RAILROAD GAZETTE

ESTABLISHED IN APRIL, 1856.

PUBLISHED EVERY FRIDAY BY THE RAILROAD GAZETTE AT 83 FULTON STREET, NEW YORK.
BRANCH OFFICES AT 870 OLD COLONY BUILDING, CHICAGO, AND QUEEN ANNE'S CHAMBERS, WESTMINSTER, LONDON.

EDITORIAL ANNOUNCEMENTS.

THE BRITISH AND EASTERN CONTINENTS edition of the Railroad Gazette is published each Friday at Queen Anne's Chambers, Westminster, London. It contains selected reading pages from the Railroad Gazette, together with additional British and foreign matter, and is issued under the name Railway Gazette.

CONTRIBUTIONS.—Subscribers and others will materially assist in making our news accurate and complete if they will send early information of events which take place under their observation. Discussions of subjects pertaining to all departments of railroad business by men practically acquainted with them are especially desired.

ADVERTISEMENTS.—We wish it distinctly understood that we will entertain no proposition to publish anything in this journal for pay, EXCEPT IN THE ADVERTISING COLUMNS. We give in our editorial columns OUR OWN opinions, and these only, and in our news columns present only such matter as we consider interesting and important to our readers. Those who wish to recommend their inventions, machinery, supplies, financial schemes, etc., to our readers, can do so fully in our advertising columns, but it is useless to ask us to recommend them editorially, either for money or in consideration of advertising patronage.

CONTENTS

VOL. XLIII., No. 1. FRIDAY, JULY 5, 1907.

We show in another column photographs of some of Governor Hughes' new Public Service commissioners. The formation of the two boards was announced last Friday, only three days in advance of the time when it was necessary for them to commence their duties. A plain characteristic of both the up-state and the New York City commissions is that they have been chosen on purely non-political grounds. The Governor evidently does not regard these commissions as a sailors' snug harbor for worthy politicians, and it is sure that so long as Mr. Hughes remains in office he will keep the ten places filled with the best men he can get to accept the somewhat arduous conditions of service. We have no comment to make as to the special fitness of the men chosen to perform the monumental task at hand. We believe that they will be conservative and that they will earnestly try to drive the team of unruly horses committed to their charge. We venture the prophecy that a great deal of the future state corporation regulation in this country will depend upon the success of their efforts.

While the discussion on rails at the annual meeting of the American Society for Testing Materials was disappointing in that it failed to emphasize specifically the many bad features of present mill practice and bring out any strongly expressed opinions as to how better rails could and should be made, it at least had the effect of forcing a show of hands by the rail makers in the specifications presented for adoption. These specifications, which are printed elsewhere in this issue, were obviously a compromise on the part of the members of the committee representing the railroads. They got all they could get, not all they wanted to get, from the representatives of the rail makers. For the purpose of getting the committee report before the meeting the railroad representatives concurred with the rail makers and signed a specification under which, with present conditions, it is practically impossible to get high quality rails even if the maker adheres rigidly to all the provisions. The time for such action was opportune in the light of other circumstances. The committee on rails of the American Railway Engineering & Maintenance of Way Association has agreed on a specification drawn to give the railroads what they want, regardless of what the steel makers are willing to furnish. The committee on rails of the American Society of Civil Engineers, it is understood, will recommend for future, not present consideration, a redesign of the section for heavy rails, together with rigid requirements as to methods of manufacture. At the coming conference between the rail makers and the committee of the American Railway Association the issue can be sharply drawn by comparing these three specifications, one representing the extreme requirements acceptable to the rail makers; the other two representing the lowest requirements acceptable to the railroads.

We should seize the opportunity that is presented by legislation in other states tending to make further railroad construction there unprofitable, to attract railroad capital to Kentucky. We should offer the equal protection of the law, fair treatment and an assurance that those who are willing to benefit Kentucky by making investments in the state will have the good will of her people.

Does this quotation from a set of resolutions passed by the Louisville Board of Trade June 17 indicate that the tide has turned? Can it be taken to show that the wave of hostility towards corporations in general and railroads in particular has reached the high-water mark and that henceforth the efforts of the agitators will recede gradually, each from the high record made by the one before him? We hesitate to believe that this is the case and yet we feel that the earnest efforts of a few more boards of trade supplemented by the example and precept of a few more governors like Mr. Hughes who know how to veto, would go far towards correcting a very socialistic and dangerous state of the public mind. Why cannot influential and sober minded citizens in every state assemble together as the Louisville Board of Trade has done and put themselves on record in some fashion like the following, which we quote:

> This board favors legislation, if such be necessary, to prevent fictitious capitalization while demanding the enforcement of laws to correct corporate abuses, as well as the punishment of those who fail to obey such laws; but it believes that what is now in order and for the interests of the public, as well as for the interests of the railroads, is co-operation between the people of the state and the railroads with a view to the good of both. We believe that if the railroads honestly accept their responsibilities to the public and endeavor to live up to them, then the public should as honestly strive to make the business of the railroads successful and profitable. Public hostility, harsh criticism and drastic legislation can serve no good end.

If this were done, we believe that a little wholesome competition between the states to encourage the development of corporations

would prove a good deal more profitable for all concerned than the present competition to drive them out of business.

In civics there is the familiar adage that "politics makes strange bedfellows." In railroading there ought to be some like proverb to express the strange incongruities that events bring about and especially those events that sometimes attend great railroad mergers. It is, for example, a scant two years since the New York, New Haven & Hartford took in the Ontario & Western. Its uses in the Connecticut legislature were immediate and effective. The New York Central was, as an offsetting step, seeking a cross-cut through northwestern Connecticut to the Boston & Albany line, and was making its survey. The new line could be built under the Connecticut general railroad law. But President Mellen flung himself athwart the path. He appealed in "open-air lobby" to the state legislature for what was practically a repeal of the general railroad act. Were Connecticut and New England to be cut off from cheap coal via the O. & W.? Was the New Haven to be penalized for this beneficent act by the legislature's assent to the New York Central crosscut? The legislature answered with an emphatic "No," and granted the repealer. Two short years have passed and lo! the omens point to return of the philanthropic O. & W. to the New York Central as, presumptively, a makeweight in the Boston & Maine deal. There is another odd historical twist in New England railroad happenings not so incongruous as it is picturesque. It will be recalled how some fourteen years ago President C. P. Clark, of the New Haven, agreed with the Connecticut River Railroad Company's directors for an absorption of their snug and profitable property, reaching up into Boston & Maine territory; and how Boston & Maine interests, acting through Boston bankers, bought up, at a great price, a majority of the scattered Connecticut River shares, blocked the deal and merged the line with the Boston & Maine system. Now, a decade and a half later comes along with giant strides the New Haven again and engorges not only the Connecticut River child, but the Boston & Maine parent. Thus, on the railroad stage, is American comedy—and now and then Greek tragedy—enacted in vivid colorings and contrasts.

A discussion of the trolley situation in Ohio, as regards competition with the steam railroads, was printed in the *Railroad Gazette*, February 6, 1903, and figures of the losses to the steam roads in the vicinity of Cleveland were shown. These have been widely quoted, turning up this spring in Herrick and Boynton's *American Electric Railway Practice.* We are now enabled to bring this table up to the year 1907, as follows:

LAKE SHORE & MICHIGAN SOUTHERN.

Passengers Carried Between Cleveland and Oberlin, and Intermediate Points.

Year.	Westbound.	Eastbound.	Total.	Average per month.
1895.....	104,426	98,588	203,014	16,918
1902.....	46,328	45,433	91,761	7,647
1906.....	58,837	57,294	116,131	9,678
Passengers Carried Between Cleveland and Painesville and Intermediate Points.				
1895.....	97,460	101,832	199,292	16,608
1902.....	13,106	15,602	28,708	2,392
1906.....	19,204	21,982	41,186	3,432

NEW YORK, CHICAGO & ST. LOUIS.

Passengers Carried Between Cleveland and Lorain.

Year.	Total passengers.	Revenue.	Average revenue.
1895.....	42,526	$25,523	60.0 cents.
1902.....	9,795	4,379	44.0 "
1906.....	7,422	3,836	54.7 "

Oberlin is 34 miles from Cleveland, Painesville 29, and Lorain 26. The statistics of the trolley roads are not kept in such fashion that exact comparisons can be made of the gains to offset these losses. Seven years after the trolley lines began active business, one of them, covering approximately the territory described in one of the above classifications, was doing thirty times the short-haul business of the steam road between the same points. It is worthy of note that the passenger business on the Lake Shore & Michigan Southern, between the points cited, after languishing to a minimum in 1902, is now increasing again, though the increase is slight. On the other hand, the business between Cleveland and Lorain, on the New York, Chicago & St. Louis, is even smaller than it was five years ago. It is to be regretted that there is no statistical method of showing the increases in general business arising from the building up of suburban traffic by the trolley lines. Nevertheless, it may be risked with assurance that the total effect of this trolley line development has been to increase, rather than decrease, the earnings of the steam roads.

VOLUNTARY PUBLICATION OF ACCIDENT REPORTS.

Mr. Kruttschnitt's decision to publish the true causes of all accidents which may occur on the Union or Southern Pacific lines is warmly to be commended.* There can be no doubt that the only motive actuating either the managing officers or the directors above them is the laudable one given in the announcement—to "reduce the risk of casualties to the extreme minimum." And yet a perusal of this announcement suggests some mild speculations concerning the probable actual results. A "policy of perfect frankness" toward the public will have to contend with a chilling atmosphere. Not that people will refuse to take the railroad's word at its full value; but "the public" is such an elusive entity to deal with. The average reporter and the average editor believe in blaming the company instead of the employees for most accidents, and this bent of their minds will influence everything that they say or do. And, for better or worse, these managers of the news-machine do mould public opinion in this matter. In some newspapers, the railroad's statements will have to be stereotyped by the road itself, to insure a fair presentation, if we may judge by those papers' treatment of accident news in the past.

The announcement expresses the hope that publishing the causes of accidents will help the company to enforce better discipline; which must mean that the superintendents, when acting in private, cannot enforce their orders. This is equivalent to a declaration that the employees are decidedly unruly; and as the first article of the newspapers' creed is friendship to the employee no one need expect that facts unfavorable to an employee are going to be heralded with any excessive gladness. The statement that an engineman is directly responsible for a collision, and therefore should bear, say, 99 per cent. of the responsibility, and that the superintendent who made or approved a faulty rule or failed to detect the faults of a faulty man is chargeable with only 1 per cent., will be received with incredulity. In any event the newspaper critic will advocate the imposition of 99 per cent. of the punishment on the company. That is the attitude of juries also. It takes a strong and determined judge to make jurymen accept any other view: and if they accept it they are likely still to acquit or disagree.

The newspapers, with rare exceptions, aim to please the greatest number of readers, which, in the case of "labor"—the brotherhoods—versus a railroad company means please "labor" every time. The employees' brotherhoods believe that brothers should go free of punishment even when they have caused a collision or a derailment—for the reason, perhaps, that they think the penalties under the criminal laws are too severe.

But publicity in this matter will do good whether it does or does not result in immediately strengthening the arm of justice. The attitude of the press could not easily be changed even if Mr. Kruttschnitt were to have his accident investigations made and published by expert outside unbiased critics; but it seems a pity that this could not be done. Our Government has been inexcusably slow in this matter. Government investigation has not always been char-

*The Union Pacific System and Southern Pacific Company, courting full investigation, have decided to give freely and fully all information at command to throw light upon the causes and responsibilities for railroad accidents. The findings of boards of inquiry will be given to the daily papers, and the policy of the company will be one of perfect frankness with the public as to these matters.

Investigation of accidents by such boards of inquiry have long been an established policy, having been inaugurated on the Pacific System over four years ago, and on the Union Pacific Lines for more than three years. Whenever an accident occurs the cause of which is not apparent beyond question, the Division Board of Inquiry, made up of the division superintendent, the master mechanic and the resident engineer, is convened immediately . . . and submits its findings by wire to the general office with formal reports by mail, the report being signed by all members concurring in the conclusions. All employes involved are independently questioned, their answers being taken down in writing. Examinations are made of rolling stock and track where accidents may have possibly been traceable to such causes, and every effort is made to determine the cause of the accident clearly and unquestionably. The report "causes unknown" will not be accepted until every means of locating the cause has been exhausted.

Where members of the Division board do not agree, or where their report is not satisfactory, a second board of inquiry, made up of the General Superintendent, the Superintendent of Motive Power and the Chief Engineer in charge of Maintenance of Way and Structures, is convened by the General Manager. This higher board proceeds to the scene of the accident and . . . must likewise submit its finding to the General Manager. If the General Manager still has any doubt, he is authorized to employ expert assistance and adopt any other means necessary to determine the cause of the accident. The findings of the Board of Inquiry conducted in this manner are absolutely unbiased, and it is hoped that this policy, taken in connection with the surprise tests of signal observations by train and engine men and the large amount of block signals lately erected, which at the close of the year should provide this protection on nearly 4,700 miles of track—most of this work being done in the past two years—together with earnest and well-directed effort on the part of the officers, will be of material assistance in reducing the risk of casualties to the extreme minimum.

acterized by perfection, even under the excellent system established by the British government, but notwithstanding the limitations of human fallibility a railroad manager finds a government report a much more satisfactory means of answering criticisms of newspapers or individuals than any statement which he can himself make. He cannot possibly write or speak with the true perspective—or at any rate not with a perspective that will satisfy the public. He can be unprejudiced but he can never make people generally believe that he is. Railroads have for years in important accidents admitted the fullest responsibility for the fault by paying immense sums in damages beyond what a strict construction of the law would require of them, and yet public criticism is not allayed.

The thing that would most please the public would be to let people see what is done to cure the accident evil. Levelheaded citizens are not so much interested to know whether it is Engineman Brown or Conductor Jones that is responsible, as to see what is done to prevent conductors and enginemen from committing the same error in the future. In this matter the English system falls short of satisfying the public. The railroad journals publish the Government inspectors' reports with all necessary fulness, but these do not say what discipline has been administered, nor—until perhaps a year or two afterward—does the public know anything as to how fully the companies carry out the recommendations of the inspectors.

In speaking of this feature of the subject we are not criticising Mr. Kruttschnitt in particular for he has done as much, probably, as any manager in America, toward carrying out a true policy of frankness and in making the practices of the subordinate officers such that they will bear publicity. In his plans for block signaling thousands of miles of line within a single year he has evinced a financial and practical boldness never before heard of; and, judging by the testimony of unprejudiced eastern railroad managers who have visited the Union Pacific lines, the discipline of trainmen on those lines is as marked in its excellence as is the policy of the company in easier problems. If any eastern railroad officer desires to take a summer-school course in the Great American Railroad University he cannot afford to neglect the advantages offered by the "field observations" available west of the Missouri river. Indeed, we do not know but this is what Mr. Eustis means when he advertises so loudly in the magazines to "Spend Your Vacation in Colorado."

SALE OF THE CENTRAL OF GEORGIA.

The Central of Georgia operates 1,890 miles of line, about two-thirds of which is in Georgia, one-third in Alabama, and 41½ miles, over which it reaches the city of Chattanooga, in Tennessee. Its most important through lines are from Chattanooga, Tenn.; Atlanta, Ga., and Birmingham, Montgomery, Andalusia and Lockhart, Ala., via Macon, Ga., to Savannah. Several parts of it parallel lines of the Southern Railway. The Central of Georgia has within recent years come to be prosperous. Beginning with the first payment on the third series in 1905, 5 per cent. has since been paid on the first, second and third preference income bonds. The first payment on the second incomes was in 1904, before which the two junior series had never received any return. These securities are the ones in which the public is interested. The exact ownership of the $5,000,000 stock was not generally known up to last week except that it was in some way held in trust in the interests of the Southern Railway, which, because of its parallel and competing lines, was unable to take over control as a matter of public record. However, the late Samuel Spencer and another Southern Railway director were directors of the Central of Georgia. It now appears that this stock has been held by the same committee which in 1894 reorganized the old Richmond & West Point Terminal Railway & Warehouse Company, of which the Southern Railway is the successor company. This committee has maintained its existence in order to hold this Central of Georgia stock which came to it in the course of reorganization of certain roads in Georgia in which the Richmond Terminal Company was interested. It was announced last week that the Richmond Terminal reorganization committee has sold its holdings—almost the entire capital stock of the Central of Georgia—to Oakleigh Thorne, a New York banker, and Marsden J. Perry, of Providence, R. I., who are for the present to operate and develop the road as an independent property. The proceeds of this sale are to be turned over to the Southern, which, though it never actually held control of the Central of Georgia, is entitled to the financial benefit of any sale of the stock held by the Richmond Terminal committee. This sale of the road by the reorganization committee apparently marks the [illegible] on the part of the Southern Railway that it is preferable to give up the advantages of an allied control in order to set itself right in the eyes of the people of Georgia, who have shown great dissatisfaction with its alleged control of the local road. One of the most valuable parts of the property thus sold is the Ocean Steamship Company, which has lines from Savannah to New York and to Boston. As no report of its operations is made and as it is carried upon the balance sheet of the Central of Georgia at an absurdly small figure it is not possible to judge accurately as to its value; but it is one of the most successful coastwise lines, and we are inclined to think that it could have paid the whole cost of one or two new steamers out of its aggregate surplus earnings for the last three years. Since the sale was announced it has been suggested that the Central of Georgia will eventually be sold to the Rock Island Company in order to give the St. Louis & San Francisco an outlet to the Atlantic seaboard. The two roads connect at Birmingham, Ala. Should this be done, the Rock Island lines in the West would have the same sort of an advantage in rate-making that the Southern Pacific has as a trans-continental line by reason of its control of steamers from New Orleans to New York. It would then be possible to ship goods from northern Atlantic ports to Savannah by the Ocean Steamship Company and carry them from Savannah to the territory west of the Mississippi river entirely over Rock Island lines, thus giving a through water and rail line between the Southwest and New York and Boston under Rock Island management, which could compete even with the trunk lines if necessary. At the rate the Southwest is now developing, such a new through line from the north Atlantic ports should at once find plenty of traffic in addition to its potential advantages to the Rock Island Company as a rate-maker.

In India, it appears, there is no traffic department as we understand the term, the department which holds that title being almost entirely concerned in moving rather than getting the traffic. The *Indian Railway Gazette* in an editorial urges the establishment of a real traffic department with freight and passenger solicitors, after the fashion of English and American practice. At first sight this would appear to be unnecessary as for the most part there is no competition between different lines in India. Each road has its own sphere of influence and tariffs cannot be reduced below a fixed minimum. It is believed, however, that by the establishment of a separate department concerned only with securing traffic, it would be possible to extend and widen the business of any particular road by branching out in new directions and creating new industries and a desire to travel where they do not now exist. In regard to the passenger traffic, first, second and intermediate class traffic is unprofitable in India, while it is the third class traffic, made up of natives, which pays. This makes up nine-tenths of the passenger business, yet the time-tables are printed in English and are, therefore, useless to most of these travelers. Time cards and guide books might be printed in the vernaculars and distributed among the towns and villages along a line, and attractive posters setting forth the sanctity and virtue of some particular (non-competitive) shrine, posted in conspicuous places. As a unique example of progressiveness in the attraction of travel the case of a certain railroad is cited which presented to a native shrine of some sanctity a valuable jewel, in order to increase pilgrimages over its line to that point. Although it is evident from this instance that English or American traffic methods would have to be adapted to Indian conditions, yet the history of the traffic department, particularly in this country, amply proves that such an officer would be likely to succeed on an Indian railroad. The great skill of the traffic department has been its ability to adapt itself to conditions and originate means for securing traffic, and this same ability could be applied, we have no doubt, with equal success in India.

NEW PUBLICATIONS.

Proceedings of the Society for the Promotion of Engineering Education. Vol. XIV. 300 pages, 5⅝×8½ in.; cloth. Edited by Dugald C. Jackson, Charles L. Crandall and Wm. T. Magruder, Committee. The Engineering News Publishing Co., New York. 1907.

The volume at hand contains the roll call of the society, a report of the fourteenth annual meeting, and a collection of some 19 papers presented at the meeting. These give a pretty wide outlook of the problems arising in the education of young engineers, and are well worth reading by those interested in the subject.

Specifications for Street Roadway Pavements. By S. Whinery. New York: The Engineering News Publishing Co., 1907. Pamphlet, paper cover; 6 in. × 9 in. Price, 50 cents.

The municipal engineer is often called on to frame specifications for street pavements and if he is not, by reason of wide experience, familiar with the many peculiar conditions of this class of work,

he may find difficulty in adopting a specification from other sources which will properly safeguard the municipal interests and be fair to the contractor. In such cases a broad general specification is of value as a guide, and such a specification based on the best current practice in street paving is contained in this pamphlet. Mr. Whinery, recognizing the wide difference of opinion among engineers as to many details of practice and standards, has not laid down the conditions covering these points in a dogmatic spirit. Throughout the pages there are numerous explanatory footnotes giving the author's reasons for the wording used or outlining alternative methods which might be employed.

The general spirit of the specifications is to lay down the methods and standards of material to be used leaving the engineer to assume the responsibility for the results. This requires rigid enforcement of the provisions of the contract, but in the author's opinion is better than a specification framed to secure only the required results without regard to the methods or materials employed, or on the other hand, a specification which attempts to lay down the methods and place the responsibility of the results on the contractor.

The specifications here given include the introductory general clauses, foundations of concrete, paving stone and broken stone, bituminous or asphalt pavements both sheet and block, granite, brick and wood block pavements, and a broad general specification for new and untried pavements laid under service guarantee only.

CONTRIBUTIONS

Rolling Rails in a Universal Mill.

Chicago, June 26, 1907.

To the Editor of the Railroad Gazette:

In your issue of June 7 you published a new section for 100-lb. rails designed by Capt. R. W. Hunt, which has been adopted by a large railroad system. Capt. Hunt says that this section is designed to overcome the imperfections due to the difficulty in making the metal fill out the thin flanges, which necessitates rolling the steel at a much higher temperature than would be necessary if the flanges were made thicker, as he proposes. This may be true, but the proposed section will not cure the difficulty.

The trouble with the wide rail flange is in the delivery from the rolls, the angle made by the face of the flange with the axis of the rolls being such that true rolling action is impossible; so that, with the exception of perhaps one or two passes, the metal in the flange gets very little work other than the churning of the lower roll on the face of the flange. Moreover, if the defects in the flange are due to the high finishing temperature, why does not the head develop still greater defects, since the finishing temperature of the head is much higher than that of the flange?

The weakest part of the American rail has always been in the flange, in spite of the fact that the sections are unbalanced; that is, the center of gravity of the section is nearest the flange. In a paper read before the Western Society of Engineers, May 29, 1907, the writer called attention to the defect in the standard rail sections in this regard; but the proposed section is even a greater offender in this respect.

In any beam subject to bending, the distance of the outer fibers from the neutral axis should be the same, both above and below the neutral axis, in order to have no part of the section on one side subjected to a higher stress than on the other side. In other words, the center of gravity of the section should be in the center of the figure. This is fundamental. The proposed section departs so far from this principle that the metal in the head will be subjected to a stress 24 per cent. higher than in the flange, so that, although the rail has been made deeper, its efficiency as a beam has been actually reduced. To be sure, this will relieve the metal in the flange from some of its duty, but it will be at the expense of the metal in the head.

If the metal in the flange is inferior to the metal in the head, then there is only one remedy, and that is to give the metal in the flange more work. This points to the utilization of a universal mill of the Grey type, such as is in operation in Differdingen, Germany, for rolling broad-flange beams. Such a mill is now being built by the Bethlehem Steel Company for rolling beams in this country. The Bethlehem Steel Company considered the rolling of rails in such a mill, but they felt that the development of the Grey mill for producing structural shapes was a sufficient burden to undertake, for the present at least. Thus the idea of rolling rails in a universal mill is not new, and has been proposed by Mr. Henry Grey, the inventor of the Grey mill.

In considering the rolling of rails in a universal mill, the question will arise as to the possible tonnage capacity of such a mill as compared with the present three-high mill. This can be answered by making the horizontal rolls, and perhaps the vertical rolls as well, three-high in the proposed universal mill, so that the metal in the rail, in all of its parts, would receive exactly the same amount of work. A three-high universal mill for rolling thin skelp is now in operation at the National Tube Works, McKeesport, Pa.

J. W. SCHAUB,
M. Am. Soc. C. E.

The Italian Railroads.

Rome, Italy, May 22, 1907.

To the Editor of the Railroad Gazette:

In your generally so well informed paper I am sorry to notice a paragraph about the present state of Italian railroads, which, I am glad to say, is absolutely unfounded. The incident about the King of Italy having to abandon a trip because he could not find a spare engineman is too amusing, and you yourself express doubt about its truth. I am glad to say it was not true.

The Mayors of Genoa, Milan and Turin met, but they met for the purpose of spurring the government to build a new, more direct line between these cities; and the project has been given careful consideration. The proposal to buy more rolling stock was made in November, 1905—rather a long time ago—and a very large proportion of the new material has already come into service, and the rest will be completed and put in use before autumn.

The wages of the *personnel* have all been increased from 10 to 20 per cent., and a very good feeling now has been cemented between our employees, the administration in general, and its able Director-General, Commendatore Riccardo Bianchi, who is absolutely idolized by his friends, and even respectfully admired by his political opponents.

On the whole, I am glad to say, Italian railroads are now on an excellent basis, and the service has become quite normal and satisfactory, notwithstanding the enormous increase in the traffic—fully 22 per cent.—in comparison with 1905, and the inevitable difficulties arising from the welding together of four different railroad systems, with more than 120,000 employees, with different regulations and habits, and accustomed even to different signals. For several months no complaints have been made against the service, which is settling down to a normal and active pace.

LUIGI LUIGGI,
Administration Councillor, State Railroads.

The Highest Railroad Station.

Newark, Del., June 3, 1907.

To the Editor of the Railroad Gazette:

There are a number of railroad stations in Peru that are higher than the one at Corona, Colo. Vincocaya, on the Arequipa & Puno R. R., is 14,360 ft. On the Central Railroad of Peru there are several.

Chicla	12,215 ft.
Casapalca	13,606 "
Yauli	13,420 "
Oroya	12,178 "
Cerro de Pasco at the end of branch from Oroya is	13,974 "
Oroya is the lowest point on that road.	
The lowest point on the Central system is on the dock in Callao; it is	8.7 "
The highest is in the Galera Tunnel	15,666 "

All of these are standard gage railroads.

JAS. R. MAXWELL.

Sixty-six Miles an Hour for Twenty-four Hours.

New York to Chicago in 13 hours, 45 minutes, would mean a speed unheard of for that distance, namely, 66 miles an hour; but that is the rate which was made with an automobile in England last week on a three-mile racing track in a 24 hours' continuous run, the total distance traveled being 1,581¾ miles. This run of a day made by the same man, equals the distance from New York by the New York Central, the Rock Island (via Englewood) and the Union Pacific to Thummel, Neb., 126 miles beyond Omaha, and nearly to Central City; or from Jersey City by the Pennsylvania and the Burlington to within eight miles of Holdrege, Neb. The following details are from the *New York Times*:

In the 24 hours ended at 6 o'clock Saturday evening, June 29, S. F. Edge, in his six-cylinder Napier motor car, traveled 1,581 miles and 1,310 yards over the Brooklands racing track at Weybridge, and nothing approaching that speed had ever been maintained for 24 hours by motor car, railroad train or any other locomotive apparatus. Mr. Edge undertook to cover 1,440 miles in 1,440 minutes, and bettered it by 141 miles 1,310 yards. Never once did Edge's speed fall under 60 miles an hour. Many times the daring rider had to stop on account of punctured tires to have a wheel replaced with lightninglike quickness by expert mechanics. Two cars accompanied him, driven by relays of drivers. The cars swayed on their springs like hammocks, now and again bumping over obstacles with a jerk that would have sent an unwary rider headlong. The feeding of Edge was entrusted to the mechanician who accompanied him. He gave tabloids and coffee nibs. Edge thinks with a racing car he could make 85 miles an hour for 24 hours.

In the ninth hour the distance traversed was almost 72 miles;

in the fourteenth hour 78 miles and 450 ft. The Brooklands track is at Weybridge. It is pear shaped, the two long sides being each one mile long. It was built specially for automobile speeding and is 100 ft. wide. In the curved portions the outer half is banked, the outer edges being perpendicular. The roadway is of concrete. It is impossible to walk up the banking higher than 15 ft. from the top. Around the course are entry boxes equipped with telephones. A special staff, an ambulance car, and a breakdown gang are always in attendance. For spectators there are three inclosures, with a total seating capacity of 30,000 and a holding capacity of 500,000. The track is practically an inverted coliseum, for while in the Roman amphitheater the spectators surrounded the arena, at Weybridge the arena surrounds the spectators. The entrance to the inclosures is by means of three tunnels under the track.

Changes in the Rules of Interchange.

The Arbitration Committee of the Master Car Builders' Association this year recommended a number of changes in the Rules of Interchange which were adopted as a whole by the Association. We give below the principal revisions referring to the numbers of the rules in force during the past year.

Rule 2.—The following paragraph is added: "In case cars are rejected by the receiving road and returned to the delivering company all the defects objected to must be designated on a return card of the following form, placed on the car adjacent to the destination card:

RETURN CARD.

..... Car No. . . . .

from ..... Ry.,

to ..... Ry.,

for the following defects: .....

.....

.....

.....

.....

.....

.....

Inspector.

Rule 21.—Omit "For wheels cast after Aug. 31, 1904," on the drawing accompanying the rule.

Rule 22.—Changed to read: "Axles broken or having seamy or pitted journals, fillets in back shoulder worn out, or collars broken off or worn to ¼ in. or less under fair usage."

Rule 29.—Changed to read: "Torn air hose, defective, missing or worn-out parts of brakes, not elsewhere provided for, which have failed under fair usage, except missing material on cars offered in interchange. Owners responsible."

Rule 32.—Changed to read: "Missing air-brake hose or missing or broken air-brake fittings, etc. Delivering company responsible."

Rule 34.—Omit the words "or air-brake pipes, but no air-brakes."

Rule 36.—Omit that part of the rule referring to date.

Rule 46.—Heading covering combination of defects changed to read: "Combination of defects which denotes unfair usage if occurring at the same end of the car."

Rule 48.—Changed to read: "Damage to coupler, accompanied by damage to either combined front and back coupler stop, filling block draft timber or its substitute, or end sill."

Rule 50.—Changed to read: "Damaged combined front and back coupler stop or filling block, accompanied by damage to either coupler or end sill."

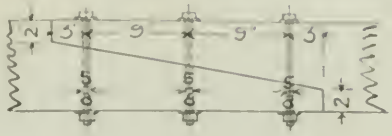
Rule 53.—Changed to read: "Damaged end sill, accompanied by damage to either coupler, coupler pocket, combined front and back coupler stop, filling block, draft timber or its substitute, or longitudinal sill."

