the wainscot.

The wall, or at least the portion above the wainscot, is almost universally plastered, metal lath being used exclusively or generally on most roads. The woodwork is ordinarily of pine, fir or oak, depending on the grade of the station. Plaster or wall board has been used to a limited extent on a number of roads and has been found very satisfactory by some. The Lehigh Valley has found that the board must be well seasoned, for if it is placed when green, it pulls away from the nails. The New York Central has used this wall finish in some temporary stations and in one or two small permanent buildings. This road prefers the imitation wood finish. On the Santa Fe some wall board has been used in localities where water is very scarce, rendering it difficult to make plaster. Pressed brick facing has been used in the public rooms in a few cases on the New York Central and the Lackawanna and a number of roads have faced the baggage and freight rooms with brick. Glazed tile are common in toilet rooms and the Buffalo, Rochester & Pittsburgh has used some sheet steel for lining train order rooms.

Wooden floors that have been almost universally used in the past are still being installed to a large extent on many roads. The comb-grained yellow pine which has been generally favored for this use is becoming increasingly difficult to secure and Oregon fir is being used in its place by some companies. The Buffalo, Rochester & Pittsburgh has built a number of stations with a double floor, consisting of 7/8 in. tongue and grooved hemlock, laid diagonally on the joists with a layer of building paper separating it from the surface layer of 7/8 in. tongue and grooved comb-grained Georgia pine. Maple flooring is used on a number of roads in the ticket office and a plank flooring is frequently laid in the baggage, express and freight rooms. Wooden floors have the disadvantages that they are not sanitary or fireproof and under severe wear do not have a long life. Tile floors are preferred to wood on the Lehigh Valley, the New York Central and the Rock Island, although their cost is, of course, greater. Concrete has been satisfactorily used in many of the stations built by the Santa Fe and on the Burlington a reinforced concrete floor with a cement tile surface is generally provided. Granulithic and terrazo floors have been used almost exclusively by the Lackawanna and cork has been used by the New York Central in some ticket offices. Baggage rooms on the Rock Island are laid with a brick floor practically the same as the platforms.

A Brick Station on the Lackawanna with Separate Waiting Rooms for Traffic on the Opposite Track

HEATING, LIGHTING AND PLUMBING

All stations built in the northern and central portions of the country require some provision for heating. For the very cheapest buildings on the Lackawanna, New York Cen-

tral and many other roads, stoves are still used, although the Pennsylvania puts very few stoves in new buildings. The Buffalo, Rochester & Pittsburgh provides a coke-burning stove for the very small buildings. The Lehigh Valley has tried car heaters for some of its stations and also has two vapor systems in service. For stations of medium size, however, steam and hot water heating plants are the most usual. The Lehigh Valley, the New York Central, the Lackawanna and the Pennsylvania prefer steam in most cases and the Burlington, Rock Island, and the Santa Fe prefer hot water. The Rock Island uses steam on its northern lines and hot water on the southern lines because of the possibility of maintaining an even temperature with a hot water plant when only a small amount of heat is required. In general the first cost of a steam plant is less than that for a hot water heater, but the latter is cheaper to maintain and uses less fuel. A factor considered by some roads is the danger of an explosion in a steam boiler while the worst that can happen to a hot water plant is for one section to burst and flood the fire.

The heating plants are usually located in a basement if possible, although in some localities the height of the ground water will not permit an excavation to be made under the building. On most roads the basements are made only large enough for the furnace and for coal storage, although the

A Brick Station on the Buffalo, Rochester & Pittsburgh in a Small Rural Community

Pennsylvania usually excavates under the full building in order to make all pipes accessible without the use of tunnels or conduits. Several roads endeavor to locate the basement under the toilets so that the plumbing is accessible from below. The Rock Island provides a reinforced concrete floor in all basements. The alternate location for a heating plant is usually in the baggage room or freight room, where it is common to set the furnace in a shallow pit a few feet below the floor level. The Lehigh Valley lays pipe runs in vitrified clay conduit under the floor, arranged to pull the pipe out if necessary. On the Lackawanna short pipe runs are laid in conduit and long ones in a covered box in the floor. The Rock Island usually provides a tunnel for the pipes and on the Santa Fe and the Burlington the feed pipes of the hot water system are run overhead in the attic with the returns outside the building in conduit or in a tunnel under the floor.

In general, radiators are located along the wall, under the windows or near the doors. The New York Central avoids exposed radiators wherever possible, ordinarily placing them against the outside walls back of the seats. The obvious objection to an exposed radiator is that it soon becomes a litter box and a cuspidor. The Burlington does not favor the location of radiators under seats, as this practice prevents the rearrangement of seating facilities. In some cases attention must be paid to the location of radiation with reference to the coldest extremity of the building.

The provision for lighting stations depends largely on the system in use in the community. If electricity is available, it is almost universally utilized, gas is piped to the station in many instances and in many of the smaller stations only oil lights are justified.

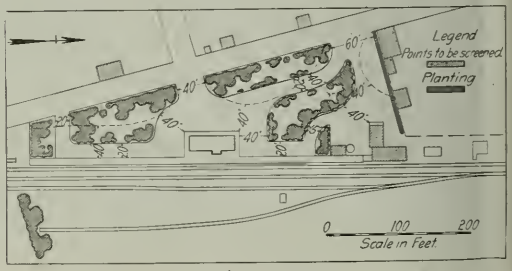
The provision of sanitary plumbing is also dependent to a certain degree on the ability of the roads to connect with water and sewer systems in the towns. It is almost a universal practice to provide such connections whenever possible and in many cases, particularly on eastern roads, cesspools and septic tanks are installed when the towns have no sewer systems. In the central and western states it is unusual to find a town in which a medium sized passenger station is justified which does not have a water and sewer system. The Lehigh Valley uses cesspools 6 to 8 ft. in diameter and 15 ft. deep or a rectangular box of brick, hollow tile or stone. On the Pennsylvania large double cesspools laid up dry are used. These are built of stone or brick and are usually 7 to 8 ft. in diameter and about 15 ft. deep.

Drinking fountains are frequently provided even in the small stations and there is an increasing tendency toward the use of sanitary or bubbling fountains. A number of roads, however do not consider the provision of drinking water important and if not convenient omit it. When ice is provided the better practice is to put the water through coils, around which the ice is packed.

PLATFORMS AND STATION GROUNDS

Station platforms on the Lehigh Valley and the Lackawanna are usually of concrete and on the Rock Island, the Buffalo, Rochester & Pittsburgh, the Santa Fe and the Burlington, of brick. The New York Central uses both concrete and brick, finding the latter better in northern climates where snow and ice collect. Brick platforms are usually laid either in the herringbone pattern or at right angles to the length of the platform. The former is considered to give a little better support for trucking, but requires cutting the bricks and using small pieces at the edges. Brick platforms are laid on sand or gravel fill or on a concrete base and are usually provided with a concrete curb. On the Burlington these curbs are built in a company plant and shipped to the site in the manufactured state. It has been found that in this way a curb fully as cheap as a creosoted timber can be provided. On the Santa Fe the concrete curbs have bricks on top.

One of the most marked advances in practice during recent years is indicated by the increased attention being paid to the appearance of station grounds. Many expensive and



A Typical Layout of Drives and Shrubbery at a Small Station on the Pennsylvania

well designed buildings have in past years been located among such squalid surroundings as to lose almost entirely their architectural value. This condition is fast being remedied, however, by the sodding of the station grounds, laying out walks and drives where the opportunity is presented and in many cases by planting trees or shrubs. The Pennsylvania has given special study to this work and has in its maintenance department an office which prepares landscape plans and supervises generally the use and care of all plants.

Trained men handle features not ordinarily given their due share of attention, such as the views to be had of railroad structures and the surrounding country from the approaches to the building, and from passing trains, and the use of every opportunity for artistic arrangements that do not conflict with the utilitarian objects of the station. General plans are drawn on a 40-ft. or 20-ft. scale to show all buildings and landscape features, trees, shrubs, etc., around the station and on this plan very careful location of each tree and shrub is possible. The accompanying drawing illustrates in dotted lines the way the drives at a small station would have been located had not the rearrangement shown in solid lines been suggested by those who appreciated the need to screen the very objectionable appearing buildings on adjoining property. A company nursery on this road furnishes most of the trees and shrubs and a gardener foreman with a small gang on each division tends to the planting, watering and other maintenance.

The Lackawanna also makes detailed plans of station grounds showing driveways, walks. shrubbery, etc., particularly for suburban stations. There is also an organization connected with the maintenance department to look after this class of work.

On the New York Central station grounds are always graded and vacant spaces sodded, any parking or decoration that may be desired being left to the superintendent and the station agent. On the Rock Island the division officers lay out drives and walks, shrubs, etc., and the local men maintain them, while on the Burlington the architect's office prepares the layout for station grounds and the division force takes care of the maintenance.

INCOME FROM THE MAINTENANCE OF WAY DEPARTMENT

By "Supervisor"

The maintenance of way department of any railroad organization is primarily a spending organization. Any income from this source is necessarily incidental, and in no way can it be regarded as a main function of the department to turn any considerable sums into the treasury. Admitting these premises, there still remains the fact that the maintenance organization can do something toward swelling the general income of the railroad. In times such as these, any addition, however small, to the net income, is extremely welcome to the management, and this article purposes to outline how one maintenance officer paid his annual salary back to his company several times over by devoting a little time and trouble to increasing the sales of scrap material to outside parties.

The territory in charge of this man is a single-track branch line running through a fertile farming country and serving two large and one small industrial towns, the seats of large iron and steel manufacturers. When the idea first presented itself the prospect seemed rather poor, for there was apparently little which the railroad man could offer for sale which would appeal to the public along his tracks. His main commodities were old rails, old ties and engine cinders, and his first duty was to go out and make a market for these goods. His first step was to call upon the purchasing agents of the various industries located along his tracks. He found that their purchases of scrap iron and steel were made in such lots and at such prices that they could best be handled by the purchasing agent of his own company. His offers of engine cinders for filling, etc., met with no response. His offers of old ties, however, were considered, and after consultations with furnace and mill superintendents he was able to place orders for several carloads of old ties at a price which netted his company a good profit over the cost of loading and hauling them to the point of delivery. These ties are used by the furnace people for kindling, and gave such satisfaction to their purchasers that he was able to turn in over $400 from this source for the year 1914, with the iron business at a low ebb.

When main or running-track rail renewals release rails in fairly good condition, but too light for further railroad use and not quite good enough for sale in the open market as relayers, the matter is taken up by personal calls upon superintendents, managers and owners of industrial tracks along the line, frequently with success. By quoting prices slightly lower than the current prices for relayers plus the freight on them, by being able to guarantee condition and by permitting inspection and rejection while the rail is being loaded, he has been able to sell several cars of light rail per year at prices from $5 to $8 per ton above their scrap sale value. Fittings are also sold at a large increase over their scrap prices. During 1914 about 95 tons of rail and $160 worth of fittings were sold at prices averaging $6 per ton above normal scrap values. Without personal effort to dispose of this stock it would have gone to the scrap pile.

By getting in touch with township road authorities another market was opened. Rails were sold for re-enforcing culverts and small bridges. After the free gift of enough engine cinders to surface several stretches of mud roads, a market developed for this class of material. Farmers and country merchants came to recognize that cinders were the best and cheapest material for private roads around their buildings and into their fields. Building contractors were next approached, generally with successful results. These men buy second-hand lumber, for which the railroad has no further need, rails for concrete work and large quantities of engine cinders for foundations, for paving construction and for filling. Between the road supervisors, the farmers and the contractors the sale of engine cinders now runs from 600 to over 1,000 cars per annum. This is a saving in two ways, as formerly a large amount of these cinders was unloaded on waste dumps at considerable expense for labor. The demand for these cinders now is frequently larger than the divisional supply.

From these various sales of materials at his disposal he was able to show an income averaging considerably over $10,000 per year during 1913 and 1914, including in this sum only the difference between the scrap value of rails, etc., and the sums actually received for them, and making no account of the labor saved from wasting cinders. The cost of hauling to the consignees has also been omitted (all material was sold f. o. b. destination), but most of it would have had to be handled by trains under any circumstances. No small part of the credit for this showing is due to the railroad's purchasing agent, who set the prices at which this material should be sold, and who used every means in his power to assist the man on the ground and gave him every facility for quick and fair selling.

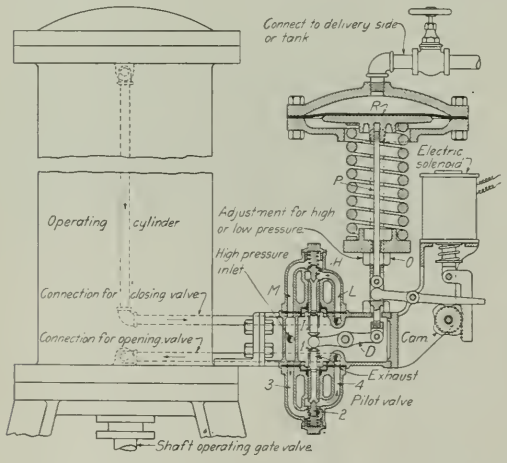
While the sum mentioned above as the annual turnover of profits is small in comparison with other sources of railroad income, yet it is new business. It has been developed from practically nothing, the selling expense is nil, and it shows that even the maintenance of way department can in its small way put something on the right side of the big ledger.

Nyasaland Railway Opened for Traffic.—The extension of the railway running between Port Herald, in Nyasaland (the southern terminus of the Shire Highlands Railway), and Chindio (a point on the northern bank of the Zambesi) was opened for traffic on April 1. This line forms complete railway communication between the Zambesi and Blantyre (the capital of British Nyasaland). It is 61 miles in length and crosses a tributary of the Zambesi by a steel bridge of 38 spans, over a third of a mile in length. The chief importance of the line is that it facilitates transport between Nyasaland and a navigable point on the Zambesi. At Port Herald the river is only navigable for a few months in the year, while at Chindio boats can run all the year round.

AUTOMATIC CONTROL FOR A GATE VALVE

An application of the Golden-Anderson automatic control device to a hydraulic gate valve for automatically maintaining the water level in tanks, standpipes or reservoirs, has recently been developed by the Golden-Anderson Valve Specialty Company, Pittsburgh, Pa. The latest form of this valve for controlling a globe valve was illustrated in the *Railway Age Gazette* of March 19, 1914. In the design illustrated herewith the gate valve is opened and closed by an operating cylinder, the piston of which is actuated by hydraulic pressure through pipe connections to the pilot valve of the control device.

When the valve is open and water is flowing freely to the tank or reservoir the parts of the control device are in the position shown in the sketch. This condition exists as long as the pressure in the tank or on the outlet side of the valve, which is transmitted to the upper side of the diaphragm "R" through a pipe connection, is less than that for which the heavy spiral spring has been adjusted by the nut "O," for under this condition the spindle "P" is forced upward by the spring and the arm "D" closes the exhaust valve 1 and opens the high-pressure valve 2, at the same time allowing the exhaust valve "I" to open and the high-pressure valve "H" to close. The full pressure in the pipe line on the inlet side of the valve is transmitted to the pilot valve through a pipe connection to the high-pressure inlet, and thence



Improved Arrangement of Control Valve for Use with a Gate Valve

through the ports 3 and 4, and the pipe leading to the lower side of the operating cylinder. The piston in the cylinder is allowed to move upward under this pressure as the water above it is exhausted through the pipe to the pilot valve and the port "L" to the atmosphere.

When the pressure in the tank or on the outlet side of the valve has exceeded the pressure maintained by the coil spring, the spindle "P" is forced downward by the diaphragm "R" operating the arm "D" which then closes the exhaust valve "I," opens the high-pressure valve "H" and permits the exhaust valve 1 to open and high-pressure valve 2 to close. The pressure from the inlet side of the valve is then transmitted through ports "M" and "L" and the pipe connection to the upper side of the piston in the operating cylinder. As the water underneath the piston is allowed to exhaust through port 4 to the atmosphere, the valve is closed smoothly and positively.

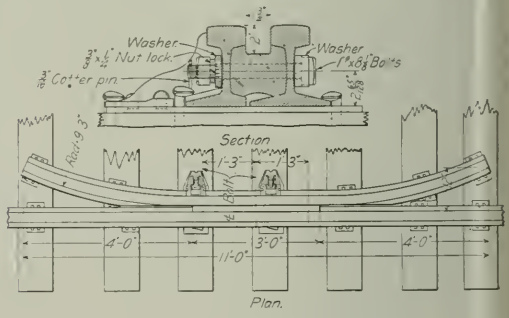
An electric solenoid attachment similar to that used on previous forms of this device can be attached to enable the valve to be opened or closed electrically from any number of distant points. As the electric current is only applied to the solenoid for a few seconds in the operation of the valve there is no waste of current. In a similar manner the addition of an extra diaphragm attachment in place of the electric solenoid allows the valve to be hydraulically closed at any time by putting increased pressure on the main. This diaphragm can be adjusted to a few pounds above the normal supply, this increased pressure operating the pilot valve as described above.

It is also possible by connecting the inlet pressure pipe both to the pilot valve and the top of the diaphragm to operate the control valve in both directions, allowing water to flow into the tank or reservoir and to return through the same pipe whenever the pressure is less on the inlet side than in the tank.

THE B. R. & P. STANDARD GUARD RAIL

One of the most difficult of the smaller details of maintenance of way work with which the track man has to contend is that of guard rail maintenance. In common with other roads, the Buffalo, Rochester & Pittsburgh has experimented with guard rails of different lengths supported by numerous types of guard rail braces, clamps and fasteners, as a result of which it has adopted as standard the design shown in the accompanying drawing.

The standard guard rail for both main and turnout tracks is 11 ft. long with a 3-ft. cast filler block bolted through both the guard and main rails with three 1-in. bolts spaced 15 in. apart. Both the guard and main rails are full tie plated with standard plates. The guard rail is straight for a distance of 3 ft. in the



B. R. & P. Standard Guard Rail

center, beyond which it is curved to a radius of 9 ft. 3 in. at each end, giving a clear distance of 12 in. between gage lines at the ends. The center of the guard rail is placed 6 in. ahead of the point of the frog, leaving 12 in. of straight flangeway back of this point. Two dimensions of cast filler blocks are used, that for the main tracks providing a 1¾ in. flangeway, while that on the turnout side of the frog provides for a 2-in. flangeway to correspond with the standard practice of widening the gage ¼ in. through the turnout. The 1-in. bolts are provided with a washer on the head end and a washer, a ⅜-in. nut lock and a 3/16-in. cotter pin on the opposite end. The fillers are made of ordinary cast iron and can be cast in any foundry while the guard rails are sheared and drilled complete in the company's shops.