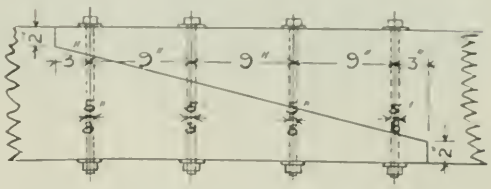
Rule 56.—Footnote regarding American continuous draft key changed to include also the draft rod.

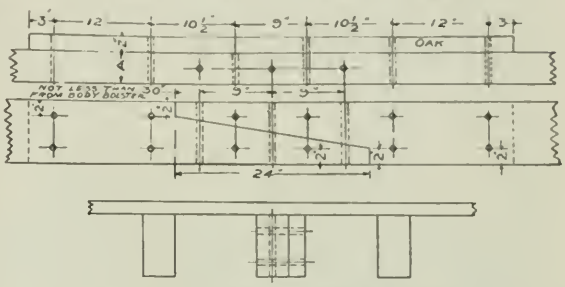
Rule 65.—Changed to read: "The splice may be located either side of body bolster, but the nearest point of any splice must not be within 12 in. of same, excepting center sills, which must be spliced between body bolster and cross-tie timbers and not within 30 in. of either. The splicing of two adjacent sills, *except center sills*, at the same end of car or the splicing of any sill between cross-tie timbers, will not be allowed.

"Steel sills may be spliced as shown in Figs. A, B and C at any point, and one or more sills may be spliced at same end of car."

The form of splicing wooden sills shown herewith is approved.







Rule 72.—Changed by the addition after the word "car" in the third line the words "or if the light weight is obliterated."

Rule 89.—Schedule of prices for wheels and axles revised as follows:

	New.	Second-hand.	Scrap.
One 36-in. cast-iron wheel	$10.50	$7.75	$5.25
One 33-in. cast-iron wheel	9.00	7.00	4.75
One 33-in. steel or steel-tired wheel	23.00	17.25	5.00
One axle, 100,000 lbs.	21.50	14.75	7.75
One axle, 80,000 lbs.	17.75	10.00	6.50
One axle, 60,000 lbs.	14.00	7.75	5.25
One axle, 50,000 lbs. (or under)	11.50	6.25	4.25

Also omit sentence reading: "All steel or steel-tired wheels of the different makes to be charged at current market prices, less freight charges."

Rule 91.—The prices charged under this rule have been revised to bring them more nearly on a level with current market prices. Prices have been inserted for the different parts of the 10-in. air-brake equipment as well as the 8-in. The following are the principal changes:

	Charge.	Credit.
Castings, rough iron, per pound	$0.02	$0.00 9/10
Castings, rough, malleable, per pound	.03½	.00½
Coupling, dummy	Eliminate.	
Coupler, M. C. B., complete, new, malleable iron 5x5 shank	Eliminate.	
" M. C. B., complete, new, steel, 5x5 shank	8.75	.....
" M. C. B., complete, new malleable iron, 5x7 shank	Eliminate.	
" M. C. B., complete, new, steel, 5x7 shank	9.50	.....
" body, one, new, malleable iron, 5x5 shank	Eliminate.	.90
" body, one, new, steel, 5x5 shank	6.50	1.05
" body, one, new, malleable iron, 5x7 shank	Eliminate.	1.00
" body, one, new, steel, 5x5 shank	7.75	1.15
" knuckle, one, new, open, omit charge, credit remain	.....	.40
" Knuckle, one, new solid	2.00	.45
Other individual malleable, wrought or steel parts	.04	.....
Door for end of box or stock car, wooden, each, applied, no credit for scrap	1.95	.....
" for end of box or stock car, ventilated (wooden frame with iron rods), each, applied, no credit for scrap	3.30	.....
" for side of box or stock car, wooden, each, applied, no credit for scrap	3.65	.....
" for side of box, or stock car, ventilated (wooden frame with iron rods), each, applied, no credit for scrap	5.50	.....
" (new item) for side of carriage, automobile or furniture car, wooden, each, applied, no credit for scrap	5.00	.....
" for side of stock car, with iron rods, each, applied, no credit for scrap	4.40	.....
" for roof of coke car, wooden, each, applied, no credit for scrap	2.45	.....
" for roof of stock car, wooden, each, applied, no credit for scrap	.85	.....
Half-door, for side of box or stock car, each, applied, no credit for scrap	2.50	.....
Journal bearings, brass or bronze, lined or unlined, per pound, applied	.20	.15
Journal bearings, filled, brass or bronze, shell, per pound, applied	.15	.11

(The weight charged for new journal bearings

for 7-in. journals and over, but not 8 in. long, shall be 10 lbs.; for scrap bearings, 6 lbs. The weight charged for new journal bearings for journals 8 in. long and less than 9 in. long shall be 13 lbs.; for scrap bearings, 8 lbs. For new journal bearings for journals 9 in. long or over, but not 10 in., 20 lbs.; for scrap bearings, 12 lbs. For new journal bearings for 100,000-lb. capacity cars 15½x10 in. the weight shall be 25 lbs.; for scrap bearings, 15 lbs.		
Labor per hour	.25	.....
Lumber, as specified, per ft.	.03½	.....
Steel for springs, rough, per lb.	.05	.00¾
Steel, pressed and sheet, per lb.	.03½	.00½

Rule 97.—Change word "channels" to "structural steel."

Rule 105.—Increase charge for altering height of one end of one car from $1 to $1.10 net.

Rule 106.—Changed as follows: Cut out item reading, "coupler stops, all, at one end of car, replaced, 3 hours," and change the next two items to read as follows:

Coupler, with stem attachments, coupler springs, one or more follower plates, American continuous draft key, American continuous draft rods, one or *more* coupler stops, renewing or replacing, any or all, at same end of car, at same time	3 hrs.
Coupler, with pocket attachments, coupler spring, one or more follower plates, one or *more* coupler stops, coupler pocket, coupler pocket rivets, renewing or replacing any or all, at some end of car, at same time	4 "
Siding, removed and replaced, per lin. ft.	15 cts.
Siding, removed and replaced, where nails are set and holes puttied	20 cts.
Each side or intermediate sill spliced, when *longitudinal* sills have to be replaced, as above	6 hrs.
When necessary to remove lead to replace body center plate, bolt or bolts, one or two draft timbers or draft timber bolts, at one end of car	3 hrs.
Removing temporary advertisements tacked on car, per car	50 cts.
Removing temporary advertisements, pasted, glued or varnished on cars, per car	$1.00

Under the head of "Repairs of Steel Cars," increase the rate per hour for straightening or repairing parts from 20 cents to 25 cents.

Rule 112.—All the items for air-brake repairs are increased slightly and an additional sentence added to the rule as follows: "No labor to be charged for adjusting brakes."

Rule 113.—Prices for car bodies advanced as follows: The settlement prices of new eight-wheel cars shall be as follows, with an addition of $27.50 for each car equipped with an 8-in. air-brake equipment and $35 for 10-in. air-brake equipment. The road destroying a car with air-brakes may elect to return the air-brake apparatus, including such attachments as are usually furnished by the air-brake manufacturer, complete and in good condition:

BODIES.

Wood.

Box car, 8-wheel, 40 ft. long or over	$440.00
" " 36 ft. long or over, but under 40 ft.	385.00
" " 34 ft. long or over, but under 36 ft. long	360.00
" " 32 ft. long or over, but under 34 ft. long	330.00
" " under 32 ft. long	265.00
" ventilated, 8-wheel, 40 ft. long or over	470.00
" ventilated, 8-wheel, 36 ft. long, but under 40 ft.	415.00
" ventilated, 8-wheel, 34 ft. long, but under 36 ft.	385.00
Flat car, 8-wheel, plain, 40 ft. long or over	200.00
" 8-wheel, plain, 32 ft. long or over, but under 40 ft.	155.00
" " plain, under 32 ft. long	110.00
Gondola car, 8-wheel, drop-bottom, 40 tons capacity or over	330.00
" 8-wheel, drop-bottom, 30 tons capacity or over but under 40 tons	300.00
" 8-wheel, drop-bottom, 25 tons capacity or over, but under 30 tons	275.00
" 8-wheel, drop-bottom, 20 tons capacity or under	200.00
" " hopper-bottom, 50 tons capacity	440.00
" " hopper-bottom, 40 tons capacity or over, but under 50 tons	360.00
" 8-wheel, hopper-bottom, 30 tons capacity or over, but under 40 tons	330.00
" 8-wheel, hopper-bottom, 25 tons capacity or over, but under 30 tons	290.00
" 8-wheel, hopper-bottom, 20 tons capacity or less	220.00
" " plain, 50 tons capacity and over	350.00
" " " 40 tons capacity, but under 50 tons	300.00
" " " 30 tons capacity, but under 40 tons	275.00
" " " 25 tons capacity, but under 30 tons	250.00
" " " under 25 tons	140.00
Stock car, 8-wheel, 34 ft. long or over	330.00
" " 32 ft. long or over, but under 34 ft.	300.00
" " under 32 ft. long	265.00

The lengths of cars above mentioned, refer to the lengths over the end sills.

In the case of double-deck stock cars, $25.00 may be added to the prices given above for stock cars.

Where the capacity of the car is 60,000 lbs. or over, 10 per cent. should be added to the above prices for the car bodies.

When cars of 60,000 lbs. capacity or over, and so stenciled, have trucks with journals 4 in. or over in diameter when new, $10 per car shall be added to the figure as given above for the values of car bodies, when equipped with metal bolsters.

When cars are equipped with metal center sills, $40 shall be added to the values of bodies for cost of such metal sills.

Steel.

Box car wooden body, metal underframe, 8-wheel, 50 tons capacity, 38 ft. 6 in., or over, over end sills	$825.00
wooden body, metal underframe, 8-wheel, less than 50 tons capacity, 36 ft. or over	740.00
Flat car, wooden floor, metal underframe, 8-wheel, 50 tons capacity, 40 ft. over end sills	770.00
Flat car, wooden floor, metal underframe, 8-wheel, 40 tons capacity, 40 ft. over end sills	590.00
Gondola car, all metal, 8-wheel, hopper bottom, 50 tons capacity, 33 ft. over end sills	825.00
Gondola car, all metal, 8-wheel, drop-bottom, 50 tons capacity, 40 ft. over end sills	815.00
Gondola car, all metal, 8-wheel, plain, 50 tons capacity, 40 ft. over end sills	790.00
Gondola cars, wooden body, metal underframe, 8-wheel, flat bottom, 40 ft. over end sills	790.00
Gondola car, wooden body, metal underframe, 8-wheel hopper bottom, 32 ft. over end sills, but under 40 ft.	650.00
Flat car, wooden floor, metal underframe, 8-wheel, 40 tons or over, but under 50 tons, 34 ft. long end sills, but under 40 ft.	510.00
Stock car, 8-wheel, wooden body, metal underframe, less than 50 tons capacity, 36 ft. long or over	715.00

TRUCKS.

50,000 lbs. capacity, with metal transoms and wooden bolster, pr pair	$215.00
60,000 " " " or under, with wooden bolster, per pair	215.00
60,000 " " or under, all metal, per pair	315.00
80,000 " " or under, but over 60,000 lbs., all metal, pr pair	400.00
100,000 " " or under, but over 80,000 lbs., all metal, pr pair	425.00

Prices include brake-beams complete, truck levers, dead-lever guides and bottom connection rods.

For trucks with steel or steel-tired wheels an additional allowance of $112 per car shall be made.

All trucks in service of 60,000 lbs. capacity or over, which consist entirely of metal, with the exception of the spring plank, shall be known hereafter as all-metal trucks.

Rule 114.—Changed to read: "In the case of wooden cars, the depreciation due to age shall be estimated at 6 per cent. per annum upon the yearly depreciated value of the bodies and trucks only. In the case of all-steel cars and cars with steel underframes, the depreciation shall be 5 per cent. per annum for the bodies of all-steel cars; for bodies of cars with steel underframes the depreciation shall be at the rate of 5½ per cent. per annum, with the exception of flat cars with wooden floors, which shall be 5 per cent. per annum. The depreciation on the value of trucks of steel cars shall be 5 per cent. per annum. Allowances for depreciation shall in no case exceed 60 per cent. of the value new. The amounts $27.50 and $35 for air-brakes shall not be subject to any depreciation."

Rule 115.—Paragraph added reading: "In the case of cars equipped with racks for carrying coke and other purposes, and also stock cars fitted with feeding and watering attachments, the actual cost of these equipments shall be added to the standard settlement price for such cars."

Rule 129.—Changed to read: "Companies shall promptly furnish to each other, upon requisition, and forward free over their own road, material for repairs of their cars injured upon foreign lines, excepting that the company having car in its possession at the time shall provide from its own stock the following:

"Lumber, forgings, hardware stock, paint, hairfelt, piping, air-brake material and all M. C. B. standard material.

"Requisitions for such material shall specify that same is for repairs of cars, giving car number and initial of such car, together with pattern number or other data to enable correct fitting of requisition."

Ten-Wheel Locomotive for the Chicago & North-Western.

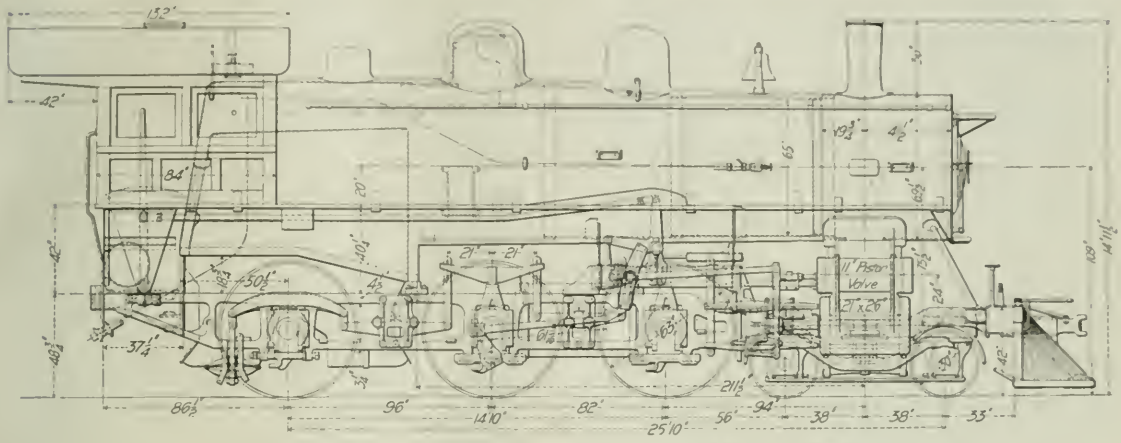
The Schenectady Works of the American Locomotive Company have recently delivered an order of 30 ten-wheel locomotives to the Chicago & North-Western Railroad, five of which are equipped with the Walschaert valve gear. These engines are for all-round freight service, and except for the valve gear are of the same specification as the class R-1 engines of that road, which have for several years been their standard engine for this class of service. To the best of our knowledge, however, these are the first engines on the Chicago & North-Western to be equipped with the Walschaert valve gear, which is another proof of the increasing opinion among railroads in favor of this type of gear.

The illustration shows clearly the application, which differs from any arrangement used on previous locomotives built by this company.

The link is supported in a steel casting bolted to the end of the cross-tie or yoke located between the front and middle pair of driving-wheels and extending beyond the driving-wheels. Connecting this cross-tie and the guide yoke and outside of the driving-wheels is a steel plate 1¼ in. thick and 10 in. deep. The reverse shaft bearing is bolted to the top of this plate just back of the center of the forward driving-wheels, and the backward extending arm of the reverse shaft is connected to the radius bar by means of a lifting link.

Another interesting feature in this design is the use of corrugated firebox side sheets. As will be seen from the boiler card, the side sheets are provided with a series of vertical corrugations throughout the length of the sheet to within the last three rows of staybolts at the front and back end, making a waved sheet. The staybolts are located at the top of the waves or in that portion of the sheet which is furthest from the fire. It is a well-known fact that the expansion and contraction that takes place in a firebox shell, due to changes of temperature, causes cracking of the sheets, and it is claimed for this arrangement that the corrugations afford sufficient elasticity to overcome those strains which finally result in the rupture of the sheet. Moreover, in the ordinary flat plate the heads of the staybolts project beyond the face of the plate so that they are more highly heated than the plate and unequal expansion takes place between the head of the bolt and the plate, causing leaks around the head of the bolt. With this arrangement the head of the bolt is somewhat protected from the fire so that the plate and the head of the bolt are more uniformly heated. In addition to these vertical corrugations in the side sheet there is a large and bulging corrugation 2 in. deep, turned on a radius

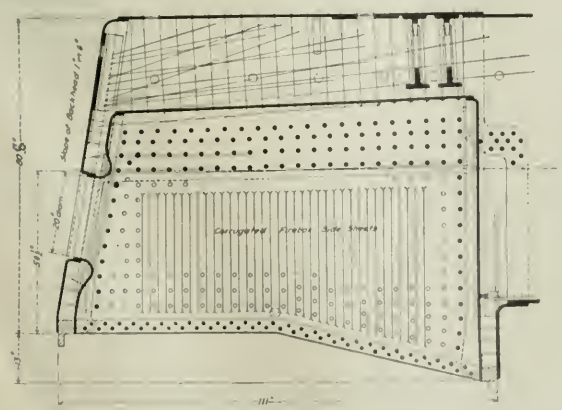
Ten-Wheel Freight Locomotive for the Chicago & North-Western; Built by the American Locomotive Co.



Side Elevation, Ten-Wheel Freight Locomotive; Chicago & North-Western.

of 2¾ in. in the back head surrounding the fire door. This is a rather unusual form and is one that ought to relieve the flanging at that point of much of the stress due to poor circulation and varying temperatures that are apt to result in the cracking which is so difficult and expensive to remedy.

As for the corrugations in the side sheets, this is a survival of an old practice that has been made successful on this road in some way, probably through persistence in its use on the ground of its theoretical correctness. A number of years ago the use of corrugated side sheets was quite common on some roads, but owing to lack of skill in forming the plates or the lower grade of the steel, or a combination of the two, it was not found that any advantage was gained and this form of sheet was abandoned. That it should possess the advantages claimed for it there is no doubt, provided sufficient care is taken in the forming so that undue internal stresses are not set up.



Longitudinal Section Through Firebox, 10-Wheel Freight Locomotive; Chicago & North-Western.

In view of another locomotive recently built by the same company at another works of about the same tractive power as this one, it may be interesting to make some comparisons of the boiler capacities. Referring to the Pacific (4-6-2) passenger locomotives for the Atlanta & West Point Railroad having 22-in. by 28-in. cylinders and with the same boiler pressure of 200 lbs., we find that there is but 1,100 lbs. difference in tractive power to be exerted on six driving wheels in each case, and that they carry but 4,000 lbs. difference in load. Instead, however, of the 1,100 lbs. extra tractive power belonging to the engine with the heavier load, it belongs to the one with the lighter one. In the working of the engines it will probably be found that the Pacific passenger locomotive with the higher calculated tractive power and lower weight is exerting, for the greater portion of its run, a much lower pull than the freight engine, which therefore really needs the increased weight in its practical working. But the greatest difference is to be found in the boilers. They have diameters of 72½ in. and 66¾ in. respectively. The Pacific engine has 278 tubes 2¼ in. in diameter and 20 ft. long, with 3,261 sq. ft. of heating surface. This 10-wheeler of the North-Western, although the boiler is the smaller, has 334 tubes of 2 in. diameter, 16 ft. long, and with but 2,808.4 sq. ft. of heating surface. This, as far as heating surface is concerned, is what would be expected from the dimensions; but, when this tube heating surface is equated to an equivalent firebox heating surface by the Vaughan formula, we find that that of the Pacific engine equals 729.8 sq. ft. while that of the 10-wheeler is equal to 703 sq. ft. Here is a difference of but 26.8 sq. ft. of what may be called effective heating surface, while the actual difference is 453 sq. ft. Of course, a large portion of this apparent discrepancy is due to the difference in number and size of the tubes in the two boilers. But still it does exist and it is an interesting question, the solution of which would be of great economic value, to decide upon the best diameter and length of tubes to be used in a locomotive boiler. Certainly it is not a matter that can be decided off-hand on any academic considerations or even from any practical data that is now available. This is considering the matter purely from the standpoint of cost, as represented by that of installation, maintenance and operation and disregarding the question of construction which sometimes regulates the length of tubes, so as to meet a desired arrangement of wheels and weights.

The boiler illustrated in connection with this Chicago & North-

Western locomotive is one that has been in use upon that road for several years with very satisfactory results.

The following are some of the principal dimensions of these engines with the ratios between a portion of them:

Cylinder, diameter	21 in.
Piston stroke	26 "
Wheel base, driving	14 ft. 10 "
" " total engine	25 " 10 "
" " total engine and tender	57 " 9 "
Weight on drivers	134,000 lbs.
" of engine	176,000 "
" of engine and tender	315,500 "
Heating surface, firebox	150.79 sq. ft.
" " tubes	2,808.4 "
" " total	2,959.19 "
Grate area	46.27 "
Journals, main driving	9 in. x 12½ in.
" coupled, driving	8½ " x 12½ "
" tender	5½ " x 10 "
Boiler, diameter	66⅜ "
Firebox, length	102½ "
" width	65¼ "
" thickness crown, side and back sheets	⅜ in.
" thickness tube sheet	½ in.
" water spaces	4 in.
Steam pressure	200 lbs.
Tubes, number	337
" diameter	2 in.
" length	16 "
Nozzles, single, diameter	5 in., 5¼ in., and 5½ in.
Stack, diameter	14 in. and 16½ "
Stock, above rail	14 ft. 11⅜ "
Wheels, diameter, driving	63 "
Wheels, diameter, truck	30 "
Valves, type	Piston
" travel	5¾ in.
" lap	1 "
" lead	1/8 in.
Tank capacity, water	7,500 gals.
Tank capacity, coal	10 tons
Tractive effort	30,900 lbs.

$$\frac{\text{Weight on drivers}}{\text{Total weight}} = 0.76$$

$$\frac{\text{Weight on drivers}}{\text{Tractive effort}} = 4.37$$

$$\frac{\text{Total weight}}{\text{Tractive effort}} = 5.7$$

$$\frac{\text{Tractive effort x diameter of drivers}}{\text{Heating surface}} = 660$$

$$\frac{\text{Heating surface}}{\text{Grate area}} = 64$$

$$\frac{\text{Firebox heating surface}}{\text{Total heating surface}} = 5.09$$

$$\frac{\text{Firebox heating surface}}{\text{Tube heating surface}} = 5.37$$

$$\frac{\text{Weight on drivers}}{\text{Total heating surface}} = 46$$

$$\frac{\text{Total weight}}{\text{Total heating surface}} = 59.48$$

$$\frac{\text{Volume of cylinders}}{\text{Heating surface}} = 284$$

$$\frac{\text{Grate area}}{\text{Volume of cylinders}} = 4.45$$

Volume of cylinders	10.4 cu. ft.
Tube heating surface equated for firebox heating surface (Vaughan formula)	703.0 sq. ft.
Total equated firebox heating surface	853.79 "

Examination of Telegraphers for Railroad Work.*

Upon arrival of the applicant at headquarters, he is taken in charge by the chief operator and examined as to his ability as a telegrapher. Due allowance is made for natural nervousness of the candidate under examination and every opportunity is afforded him to show what he can do. To meet the standard he has to copy three train orders in succession of different phraseology. They must be of legible penmanship and correct without a scratch or fumble, interlineation or alteration, at a rate of speed from 23 to 30 words per minute, averaging five letters per word, and he must correctly transmit and repeat back the same at same average speed. Otherwise he is rejected. Sometimes several applicants in a day are rejected. After passing examination in telegraphy, his letters of recommendation or service cards from previous employers are called for and a copy of same made. They must show a clear record for the previous five years. His credentials are returned to him. If he has no credentials, he is required to wait until his previous employers are communicated with by wire and his record established. Letters of recommendation are verified by mail or wire to insure their being genuine.

The applicant is required to fill out three application blanks, one for the superintendent of telegraph and signals, one for the general superintendent and one for the claim agent. These blanks have a printed form on reverse side for the chief operator's report of examination, that is, proficiency in telegraphy and standing on sight, hearing and colors.

To pass a normal physical examination, an applicant must be able to read with each eye separately printed letters ½ in. long, composed of lines an eighth of an inch wide on a chart at a distance of 24 ft. He must hear the tick of a watch with each ear separately a distance of 36 in. Where the ratchet acoumeter is used the examinee must call off the clicks numerically as they are produced by the examiner, first slowly, then rapidly, first in regular time singly, then by twos and threes with a pause between each two groups of clicks at the required distance. He must group in each class to which they belong five different shades of the following colors (using the Thomson yarns): red, green, blue, yellow, pink, brown and white. The Williams lantern is also used in making an examination on colors. The examinee, at a distance of 20 ft., must call off the names of the different colors as they are given by flash light in rapid succession at the option of the examiner. The lenses vary in diameter, the largest representing switch lights at a distance of 150 ft., the next 600 ft. and the smallest 1,300 ft.

It is found that 10 per cent. of the applicants are disqualified by reason of defective eyesight, 3 per cent. by defective hearing, and 6 per cent. by defective color perception.

If the applicant's record is found to be acceptable, a book of rules is given him to study, and afterwards a pamphlet entitled "Operators' Examination," in which he must answer upwards of 200 questions in writing bearing on the duties of a telegrapher. These answers are checked over and the writer advised of any that are wrong, which he must correct. This is termed his second examination.

After this is done, he is subjected to a third examination which is oral, lasting from four to six hours, on rules considered essential to safety of passengers and trains.

All station helpers and apprentice telegraphers from points along the system who have not previously been present on a similar occasion are brought to headquarters to listen to this oral examination. They hear the important rules explained, the questions, the answers, the comments, the important troubles which telegraphers have had on the road and throughout the country during the last 15 years, the cause and remedy, and the general instructions which have been issued to guard against these troubles are related to them. No applicant, however, is assigned to duty as a telegrapher until, in addition to the foregoing, he has himself passed a satisfactory written and oral examination. The examination of the other man is for him simply a preparation. In this way he goes to work not as a green hand but as one who has had 15 years of experience.

After passing examination on rules, he is seated at the telegraph examination table, furnished with train order signal, train order manifold, carbon sheets and stylus and required to receive orders in regular form in accordance with the rules on which he has just passed examination, displaying his train order signal, giving the proper responses, repeating the orders, etc., and drilled in this way until he can handle the orders rapidly and correctly and without any prompting. This done, he is ready for duty. If he is to be an agent, or perform clerical work, or fill high position as a telegrapher, he is sent to the division superintendent for inspection that the latter may know him before he goes to work. Otherwise he is sent direct to the agent at the station at which he is to serve.

No one under 21 years of age is made an agent, and none are appointed telegraphers under 18 years of age. If the position is one requiring bond, notice is immediately sent to the comptroller. In case of appointment to an important position as ticket agent or ticket seller, the approval of the general passenger agent is also obtained. Promotion to the position of agent is made from the ranks of telegraphers; when possible, brains being equal, preference is given to seniority of service. Train despatchers are generally made by promoting telegraphers in train despatcher's office. Candidates for telegraphers in despatcher's office are selected from the best material on the division.

When an agent is desired for one of the larger stations the traffic department is conferred with.

In addition to the personal record blank, a personal record is kept of every one connected with the telegraph and signal department from apprentice up, showing date of appointment, capacity, station, term of service, promotions, suspensions, errors, dismissals, etc. A telegrapher leaving the service for any cause is given a service letter addressed to himself stating the time and character of service and specifying the reason for leaving.

It takes from one to three days for a telegrapher to complete his examination. One day is sufficient for an experienced energetic man.

It has been our experience that a man who has reached the age of 18, after having passed the required examination, is fully qualified to handle train orders. In proportion to the number of men employed over 21, as against the same number between 18 and 21, the men over 21 are in the majority of those who have caused trouble in the operation of train movements.

The discipline of telegraphers is accomplished through the tel-

* A paper read before the Railway Telegraph Superintendents' Association at Atlantic City, June 19, by H. C. Hope, Superintendent of Telegraph and Signals, Chicago, St. Paul, Minneapolis & Omaha.

egraph and signal department and the division officers. It is the duty of the travelling telegrapher to observe how all matters pertaining to the telegraph and signal service are being maintained, to see that all signal lamps and batteries are cared for in a way to obtain the best results, that blocking between adjoining stations by signalmen, keeping of block records, handling of train orders and block cards and operation of block signals is properly done, correcting and instructing those who need it and making regular and systematic inspection reports to headquarters covering each office within his district. It usually takes three days for operators coming from other railroads having similar rules to ours to qualify and get acquainted with our methods, requirements, etc.

Each agent, telegrapher and apprentice telegrapher is furnished with a pamphlet entitled, "The Monitor," containing 100 questions and answers bearing upon matters pertaining to passenger traffic.

The Northern Pacific's Own Valuation.

The Northern Pacific has filed with the Interstate Commerce Commission statements and figures showing what it would cost to duplicate the railroad property and the cost of improvements. The table showing the estimated cost of reproducing the Northern Pacific Railroad at present follows:

	Miles.	
Main line and second tracks	2,860.67	
Branch line, spurs and sidings	4,834.12	
		7,694.79
Engineering, 5,785 miles at $1,500		$8,677,500
Right of way and station grounds		106,890,088
Grading		71,174,744
Tunnels		4,383,948
Bridging		20,344,934
Ties		13,810,326
Rails		27,563,754
Fastenings		3,656,095
Switches		1,181,250
Ballasting		8,238,758
Track laying		7,573,550
Fencing right of way		759,450
Cattle guards		289,250
Signal apparatus		167,862
Telegraph lines		1,445,013
Station buildings and fixtures		2,511,264
Roundhouses		3,972,125
Machinery and tools		1,100,000
Docks, wharves		1,454,450
Water stations		1,966,900
Fuel stations		636,350
Warehouses		2,886,076
Miscellaneous structures		2,299,668
Seattle terminal facilities		2,457,000
Ferry equipment		617,000
Legal expenses		289,250
General expenses		289,250
Interest		35,632,295
Contingencies		12,994,717
Total		$345,262,867
Average cost per mile		59,734
Average cost per mile, not including land		41,257

Right of Way and Station Grounds.

Large terminals.	Acres.	Total value.
Superior	982.62	$1,552,020
Duluth	600.91	5,155,204
Duluth Union Depot	6.94	420,625
St. Paul	676.97	9,579,177
Minneapolis	284.61	5,065,082
Spokane	422.31	7,240,293
Tacoma	680.84	12,160,000
Seattle	461.03	30,167,050
Butte	233.76	2,000,000
Everett	124.68	374,040
Bellingham	67.86	339,300
South Bend	35.63	249,419
Aberdeen and Hauquiam	69.83	698,300
Total	4,637.99	$75,000,501
Other right of way and station grounds	152,185.00	31,889,589
Total	156,822.92	$106,890,988
Average cost, right of way and station grounds, per acre		$209.53
Average cost, right of way and station grounds, per mile		$5,533

The cost of improvements on the estate of the Northern Pacific—total 7,694.79 miles—has been $302,815,326, and their present value is $288,695,095.

Annual Meeting of the Freight Claim Association.

The Freight Claim Association, which is composed of 330 railroads, steamship companies and fast freight lines, held its sixteenth annual session at Denver, commencing June 19th, 170 different carriers being represented. The first two days of the session were taken up in discussing and adopting the reports of the Committees on Constitution and By-Laws and Rules, perfecting and amending the constitution and the rules, the object being to simplify and expedite the manner and methods under which claims shall be handled, and determining the proportions in which claims shall be divided, and in perfecting the method of arbitrating claims when proper divisions are not agreed upon by the interested carriers. That is the corner stone of the Association, as without some plan by which claims in dispute between carriers could be arbitrated and finally disposed of the Association would be worthless.

The third day was largely devoted to the discussion of the principal business of the Association, which was the adoption of a new plan, which had been considered at a special meeting of the Association held at Cincinnati in February last, for the purpose of improving the methods now in force in relation to the making of the investigation and settlement of freight claims. After discussion the matter was finally voted upon, the vote being taken by roads, and the plan received the necessary two-thirds vote of those present. Under the constitution of this Association no rule or bylaw can be adopted unless it receives the vote of two-thirds of the members present. Below is a copy of the new plan, which takes effect September 1 next on all claims presented on and after that date.

[illegible]

When claim is presented it shall be investigated and settled on its merits and in conformity with legal liability by carrier to whom presented.

Provided, when claim arises from fire, flood, wreck, act of [illegible] of public enemy, act of public authority, act of shippers, or [illegible] of goods, disaster on land or water, or marine loss or damage, papers must be submitted for authority to Freight Claim Officers of carriers deemed liable.

(*a*) Settling carrier shall investigate claim to establish validity and apportion liability.

Inquiry shall be addressed direct to agent of interested carrier whenever practicable, and to Freight Claim Officer only after failure to obtain information from agent or when necessary from nature of inquiry.

(*b*) When agent of another carrier fails to answer within twenty (20) days from date of inquiry, copy of inquiry, with request for reply, shall be sent by express, postal mail, or messenger, to Freight Claim Officer of delinquent carrier. When answer is not received within thirty (30) days to such request to Freight Claim Officer regarding a paid claim, paying carrier may, provided liability is not in its opinion located, charge full amount of claim to delinquent carrier, or if there are two or more delinquent carriers, then to delinquent carrier nearest paying carrier in direction of destination, and shall forward all papers relating to the claim to such delinquent carrier, who shall take the place of settling carrier, and make further investigation and distribution of amount of the claim.

(*c*) Claim shall be apportioned according to rules and rulings of the Freight Claim Association.

(*d*) Distribution Statement, Form —, shall be securely attached by paying carrier to each claim. When one carrier only is interested, statement and claim papers shall be set to it. When two or more other carriers are interested, original statement and claim papers shall be sent to most distant carrier and copy of statement showing disposition of claim papers to each other interested carrier. When paying carrier is an intermediate carrier, claim papers shall be sent to last interested carrier in direction of destination. Any interested carrier shall have the right to obtain papers from carrier with whom they are filed.

(*e*) When an amount charged in accordance with preceding paragraphs is for any reason unsatisfactory to debited carrier, it may be recharged to paying carrier within one year from date of first charge, and shall not again be charged until authorized or arbitrated. When interested carriers cannot agree on such recharge, amount shall be carried by paying carrier and case referred to Arbitration Committee for decision. Provided, that an amount not so recharged within one year as aforesaid shall not be subject to recharge except by agreement.

(*f*) No carrier shall be charged with an amount exceeding one hundred dollars ($100.00) on any one claim, until claim papers have been submitted to its Freight Claim Officer, and authority for such charge given.

(*g*) Claim in which non-member line is interested does not come under this rule.

(*h*) Fast Freight Line ogranizations handling claims shall be considered as carriers.

The following covers the accounting features of the plan tentatively adopted at Cincinnati:

SETTLEMENT OF INTERLINE CLAIMS BETWEEN CARRIERS.

The following plan, having been endorsed by a committee of the Association of American Railway Accounting Officers, is recommended to members of The Freight Claim Association:

On or before the 10th of each month, or weekly by special agreement, if necessary, to avoid a large accumulation), paying carrier shall render a statement on Form — of amounts due from each debtor carrier, with claim papers and distribution statements, to Freight Claim Officers as provided for in Freight Claim Association Rules, by express, postal mail or messenger. Draft may be made on or after the 25th of month for total of statement, or for balances as may be agreed upon by the interested carriers, which shall be paid by debtor carrier upon presentation.

While the plan is by no means perfect, it is believed by a large majority of the Association that it will bring about more expeditious methods in the settlement of interline claims and to a great extent wipe out the large suspense accounts, which are now being carried by nearly every railroad in the country.

A rule in relation to what constitutes delivery of cars to connecting line was adopted by the Association, having been agreed upon by a joint committee composed of representatives of the American Railway Association, Master Car Builders' Association, and the Freight Claim Association. The rule is as follows:

"Cars shall be considered as having been delivered to connecting railroad when placed upon track agreed upon and designated as the interchange track for such deliveries, said cars to be in safe, serviceable condition and accompanied or preceded by regular waybill or running slip, the receiving road to be the judge in cases not provided for in the Master Car Builders' rules. All defects existing at time of delivery to be designated by receiving road when car is first tendered, the liability for per diem for value of car and contents to commence immediately upon placing car on track for delivery and continue until car has been inspected and accepted or rejected by receiving line."

The committee on arrangements, consisting of Messrs. Writer, Tucker, Wing, H. A. Johnson, Jones and C. A. Johnson, of the

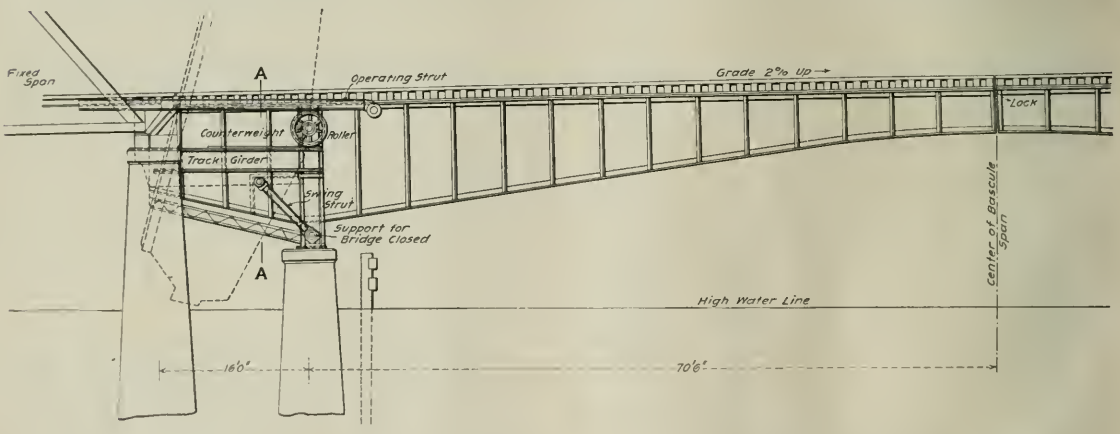
Colorado railroads, provided an elaborate programme for the entertainment of the members of the Association and their families, and most royally carried out the plans. A single pass, good for a month and bearing nine signatures, passed the members and their families over all the Colorado roads.

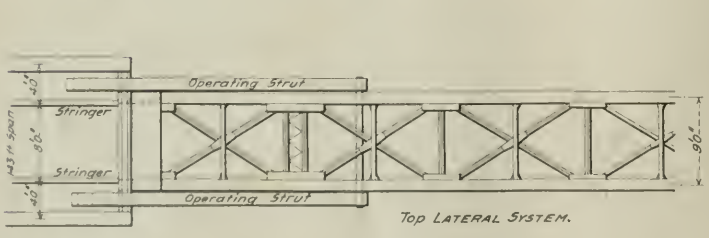
The next meeting of the Association will be held at Atlantic City in June, 1908. The officers elected were: R. C. Richards (C. & N.-W.), Chicago, President; W. S. Battle, Jr., (N. & W.), First Vice-President; J. S. Tustin (Mo. Pac.), Second Vice-President; W. P. Taylor (R., F. & P.), Secretary.

Rall Bascule Bridge over the Illinois River at Peoria.

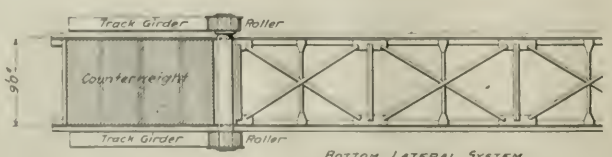
A double-leaf bascule bridge of the Rall type, the second of this type of bridge to be built, was completed recently at Peoria, Ill. The first Rall bridge is on the Pittsburg, Fort Wayne & Chicago line of the Pennsylvania Lines West of Pittsburg, across the Miami and Erie canal at Delphos, Ohio. It is a single-leaf, double-track span, 26 ft. $2\frac{1}{2}$ in. between supports, and has been in service several years. The Peoria bridge is the draw span for the Illinois river crossing of the McKinley Interurban Syndicate. It consists of

Rall Bascule Span in the Illinois River Bridge at Peoria for the McKinley Interurban Syndicate.

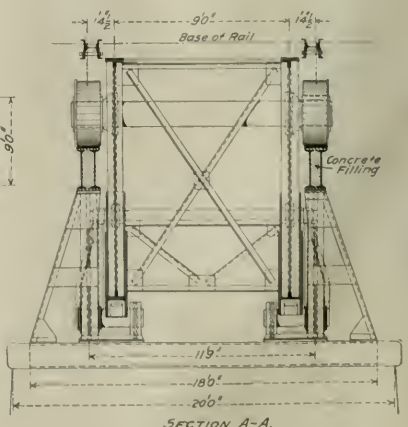




Top Lateral System.



Bottom Lateral System.



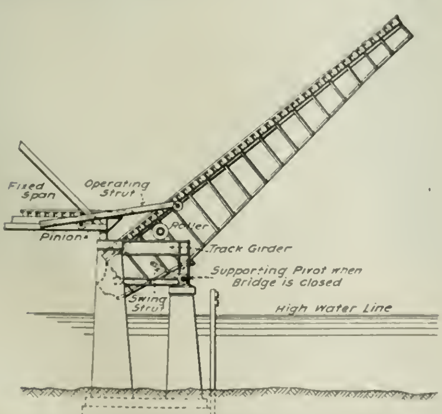
Section A-A.

Details of Rall Lift Bridge at Peoria.

four riveted through truss spans 142 ft. 10 in. center to center of piers, and the bascule span, which is 17[illegible] ft. center to center of back piers. The span between supports is 141 ft. and the clear opening at right angles to the river channel is 12[illegible] ft. It is a double-leaf deck bridge requiring no tail pits, as the grade is high above the water line, the head room at high water being 10 ft. 6 in.

Photographs and general drawings of the bascule span are shown herewith. The features peculiar to this type of lift bridge are as follows: The leaf is so counterweighted that the center of gravity coincides with the center of the roller shaft around which the leaf rotates. Each leaf has a pair of swing struts connected to the pier at one end and to the main girders at the other; also a pair of operating struts, which in the closed position are just outside of and approximately parallel to the top of the girders. On the bottom face of each operating strut is a rack which gears with a pinion back of the back pier, shown in the sketch of bridge in half-open position. These pinions are driven by a 25-h.p. motor, there being one for each leaf.

Rail Bascule Bridge in Open Position.



Sketch Showing Lift in Half Open Position.

In the closed position the bridge rests upon fixed supports on the piers and the rollers are lifted slightly above the track, and therefore are relieved of any load. When the leaf starts to open it first rotates around the point of fixed support until the rollers come to bearing on the track girders. Then as the pull on the operating struts continues, the swing struts, moving in the arc of a circle, draw the tail downward, and the entire leaf rolls back horizontally along the track girders as it revolves. The bridge is opened and closed in three quarters of a minute. Including the insertion of the tail and rail locks for both leaves, a complete operation requires two minutes. The operating machinery is below the deck, nothing showing above except the operator's house and the [illegible].

The advantages claimed for this type of bascule bridge are summarized as follows:

1. For the bridge closed the length of span is a minimum and equal to the distance center to center of river piers.

2. The length of travel of the bridge is a minimum, being just sufficient so that the tail part containing the counterweight will clear the river pier when the bridge is fully open.

3. The shop work on the bridge proper is simple and of a character that can readily be turned out by a bridge shop having ordinary facilities.

4. The wheels or rollers on which the bridge moves are solid steel castings having smooth treads. These castings may be made of any proportions that will be suitable. There are no rivets to give out. There is nothing to bind and the motion is smooth and noiseless.

5. The track girders for the Peoria bridge are double 24-in. I-beams with flange plates on top and bottom and track plates riveted to the top.

6. Should it be desirable to remove or repair the wheels it can readily be done, as the bridge in the closed position does not bear upon the wheels. For the same reason the track girders also can easily be removed or repaired without disturbing traffic over the bridge.

7. Besides the foregoing advantages, this type of bridge is very economical both as to quantities and cost.

The bascule bridge was designed and the superstructure built by the Strobel Steel Construction Company, Chicago. The engineer for the McKinley Syndicate is Ralph Modjeski, Chicago. Four additional bridges of the Rall type, with through instead of deck girders without pits, are being built by the Strobel Company at Indiana Harbor, Ind. Two are for the Lake Shore & Michigan Southern, one for the Baltimore & Ohio and one for the Pennsylvania Lines. They are single-leaf, double-deck spans, 86 ft. between supports.

The Elliot Junction Collision.

The British Board of Trade has published its report on the disastrous rear collision which occurred in a snowstorm in Scotland, December 29, when 22 passengers and employees were killed; and the accident appears to have been due principally to the fact that the engineman was under the influence of liquor. The report was issued late in April, but it is dated February 26. It says nothing about the punishment of the engineman, but from a recent press despatch it appears that he was sentenced to five months' imprisonment on a charge of manslaughter. This sentence was subsequently reduced by the court to three months. The place where this collision occurred was Elliot Junction, on the Dundee & Arbroath Joint Railway, owned jointly by the Caledonian and the North British companies. The negligent driver, George Gourlay, is 60 years old and has been in the service 47 years, with a good record.

While the explanation of the collision is thus in a sense quite simple, the 50-page report of Major J. W. Pringle gives many circumstances which will be of interest to the American reader. Major Pringle gives his conclusions under seven heads: (1) the situation on the line; (2) the driver and his conduct; (3) a discussion of the different explanations offered to account for the collision; (4) precautionary methods which might have been adopted; (5) minor matters; (6) summary of conclusions, and (7) proposals for the prevention of such collisions.

The train was running from northeast to southwest, and the engine was moving backward. The coal, piled high on the tender, interfered somewhat with the engineman's view ahead. The train had started from Arbroath about 3.14 p.m., and after running 1½ miles it struck a standing train at Elliot Junction, having passed distant and home signals which were against it. Owing to the severe and unusual snow and wind, block working had been suspended and the train was running under a "time interval and caution" rule, the requirement being practically that enginemen run constantly under control. The standing train had been held at Elliot Junction because of the derailment of a freight train a short distance ahead. The station master had just decided to take the passengers out of the standing train, but the collision occurred before this purpose could be carried out.

It appears that Engineman Gourlay had been repeatedly warned that block working had broken down, both wires and poles having

failed. The preceding train had been gone from Arbroath 10 minutes.

In discussing the time interval rule Major Pringle says that safety is dependent, firstly, on the preservation of a time interval, and, secondly, caution on the part of engine drivers. He lays no responsibility on the leading train.

The chief guard of this passenger train was riding in his van next to the engine, and says that he could see nothing at all out of his window; for the last half of the journey from Arbroath the speed was increased, he estimated, from 20 miles an hour to 25 or 30.

The Government inspector tries to fix the exact time that the collision occurred, and makes detailed comparisons of clocks, but, as in most other cases of this kind, his conclusions concerning the accuracy of different clocks and, as deduced therefrom, the speed of the train, are of little or no value.

The signals approaching Elliot Junction are 35 to 40 ft. high with the sky for a background. The engineman made some claim that the signals were off, but the distant signal had not been used since the night before, so it is hardly possible that it was workable at this time. Many of the signals drooped, and three minutes after the collision the home signal drooped 10 deg., but it was clearly a danger signal.

Under the head of explanations, Major Pringle considers first the suggestion that Gourlay had lost his way; but there are many landmarks along the line, and this theory is untenable. The coal on the tender made an obstacle, but with such high semaphore signals the view is not seriously obstructed. Running with the tender ahead is objectionable, but Major Pringle does not lay down an absolute rule condemning the practice; though the management of the road is warned that it is resorted to more frequently than is necessary; it should be discouraged. The reason that this engine was not turned was that the turntable was obstructed by snow, but the inspector holds that if the station agent or the engineman had really been determined to have the engine turned, it would have been reasonably possible, though the trackmen were overworked at all points and many switches and crossovers, covered deep with snow, had been neglected. Several other enginemen had run their engines backward that day with success.

After the collision Gourlay was pinned down in his cab for half an hour. He was then taken out and soon after given by some one three-quarters of a glass of brandy. Shortly afterward a policeman noticed his apparently intoxicated condition and called three physicians to examine him. These doctors concluded that this brandy which he took after the collision was not sufficient to fully account for the alcoholism observed. Before leaving Arbroath, Gourlay's train had been standing at or near the station about three or four hours, and at one time the cab of the locomotive was filled with passengers. Gourlay had drank out of a bottle in the cab, apparently brought there by some passenger, and he had been treated to 3 pence worth of whisky at the Victoria bar, which was close to the platform. A porter and two other men who saw Gourlay in the cab at one time thought he had been or was going to be sick. Yet when he ran his engine around the train, just before starting, he performed the operations with all reasonable steadiness and care. In the face of the conflicting evidence Major Pringle finds it "a difficult and invidious task" to decide as to Gourlay's condition. The inspector says:

> His previous record and character, as well as his behavior on the downward journey, prove that he was normally a careful driver. There must be some reason to account for the unusual carelessness shown on the upward journey. If it is true that he took no more than two half glasses of whiskey, whilst waiting at Arbroath, it is evident that this amount of alcohol could not have caused the effects noticed by Morrison, Briggs and Whitton. There is nothing to show that he was out of health, or suffering from any illness, which would account for the strangeness in his appearance and conduct which they observed. He was accustomed to work his train from Arbroath to Dundee as an express, without stopping at any intermediate stations. It is possible that he did not fully understand the special instructions given to him on this occasion. Confusion of ideas or deadening of faculties may account for his conduct. The evidence suggests no cause for such confusion, or lack of alertness, other than the bemusing effects of either extreme cold or of alcohol. The cold, admittedly severe, more especially in the unprotected position of tender first, could hardly, in so short a time as two or three minutes, have alone produced such a serious effect on a robust constitution. I have, therefore, most reluctantly, been forced to accept the alternative, and give it as my opinion that the lack of intelligence or of caution and alertness, displayed by driver Gourlay on this occasion were in part, at all events, induced by drink, the effects of which may possibly have been accentuated, after he left Arbroath, by exposure to weather.

Considering now possible precautionary measures, Major Pringle decides that when block working has broken down all semaphores should be kept at danger, and the signals to enginemen be given by hand. There is no general rule on the Joint line, and some of the signalmen did this while others did not. At Elliot Junction the home signals were used to admit trains to the station. This should not have been done. All of the arms were in an imperfect position. Where a driver, reaching a home signal, is not near enough to see a flag in the signal box a flagman should be appointed to stand at the signal. In a blinding snowstorm fogmen with torpedoes should be stationed at the distant signals, but this was not done in this case, and it appears that the Joint line has always done without fogmen. The explosion of a torpedo at the distant signal would, in all probability, have prevented this collision by arousing Gourlay. The claim that the guard of the standing train at Elliot Junction should have sent out a man with torpedoes is not admitted. Major Pringle holds that a train protected by home and distant signals, as in this case, need not send out a man.

Under his fifth head Major Pringle criticises a general inefficiency which he found in many things. Telegraph and telephone communication was interrupted, but the station agents, inspectors and others took little care to keep in touch with each other by extemporized methods. The derailed freight train blocked one track at 8 a.m., but systematic single-track working on the other track was not established until 2 p.m. Certain superintendents interested were not advised of this disaster until after 11 p.m. The Joint line is 17 miles long. There are 95 men employed on the track; but this was the worst storm known in 15 years, and somebody ought to have engaged additional men, if possible. Snow plows were run over the road backward because turntables were not properly cleared of snow. The Joint line has no cars or engines of its own, and the separate roads each send their own men over it. This leads to division of responsibility and to poor discipline. Wrecking cars and even jacks are insufficient and not properly located. Evidence of lack of discipline appeared from the presence of passengers in the cab of the engine at Arbroath; and the proximity of the Victoria bar is "a very undesirable feature."

Under the sixth head driver Gourlay is found to have received repeated and very explicit instructions to drive with caution and to stop at all stations. He passed the distant and home signals at Elliot Junction without having applied his brake, and ran 400 ft. beyond the home signal. The proper place for him to come to a full stop was about 300 ft. farther. It is evident that he was not prepared to stop at the platform. He broke the rules in leaving his engine while waiting at Arbroath, and his disregard of discipline, with other circumstances, forces the inspector to "conclude, most unwillingly, that his conduct was to some extent due to the effects of alcohol." He had been on duty about nine hours. The inspector then goes on to summarize other points mentioned above; and next, taking up his seventh section, considers, first, speed indicators, which are largely used on Continental railways and which in some countries are required on all engines. Speed indicators have been improved so that now they are reliable, but there is no evidence that they would be useful in the prevention of collisions like this. The driver himself must determine the speed which particular circumstances call for.

A third man in the cab is next considered, but the expense of this would be a serious obstacle, and there is not much space available in the cab. Unless the complete control of the steam and brake gear is placed in the hands of the third man, it will be difficult to hold him primarily responsible for safety; and if we do thus hold him, then he will be in exactly the same position as a driver is at present, and the office of driver would practically become a sinecure; therefore, Major Pringle does not support this suggestion. It would be better to adopt automatic stops. These are now in use on the underground railways in London, and have been found reliable at speeds as high as 35 miles an hour. Other railroads are trying automatic fog machines and bells and whistles on engines. None of these arrangements, however, have yet stood the test of time sufficiently long to be at present accepted as fully reliable. It has been proposed to have larger and stronger poles for the electric wires, so as to prevent the failure of block working; but Major Pringle thinks the only practicable remedy would be to have poles set nearer together. Putting wires under ground is the best remedy, but that would be very costly, and only in exceptional circumstances would the expense be justified.

Salaries on Hungarian State Railroads.

The Hungarian State Railroads have recently adopted a new scale of salaries for their officials. With each salary is an allowance for house rent, and this allowance varies with the localities where the employee is stationed. The officials of lowest class are to receive $320 to $480 per year, with allowances of $80 to $160 for rent. Such of them as are graduates of technical schools have a minimum salary of $460. There are two classes of engineers, with $580 salary and $180 house money for the lower and $760 salary and $200 house money for the higher class. Moreover, engineers of the latter class are entitled to an advance of $60 a year after five years and another $60 after 11 years' service. A "chief engineer" has $1,000 a year and $250 house money. Three grades of superintendents have $1,080, $1,200 and $1,320 a year, with $210 to $300 house money; "general superintendents" get $1,440, $1,560 and $1,680 salary, with $320 to $360 house rent; a general manager, $2,400 salary and $500 house rent; while the President has $3,000 salary and $600 house rent. The offices are not quite the same as those designated by these names in this country.

Four New York Public Service Commissioners.

William R. Willcox was born at Smyrna, N. Y., in 1863. He was educated at the University of Rochester and at Columbia Law School. In 1900 he was a candidate on the Republican ticket for Congressman from the Thirteenth district, but was defeated by a small majority. Later he was appointed to the New York City Park Commission by Mayor Low. While in this office he did much to establish public playgrounds, gymnasiums and parks. He was appointed Postmaster of New York City in 1905. Mr. Willcox is President of the Grand River Irrigation & Development Company and of the Willcox Canal Company.

Thomas Osborne, of Auburn, N. Y., was born in that city in 1859. He was educated in the Auburn public schools and Adams Academy at Quincy, Mass., and graduated from Harvard University in 1884. He then began work in his father's farm tool factory, of which later he became the head. He was a member of the Auburn Board of Education from 1885 to 1888, and also from 1893 to 1896. He was a delegate to the Democratic National Convention in 1896 and ran for the office of Lieutenant-Governor on the Independent Citizen Union Ticket in 1898. From 1902 to 1905 he was Mayor of Auburn. Mayor Osborne has always been greatly interested in prison reform and in the workings of the Civil Service law. In a speech which he made before the Civil Service Reform this spring, he showed with earnestness and breadth of view the difficulties which strict enforcement of civil service tenure places on officials whose primary concern is efficient administration.

T. M. Osborne.

M. S. Decker.

James E. Sague.

James E. Sague, of New Hamburg, was born in Poughkeepsie, N. Y., in 1862. He was educated at the public schools and graduated as a Mechanical Engineer from Stevens Institute in 1883. He began railroad work on the Chicago, Burlington & Quincy, and afterwards went to the Erie. He spent two years on the Jamaica Railroad in the West Indies, and then went to the Schenectady Locomotive Works of the American Locomotive Company. He was Chief Mechanical Engineer of this company for six years, and was then made Assistant Vice-President and finally First Vice-President in charge of Engineering and Manufacture. He resigned this position on March 1 of the current year.

Martin S. Decker, of New Paltz, is now Assistant Secretary of the Interstate Commerce Commission. He was born at Rosendale in 1858. After a public school education he began work as a telegrapher. He later studied law and held several positions in Ulster County, when he was made Assistant Secretary to the Interstate Commerce Commission in 1887, and has frequently taken evidence as a Deputy Commissioner.

The Italians have made the discovery that one of the results of sundry reductions of railroad rates, accompanied by increases in wages of employees, both prescribed by law, has been an increase in the percentage of working expenses. Thus, gross earnings increased 23½ per cent. from 1895 to 1901, and 37 per cent. from 1901 to 1907; but meanwhile wages increased 12½ per cent. in the first period and 45 per cent. in the last, when the advances in pay and reductions in rates took place. The working expenses, which were 66 per cent. of the gross earnings in 1895 and 67½ per cent. in 1901, will be 70 per cent. the current year (ending with June). The pay of employees absorbs 49 per cent. of the earnings this year. Of the increase of earnings in the first period, 22 per cent. went to the employees; in the second period, 45 per cent. The chief changes in wages were made before the state began to work the railroads two years ago.

American Society for Testing Materials Specifications for Steel Rails.

At the annual meeting of the society in 1906 the report of Committee A on standard specifications for steel rails was referred back to the committee with instructions to report at the next annual meeting proposed standard specifications for steel rails which would give promise of correcting as far as possible the defective quality of rails obtained under existing specifications. A sub-committee consisting of W. A. Hostwick, P. E. Carhart, Charles B. Dudley, E. F. Kenney, Edgar Marburg, George E. Thackray and W. R. Webster, was appointed to prepare these specifications, which were accepted at the last meeting and referred to letter ballot for adoption.

STANDARD SPECIFICATIONS FOR STEEL RAILS.

(1) (a) The entire process of manufacture and testing shall be in accordance with the best current practice, and special care shall be taken to conform to the following instructions:

(b) Ingots shall be kept in a vertical position in the pit heating furnaces until ready to be rolled or until the metal in the interior has time to solidify.

(c) No bled ingots shall be used.

(d) There shall be sheared from the end of the blooms formed from the top of the ingots not less than — per cent., and if, from any cause, the steel does not then appear to be solid, the shearing shall continue until it does.

(2) Rails of the various weights per yard specified below shall conform to the following limits in chemical composition.

	—Per cent.—				
	50 to 59 lbs.	60 to 69 lbs.	70 to 79 lbs.	80 to 89 lbs.	90 to 100 lbs.
Carbon	0.35-0.45	0.38-0.40	0.40-0.50	0.43-0.53	0.43-0.55
Phosphorus shall not exceed	0.10	0.10	0.10	0.10	0.10
Silicon shall not exceed	0.20	0.20	0.20	0.20	0.20
Manganese	0.70-1.00	0.70-1.00	0.75-1.05	0.80-1.10	0.80-1.10

(3) One drop test shall be made on a piece of rail not less than 4 ft. and not more than 6 ft. long, selected from every fifth blow of steel. The test shall be taken from the top of the ingot. The rail shall be placed head upwards on the supports, and the various sections shall be subjected to the following impact tests under a free falling weight:

Weight of rail, lbs. per yard.				Height of drop
45 to and including			55	15 ft.
More than	55	" "	65	16 "
	65	" "	75	17 "
	75	" "	85	18 "
	85	" "	100	19 "

If any rail break when subject to the drop test, two additional

tests, taken from the top of the ingot, will be made of other rails from the same blow of steel, and if either of these latter tests fail, all the rails of the blow which they represent will be rejected, but if both of these additional test pieces meet the requirements, all the rails of the blow which they represent will be accepted.

(4) The number of passes and speed of train shall be so regulated that on leaving the rolls, at the final pass the temperature of the rail will not exceed that which requires a shrinkage allowance at the hot-saws, for a 30-ft. rail of 100 lbs. section, of $6^{11}/_{16}$ in., and $^1/_{16}$ in. less for each 5 lbs. decrease of section. These allowances to be decreased at the rate of .01 in. for each second of time elapsed between the rail leaving the finishing rolls and being sawn. No artificial means of cooling the rails shall be used between the finishing pass and the hot-saws.

(5) The drop testing machine shall have a tup of 2,000 lbs. weight, the striking face of which shall have a radius of not more than 5 in., and the test rail shall be placed head upwards on solid supports 3 ft. apart. The anvil block shall weigh at least 20,000 lbs., and the supports shall be part of, or firmly secured to, the anvil. The report of the drop test shall state the atmospheric temperature at the time the test was made.

(6) The manufacturer shall furnish the inspector, daily, with carbon determinations for each blow, and a complete chemical analysis every 24 hours, representing the average of the other elements contained in the steel, for each day and night turn. These analyses shall be made on drillings taken from a small test ingot.

(7) Unless otherwise specified, the section of rail shall be the American standard, recommended by the American Society of Civil Engineers, and shall conform, as accurately as possible, to the templet furnished by the railroad company, consistent with paragraph No. 8, relative to specified weight. A variation in height of $^1/_{64}$ of an inch less, or $^1/_{32}$ of an inch greater than the specified height, and $^1/_{16}$ in. in width will be permitted.

(8) The weight of the rails will be maintained as nearly as possible, after complying with paragraph No. 7, to that specified in contract. A variation of one-half of 1 per cent. for an entire order will be allowed. Rails shall be accepted and paid for according to actual weights.

(9) The standard length of rails shall be 30 ft. Ten per cent. of the entire order will be accepted in shorter lengths, varying by even feet to 24 ft., and all No. 1 rails less than 30 ft. shall be painted green on the end. A variation of one-fourth of an inch in length from that specified will be allowed.