Approximately 4,500 of these guard rails are now in use on this line. Loose guard rails are practically unknown, and the wear on switch ties and frog points as well as the element of danger have been very largely eliminated. In addition to the guard rail remaining in its proper position, the labor of keeping the flangeway free from ice in winter is eliminated since it is only necessary to drop a little salt in the flangeway. When a section foreman orders a guard rail it is furnished to him complete with all accessories, including the rail, bolts, washers, filler and guard rail fasteners complete.

Renewal of Ties—Inspection, Marking and Records

Methods Being Used to Insure Best Results in Removal of Old and Distribution and Use of New Ties

The latest official statistics show that the railroads spend annually about $55,000,000 for the ties used to replace those removed from the track on account of wear, decay, accidents, etc. This figure, which does not include the cost of labor for distributing the new ties, placing them in the track and disposing of the old ones, together requiring so large a part of the trackmen's time during the spring and summer, is about 15 per cent of the total cost of maintenance of way and structures and 3 per cent of all operating expenses. It is obvious then that particular care is justified to insure the lowest percentage of renewals consistent with proper maintenance standards and important as this subject is at present, it is becoming increasingly so on account of the rapidly increasing cost of ties.

Theoretically, to attain the maximum economy every tie should remain in the track until it reaches the point in its deterioration when it will no longer support the rails with the proper factor of safety and should then be removed immediately. Practically, since ties are renewed once a year it is the general rule to remove all that will not safely carry the loads for another year, and on account of the disadvantages resulting from tearing up the roadbed as is necessary to a certain extent in tie renewal, it is practical economy to remove ties with even a greater life than this during general surfacing, reballasting or rail renewal.

Some roads have tried to assign a reasonable number of ties to each section and leave it to the foremen to use them to best advantage, but the imperfections of this scheme are obvious. It is almost universal therefore to base the requisition for ties on an inspection of the track prior to the season of renewal, although the methods of making this inspection, of checking the reports and of supervising the work of placing the new ties in the track vary widely. These differences as they exist on 16 typical important roads are discussed in the following paragraphs.

INSPECTION AND MARKING

The inspection upon which the requisition and allotment of new ties is made is left to the section foremen on the Central Railroad of New Jersey with very satisfactory results. The supervisors are constantly in touch with the foremen, walking each section during the year and familiarizing themselves with the details. Each foreman is allowed to ask for as many ties as he thinks he will require. This data is then checked up by the supervisors, who have acquired during the course of the year an approximate idea of what the needs of each section will be. The requirements are then forwarded to the engineers maintenance of way, who tabulate the data and make requisition for the necessary ties. After renewals have started, the supervisors and assistant supervisors examine all ties removed very carefully, and if a foreman is found to be removing too many ties, or leaving poor ties in the track, his attention is drawn forcibly to the fact. The engineers maintenance of way as well as the superintendents also inspect ties that are removed at frequent and unexpected intervals in their trips over the line. Any ties removed from the track that are found to have any additional life are sorted and picked up by the work train and used in siding repairs or construction, being spotted in with good or new ties. Under this system the situation has gradually improved until it is scarcely ever necessary to draw a foreman's attention to any misjudgment, and much better results are being secured than by methods previously employed. The objection to leaving the selection of ties to be removed from the track entirely to the section foreman, which is advanced by some maintenance men, is that there is too great a tendency under this method to praise the man who puts in the most ties per day per man, resulting in the removal of some ties from which additional life could be secured.

Several roads have found it advantageous to combine the detailed inspection of the foremen with check inspections by supervisors, roadmasters, engineers or superintendents. On the Boston & Albany the foreman's statement is checked by the supervisor or his assistant and is then sent to the division engineer for approval. On the Pennsylvania the practice is similar except that the division engineer, usually accompanied by the supervisor, also makes frequent independent inspections to see that the proposed renewals are proper and economical. In addition, there are men assigned to special duty both on the division and in the office of the engineer maintenance of way, who regularly follow up tie renewals, making an inspection both of the ties removed from the track and those left in. These men submit reports on what they find and any cases of bad judgment are taken up through the regular channels. During the time that this practice has been followed, covering the last six or seven years, there has rarely been any cause for criticism.

The reports of the Northern Pacific section foremen are checked by the roadmasters walking over a part of each section, and in addition the division superintendent goes over at least three sections on each roadmaster's district accompanied by the roadmaster on a hand car or on foot to verify the tie requirements. The Illinois Central requires the supervisors, after receiving the foremen's reports, to make an independent inspection and then forward the foremen's reports with their recommendations. The roadmasters, on receipt of the supervisors reports, walk over selected miles with the division superintendents to check the judgment of their men.

Some roads place the responsibility for the tie inspection entirely on the supervisors or roadmasters. Such roads include the Atchison, Topeka & Santa Fe, the Norfolk & Western and the New York Central. On the Baltimore & Ohio all tie inspections are now being made by the supervisors and a general tie inspector for the system checks up these reports. This method has been found better than a previous one in which tie inspectors alone handled this work. Other roads, including the Chicago & North Western, the New York, New Haven & Hartford, the Philadelphia & Reading, the St. Louis & San Francisco, and the Union Pacific, require the roadmaster or supervisor and the section foremen to go over the line together for the inspection of ties to be renewed, thus combining the broader experience and better judgment of the superior officer with the detailed knowledge of local conditions possessed by the foreman.

On two of the roads considered, the tie inspector is used with satisfaction. The Queen & Crescent inspectors are selected by the roadmasters and report to them. They are accompanied in making their trip over the line by each supervisor while working on his district. The Buffalo, Rochester & Pittsburgh selects the most intelligent extra gang foremen for tie inspectors, making them report to the division engineers. They are accompanied by the section foremen in going over the line. The roadmasters and foremen are not relieved of responsibility for the safety of their track on this road and are given a proper voice in the matter of tie renewal. Objections are advanced to the use of tie inspectors by some roads, one of these having found that the best section foremen on the road when made tie inspectors could not spot all of the bad ties and would spot some good ones so that the net results were less satisfactory than when the work was handled by men familiar with the local conditions.

The time of making tie inspections is also extremely variable, so that considering April 1 as the beginning of the tie renewal season, the inspection is begun on some roads as much as nine months before that date and is not finished on others until three months after it. The Boston & Albany and the New York Central are among those that begin early, the former making its

inspection during July and August, and the latter usually finishing it before October 1. The Union Pacific, the Chicago & North Western, the Pennsylvania, the Central Railroad of New Jersey, the St. Louis & San Francisco, and the New Haven, require the inspection to be made during the fall, and the Queen & Crescent specifies December. On the Baltimore & Ohio the work is begun as soon as possible after January 1 and is completed before July 1. The months of April and May are designated for tie inspection on the Illinois Central, and on the New Haven and the Buffalo, Rochester & Pittsburgh, the work is handled during the spring, beginning on the latter road as soon as the frost is out of the ground.

The points to be considered in an inspection of ties in the track may be left entirely to the judgment of the inspector or be covered more or less completely by written instructions, depending on the practice of the individual roads. When such instructions are brief they ordinarily mention a close examination including the ties on each side of the one under consideration, the local roadbed conditions, the location, whether in curve or tangent, the amount and character of the traffic, the visible rot or crack, and a test with an adze or other suitable tool to determine interior soundness. A very complete set of instructions is issued to the tie inspectors on the Buffalo, Rochester & Pittsburgh, from which the following abstract is taken:

There are two standards for making renewals in main track; first, where the track is not to be disturbed and the ties will therefore be dug in and, second, where the track is to be raised off of the old bed allowing the ties to be placed during the raise. Under the first condition ties must be inspected by driving a pick in each side adjacent to the rail seat near both the bottom and the top faces below the sap line. The pick must be driven into the ties toward the center and be drawn with as little prying as possible. The ties must not be tested on the top except in an endeavor to find decay around the tie plate and spike, and in such tests the ties must not be mutilated more than absolutely necessary. To test the tie for strength, one end of a pick should be inserted under the end of the tie and the pick used as a lever. It the tie is broken under the rail seat this will usually determine it. If two ties with only one year's safe service are adjacent, one must be removed. In a group of ties, all of which have only one year's safe service, enough must be renewed to leave each doubtful tie with one good neighbor. Sap rot alone is not sufficient to condemn a tie. A tie cut down by rail wear should not be renewed unless the rail has cut into the face more than ¾ in. This applies to ties on tangent, as all curves are tie plated. On curves when by being adzed repeatedly for rail renewal, a tie is cut down sufficiently to weaken it, it should be removed and used for side track renewals if the timber is sound. On tangents where a good tie is cut down ¾ in. by rail wear or adzing it should be protected with tie plates against further cutting. Careful attention must be given to the inspection of red oak and pin oak ties, as this timber usually rots from the center, leaving a hard shell which can be detected only by careful inspection. In track that is subject to heaving and where shimming is necessary, care must be taken to insure enough good ties

for spiking and bracing and special attention must be given to the inspection of ties through road crossings, station platforms and other places where they are covered and likely to be overlooked by the section men.

The second condition governing the marking of ties for renewal arises from the policy of the company to resurface out of face a part of the main line on each section each year in addition to the reballasting of track when new rail is laid. In such cases it is the intention to make sufficient renewals to last two or three years without having to disturb the track during that time. Under this condition the inspectors test the ties as previously described, removing all that will not last more than two years. Where new steel is laid, no bad ties must be left under the joints. In making renewals in this case, some fairly good ties may be

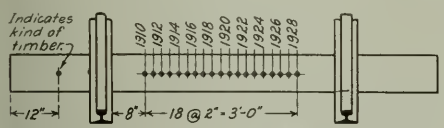
INSTRUCTIONS—Section Foreman must fill out one of these reports covering treated ties taken out of main tracks and sidings for each mile, and mail to Roadmaster at close of each day. Show under proper heading all ties having corresponding letter on nail, and show those having same date on dating nail on the same line and give date. In case number on dating nail cannct be read, give date as shown by position of nail in tie in accordance with standard instructions. Note opposite each switch and crossover set, under proper heading, the number of pieces of each kind of timber, and show station and side track number where located. Show station where side track is located in remarks column opposite.

A Report Covering Treated Ties Taken Out of Track

taken out, in which case they should be carefully sorted and piled, to be picked up and distributed for side track renewals. A lower standard of inspection is used for mine tracks and side tracks, and especially for standing tracks in yards where no ties are taken out until their safe service is passed. In passing tracks care should be used to see that all ties around turnout curves are in good condition.

Although a large majority of the roads considered require the officer making the first inspection to mark each tie in some distinctive manner for future identification, several roads, including the Pennsylvania, the Union Pacific and the Central Railroad of New Jersey use no system of marking. The two commonly recognized methods of designating ties for renewal are by cutting with an adze or axe, and by painting a line on the web or base of the rail directly over the tie. Various forms of cutting are in use, such as chipping off one corner, and notching the side or top of the tie, while on the Northern Pacific two gashes about 3 in. apart are cut on the side near the end. The Buffalo,



Method Used on the B. R. & P. for Marking the Kind of Timber and the Year Ties Are Put in Track

Rochester & Pittsburgh, the Queen & Crescent, the Baltimore & Ohio, and the Atchison, Topeka & Santa Fe use paint.

RENEWALS AND RECORDS

On the Union Pacific it is the practice to distribute enough ties before March 1 to care for the renewals on each section up to June 30, the remainder being piled in yards and distributed after July 1, so as not to interfere with the mowing of the right of way. The roadmaster selects the locations at which the renewals are to be made each month and inspects the ties after renewals. On the Pennsylvania the foreman "blazes" or marks with kiel the ties that are to come out just previous to their renewal. The ties removed are held for inspection and the good ones returned to side tracks, the rest being burned or destroyed. On the New York Central the foremen are instructed to avoid as far as possible the renewal of ties to face and they are cautioned particularly against damaging the ties by picks or by hammering them in spacing. Tie tongs are furnished on all sections where treated ties are used and tie plugs are required to be driven in the holes whenever a spike is drawn. To reduce the tendency to decay around the holes these plugs are treated.

On the Queen & Crescent the foreman, during the renewal of ties, examines carefully each tie spotted for renewal by the inspector and leaves in the track any that he thinks will last another year. He also reports any ties not spotted that he thinks should be removed, giving their location, but waiting for authority from the roadmaster before taking them out of the track. On the Buffalo, Rochester & Pittsburgh the foremen renew only the ties spotted by the inspectors on track that is not to be raised. In case they think additional ties should be removed they report to the roadmaster, who has the ties reinspected. In track that is being raised the foremen are allowed to remove unmarked ties which should come out, placing a cross on them for special inspection later. Such ties are used again if possible. The inspectors on this road are instructed to watch carefully the practice of section forces in renewing ties and to report any improper practice. It is customary on most roads to pile and burn the ties removed after proper inspection to secure ties that may have additional life in side tracks or yards. Special precautions are necessary in burning ties to prevent fire damage to the telegraph line, right of way fence and adjacent property.

The number and kind of records of tie renewals kept for future reference differ considerably on the roads considered. These permanent records are kept by various officers ranging from the division engineer to the general manager and the records may be intended simply for a check of the actual renewals with the requisition or for comparisons of the renewals on each mile for a period of years to make possible close supervision. On the Union Pacific each roadmaster is given an allowance showing the number of ties that can be used each month to avoid getting the expense for all renewals in one month. To supplement the record turned in by the tie inspector, the foremen on the Queen & Crescent are required to make a monthly report to the roadmaster showing the number of ties on each mile spotted for renewal, but found good for another year, and also the number not spotted but removed, with the cause of their removal. The Boston & Albany keeps a record by weeks of all ties taken out of track on the forms reproduced herewith.

The Buffalo, Rochester & Pittsburgh requires a daily report

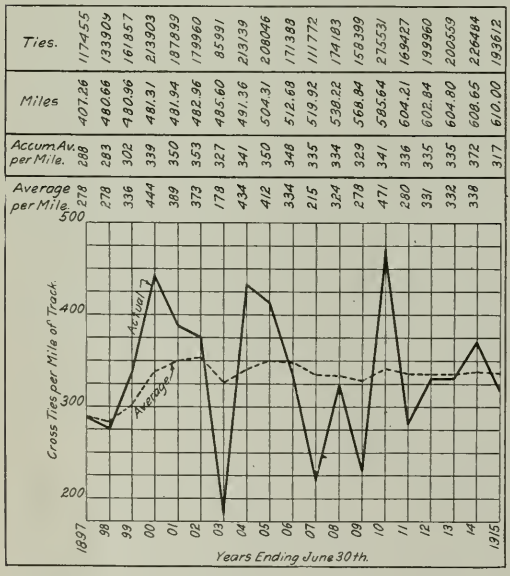
The Boston & Albany Form for Reporting Cross Ties Taken Out of Track

similar nail bearing the date is placed in the upper face of the tie between the rails, the position along the tie also being varied by an increment of 2 in. for each year. On the Baltimore & Ohio the record of ties marked for renewal is transferred in the office of the division engineer to forms covering main and side track, tie inspection and renewals, blue prints of which are sent to the engineer maintenance of way through the office of the district engineer maintenance of way immediately upon the completion of the inspection for the division. During the season of renewals the foremen report monthly on the ties removed from track, this report accompanying and checking the material report. This information is also entered on the forms mentioned above, furnishing a complete record of the renewals of the year by miles.

On the Illinois Central a record is kept in the office of the chief engineer of all ties used each year for construction and maintenance and also a special graphical record of the renewals in main track. Each district has a separate chart, and these are bound in book form. A book covering the entire system is kept in the office of the chief engineer and one covering each division



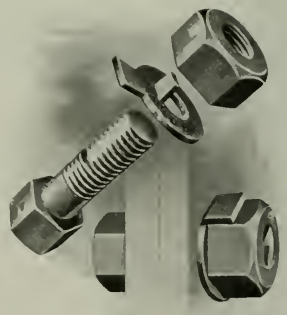
A Chart Kept by the Illinois Central, Showing the Actual Annual Consumption and the Accumulative Average Annual Consumption of Ties per Mile of Main Track on One Division

is furnished to the division superintendent. As soon as the recommendations for tie renewals are made they are plotted on the chart and when any important difference from the accumulative average is shown an investigation is immediately made by an assistant engineer from the office of the engineer maintenance of way or by an old roadmaster selected by the engineer maintenance of way on account of his previous good record in tie renewals. The curves shown herewith illustrate the manner of keeping this record for a typical division.

In determining the average number of ties per mile used in renewals each year, a correction is applied in cases where new lines have been constructed, so that the average derived furnishes a comparison of the renewals on all districts regardless of the date the line was constructed. The mileage of new track is therefore added not in its entirety the year the line is built but in sections during a period of nine years. The amount added each year is proportionate to the estimated tie renewals required for that year. The first addition is made during the third year, amounting to 2 per cent, the remainder being added as follows: fourth year 3 per cent, fifth year 5 per cent, sixth year 5 per cent, seventh year 25 per cent, eighth year 50 per cent, and ninth, 10 per cent. On account of the increased average life of ties resulting from the use of tie plates and preservative treatment these percentages will be revised in the near future. Two averages are shown on the chart, the solid line representing the average ties per mile used in renewals in the years shown, and the dotted line the accumulative average per mile used in renewals since 1897, the year in which the chart begins. The actual number of ties used each year is shown at the top of the chart and the scale of miles is corrected, not actual.

A COMBINED NUT LOCK AND WASHER

The nut lock manufactured by the Positive Nut Lock & Tie Company, Grand Rapids, Mich., has been in satisfactory service on 150 track bolts in the crossing of the Pere Marquette and the Michigan Central in Grand Rapids, Mich., since May, 1913. Other tests have also been made to demonstrate its adaptability to cars, locomotives, and various other machines. The device consists of a soft steel washer with a lug extending on one side and a wedge shaped tongue projecting at right angles from the edge of the hole through which the bolt passes. One side of



The Goble Nut Lock

the bolt is cut off at the end for the distance it is desired to screw down the nut. The tongue on the washer rests against this flat side of the bolt so that when the nut is turned on it will cut a thread on the surface of the tongue, thus forming a threaded wedge. When the nut is turned into the desired position, a lug on the outer edge of the washer is bent down to engage the side of the nut so that the bolt, nut and washer are all bound firmly together.

The advantages claimed for this device are that it does not injure the threads of the nut, it is adjustable and can be locked in any position lengthwise on the bolt and can be unlocked, removed and relocked as often as desired without injury. Old bolts in good condition can be slabbed and equipped with these nut locks, although the company is prepared to furnish new bolts already slabbed. With the use of such a device a better grade of steel than is commonly employed is recommended for bolts subject to particularly severe strain since the nut lock prevents the nut from giving, resulting in a lengthening of the bolts unless the material is designed to withstand this strain.