(10) Circular holes for splice bars shall be drilled in accordance with the specifications of the purchaser. The holes shall accurately conform to the drawing and dimensions furnished in every respect, and must be free from burrs.

(11) Straightening.—Care must be taken in hot-straightening the rails, and it must result in their being left in such a condition that they shall not vary throughout their entire length more than 5 in. from a straight line in any direction when delivered to the cold-straightening presses. Those which vary beyond the amount or have short kinks shall be classed as second-quality rails and be so stamped.

The distance between supports of rails in the gagging press shall not be less than 42 in.

Rails shall be straight in line and surface when finished—the straightening being done while cold—smooth on head, sawed square at ends, variation to be not more than $^1/_{32}$ in., and, prior to shipment, shall have the burr occasioned by the saw cutting removed, and the ends made clean. No. 1 rails shall be free from injurious defects and flaws of all kinds.

(12) The name of the maker, the weight of rail and the month and year of manufacture shall be rolled in raised letters on the side of the web, and the number of blow shall be plainly stamped on each rail where it will not subsequently be covered by the splice bars.

(13) The inspector representing the purchaser shall have free entry to the works of the manufacturer at all times when the contract is being filled, and shall have all reasonable facilities afforded him by the manufacturer to satisfy him that the finished material is furnished in accordance with the terms of these specifications. All tests and inspections shall be made at the place of manufacture prior to shipment.

(14) No. 2 rails will be accepted up to ten (10) per cent. of the whole order. Rails that possess any injurious defects, or which for any other cause are not suitable for first quality, or No. 1 rails, shall be considered as No. 2 rails; provided, however, that rails which contain any physical defects which impair their strength shall be rejected. The ends of all No. 2 rails shall be painted white in order to distinguish them.

Mr. Webster in presenting the specifications, said:

If the important factors that have a direct bearing on the quality of the finished rail are considered, most of the conflicting opinions can be harmonized. The committees at work on the problems are doing this. They are endeavoring to secure good uniform methods of manufacture by specifying chemical composition, amount of discard from top of ingot, finishing temperature in rolling, limit of camber in rails coming to the gag press for cold straightening, and drop tests. They are nearer together now on these requirements than ever before, and it is to be hoped that a specification will soon be arrived at, by interchange of views, which will be acceptable to all.

It must be admitted that the best rails are produced from steel low in phosphorus, rolled with light reductions and finished at proper low temperature; but the sections now in use make it almost impossible to continue the work of rolling on the head to a low enough temperature to produce the fine grained structure desired. Therefore, a good starting point for discussion would be in reference to section.

In a recent discussion it was claimed that the old committee of the American Society of Civil Engineers kept in mind the importance of low-finishing temperature, in designing their rails, and gave sections best suited for that purpose. As a matter of fact, the effect of the heat treatment of steel was not properly appreciated at the time the committee made its report, in 1892, and the sections do not permit of a low enough finishing temperature in rolling, owing to the wide, thin flanges. This, to a large extent, has caused the great trouble with 100-lb. rails rolled to these sections. Other 100-lb. sections gave trouble, and on March 25, 1901, I wrote to the American Society of Civil Engineers, asking for a new rail committee to investigate and report on standard rail sections. The committee was appointed in 1902. It is still struggling with the problem. In the arguments against the appointment of such a committee it was claimed that sufficient evidence had not been produced to show that the heavier rail sections were not giving as good results as the lighter. Those present to-day must admit that the results of the past five years have given conclusive evidence that a change in section is advisable.

It has been the invariable experience in changing from a light to a heavy section in any class of rolled steel, that difficulties have been met and modifications have been made in the methods of rolling, in order to get as good a structure in the heavier section as was formerly obtained in the lighter section. In ordinary sections other than rails, it was a comparatively easy matter to overcome the trouble and get a good structure; but the thin flange of the rail and the higher carbons called for in the heavier sections further complicate matters.

If a rail with the same width of head as the present American Society of Civil Engineers 100-lb. rail is required, the head will have to be made thicker and the radius under the head larger, in order to prevent the sides of the head from shearing or breaking off, as at present, and more metal put in the web and flange in order to carry the heat and thus allow the head to be finished at the proper low temperature. This would mean a rail of 120 to 125 lbs. per yd. I believe we are coming to heavier rails before we get rid of our present troubles.

In all justice, it must be admitted that a fair percentage of breakages is caused by the great increase of wheel loads since 1892, increase in speed of trains, use of large capacity steel cars; also that we do find poor track, poor rail joints, driving wheels not properly counterbalanced, flat wheels, etc. These conditions will no doubt be improved, but they must be considered in deciding on the rail for the future.

Open-hearth steel rails of the present weight and section, rolled under the present conditions of manufacture, cannot be relied on to overcome all troubles. Most of the basic open-hearth steel manufactured in this country is much lower in carbon than is required for rail steel, and it is therefore much easier to control the uniformity of such steel. The common practice of Bessemer steel rail mills is to allow 10 points leeway in carbon, and some of the basic open-hearth mills claim to work within these limits, but even as high as 18 points leeway has been asked. It is easier to work within narrow limits of carbon in the acid open-hearth steel process than in the basic.

What is wanted is a steel as nearly uniform in carbon and other chemical elements as possible without inflicting too great hardship on the manufacturer. We desire full expression of opinion from the basic open-hearth steel manufacturers as to just what chemical requirements and limits they would agree to work to in rail steel.

It would be a very simple matter to roll a thousand tons of extra heavy rails of basic open-hearth steel, and one thousand tons of the same section of Bessemer steel, with enough metal in the web and flange to finish them in rolling at the lowest possible temperature without injuring the metal in the flange. In other words, approach as nearly as possible the rolling conditions of the old bullhead rail, which has been rolled with only 4½ in. shrinkage allowance in a 30-ft. rail. Let the chemical composition, per cent. of discard, and conditions of manufacture be in accordance with best modern practice. The expense of preparing rolls and rolling such rails would be trifling in comparison with the information obtained, and the rails would be better than any heavy rails ever rolled.

Recommended Uniform Car Service Rules.

The following uniform car service rules were adopted by the National Association of Car Service Managers in annual convention at Cincinnati, Ohio, May 28-30, 1907, and were recommended for adoption by all railroads. The first set of similar rules was recommended by this association in 1902. These were revised in 1904 and have been further revised this year. They are, however, substantially the same as those twice previously recommended. The proposed rules follow.

RULE 1
CARS SUBJECT TO RULES.

(A) Cars held for or by consignors or consignees, for loading, unloading, forwarding directions, or for any other purpose are subject to the following car service rules.

(B) Cars loaded with live stock, and through consignments not held for orders are not subject to these rules.

RULE 2.
TIME ALLOWED

(A) On all commodities for loading or unloading, forty-eight (48) hours (two days) will be allowed.

(B) On cars re-consigned, held or stopped in transit upon request of consignor or consignee, or by reasons attributable to them, twenty four hours, one day, will be allowed.

(C) When cars are interchanged with minor railroads or industrial plants performing their own switching service, they handling cars for themselves or other parties, an allowance of twenty four (24) hours (one day) will be made for switching in addition to the regular time allowed for loading or unloading, the time to be computed from first 7 a. m. following delivery upon interchange tracks until return thereto.

(D) Freight in bond will be allowed forty-eight (48) hours (two days) for removal after permit to receive goods is issued to consignee by Collector of Customs.

(E) Cars containing freight consigned locally to the ocean or gulf ports, will be subjected to the forty-eight (48) hour car service rule, except that on shipments for coastwise movement via steamers and all freight for foreign export a maximum of ninety-six (96) hours will be allowed when the terminal agent is advised within forty-eight (48) hours after arrival of freight that such disposition will be made of same, the railroad reserving the right to unload the cars at any time it may see proper.

RULE 3.
COMPUTING TIME.

NOTE.—In computing time, Sundays and legal holidays are excluded.

(A) Time will be computed from the first 7 a. m. after cars are placed on public delivery tracks for loading.

(B) Time will be computed from the first 7 a. m. after notice of arrival when cars are held for orders, and from first 7 a. m. after placing on public delivery tracks when cars are held for unloading.

(C) On cars to be delivered on private tracks time will be computed from the first 7 a. m. after placing on such tracks, or after notice to consignee of readiness to so place the same.

(D) The placing of a car upon a private track, or notice to consignee of readiness to so place the same, shall be considered notice of delivery.

(E) Prompt notice shall be given by agents to consignees of the arrival of all freight subject to these rules.

RULE 4.
CAR SERVICE CHARGES.

(A) At the expiration of time allowed a charge of $1.00 per car per day or fraction thereof will be collected for detention of all cars held for loading or unloading, or subject to order of consignor, consignee or their agents.

(B) When both cars and tracks are owned by the same private party no charge will be made while cars are on such private tracks.

RULE 5.
PLACING CARS.

(A) Cars containing freight to be delivered on public delivery tracks or private sidings shall be placed immediately upon arrival, or as soon thereafter as the ordinary routine of yard work will permit. When delivery cannot be made on specially designated tracks, on account of such tracks being fully occupied, or for any other reason beyond the control of the carriers, delivery shall be made at the nearest available point.

(B) Cars for unloading shall be considered placed when such cars are held awaiting orders from consignor or consignee, or for the payment of freight charges, or surrender of bill of lading.

(C) The delivery of cars consigned or ordered to private tracks shall be considered to have been effected when such cars have been placed on the tracks designated, or if such tracks be full, when the railroad tenders cars by giving written notice of their arrival.

(D) Cars for loading shall be considered placed when such cars are placed, or held upon orders of shippers.

(E) If a car is placed for unloading and is reloaded by the same party each transaction shall be considered as independent of the other. If loading is begun before unloading is completed, car must be recorded as released from unloading, and placed for loading at the time loading is begun, and the time for loading will be computed from first 7 a. m. thereafter.

(F) When empty cars placed for loading on orders are not used, car service will be charged from first 7 a. m. after placing or tender, until released, with no time allowance.

RULE 6.
DECLINING TO RECEIVE CARS FROM CONNECTING LINES.

In cases where any railroad is unable or unwilling to receive freight tendered by another to be placed for delivery, it shall promptly notify the line tendering of its inability to receive, in order that proper notice may be given to consignee or consignor that delivery cannot be effected, and that request may be made for other disposition of the freight. Should such freight not be disposed of within [illegible] allowed after notice has been served upon consignee or consignor in accordance with the above car service will be charged.

RULE 7
CLAIMS.

Claims for relief or refund of charges accruing under these rules should in each case plainly state upon what ground any refund or relief is requested. Paid expense bills must be attached to claims for refund.

Car service charges may be refunded, waived, or cancelled under the following conditions:

(A) In case of overcharge or error in the assessment of charges.

(B) In case of failure on the part of the delivering railroad to properly handle freight, when such failure is directly responsible for the charges.

(C) In case extreme cold weather, rain or snow interferes with or prevents the loading or unloading of freight within the time allowed by these rules.

(D) In the event of unavoidable failure or breakdown of the machinery necessarily used in the loading or unloading of cars, when charges directly result from such failure, or breakdown, a refund of fifty (50) per cent. may be made.

(E) In case fires or strikes interfere with or prevent loading or unloading of freight, a refund or cancellation of fifty (50) per cent. may be made.

(F) In case freight cannot be disposed of by sale for sufficient amount to realize both freight and car service charges.

(G) In case of bad order, cars held on minor o rindustrial railroads for repairs, refund or cancellation of fifty (50) per cent. may be made.

Proposed New Union Passenger Station at Buffalo.

For more than 20 years the city of Buffalo and the 13 railroads entering that city have been trying to agree on a plan for a Union passenger station and the consolidation of the local freight terminal facilities. Numerous commissions have been appointed by the Mayor and the merchants of Buffalo to consult with the railroads and to formulate plans for the consolidation of the freight and passenger terminals. No less than six different sites have been considered. Three years ago the city commission which was then serving recommended, with the approval of all of the railroads, a plan for a Union station at the foot of West Genessee street. A definite offer was made to the city by the railroads that they would unite in the construction of a Union station on this site provided the city would undertake the opening and changing of a number of streets and canals. This offer was not accepted and for a time the agitation rested. There were serious objections to this site from an operating standpoint, chiefly the lack of room for adequate future expansion, but as it seemed to have many advantages in location by reason of its being near the business center and the center of population the railroads agreed to accept the plan.

Many studies have been made for the location of a Union passenger station on what is known as the Exchange street site extending as far west as Main street and south to Perry street. This ground is at the present time occupied by the freight and passenger terminals of the New York Central lines and the Erie. The principal objections to this site, however, are: (1) The necessity of scattering the present local freight terminals to remote parts of the city; (2) lack of room for future expansion; (3) interference between freight and passenger traffic due to grade crossings, and the fact that such a station would require an arrangement of stub tracks. Other sites have been suggested at Lafayette square, Driving Park and Eagle street, but none of these meets any of the requirements.

After the failure to agree with the city on the terms under which the Genessee street site could be acquired, the municipal commission resigned in disgust and it was not until about a year ago that the present commission, consisting of Henry J. Pierce, Carl Machener and W. H. Gratwick, was appointed. The railroad companies appointed a committee consisting of W. J. Wilgus (New York Central), Samuel Rea (Pennsylvania Railroad), and J. M. Graham (Erie). On June 11, 1907, this joint committee submitted a report recommending the construction of a Union station on the so-called Fillmore site, and with the report presented a proposed plan for a Union passenger station at that point and for the consolidation of the local freight terminals at Exchange street on the ground now occupied by the passenger and freight stations of the New York Central Lines and the Erie. While these plans are little more than a preliminary study, they indicate the advantages to all concerned of the entire rearrangement of the passenger and freight facilities in Buffalo. The Fillmore site has long been considered by most of the railroads as the most advantageous location in the city, and even before the Genessee street site was agreed upon its adoption had been strongly urged. It covers a large tract of land now occupied by the East Buffalo freight and stock yards of the New York Central lying between William street and Bailey avenue. It is about 1½ miles long and contains 300 acres free from intersecting streets. The New York Central is now building a large new yard near Gardenville on the Terminal Railway of Buffalo, on the completion of which all of the East Buffalo facilities will be transferred there. The ground thus to be vacated will then be available for the Union passenger station. While a passenger station built here would be farther from the business center of the city than the present passenger station, it would be much more

North Front of Proposed Union Station at Buffalo.

convenient to the largely growing population in the east, south and northern sections of the city. By widening William street and opening a new boulevard from the intersection of Broadway and Fillmore parkway to and under the passenger station to a connection with William street two fine thoroughfares would be opened between the business section of the city and the new terminal. Fillmore parkway intersects all of the streets in the residential section west of Main street and would thus afford convenient communication with the new terminal without the necessity of passing through the congested business streets. A further scheme for making the station more accessible is the electrification of the present Belt Line, which could be used as a distributing loop for suburban trains of all of the railroads making local stops at the intersections with the principal streets. A large station could be built at the Terrace convenient to the business and residential sections, and at this station passengers could buy through tickets and check baggage before taking a belt line train to the Union station. Similar facilities could be provided at other important stations.

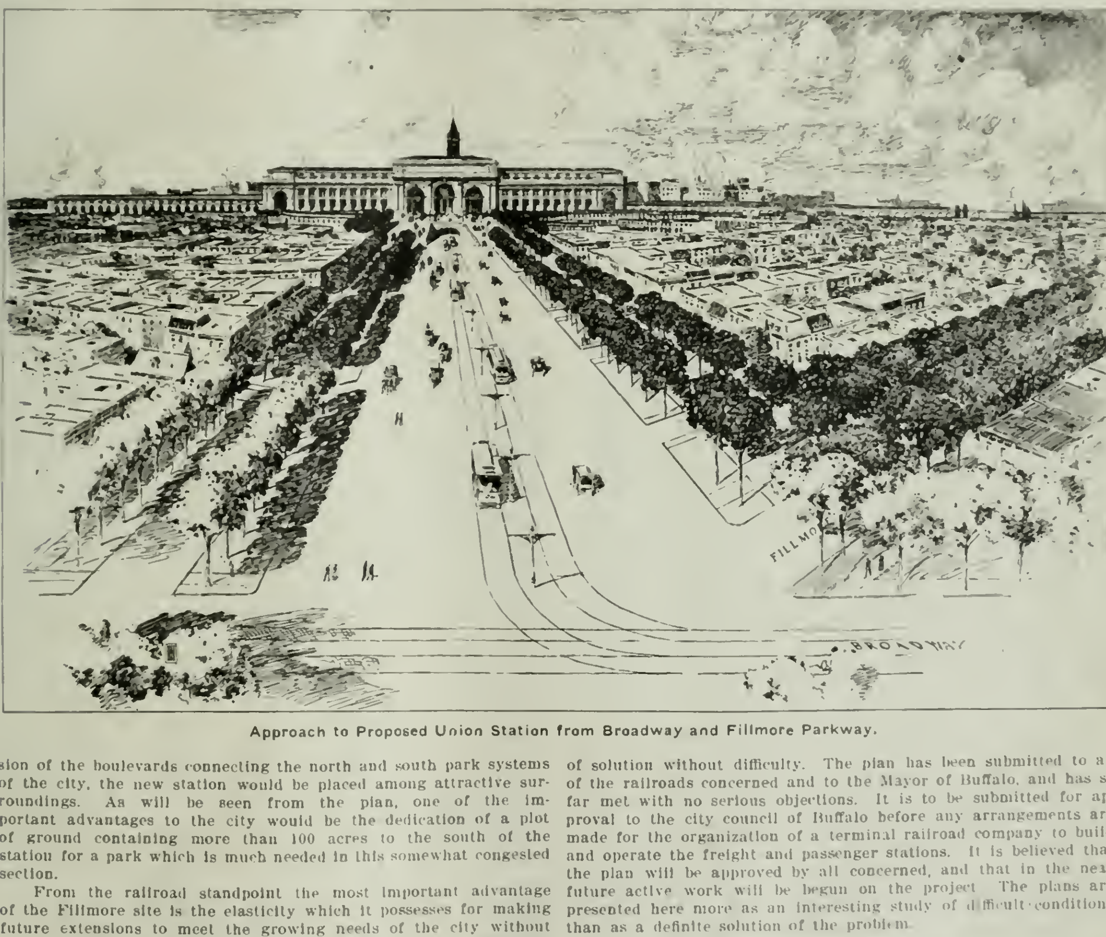
The street-car system could be easily adjusted to the conditions so that on the average no more time would be consumed in reaching the station from the residential sections than is now required to reach the present isolated stations. With the extension of the boulevards connecting the north and south park systems of the city, the new station would be placed among attractive surroundings. As will be seen from the plan, one of the important advantages to the city would be the dedication of a plot of ground containing more than 100 acres to the south of the station for a park which is much needed in this somewhat congested section.

From the railroad standpoint the most important advantage of the Fillmore site is the elasticity which it possesses for making future extensions to meet the growing needs of the city without any radical changes or reconstruction. Ample ground is available for adding future facilities which would take care of business for many years to come. Another point hardly less important is the fact that the station could be built without the least interference to traffic on any of the roads. The ground would be available for building even before all of the present yards are transferred to Gardenville, and the entire station and yards could be completed without interfering in any way with the present passenger or freight terminals of any of the roads. When completed and occupied the present terminals could be abandoned and the reconstruction and consolidation of the freight stations begun.

The adoption of this site for a Union passenger station will permit the centralization of the local freight terminals of all the railroads near the [illegible] of the city on an area of approximately 100 a[illegible] Washington, Scott and Hamburg streets. Buffalo would then have [illegible] terminals which, for convenien[illegible] of location [illegible] retail merchants and manufacturers and efficient operating features would not be equalled in any other city in the country. The business streets connecting with the freight houses and team tracks lead to the shipping districts without any steep grades or grade crossings of railroad tracks. A great saving of time and money to shippers would be made possible by this consolidation as mixed shipments for various lines could be delivered with a minimum loss of time.

In connection with the freight houses and team tracks the studies show large storage yards with independent switching leads and an absence of interruption of operation by passenger trains together with direct connections to the main outlying yards of the several railroads.

The accompanying maps and sketches of the proposed passenger station show the general features of the scheme as proposed. While they are, of course, tentative, they are the result of a careful study of all of the conditions, and it is believed that the many details of freight and passenger connections in and out are entirely possible of solution without difficulty. The plan has been submitted to all of the railroads concerned and to the Mayor of Buffalo, and has so far met with no serious objections. It is to be submitted for approval to the city council of Buffalo before any arrangements are made for the organization of a terminal railroad company to build and operate the freight and passenger stations. It is believed that the plan will be approved by all concerned, and that in the near future active work will be begun on the project. The plans are presented here more as an interesting study of difficult conditions than as a definite solution of the problem.



Approach to Proposed Union Station from Broadway and Fillmore Parkway.

Dry Battery for Block Signal Wires.*

In 1905 we placed 16 dry cells on the block wire at each of two stations, Brookfield and Waukesha. On account of earth currents at Waukesha we used one of our other telegraph wires for a return, arranging the keys at both stations with front and back contacts, removing the circuit closers, and arranging the circuit to close on the back stop without the battery and on the front with the battery, in a manner well known to you all. This circuit, including two 50-

*A paper by [illegible] J. Fry (C., M. & St. P.), read at the annual meeting of the Railway Telegraph Superintendents.

ohm sounders, measured 271 ohms. Each cell, when put in service, measured 1.5 volts and .125 ohms internal resistance. At Brookfield we set the battery on a shelf which had been used for gravity battery and left in a somewhat unclean condition. At the expiration of 23 months each cell measured 1.31 volts and 2 ohms internal resistance. At Waukesha we placed the battery far back on a new and clean shelf in the telegraph table, with a closed door. After 23 months each of these cells measured 1.38 volts and .68 ohms internal resistance. We are inclined to attribute the difference in condition of these cells to the condition of the shelves on which they were placed, because the service performed by each has been about the same. We estimate each system of cells has been used approximately 120 times a day, 3,600 times a month, and, if continued, this would amount to 43,200 times a year. We also estimate the keys were closed 3,360 times a day, making dots and dashes necessary to form letters and figures, which, for one month, would amount to 100,800 times, 1,209,600 times a year, or 2,419,200 times in two years. From the way this circuit works now we know it will continue to work two years, and, perhaps, longer. Taking these two systems together we had, to begin with, 32 cells and 48 volts. At the end of 23 months we had 20.96 and 22.08 volts, respectively, or 43.04 volts, a loss of, approximately, 5 volts. The 32 cells cost $5.12.

To secure the same voltage with gravity battery would have required 48 cells at an initial cost of 42 cents per cell, or $20.16, to which we add the expense for maintenance at $1 per cell per year, making a total of $68.16 for one year, and $116.16 for two years.

For each additional two years the expense for maintenance would be $5.12 and $96, respectively, for dry and gravity cells.

At present about two gravity cells per mile are used on block wires on many of the Western and some of the Eastern roads. Many of the block stations are closed during the night, and the arrangement of the dry cells to provide for the extended sections at night will, we assume, take double the number of dry cells, or four per mile, to accomplish the same results.

Assuming the life of the dry cells properly installed and maintained to be two years, we will estimate the maintenance only on a 100-mile block wire circuit for a period of 10 years, as follows:

One hundred miles, at 2 cells per mile gravity, would require 200 cells. To secure the same voltage we should need 133 dry cells, but on account of the longer sections at night 266 dry cells would be necessary.

For a term of 10 years each gravity cell would cost $10, while the dry cell only 80 cents, or comparatively,

Gravity	$2,000.00
Dry	212.80

I would not recommend cutting down the number of dry cells to the same voltage, but would recommend using twice as many dry cells as you would use of gravity, and thus secure 50 per cent. more current to start with, and sufficient to hold up the service near the end of each two years. I estimate the total expense as follows:

200 gravity cells, 10 years	$2,000.00
2,000 dry cells, 10 years	320.00
A saving of	$1,680.00

This would make a saving of $168 per year, or $1.68 per mile per annum.

In addition to this we do not need battery cupboard space in our stations, and are free from the accumulation of dirt, etc., accompanying gravity battery, and save the services of the lineman at each battery station four times a year, which is now an expense of about $10 per battery station per year.

We are about to equip two block wire circuits, one 285 miles and the other 125 miles long, with the dry batteries. A special key and a two-lever three-point switch have been designed to take the place of the old standard telegraph key and one-lever two-point switch, for the purpose of preserving in a block wire all the good features. While we eliminate the only objection to the present arrangement, namely, the operator at one station is unable to extend the circuit between the stations on each side of him without cutting his entire set out. This will prevent the signals passing any office and overcome the danger of operators making mistakes which are liable now when the circuit is cut through as above referred to.

In addition to using dry battery for our block wires, I shall submit a proposition to the telegraph company before long for the use of dry cells on our short branch lines, where there are only two or three offices, and where but a small amount of business is transacted. We are also using the dry cell exclusively in connection with our private line telephone systems, and use it in connection with our synchronizing self-winding clocks; also in our office bell and buzzer service; in fact, we use the dry cell wherever we can, to the exclusion of all others.

Beet Sugar Production.

The following statistics of beet sugar production are taken from a recent report to the Department of Agriculture:

By States, for 1906.

State and year.	Factories in operation.	Area harvested, acres.	Average yield of beets, per acre, short tons.	Beets worked, short tons.	Sugar manufactured. Pounds.	Sugar manufactured. Tons of 2,000 lbs.	Estimated average extraction of sugar, per cent.	Average: Sugar in beets, per cent.	Average: Purity coefficient of beets.	Average: Length of campaign, days.
California	8	60,141	11.17	671,571	185,480,000	92,740	13.81	16.7	82.7	115

*In long tons of 2,240 lbs. except in the case of European beet sugar production, which has been reduced to metric tons of 2,204 lbs., or orders estimated by Licht. Other data are mainly from Willett & Gray, but in the case of British India official estimates of production have been substituted.

†Not including the Philippine Islands, which are included under Asia.

‡Equal to 481,971 short tons, or 1,350 tons greater than the preceding shown in table on page 104.

GENERAL NEWS SECTION

NOTES.

The Baltimore & Ohio has begun suit in Fayette county, Pennsylvania, to contest the constitutionality of the law of that state limiting passenger fares to 2 cents a mile.

The members of the Western Passenger Association have voted to make no more contracts for special trains for picnic parties—a decision which probably has a string to it

By the People's Line of steamers between New York and Albany the one-way fare is now $2 instead of $1.50, as in former years. The round trip fare has been advanced to $3.50

The Governor of New Jersey has signed a bill, passed by the legislature last winter, regulating demurrage on freight cars. The law requires railroads to give consignees three days' free time for unloading.

Press despatches one day last week reported malicious tampering with automatic block signals on two roads, the Philadelphia & Reading and the Atchison, Topeka & Santa Fe. In both cases trains were repeatedly stopped without cause.

Eight Colorado railroads have filed quo warranto proceedings in the district court at Denver against the Railway Commission and the State Treasurer, demanding that the commission be ousted from office and the law declared unconstitutional.

In a fire at Southwick, Mass., July 1, at the ice station of the New York, New Haven & Hartford, 40 freight cars were burned up, together with icehouses and machinery, involving a loss, including that on 75,000 tons of ice, aggregating $200,000.

A press despatch from Little Rock says that certain suits filed by Prosecuting Attorney Rhoton against the St. Louis, Iron Mountain & Southern for issuing mileage books to members of the 1905 legislature have been compromised by the railroad company agreeing to pay $12,500.

The new State Railroad Commission of New Jersey already has before it 17 complaints against the railroads. These are to be investigated as soon as inspectors are appointed. The members of the commission are J. W. Congdon, of Paterson (President); B. D. Dudley, of Orange, and E. Wilson, of Red Bank.

On Saturday, June 29, the new turbine steamship "Yale," of the Eastern Steamship Co., made the trip from New York to Boston in 12 hours 16 minutes, or at an average speed of 21¼ knots per hour. It is said that the best run ever before made between New York and Boston took 15 hours. The tide was against the "Yale" all the way.

On July 1 the New York Central made advances of about 10 per cent. in season-ticket rates between New York and Mount Vernon, White Plains and other stations on the Harlem division. Between Yonkers and 155th street, on the Putnam division, the single-trip rate has been reduced from 25 cents to 15, and the round trip from 40 cents to 25.

The Attorney-General of Missouri has requested the railroads of the state to cancel state passes now in the hands of persons other than railroad employees, so that the three-months' test of the two-cent law recently begun may be a fair one. Attorney-General Hadley says that if these passes continue in force no true estimate of the workings of the two-cent law can be made. There is no anti-pass law in Missouri.

The Trunk lines have issued a revised freight classification, to take effect August 1, in which a large number of items, said to be two-thirds, have been changed, many of them in such a way as to increase the freight rate. In a column article printed in a New York daily paper, designed to show that the increases are material, we find, however, hardly any evidence of important increases, except that the minimum weight for carloads is, in some cases, increased.

Reduced Passenger Fares.

Two-cent fares were adopted on all the principal railroads of Illinois, July 1, in accordance with the law of that state. The newspapers say that the railroads have decided not only to refrain from contesting the law until after some months' trial, but that they also intend soon to reduce interstate rates to a level with the rates prescribed by state laws. In Illinois passengers paying cash on trains, when they might have bought tickets, may still be charged 3 cents a mile. The order of the Virginia State Corporation Commission to sell tickets at 2 cents a mile has not been obeyed by the principal railroads of that state. A despatch from Norfolk says that the Norfolk & Western, the Chesapeake & Ohio and the Atlantic Coast Line began July 1 selling tickets with a coupon attached, entitling the buyer to a refund in case the price charged for the ticket should be finally decided unlawful.

The Engineers' and Constructors' Club.

This society, limited in membership to the engineers composing the organization of Dodge & Day, has been formed in Philadelphia to discuss subjects relating to engineering and construction, and to give all members the benefit of the experience gained by each in his particular line of work. Four meetings have been held and papers have been presented on Civil Engineering Preliminaries for an Interurban Trolley, by Charles Reed Marsh, Electric Welding, by J. H. Gravell; Gas Producers and Internal Combustion Engines, by John E. Zimmermann, and on Concrete Piling by Julian C. Smith. The proceedings of the club, giving the papers presented and the discussions, will be published regularly.

The Summer Season in Sioux City.

Sioux City, June 25.—Four railroads were rendered inoperative to-day when several thousand honey bees swarmed on the handle of an important switch in the terminal yards. A train of cars lay across the yards and obstructed traffic, but none of the two score of idle trainmen dared approach the switch. Aid came through a small boy, who declared that his father could capture bees. He was hailed as a saviour and despatched for his father. The latter showed up in half an hour and calmly loaded the bees into a wash boiler, and the wheels of commerce again revolved.—*Press Despatch.*

Two Ways of "Moving" Freight.

The freight agents of the Southern Pacific in California and Oregon have been rousing consignees to unload freight cars more promptly and figures have been published showing the degree of success attending their efforts. At Portland, April 1, the number of cars on hand waiting to be unloaded was 674; and on May 1, 823, but on June 11 this number was reduced to 216. At San Francisco the number of cars April 1 was 1,860; on May 1, 2,358, and on June 12, 1,640. At Sacramento and Los Angeles the number on June 12 was a little larger than on the 1st of May.

The foregoing was issued by a press bureau connected with the railroad. Another item on a cognate subject comes in the press despatches of June 20, and gives the interesting information that consignees in San Francisco who have wanted their cars badly enough to pay $50 each for having them expedited, have had no difficulty in getting prompt delivery. According to this despatch a former employee of the Southern Pacific, named Manvais, on payment of the sum named, telegraphed to Sparks, a division terminus in Nevada, and by dividing his fees with somebody at that point got the desired cars switched out and sent forward. The report says that Manvais did such an extensive business that he had to hire a secretary.

A Sane Gubernatorial Candidate.

Henry M. Whitney, outcast by Mr. Roosevelt, is a possible Democratic nominee for the governorship of Massachusetts. A part of a public speech of his on June 22 is as follows:

"The policy that has controlled the management of the railroads of the country, both east and west, has been a policy that has inured to the benefits of shippers of freight everywhere. And these shippers of freight who reside furthest from the centers of trade have received the greatest proportional benefit from it. Any change of policy brought about by government control or government ownership would, in my judgment, seriously menace all New England industries.

"I believe that it is everywhere admitted that the consolidation of the railroads has been productive of general benefit to the public. It happens that there is now under discussion a consolidation of railroad interests in New England, the largest and most important of any that have ever taken place in New England. * * *

"If we can safely be guided by the light of experience, there is no reason for distrusting the effect of this proposed consolidation upon the interests of the people of Massachusetts. I speak in this matter wholly as a citizen of Massachusetts. I have said that I had no part or lot in the arrangements for the exchange of stock. Had

I been consulted about it I should have advised the parties in interest to go about it in a more open manner. I think it was a tactical mistake in not having so proceeded.

"But the real question is, after all, whether this consolidation is or is not for the benefit of the people. I believed that the consensus on the part of the business men generally throughout the state would be well-nigh unanimous in its favor."

Censoring Railroad Messages.

The telephone service as well as the telegraph needs constant censoring, for the double reason that the telephone equipment is more expensive, and more easily accessible to those to whom "talk is cheap." The telegraph censor will probably find that the best means of checking telephone use is to have a record kept of stations or lines that are often reported busy, and get after the persons who use those lines and cut short their talk.—*F. E. Bentley, Terminal R. R. Association, St. Louis.*

Railroad Consolidation in Argentina.

Negotiations are being made for a consolidation of the Buenos Ayres & Pacific and the Argentine Great Western, together with the Argentine Transandine, which is under construction. If such a merger is carried out the resultant company will control a line from Buenos Ayres across Argentina to a connection with Chilean railroads, which will bring it to Valparaiso on the Pacific coast. The Buenos Ayres & Pacific runs from Buenos Ayres to Villa Mercedes, about 400 miles, where it connects with the Argentine Great Western. The latter goes as far as Mandoza, 200 miles west of Villa Mercedes. The Transandine is building from Mandoza across the Andes, and most of the work has been finished, the most important still undone being several miles of tunnels. The Argentine Great Western a short time ago arranged to operate the Transandine, and the Buenos Ayres & Pacific and the Argentine Great Western have jointly guaranteed the interest on the Transandine bonds. The plan for the merger of the companies is as follows:

The Buenos Ayres & Pacific is to take over both the other companies and agree to pay the Argentine Great Western interest charges, 6 per cent. dividends on the Argentine Great Western preferred stock and additional distributions on a rising scale in proportion to the dividends paid on Buenos Ayres & Pacific common stock. The Argentine Great Western common stock will rank with the Buenos Ayres & Pacific second preferred; it will receive 6 per cent. dividends and will also share with the Argentine Great Western preferred in receiving additional payments. The Buenos Ayres & Pacific has £6,950,000 ($34,750,000) debenture stock, £1,200,000 ($6,000,000) 5 per cent. cumulative first preferred, £1,000,000 ($5,000,000) 5 per cent. non-cumulative second preferred, and £6,000,000 ($30,000,000) common stock. The company also guarantees dividends on £5,059,718 ($25,298,590) stock of subsidiary companies. The Argentine Great Western has £3,975,517 ($19,877,585) debenture stock, £1,312,500 ($6,562,500) preferred, and £2,937,500 ($14,687,500) common stock.

Cigarettes Worse Than Whisky.

In April last the Pittsburgh Railways Company of Pittsburg, operating 490 miles of track and 1,800 cars, issued a notice to employees that for the betterment of the service and the safety of the public, it would thenceforth be the policy of the company to not retain in its employ men who use intoxicating liquors or cigarettes or are in the habit of gambling. Concerning this notice General Superintendent John Murphy, writing to the *Sunday School Times*, says:

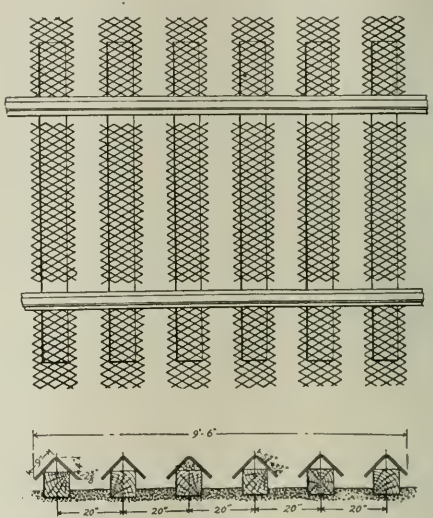
Being an officer of a company that carries over two hundred and twenty-five million passengers yearly, it becomes my moral and legal as well as my public duty to use all reasonable means to protect the lives and further the comfort of this large number of passengers. Having for some time back noticed that our accidents were increasing, upon investigating the cause I satisfied myself that the standard of our men who did not use liquor or tobacco (the latter in the form of cigarettes) was much above that of those who used either. I therefore deemed it my duty to abate the evil so far as lay in my power to do so, and tried to uproot it and cast it out through discipline, but found this method inadequate and ineffectual. I then went further, and concluded the desired end could be attained only by removing from the service or refraining from employing all men addicted to the objectionable habits alluded to.

It is my aim and intention to pursue this policy without abatement, since I have let it proved beyond all doubt that it has raised the standard of our men. I have been criticized for the stringency of the order, especially the prohibition of the use of cigarettes; but on the other hand I have the assurance of our division superintendents (of which we have 12), aided by my own observations, that persons addicted to the use of cigarettes, especially young men, are the most careless in their duties and less able to perform them than men using liquor in moderation. I may also mention that in 17 years' experience as manager of public utility corporations I have had occasion to promote many of our men from the rank of conductors and motormen to officers, and in no case has a man using whisky come up to the requirements.

An Expanded Metal Cattle Guard.

An expanded metal cattle guard has been designed by F. W. Stewart, General Manager of the Climax Stock Guard Co., Chicago. It is made in sections 2 ft. long and 18 in. wide, bent to a trough shape, each side thus being 9 in. wide and 24 in. long. These sections are set one over each tie, extending 4 in. above and 2⅜ in. below the top. The ballast between ties is removed to a depth of about 6 in., making it even more difficult to cross the guard. When cattle attempt to cross their feet go into these shallow pits, and the projections from the expanded metal, striking their legs in a tender part, make it painful to proceed. The guard, however, does not prevent them from withdrawing their feet. The mesh of the expanded metal may be made any size desired.

The tie spacing may be anything desired, that in the drawing being 20 in.; also any number of ties may be covered. Track work and tie inspecting may be done without removing the guard. Each



A New Expanded Metal Cattle Guard.

section is fastened in place with from eight to 15 staples. If a section should be crushed or mashed out of shape it may be restored and again put in service with little expense or trouble. It is cheap in first cost and if galvanized or properly painted, will last a long time. These guards have had numerous tests with satisfactory results. They are light and are shipped in bundles, so that they occupy little space, and the freight rate on them is low.

Fire Test of a Concrete-Block Building.

A fire test of a concrete-block business building, by actual conflagration, occurred at Nashville, Tenn., a short time ago. It was the five-story Montgomery building, built of two-piece concrete blocks by the Granitoid Construction Co., of Nashville, the blocks being made under the American hydraulic system. According to the report, at one time during the fire the upper walls of the building as well as the concrete ornamental cornice and top courses, were almost at a white heat, appearing to be transparent, but notwithstanding the great volumes of water poured on them while in this condition, little or no damage resulted, except for a few chips in the sills of the windows and the blocks adjacent to such openings. The walls remained intact. This was an excellent demonstration of the fire-resisting qualities of concrete blocks made of the materials used in the construction of this building, namely, crushed limestone, granite screenings and Portland cement. The building was stocked with highly inflammable material, being occupied as warerooms by a firm of furniture dealers. The building was valued at $35,000, but the damage was estimated at not over $8,000.

The walls of the building are 16 in. thick, with a 50 per cent. air space, except the top story, which is 12 in. thick, with a 40 per cent. air space. The headquarters of The American Hydraulic Stone Co., under whose system the blocks were made, are at Denver, Colo.

Abyssinian Railroad Fails.

The Abyssinian Railroad, being unable to pay dividends, has applied for liquidation. M. K[illegible], a Frenchman, has been appointed receiver and will conduct the negotiations for carrying out the construction of the extension of the line to Adis Abeba, the capital of Abyssinia.

The Abyssinian Railroad runs from the port of Djibutil, French Somaliland, to Dire Dawa, about forty miles from Harar, in Southeast Abyssinia, a distance of about [illegible] miles.

It was opened for traffic December 20, 1902. The total receipts in 1904 amounted to about $[illegible] and the total expenses, including financial charges, to about $[illegible], leaving a deficit of about $[illegible]. The line had the effect of diverting to Djibutil the Abyssinian trade which used to pass through the port of Zaila, British Somaliland. Last year France, Great Britain and Italy negotiated a joint treaty with Abyssinia, the main features of which are a guarantee of the integrity of the Abyssinian empire, the open door, commercial equality for all countries and the continuation of the construction, under French auspices, of the railroad from Dire Dawa to Adis Abeba, Great Britain and Italy naming representatives on the railroad directorate. King Menelik, in agreeing to the international control of the railroad, made the reservation that it should in no way limit his sovereign rights.—*New York Tribune.*

"Put Knocks in the Box."

This, according to the Chicago reporters, is what the Burlington road has invited its passengers to do. A locked box, with an opening in the lid, is fixed in the observation cars on trains 47 and 48 between Chicago and St. Paul, and passengers are invited to drop into the box any suggestions they may have to offer concerning the quality of service on the trains. One swallow does not make a summer, but one complaint box appears to have been sufficient, in this case, to lead the industrious reporters to herald this new "enterprise" of the Burlington as having been put in vogue throughout the company's lines. If now, this enthusiastic passenger department would invite growlers to growl into a box, or something of the sort, at all the small stations and on the non-luxurious trains, and would publish the results, some interesting reading might be brought out.

Service on Public Commissions.

Legislated out of existence, the New York Rapid Transit Commission will pass into our municipal history as one of the most remarkable civic bodies ever created with a special end in view. It has been a fine example of public service. Many of our best citizens, on this Commission, have been willing to give unstintingly of their time and talents in order to help on the progress of New York. Governor Hughes has had difficulty in securing the type of men he desired to appoint to the new commission. The salary of the position is ample; but the labor that will have to be faced is great. Very much—perhaps too much—will be expected of the new Commission. This is why some whom the Governor sought to induce to serve have declined. They are not afraid of work, but they do not like to undertake impossible tasks; and they think that the public is now in a mood to demand impossibilities. * * * More than this, a salary of $15,000 does not now look so tempting as it did when its purchasing power was greater. Then, too, in order to earn it, a great deal of hard and confining work will have to be done. This prospect might well deter a man not in robust health, as it surely would a lover of ease, but even this is not the greatest difficulty. Competent men, otherwise willing, dread the criticism and unfair attack which, they say, more and more befall those who try to work for the public. Criticism of men on public commissions of all sorts is more constant and searching than it used to be. This is due, not so much to the development of a carping temper in people, as to the increased facilities for making and distributing comment, forming and echoing judgment. The complaint of one aggrieved citizen is now caught up in the press and talked about by thousands, in a way once wholly impossible. But to have his best work found fault with, his real achievements minimized, and his failures magnified, is what any man must look forward to who consents to serve on a Rapid Transit Commission, a Board of Education, or a Public Service Commission. But what of it? It should all be taken as simply a part of the day's work.—*Evening Post,* New York.

More Safety Appliance Law Violations.

Attorney-General Bonaparte has brought suits against 32 railroads to recover penalties for violation of the safety appliance law. These prosecutions are based on information reported by the safety appliance inspectors of the Interstate Commerce Commission. The roads made defendants are as follows: Alabama Great Southern; Baltimore & Ohio (10 violations); Chicago & Eastern Illinois; Chicago Great Western ([illegible] violations); Chicago, Rock Island & Pacific (21 violations); Big Four; Chesapeake & Ohio; [illegible] & Cincinnati [illegible] & [illegible] & [illegible]; [illegible] & Southwestern; [illegible] Harrisburg & San Antonio; Georgia Railroad; Great Northern; Illinois Central ([illegible] violations); Kansas City Southern ([illegible] violations); Louisville & Jeffersonville Bridge Company; Nashville, Chattanooga & St. Louis; [illegible] Railway ([illegible] violations); Pennsylvania Railroad; Philadelphia & Reading; Mobile & Ohio; New York, New Haven & Hartford; Northern Pacific; St. Louis & San Francisco; St. Louis, Iron Mountain & Southern; Southern; Terminal Railroad Association of St. Louis; Texas & Pacific; Wabash; [illegible] & [illegible] River; Yazoo & Mississippi Valley. About two months ago similar suits were brought against [illegible] railroad companies for similar violations.

INTERSTATE COMMERCE COMMISSION RULINGS.

Privileges in Transit Must be Published to be Effective.

In an opinion by Commissioner Clements the Commission has dismissed the complaint of R. R. Shiel & Co. against the Illinois Central and others, holding that the privilege of stopping in transit hogs shipped from western points to the East in order that they may be sorted and reconsigned under the through rate from point of origin cannot be enforced against carriers in favor of any single place or shipper in the absence of lawfully established tariffs making such privilege open to the public at large. To whatever extent long previous existence of lower rates in actual use may justify a presumption that they are sufficiently high, the mere publication of such rates, under which there has been no appreciable movement of traffic, is not conclusive proof that they are reasonably remunerative to the carriers. All privileges accorded on shipments in transit which affect the value of the service performed must be published in the tariffs, and reparation based on breach of contract for a privilege which was not mentioned in the tariffs must be denied the shipper because its allowance without publication was in violation of law. The facts bearing on the question of the reasonableness of the rates at issue have not been sufficiently developed to afford a proper basis for satisfactorily determining that question.

Coal Rates to Dallas, Tex.; Principle of Rate Comparison.

The Interstate Commerce Commission has announced decision in the case of Dallas Freight Bureau vs. Gulf, Colorado & Santa Fe and others (opinion by Commissioner Harlan). Rates to Dallas, Tex., from certain mines on the carriers' lines in Indian Territory and southern Arkansas have lately been increased from $1.25 to $1.50 a ton on slack coal and from $1.85 to $2.10 a ton on mine-run coal. On complaint that the present rates on such coal are unreasonable and request that the lower rates be restored, the Commission decides that following former decisions of the Commission on the reasonableness of coal rates of these carriers in adjacent territory, the rates from the mines that now take the $2.10 and $1.50 rates to Dallas should not for the future exceed $1.90 on mine-run and lump and $1.40 on slack coal. For the mines that now take rates of $1.85 and $1.25 to Dallas there should be some corresponding reduction, but as to these mines no order is now made.

The Commission further says that while the revenue per ton-mile over other routes on other lines and to other destinations is often suggestive in arriving at a proper estimate of the reasonableness of a rate over a route complained of, it is by no means conclusive. Varying conditions existing on different lines must of necessity justify differences in rates for hauls of the same distance. The real question in any complaint is between the particular points in question. In testing such a rate the rates on the same or adjacent lines in the immediate territory where the same conditions exist are of much greater significance and afford a much more accurate basis.

Classification of Different Kinds of Brick; Principle of Classification.

In an opinion by Commissioner Lane, the Commission has announced decision in the case of the Stowe-Fuller Co. against the Pennsylvania Company, Pennsylvania Railroad, and the Baltimore & Ohio. The complaint in this case was directed solely against present differences in the carriers' rates on fire, building and paving brick from Empire, Strasburg, and other points in Ohio to New York City and other eastern destinations, but no attack was made on the reasonableness of the rates on either kind of brick except as involved in the claim that any difference in the rates for the different kinds is unlawful. The Commission holds that no such distinction between these three classes of brick, which are made of the same material, come out of the same kiln, are nearly alike in color, and are of the same size and weight, exists as justifies a difference in rates. To hold otherwise would be to promote false billing by

the shippers and to require carriers to make an almost impossible examination of the use to which each shipment of these brick was put. The Commission further says that classification must be based upon a real distinction from a transportation standpoint. Aside from the difficulty in learning what use the brick were to be put to, the Commission cannot regard a classification as scientific, or a difference in rates as well based, which is altogether founded upon a distinction that has no transportation significance. Such a differentiation, if permitted and extended throughout the various classes of freight, would lead to an almost endless multiplication of rates which could find no excuse save the use which might be made of the article transported.

Territorial Classification Upheld.

In an opinion by Commissioner Prouty, the Commission decides the case of Desel-Boettcher Co. vs. Kansas City Southern and others. For the purpose of naming rates to various points in Texas, stations on the Kansas City Southern are grouped in territories as follows: South from Kansas City all stations up to, but not including Siloam Springs, are in Kansas City territory, while Siloam Springs and stations for a certain distance south are embraced in Little Rock territory. The carriers transferred Siloam Springs from Little Rock territory into Kansas City territory. The complainant alleged that this change, resulting in an advance of the rates on green apples in carloads from 49 cents to 58 cents per 100 lbs. from Siloam Springs to Houston, Tex., was unwarranted. The Commission holds that group rates must of necessity result in a certain amount of discrimination, but they should produce as little discrimination as possible; and that, upon the facts of this case, the change of Siloam Springs from the Little Rock group to the Kansas City group did not result in undue discrimination.

Passenger Rates on the St. Louis & North Arkansas Upheld.

In an opinion by Commissioner Clements the case of the Railroad Commission of Arkansas vs. the St. Louis & North Arkansas Railroad is decided. The petition of the Railroad Commission prayed for a reduction in the interstate passenger fares of this company between Arkansas points and interstate points. The complaint against the railroad company is dismissed and the Commission holds that the defendant road being unfinished, without through connections, not extravagantly managed, under the necessity of making extensions by public authority and in need of equipment and extension, and not earning sufficient to more than meet its operating expenses, and fixed charges not having been shown to be excessive, should not be required to transport interstate passengers at the same rates per mile as are finished, well-equipped and prosperous roads.

Moultrie Gets Better Rates.

The Interstate Commerce Commission, in an opinion by Commissioner Clements, has announced its decision in the case of Southern Grocery Company and Holmes-Hartsfield Company vs. Georgia Northern Railway and others. The complaint alleged that the carrier's rates, which are higher from Louisville, Cincinnati, Memphis and Nashville to Moultrie, Ga., than from the same points of origin to Tifton, Valdosta, Quitman, Thomasville and Fitzgerald, Ga., are unreasonable. The Commission decides that the circumstances and conditions surrounding transportation of freight by the carriers from such points of origin to Moultrie are not substantially dissimilar from those from such points of origin to said other nearby Georgia points, and that the practice of charging such higher rates to Moultrie is unjustly discriminatory, unreasonable and unlawful; and the Commission further decides that the just and reasonable practice would be to charge for such transportation to Moultrie the same rates from such points of origin as are charged therefrom to Tifton, Valdosta, Quitman, Thomasville and Fitzgerald. An order in accordance with such decision is entered.

The South Versus New England Again On Cotton Rates.

The Interstate Commerce Commission in an opinion by Commissioner Prouty has announced its decision in the case of the China & Japan Trading Co. and others against the Georgia Railroad and other lines forming through routes to the Pacific coast. The carriers' rates on cotton-piece goods from New England mills through Pacific coast points to the Orient is $11.25 for 40 cu. ft. of measured space, equivalent to about 85 cents per 100 lbs. Through rates on the same articles from Southern mills over the same route is $1.25 per 100 lbs. On complaint that this adjustment is unreasonable in itself and also discriminates against Southern mills in favor of New England mills, the Commission holds that the complaint is not sustained. The evidence of complainants strongly tended to show that an illegal agreement to advance rates on cotton-piece goods was made by transcontinental lines, and that the advanced rates were put in under that agreement; but it is not necessary to pass upon that question, because even if it were answered in favor of complainant the Commission would still be of opinion that this would afford no ground for either reducing the rate from Southern mills or awarding reparation. The mere fact that the advance was the product of an unlawful combination will not justify the setting aside of such rate if the Commission is of the opinion that such rate is not unreasonably higher than the previous rate.

Lower rates from New England than from the South on cotton products were upheld by the Commission in the case of Enterprise Manufacturing Co. et al. vs. Georgia Railroad et al. decided May 1, 1907. This decision was quoted in part and commented on in the *Railroad Gazette* of June 28, 1907, under the editorial, "The Working of the Rate Law."

TRADE CATALOGUES.

Chicago, Burlington & Quincy.—A pamphlet issued by the passenger department takes as its text, "How can you afford not to visit Yellowstone Park?" and makes out a strong case. It points out that it is not necessary in touring the Yellowstone to endure such hardships as many think of as being inseparable from the trip; also that the park is not merely a show place to be rushed through, guide book in hand, in a few days, but is also an excellent region for rest, both climate and diversions being salubrious. The pamphlet, which includes a large map of the park, then goes on to describe in detail the hotels, the coaching tours and excursions, the fishing and the natural phenomena for which the park is best known. It also gives suggestions as to what to wear and take and the cost of tours from different cities of the Middle West. Another of the company's folders describes a two weeks' tour via Denver and Colorado Springs through the Yellowstone Park and return.

Flexible Metallic Hose.—Bulletin 25 of the New York Flexible Metallic Hose & Tubing Co., New York, illustrates and describes "Nyflexmet" lead covered flexible metallic hose and tubing. This form of hose is built up of spirally twisted, ribbon-like strips of pliable steel or copper, having the edges formed into interlocking lips, the joints of which are packed with asbestos or rubber. For special purposes where it is required to resist corrosion, as for example, gas mains, it is furnished with an outer casing of lead. For water mains and similar purposes it is made with both an inner and outer lead tube. All sizes from ¼ in. to 12 in. internal diameter are furnished and the lightest construction is made to stand a pressure of 500 lbs. per sq. in.

Coupler Repair Parts.—The McConway & Torley Co., Pittsburg, Pa., has prepared a small pamphlet containing illustrations and information for ordering all repair parts for Janney, Kelso and Pitt couplers, and also Buhoup three-stem buffer equipment. The pamphlet is intended for distribution among car repairmen and purchasing agents to aid them in ordering repair parts direct from the makers instead of from irresponsible outside companies whose product is often of inferior quality and not perfectly interchangeable. It will be sent to anyone interested on application.

The Bucyrus Co., South Milwaukee, Wis., has reprinted the President's message on the Panama Canal, communicated to Congress last December, in a handsome book which it is distributing. The printing is in brown on cream paper, with paragraph headings in red, and there are fine half-tone illustrations, also in brown. The cover is flexible brown board with gold embossed lettering, tied with brown silk cord. There is also a map of the Isthmus showing the canal route. The Bucyrus Co. has furnished all the steam shovels thus far ordered by the Canal Commission.

MANUFACTURING AND BUSINESS.

It is said that the Pullman Company is figuring on plans for a steel car plant at Hammond, Ind.

The Union Refrigerator Transit Co. has ordered Neponset insulating paper for repairs and new work on refrigerator cars. The paper is made by F. W. Bird & Son, East Walpole, Mass.

Clarence Price has been elected a Vice-President of the American Car & Foundry Company, New York. William M. Hager, Assistant Secretary, has been elected Secretary, succeeding D. A. Bixby.

G. M. Genter, Jr., has been appointed Assistant Engineer in charge of estimating and drafting in the reinforced concrete department by the General Fireproofing Company, Youngstown, Ohio.

H. M. Beugler, formerly Superintendent of Railways for Ford Bacon & Davis' operating department, operating the Newman properties in Houston, Tex., Memphis, Little Rock, Birmingham, Nashville, Knoxville, has gone to Dodge & Day, Philadelphia and New York.

The exhibit of the American Blower Co., Detroit, Mich., at the Atlantic City conventions contained a mystifying novelty which attracted much attention. A high-pressure blower, running at speed and emitting a blast of air at high velocity, held suspended about 4 ft. from the outlet and at an angle of 45 deg. from the perpendicular, a light sphere about 12 in. in diameter. Observers were asked to explain why the sphere remained at that point instead of flying off into the ocean, but it is claimed no satisfactory solution was advanced by the engineers and others who saw it.

Iron and Steel.

About 3,000 tons of steel will be needed for the new shops of the St. Louis & San Francisco, at Springfield, Mo.

It is reported that the Atchison, Topeka & Santa Fe has given an order to the Bethlehem Steel Corporation for 10,000 tons of rails to be delivered in 1908. The price, it is said, is above $30 a ton.

OBITUARY NOTICES.

Daniel Jones, formerly Comptroller of the Philadelphia & Reading, died on June 24 at his home at Oaklane, Pa. Mr. Jones was 61 years old, and had been retired on a pension in January, 1905.

ELECTIONS AND APPOINTMENTS.

Executive, Financial and Legal Officers.

Canadian Pacific.—A. D. MacTier, General Fuel Agent, has been appointed Assistant to the Vice-President, with office at Montreal. Thomas Britt has been appointed Acting General Fuel Agent, with office at Montreal.

Central of Georgia.—Charles Steele and George G. Haven have resigned from the Board of Directors. Oakleigh Thorne, Marsden J. Perry and William F. Sheehan have been elected Directors.

Chicago, Milwaukee & St. Paul.—Walter P. Bliss has been elected a Director, succeeding Herman S. Leroy.

Delaware & Hudson.—Clifford Stanley Sims, who succeeded A. I. Culver as Second Vice-President and General Manager, was born in 1868 at Prairie Ridge Plantation, Ark. He was educated at Mount Holly, N. Y., and in 1885 immediately after graduation began railroad work in the Engineering department of the Pennsylvania. In 1888 he was made assistant supervisor of the Pennsylvania Lines West at Cleveland, Ohio. Two years later he was appointed Assistant Engineer of Maintenance of Way at Fort Wayne, Ind., and in 1894 was made Acting Assistant Engineer of Motive Power. Next year he was promoted to be Engineer of Maintenance of Way at Toledo, Ohio, and in 1896 was transferred to Allegheny, Pa., with the same title. Three years later he was made Engineer of Maintenance of Way of the Chicago Terminal division, and in 1901 was appointed Superintendent there. The next spring he went to the Baltimore & Ohio as General Superintendent at New York, and in 1903 was made General Manager. In 1905 he went to the Erie, where he remained until he went to the Delaware & Hudson.

C. S. Sims.

New York Public Service Commissions.—The Commissioners appointed for the First district, consisting of New York, Kings, Queens and Richmond counties, are: William R. Willcox, of New York, Chairman; William McCarroll, of Brooklyn; Edward M. Basselt, of Brooklyn; Milo R. Maltbie, of New York, and John E. Eustis, of The Bronx. The Commissioners for the Second district, which includes all the other counties in the state, are: Frank W. Stevens, of Jamestown, Chairman; Charles Hallam Keep, of Buffalo; Thomas Mott Osborne, of Auburn; James E. Sague, of New Hamburg, and Martin S. Decker, of New Paltz.

Illinois Central.—See Yazoo & Mississippi Valley.

New York, New Haven & Hartford.—Charles M. Pond and Lewis C. Ledyard, of New York, and Richard Olney, of Boston, who were recently elected Directors, have resigned.

Yazoo & Mississippi Valley.—I. G. Rawl, Vice-President of the Illinois Central, has been made also Vice-President of the Yazoo & Mississippi Valley, in charge of construction and operation.

Operating Officers.

Chicago & Alton.—William L. Derr, Superintendent at Bloomington, Ill., has resigned to become General Superintendent of the New York City Railway.

Chicago, Milwaukee & St. Paul.—J. H. Foster, Superintendent at Marion, Iowa, has been appointed Assistant General Superintendent at Minneapolis, succeeding H. B. Earling, promoted. W. B. Foster, Superintendent of the River, Chippewa Valley and Wabash divisions, succeeds J. H. Foster. H. T. Van Vliet, Superintendent of the Hastings and Dakota divisions, succeeds W. B. Foster, with office at Minneapolis. G. A. Van Dyke succeeds Mr. Van Vliet, with office at Minneapolis.

Illinois Central.—See Yazoo & Mississippi Valley.

New York Central & Hudson River.—Clinton Lloyd Bardo, who was recently appointed Superintendent of Grand Central Station and the Electric division, was born at Montgomery, Pa., in 1867. He began railroad work in 1885 as an operator on the Pennsylvania. The next year he worked as operator on the Philadelphia & Reading, and then went to the Tidewater Oil Company as operator and supply agent in the Construction department at Mauch Chunk, Pa. In 1887 he went to the Lehigh Valley as operator, being later made train despatcher. In 1892 he was appointed Assistant Trainmaster of the Wyoming division, and after a few months was made Trainmaster of that division. He was transferred to the New York division in 1901, and in 1904 went to the New York Central as Freight Trainmaster of the New York division. He was appointed Assistant Superintendent of this division in 1905, where he remained until his recent promotion.

C. L. Bardo.

St. Louis, Iron Mountain & Southern.—John William Dean, who was recently appointed Superintendent at De Soto, Mo., was born on January 15, 1867, in Lafayette County, Mo. After a public school education, he began railroad work in 1878 as a messenger boy on the Chicago & Alton. He served as operator, brakeman and agent on the Kansas City, Springfield & Memphis, now part of the Frisco Lines, and then went to the Missouri Pacific as operator and despatcher. After being operator and brakeman on the Southern Pacific, he went in 1887 to the Atchison, Topeka & Santa Fe as operator. He was made successively despatcher, chief despatcher, yardmaster and Trainmaster, and then in 1902 was made Trainmaster of the Denver & Rio Grande. After being appointed Superintendent of Terminals on this road, he went to the Colorado & Southern in 1903 as Superintendent. From 1904 to 1905 he was Superintendent of Terminals at Mexico City of the National of Mexico, and then went to the Illinois Central as Trainmaster of Ter-

J. W. Dean.

minals. He went to the St. Louis, Iron Mountain & Southern in September, 1905, as Superintendent of Terminals at Little Rock, Ark., and on February 1, 1906, was appointed Superintendent at Van Buren, Ark., where he remained until his recent transfer.