SIGNALS IN THE UNITED KINGDOM.—An English signaling authority has recently estimated that there are approximately 310,000 switch and signal levers on the railroads of the United Kingdom, and the approximate number of signals is 171,000.

Practical Bridge Erection and Maintenance Methods

First Series of Contest Papers Describing Solutions of Various Common and Special Problems by Bridge Men

As outlined in the *Railway Age Gazette* of April 16, 13 men, representing 11 roads and one contracting company, submitted 16 papers in the contest on Bridge Construction Methods which closed March 10. The judges in this contest awarded the first prize to S. T. Corey, chief draftsman, bridge department, Chicago, Rock Island & Pacific, Chicago and the second prize to James H. Stack, secretary, the Thomson Bridge Company, San Francisco, Cal. These and other papers are published below and the remaining contributions will appear in early issues of the maintenance section.

FIRST PRIZE—AN ECONOMICAL METHOD OF REPLACING TRUSSES WITH GIRDERS

By S. T. Corey

Chief Draftsman, Bridge Department, Chicago, Rock Island & Pacific, Chicago, Ill.

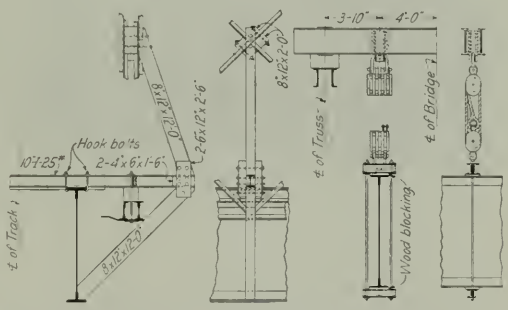
The main line of the Missouri division of the Chicago, Rock Island and Pacific crosses the Iowa river about one mile east of Columbus Junction, Iowa. The early history of this crossing is not available, but the first channel spans of the Warren or Thatcher combination type, resting on stone piers, were probably erected about 1868. In the early 90's these spans were replaced by six through lattice spans, each approximately 150 ft. long, on the original substructure. In 1903 it was noted that these stone piers

The Old Rock Island Latticed Truss Bridge Over the Iowa River Near Columbus Junction, Iowa

were deteriorating rapidly, and the latticed spans were therefore placed on falsework and four new concrete piers constructed. The present bridge consists entirely of deck plate girder spans on concrete piers and is approximately 1,550 ft. long.

This article covers the replacement of the six through latticed spans by 11 girder spans, which was mentioned briefly in the *Railway Age Gazette* of January 19, 1912. The old bridge was designed for two 95½-ton engines followed by a uniform load of 3,300 lb. per lineal foot, without impact and with a unit stress of about 8,000 lb. With a unit stress of 22,000 lb. per sq. in. (including impact determined from the formula $\frac{300}{L+300}$) it was found that the limiting classification of the spans was equivalent to Cooper's E-45. The weight of the motive power had already reached the E-45 classification, and in a few cases exceeded it, and the introduction of still heavier power was imminent. The elastic limit of the steel was probably not much in excess of 30,000 lb. per sq. in., and great eccentricities existed at nearly all the chord joints. Furthermore, it was thought necessary to renew several combination spans on various branches of the system.

The accompanying elevation indicates the extent of the change made. Piers 2, 3, 4, and 6 had been constructed in 1903, replacing the original stone piers. Their tops were remodeled for the reception of the new girder spans. Piers 1, 1a, 2a, 3a, 4a, 5a, 6a, and 7 were built new, pier 1 replacing one of the original stone piers which had been patched up in 1903 to yield a few more years' service. Pier 5, which was also part of the original substructure,

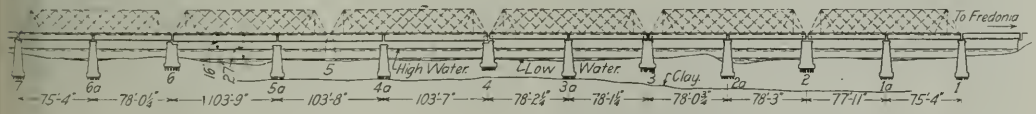


Method of Supporting Old Trusses to Defer Dismantling, and Tackle Used to Support New Girders from Old Trusses

was abandoned. The opening between piers 4 and 6 was divided into three equal parts rather than four, it being figured that the cost of a third pier would be somewhat greater than the cost of the additional weight of the longer spans.

The aggregate length of the truss spans was 928 ft. 9½ in., and to drive falsework under them was estimated to cost at least $7,500 besides greatly hampering traffic during the driving. There was also the probability that the falsework would go out with the first spring freshet with attendant interruption of traffic and loss of the old spans. As an alternative, it was decided to utilize the lattice trusses in the erection of the new girder spans.

Briefly, the method determined upon to erect the two 75-ft., and the six 77-ft. 9 in. spans, comprised the following operations: A girder span, completely riveted up and with deck on, was brought in on flat cars, being spotted immediately above its final location,



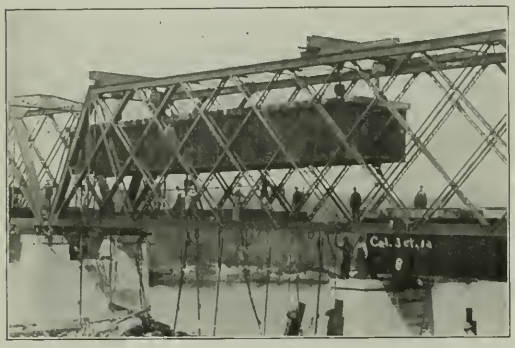
General Elevation of the Chicago, Rock Island & Pacific Bridge Over the Iowa River Near Columbus Junction, Iowa

and then raised by block and tackle fastened to loading beams placed across the top chords of the trusses. The old floor was removed while the span was suspended and the latter then lowered to its seats. The loading beams were made from second-hand material.

The steel for the new superstructure was stored in the yard at Fredonia, about one-half mile east of the bridge site. Here the spans were assembled on flat cars, riveted up, and the new decks put on. This arrangement was very effective, as the work of assembly was carried forward without interruption from passing trains. The traffic at this point was heavy, the maximum

interval during the day being about 2½ hours. The work was arranged to allow the setting of one girder span within this period. No attempt was made to set a record, and no chances were taken other than those inherent in the method used.

Previous to the beginning of the two and one-half hour period, the loading beams were placed in position on the top chords, blocked and lashed. Snatch blocks, rigged in pairs, with lines to be utilized in removing the old floor, were fastened to the truss diagonals. The lines, of which there were two, were operated by



Removing the Old Bridge Floor Under One of the Short Girder Spans Suspended from the Upper Chord of the Old Trusses

the derrick engine; first in one pair of blocks and then in the other, as the removal of the floor progressed.

In the yard at Fredonia, meanwhile, the suspenders, block and tackle, were fastened in correct positions on the new span, which, when loaded upon the two flat cars, was placed between the derrick car and a work engine. After the departure of the passenger train, the two cars were moved to the bridge site and spotted, after which the suspension tackle was fastened to the loading beams and the lines carried back to the engine. The engine was cut off from the cars and backed slowly, lifting the span from the cars and raising it as far as the truss clearance would permit. The two cars were then cut off from the derrick

Removing the Old Truss Members Showing Bracing Used for Their Support

and moved clear of the suspended span in the direction of the engine, the lines to the latter being long enough to permit the cars to intervene between the end of the span and the engine when the former was lowered on to the masonry.

The rivets in the stringer and floor beam connections had been previously cut out and bolts substituted, so that by means of the lines through the snatch blocks, these members could be removed and lowered into the river in 15 ft. of water. To facilitate recovery of the pieces, a rope long enough to reach to the surface of the water was fastened to each and attached at the other end to a float or to the bottom chord of the old truss. After completing this operation the engine slowly moved forward, and the span was lowered to its seats. While the rails were being laid on the new span, the bracing shown in one of the drawings was placed. The track was then made ready for traffic, the entire operation consuming about 2¼ hours.

On account of the great weight and length, it was deemed inadvisable to erect the 103 ft. 4 in. spans in the manner described. An investigation of the stresses resulting in the web systems

The Completed Deck Plate Girder Structure About 1,550 ft. Long

of the truss spans, from the local concentrations of the loading beams carrying these longer spans, showed an ample theoretical margin of safety, but the age of the old spans, the heavy load, and the possibility of unforeseen contingencies developing, made it desirable, if not necessary, to employ other means to erect these spans.

Like the short spans, the 103 ft. 4 in. spans were riveted up complete in the yard, but the deck was not put on for the reasons that greater space under the girders would facilitate subsequent operations, and that the omission of the deck reduced the load to be handled by about 25 tons. Two wrecking cranes, of 100 tons capacity each, were borrowed from the operating department, and, when everything was in readiness a span was picked up by them, one at either end, lifted a few inches above the top of rail, and moved to a point over its final location in the bridge.

Span 5a-6 was the first long span to be erected, and just previous to the arrival of the wreckers with the steel the top lateral bracing was removed from the truss span 6-5 to allow the boom to pass. Girder spans 6a-7 and 6-6a were already in

Placing One of the Long Girder Spans with Two Wrecking Cranes

place, and truss span 6-7 had been removed. The old stone pier No. 5 was in such bad condition that it was thought advisable to place three frame falsework bents in each aperture 5-5a and 4a-5 to relieve the pier and also to allow the concentrations of the wrecker to pass directly to the ground. The bents were designed of the two-story type, so the tops could be quickly pushed off when span 4a-5a was placed.

When the two wreckers with the span between them had been spotted, they were clamped securely to the track, and the span was then raised as high as the temporary top lateral bracing, which had been put in after the passage of the first wrecker,

would allow. The old floor was removed in the same manner as previously outlined for the short spans, the span lowered to its seats, and the deck and rails put on. The old trusses were braced in the same manner as previously described.

Piers 2, 3, 4, and 6 had to be prepared for the reception of the new superstructure, since the distance from base of rail to masonry of the truss spans was about 3 ft., while for the girder spans it varied from 9 ft. 8 in. to 12 ft. 11 9/16 in. Fortunately, by cutting the piers in two vertical planes parallel to the axis of the bridge and passing close to the inner edges of the truss shoes, it was possible to provide room for the girders and still leave the truss seats intact. The concrete was cut down low enough to allow about two feet of new concrete to be placed for the girder seats. These were reinforced to prevent cracking and copings were put on. While this work was going on, the end stringers of the old trusses were supported by 8 in. by 16 in. timbers, spanning the notch and resting on the masonry left to carry the trusses. After the old spans were removed, these portions were removed and capped to match the coping already constructed under the new spans.

The following cost data compiled from the erection foreman's reports does not include rent of erection apparatus and tools nor depreciation on the same. The total cost for engineering, including the preliminary investigations, detailing, checking and tracing the plans for the entire job amounted to $700, and the salary of the field inspector amounted to $960, making a total of $1,660. Classifying inspection as engineering, this gives a percentage of approximately 2½ on $70,000, the total cost of the work.

WEIGHTS

Span length	No. of spans	Weight each	Weight with deck
75 ft.	2	39 tons	58 tons

The work was carried out under the direction of J. B. Berry, formerly chief engineer, while I L. Simmons, bridge engineer, prepared the plans and supervised the erection.

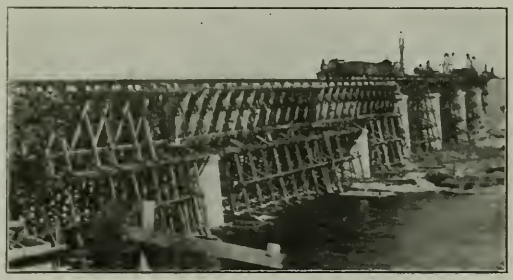
SECOND PRIZE—DROPPING OLD TIMBER TRESTLES WITH DYNAMITE

By James H. Stack

Secretary, The Thomson Bridge Company, San Francisco, Cal.

In replacing a number of wooden bridges and trestles on the coast division of the Atchison, Topeka & Santa Fe between Los Angeles, Cal., and San Francisco, a unique method of placing steel girder spans without delay to traffic was worked out by O. J. Crossfield, general manager of the Thomson Bridge Company, San Francisco, Cal, which had the contract for the erection of the new structures. The piers and abutments for these bridges had been built under a separate contract and the steel was delivered at the nearest convenient unloading point to the various sites.

One of the bridges to be replaced was that across the San Joaquin river at Herndon, Cal., which consisted of three 150-ft. Howe truss spans on pile piers and 450 ft. of framed trestle bents 16 ft. center to center, resting on pile bents, capped just above the ground line. The highest point of the trestle was about 70 ft. above the river bottom. The new bridge consisted of two pin-connected spans 200 ft. long, three 100-ft., one 80-ft. and one 48-ft. deck girder spans, all of which carried an 8-in. creosoted floor with ballasted deck. The alinement of the new bridge was the same as that of the old and the specifications required that "all operations must be so conducted that traffic may not be interrupted." The intervals elapsing between trains varied



General View of Santa Fe Bridge at Herndon, Cal., Replaced by Dynamiting Trestle Spans

from 45 min. to 3½ hr. The steel for this bridge was unloaded at a siding about 3½ miles from the site.

The erection of the pin connected spans could be carried on without difficulty, but the girder spans presented a serious problem. They had to be transported 3½ miles, the rails, ties, stringers and trestles of the old bridge removed, the girders riveted, the creosoted floor laid and fastened, and the ties and rails placed, all within the interval between two trains. The construction of falsework was out of the question on account of the height.

The method adopted was to support a complete girder span between two special derrick cars and to remove the old trestle by dynamiting the posts. Each derrick car consisted of two 40-ft.

New Girder Spans in Place, Showing Section of Trestle Dropped by Dynamiting

steel flat cars of 50 tons capacity, which were coupled and bolted together so as to be able to travel without changing the distance from end to end. Cross timbers were placed on these cars at intervals of about 10 ft., on which were laid long sills the full length of the two cars to support the towers, boom and engine. The sills were sway-braced to stiffen them laterally and fastened only at the ends so that the cars could pass around curves without bending the sills. The tops of the cross-timbers were also thoroughly greased. A tower 20 ft. high was erected at one end of this outfit, being built up of 12 in. by 12 in. timbers, with a

rigid A-frame boom 35 ft. long projecting at an angle of 45 deg. from the foot of the tower. The back guys were passed over the towers and carried to the farther end of the sills. The derrick and towers were designed to carry safely a load of 100 tons and the cars were ballasted with old rails. Six-sheave steel blocks designed and built especially for this work were provided.

A complete girder span was assembled and riveted on rail skids in the material yard, the creosoted floor being placed and fastened so that as soon as a train had passed the bridge, the span could be picked up by the two derrick cars and the entire train with the girder span between the derricks could be run out to the bridge site. Meantime, a force of men at the bridge bored two holes in each post of the trestle within two feet of the bottom of the posts, and two holes about 12 ft. above these at right angles to them. A stick of dynamite with an electric detonator was inserted in each hole and the entire series wired so that they could be exploded simultaneously.

The train was spotted on the trestle so that the span was in correct position over the pier, the old rails and ties were removed and the stringers cut over the center of the pier. The dynamite was then discharged, cutting off the posts 15 ft. from the bottom and causing the entire trestle between the piers to drop far enough to allow the girders to be lowered into position. The ties and rails were then replaced and the derricks removed. The longest time required for placing one span from the time the regular train crossed the bridge until the rails were placed on the new span was 2 hr. 40 min., and the shortest time 1 hr. 45 min. The trestle bents in many cases dropped so true after the explosion of the dynamite that the posts landed on the sills and remained standing as though originally built there.

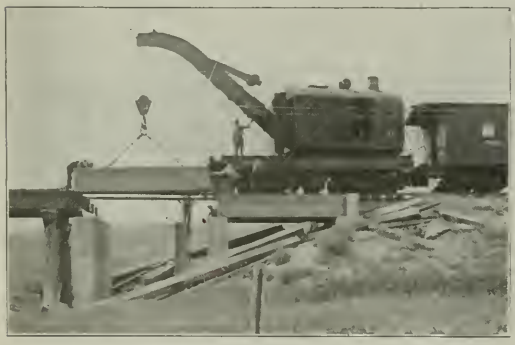
ERECTING REINFORCED CONCRETE TRESTLES

By E. M. Grime

Supervisor Bridges and Buildings, Northern Pacific, Dilworth, Minn.

A number of reinforced concrete trestles have been built on the Northern Pacific, particularly where the main line crosses the bad lands of North Dakota. The alluvial soil of this locality is easily eroded and dry runs become raging torrents during the early spring and summer storms, making it necessary to maintain comparatively large bridge openings.

These concrete trestles consist of reinforced concrete piers,



Placing Concrete Slab on Typical Reinforced Concrete Trestle on the Northern Pacific

spaced 16 ft. center to center, resting on reinforced concrete piles and spanned by reinforced concrete slabs. Erection of bridges of this type is a little more difficult than the ordinary pile bridge, but it was found that the men soon became familiar with the work and it was not long before they would rather drive the heavy concrete piles than ordinary timber piles. The spans being made practically the same length as those in the old bridges which were replaced, the piers were easily located to clear the old structure and a minimum of additional falsework thus required. These piers enclose the piles for a height of not less than three feet and frequently six or eight feet where the piles have not penetrated to the previously estimated depth. The piers are 30 in. wide and are reinforced both horizontally and vertically, this reinforcing being tied to the piles by ¾-in. steel rods wound around them. On this account it is necessary to drive the piles practically true to line and with a variation not exceeding 3 in. from the vertical.

The driving of the piles thus becomes one of the most difficult features of the erection of this type of structure and it was found that this part of the work could be greatly facilitated by the addition of a water jet to the regular division pile driving equipment. This consisted of a Fairbanks-Morse duplex general service pump with a working pressure of 150 lb., which at times could be increased to 200 lb. The pump was mounted on the tender of the driver and had a 5-in. suction connected with the water car and a 4-in. discharge reduced to a 3½-in. pipe leading up to the driver leads. To this was attached a 2½-in. six-ply armored hose ending in the goose neck, which was reduced to a 2-in. jet pipe about 40 ft. long, having a 1-in. nozzle.

As the driver was spotted in position for driving a bent, the jet pipe was drawn up along the leads and five vertical holes were jetted down to the exact position for the piles and to about the depth the piles were expected to penetrate. The jet left a neat hole about 5 in. in diameter which the piles readily followed as driven, and this proved to be a great help in keeping the piles in correct alinement. It was thought the piles might not stand the battering of the 4,500-lb. hammer, but by using a short piece of oak block and a layer of hemp rope to act as a cushion on top of the piles, and with the hammer dropping from 6 to 15 ft., no serious damage was done. They were driven until the penetration was ¼-in. or less with a 15 ft. drop of the hammer. The piles were selected in from 16 to 30 ft. lengths as best suited the location according to data from the pile driving record of the old bridge.