Norfolk & Western.—The lines of this company are now operated in two general divisions. A. C. Needles, heretofore General Superintendent of the entire road, has been appointed General Superintendent of the Eastern General division, consisting of all lines east of Bluefield, W. Va., including Bluefield terminals, with office at Roanoke, Va. George P. Johnson, Superintendent at Portsmouth, Va., has been appointed General Superintendent of the Western General division in charge of all lines west of Bluefield, including Bluefield terminals, with office at Bluefield. E. A. Blake, Superintendent at Roanoke, Va., succeeds Mr. Johnson. James P. Carey, Assistant Superintendent at Bluefield, succeeds Mr. Blake.

Northern Pacific.—B. E. Palmer, Assistant General Superintendent at Tacoma, Wash., has been appointed General Superintendent of Western lines, from Trout Lake, Mont., west. J. G. Cutler, General Superintendent of the Washington & Columbia River, has been appointed Superintendent of the Northern Pacific at Pasco, Wash.

Tehauntepec National.—J. N. Galbraith, General Manager, has resigned. W. B. Ryan, Vice-President, has been appointed also General Manager. H. W. Morris, Assistant to the General Manager, has been appointed Assistant to the Vice-President and his former office has been abolished. The offices of both are at Rincon Antonio, Oaxaca.

Washington & Columbia River.—See Northern Pacific.

Yazoo & Mississippi Valley.—F. B. Harriman, General Manager of the Illinois Central, has been appointed also General Manager of the Yazoo & Mississippi Valley.

Traffic Officers.

Northern Pacific.—S. B. Calderhead, General Freight and Passenger Agent of the Washington & Columbia River, has been appointed General Agent of the Northern Pacific, with office at Walla Walla, Wash.

Philadelphia & Reading.—E. B. Crosley has been appointed Coal Freight Agent, with office at Philadelphia, succeeding John H. Jones, retired.

St. Louis & San Francisco.—E. T. Willcox, Division Freight Agent at Birmingham, Ala., has been appointed Assistant General Freight Agent at Memphis, Tenn.

Seaboard Air Line.—C. D. Wayne, chief clerk in the General Passenger Agent's office, has been appointed Assistant General Passenger Agent, with office at Portsmouth, Va.

Washington & Columbia River.—See Northern Pacific.

Engineering and Rolling Stock Officers.

Illinois Central.—H. R. Safford, Assistant Chief Engineer of this company and of the Yazoo & Mississippi Valley and of the Indianapolis Southern, has been appointed to the new office of Chief Engineer of Maintenance of Way of the three companies, with office at Chicago, and the office of Assistant Chief Engineer has been abolished.

Indianapolis Southern.—See Illinois Central.

Yazoo & Mississippi Valley.—See Illinois Central.

LOCOMOTIVE BUILDING.

The Portland & Seattle, being built by the Northern Pacific, is in the market for five switching locomotives.

Stanley, Merrill & Phillips have ordered one consolidation locomotive from the Baldwin Locomotive Works.

The Illinois Steel Company, Chicago, has ordered one heavy four-wheel saddle tank switching locomotive from the Baldwin Locomotive Works.

The Minnesota Land & Construction Company, Duluth, Minn., has ordered three locomotives from the American Locomotive Company.

The Galveston Wharf Co., Galveston, Tex., has ordered eight six-wheel switching locomotives from the American Locomotive Co., with cylinders 19 in. x 26 in.

The Sierra Madre Land & Lumber Company, as reported in the *Railroad Gazette* of February 15, has ordered two consolidation locomotives from the American Locomotive Company.

The Henry Cowell Lime & Cement Co., Cleveland, Ohio, is said to have ordered two four-wheel saddle tank locomotives and two six-wheel switching locomotives from the Baldwin Locomotive Works.

The Virginia & Southwestern, as reported in the *Railroad Gazette* of June 14, has ordered three simple consolidation locomotives from the American Locomotive Company for September, 1907, delivery.

General Dimensions.

Type of locomotive	Simple consolidation
Weight on drivers	154,300 lbs.
Weight, total	171,000 "
Diameter of cylinders	21 in.
Stroke of pistons	26 "
Diameter of drivers	51 "
Boiler, type	Straight top
" working steam pressure	200 lbs.
" heating surface	2,562.7 sq. ft.
" tubes, number	350
" " material	Shelby steel
" " outside diameter	2 in.
" " length	15 ft.
Firebox, length	120¼ in.
Firebox, width	40⅝ "
Grate area	34 sq. ft.
Tank capacity for water	6,000 gals.
Coal capacity	11 tons

Special Equipment.

Air-brake	Westinghouse
Boiler check	Phillips
Boiler lagging	Johns-Manville
Injector	Nathan simplex
Lubricators	Franklin
Piston rod packing	United States
Valve rod packing	United States
Safety valve	Crosby
Sanding devices	Coates
Sight-feed lubricators	Nathan Bull's-eye
Steam gages	Crosby
Tires—driving wheel	Latrobe

CAR BUILDING.

The New York City Railway is figuring on some new street cars.

The Duluth, Missabe & Northern is figuring on eight passenger cars.

The Northwestern Elevated, Chicago, is in the market for 40 cars.

The Oregon & Eureka is in the market for 10 flat cars of 60,000 lbs. capacity.

The Missouri, Oklahoma & Gulf is in the market for 200 coal cars of 80,000 lbs. capacity.

The Marquette & Southeastern has ordered 20 flat cars from the Hicks Locomotive & Car Works.

The Chicago & Eastern Illinois has ordered 2,000 drop bottom coal cars of 100,000 lbs. capacity.

The Chicago, Burlington & Quincy is asking prices on 2,000 steel gondola cars of 100,000 lbs. capacity.

The Pere Marquette, it is understood, has ordered 800 freight cars from the American Car & Foundry Company.

The Chicago, Lake Shore & Eastern has ordered 400 steel underframe box cars of 100,000 lbs. capacity from the Western Steel Car & Foundry Company.

The Tampa & Sulphur Springs Traction Company, Tampa, Fla., has ordered six double truck, 42-ft. open cars from the McGuire, Cummings Manufacturing Company.

The Armour Car Lines, Chicago, as reported in the *Railroad Gazette* of June 28, has ordered 35 tank cars of 80,000 lbs. capacity from the Bettendorf Axle Co., for September delivery. These cars will be 31 ft. long and 9 ft. wide, over all. The special equipment includes Bettendorf bolsters.

The Morris & Co. Tank Car Line, Chicago, as reported in the *Railroad Gazette* of June 28, has ordered 10 tank cars of 80,000 lbs. capacity from the Bettendorf Axle Co., for September delivery. These cars will be 31 ft. long and 9 ft. wide, over all. The special equipment includes:

Bolsters	Bettendorf
Brake-beams	Damascus
Draft rigging	Cardwell
Dust guards	Harrison
Journal boxes	Bettendorf
Trucks	Bettendorf

The Buffalo & Lake Erie, as reported in the *Railroad Gazette* of June 14, has ordered 25 combination baggage and passenger cars, with seating capacity for 50 people, from the Cincinnati Car Company. These cars will weigh 43 tons, and will measure 56 ft. 7 in. long, 9 ft. 4 in. wide and 13 ft. high, over all. The bodies will be of wood and the underframes of steel. The special equipment includes:

Brakes	Westinghouse
Couplers	Tomlinson
Curtain fixtures	Protected groove
Curtain material	Pantasote
Draft rigging	Tomlinson
Heating system	Hot water
Journal boxes	Symington
Light	Holophane globes
Springs	Triple elliptic
Trucks	Baldwin

The Arms Palace Horse Car Co., Chicago, as reported in the *Railroad Gazette* of June 7, has ordered 10 express horse cars of

50,000 lbs. capacity from the Pullman Co. for September delivery. These cars will weigh [illegible] lbs. and measure [illegible] ft. long, [illegible] ft. wide and 8 ft. 6 in. high, inside measurements. The special equipment includes:

Brake beams	National Hollow
Brake shoes	Streeter
Brakes	Westinghouse
Brasses	Hewitt
Couplers	Tower
Draft rigging	[illegible]
Journal boxes	Franklin
Paint	Heath & Milligan
Roofs	[illegible]
Springs	Pittsburg Spring & Steel Co.
Trucks	Pullman
Wheels	Standard Steel Co.

RAILROAD STRUCTURES.

BETHLEHEM, PA.—At a recent meeting of the Commissioners of Lehigh and Northampton counties, the Bethlehem Borough officials, and the Lehigh Valley Transit Company, it was decided to build a new concrete arch 60 ft. wide and 175 ft. long to cost $100,000, to replace the bridge at Broad street.

CHANUTE, KAN.—It is said that the Atchison, Topeka & Santa Fe is about to build at this place the shops which it has had under consideration for a long time.

HARTFORD, CONN.—The terminals, yards and shop building of the Central New England, now part of the New York, New Haven & Hartford, were recently damaged by fire; loss $75,000.

LONDON, ONT.—The Grand Trunk, it is said, has plans ready, and has appropriated $50,000 for extensions to its shops here.

NEWCASTLE, N. B.—Local reports state that the Intercolonial has appropriated a large sum of money for bridge alterations on its lines.

RICHMOND, IND.—The Pennsylvania has bought land as a site on which it will put up a new freight house at a cost of $20,000.

ST. JOHN, N. B.—The New Brunswick Government has under consideration plans for a cantilever bridge to carry two tracks for electric cars, and a highway for street travel over, the St. John river at its mouth, to replace the present suspension bridge.

TAMPA, FLA.—The Tampa Northern has given a contract to H. L. Parker for a new freight house 55 ft. x 190 ft., to cost $22,000. The work to be finished by September.

TORREON, MEX.—The Mexican Central, it is said, will shortly start work on a new passenger station here. The proposed structure may also be used by the Mexican International.

RAILROAD CONSTRUCTION.

New Incorporations, Surveys, Etc.

ARKANSAS, LOUISIANA & GULF.—Preliminary surveys have been made by this company for its proposed line from Pine Bluff, Ark., south to Monroe, La., 133 miles, with a branch from Crossett to Rolfe Junction, nine miles. Most of the right of way has been secured. Grading contracts are reported let to J. Harris, of Monroe, for 3½ miles; and to J. A. Purdue & Co., of Pine Bluff, Ark., for 20 miles. Additional contracts covering about 42 miles are to be let shortly. (April 26, p. 598.)

ATCHISON, TOPEKA & SANTA FE.—The Arizona & California is reported finished and in operation from Wickenburg, Ariz., west to Parker on the Colorado river, 113 miles. Track was laid last year for 80 miles. Bids were recently opened for building a bridge over the Colorado river, to be ready for use by July, 1908. On the section west of the river grading is under way in California to Bengal, 92 miles, where connection is to be made with the main line of the Santa Fe. (March 15, p. 379.)

ATLANTA, GRIFFIN & MACON.—Local reports state that contracts were recently let, and that work is to be started at once on this line, projected from Atlanta, Ga., south to Macon, 90 miles. Surveys are also being made from Macon south to Albany, 100 miles. The office of the company is at Macon. (March 15, p. 379.)

BAUXITE & NORTHERN.—An officer writes that this company has grading finished and track laid for about one-third of the distance on the line it is building from Bauxite, Ark., north to Bauxite Junction, on the St. Louis, Iron Mountain & Southern, 2½ miles. The work included a bridge, which has been finished.

CHESAPEAKE & OHIO.—This company has stopped work on a number of important improvements. Contractors, Langhorne, Carpenter, Lane and Matthews were directed to cease work on their double-tracking contracts July 1. It is said that no more funds are at present available, and that continuance of work would depend on selling bonds at unfavorable prices. Two thousand men are affected by this order.

CHICAGO, INDIANAPOLIS & EVANSVILLE.—This company, which was incorporated in Indiana in 1905, to build a line from Evansville, Ind., north to Indianapolis and [illegible] Chicago, [illegible] miles, with a branch from [illegible] north to South Bend, [illegible] miles, has executed a contract to secure funds to carry out the work. Contracts are reported let to the [illegible] Construction Company, of Indianapolis, to build the entire main line. The necessary franchises, it is said, were secured some time ago. W. M. K[illegible] & Co., of Kansas City, are the financial backers of the project. The officers are: William K[illegible], President; J. B. [illegible], Vice-President; C. A. Dunnean, Secretary, and R. Z[illegible], Treasurer, Indianapolis, Ind. (June 14, p. 878.)

COLORADO, OKLAHOMA & SOUTHEASTERN.—An officer writes that the projected route of the proposed line is from Weatherford, Okla., on the Chicago, Rock Island & Pacific, northwest via [illegible] to Woodward, on the Atchison, Topeka & Santa Fe, 9[illegible] miles. A branch is also projected from the main line at [illegible] west to Gage, on the Atchison, Topeka & Santa Fe, 30 miles. P. A. McCartney, Chief Engineer, Lufkin, Tex.

GRASSY CREEK & ELKHORN.—Organized to build a line from Grassy Creek, Ky., south to the mouth of Elkhorn creek, 16 miles, surveys under way. The incorporators include: W. F. Rapp and O. W. Litner, of Ironton, Ohio, and Leon Isaacson, of New York.

HEARD COUNTY.—Incorporated to build a line from Roanoke, Ala., on the Central of Georgia, northwest to Newnan, Ga., also on the Central of Georgia, 40 miles. Most of the right of way has been secured. Dr. J. W. Daniel, President, and Dr. W. S. Trent, Secretary, Franklin, Ga.

HOUSTON & BRAZOS VALLEY.—Work has been started on an extension of this road, formerly the Velasco, Brazos & Northern. The proposed route is from Anchor, Tex., north to a connection with the Trinity & Brazos Valley, near Houston. (April 2, p. 581.)

LORAIN & ASHLAND.—All the right of way for the proposed extension of this road from Wellington, Ohio, south to Loudonville, 39 miles, it is said, has been obtained, and work is to be started shortly. The company is planning to build about 62 miles this year. (March 15, p. 386.)

MEXICAN SOUTHERN.—A concession has been granted by the Mexican Government to James P. Taylor, of Mexico City, to build a line from Gomacho, on the Mexican Central, in the northern part of the state of Zacatecas, via Tecolote and Cedros to Bonanza; also to build a branch from Cedros to Mazapil and Salaverna. According to the terms of the concession, surveys must be started within six months, and 22 miles built each succeeding year until the entire road is finished; and all the work must be completed within six years. (May 31, p. 759.)

MEXICAN ROADS (ELECTRIC).—A concession has been granted to Dr. J. W. Lim, of Torreon, by the state of Coahuila, to build an electric line from Torreon east to Matamoras, about 6½ miles. Surveys are now being made and work, it is expected, will be started soon.

MINNEAPOLIS & ST. LOUIS.—The Minnesota, Dakota & Pacific, under construction from Conde, S. Dak., west to Le Beau, on the Missouri river, 115 miles, on which track was laid last year to Northville, 24 miles, is now in operation to Cresbard, 42 miles. (March 15, p. 387.)

MINNESOTA, DAKOTA & PACIFIC.—See Minneapolis & St. Louis.

MISSOURI ROADS.—A company is being organized by Frank Russell and other St. Louis capitalists to build a line to develop coal fields in Boone County.

MISSOURI RIVER & NORTHWESTERN.—This company, operating 34 miles of road from Rapid City, S. Dak., west to Mystic, recently incorporated the Wyoming Western, to build from Mystic, S. Dak., west to Buffalo, Wyo., 200 miles. The new company has a capital of $4,000,000 and offices at Rapid City. C. S. Crouch, V. E. Crouch, C. E. Fulton, J. S. Gantz and E. L. Hurlburt, all of Rapid City, are incorporators.

NASHVILLE, SHELBYVILLE & DECATUR.—Application has been made by this company for a charter to build a line from Nashville, Tenn., south to Decatur, Ala., about 115 miles. The incorporators include: W. G. Hill, H. C. Dyer and H. B. Cowan, of Shelbyville, W. Z. Dozier, of Fayetteville, and W. R. Hall, of Decatur.

NEW JERSEY ROADS (ELECTRIC).—Announcement is made that a company is being organized, with the backing of John H. Starin, C. S. Smith and W. Langdon, former members of the New York Rapid Transit Commission, to build a four-track elevated high-speed monorail line from Newark, N. J., to Jersey City.

NORTH & SOUTH TEXAS.—An officer writes that contracts are let to Cox & Chessher, of Groveton, Tex., for clearing the right of way, and to C. M. McConnico, of Lufkin, for other work on the line it is building from Groveton north to Cedar, about 21 miles. At Cedar connection is to be made with the Texas Southeastern, from which point trackage rights have been obtained to Lufkin, 14 miles. The

line will be laid with 60-lb. rails. P. A. McCarthy, Chief Engineer, Lufkin, Tex. (March 15, p. 388.)

National of Mexico.—This company is planning to change all its branch lines, aggregating over 400 miles, from narrow gage to standard gage. Work is well under way changing the gage between Gonzalez Junction and Acambaro, 54 miles, and when finished work will be started between Acambaro and Urapan, 143 miles. The company is also building on the northern end of its road a new branch from Jarita to coal fields near the Texas border at Columbia.

Oklahoma & Golden City.—Surveys, it is said, have been made by this company, and contracts may be let this month for building from Jefferson City, Mo., southwest to Pawhusa, Okla., about 270 miles, with a branch from the main line at Climax Springs in Camden County, Mo., south to Springfield, 67 miles. W. K. Palmer, Chief Engineer, Dwight building, Kansas City, Mo. (March 29, p. 468.)

Open River Railway & Navigation.—Surveys reported made and rights of way secured for a proposed 17-mile line, one end of which is at Holdman, Ore. Contracts for the work are to be let about October 1. C. E. Curry, Portland, Ore., is President.

Pennsylvania.—Under the name of the Pennsylvania Tunnel & Terminal Company, the Pennsylvania, New Jersey & New York and the Pennsylvania, New York & Long Island have been consolidated.

Pennsylvania Tunnel & Terminal.—See Pennsylvania.

St. Louis, Mountain Grove & Southern.—Incorporated in Missouri with $300,000 capital and office at Mountain Grove. The company proposes to build a line from Mountain Grove in Wright County, on the St. Louis & San Francisco, south to Bryant creek, in Ozark County, 30 miles. J. J. Hedges, J. H. Jarrett and E. L. Richardson, of Springfield; J. Allhands, of St. Louis, Mo., and P. M. Johnston, of St. Elmo, Ill., are directors.

Savannah, Augusta & Northern.—This company has given notice of an amendment to its charter so as to increase its capital stock from $8,000,000 to $11,000,000. The company was organized to build from Savannah, Ga., northwest to Rossville, about 330 miles, with a branch to Augusta, 30 miles. Contracts for some of the work are reported to have been let to J. W. Oliver, of Nashville, Tenn. (June 21, p. 917.)

Southern Pacific.—Local reports state that this company has plans made to establish a new route to avoid the marshes and sinks between Benicia, Cal., and Suisun. This is to be accomplished by abandoning the piers at Port Costa and the ferry from that point to Benicia. New piers are to be built at Rodeo, on Pinole Point, and a ferry run from that place to South Vallejo. From South Vallejo the route is over the existing line to Flosden, thence by a new line northeast through American canyon to Cordelia on the Napa Junction and Suisun line, connecting with the main line at Sacramento.

Velasco, Brazos & Northern.—See Houston & Brazos Valley.

Wyoming Western.—See Missouri River & Northwestern.

RAILROAD CORPORATION NEWS.

American Railways Co.—A syndicate consisting of Bioren & Co., Newburger, Henderson & Loeb and E. C. Miller & Co., all of Philadelphia, is offering at 96 and interest a block of $600,000, 10-year, collateral trust, 5 per cent. bonds, being part of an authorized issue of $2,500,000. The bonds are dated April 1, 1907.

Atchison, Topeka & Santa Fe.—See Eastern Oklahoma.

Broxton, Hazlehurst & Savannah.—See Fitzgerald, Ocilla & Broxton.

Chesapeake & Ohio.—This company has sold to Blair & Co., New York, $5,000,000 6 per cent., three-year notes; they are to be secured by the $10,000,000 general improvement and equipment 5 per cent. bonds, an issue of which will be authorized later. The proceeds of the sale of the notes are to go towards paying off floating debt and other current needs.

Chicago & Alton.—The Union Pacific and the Chicago, Rock Island & Pacific Railway Company have jointly agreed to guarantee that the Chicago & Alton will have at least $1,666,000 to spend on improvement work now under way, consisting particularly of track elevation at Chicago. The Chicago & Alton is to use its surplus for this purpose, and if this surplus is not enough, the other two companies will lend it money, up to the amount named, taking Chicago & Alton notes in return.

Chicago, Burlington & Quincy.—The lease of the Chicago, Burlington & Quincy Railroad to the Chicago, Burlington & Quincy Railway Company has been rescinded, and the railroad company has resumed the operation of the road. The railway company was organized in 1901 for legal reasons.

Chicago, Rock Island & Pacific.—See Chicago & Alton.

Colorado Southern, New Orleans & Pacific.—An agreement has been concluded by which this company will temporarily use the terminal facilities of the Kansas City Southern at Beaumont, Tex. The C. S., N. O. & P. has already trackage rights over the Kansas City Southern from De Quincy, La., to Beaumont. It will later build its own terminal.

Denver, Enid & Gulf.—See Eastern Oklahoma.

Eastern Oklahoma.—The Denver, Enid & Gulf, which was taken over by the Atchisou last year, has been transferred to the Eastern Oklahoma, which operates most of the Atchison branch lines in Oklahoma.

Fitzgerald, Ocilla & Broxton.—This is the successor company to the Broxton, Hazlehurst & Savannah, which company owns the Ocilla & Valdosta. The entire line runs from Broxton, Ga., to Irwinville, 33 miles, with a five-mile branch to Fitzgerald.

Kansas City, Mexico & Orient.—This company is offering for subscription at par $400,000, first mortgage, 4 per cent. bonds of 1951. A bonus of $400 preferred stock and $400 common stock is given with each $1,000 bond. The proceeds of the sales are to be used to finish grading from Emporia, Kan., to Kansas City. It is expected to have the road in operation from Emporia to San Angelo, Tex., at the end of the year, and at that time also 65 per cent. of the line in Mexico will be ready for operation.

Kansas City Southern.—See Colorado Southern, New Orleans & Pacific.

Medford & Crater Lake.—See Pacific & Eastern.

Pacific & Eastern.—This company has been organized to own and operate the Medford & Crater Lake, which runs from Medford, Ore. to Eagle Point, 11 miles, and was sold at receiver's sale on May 11 for $82,500. The new company is to extend it to Butte Falls and Klamath Falls, 89 miles. The Rogue River Valley Railroad, which runs from Medford to Jacksonville, 6 miles, has been bought by the same interests. The new company has $1,000,000 authorized capital stock, of which $500,000 is outstanding and $1,000,000, 6 per cent. bonds of 1937 authorized, of which $200,000 is outstanding.

Pennsylvania, New Jersey & New York.—See Pennsylvania Tunnel & Terminal.

Pennsylvania, New York & Long Island.—See Pennsylvania Tunnel & Terminal.

Pennsylvania Tunnel & Terminal.—This company has been incorporated in New York State with $40,000,000 capital to take over the Pennsylvania, New York & Long Island, and the Pennsylvania, New Jersey & New York. (June 21, p. 918.)

Pittsburg, Fort Wayne & Chicago.—The New York Stock Exchange has listed $1,431,900 additional guaranteed, special improvement stock, making $38,806,400 outstanding. The stock was sold to the Pennsylvania Railroad to partially reimburse that company for motive power, rolling stock, additional tracks, track elevation and other improvements. The stock is guaranteed by the Pennsylvania Railroad; and the Pennsylvania Company, according to its last annual report, holds in its treasury $33,443,400 of it.

Public Service Corporation.—An initial quarterly dividend of 1 per cent. on the $12,500,000 outstanding capital stock of this company was paid on July 1. The company controls nearly all the street railways of northern New Jersey, and gas and lighting interests in the greater part of the state. It owns and operates 258 miles of road and controls about 200 miles more.

Rogue River Valley.—See Pacific & Eastern.

United Railways of St. Louis.—The Mississippi Valley Trust Company and Francis, Brother & Co., of St. Louis, are offering 95.54 and interest for $200,000, two-year, 5½ per cent. collateral trust notes due July 1, 1909, but subject to call after July 1, 1908. They are secured on $1,500,000 general first mortgage, 4 per cent. bonds and $500,000 preferred stock. The proceeds of the sale will be used for paying up the majority of the $1,500,000, 6 per cent. bonds of the Citizens' Railway, a subsidiary.

Union Pacific.—See Chicago & Alton.

Yosemite Valley.—N. W. Halsey & Co., New York, have sold the majority of the $3,000,000 first mortgage, 5 per cent. bonds of 1936 of this company, which was recently put in operation from Merced, Cal., on the Southern Pacific and the Atchison, to the Yosemite National park, 80 miles. The terminal is connected with the government roads in the park by a new stage road. The railroad is to be operated all the year round.

RAILROAD GAZETTE

ESTABLISHED IN APRIL, 1856.

PUBLISHED EVERY FRIDAY BY THE RAILROAD GAZETTE AT 83 FULTON STREET, NEW YORK.
BRANCH OFFICES AT 375 OLD COLONY BUILDING, CHICAGO, AND QUEEN ANNE'S CHAMBERS, WESTMINSTER, LONDON.

EDITORIAL ANNOUNCEMENTS.

THE BRITISH AND EASTERN CONTINENTS edition of the Railroad Gazette is published each Friday at Queen Anne's Chambers, Westminster, London. It contains selected reading pages from the Railroad Gazette, together with additional British and foreign matter, and is issued under the name Railway Gazette.

CONTRIBUTIONS.—Subscribers and others will materially assist in making our news accurate and complete if they will send early information of events which take place under their observation. Discussions of subjects pertaining to all departments of railroad business by men practically acquainted with them are especially desired.

ADVERTISEMENTS.—We wish it distinctly understood that we will entertain no proposition to publish anything in this journal for pay, EXCEPT IN THE ADVERTISING COLUMNS. We give in our editorial columns OUR OWN opinions and these only, and in our news columns present only such matter as we consider interesting and important to our readers. Those who wish to recommend their inventions, machinery, supplies, financial schemes, etc., to our readers, can do so fully in our advertising columns, but it is useless to ask us to recommend them editorially, either for money or in consideration of advertising patronage.

OFFICERS.—In accordance with the law of the State of New York the [illegible] and name of the paper is made of the office of publication, at 83 Fulton St., New York, N. Y., and the names of the officers and editors of The Railroad Gazette are:

OFFICERS:

W. H. BOARDMAN, *President and Editor*	RAY MORRIS, *Secretary*
E. A. SIMMONS, *Vice President*	R. S. CHISHOLM, *Treas.*
	I. H. RINES, *Cashier*
	L. B. SHERMAN, *Western Manager*

EDITORS:

RAY MORRIS, *Man'g Editor*	GEORGE L. FOWLER
BRAMAN B. ADAMS	FRANK W. KRAEGER
CHARLES H. FRY	HUGH RANKIN
RODNEY HITT	BRADFORD BOARDMAN

CONTENTS

VOL. XLIII., No. 2. FRIDAY, JULY 12, 1907.

A. C. Shand, Chief Engineer of the Pennsylvania Railroad, makes the following comparative statement of rail failures on the lines east of Pittsburg and Erie:

"During the year 1901 there were removed from main running tracks on the Pennsylvania Railroad east of Pittsburg and Erie, 675 defective rails, a very large portion of these, however, were not broken, but were rails that were not properly holding up under the traffic and were what is commonly known as 'mashing' on account of the loads passing over them. This represents 46.6 rails removed from tracks on account of defects for every 1,000,000,000 tons of freight moved one mile. In the year 1905 there were removed 1,747 defective rails, or 90 rails per 1,000,000,000 tons moved one mile. Not one-tenth of these rails were broken."

The rest of the statement is a deserved advertisement of the safety of passenger travel on the Pennsylvania, a safety obtained by vigilance and a high grade of inspection. But Mr. Shand makes the unusual deduction from his figures that, "The Pennsylvania Railroad has little cause for complaint on account of defective rails," although the failures in proportion to tonnage were nearly twice as great in 1905 as they were in 1901. Moreover, the overwhelming evidence of bad rail making developed during the year 1906, and that year is not referred to in the comparison. Another general officer of the Pennsylvania made, in April of this year, the following statement of present conditions which would seem to indicate that if Mr. Shand would bring his statistics up to date they might be still more enlightening, although less valuable as an advertisement of safety on the Pennsylvania:

"We have been in danger in the past, but we are in more danger at the present time. We received one lot of rails this year from a mill; they travelled but a short distance on the cars, and there were eight of those rails broken when they arrived at their destination. We unloaded those rails as carefully as we could on skids, sliding them down so they would not strike, and there were seven broken in unloading. Now, that shows that you are not making as good a rail as you were some time ago, and yet you see the danger we are in, and until you make an open hearth or some other better kind of rail we are still in greater danger."

The Perry theory of boiler efficiency as developed under the auspices of the United States Geological Survey (see paper on Boiler Efficiencies in another column) promises to be of a value that it is difficult to estimate. As stated in the resumé of the scope of the work, its verification will result in "placing the steam boiler on a fairly secure mathematical basis." The first statement of the theory would be more than apt to excite the skepticism of any one familiar with the data available regarding boiler practice, it is so startling in its novelty. But when it is presented from a source of such undoubted honesty, and when this presentation is accompanied by a statement to the effect that the experiments that have been made have verified the theory to a wonderful degree, it must attract respectful attention. With such promises of a final establishment of the theory, it goes without saying that the future bulletins that shall be issued by the department will be awaited with a high degree of interest. The theory is by no means new, since it was set forth several years ago; but, while it attracted attention at the time, it was regarded more as the theory of an individual than a statement of a general law that must command respect as such. Further, it lacked, at the time, the corroborative experimental data needed to establish its correctness, and it is this experimental data that the United States Geological Survey has taken it upon itself to provide.

BAD RAILS BY BAD MAKERS.

The present attitude of the United States Steel Corporation is not unlike that of its principal predecessor in the days when money getting was his sole object and possible enforcement of law and penalties for violated contracts constituted his restraint. His not infrequent smiling answer to indignant remonstrance was: "Why didn't you get it from me in writing?" Or, in other cases: "Look at the penalty clause; there's your liquidated damages." The attitude of the rail makers, while not precisely comparable, has a like result of tonnage, reckless tonnage ignoring the increasing losses of life and property due to bad tonnage, relying on the restraint due to the power to divert traffic from any one railroad to prevent any one railroad company from insisting on good tonnage; relying also on its arrangement with foreign makers for restraint of competition, sustained by the United States protective tariff of about $7 a ton.