As soon as the driving of a bridge was completed the concrete crew proceeded with the building of the piers and when these were 30 days old or more, they were ready for the placing of the slabs which had previously been made at the concrete plant and shipped to the site of the work, being unloaded along each side of the track at one end of the bridge. The placing of the slabs, two of which are required for each span, is shown in the illustration which also shows the method of removing the deck of the old bridge one span at a time and blocking up the ends of the stringers on the edge of the new pier, so the bridge can be opened to traffic quickly after the slabs are placed and the track laid. Each slab is 7 ft. wide and 15 ft. 11 in. long and weighs about 15 tons, so it was found advisable to handle them with the locomotive crane working forward from the end of the bridge and building track as the slabs of each span were placed in position. Most of these bridges being located on a rather busy section of the main line, the placing of slabs was not attempted except at times when the despatcher could allow several hours between trains. In this way the work was accomplished without any serious delay to important trains.

The slabs and piles for this work were manufactured at the Glendive, Mont., concrete plant under the direction of M. F. Clements, assistant engineer, and the writer had charge of construction in the field.

REPLACING CAPS ON HIGH TRESTLES

By W. L. Ratliff

Supervisor Bridges and Buildings, Illinois Central, McComb, Miss.

In replacing caps on high ballasted deck trestle bridges the cost of building cribs to support jacks is often very expensive, especially when only one or two caps are to be replaced and large quantities of old timber are not available. This situation can be met by lashing a 10 in. by 12 in. timber 14 or 16 ft. long across the piles in the bent on which the cap is to be renewed using chains of sufficient length to go around the pile and the stick of timber twice. This timber should be placed at the

proper distance from the lower side of the deck for the operation of a 4 or 5-ton jack which can be used to raise the deck a sufficient distance to allow the caps to be changed. In cases where there are stringer joints on the caps another stick of timber can be bolted to the lower side of the stringers on the opposite side of the caps from the jacks, being sure to place it far enough away to allow swinging the caps, the guard rails in this case being depended on to carry the load of the deck or the short stringers under which jacks cannot be placed. It has been found that a cap can be renewed in this manner in a very short time and at much less cost than by cribbing.

REPLACING A SMALL BRIDGE OVER A HIGHWAY

By C. V. Chamberlin

Assistant Supervisor of Bridges, New York Central, Utica, N. Y.

The timber trestle over State street in Dolgeville, N. Y., on the Little Falls & Dolgeville division of the New York Central, was recently replaced with a steel bridge on concrete abutments and intermediate steel bents on concrete piers. The old trestle was about 124 ft. long, composed of framed bents and 8-in. by 16-in. stringers, the spans varying from 9 to 16 ft. The new structure consists of three spans of second-hand girders remodeled by the addition of new lateral bracing and floor system. The center span of the through girders is 38 ft. long and the two deck girder approach spans are 26 ft. 9 in. and 28 ft. 9 in. long, respectively. The base of rail was raised to preserve the necessary under-

Progress in Erection of Steel Bridge Replacing Timber Trestle

clearance and the alinement was thrown to a uniform 8-deg. curve as it was previously quite irregular.

The falsework and masonry were put in during December and January. Pile bents were driven at the two abutments and the temporary stringers set for the new base of rail. At the same time the base of rail on the old trestle was raised by laying stringers on the old deck and placing on these stringers a new temporary deck. This has the advantage of stiffening the old structure. Where the excavation for the piers endangered the old timber bent, two piles were driven and capped to support the caps of these bents and be outside the lines of the excavation. This allowed placing the new masonry with the smallest amount of alteration to the old trestle and as the excavation in some cases had to be carried 8 ft. in rather wet material the piles were quite necessary to the safety of the structure. The steel was laid out on blocking at a convenient level spot where the necessary changes were effected. The floor system for the long span was set in place so the drilling and reaming of the girders would be accurate. The approach spans were cut apart, placed on the necessary skew and the new cross bracing riveted in. The new deck of 8-in. by 10-in. by 12-ft. ties was framed with elevation blocks for 4 in. of superelevation in the track.

The bridge was erected on February 19 with a 12-ton long boom derrick car. The accompanying illustration shows the old trestle just previous to its removal, the derrick car erecting one of the approach spans and the new structure after the erection of the center span. The work was finished between 11:30 a. m. and 5:20 p. m., 5 hr. and 50 min. As the passenger traffic is light and most of the passengers use the Main street station which is south of the bridge, it was possible to cut out traffic completely over the structure during its erection. This work was handled under the direction of E. L. Jenkins, supervisor of bridges.

RENEWING HOWE TRUSSES WITHOUT DELAY TO TRAFFIC

By J. J. Wishart

Supervisor Bridges and Buildings, New York, New Haven & Hartford, Hartford, Conn.

The two-span wooden Howe truss bridge of the New York, New Haven & Hartford over Water Shops Pond, Springfield, Mass., which had been in service 39 years, was recently replaced by a four-span deck plate girder bridge without interference to traffic. Each of the old spans was 153 ft. 3 in. long, supported by a brown stone pier and abutments. The new spans are each 76

Replacing Howe Trusses with Deck Girder Spans on the New Haven

ft. 8 in. long, requiring a new concrete pier at the center of each old span.

The old center pier had to be renewed down to the water's edge, a distance of about 8 ft. The brown stone was cut away between the two lower chords, leaving the bridge supported on two small pedestals above the water. The cutting was done by contractors and a company mason followed, pointing all seams and old cracks. On the surface of the two small pedestals 25 bbl. of cement were poured, making them solid and saving the cost of carrying the bridge on falsework, which would have amounted to several hundred dollars.

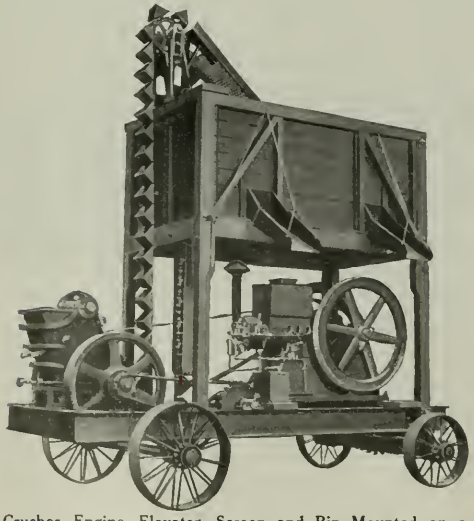
In the construction of the first new pier a cofferdam was driven and the water had been lowered about 21 ft. when the bed of the pond inside the dam broke, allowing water and mud to rush in. An attempt was made to place sand bags to seal the dam, but this proved unsuccessful. Permission was therefore secured to drive piles on which to carry the pier, a self-propelling pile driver working on the old bridge with a 20-ft. follower and a set of gins on the lower chord, being used for placing these piles. The surface of the water was 30 ft. below the top of the bridge. The water was 22 ft. deep and 23 ft. of sand and mud overlaid

the solid bottom. After the piles were driven, the bottom was sealed by placing concrete through a 10-in. galvanized tube to a depth of 4 ft. The cofferdam was then pumped out, the piles cut off and the pier finished. The foundation for the second pier was handled without trouble in the same manner.

During the erection of the new steel the old trusses were blocked on the new piers, as the derrick car when setting the girders was 60 tons heavier than the capacity of the bridge. The derrick boom was only 35 ft. long. The first span was replaced on a Friday morning, the ties and floor stringers over the first pier being cut and the tower set between trains. After a passenger train crossed the bridge at 10:20 a. m., the rails, ties, stringers, top rods, top lateral braces and sway braces were removed with the derrick car, and the new girders erected in the space between the old trusses. While the girders were being set the bridge and section gangs brought new ties on push cars from the west shore and while the braces and laterals were being bolted up the bridgemen placed the ties and the section men the rails. A freight train passed over the bridge at 1:05 p. m., 2 hr. 45 min. after breaking the track. On Sunday two towers and two spans were placed, there being no trains to interfere with the work, and on Tuesday the last span was set between trains.

A SMALL PORTABLE STONE CRUSHING OUTFIT

A considerable number of railway structures are built of concrete every year in locations considerably removed from a source of crushed stone, making this material unusually expensive, although field boulders or stone from excavations may be available near the work. In order to make it possible to utilize such material as aggregate in concrete a small portable crushing outfit has been developed by the Smith Engineering Works, Milwaukee, Wis. As the first requisite for such an equipment had to be small size and portability, and, as it is intended solely for use on



Crusher, Engine, Elevator, Screen and Bin Mounted on a Steel Truck

small work where the volume of stone needed does not warrant the expense of moving and setting up a big crushing plant, the output and cost of production can scarcely be compared with ordinary figures of this kind. It is estimated, however, that the cost of crushing stone with this equipment is from $0.70 to $0.80 a cubic yard, based on the use of field boulders and including the cost of gathering and hauling the stone. This also includes an allowance for depreciation, fuel, interest on the investment, etc. The capacity of the plant in producing ½-in. stone is 2 to 2½ tons per hour, and in producing 1½-in. sizes and under the output is about 4 tons per hour.

The outfit, which is known as the No. 7 contractor's portable crushing rig, consists of a No. 7 Telsmith jaw breaker, a 12-hp. double opposed cylinder engine, elevator screen and bin, all mounted on a single steel truck. The crusher has a 7-in. by 10-in. opening, manganese steel die plate, cast steel frame, direct crushing stroke and enclosed eccentric. The double opposed cylinder engine is particularly adapted to this work because of its reduced weight and continuous power. A reciprocating feeder conveys the stone from the crusher to the elevator, the feeder being operated by the swinging jaw of the crusher. The stone is raised to the bin by a vertical single-chain elevator, with 7-in. by 4½-in. by 5½-in. bucket, the chain being of malleable iron and the boot of steel. The elevator has a folding section at the top to reduce the required head room. The equipment can be furnished with a chute screen with perforations made to suit, or a rotary screen of the central shaft type 16 in. in diameter and 4 ft. long. The bin is of the flat bottom, portable type, with four bin gates. It has a total capacity of five tons, of which about three tons will run out by gravity.

The equipment is mounted on an all-steel truck with 8-in. channel sills strongly braced. The front axle is a steel channel with cast steel skeins, and the rear axle is of cold rolled shafting 2 15/16 in. in diameter. The front wheels are 24 in. by 6 in., and the rear wheels 30 in. by 6 in. The entire outfit weighs about 9,000 lb. without a rotary screen, which adds about 400 lb. to this. It can be pulled by two horses on a paved street, and four horses will take it anywhere that an automobile can be driven.

AN ORNAMENTAL TYPE OF METAL SHINGLE

A new type of metal shingle which is adapted to use on the roofs of railway buildings where the pitch allows, has recently been placed on the market by The Berger Manufacturing Company, Canton, Ohio. The principal change in design as compared with the "Chieftain" and "Swanee" metal shingles made by this company, is that the design is more ornamental than the previous patterns. In common with the other Berger shingles the new

The "Berco" Metal Shingle

design is made with a three-point contact lock construction and an end lap providing high corrugations at the top. This serves a two-fold purpose, facilitating the application and at the same time making the shingles automatically interlocking and self-alining, while the knife edge at the top insures a tight joint and prevents capillary attraction. These shingles are 10 in. by 14 in., and are made either from galvanized rust-resisting Toncan metal, galvanized open hearth steel or painted terne plates.

The Organization for and Methods of Relaying Rail

Three Discussions of Practical Organizations for This Work, on Lines Having Heavy and Light Traffic

One of the most important classes of work in which the maintenance of way department on most roads is now engaged is that of relaying rails. Because of its direct interest at this time we publish below three articles discussing various phases of this problem as they have been worked out on different roads.

LAYING RAIL ON A BUSY LINE

By W. F. Rench

Supervisor, Pennsylvania R. R., Perryville, Md.

On lines of intensive operation where the available intervals between trains are never more than 25 min. and where intervals as low as 12 min. must frequently be utilized it is of the utmost consequence that the preliminary work be done to the last item. No single operation that can be completed before the track is broken must be omitted. The cutting of a closing rail is entirely out of the question and this must be provided for beforehand by careful determination with the steel tape. The number of rails that can be laid in a given interval must be known and though this is somewhat variable it will be found close to a rail a minute for intervals between 10 and 25 min.

The rails must be as near the place where they are to be applied as possible and all needed material must be close at hand. The distant flagman must be trained to receive instantly the flag signal to begin protecting and must respond just as promptly when the signal is given to withdraw. The need for immediate action by each member of the rail laying force is no less insistent.

There is no item of work wherein the matter of detail is of such importance as rail renewal, which of necessity causes a break in the track. A specific duty is laid upon each member of the gang and remains for every operation, so that no further line-up is required. Maintenance rules generally require that the rails shall be laid one at a time and similarly forbid the withdrawal of spikes or the removal of bolts in advance of the renewal. This severe but necessary restriction can be met by perfect organization.

The bolts at the joints to be broken have washers added until the nut has just a safe hold. Two of the best workmen are assigned to each end of the run to be relaid. Ten men with claw bars are delegated to remove from the chosen side of the rail the spikes which have previously been started to assure their coming out readily. Eight men with lining bars push the old rail aside, two dislodging it, one guiding it across the new rail and five lining it away. Four men follow closely, two with spike mauls and punches to drive down the butts of broken spikes, one with an adz and one with a stiff broom to sweep aside chips of wood, pieces of ballast and spikes. Twelve men with tongs put the new rails in place as fast as the old are removed and 10 men working in pairs apply the splices with half their complement of bolts. Two men push the rail under the spike heads and spike the joints and centers while the 10 men who were pulling spikes but who are now free spike the rail upon every other tie. Four utility men put the cut rail in place and look after the compromise joint in case a different section is being laid. The gang which threw out the old rail completes the full spiking and the men with the tongs assist in applying the remaining bolts, giving them all as full tension as possible. This force of men generally consists of two gangs and, in addition to foreman and assistants, numbers about 50 men.

The preliminary work in renewals of this character largely determines the efficiency of the gang. In the event a different section of rail is used in renewal, the first work upon the arrival of the relaying gang is to remove the tie plates, the ties that were without tie plates being adzed down when these are in the minority and those surfaced up that carried the tie plates when they are in the minority. After this is done the detailed surface of the track is given attention so that the new rail may lie upon as smooth a bed as possible. The ties must then be adzed to a level seat alongside the rail. The point of beginning must next be established and where possible this should have especial regard for the existing locations of block joints when these cannot be changed so that the introduction of unusual lengths of rail in the main track at isolated points may be avoided. In the event that this necessitates laying the rail against the current of traffic, temporary rails of the new section are used so that the approach ends of the permanent rails will not be injured. The rails are then strung out just outside the ends of the ties to be as near their final positions as possible and incidentally to indicate the new positions of the joints for use in the preliminary tie spacing. This method is not accurate on sharp curves and the position of the joints must be determined in such cases by careful measurement with a steel tape after the average length of the new rails has been carefully ascertained. When the rails are set up for the purposes named it would be an unnecessary refinement to use shims and many of the shims would surely become lost. It is quite sufficient to place a number of the rails, five in summer weather, with their ends in contact and separate each five with a spike, which represents the aggregate of the several spaces.

When the preliminary spacing is completed so as to assure the flanges of the splices entering without exception the word is given and the men line up to await the foreman's signal that use of track has been given, communicated from the telephone box or from his field telephone connected with the despatcher's telephone line. The principal protection is the distant flagmen, who not only display a red banner but place torpedoes on the rail. The signalmen, whose duty it is to bond the track, further by means of a wire shunt the track circuit so as to display the danger signal at the nearest signal; but at the immediate location the foreman's red flag is always in evidence until replaced by a white one to indicate that all protection may be withdrawn and traffic be allowed to run as usual. This assumes that all ties are fully spiked, all bolts inserted and made tight and at least two bond wires are in place at each joint.

RAIL LAYING ON LINES OF MODERATE TRAFFIC

By E. R. Lewis

Assistant to General Manager, Duluth, South Shore & Atlantic

It must be borne in mind by all concerned that rail laying is, in its sphere, of equal importance with train operation; that it is a necessary menace to safety; and that extraordinary vigilance is required to prevent accidents to persons and to property, from the time of distributing the first car of rail until the cancellation of the last slow order. No more important duties are delegated by the track foreman to any employee than those of the flagman. Flagmen should be most carefully selected, drilled and instructed. Preferably they should be experienced trainmen. The track foreman's orders to flagmen and to material trainmen, insofar as is possible, should be given in writing from carbon copy note books. Too much care cannot be exercised to prevent misunderstanding of orders affecting traffic.

The efficiency of a track-laying gang depends on the program laid down, on the continuity of the work, on the delivery of materials, on the class of labor available, on the personality of the foreman, and most of all on the completeness of understanding and the helpful co-operation existing among officers and employees of all departments. On lines of moderate traffic, depending in part on the weight of materials to be handled, and in part

on the mechanical contrivances in use, a track laying gang may be organized about as follows:

1 foreman,
1 or 2 assistant foremen,
1 time keeper and material clerk,
2 flagmen,
4 splice men,
8 tong men,
2 tie plug drivers,
5 adz men,
5 spike pullers,
6 spikers,
2 tie plate handlers,
5 men of all work,
1 tool car man,
1 water boy.

If, as is usual on lines of moderate traffic, a boarding train is necessary, one cook, one assistant cook and one or two chore boys will probably also be needed. Since the boarding train must be set out on temporary spur tracks between stations, a field telegraph office and a telegrapher will be of decided advantage, especially to the material train operating in conjunction with the track laying gang.

The boarding train may consist of:

1 foreman's car with office and sleeping quarters for 6 men.
Sleeping cars for 45 men, so partitioned that not more than 4 men sleep in one well ventilated compartment, in single bunks preferably of metal frames requiring no mattresses.
1 cook's car, to accommodate 4 men.
1 kitchen car.
1 stores car.
1 dining car—Foreman and men should eat together—Special diners and special dishes breed trouble.
1 fuel car.
1 tool and blacksmith's car.
1 laborers' day coach for use of laborers with material train.
1 locomotive tank—for water supply.