During the early period of rising indignation and protest from a few outspoken railroad officers, the steel company was silent. Later, as if in reply, we had statements of the number of months ahead for which the capacity of the mills was booked. This year

the possibility of some recognition of the charge that the rail product was bad was foreshadowed in its report as follows: "Since January 1, 1907, the orders received have been somewhat less than they were during the months immediately preceding that date." Soon after this came a childish statement by one of the heads of the steel corporation that rails break because of increasing wheel loads. Following this first indication of attention there has been an indirect and non-authoritative spreading abroad of the statement that rails are now being made according to the wishes of the consumers, who want and get cheap rails; that if better rails are demanded the price will be increased to a degree not yet intimated.

For about five years the steel company has maintained a somewhat uniform price, during slack times and flush times, and has earned by this one action the approval of thinking people because of its conservative and tempering effect. It is only in recent years that greed for tonnage and its profits has led to increasing adulteration of the product, and this is made possible by an undue protective tariff on imported rails, as well as by control of an enormous traffic which can be diverted from one railroad to another. We all recognize that "trusts" are dangerous, and here is the most conspicuous modern example of a trust imperious, with its power for injury to the whole people derived from a kindly paternal law and the lack of united action by the railroads.

It may be well to repeat one at a time in order that the non-technical man may more fully appreciate them, some of the bad practices in rail making. Only about three-quarters of a Bessemer steel ingot, even after it is elongated and compressed to a bloom, consists of tough homogeneous steel. In the upper part of the ingot, which cools last, pipe holes occur and the phosphorus, silicon and other constituents are "segregated" from the iron—the steel is not homogeneous and strong. It is decidedly unfit material for rails. That due to this cause alone many rails are treacherous and liable to cause loss of life was plainly shown in eight of the twelve photographs of broken rails shown in this paper for May 17 on pages 676, 677 and 678. The rail makers now cut off and discard from 10 to 12 per cent. of the ingot. It has been conclusively shown by experience that unless an average of something like 25 per cent. is rejected many of the resulting rails are not simply dangerous, they are sure to break, and the only element of uncertainty is the loss involved in that foreordained failure.

It would seem that with full knowledge by the railroad officer and the rail maker of this one defect, too small a discard from the top of the ingot, there would be nothing left to discuss. The railroad company wants rails that are safe for 15 to 20 years, not those that are unsafe for 15 to 20 weeks. The rail maker wants a sale for the greatest possible tonnage, but it is not conceivable that he hopes for a permanently increased demand due to a heavy percentage of failure of bad product. No, his answer may be expected to be that he cannot remelt and use this increased discard from the ingot in Bessemer steel rails; that, although this discard might be used in open hearth steel, it would take some years to get such open hearth plant in operation, and there are other objections. Meantime, before taking any step toward improvement, and while defiantly continuing to produce more than 150,000 tons a month of rails with a heavy percentage of a kind doomed to break, he is ready to consider an agreement for an increased price. This is a hold-up similar to that of a powerful and reckless trade union, and needs to be treated with similar methods to secure the same end. Tariff protection for dishonest product is not justifiable and combined action can baffle threats of traffic diversion.

THE NEW HAVEN-BOSTON & MAINE ANTI-MERGER LAW

The passage with outward unanimity of the New Haven-Boston & Maine anti-merger bill by the Massachusetts legislature again reminds one how the wave of corporation restriction, starting at the West, has surged over conservative New England. Vermont two or three months ago enacted drastic railroad legislation that makes many of the wild western statutes seem tame. New Hampshire, at about the same time, had her wrestle with the railroads, but along more ethical and common sense lines. And, later, in the last tepid days of a long legislative session, Massachusetts, too, has taken her throw out of the railroads. In the Massachusetts episode there was an antecedent element of comedy. Boston went into convulsions of dread when it was announced that President Mellen might sell out his Sound fleet to Mr. Morse. Boston next reverted to effusive gratitude when the Morse offer of $20,000,000 was declined. And then, in yet a new revulsion of feeling, Boston joined with outer Massachusetts in angry condemnation of the New Haven-Boston & Maine merger and Beacon Street made pact with Berkshire in resisting it. In it all, doubtless, as reported, was a deep vein of politics. Each party feared the other party would "get the drop" on it in an anti-merger appeal to the people at the next state election. But this is a mere sidelight on one of the most remarkable pieces of legislation that ever emerged from under the gills of the symbolic and sacred codfish.

Reversing the order of nature the ostensible sting of the law is in its head. The first section prohibits any railroad corporation of the state or "any person or corporation acting in its interests," from acquiring or attempting to acquire in any way any shares of a domestic railroad company. No such corporation, or any person acting in its behalf, before next July shall vote or attempt to vote on any stock already acquired or "attempt to exercise, directly or indirectly, any control, direction, supervision or influence whatsoever over the acts or doings of such domestic corporation by virtue of such holdings of stock therein." On the domestic corporation, by the next section, a similar prohibition is laid against like acts of the persons or corporation that has acquired stock, and at the annual meeting the election is nullified if less than a majority of stock is represented. Other sections of a somewhat prolix measure give large powers to the railroad commissioners to restrict consolidation, and require that, in consolidation, there shall be no increase of freight rates or fares, or of the united capital stock of the merged companies or decrease of transportation facilities. The penal clause is not only pungent but applies to partnership, trustee and persons as well as corporations, which for violation of the act must be punished—in the case of the corporation—by a fine of $10,000 for each offence and persons by a fine of $1,000 for each offense or not less than six months or more than a year imprisonment, or such fine and imprisonment both.

Passing by the act as a curio in railroad statute-making and viewing it seriously, it has one or two interesting constitutional aspects. Its root idea is, obviously, the theory that a corporation is absolutely the creation and creature of the state in which all individual interests are submerged. But how about the same corporation's rights in other states? The Boston & Maine has charter and statutory powers in New Hampshire, and, if we are not mistaken, in Maine also. Can a law of Massachusetts bind the investments of a Boston & Maine stockholder in New Hampshire, Maine, Connecticut or New York? Where would he the legal line in conflicting legislation on the subject in Massachusetts and New Hampshire? What, in international law, is called the principle of exterritoriality thus becomes in the case of such a sweeping and radical statute important as well as complicated. Again, corporation statutes of the kind usually attack acts and almost exclusively corporation acts done by officers. But here is a unique statute not only leveled at individuals chiefly but at *motive*. It goes beyond the materialisms and invades the airy domain of psychology. Perhaps it is a laical view but one is tempted to inquire also whether in such cases, as a fundamental proposition, there is not a personal and basic right belonging to the citizen such as the right of purchase, sale and bargain. Certainly the vague and indeterminate theory of the "police power" of a state must be strained far to include some of the provisions of this singular "psychological" law of Massachusetts. Tried out in the courts and carried to the highest tribunal of the land the decision would be interesting both in tenor and text.

But the act is not to traverse the tedious and mazy path of litigation. The New Haven corporation has elected to submit, "stand pat" and await the action of the next Massachusetts legislature. This creates a situation almost as unique as the anti-merger law itself. Neither party to the merger can act. Meanwhile, as the sequel of transfers previous to the passage of the law, the New Haven owns—through its agents—about 120,000 shares of Boston & Maine stock, or about two-fifths of all the capital outstanding, and under ordinary conditions sufficient for control. The official announcement that this stock will not—as indeed is forbidden by the law—be voted, only complicates a condition in which the merger is hung up between wind and water. Can the state of Massachusetts ever by the severest of "psychological" statutes prevent Boston & Maine management from being amenable to the actual control even if not immediately, directly and formally exercised? Meantime large plans of improvement must pause, the positive benefits of a merger be postponed and all the delays and risks of an anomalous railroad interregnum be incurred. In the case of the swift and progressive policy of President Mellen this means a good deal. In the interval the state of Massachusetts can exercise its de-

tentative facility in bringing to light the telepathic relation between the two great corporations and solving some of the problems of railroad mysticism. One of them, by the way, may possibly be a subtle harmony of their attitude on the demurrage rule.

A little more common sense, less politics and an appeal to experience would have steered the Massachusetts lawmakers to a different port. They would have descried manifest destiny in the merger of two connecting corporations owning properties only in the slightest degree competitive. They would have seen the public benefits to accrue from the dominant policy of a corporation which has been aggressive and expansive as compared with a corporation which has not cultivated its transportation field. They would have let go unheeded the "monopoly" cry in times when it is peculiarly a restraint on unjust railroad aggression, and, searching deeper into the facts, they would have found that, during the last fifteen years, the complete monopoly of southern New England has made a far better record in reduction of freight rates and fares than the incomplete monopoly of southern New England or the fiercely assailed Boston & Albany, which is no monopoly at all. Along with such reasonings would have come thoughts of what consolidation would have wrought in the way of improved inland subsidiary service on the one hand and the more important coastwise service on the other. The merger proposition might have justified some mild restrictive conditions coupled with the permit to go ahead. Instead there has been a statute so radical as to be fantastic and a perilous delay that awaits the dawn of legislative intelligence.

HEAVY FREIGHT TRAINS.

In Mr. Priestley's report on American railroads to the Indian Government, he emphasizes and reiterates again and again the use and value of statistics as they are compiled in the United States. Their chief value is attributed to the fact that they enable a railroad manager to compare the performances of to-day with those of yesterday or last month or last year and thus put himself in a position to curb losses and estimate the value of improvements. To those who are not in immediate charge, the interest in comparative statistics lies in the fact that they make it possible to keep posted as to the progress of events and the changes that have taken place in the methods of obtaining the same results or in doing the same thing. Thus attention has been called in these columns, from time to time, to the growth and development of the modern car and locomotive from those in use 25 or 30 years ago, and the changes have been startling. Most of this present condition has, however, come upon us so gradually that it is difficult to realize what it means until we resort to our comparative statistics and note what has actually been accomplished.

For example the gulf between the freight train weights of 10 years ago and now is greater than appears to the casual observer. To the man on the street there is but little difference in the appearance of the freight train of 1896 and of 1906. If he had counted the cars on some of our principal lines then and now he would have found what to him would seem an insignificant increase. For instance, he would have found trains averaging about 47 cars long on a number of roads in 1896, and that these had grown to about 52 in 1901, and to 56 in 1906. To be sure, this represents a growth of something more than 19 per cent. in train length in 10 years; but, at the same time, he would have found that on some roads there had been an actual falling off in the number of cars hauled per train. In the case of the Middle division of the Pennsylvania, for example, which probably stands for the heaviest traffic on the line, there has been a steady decrease in the number of cars hauled per train during these 10 years. In 1896, the average number of cars loaded and empty hauled per train over this division was 54.52. In 1901 it had fallen to 50.04, and in 1906 to 42.83. So that it is evidently necessary to go behind mere external appearances in order to obtain a correct idea of what is being done.

That the growth of the car capacity has been very great we all know. It has risen from an average maximum of about 60,000 lbs. to 110,000 lbs., and if a comparison of engine sizes were to be made on the same basis as that of train lengths first outlined we would find that, taking cylinder capacity as the standard, the 19-in. by 24-in. cylinder of 1896 had grown to 22 in. by 26 in. in 1901 and to 22 in. by 28 in. in 1906. And when this increase is coupled to a rise in steam pressure from about 165 lbs. to 200 lbs., the tractive power of the locomotive rises accordingly and we find that its increase has been about two-fold, or from 20,000 to 40,000 lbs. This, of course, means that the actual tonnage hauled has increased in some relative proportion, for these heavy locomotives are not built, except in rare instances, to do the work of the lighter power that preceded them.

Taking the Middle division of the Pennsylvania as a concrete example of this we find that the average weight of the train was 1,326.11 tons in 1896, 1,444.63 tons in 1901, and 1,754.95 tons in 1906. As for the tractive power of the typical consolidation locomotive in these three years, it was 23,040 lbs. for the first year and 39,688 lbs. for the last two, thus showing an increase of about 72.26 per cent in tractive power and but 18.2 per cent in the average weight of the train hauled. This must not be taken to mean that the extra increase in engine power is wasted because in the figures given it is the average train load that is considered, and this includes not only all loading up to the capacity rating of the engine but light and empty trains, by which the requirements of railroad service will invariably cut the average down to a point far below the maximum. Where the figures are available and it is possible to separate the train weights in the direction of traffic from the empty haulage, the relation between the tractive effort of the engine and train weights is naturally much closer. For example, on the Chicago & Alton, on the double-track line between Bloomington and Brighton Park, the engines used in 1896 had cylinders 18 in. by 24 in. and a tractive power of 18,176 lbs.; in 1901, the cylinders were 21 in. diameter by 32 in. stroke, and the tractive power was 42,090 lbs.; in 1906 these figures were 22 in. by 30 in. and 43,305 lbs. Meanwhile the train tonnage northbound was 1,350, 2,700 and 3,206 tons for the three years, respectively. A comparison of the increases for the three years may be stated as follows:

	Tractive power.	Train weights.
1896	1.00	1.00
1901	2.32	2.00
1906	2.33	2.37

This illustration shows that, in this case, at least, the engine rating has increased in almost exactly the same ratio as the tractive power. The greater increase of the former is undoubtedly due to the lower resistance per ton of the heavy train as compared with the light one; though in this instance there was a marked increase in the number of cars. In 1896 the train referred to contained thirty 60,000-lb. capacity cars, while in 1906 there were 56 cars of 100,000 lbs. capacity.

In collecting data regarding heavy train loads a letter from the superintendent of motive power of the Pittsburg & Lake Erie states that the "heaviest freight engines have 21 in. by 30 in. cylinders, with 50-in. drivers, and carry 200 lbs. of steam, with a tractive power of 44,100 lbs. The average revenue train load for 1906 was 1,188 tons. This is probably the heaviest hauled by any railroad in the country. Were the southbound tonnage equal to the northbound, this train load could easily be run up to 2,000 tons. The rating for the engines given above is 3,500 tons, but they have hauled 4,200 tons and have made very good time. The train load for the past few years has increased about 8 per cent. yearly."

On the Mohawk division of the New York Central the drawbar pull of the standard freight locomotives was 20,600 lbs. in 1896; 31,200 lbs. in 1901, and 47,100 lbs. in 1906, and the average number of eastbound cars hauled in the three years was 46, 56 and 67, carrying a tonnage of 1,301, 1,834 and 2,421 respectively.

The Philadelphia & Reading tells the same story of a marked increase. Here the southbound tonnage from Reading to Philadelphia was from 1,950 tons in 1896 to 2,910 tons in 1901 and 3,300 tons in 1906. With the increased length of train and the greater weight of cars and engines, there has also come a slower average speed over the division in some cases, though this is not always true. The Middle division of the Pennsylvania is a notable exception to what appears to be the ordinary rule. For example, the time of slow trains was 11 hrs. 13 min. in 1896; 14 hrs. 29 min. in 1901, and 11 hrs. 47 min. in 1906; while that of preferred trains dropped from 9 hrs. 32 min. in 1901 to 7 hrs. 46 min. in 1906, showing that the facilities for handling the traffic have more than kept pace with the increase of tractive power and engine rating, since the time of delays has dropped from three to two hours, thus somewhat lowering the running speed, which is probably due to the higher proportional rating of the locomotive. This is, however, an exceptional state of affairs; for, in most cases the time required to cover a division has increased; increased both in the actual running time and in the delays, showing that not only is the speed slower because of the probable higher engine rating but that the traffic facilities for handling trains has not always kept pace with the increase of train load as combined with the greater number of trains, although in some cases the latter is not a factor of appreciable importance. An instance of this is found in one

road where the average delays increased from 2 minutes to 1 hour and 3 minutes between 1896 and 1906, while but one train a day was added. Yet the average length of train was increased more than 45 per cent. In this case the delays can undoubtedly be traced to inadequate terminal facilities, as the yard that has to handle this traffic has been built up by accretions and is not particularly well adapted for rapid work with long trains. Other roads that show the same running speed as formerly present the same record of increase of delay time; while others again show both the falling off in running speed and increase of delay time that has been referred to, in some cases the delays having risen from 25 to 50 per cent. on an already liberal margin.

Now by reverting to the conditions set forth in the early portion of this paper we find that on the Pennsylvania Middle division there has been an actual falling off in train lengths so that yard capacity has merely been obliged to keep pace with the increase in the number of trains which is apparently a far easier proposition than that of providing for extra and often extraordinary train lengths. In this case the traffic rose from 30 trains per day in 1896, to 45 trains in 1901 and 50 in 1906; and, as already stated, the delays dropped from three to two hours. There may be other causes contributing to this excellent showing, but it certainly does appear to be a fine demonstration of the value of keeping train lengths down to such dimensions that they are readily handled in the yards, a condition that can only be economically attained where heavy motive power is worked, by the liberal and almost exclusive use of cars of high capacity.

Of course it is quite impossible to make a comparison of train lengths between different roads that would be of the slightest value because of the natural differences in the character of the traffic, grades, power, cars and terminal facilities; but, by comparing the past and present performances of individual roads, a general average of the increase of work done per train can be obtained, and this will probably average an increase that can be estimated at not far from 60 per cent.; though, in individual cases, it will rise much higher than this. This latter is especially true where superintendents have gone tonnage mad and put up engine ratings to a point where delays and slow time will cut out all profit; and, in this, experience seems to show that short trains are better than long ones.

The elements that make for this increase of train load and render it of the greatest value are, taking the track to be of a suitable character, first the heavy power, then high capacity cars, and then suitable yard facilities. In this the high capacity car plays an important role by facilitating yard movements, and it appears to be of prime importance that the train should be made of a length that can be readily handled instead of being increased to such dimensions as to add to the delays that must always be vexatious under the best of conditions. Superintendents and managers are coming to a better realization of this and see that long trains are not always the most profitable. While it would be hazardous to say what will be the ultimate weight and length of train on any road, it is at least interesting to note the great advance that has been made along these lines during the past 10 years, the means by which it has been accomplished and the results that have been attained.

Train Accidents in May.[1]

Our record of train accidents occurring on the railroads of the United States in May includes seven collisions and 21 derailments, 28 accidents in all. This record is not published in full, as was formerly done, except in the cases of the few accidents which are especially prominent—in the present instance two collisions and one derailment. The record of "ordinary" accidents—which term includes, for our present purpose, only those which result in fatal injury to a passenger or an employee or which are of special interest to operating officers—will henceforth be given as below, in the shape of a one-line item for each accident, showing date, location, class and number of deaths and injuries.

This record is based on accounts published in local daily newspapers, except in the cases of accidents of such magnitude that it seems proper to send a letter of inquiry to the railroad manager. The official accident record published quarterly by the Interstate Commerce Commission is regularly reprinted in the *Railroad Gazette*.

Only one accident in May was decidedly prominent as compared with the rest. That was the derailment at Honda, Cal., on the 11th. This accident was reported in the *Railroad Gazette* of May 17, page 691, though the number of casualties proves to have been much larger than was then reported. Of the 55 injuries to passengers, however, 45 are classed as slight. The cause of the accident could not be determined. An officer of the road says that a board of inquiry consisting of three general and four division officers, assisted by others, investigated the circumstances thoroughly, yet found it impossible to decide as to the cause. The members of the board felt sure it was not a defective switch. The train was running at regular but not unusually high speed.

One other accident caused the death of six persons and a third one killed four. The six men killed (at Dayton, Tenn., on the 21st) were miners riding from their work to their homes on coke cars which, it appears, are regularly used for this purpose. The car in which the victims were riding was at the rear of a short train and it was struck by some runaway cars which had escaped from a side track where they were being moved by means of a pinch bar and hand power, with the intention of changing their position slightly to facilitate unloading. The point where they escaped control was on a grade of about 35 ft. to the mile, and the cars soon attained such speed that they overtook the car carrying the miners. These men saw their danger but their own train was moving so fast that they dared not jump off.

The third prominent accident was the butting collision at Rosby's Rock, W. Va. A passenger train collided with a freight while the latter was entering a side track. There was a dense fog at the time, and it is said that although a flagman was sent out by the freight, the engineman of the passenger train did not see him.

Among the usual newspaper reports of accidents to electric cars in the month of May we find six cases which were accompanied by fatal injuries, the total number of deaths in these six cases being 12 or more, and of injuries 123. In one rear collision at Elyria, Ohio, seven persons were killed and six injured; and in collisions at Brooklyn, N. Y.; Akron, Ohio, and Bowling Green, Ohio, the aggregate number of casualties was 112.

Train Accidents in the United States—May, 1907.

[1] Abbreviations used in Accident List:
rc.—Rear collision.
bc.—Butting collision.
xc.—Other collisions; as at crossings or in yards. Where only one train is mentioned, it is usually a case of a train running into a standing car or cars, or a collision due to a train breaking in two on a descending grade.
b.—Broken.
d.—Defective.
dr.—Defect of roadway.
eq.—Defect in car or engine.
n.—Negligence.
unf.—Unforeseen obstruction.
unx.—Unexplained.
derail.—Open derailing switch (negligence of engineman or signalman).
ms.—Misplaced switch.
acc. obst.—Accidental obstruction.
malice.—Malicious obstruction of track or misplacement of switch.
boiler.—Explosion of boiler of locomotive on road.
fire.—Cars burned while running.
Pass.—Passenger train.
Ft.—Freight train (includes empty, engines, work trains, etc.).
*Wreck wholly or partly destroyed by fire.
†One or more passengers killed.

Boiler Efficiencies.

Experiments now being conducted by the boiler division of the United States Geological Survey fuel-testing plant at St. Louis, Mo., on the nature of boiler efficiencies have suggested that stationary boilers ought to be made to do ten to twenty times as much work per unit of heating surface as they do now.

This great increase in capacity is to be attained by subdividing the heating surface and water streams more finely and by allowing less restriction of the water inside the boilers and by using high

forced and induced draft to put a large mass of gases through the boiler at a very high speed.

Up to the present time there have been only vague ideas among engineers as to what factors influenced the efficiency of the steam boiler portion of the steam generator apparatus so as to cause it to absorb more or less of the heat generated by the combustion. John Perry, a distinguished mechanical and electrical engineer of England, went into the subject mathematically a few years ago and set forth general conclusions tentatively in his book on the "Steam Engine and Gas and Oil Engines."

About a year ago the government testing plant took up the mathematical investigation of the theory of the steam boiler and of heat absorption, and extended Mr. Perry's theory somewhat. For some weeks past Walter T. Ray, assistant engineer, acting under the supervision of Prof. L. P. Breckenridge, engineer-in-charge of the boiler division, has been conducting a series of experiments on small multi-tubular boilers so dimensioned as to enable the theory to be verified, or modified, or refuted. The boilers are fed with air heated electrically. Mr. Perry's theory states that modifying conditions being omitted from consideration, every boiler will always absorb by convection from the gases passing through it, the same percentage of heat which could possibly be absorbed by any boiler containing water at a given steam temperature. This efficiency is, therefore, independent of the temperature of the entering gases and of the amount of gases flowing through the boiler. Of course, it must be understood that the above statement of the theory is slightly subject to modification even theoretically, and more so in practice.

As a practical example, assume that the water in a boiler circulates with entire freedom, which is an unwarranted assumption, and that its temperature is 300 deg. F.; let the gases enter the boiler at 1,300 deg. F., then the difference between the two is 1,000 deg. F., and consequently it would be possible for a boiler infinitely long to reduce the temperature of the gases passing through it to 300 deg. F. Let us assume, however, that the gases leave the boiler at 500 deg. F., which is 200 deg. above steam temperature. The efficiency of the boiler then is 80 per cent., because it has reduced the temperature 800 deg. out of a possible reduction of 1,000 deg.

If the same boiler be supplied with gases at 2,300 deg. F., the gases enter the boiler at 2,000 deg. F., above steam temperature. Mr. Perry's theory states that this particular boiler will reduce these gases 80 per cent. as much in temperature as would a boiler infinitely long; that is, to 400 deg. above steam temperature, which is 20 per cent. of 2,000 deg., or to 700 deg. F. It will be noticed that the mass of gases does not enter into consideration at all.

This surprising deduction is being accurately verified by the aforementioned division of the survey, from which it is found, when keeping other conditions the same and when keeping the initial temperature of the gases constant, that the final temperature of the air remains the same whatever the amount of air sent through the boiler per second. So far the upper limit has not been reached with tubes clean inside and out, although the rate of evaporation has already been pushed up to many times that obtained even in locomotive practice.

Perry's theory takes into consideration four fundamental features affecting heat absorption at any point of the heating surface:

First—Temperature difference between the gases outside any portion of the boiler tube and the water inside.

Second—The number of molecules per cubic inch in the gases outside the boiler tube.

Third—The specific heat of the gases at constant pressure.

Fourth—The velocity of the gases parallel to the heating surface.

Of the four above factors, only the first has usually been considered. It will be readily seen that if we increase the temperature of the gases we decrease the number of molecules beating against any square inch of tube heating surface, and thus the second factor largely neutralizes the first, especially at high furnace temperatures.

The third factor can be taken as constant equal to .24.

The fourth factor is the new and surprising one. Mr. Perry considers that a high velocity of gases parallel to the heating surface scrubs off more or less of the dense film of gases adhering to the metal surface, which film of gases has already become cold by proximity to the metal. The higher the velocity of gases the more the scrubbing effect, and consequently the greater the amount of heat transmitted. This theory necessarily assumes that the ability of the metal to transmit heat is practically infinite, and when we consider that we ordinarily never put through a boiler tube more than 1/1000 of heat it could possibly carry, it will be realized that this assumption is warranted.

Mr. Perry's theory and the Survey's verification of it will result in placing the steam boiler on a fairly secure mathematical basis, the same as generators and motors are now on. Thus far the experiments check out the theory excellently. The theory and results will be embodied in a special [illegible] or three months to be followed by [illegible] as the work proceeds.

The Iles-Murrayville Cut-Off of the Alton.

The cut-off which the Chicago & Alton has been building from Iles, Ill., a point just below Springfield on its Chicago-St. Louis line to Murrayville, on its Kansas City line, has been completed and it is expected to have trains running over it about the first of August. The Kansas City line leaves the main, or Chicago-St. Louis line, at Bloomington, running southwest to Roodhouse, where it is joined by a northerly branch from St. Louis, Roodhouse being the division point for the eastern and western divisions of the system. The present Bloomington-Roodhouse line is unsuited for heavy-tonnage freight or high-speed passenger operation, because of its numerous curves and 0.8 and 1 per cent. grades. Traffic requirements to and from the western territory necessitated either revising and rebuilding the old line or some other provision to permit maximum tonnage freight trains to be run from Roodhouse to Chicago.

The Alton's heaviest tonnage is in coal from the fields at and south of Springfield, and the Chicago-St. Louis line had already been rebuilt for the most part to a gradient and curvature suitable for this traffic. It is now double-tracked between Chicago and Bloomington, 126.6 miles, and between Lawndale and Iles, 37.6 miles, and the gap of 23 miles from Bloomington to Lawndale is to be completed in the near future. By building a cut-off from Iles, which is 2.2 miles south of Springfield, to Murrayville, 10 miles above Roodhouse, a low-grade line about five miles shorter than the existing line between Roodhouse and Bloomington was obtained at about what it would have cost to revise and rebuild the old line. Also the cut-off traverses considerable territory not previously served by a railroad.

The cut-off is 34.34 miles long. In one respect it is remarkable, in that it is a tangent for its entire length except for the junction curves with the two existing lines, these being 1 deg. at Iles and 20 mins. at Murrayville. The controlling gradient is 0.3 per cent. both ways. The country traversed is nearly level and the line is located for its entire length on the divide between Sangamon river on the north and Apple creek on the south. There are, therefore, no waterway crossings requiring bridges. There are three crossings with other railroads. At two of these the grades are separated. The third is temporarily a grade crossing protected by interlocking, the plans for which have been approved by the Illinois Railroad and Warehouse Commission. Ultimately these grades also will be separated. Avoidance of the two grade crossings first mentioned increased the cost of the line by more than 10 per cent. Many highway crossings also have been avoided, the grade of the line being quite high throughout its length. The line is gravel ballasted throughout and laid with 80-lb. rails. It is to be equipped with automatic block signals in conformity with the Alton main line practice. There are five stations on the cut-off, named Cockrell, Knapp, Prouty, Yeomans and Clements, after the members of the Interstate Commerce Commission as it was constituted at the time the names were assigned. Following is a brief comparative summary of the new line and present line between Roodhouse and Bloomington:

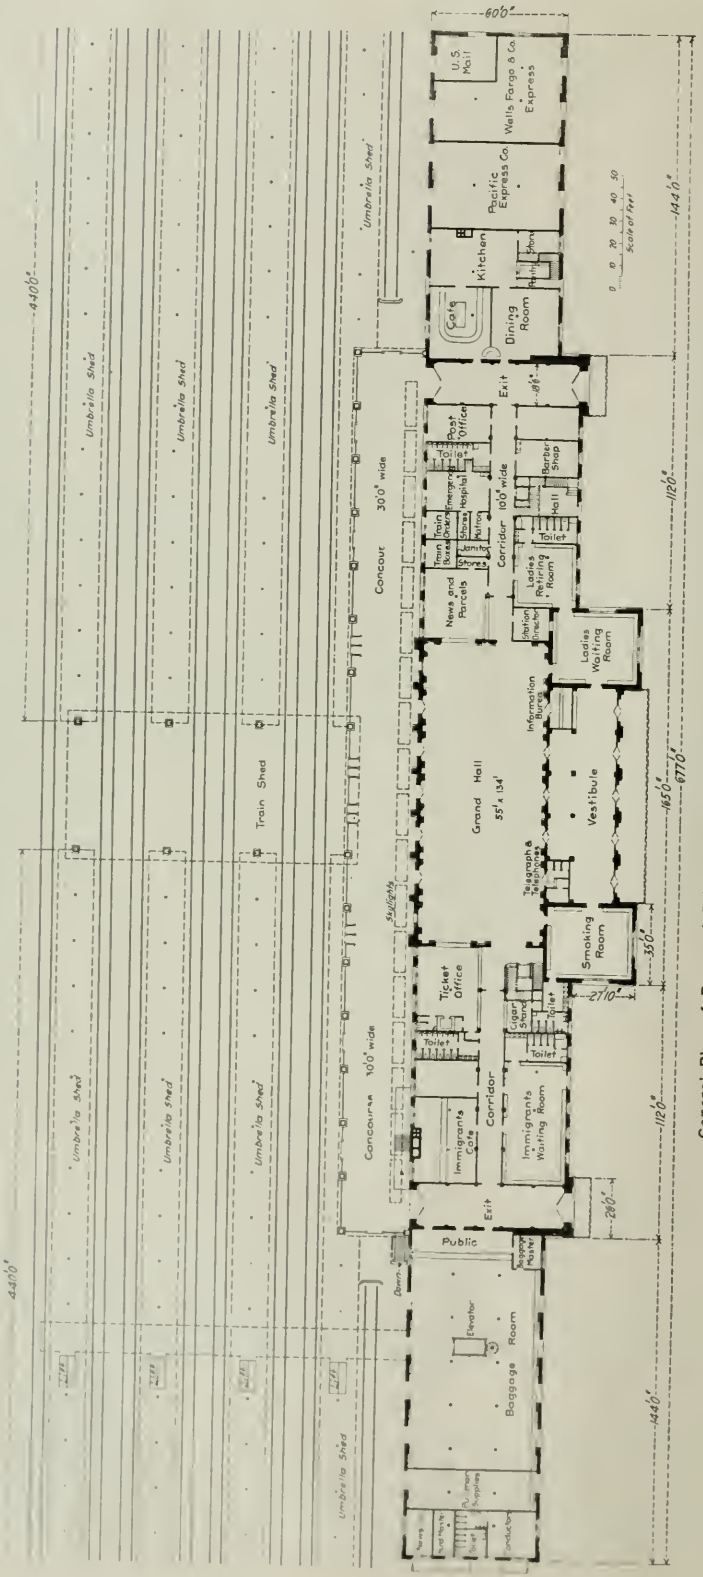
	Via Jacksonville, (old line).	Via Springfield, (new line).
Distance, miles	110.5	105.4
Total rise, ascending grades, ft.	1,059.0	512.0
Total fall, descending grades, ft.	934.0	387.0
Total degrees curvature	940.0	226.0
Maximum degrees of curvature	5.0	2.0
Controlling grade northbound, ft. per mile	38.6	15.8
Controlling grade southbound, ft. per mile	52.8	37.4

New Station, Yard and Terminal Facilities of the Harriman Lines at Salt Lake City.