The most important man of the organization is the foreman. To be successful he must be an organizer of executive ability. Preferably he should be permanently employed and well acquainted with the road, its rules and its labor supply. If so, he will be able to attend in part to the outfitting of the boarding train and the gathering of a small gang at least, of track laborers who are well acquainted with the territory, expert in their duties, and of service in teaching new men. The foreman will be able to help select his tools and equipment, and to profitably employ the gang while recruiting is in progress. The more efficient the foreman, the better will be the assistants he hires, and the gang he keeps. Understanding between the foreman and men minimizes the difficulties of nationality. There are rail laying gangs composed of natives of various countries other than America equal to the best American labor.

The idea that foreign labor is inferior to our own is largely the result of American ignorance of, and carelessness about, learning foreign ways. Proper treatment and determination to establish an understanding with laborers of any nationality, will usually overcome most obstacles to efficiency. It is largely a case of placing oneself mentally in the foreigner's position, of getting his view point and of treating him accordingly.

A good track foreman will devise ways and means of retaining the services of a gang almost intact during a season's work. This requires tact, system, ability to teach, to understand, to deal justly and wisely, to organize, to grade and reward and punish, and through all to retain respect. Yet such foremen are available and ready on every railway. Much of the present scarcity of good foremen is due probably to a certain dearth of judgment of human nature in those who must select and train them. The assistant foremen should be experienced trackmen, preferably extra section foremen, or sub-foremen. They should be carefully selected, trained and given direct charge over not more than 20 men. Their ambition for advancement should be carefully nurtured.

A good blacksmith should be selected, if possible, as tool car man. Besides caring for and accounting for the tools he can, if provided with a blacksmith's kit, a small anvil and a portable forge, save the company time and money by repairing rail laying tools promptly and by saving the shipping of them to and from division points for repairs.

The selection, transportation, refrigeration and serving of clean, plain, wholesome food; the sanitation of the camp; the disciplinary arrangements for the "off days," Sundays, pay days, holidays and rainy days; the weeding out of undesirables; the grading of wages; the excellence of the work report system; and forethought in ordering supplies of all kinds, are matters of moment in rail laying economics.

This procedure depends in fact on the same team work, on the same individual efficiency, on the same intelligence, integrity, diligence and wisdom as form the basis of all worthy human endeavor. The best results are only obtainable through the best efforts of mind and body of the men of all ranks employed on the work.

LAYING RAIL ON THE LEHIGH VALLEY

By G. L. Moore

Engineer Maintenance of Way, Lehigh Valley, South Bethlehem, Pa.

All rail is handled by machines—locomotive cranes, steam ditchers, steam derricks and air loaders being used. Several machines are used in one work train in distributing new rail. The length of track per car load is blocked out, and the work train is split up into sections so that the locomotive handles the air loaders and each locomotive crane handles a section consisting of itself, two cars of rail and a steam unloader, the locomotive crane propelling the section and unloading one car of rail on one side of the track and the steam derrick or ditcher unloading the other car of rail on the opposite side of the track. Short rails are unloaded at each signal or cut section to permit squaring the insulated joints within 10 ft. without cutting rails. Joints, bolts and new anti-creepers, where required, are unloaded the same day.

In loading up relayer rails, the work trains are operated in the same manner as in unloading. Each rail is numbered in the order in which it came out of the track and is loaded consecutively in the same order so that when relaid in side lines or freight main tracks they are in the same order, thus avoiding any possibility of mis-matched joints. The rails are loaded in the cars in single tiers, heads up, with strips between each tier.

The high record so far for loading relayers with one work train in one day is 115,817 ft. of 90 lb. rail, including joints and bolts, in 37 cars. Nine machines were used in this train. Figuring in miles of track 10.96 miles of track was cleaned up of rail, joints and bolts with one work train in one day. This was all of the rail in this particular stretch and from our experience in this and other cases, we know that we have not reached the limit of efficiency in this work and believe that it is possible to load or unload the rail for 15 miles of track with one work train in one day.

The high record amount of new rail unloaded by one train in one day has not as yet quite equalled the figures for loading rail quoted above, but there is nothing, in our opinion, to prevent doing so and when we next receive new rail, which will be next fall, we fully expect that we shall find it possible to unload the rail, joints and bolts for 15 miles of track in one day with one work train.

The cost of loading or unloading rail, using several machines in a work train, runs from 18 to 23 cents a ton. The rails are placed on the ground in exactly the same location or order for convenient laying as though the work were done by one machine or by manual labor, and the rails are loaded in exactly the same manner and placed in the cars in order for convenient unloading again, the same as though done with a work train using only one machine and much better than when done by a loading gang of men.

It may be well to call attention to the fact that in using machines, whether one or several, in a work train, the rail is not injured and neither in our experience have men been injured; while in handling rails by hand the rail may be damaged and it is known from past experience that the men are frequently hurt and in many cases very severely.

Expansion is allowed in laying rail as follows:

100 deg. F., lay rails tight.
80 deg. F., lay rails 1/16 in. apart.
60 deg. F., lay rails ⅛ in. apart.
40 deg. F., lay rails 3/16 in. apart.
20 deg. F., lay rails ¼ in. apart.
At zero F., lay rails 5/16 in. apart.

Steel shims are used and thermometers are frequently consulted. The temperatures shown in the table are those shown by a thermometer in the shade. Anti-creepers are applied the

same day the rail is laid and their application is considered a part of the work of laying rail.

We lay practically all of our rail in the winter. Wherever there are any low ties, thin shims are used. We find it necessary to use very few such shims and our experience shows that our rail is not damaged either by the methods of laying it or by our plan of maintaining track.

During the past winter we laid 34,464 tons of new 100 and 110-lb. rail. We shall lay no more new rail until next winter; this conformance with the policy which we adopted five years ago of laying our new rail in the winter, reserving the summer season for the work of surfacing track and renewing ties. During this time we have not disturbed our track for the express purpose of spacing the ties to fit the joints and we now have in our main passenger and freight running tracks about 160,000 tons of rail so handled. We have yet to find the first case of damaged rail by reason of not spacing joint ties, but have been able to greatly improve our track by diverting the labor, in former years so employed, to the most important work of improving the surface and line and renewing of ties. We feel that there is absolutely no good reason for spending large amounts of money simply to space ties to fit the joints, which money applied otherwise would count for so much more.

In common with many other heavy traffic lines which had not done so before, we have for the last four seasons been increasing the number of ties in our heavy traffic track. Where formerly we used 18 ties under a 33 ft. rail, we are now putting in 20 ties. This work will near completion this season. In surfacing our track, renewing bad ties and increasing the number of ties to 20 to the rail, in many instances where the renewals are heavy and where it may be done without increased cost, we do space the ties to fit the joints. We have still in our main passenger tracks stretches where there are 18 ties per rail length where the ties were never spaced to fit the joints and we have many stretches of track where the track was surfaced and 20 ties per rail used before the new rail was laid and where nothing was or will be done in the way of respacing the ties. One of the great advantages of our method is that it is not necessary to wait until any specified time to surface bad track because we are going to lay new rail, but at all times we rebuild our worst track first regardless of rail renewals, and after new rail is laid and the track surfaced, it is impossible to tell, except by inspection on the ground, which was done first or, in other words, whether the ties are spaced to fit the joints or not.

Most of the rail is laid with large forces, frequently trains being detoured over other tracks. The organization for rail laying under such conditions is as follows:

	Foremen	Men	Wages
Removing anti-creepers	1	3	$6.95
Pulling spikes	1	18	29.45
Throwing out rail	1	10	17.45
Setting in rail	1	24	38.45
Spiking	2	14	25.90
Drilling for bonding	..	10	15.00
Bonding	..	4	10.20
Jointing and bolting	2	24	40.90
Reapplying anti-creepers	1	10	17.45
Motor car distributing water and material and signal work	t	3	6.95
Total	10	120	$208.70

Very frequently forces from adjoining supervisors' territories are used, each force laying the rail on one side of the track. In some instances we have had three such forces together and the greatest amount of rail laid in one day was 7.85 miles of track. Doing the work in this way, great rivalry is set up between the different forces and the rail is laid very rapidly and very cheaply. Another argument in favor of this plan is that the delay to traffic is small and covers one day only for such a stretch of track, whereas using small forces the traffic would suffer delays many days.

Our rail gangs are all supplied with portable telephones, so that the foremen are in frequent communication with the despatcher and in locations where it is impossible to divert trains over adjoining tracks the delays both to trains and to the gang laying rail are reduced to the minimum.

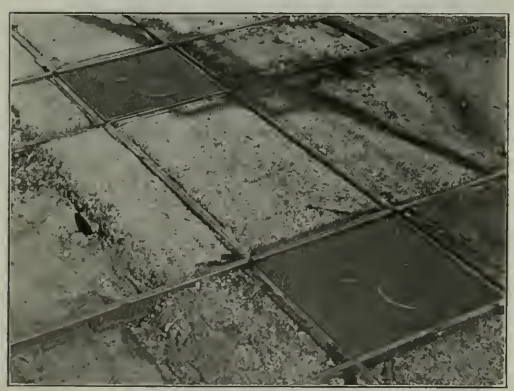
On a single track main line loop over which our important passenger trains are run, besides considerable other traffic, 4.5 track miles of new rail was laid in one day during the past winter, two forces as per the statement above being employed. In this case, of course, it was necessary to close up for the passage of all trains. On our light branches, it is impracticable to get such large forces together and the work is usually done with a small extra gang combined with nearby section gangs. On these branches there is no signal work to be done.

In all our work we endeavor to foster a spirit of friendly rivalry between divisions and between sub-divisions. Records worthy of note of all work accomplished in one day by any division is published on all divisions. The high records so far are as follows:

Laying new rail on track from which traffic has been diverted for the purpose of the day	7.85 miles
Laying new rail on track from which traffic could not be diverted	4.56 miles
Track miles of rail handled with one work train in one day	10.96 miles
Coal cars of ashes unloaded for shoulder on main line with one work train in one day	125 cars
Cross ties unloaded and distributed along main line track for renewals with one work train in one day	128 cars containing 28,094 ties

THE COBB SHOCKLESS RAILROAD CROSSING

At the intersection of the four-track line of the Pacific Electric and the single track line of the Atchison, Topeka & Santa Fe at Slauson Junction, near Los Angeles, Cal., two crossings of a new type with movable rails are in service. The first of these has been subjected to a very heavy traffic at this point for more than six months. The electric road handles a daily traffic of over 15,000 tons, consisting of 360 high speed electric cars made up in 240 trains and the steam road handles about 5,000 tons of traffic per day, a large part of which is in heavily loaded oil trains hauled by Consolidation locomotives. During the time these crossings have been in operation they have never caused a delay to trains and they have cost nothing for repairs and maintenance with the exception of the general inspection and lubrication, which is given to all of the mechanism in the interlocking plant.



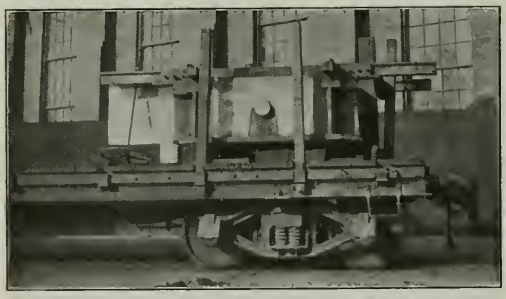
Two Cobb Shockless Crossings in the Tracks of the Pacific Electric and the Atchison, Topeka & Santa Fe

This design consists of four or more rails forming the closing members of the intersection, which are moved vertically between solid fixed guides to bring them up level with the rails on either side or to drop them out of the way of wheel flanges on the cross track as may be desired. The ends of the movable rails are mitered to form an interlocking joint, providing for continuous support of the wheels passing over the crossing on either track. The vertical motion amounting to 1¼ in., is imparted by two wedges under each rail at its extremities, as at the ends of a draw bridge, these wedges moving longitudinally with

respect to the rail and being designed to draw the rails downward when they are withdrawn. The wedges under the several rails are so connected that when one pair of rails is raised to the operating position the other pair is drawn downward to its lower position. The rail is under absolute control in all its positions and is locked solid when in position for use, so that no rolling load comes upon the wedges except in the fixed position.

The operating mechanism is located below the surface of the ground and enclosed in the main foundation frame of the crossing. This mechanism consists of gears, links and wedges, all having slow motion and ample wearing surface. In the two installations referred to the crossings are operated by motors enclosed in small water tight boxes within the foundations, but it is possible to arrange the mechanism for operation by hand, switchstand, compressed air or any other method deemed advisable or necessary, the only requirement being that the main driving shaft running under the crossing shall be revolved 180 deg. to bring one pair of rails into the effective position, and then 180 deg. in the opposite direction to bring the other pair up. There are no moving parts above the surface of the ground, the entire space within the crossing rails being covered as shown in one of the illustrations.

When the first crossing was placed in service it was equipped with a ½-hp. second-hand slip switch derail motor and a pole changer, borrowed from the signal department of the Pacific Electric, the entire arrangement being considered temporary in order to test the device and allow any mistakes that had been made in its construction to be corrected. As this crossing worked



A Cobb Shockless Crossing Ready to Install

with absolute satisfaction, with the exception of the improvised actuating mechanism for more than three months under adverse weather conditions and heavy freight and passenger traffic, it was taken out for the purpose of installing suitable actuating and control apparatus for the permanent installation. The new motors, quick acting device and proper pole changers which were installed have given such good satisfaction that a second installation with the same details has been made. The present motors consume about 6 amperes of current at 110 volts in operating the crossing, requiring about 3½ seconds for the change of position. The crossings are also equipped with an emergency provision for operating by hand, and it has been found that a man can readily operate the rails with a hand wheel similar to those used on ordinary hand brakes, indicating that the power required for operating the device is small.

These crossings are controlled by a lever in the all-electric machine in the interlocking tower and are properly interlocked with the signals, derails and switches. It is so arranged that the crossings cannot be thrown when a train is standing on them or is approaching them. The cost of installing these crossings is said to be no greater than that of an ordinary intersection, and the cost of manufacture is only slightly greater than that of a built-up rail crossing. The only additional expense for most installations would be that represented by the cost of electric motors or hand operating mechanisms for moving the rails.

The claims made for this crossing include the following: It prevents shock, which with ordinary crossings results in noise and in wear on equipment and track work entailing additional maintenance costs. The main frame or body when once placed on a good earth or concrete foundation, will last indefinitely and all parts subject to wear can be replaced without disturbing the foundation. The rails used may be of any cross section used in the adjacent track, and they do not wear any faster than the rails in the adjacent main line, as they are subjected only to rolling wear without shock. The crossing can be operated from a tower, from a moving train by electrical contact, or by hand, air pressure, or otherwise. It can be applied to any angle of intersection or to combined intersections of broad and narrow gage track, or to a three-rail intersection when both broad and narrow gage tracks use one of the three rails in common. The rails cannot be moved sideways by a force less than that which would cause the flange to climb the rail; the rails cannot be clogged by snow or ice or by any material dropped or placed on any part of the crossing; there are no parts of the operating mechanism exposed to view or to the weather preventing their being tampered with.

This crossing is made by the Cobb Shockless Railroad Crossing Company, 1121 Central building, Los Angeles, Cal.

ABSTRACT OF ENGINEERING ARTICLES

The following articles of special interest to engineers and maintenance of way men, to which readers of this section may wish to refer, have appeared in the *Railway Age Gazette* since April 16, 1915:

Substructure of the New "Harahan" Bridge at Memphis.—The Rock Island, the Iron Mountain and the Cotton Belt, are building a joint bridge across the Mississippi river at Memphis. The substructure, completed last January, involved a number of interesting problems which were described and illustrated in the issue of April 23, page 877.

Frisco Seawall at Cape Girardeau, Mo.—The St. Louis & San Francisco is constructing a concrete and riprap retaining wall 1,800 ft. long at Cape Girardeau, Mo., to reclaim a considerable area from the Mississippi river and permit the straightening of the main line. This wall was described in a short illustrated article in the issue of April 23, page 889.

The Alaskan Government Railways.—The adopted location for the Alaskan government railways was described briefly in an article accompanied by a map in the issue of April 23, page 896.

The Success of Main Line Electrification.—The results secured from the electric operation of the main line of the New Haven from New York to New Haven, including the Westchester, Oak Point and Harlem River yards were described by W. S. Murray in an illustrated article in the issue of April 30, page 923. This article was accompanied by several tables giving detailed data.

Reasons for Building the B. & O. Magnolia Cut-Off.—The Baltimore & Ohio has recently completed the Magnolia cut-off described in the issue of July 17, 1914. The reasons justifying this $6,000,000 expenditure were outlined by A. W. Thompson, third vice-president, Baltimore & Ohio, in the issue of April 30, page 934.

New Clearance Regulations in Illinois.—The State Public Utilities Commission of Illinois has recently issued new horizontal and vertical clearance regulations which were published in our issue of April 30, page 940.

Construction of New Line to Reach Utah Coal Fields.—The Utah Railway Company has recently completed a line 27 miles long to reach coal fields at Mohrland, Utah. The construction of this line involved a number of interesting problems in connection with the disintegration of shale in embankments. This line was described in an illustrated article in our issue of May 7, page 971.

Lining Tunnels on the New Lewistown-Great Falls Line of the St. Paul.—On the Great Falls extension of the St. Paul, described in the *Railway Age Gazette* of April 2, 1915, there were six tunnels aggregating one mile in length, all but one of which were lined with reinforced concrete. The methods by which this lining was placed were described in the issue of May 7, page 978.

The Pennsylvania Improvements Through Piqua, Ohio.—The Pennsylvania has recently completed extensive improvements through Piqua, Ohio, involving interesting work which was described in our issue of May 14, page 1003.

The Federal Valuation Program.—The Interstate Commerce Commission has outlined the program for the valuation work for the next two years. This program was published in our issue of May 14, page 1014.

New Line of the Chesapeake & Ohio Northern.—The Chesapeake & Ohio recently let contracts for the construction of a new line from Edgington, Ky., to a point near Waverly, Ohio. This new line was described briefly in the issue of May 14, page 1017.

DETERMINATION OF ANNUAL CHARGE FOR TIES, POLES AND FENCE POSTS

By W. F. Goltra

President, W. F. Goltra Tie Company, Cleveland, Ohio

At the last annual meeting of the American Railway Engineering Association the Committee on Ties presented a report on the economic comparison of railroad ties of different kinds for adoption and publication in the Manual, which included the following formula to determine the annual charge:

$$r = C \times \frac{(1+p)^n \times p}{(1+p)^n - 1}$$

In which

r = annual maintenance charge or return.

C = initial expenditure or cost of material in place or investment.

n = average useful life of material or years of recurring period.

p = rate of interest including taxes.

In order to determine the relative economy of different materials such as ties, poles and fence posts, it is first necessary to ascertain the annual maintenance cost of each of the materials compared. The annual cost or annual charge is dependent upon three elements; first, cost of the material in place, second, useful life of the material, and third, rate of interest on the investment, including taxes.

TIES

By the above formula the annual sum (r) required to liquidate within the course of (n) years a debt now incurred is ascertained by dividing the cost of the material in place (C) by the present value as shown in the accompanying table, prepared by the author to facilitate the computations. To calculate each case separately according to the formula would be very tedious and laborious. For example, suppose C = $1.00, n = 10 years and p = 7 per cent. Substituting these numerical values in the equation, we have,

$$r = \$1.00 \times \frac{(1+0.07)^{10} \times 0.07}{(1+0.07)^{10} - 1}$$

The quantities in brackets should be multiplied so as to raise the product to the tenth power. When it is necessary to raise the power to 20, 30 or more, one can realize the amount of figuring required. The final result of the above equation is r = 14.24 cents a year. The same result may be obtained at once by dividing $1.00 by the factor given in the table, namely, 7.02.

If an untreated tie costs 50 cents delivered at the treating plant, 25 cents is spent for treating it and 20 cents for distributing and placing it in track, or a total cost of 95 cents (C), and if it lasts 15 years, the annual charge at 7 per cent. interest would be ascertained by dividing 95 cents by 9.10 (from the table) and the quotient (r) would be 10.44 cents a year.

After determining the annual maintenance cost of the two items that are to be compared, their difference should be multiplied by the mean number of years. For example, taking the two cases above mentioned we get the following result:

Annual charge for untreated tie	$ .1424
Annual charge for treated tie	.1044
Difference per year	$ .0380

Multiplying .0380 by the mean number of years, which in this case is 12.5, the product is 47.5 cents in favor of the treated tie.

TELEGRAPH AND TELEPHONE POLES

The relative economy between treated and untreated telegraph poles can be ascertained in the same manner. For example, if a 35-ft., 7-in. top, cedar pole costs $6, setting up costs $5, and it lasts 12 years, while a pine, chestnut or oak pole of the same size costs $4.50, treating the butt with creosote costs $2, and setting up, $5, and it lasts 20 years, with interest at 6 per cent in both cases, the comparison would be as follows:

Cedar pole.—$11.00 divided by 8.38 = $1.31 a year.

Treated pine, chestnut or oak pole.—$11.50 divided by 11.47 = $1.00 a year.

The difference in favor of the treated pole is 31 cents a year. Multiplying this by the mean life, which in this case is 16 years, gives $4.96 in favor of each treated pole. The larger the poles the greater is the percentage of economy. Some people treat the whole pole, but most people treat only eight feet of the butt in open tanks and that is generally considered sufficient for cedar and chestnut poles.

FENCE POSTS

In like manner the relative economy between wooden, concrete and steel posts may be ascertained. For example, assume that a 5-in. top, 8-ft., cedar post costs 18 cents delivered, the setting costs 4 cents, and it lasts 16 years, also that a concrete post 4 in. by 5 in. by 8 ft., costs 35 cents delivered, the setting costs 6 cents and it lasts 25 years, with interest in both cases at 6 per cent., the following comparison is obtained:

Cedar post.—$0.22 divided by 10.11 = $.0217 a year.

Concrete post.—$0.41 divided by 12.78 = $.0321 a year.

The difference in favor of the wooden post equals $.014 a year. Multiplying this by the mean number of years, which in this case is 20½ years, gives $.213 in favor of the wooden posts.

Now, supposing the above wooden cedar posts were given a preservative treatment at a cost of 6 cents each and the life was thereby increased 10 years, the relative economy would be found by dividing $0.28 by 13.00 which equals $.0214 a year, practically the same as for the untreated post. The economy in treating fence posts is not so pronounced as with ties and poles, for the reason that fence posts are a cheaper class of material than ties and poles, besides the cost of setting or placing is much less and owing to the conditions of service they have comparatively much longer life. Treated fence posts, however, show an economy over steel or concrete posts.

DISCOUNTED PRESENT VALUE OF AN ANNUAL RETURN OF 1, OBTAINABLE FOR n YEARS AT VARIOUS RATES OF INTEREST

Years n	Rate of interest (p) per cent 4	5	6	7
1	0.96	0.95	0.94	0.93
2	1.89	1.86	1.83	1.81

RAILWAY LINES NEAR THE TRENCHES.—Many of the railway lines between France and Belgium intersect the trenches, and regular trains cannot be run in those localities; but the Germans have utilized these lines by bringing in cars operated by storage batteries and operating them singly to remove the wounded from the battle front, and to bring back supplies.

General News Department

The roundhouse, machine shops, car shops and a large part of the rolling stock of the Alaska Northern Railway (the government-owned road) at Seward, Alaska, were destroyed by fire on May 10.

For the purpose of interesting school boys along its line in railroad work, the St. Louis & San Francisco has arranged a plan to have its division superintendents and other officers give short talks on the different branches of railroad service at schools at points on their divisions or other places when opportunity is offered.

Prominent railroad officers in California are proposing to test the constitutionality of the law of that state which requires railroads, street railways and steamship companies to carry without charge the members of the State Public Utilities Commission and its employees. In the recent decision of the United States Supreme Court in the case of the Northern Pacific against the state of North Dakota it was said that a carrier cannot be required to carry persons or goods gratuitously; and that this principle holds even if it be claimed that the public interests demands such free transportation. In California these officers of the state ride free on the railroads many hundred miles when they are engaged in business not connected with transportation, such as the inspection of light, power and water plants. The street railways of San Francisco carry large numbers of state employees free, and the free tickets are said often to find their way into the hands of persons not entitled to use them.

American Railway Association

The spring session of The American Railway Association was held at The Biltmore, New York City, on Wednesday of this week, President H. U. Mudge in the chair and 250 members being represented by 180 delegates.

The executive committee reported that a special committee (Julius Kruttschnitt, chairman), appointed to confer with the statistician of the Interstate Commerce Commission on a proposed revision of the rules governing the monthly reports of railway accidents, had arranged to have the effective date of the revision postponed until the railways have had a further opportunity to consider it. The special committee has also submitted one accident blank in place of six as proposed, which blank can be used by the railways in making reports to the several state and Public Service Commissions, as well as to the federal body, and also proposed a revised draft of the instructions.

The Committee on Maintenance, which has been examining the clearances for switch-stands, signal-stands, platforms, platform-shelters, mail-cranes, water-columns, coal-chutes and water tanks, has collected from the members of the association much data, and has reported that the subject is receiving attention by the American Railway Engineering Association. The committee included in its report a summary of replies to circular No. 1511, respecting the number of freight cars, passenger cars and locomotives equipped with safety appliances as required by the United States Safety Appliance Standards, as of January 1, 1915. On that date the number of freight cars in service (413 roads reporting) was 2,556,443; number fully equipped, 1,469,111; an increase of 398,358 over January 1, 1914. All cars in service, both freight and passenger, are fully equipped with grabirons as required by the laws of 1893, 1896 and 1903.

The Committee on Transportation reported that the revision of the train rules is substantially completed, but it will not present the revised code to the association for adoption until the fall session, by which time a revision of the block signal and interlocking rules will probably be ready.

The Committee on Transportation of Explosives presented the eighth annual report of the chief inspector of the bureau of explosives. (Noticed in the *Railway Age Gazette* of April 9.) On the recommendation of the committee, the association's rule, No. 1302, concerning the shipment of dangerous articles in baggage cars, was amended so as to provide that such shipments must be packed, marked and labeled as prescribed for express shipments and must not be transported in that part of any car used for the transportation of passengers.

The committee also called attention to the need of securing a revision of Section 233 of the United States Penal Code, so as to cover the transportation of "Other Dangerous Articles." A resolution was adopted by the association favoring the passage of such a revision.

The Committee on Legal and Traffic Relations reported that under instructions of the association it had undertaken the representation of the American Railway Association and individually of 158 railways, representing 190,871 miles, in the Interstate Commerce Commission's investigation of embargoes.

The Committee on Relations Between Railroads reported that Messrs. G. E. Evans (L. & N.) and J. J. Bernet (N. Y. C.) have been elected members of the committee, to fill vacancies

On recommendation of the committee, the association adopted resolutions urging the more general use of interline billing of freight, the better enforcement of rules for packing and marking of merchandise, that all roads enforce more careful handling of freight and that the several subordinate associations cooperate in these activities to the end of reducing claims for loss of and damage to freight, payments on this account having amounted in the last fiscal year to over thirty-six millions of dollars.

This committee reported, and the association adopted, some revisions of the rules for weighing empty cars and amendments to per diem rule 1 and car service rules 3, 14 and 15.

The meeting approved new car service rules 18, 19 and 20, covering (a) the continuous home route card; (b) cars containing refuse, which must not be offered in interchange, and (c) allowing a receiving road to collect $2 for weighing carloads of freight received from connections not weighed. Revisions of demurrage rules were also adopted.

The election resulted in the choice of A. W. Thompson (B. & O.) as second vice-president, and T. E. Clarke (D. L. & W.) and A. H. Smith (N. Y. C.) as members of the Executive Committee.

The following were elected members of the Committee on Transportation: Boston & Maine; Hocking Valley; Pennsylvania lines west of Pittsburgh.

The following were elected members of the Committee on Maintenance: Atchison, Topeka & Santa Fe; Norfolk & Western; Pennsylvania lines west of Pittsburgh.

The following were elected members of the Committee on Relations Between Railroads: Louisville & Nashville; New York Central; Southern. Chicago was selected as the place for the next regular session, which will be held on November 17.

Report of Special Committee

The Special Committee on Relations of Railway Operation to Legislation has issued its report, No. 14, outlining the progress of its work since the last report submitted on November 3, 1914. The report states that the only bill relating to railway operation which was passed during the Congress which adjourned on March 4, was that extending the provisions of the locomotive boiler inspection act to all parts of the locomotive and tender. Since the first of January legislatures in 43 states have been in session. Of these 31 have adjourned. Up to May 1, there had been introduced 1,005 bills relating to railway operation, of which 51 related to the number of men to be employed in train or switch crews, none of which have been passed. A total of 94 bills have become laws, most of which deal with relatively unimportant features of railway operation.

The report says that it is not impossible that when the next Congress meets an effort will be made to secure legislation specifying standard horizontal and vertical clearances. In view of the fact that there is not a standard clearance for new construction recommended either by the American Railway Engineering

Association or the American Railway Association, a sub-committee of engineering officers will take this matter vigorously in hand with the proper committee of the American Railway Engineering Association, and it is hoped that the latter committee will be able to submit a report by the first of December. The report also mentions the bulletin on the progress of the construction of steel and steel underframe passenger cars, and says that inasmuch as the construction of wooden cars for passenger service has practically been discontinued, it appears that no necessity exists for legislation on this subject from any point of view.

Revenues and Expenses of Express Companies for January

The following statement, which is subject to revision, has been compiled by the Interstate Commerce Commission from the monthly reports of operating revenues and expenses of the principal express companies for January, 1915. (The express companies have three months in which to make reports.)

A.—FOR THE MONTH OF JANUARY

Item	Adams Express Co.		American Express Co.		Canadian Express Co.		Globe Express Co.		Great Northern Express Co.

Fuel Association Exhibitors

The following railway supply concerns had exhibits at the International Railway Fuel Association convention, which was held at Chicago this week. An abstract of the proceedings of the professional sessions of this association will be found elsewhere in this issue.

American Arch Company, New York.—Security arch. Represented by Guy Bean, W. L. Allison, F. G. Boomer, G. C. Denney, J. T. Anthony, J. P. Neff, H. D. Savage, LeGrand Parish and John L. Nicholson.

Barco Brass & Joint Co., Chicago.—Barco metallic engine and tender air and steam heat connections. Represented by F. N. Bard and C. L. Mellor.

Casey-Hedges Company, Chattanooga, Tenn.—Hawkes boiler and Casey-Hedges horizontal water tube. Represented by C. W. Hawkes and Henry Vick.

Economy Devices Company, New York.—Woodward truck, radial buffer and Economy exhaust nozzle. Represented by J. L. Randolph.

Fairbanks, Morse & Co., Chicago.—Photographs of coaling stations, mine tipples and ground storage. Represented by J. C. Flannigan.

Franklin Railway Supply Company, New York.—Franklin fire door. Represented by C. W. F. Coffin, Jos. Sinkler, Ralph Coburn and Sam Rosenfelt.

Goodman Manufacturing Company, Chicago.—Photographs of coal mining machinery and electric mine locomotives. Represented by H. H. Small and A. F. Fors.

Heat Saver Company, Chicago.—Blaske fuel saving devices. Represented by G. A. Smith and R. L. Holmes.

Hulson Grate Company, Keokuk, Iowa.—Hulson locomotive grate. Represented by A. W. Hulson.

Industrial Instrument Company, Foxboro, Mass.—Pyrometers, gages, thermometers, tachometers, temperature controllers and steam flow meters. Represented by F. W. Carret.

Jeffrey Manufacturing Company, Columbus, Ohio.—Photographs of single roll coal pressure, Arcwall mining machine and electric mine locomotives. Represented by W. J. Armstrong, P. C. Dierdorff, S. S. Shive and C. C. Ford.

Link Belt Company, Chicago.—Photographs of coaling stations and stations for storage of coal. Represented by J. C. Nellegan.

Locomotive Stoker Company, New York.

Locomotive Superheater Company, New York.—Photographs of superheater and pyrometer. Represented by Geo. Fogg, Wm. Boughton, J. Mourne, R. R. Porterfield, Gilbert Ryder and G. Spangler.

Manistee Iron Works Company, Manistee, Mich.—Centrifugal pumps and traveling grate stokers. Represented by Henry Vick.

Manning, Maxwell & Moore, Inc., New York.—Hancock inspirators, Ashcroft gages and boiler fittings. Represented by C. L. Brown and F. J. Wilson.

National Graphite Lubricator Company, Chicago.—Lubricators. Represented by E. L. Pollock.

National Railway Devices Company, Chicago.—Shoemaker fire door. Represented by J. G. Robinson, E. J. Gunnison and V. W. Goodman.

Ogle Construction Company, Chicago.—Working model of coal handling plant. Represented by C. F. Bledsoe, M. W. Powell and R. A. Ogle.

Parsons Engineering Company, Wilmington, Del.—Photographs of smoke prevention equipment. Represented by Wm. H. Savery.

Pyle-National Electric Headlight Company, Chicago.—Pyle-National headlights. Represented by L. H. Steger, Wm. Miller and R. L. Eddy.

Q. & C. Company, New York.—Ross-Schofield boiler circulator. Represented by C. F. Pierce, C. M. Jewell, J. J. Daly and E. R. Pecker.

Roberts & Schaefer Company, Chicago.—Photographs of coal and sand handling devices. Represented by C. P. Ross.

Simonds & Co., G. L., Chicago.—Dean ash tube cleaner, Vulcan soot cleaner, Hays gas analyzers and draft gages. Represented by F. A. Moreland, G. L. Simonds and A. B. Nelson.

Snow Construction Company, T. W., Chicago.—Photographs of coal and water stations. Represented by T. W. Snow and R. E. Robinson.

Stroud & Co., E. H., Chicago.—Stroud powdered coal burner and Stroud air separation coal pulverizer. Represented by E. H. Stroud.

United States Graphite Company, Saginaw, Mich.—Mexican boiler graphite, Mexicao lubricating graphite and locomotive graphite feeder. Represented by J. G. Draught and J. W. Eviston.

Whiting-Evans Manufacturing Company, Chicago.—Kerosene carburetor and stationary engines. Represented by H. Q. Turner.

Summary of Revenues and Expenses of Large Steam Roads

The following figures were compiled by the Interstate Commerce Commission from monthly reports of operating revenues and expenses of large steam roads for the month of March, 1915. No reports are included for roads whose operating revenues for the year ended June 30, 1914, did not reach $1,000,000. The figures are compiled as rendered and should not be considered final, inasmuch as scrutiny of the reports may lead to their modification before acceptance.

American Electric Railway Association

The annual convention of the American Electric Railway Association and the American Electric Railway Manufacturers' Association will be held in San Francisco, October 4 to 8.

The transportation committee has made tentative arrangements for special transportation facilities for the association members as follows:

The Red Special on Tour "A" will leave New York about September 23, and stop for passengers at Albany, Utica, Syracuse, Rochester, Buffalo and Cleveland. From Chicago it will go to St. Paul and Minneapolis, and thence over the Great Northern to Glacier Park, whence after a stopover of a day and a night it will proceed through Spokane, Seattle, Tacoma and Portland. After a day in Portland the train will leave over the Shasta Route and arrive at San Francisco on October 2.

Returning after a week's stay in San Francisco the train will proceed to Yosemite National Park, where a stop of two days will be made and thence to Los Angeles and Pasadena, where another two days' stop will be made. A two days' stop will also be made at the San Diego Exposition and the Coronado

For the Month of March

Beach Hotel. The train will also make a stop of a few hours at Riverside, a day's stop at the Grand Canyon, and after a short stop at Albuquerque will proceed via Kansas City and Chicago to New York.

The Blue Special on Tour "B" will leave New York over the Pennsylvania about September 26, and will stop to receive passengers at Newark, Philadelphia, Harrisburg, Pittsburgh, Columbus, Indianapolis, St. Louis and Kansas City, thence proceeding to Denver, Colorado Springs and through the Royal Gorge. It will stop at Glenwood Springs, and then go on to Salt Lake and Ogden and Lake Tahoe, arriving at San Francisco October 3. Returning it will follow the same route as the Red Special.

The White Special on Tour "C" will be a faster train. It will leave Chicago in time to arrive at San Francisco October 4, and will be for the going trip only.

Association of Railway Claim Agents

The twenty-sixth annual convention of the Association of Railway Claim Agents was held at Galveston, Tex., on April 13, 14 and 15. The following officers were elected for the ensuing year: President, H. B. Hull, chief claim agent, Illinois Central, Chicago; vice-presidents, W. F. Every, general claim agent, Northern Pacific, St. Paul, and A. H. Mansfield, claims attorney, Missouri Pacific, St. Louis; secretary and treasurer, Willis H. Failing, of New York City. It was decided to hold the next convention at Atlantic City.

American Society of Mechanical Engineers

The Chicago section of the American Society of Mechanical Engineers, held its last 1914-15 seasonal meeting May 14, 1915, at the La Salle Hotel, Chicago. An interesting paper on Electric Locomotives was presented by A. F. Batchelder and A. H. Armstrong of the General Electric Company, Schenectady, N. Y. The following officers were nominated for the following year: H. M. Montgomery, chairman; Joseph Harrington, vice-chairman; Robert E. Thayer, secretary, and H. T. Bentley and C. E. Wilson as other members of the executive committee.

Western Railway Club

The annual meeting and election of officers of the Western Railway Club will be held at the Hotel La Salle, Chicago, on Tuesday evening, May 25, at 8 p. m. The program for the evening is as follows: Address of Dean W. F. M. Goss, of the College of Engineering and Engineering Experiment Station of the University of Illinois; Reports of officers; Election of officers; Address of retiring president; Entertainment.

Special Agents and Police

The International Association of Railway Special Agents and Police will hold its nineteenth annual convention at the Grand Hotel, Cincinnati, Ohio, May 25, 26, 27 and 28. The secretary of the association is W. C. Pannell, who is also editor of the association's quarterly magazine, Baltimore, Md.

MEETINGS AND CONVENTIONS

The following list gives the names of secretories, dates of next or regular meetings, and places of meeting of those associations which will meet during the next three months. The full list of meetings and conventions is published only in the first issue of the Railway Age Gazette for each month.

AMERICAN ASSOCIATION OF DEMURRAGE OFFICERS.—F. A. Pontious, 455 Grand Central Station, Chicago. Next meeting, July 21, 1915, Milwaukee, Wis.

AMERICAN RAILROAD MASTER TINNERS, COPPERSMITHS AND PIPEFITTERS' ASSOCIATION.—W. E. Jones, C. & N. W., 3814 Fulton St., Chicago. Annual meeting, July 13-16, 1915, Hotel Sherman, Chicago.

AMERICAN RAILWAY MASTER MECHANICS' ASSOCIATION.—J. W. Taylor, 1112 Karpen Bldg., Chicago. Annual meeting, June 9-11, 1915, Atlantic City, N. J.

AMERICAN RAILWAY TOOL FOREMEN'S ASSOCIATION.—Owen D. Kinsey, Illinois Central, Chicago. Annual meeting, July 19-21, 1915, Hotel Sherman, Chicago.

AMERICAN SOCIETY FOR TESTING MATERIALS.—Prof. E. Marburg, University of Pennsylvania, Philadelphia, Pa. Annual meeting, June 22-26, 1915, Hotel Traymore, Atlantic City, N. J.

AMERICAN SOCIETY OF CIVIL ENGINEERS.—Chas. Warren Hunt, 220 W. 57th St., New York. Regular meetings, 1st and 3d Wednesday in month, except July and August, 220 W. 57th St., New York.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS.—Calvin W. Rice, 29 W. 39th St., New York. Next spring meeting, June 22-25, 1915, Buffalo, N. Y. Annual meeting, December 7-10, 1915, New York.

ASSOCIATION OF RAILWAY ELECTRICAL ENGINEERS.—Jos. A. Andreucetti, C. & N. W., Room 411, C. & N. W. Sta., Chicago. Semi-annual meeting with Master Car Builders' and Master Mechanics' Associations. Annual meeting, October, 1915.

ASSOCIATION OF RAILWAY TELEGRAPH SUPERINTENDENTS.—P. W. Drew, Soo Line, 112 West Adams St., Chicago. Annual meeting, June 22-25, 1915, Rochester, N. Y.

ASSOCIATION OF TRANSPORTATION AND CAR ACCOUNTING OFFICERS.—G. P. Conrad, 75 Church St., New York. Next meeting, June 22-23, Niagara Falls, N. Y.

CANADIAN RAILWAY CLUB.—James Powell, Grand Trunk, P. O. Box 7, St. Lambert (near Montreal), Que. Regular meetings, 2d Tuesday in month, except June, July and August, Windsor Hotel, Montreal, Que.

CAR FOREMEN'S ASSOCIATION OF CHICAGO.—Aaron Kline, 841 Lawler Ave., Chicago. Regular meetings, 2d Monday in month, except June, July and August, Hotel La Salle, Chicago.

CENTRAL RAILWAY CLUB.—H. D. Vought, 95 Liberty St., New York. Regular meetings, 2d Friday in January, May, September and November. Annual meeting, 2d Thursday in March, Hotel Statler, Buffalo, N. Y.

ENGINEERS' SOCIETY OF WESTERN PENNSYLVANIA.—Elmer K. Hiles, 2511 Oliver Bldg., Pittsburgh, Pa. Regular meetings, 1st and 3d Tuesday in month, Pittsburgh.

FREIGHT CLAIM ASSOCIATION.—Warren P. Taylor, R. F. & P., Richmond, Va. Annual meeting, June 16, 1915, Chicago.

GENERAL SUPERINTENDENTS' ASSOCIATION OF CHICAGO.—A. M. Hunter, 321 Grand Central Station, Chicago. Regular meetings, Wednesday, preceding 3d Thursday in month, Room 1856, Transportation Bldg., Chicago.

INTERNATIONAL RAILWAY GENERAL FOREMEN'S ASSOCIATION.—Wm. Hall, 1126 W. Broadway, Winona, Minn. Next convention, July 13-16, 1915, Sherman House, Chicago.

MASTER BOILER MAKERS' ASSOCIATION.—Harry D. Vought, 95 Liberty St., New York. Annual convention, May 25 to 28, 1915, Chicago, Ill.

MASTER CAR BUILDERS' ASSOCIATION.—J. W. Taylor, 1112 Karpen Bldg., Chicago. Annual meeting, June 14-16, 1915, Atlantic City, N. J.

NEW ENGLAND RAILROAD CLUB.—W. E. Cade, Jr., 683 Atlantic Ave., Boston, Mass. Regular meetings, 2d Tuesday in month, except June, July, August and September, Boston.

NEW YORK RAILROAD CLUB.—Harry D. Vought, 95 Liberty St., New York. Regular meetings, 3d Friday in month, except June, July and August, 29 W. 39th St., New York.

NIAGARA FRONTIER CAR MEN'S ASSOCIATION.—E. N. Frankenberger, 623 Brisbane Bldg., Buffalo, N. Y. Meetings, 3d Wednesday in month, New York Telephone Bldg., Buffalo, N. Y.

PEORIA ASSOCIATION OF RAILROAD OFFICERS.—M. W. Rotchford, 410 Masonic Temple Bldg., Peoria, Ill. Regular meetings, 3d Thursday in month, Jefferson Hotel, Peoria.

RAILROAD CLUB OF KANSAS CITY.—Claude Manlove, 1008 Walnut St., Kansas City, Mo. Regular meetings, 3d Saturday in month, Kansas City.

RAILROAD MEN'S IMPROVEMENT SOCIETY.—J. B. Curran, Erie R. R., 50 Church St., New York. Meetings, alternate Thursdays, October to May, Assembly Rooms of Trunk Line Association, 143 Liberty St., New York.

RAILWAY CLUB OF PITTSBURGH.—J. R. Anderson, Room 207, P. R. R. Sta., Pittsburgh, Pa. Regular meetings, 4th Friday in month, except June, July and August, Monongahela House, Pittsburgh.

RAILWAY ELECTRICAL SUPPLY MANUFACTURERS' ASSOCIATION.—J. Scribner, 1063 Monadnock Block, Chicago. Meetings with Association of Railway Electrical Engineers.

RAILWAY SIGNAL ASSOCIATION.—C. C. Rosenberg, Myers Bldg., Bethlehem, Pa. Stated meeting, May 26-27, 1915, Hotel Astor, New York. Annual meeting, September 14-17, 1915, Salt Lake City, Utah.

RAILWAY SUPPLY MANUFACTURERS' ASSOCIATION.—J. D. Conway, 2136 Oliver Bldg., Pittsburgh, Pa. Meetings with Master Car Builders and Master Mechanics' Associations.

RAILWAY TELEGRAPH AND TELEPHONE APPLIANCE ASSOCIATION.—G. A. Nelson, 50 Church St., New York. Meetings with Association of Railway Telegraph Superintendents.

RICHMOND RAILROAD CLUB.—F. O. Robinson, C. & O., Richmond, Va. Regular meetings, 2d Monday in month, except June, July and August.

ST. LOUIS RAILWAY CLUB.—B. W. Frauenthal, Union Station, St. Louis, Mo. Regular meetings, 2d Friday in month, except June, July and August, St. Louis.

SALT LAKE TRANSPORTATION CLUB.—R. E. Rowland, David Keith Bldg., Salt Lake City, Utah. Regular meetings, 1st Saturday of each month, Salt Lake City.

SOUTHERN ASSOCIATION OF CAR SERVICE OFFICERS.—E. W. Sandwich, A. & W. P. R. R., Atlanta, Ga. Next meeting, July 15, 1915, Atlanta. Annual meeting, January, 1916.

SOUTHERN & SOUTHWESTERN RAILWAY CLUB.—A. J. Merrill, Grant Bldg., Atlanta, Ga. Regular meetings, 3d Thursday, January, March, May, July, September, November, 10 a. m., Piedmont Hotel, Atlanta.

TOLEDO TRANSPORTATION CLUB.—Harry S. Fox, Toledo, Ohio. Regular meetings, 1st Saturday in month, Boody House, Toledo.

TRAFFIC CLUB OF CHICAGO.—W. H. Wharton, La Salle Hotel, Chicago.

TRAFFIC CLUB OF ST. LOUIS.—A. F. Versen, Mercantile Library Bldg., St. Louis, Mo. Annual meeting in November, Noonday meetings, October to May.

TRAFFIC CLUB OF NEWARK.—John J. Kautzmann, P. O. Box 238, Newark, N. J. Regular meetings, 1st Monday in month, except July and August, The Washington, 559 Broad St., Newark.

TRAFFIC CLUB OF NEW YORK.—C. A. Swope, 291 Broadway, New York. Regular meetings last Tuesday in month, except June, July and August, Hotel Astor, New York.

TRAFFIC CLUB OF PITTSBURGH.—D. L. Wells, Gen. Agt., Erie R. R., 1924 Oliver Bldg., Pittsburgh, Pa. Meetings bi-monthly, Pittsburgh. Annual meetings, 2d Monday in June.

TRAIN DISPATCHERS' ASSOCIATION OF AMERICA.—J. F. Mackie, 7122 Stewart Ave., Chicago. Annual meeting, June 15, 1915, Minneapolis, Minn.

TRANSPORTATION CLUB OF DETROIT.—W. R. Hurley, Superintendent's office, N. Y. C. R. R., Detroit, Mich. Meetings monthly, Normandie Hotel, Detroit.

UTAH SOCIETY OF ENGINEERS.—Frank W. Moore, 1111 Newhouse Bldg., Salt Lake City, Utah. Regular meetings, 3d Friday in month, except July and August, Salt Lake City.

WESTERN CANADA RAILWAY CLUB.—L. Kon, Immigration Agent, Grand Trunk Pacific, Winnipeg, Man. Regular meetings, 2d Monday, except June, July and August, Winnipeg.

WESTERN RAILWAY CLUB.—J. W. Taylor, 1112 Karpen Bldg., Chicago. Regular meetings, 3d Tuesday afternoon in month, except June, July and August, La Salle Hotel, Chicago.

WESTERN SOCIETY OF ENGINEERS.—J. H. Warder, 1735 Monadnock Block, Chicago. Regular meetings, 1st Monday in month, except January, July and August, Chicago. Extra meetings, except in July and August, generally on other Monday evenings. Annual meetings, 1st Wednesday after 1st Thursday in January, Chicago.

REVENUES AND EXPENSES OF RAILWAYS

Month of March, 1915

Name of road.	Average mileage operated during period.	Operating revenues: Freight.	Passenger.	Total, inc. misc.	Operating expenses: Maintenance: Way and structures.	Maintenance: Of equipment. Traffic News

The House public utility committee of the Illinois legislature has recommended for passage a bill permitting newspapers to exchange advertising for railroad transportation. The bill has already been passed by the senate.

The Boston & Maine announces a new local passenger tariff, between stations in Massachusetts, to go into effect June 1. The changes made include both increases and decreases. The increases are between points where the traffic is heavy and the decreases in thinly settled territory.

It is announced that the steamer James S. Whitney, of the Eastern Steamship Corporation, will this week make a trip through the Cape Cod Canal, with a view to "demonstrating" that by this route it is possible to shorten the journey between New York and Boston about four hours, as compared with sailing around the Cape.

A Suggestion to the Interstate Commerce Commission

W. H. Forsyth, second vice-president of the Curtain Supply Company, Chicago, has written a letter to Commissioner W. M. Daniels, of the Interstate Commerce Commission, who presided over the hearings in the western freight rate advance case in Chicago, suggesting that the commission "broadly authorize a universal increase in railroad rates of this country on existing tariffs, with a distinct proviso that the money derived by the railroads from this increase should be promptly and only expended for necessary renewals, replacements and improvements." Mr. Forsyth says that generally speaking the public wants service, and no one who has the welfare of the country at heart can find serious objection to a reasonable increase in rates provided such increase is spent for the upbuilding of railroad property, and that no industry could legitimately complain, providing the same proportional increase is made on the products of all its competitors. During the continuance of this increased rate, he says, "no additional rate of dividends should be paid from any moneys derived under this authority, but all should go to the actual benefit of the property," although "certain railroads whose working capital might be depleted, could perhaps be permitted to retain a reasonable amount for this purpose."

Educating the Public to Buy Tickets

T. J. Foley, general manager of the Illinois Central, has issued a pamphlet addressed to the people of Mississippi for the purpose of explaining the aims and desires of the management of the road in the matter of educating the traveling public to purchase tickets instead of paying cash fares on trains, and presenting arguments in favor of the plan of imposing a small penalty upon those who carelessly or negligently fail to buy tickets. It is stated that on the Yazoo & Mississippi Valley, particularly where stations are close together, it is often necessary to check the speed of a train and disarrange the schedule in order that the conductor may be enabled to collect the cash fares from passengers between stations.

"Please let it be thoroughly understood," Mr. Foley says, "that we do not want the extra ten cents and should be greatly pleased if it never became necessary to collect it, that is, if passengers in every instance would purchase tickets and thus relieve the company of the unpleasant duty of reminding them of their failure to do so." The practice of imposing a penalty, he says, has been fully justified and approved by the courts as well as by the Interstate Commerce Commission. In spite of this fact, the Railroad Commission of Mississippi on March 2, 1915, fined the Illinois Central $500 on the theory that it had violated an order of the commission limiting the charge for carrying passengers to three cents a mile. It is pointed out that in other states in which the company's lines are located the rule for collecting a 10-cent penalty is in full effect and working without any friction whatever. In conclusion Mr. Foley says, "We submit our case to you confident that we shall feel the force and effect of your decision, whatever it may be."

Commission and Court News

INTERSTATE COMMERCE COMMISSION

The commission has suspended until September 12 tariffs of the Erie and other roads, containing proposed advances in rates on sugar beets from points between Buffalo and Chicago to Decatur, Ind.

Rates on Scrap Iron from Gulf Ports

Opinion by Commissioner Clark:

The commission finds that the carriers have justified proposed increased rates and minimum carload weights on scrap steel and iron, from a broad territory east of the Mississippi and south of the Ohio rivers, which may be described generally as the Mississippi valley, and from certain gulf ports, including Mobile, Ala., and New Orleans, La., to St. Louis, Mo., Ohio river crossings, and points beyond. (33 I. C. C., 668.)

Ore Rates in Northern Michigan

Newport Mining Company v. Chicago & North Western. Opinion by Commissioner McChord:

Prior to January, 1913, the carriers serving mines in the northern peninsula of Michigan maintained a rate on iron ore of 40 cents per gross ton from all mines in the peninsula to the hold of vessel at nearest port, either Ashland or Escanaba except that from the mines between Ishpeming and Marquette the rate was 25 cents, and west thereof the rate was 30 cents to Marquette. In January, 1913, they filed tariffs continuing the former rate, but limited the service to originating the ore and hauling it to the dockyard only. For the dock service formerly included in the rate they made an additional charge of 5 cents a ton.

The commission finds that the effect of this charge is to increase the rate and that the carriers must justify the increased total charges.

After due consideration of the comparative ton-mile earnings and a study of the figures submitted by the carriers as to the costs of the dock, assembling and line-haul services it finds that the increased rates are justified. The rate is a blanket rate applicable via the lines of carriers of different financial condition. While the position of the North Western appears to be favorable, and while it appears from the record that its revenues meet all its operating needs and more, yet the situation with respect to the St. Paul, the Soo and the South Shore, is far less satisfactory. The reasonableness of a rate in a locality served by several carriers will not be determined alone by consideration of that line most favorably situated with respect to operations, traffic, and earnings, and conversely this is equally true, namely, that consideration of the line of poorest traffic, earnings, etc., will not control. (33 I. C. C., 645.)

Rates to Intermountain Territory

The commission has disapproved plans submitted by the transcontinental railroads for constructing rates to points east of Pacific coast terminals and in the inter-mountain country—the so-called back-haul rates.

The commission, however, has authorized the railroads to construct rates to the back-haul points by adding to the terminal rates not more than 75 per cent of the local rates from the nearest terminal to destination, or by adding arbitraries to the terminal rates, varying with the distance from the ports. The arbitraries are to be not more than 75 per cent of the local rates.

The carriers have also been authorized to extend terminal rates to these Pacific coast points: San Diego, San Pedro, East San Pedro, Wilmington, East Wilmington, San Francisco and Oakland, Cal.; Astoria and Portland, Ore.; Vancouver, Bellingham, South Bellingham, Everett, Tacoma, Seattle, Aberdeen, Hoquiam and Cosmopolis, Wash.

The commission has modified existing orders so as to permit maximum less than carload rates from the Missouri river to intermediate points on first and second-class of $1.72 per 100 lb., when lower rates are applicable to coast terminals.

Announcing that it has considered the influence of the Panama canal, the commission says: "We should authorize a certain degree of relief from the requirements of the long and short haul clause on this traffic to enable these carriers to more effectively compete with the water lines, but the rail carriers cannot expect, and the commisison should not authorize, such a degree of relief as will secure to the rail lines the same percentage of the traffic to the terminals as they enjoyed prior to the opening of the canal. They can secure a portion of the traffic to the terminals on the commodities by the establishment of the rates proposed, and such rates will afford some revenue in excess of the out-of-pocket cost involved.

"The carriers should, within reasonable limits, be authorized to make such rates to intermediate points in the so-called back-haul territory as will induce the direct movement of freight to such points from the territories served by these lines. The proportion of the freight hauled directly by the rail lines to the various destinations in the back-haul territory should be greater than the proportion hauled to the terminals and should increase as distance from the coast of terminals increases. The rates to all coast terminal points being practically the same, and the situations at intermediate points being substantially similar via all lines, the same method of constructing rates to intermediate points should be followed by all lines."

STATE COMMISSIONS

The New York State Public Service Commission, Second district, announces that it has awarded reparation in the case of A. R. Piper vs. New York Central on a shipment from Katonah consigned to Brooklyn, Bush docks. It was misrouted to Wallabout basin, involving extra cartage expense, admitted by the carrier. Amount of reparation 50 cents.

W. M. Busby, general counsel for the Public Service Commission of Missouri, has filed a brief with the state supreme court in which he takes the ground that the commission has no authority to increase maximum railroad rates fixed by statute. The brief was filed in a case in which the Kansas City Southern appealed from a decision of the commission denying authority to increase demurrage rates. The application of the road for authority to increase the rates fixed by statute was based on a decision rendered last year by the court in the case of the Missouri Southern, that the act creating the new public service commission gave the commission authority to fix rates independent of the statutory rates.

PERSONNEL OF COMMISSIONS

Daniel S. Hooker, formerly locating and construction engineer for the Colorado & Southern, has been appointed civil engineer of the Public Utilities Commission of Colorado.

H. H. Sanborn and A. B. Roehl have resigned as rate expert and assistant rate expert, respectively, of the Railroad Commission of California to engage in the practice of law.

A. L. Moler has been appointed senior inspector of motive power for the eastern district, in the division of valuation, Interstate Commerce Commission, with headquarters at Washington, D. C.

The governor of Pennsylvania has nominated for membership on the Public Service Commission the following: Samuel W. Pennypacker, chairman, and Milton J. Brecht, to succeed themselves; W. A. Magee of Pittsburgh; Congressman E. R. Kiess of Hughesville; W. D. B. Ainey of Montrose; John Monaghan of Philadelphia; John S. Rilling of Erie.

COURT NEWS

Bondholders of the Pere Marquette filed suit in the United States district court at Detroit, Mich., last week to have the Michigan two-cents-a-mile passenger fare law declared unconstitutional, on the ground that it is confiscatory of the railroad property.

Thirty Texas roads have filed suit in the district court at Austin, Tex., to set aside an order of the Texas Railroad Commission made on February 13, prohibiting the railroads from inserting in their bills of lading stipulations requiring notice of claims for damages or loss of freight to be filed within six

months. The petition says in part: "Correct business principles require a prompt presentation of freight claims. Under the application of such principles as generally observed in practice by the business world in this state, legitimate claims of all kinds are presented without unreasonable delay. A delay in the presentation of claims works to the advantage of dishonest claimants, facilitates the collection of fraudulent claims, and mulcts the railroads in damages for which they are not legally liable and which in reason they ought not to have to pay."

Liability for Servants' Acts

A passenger who had been ejected from a train by two special policemen employed by the railroad, brought an action against the company and the two policemen. The jury returned a verdict in favor of the policemen and against the company. It was held by the Iowa Supreme Court error to enter a judgment against the company, since it was liable only under the rule of *respondeat superior* for the wrongful acts of its servants, and, if they were not guilty of wrong, the company could not be.—Hobbs *v.* Illinois Central (Iowa) 152 N. W., 40.

Train Despatchers Working Twelve Hours a Day

A railroad company is held not to be relieved from liability for violation of section 2 of the hours of service act by requiring a train despatcher in a night and day office to remain on duty for more than 9 hours in each 24-hour period, by the fact that during a part of such time he is employed otherwise than as train despatcher.—Delano *v.* United States, C. C. A., 220 Fed., 635. A railroad company had on duty at a day and night office three operators, each of whom worked 8 hours a day. One was suddenly taken ill, and no other operator could be obtained. As soon as possible, which was next day, the chief despatcher sent a relief man, but the train on which he was traveling was wrecked, and he was ordered to establish an office at the wreck. This caused further delay, in consequence of which the two remaining operators each worked 12 hours a day for 4 or 5 consecutive days. It is held that the extended time during the first three days was permissible under section 2, and the further delay was due to a casualty which, under section 3, rendered the act inapplicable, and the company was not chargeable with its violation.—San Pedro, L. A. & S. L. *v.* United States, C. C. A. 220 Fed., 737.

Empty Car, Standing, is An Instrument of Interstate Commerce

The Pennsylvania Supreme Court holds that where a freight car consigned with merchandise from a point without the state to a destination within the state, after being unloaded at a freight yard is shifted to another yard to await reloading, and is stored there for a few days, and then loaded and shipped to another point without the state, it does not cease to be used in interstate traffic during the brief period of its unemployment; and the railroad company is liable for injuries to an employee in the shifting of the car from yard to yard, due to the company's failure to equip the car with an automatic coupler as required by law. Moyer *v.* Pennsylvania (Pa.) 93 Atl. 574. In an action for injuries to a brakeman the Indiana Supreme Court holds that a railroad laborer, working on a track which was to be used for both interstate and intrastate traffic, but over which interstate trains had never been run, is not engaged in interstate commerce within the federal employers' liability act.—Chicago & E. *v.* Steele (Ind.) 108 N. E. 4. In an action under the federal employers' liability act for the death of an engineman by falling into a roundhouse pit, it was held by the South Carolina Supreme Court that the plaintiff could not recover if the engineer went into the roundhouse for purposes of his own, or if there was a failure of evidence from which it could be inferred that he went there for the purposes of his employment; since the plaintiff must show that the deceased was engaged in interstate commerce at the time of his death. The court held that the jury was warranted in finding that the deceased went into the roundhouse to inspect his engine some time before taking it out on his run (although there was no rule of the company requiring him to do so), and that he was engaged in interstate commerce. Justices Hydrick and Gage dissented, being of opinion that the engineer went into the roundhouse on his own business, out of the hours, against the rules and practice of the railroad, and to unwarrantably sleep in his engine.—Padgett *v.* Seaboard Air Line (S. Car.) 83 S. E. 633.

Railway Officers

Executive, Financial, Legal and Accounting

D. F. Mustard, cashier of the Central Indiana, has been elected treasurer, with office at Anderson, Ind., and the office of cashier is abolished.

S. S. Russell, superintendent of the Central Vermont, at St. Albans, Vt., has been appointed special agent of the auditing department, with office at St. Albans.

E. M. Devereux, assistant treasurer of the Baltimore & Ohio at New York, has been appointed senior assistant treasurer, with headquarters at New York, succeeding Charles W. Rhodes, deceased, and T. H. Schultz, cashier in the general offices at Baltimore, Md., has been promoted to junior assistant treasurer, with office at Baltimore.

F. P. Gutelius, general manager of the Canadian government railways, announces that the jurisdiction of the heads of departments has been extended over the National Transcontinental from Moncton, N. B., to Winnipeg, Man., and the Lake Superior branch of the Grand Trunk Pacific from Fort William, Ont., to Superior Junction, Ont. The operation of these lines was taken over by the government May 1.

Operating

W. S. Hanley, chief engineer of the New Orleans Great Northern, has been appointed superintendent, with headquarters at Bogalusa, La.

C. M. Staples has been appointed assistant superintendent of the Houston & Texas Central, at Ennis, Tex., succeding C. M. Moursund, resigned.

J. D. Booth has been appointed acting superintendent of the Missouri, Oklahoma & Gulf, with headquarters at Muskogee, Okla., succeeding E. B. Fisher, resigned.

A. C. Showalter has been appointed assistant superintendent of the Buffalo division of the New York, Chicago & St. Louis, with headquarters at Conneaut, Ohio, succeeding C. L. Titus, resigned.

E. A. Dewey has been appointed trainmaster of the Missouri, Oklahoma & Gulf, with office at Muskogee, Okla., succeeding Harry Coughlin, resigned. Mr. Dewey was formerly with the Texas & Pacific.

J. E. Spaulding, trainmaster of the Central Indiana at Anderson, Ind., has been appointed superintendent. The office of trainmaster is discontinued and the superintendent will assume the duties of that office.

J. A. Blair has been appointed superintendent of dining cars of the Spokane, Portland & Seattle, the Oregon Trunk, the Oregon Electric, the United Railways and the Spokane & Inland Empire, with headquarters at Portland, Ore.

The jurisdiction of W. C. C. Mehan, general superintendent of the Grand Trunk Pacific lines west of Prince George, with headquarters at Prince Rupert, B. C., has been extended to include the territory between Prince George and Edmonton, Alta.

A. B. White, assistant superintendent of the Buffalo, Rochester & Pittsburgh at Punxsutawney, Pa., has been promoted to superintendent of the Middle and Pittsburgh divisions, with headquarters at Du Bois, vice P. Fraser, deceased, and R. L. Moore succeeds Mr. White.

J. E. Maun, acting assistant superintendent of the Central Vermont at Montpelier, Vt., has been appointed superintendent of the northern division, with office at St. Albans, Vt., vice S. S. Russell, assigned to other duties, and G. W. Groom, chief despatcher, at St. Albans, has been appointed assistant to superintendent and chief despatcher, with office at St. Albans.

J. Flynn, assistant superintendent of the Third division of the Denver & Rio Grande, has been appointed assistant superintendent of the Second division, with headquarters at Salida, Colo., vice D. E. Wilcox, transferred, and the office of assistant superintend-

ent of the Third division has been abolished. E. E. Eichar has been appointed trainmaster of the Third division, with headquarters at Gunnison, Colo.

A. Kilpatrick, superintendent of the Grand Trunk Pacific at Edson, Alta., has been transferred to the Lake Superior division, with headquarters at Fort William, Ont., succeeding A. A. Tisdale, who has been granted a temporary leave of absence. J. P. Kirkpatrick has been appointed acting superintendent, with jurisdiction between Edmonton and Prince George and all intersecting branch lines, with office at Edson, Alta. The jurisdiction of H. McCall, superintendent at Melville, Sask., has been extended to include the Regina division, on account of Mr. Kirkpatrick's transfer to Edson.

F. P. Brady, general superintendent of the Intercolonial Railway and the Prince Edward Island Railway, at Moncton, N. B., has been appointed general superintendent of the National Transcontinental between Quebec and Winnipeg, and the Lake Superior branch of the Grand Trunk Pacific between Fort William and Superior Junction, with headquarters at Cochrane, Ont. J. K. McNeillie, superintendent of the Canadian Pacific at Montreal, Que., has been appointed general superintendent of the Intercolonial, the Prince Edward Island and the National Transcontinental east of Quebec, with headquarters at Moncton, N. B. A. J. Gorrie has been appointed superintendent, and J. J. McManus has been appointed assistant superintendent of the National Transcontinental, district No. 1, Quebec to O'Brien, with headquarters at Quebec. W. B. Way has been appointed superintendent, and H. A. Ryan has been appointed assistant superintendent of district No. 2, O'Brien to Armstrong, excluding O'Brien, with headquarters at Cochrane, Ont., and R. S. Richardson, assistant superintendent at Moncton, N. B., has been appointed superintendent of district No. 3, Armstrong to Winnipeg, excluding Armstrong, and Superior Junction to Fort William, with headquarters at Winnipeg, Man.

Traffic

George F. DeMurray has been appointed general agent of the Chicago, Burlington & Quincy, with office at Sterling, Ill., succeeding L. C. Thorne, resigned.

Engineering and Rolling Stock

The jurisdiction of S. J. Hungerford, superintendent of rolling stock, western lines of the Canadian Northern, at Winnipeg, Man., has been extended over the eastern lines.

John J. Desmond has been appointed roadmaster of the Mississippi division of the Illinois Central, with headquarters at Water Valley, Miss., succeeding R. L. Hazlegrove, transferred.

C. E. Brooks, general foreman at the Transcona, Man., shops of the Grand Trunk Pacific, has been appointed acting superintendent of motive power, with headquarters at Transcona, succeeding Joseph Billingham, resigned.

Purchasing

Walter R. Owen, assistant purchasing agent of the Chicago, Rock Island & Pacific at Chicago, has been appointed assistant general purchasing agent, with headquarters at Chicago.

OBITUARY

Edward Harding Barnes, chief engineer of the Grand Rapids & Indiana, at Grand Rapids, Mich., died on May 15, at his home in that city.

General Thomas H. Hubbard, chairman of the executive committee of the Toledo, St. Louis & Western and a director of the Wabash, the Western Union Telegraph Company and the Southern Pacific, died at his home in New York on Wednesday, May 19. Thomas Hamlin Hubbard was born at Hallowell, Me., on December 20, 1838. He graduated from Bowdoin College and served with distinction in the civil war. He was a vice-president and director of the Southern Pacific from 1896 to 1900.

RAILWAY BRIDGE DESTROYED BY CRUISER.—The French Ministry of Marine has reported that on April 15 a French cruiser destroyed a railway bridge connecting the town of Acre with the interior railway system of Syria.

Equipment and Supplies

LOCOMOTIVE BUILDING

THE CHICAGO GREAT WESTERN is asking bids on 5 Mikado type locomotives, in addition to the 5 switching engines reported in the *Railway Age Gazette* of May 7.

THE PENNSYLVANIA LINES WEST have ordered 25 Consolidation type locomotives from the Lima Locomotive Corporation, and 25 Mikado type locomotives from the Baldwin Locomotive Works.

THE GLEN ROSE & WALNUT SPRINGS, Walnut Springs, Tex., is inquiring through the Railroad Construction Company, 80 Fifth avenue, New York, for prices on 4 65-ton Mogul type locomotives.

CAR BUILDING

THE COAL & COKE is building 100 coal cars in its shops at Gassaway, W. Va.

THE NEVADA NORTHERN is reported to be in the market for 100 dump cars. This item has not been confirmed.

THE GLEN ROSE & WALNUT SPRINGS is inquiring for prices on 10 passenger and 100 freight cars. See also item under Locomotive Building.

THE LEHIGH VALLEY has ordered 1,000 center constructions from the Standard Steel Car Company, and is said to have an option on another 1,000.

THE CHICAGO, ROCK ISLAND & PACIFIC, reported in the *Railway Age Gazette* of last week as inquiring for 5,000 40-ton all-steel box cars, is not inquiring for all-steel box cars, but rather for box cars with steel frames and single wooden sheathing.

THE PENNSYLVANIA LINES have placed orders for 16,145 freight cars as follows: American Car & Foundry Co., 3,443, including 100 refrigerator cars for the Lines West and 224 refrigerator, 1,719 hopper, 1,000 gondola and 400 box cars for the Lines East; Pressed Steel Car Company, 2,800, including 1,500 gondola and 500 hopper cars for Lines West and 500 gondola and 300 box cars for the Lines East; Standard Steel Car Company, 1,000 hopper cars, including 800 for the Lines West and 200 for the Lines East; Ralston Steel Car Company, 1,000 hopper cars for the Lines West; Cambria Steel Company, 3,300, including 3,000 hopper cars and 300 box cars for the Lines East; Haskell & Barker Car Company, 2,500 box cars for the Lines West, and the Altoona shops, 1,000 box, 1,000 gondola and 102 flat cars for the Lines East. The order is thus divided, 6,400 for the Lines West and 9,745 for the Lines East.

THE RUSSIAN GOVERNMENT, reported in the *Railway Age Gazette* of last week as having ordered 2,000 steel underframe box cars from the Eastern Car Company, and 2,000 cars from the Canadian Car & Foundry Company, has now placed orders, including the Pressed Steel Car Company's order which, however, may be still under negotiation, for a total of 22,000 cars, as follows: Pressed Steel Car Company, 7,000; Seattle Car & Foundry Company, 7,000; Eastern Car Company, New Glasgow, N. S., 2,000; Nova Scotia Car Company, Halifax, N. S., 2,000; American Car & Foundry Company, 2,000, and Canadian Car & Foundry Company, 2,000. The unconfirmed report in last week's issue to the effect that the Pullman Company had received an order for 8,000 cars is thus shown to be incorrect. All of the cars except those ordered from the Seattle Car & Foundry Company will have two trucks; those ordered from the Seattle company will be four-wheel cars.

IRON AND STEEL

THE NORFOLK & WESTERN has ordered 1,000 tons of rails from the Cambria Steel Company, and 1,000 tons from another company.

THE MISSOURI, KANSAS & TEXAS has ordered 2,368 tons of steel for through truss spans and deck plate girder spans from the Wisconsin Bridge & Iron Company.

Supply Trade News

The American Locomotive Company will soon reopen its Providence plant for the manufacture of shrapnel parts.

D. S. Woods, formerly Philadelphia salesman for Niles-Bement-Pond Company, Inc., has been transferred to New York.

The Corliss Carbon Company, Bradford, Pa., manufacturing motor and generator brushes, has moved its New York office and stock room to the Engineering building, 114 Liberty street.

The U. S. Metal & Manufacturing Company, New York, has been appointed eastern sales agent for the Union Fibre Company, Winona, Minn., makers of Linofelt for refrigerator and Feltlino for steel cars.

F. K. Irvin, formerly with the New York, New Haven & Hartford, has become connected with the Chicago office of the Niles-Bement-Pond Company. He will look after the railroad machine tool business in that territory.

The Standard Brake Shoe & Foundry Company, Pine Bluff, Ark., a new firm has taken over the Dilley Foundry Company, and will start work at once on the construction of a new $40,000 plant, including an open-hearth steel foundry.

The Ballman-Witten Manufacturing Company, 5407 Easton avenue, St. Louis, Mo., has been incorporated with $100,000 capital stock to manufacture piston rings. Lathes and boring machines will be installed. E. C. Ballman is president.

Charles William Sherburne, whose death was announced in these columns last week, was the founder of the railway supply firm of Sherburne & Co., Boston, Mass., and had been at its head for about 50 years. Mr. Sherburne was born in Boston on October 13, 1839. He was for a time employed on the Vermont & Canada, now a part of the Central Vermont, but soon returned to Boston to engage in the railway supply business, under the name of Sherburne & Co. Mr. Sherburne was a very active man, and until within a few years, he was president of the Armstrong Transfer Express Company, president of the Star Brass Manufacturing Company, a director of the Armstrong Dining & News Company, and treasurer of the New England Railroad Club. His death, in Boston, Mass., on May 6, followed an illness of three years.

C. W. Sherburne

H. E. Preston, formerly with the American Can Company, and prior to that with the Felt & Tarrant Manufacturing Company, Chicago, has joined the periodograph sales force of the Gisholt Machine Company, Madison, Wis., and will have headquarters at the company's Chicago office.

The Pittsburgh plant of the American Locomotive Company, which has been virtually idle for two years, is being overhauled and plans are being made for a complete resumption of work. It is understood that the plant has an order to repair 50 locomotives for the Seaboard Air Line.

Laurence Hamill, for some time district agent for the Buda Company, Chicago, and W. B. Hickox, formerly in charge of sales of the Adams Bagnall Electric Company, Cleveland, Ohio, have formed the Hamill-Hickox Company, with offices in the Hickox building, Cleveland. The new company will act as direct representatives in Ohio and surrounding territory for railway supplies, and will continue to handle the Buda Company account and several others.