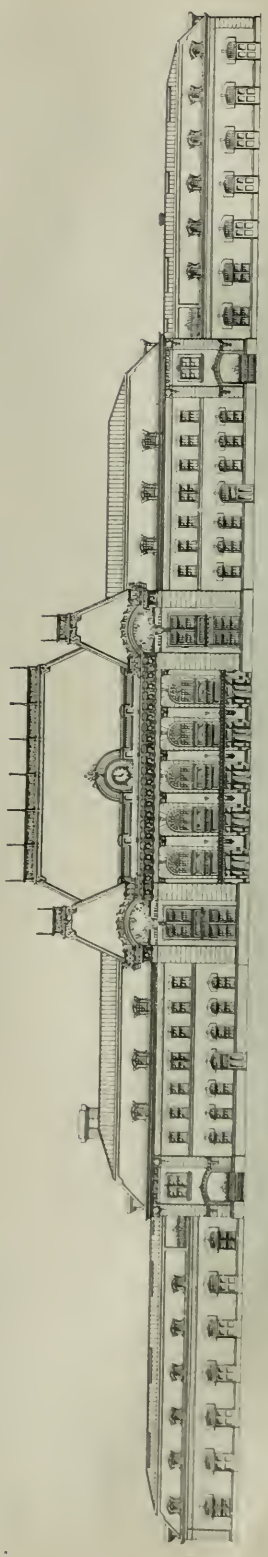
A view and brief description of the proposed new union station to be built at Salt Lake City, Utah, by the Oregon Short Line for the joint use of the Harriman lines centering there were given in our issue of January 25. Through the courtesy of J. D. Isaacs, Consulting Engineer of Bridges, Buildings and Signals for these lines, we are now enabled to present a more complete description, with plans and elevations from the architect's drawings.

In planning the station, careful study was given to securing the most desirable arrangement for the handling and comfort of its patrons. The location is ideal. It is in the center of South Temple street at the axis of West Third, affording a fine view of the building from East Temple street through rows of boxelder trees which line each side of South Temple street. The building is 677 ft. long over all by 70 ft. wide, with a height for the central portion of 100 ft. to the top of roof cresting. The entrances, five in number, leading to a spacious vestibule, are in the center of the main facade and are protected by a wide marquee supported by ornamental iron brackets and heavy chains.

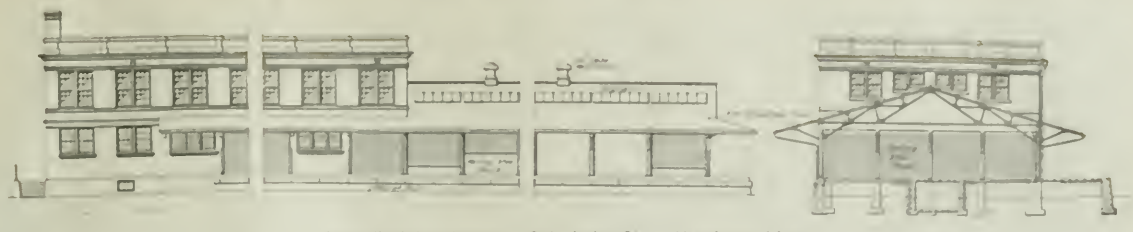
The vestibule opens into the general waiting room or grand



General Plan of Proposed Salt Lake City Union Station for the Harriman Lines.



Proposed Union Passenger Station for the Harriman Lines at Salt Lake City, Utah.

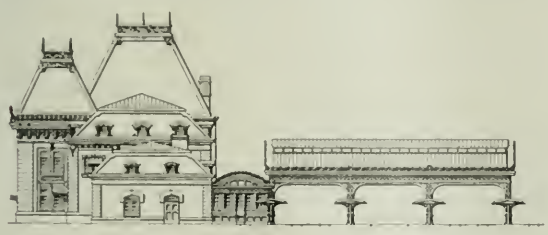


New Freight House at Salt Lake City; Harriman Lines.

hall, 55 ft. wide by 135 ft. long, with a vaulted ceiling two stories high from the spring of the arch, the ceiling being 60 ft. above the main floor. At the left or south of the general waiting room, separated from it only by a counter and screen, are the railroad and Pullman ticket offices and the telegraph and telephone offices; the news and parcel stands and the information bureau are at the north or opposite end of this room.

The two bays or towers flanking the central portion are occupied by the women's waiting room on the right and the men's smoking room on the left. In connection with the women's waiting room are a large retiring room, toilets, etc., and the remainder of this two-story wing contains the emergency hospital, station director's and matron's rooms and a branch postoffice. In the westerly two-story wing are the cigar stand, emigrants' waiting room, cafe, toilets, etc. Passengers coming from the trains do not enter the main waiting room, but pass through wide exits at each end of the two-story wings, going directly to the street or cab stands.

The baggage room occupies the extreme western wing. It has a basement floor below and a low mezzanine story above the ground floor for the storage of baggage not immediately called for. It is reached by a central corridor leading directly from the general waiting room. A telpherage system of transferring baggage will be installed throughout these three floors, with a large elevator



End Elevation; Salt Lake City Station.

running from the mezzanine to the basement floor. A passage or subway on the level of the basement floor runs transversely under all the tracks, having hydraulic lifts between each series of tracks, so that baggage can be loaded on a truck and taken directly to the car by way of the subway and lift without cutting any of the trains. In the extreme eastern wing will be a large cafe and dining room, express rooms, quarters for the Pullman Company, and rooms for trainmen, conductors, etc., with all necessary toilets and lavatories.

The second floor is reached by two stairways and elevators, one at the western end of the general waiting room, the other from a street entrance at the opposite end. On this floor are the offices of the several roads which will use the station. These offices are arranged on each side of a wide corridor. On the three sides of the general waiting room is an observation corridor for the use of the public and patrons, giving a view of the entire floor of the general waiting room.

At the rear or track side of the building is a one-story concourse, 50 ft. wide by 390 ft. long, with steel roof. This concourse is open on the track side above a height of 6 ft., but is arranged to be closed with sash during the winter season. Spanning the tracks transversely is an open train shed 40 ft. wide, with open lattice columns, architecturally designed, and of a height to allow the free passage of trains. This shed will protect passengers in bad weather. Between each series of tracks, and extending each way from the central train shed 400 ft., will be umbrella sheds 16 ft. wide and 10 ft. 6 in. high. The heating plant and other machinery will be located in a room in the basement.

In selecting a method of treatment the renaissance of the French school was adopted, and great care has been exercised to carry out the detail in true proportions as to ornamentation and application of same, so as not to make the building too ornate or overburdened with enrichment. Color effect of the materials for both the exterior and interior has entered largely into the design to produce a harmonious composition. The base or plinth above the ground line will be faced with finely tooled granite, while the walls above will be of brick with the outer face of pressed brick of a warm tone of buff, and the panels between windows of the central portion on the street elevation of Sienna marble. All belt courses, the water table and the entire cornice entablature will be of terra cotta of a color to match the brick work.

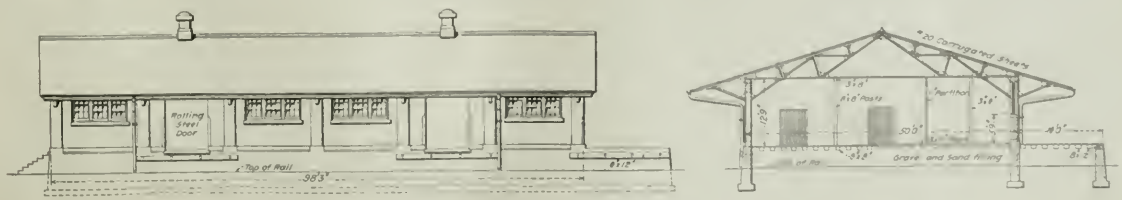
The entrance doors will be bronze, finished a dark copper color, and the marquees over the main entrance and side exits, as well as the ornamental roof cresting, will be of cast iron, plated to match the color of the doors. The entire roof will be covered with a dark green slate, laid in design, while all hips and decks of the roof will be of copper.

At the north end of the two-story wing will be an overhead iron bridge. This starts at the curb line of West Third street, gaining by easy steps a height sufficient to pass over all trains, and terminates at West Fourth street. This is to be a public thoroughfare. In the center of the main facade, above the cornice, will be a clock with the face large enough to be seen for several blocks.

The interior walls of the general waiting room are divided into panels, with pilasters placed so as to receive the ribs for the vaulted ceiling above. At the line of the second floor a cornice of ornate design will run around the entire room. The ceilings and walls at all openings will be deeply paneled with enriched plaster moulding. A large ceiling light will fill the center panel of the ceiling for about two-thirds of the length of the room, terminating with rounded ends made of art glass. Above the cornice line, at each end of the room, will be artistically designed clocks set in positions to be seen easily from any part of the room. The base and wainscot of the general waiting room and connecting corridors will be of marble and scagliola, selected for color and tone, and in harmony with the color scheme throughout the general waiting room and corridor. This color scheme will also be used in all of the second story corridors and the observation corridor. On the second floor, the observation corridor in front of the building will have arched openings, and on the opposite side there will be windows filled with art glass, appropriately designed. All of the interior wood finish throughout the building will be in quarter-sawed oak, finished in keeping with the color scheme.

The building is to be fire-proof throughout—the exterior walls of brick and the interior columns, floor girders and the floors of reinforced concrete. All of the trusses supporting the roof will be of steel, and the entire concourse and train shed will be of steel, having the roof covered with asbestos roofing. The building is to cost about $450,000, and will be built from plans made in the office of J. H. Wallace, Assistant Chief Engineer of the Southern Pacific, under the direction of D. J. Patterson, Architect for that company.

Besides the new union station, the yards and terminal facilities

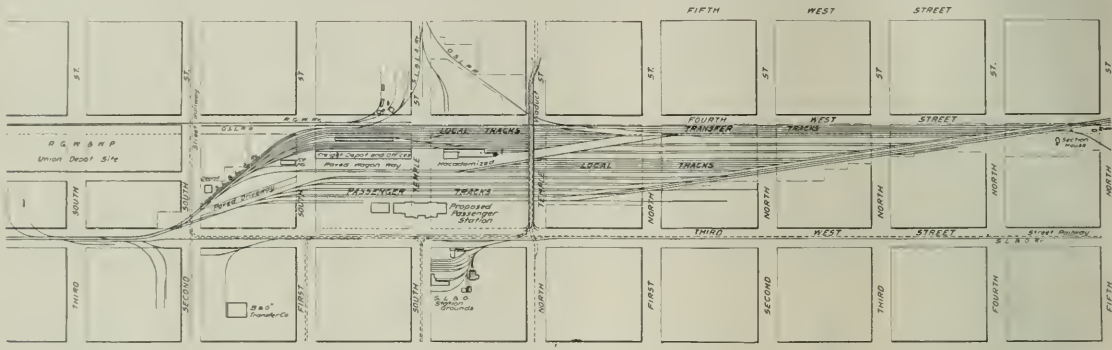


New Hide House at Salt Lake City; Harriman Lines.

of the Harriman lines at Salt Lake City, are being rearranged and extended. This work is now nearly finished. More trackage and larger terminals were needed because of the great increase in freight and passenger traffic, due to the rapid growth of Salt Lake City and the development of the resources of the surrounding country, and also in part because of the building of the San Pedro, Los Angeles & Salt Lake, which uses the yards and terminal facilities of the Oregon Short Line at Salt Lake City.

As shown on the accompanying plan, the new terminal yards are composed of two parts, called the north yard and the south yard. In the north yard are the switching, repair, roundhouse, coaling and coach cleaning tracks, while the south yard contains the passenger station tracks, transfer and local freight tracks. All incoming freight trains are sent directly to the north yard, where distribution is made as required by car lading. All outbound trains are made up in this yard. Incoming passenger trains approach the passenger station from both north and south directly over main line tracks.

The combined yards when complete will contain in all 46.8 miles of track with room for 4,100 freight cars and 455 passenger coaches. The extreme length of the two yards is 2.98 miles and the area covered 134.27 acres, most of which was acquired for this purpose. The average gradient through the yards is about 0.3 per cent. The passenger tracks are laid with 80-lb. and the freight tracks with 70-lb. rails, with No. 7 and No. 9 frogs. All tracks connecting the north and south yards at Fifth North street are protected by an interlocking plant. The crossing of the Oregon Short Line and the main line of the Rio Grande Western on Ninth South and Fifth West streets is also protected by an interlocking plant. All switches except the ones controlled by these interlocking plants are operated by hand. The entire yards are ballasted with gravel and drain to the city's drainage system.



South End of New Salt Lake City Yard.

North End of New Yard at Salt Lake City; Harriman Lines.

Note change of angle in drawing.

The new terminal facilities in the north yard include an 85-ft., 20-stall brick engine house; a 600-ton coal chute with six pockets and cable hoist; a new foundry; car repair shops; store house; coach cleaning plant; Pullman linen house, and a new ice house of 3,000 tons capacity equipped with an electric elevator of the most improved type. In the south yards a freight house, hide house, ice house, transfer platform and heavy freight platform have been built.

As indicated by the accompanying plans, the freight house is of brick, concrete and steel construction. It is 660 ft. long by 50 ft. wide, with a platform 16 ft. wide running the full length of the building on the west, or track, side. The south 157 feet of the building is two stories high, the upper story occupied by the local freight offices. The remaining 503 feet, the freight shed proper, is one story. A basement 26 ft. x 50 ft. under the south end holds a hot water boiler and coal bins. The whole building is of fireproof construction, the floors are of reinforced concrete and the roof also of reinforced concrete with surface of tar and gravel roofing. The first floor, which is on the platform level, contains the cashier's office, hallway, warm room, refrigerator room and general freight room. The cashier's office is in the south end of the freight house, directly on First South street. A vault 5 ft. 11 in. by 6 ft. 4 in. is connected with the cashier's office. The warm room, 37 ft. by 40 ft., is arranged for heating and is used for storing such freight as would be damaged by frost or cold. The refrigerator room, 10 ft. by 24 ft., is used for general freight and is connected directly with the freight shed. Rolling steel doors are installed on both sides of the building. The second floor is occupied by the local freight offices, consisting of the agent's private office, 14 ft. by 25 ft.; general clerks' office, 98 ft. by 50 ft., and record room, 32 ft. by 50 ft., complete with steel shelving and steel tables for handling the records.

The freight shed proper is built entirely of steel. Rolling steel doors, 12 ft. by 10 ft., extend the full length of the shed on both sides, enabling any part or the whole shed to be thrown open. The building is lighted throughout by electricity, the wires being enclosed in iron conduits. In the freight shed are lights about 40 ft. apart are used. The entire freight house, except the freight sher, is heated by hot water. The building was completed February 1, its total cost being $110,000.

The hide house is 50 ft. wide by 98 ft. long, and is of the same construction as the freight shed. It is used for handling green hides, beer kegs, junk, etc. It is divided in 12 compartments, each of which can be closed independently of the others. The total cost, including a 16-ft. platform on the west side, was $8,000.

North of the hide house and connected with it is the heavy transfer platform, 160 ft. long by 54 ft. wide at the south end and 30 ft. at the north end. A concrete retaining wall surrounds the entire platform. Three platform scales are provided, and at the north end there is a pillar crane of 10 tons capacity. The other transfer platform is west of the freight house and is 18 ft. wide by 400 ft. long. A corrugated iron roof covers the entire shed. The total cost of the two platforms was $7,600.

On North Temple street a solid reinforced concrete conduit was built by the railroad company across the whole width of its yards to carry the overflow from City Creek canyon. This conduit is 600 ft. long, with a sectional area of 3 ft. 9 in. by 10 ft. and a controlling gradient of about 1 per cent., while at its approach to the tracks the gradient is 6 per cent.

The North Temple street viaduct, as shown on the plan, spans

all of the Oregon Short Line tracks on North Temple street between Third West and Fourth West streets. It is a substantial steel structure of through plate girder construction supported by steel bents on concrete foundations. The length of the steel work is 916 ft. The east approach is 117 ft. long and the west approach 168 ft. long, making a total length of 1,201 ft. The minimum clearance over the tracks is 22 ft. The gradient on the east approach is 6 per cent., on the west approach 7 per cent., and on the viaduct 0.9 per cent. The floor is of wood and affords a clear roadway 24 ft. wide. On the south side a 6 ft. sidewalk is provided, which is reached by stairways at suitable points. The approaches to the viaduct are paved with stone blocks and are supported between concrete retaining walls ending in concrete abutments.

The total cost of these improvements, not including the new passenger station, will be about $1,000,000. We are indebted to W. H. Bancroft, General Manager of the Oregon Short Line, for the information. The plans for the freight and passenger yard were made in the office of William Ashton, Chief Engineer, under his personal supervision; likewise the plans for the freight house, which were prepared directly under J. P. Hill, Engineer of Buildings. The construction work was in charge of L. L. Dagron, Assistant Engineer.

June Railroad Law.

The following abstracts cover principal cases decided in June by the Federal courts:

Indictment under Elkins act.—An indictment under the anti-rebate act is not open to the objection that it sets out more than one offense, because it alleges that the defendant offered, granted and gave a rebate. United States vs. Delaware, Lackawanna & Western Railroad Co., 152 Fed. Rep. 269.

The Federal Employer's Liability Act.—Judge Hanford in the Circuit Court of Washington holds that the portion of the employer's liability act making interstate railroad companies liable for injuries, notwithstanding the contributory negligence of the employee, if the negligence of the railroad company was gross in comparison with that of the employee, is not unconstitutional as violating the commerce clause of the constitution. This statute revives the doctrine of comparative negligence—a doctrine discarded by practically every court in the United States. Plummer vs. Northern Pacific Railway Co., 152 Fed. Rep. 206.

Wilful injuries.—A railroad company cannot avail itself of the defense of contributory negligence on the part of a traveler run over and killed at a crossing if the fatal injuries were wilfully and wantonly inflicted. Lacey vs. Louisville & Nashville Railroad Co., 152 Fed. Rep. 134.

Care as to passengers boarding trains.—The rule that a train having stopped to discharge and take on passengers at a station must not be started while passengers are engaged in boarding the train, is available to one not having a ticket but intending to pay his fare on the train. St. Louis Southwestern Railway Co. vs. Wainwright, 152 Fed. Rep. 624.

Ejection of passengers.—A passenger refusing to produce a ticket or pay his fare may be removed from the train and the removal is not made wrongful because of a tender of the fare by a third person with the consent of the passenger after the process of the removal has begun. Missouri, Kansas & Texas Railway Co. vs. Smith, 152 Fed. Rep. 608.

Preferences.—An unlawful preference and discrimination is held to have been created by fixing the freight rates for common soap in less than carload lots in a new classification adopted to govern in official classification territory, at 20 per cent. less than third class, but not less than fourth class, at which that commodity has previously been rated, where the result of applying this classification to the varying rates, is to leave soap in less than carload lots in the fourth class to a considerable extent in one of the subdivisions of such classification territory and in a higher class in the other subdivisions. The Interstate Commerce Commission has the authority to order offending carriers to desist from the enforcement of such discriminations. Cincinnati, Hamilton & Dayton Railway Co. vs. Interstate Commerce Commision, 27 Sup. Ct. 648.

Transportation of liquors.—The agreement of a local express agent to hold for a few days a C. O. D. interstate shipment of intoxicating liquors at the request of the consignee to enable him to pay the charges does not destroy the interstate commerce character of the transaction and render the express company liable to prosecution for violating a state local option law. Adams Express Co. vs. Kentucky, 27 Sup. Ct. 606.

What is meant by "right of way."—Called upon to construe the meaning of the term "right of way" in a decree that one company should have the use of the "right of way" of another company, the Circuit Court of Appeals holds that the term when used to describe the real estate of a railroad company ordinarily signifies the entire strip of land which a railroad company has found it necessary or convenient to acquire for railroad purposes and is not limited to the specified part used for the main tracks of such railroad company. St. Louis, Kansas City & Colorado Railroad Co. vs. Missouri Railroad Co., 152 Fed. Rep. 849.

Liability for fire.—The Circuit Court of Appeals of the Fourth District holds that where a fire was negligently set by a railroad company's sub-boss of a bridge and trestle crew while he was engaging in one of the company's boarding cars when not on duty, the act was not performed within the line of his employment for the company, and hence it was not liable for property of others destroyed by the fire. Southern Railway Co. vs. Powers Fuel Co., 152 Fed. Rep. 917.

Condemnation of right of way for use of telegraph company.—A contract between a telegraph company and a railroad company giving the telegraph company an exclusive right of occupancy of the right of way is opposed to public policy and void, and does not prevent a condemnation of the right of way by another telegraph company. Georgia Railroad & Banking Co. vs. Atlantic Postal Telegraph Cable Co., 152 Fed. Rep. 991.

Automatic air-brakes.—A railroad company cannot be held liable for injuries, on the ground that it had not equipped its cars with air-brakes as commanded by statute, unless this violation of the statute was the proximate cause of the accident. Thus, where a pedestrian was killed on the right of way on stepping in front of a rapidly moving train without being seen by the engineer it is clear that the absence of the air-brakes was not responsible for the accident. Bookman vs. Seaboard Air Line Railway, 152 Fed. Rep. 686.

Labor unions.—Judge Cochrane, in the Federal District Court of Kentucky sustains the validity of the Federal statute punishing interstate railroads for discriminating against employees and persons seeking employment who belong to labor unions. He holds that such legislation is clearly within the interstate commerce clause of the constitution. United States vs. Adair, 152 Fed. Rep. 737.

Train Despatchers' Convention.

The twentieth annual meeting of the Train Despatchers' Association was held at Boston, June 18, 19 and 20. The attendance was large. The present membership of the association is 1,018, a net gain of 64 during the past year. The Treasurer's report showed the Association in good financial condition. The Train Despatchers' Bulletin, sent free to members, is to be increased by the addition of four pages, making 48 in all.

Discussing the report of the Train Rules Committee the association expressed belief that the "19" order is safe to be used for the superior as well as the inferior train in making meeting points provided the "middle order" be used in connection therewith. The delivery of this form of orders to the superior train contains an element of safety exceeding that of the "31" form inasmuch as the operator is on the platform for the purpose of delivering the order, and is in a position to prevent oversight of the signal.

It was recommended that a clearance card be delivered with all train orders, the card to show the number of each order, the intention being to give opportunity to conductor and engineman to check the orders with the card, thus making sure of the fact that none is overlooked. The card should be made in manifold, a copy for the conductor and each engineman (also the pilot, if there be one), the operator to retain the lowest copy.

The convention pronounced in favor of a signal to be placed on the engine of a train to denote "Schedule Fulfilled." Such a signal would be displayed on a single train if it were the only one using a schedule, or on the last of a number of sections if there were such. The present practice of displaying signals on all sections except the last is directly opposed to the foundation principle of signaling and contains an element of positive danger. No recommendatian was made as to the precise method, some members favoring a reversal of the present rule by requiring the only train on the schedule or the last section to display green signals, none being shown on the preceding sections, while others thought a distinctive signal shown on every train would more readily command the attention of those concerned.

Close to this subject is that of better means of identification of trains, the present practice being very imperfect, having caused a great amount of trouble in the past. Indicators showing the identity of each train, passenger and freight, were recommended.

The rules and usages of some roads make it important that conductor and engineman know positively when a telegraph office has been closed for meals or for the night, and it was recommended that there be some variation from the regular train order or block signal to indicate this condition.

It was recommended that a train register be used on single track at junction and terminal stations for the purpose of obtaining at first hand and in writing from the conductor of each train the information that the train has arrived, rather than from the observation of the operator. Whether this information be given to other trains by the operator or the despatcher, it should originate with and be recorded by the conductor of the train. It was

deemed that a matter of so great importance should be recognized and provided for by the Standard Code.

The "A. B. C." Rules devised by Mr. A. Beamer, Superintendent of the Northern Pacific, and used on a section of that road handling a heavy traffic, were discussed at length and with approval of the convention. Briefly stated the plan is this: All superiority between trains is eliminated, no trains orders are issued and a train leaving any station is given authority to run to the next station, and to the next only, regardless of all trains. The operators work the regular telegraph block system between themselves, and in addition the despatcher directs whether or not the train may proceed from the station. The only authority in the hands of conductor and engineman is a block card furnished by the operator under direction of the despatcher. The plan has been in satisfactory operation for several months. Train despatchers are convinced that the present system of train orders, although developed to a high standard of efficiency, is inadequate to the needs of the large traffic of to-day. The convention voted to continue consideration of the subject through its Train Rules Committee during the coming year.

The next place of meeting will be Fort Worth, Tex., and the incoming officers are as follows: President, C. H. Mullinix (Illinois Central), Fulton, Ky.; Vice-President, C. A. Mitchell (N. Y., N. H. & H.), Boston, Mass.; Secretary, J. F. Mackie (C., R. I. & P.), Chicago, Ill.

The Coal Reserves of the United States.*

Coal may be divided into three main classes—anthracite, bituminous and lignite, but in the trade these main classes are broken up into several groups, which are represented in the following diagram:

DIAGRAM SHOWING CLASS OF COAL.

Coal	Anthracite	(*a*) Anthracite.
		(*b*) Semi-anthracite.
	Bituminous	(*c*) Semi-bituminous.
		(*d*) Bituminous.
		(*e*) Sub-bituminous.
	Lignite	(*f*) Lignite.

(*a*) Anthracite coal is too well known to need description. (*b*) Semi-anthracite is a low grade of anthracite. (*c*) Semi-bituminous is a high grade of bituminous, such as the George's Creek coal of Maryland, Pocahontas coal of Virginia and West Virginia, and the Carboniferous coal of Arkansas. (*d*) Bituminous is the common grade of coal found throughout the eastern coal fields and in limited areas in the West. (*e*) Sub-bituminous is applied to coals below the grade of bituminous, but above that of lignite. They are black and shining, but are light in weight and slack badly on exposure to the atmosphere. These coals are common in the western fields of Washington, eastern part of Montana, northern Wyoming, about Denver in Colorado, and in northwestern New Mexico. (*f*) Lignite is brown and woody, and occurs in North Dakota, South Dakota, Texas, southeastern Arkansas, Mississippi and Alabama.

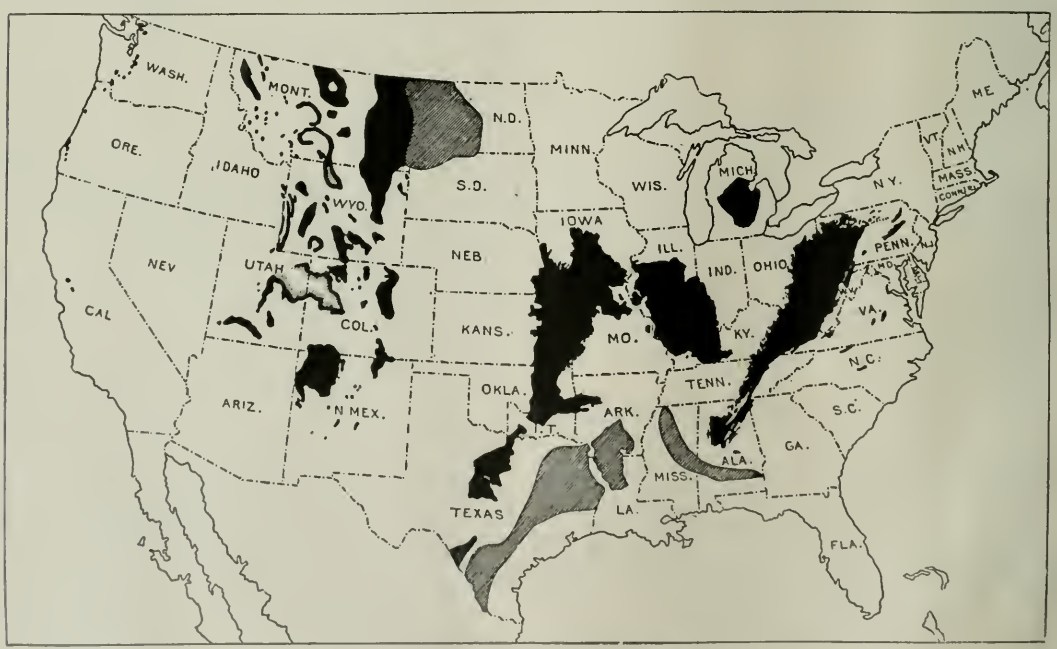
The classes noted above include all of the different kinds of coal that are known, but certain peculiarities of coals within the bituminous class have led to distinctions which are of great importance; thus the property of coking, which is limited entirely to the bituminous class, has given to coals possessing this peculiarity a value far above those coals having similar composition, but which do not possess this characteristic. The reason why one coal will coke and another will not is not understood; a practical test is the only way by which the coking properties of a coal are determined. Most of the coke is produced in the Appalachian coal field in Pennsylvania, West Virginia, Virginia, Tennessee and Alabama.

The coal output of the principal coal producing states for 1906 as reported by the United States Geological Survey was published in the *Railroad Gazette* of June 28, 1907.

The areas of the coal fields that lie within the various states differ greatly, even more than the production. The relative size of these areas is given in the accompanying diagram.

It will be a surprise to many to learn that the coal fields of Montana are more extensive than those of any other state, and that Texas is a close second. In this connection it must be understood that each of these states includes an enormous territory, equal to two or three of the smaller eastern states. It is true, however, that most of the coal territory of these states is underlain by low-grade lignite, and hence the fields are not so important as their areas would indicate. The same is true of North Dakota, which includes an extremely large area of coal territory, but the fuel is wholly lignite and of comparatively little value.

The extent of some of the coal fields is largely hypothetical. This is particularly the case with Washington, where the present estimate is probably far below the real extent of the fields. It might be supposed that Washington had been explored thoroughly enough to determine approximately the extent of its coal fields, but the peculiar conditions which prevail on the west slope of the Cascade range make it impossible to settle the question at the present time. The surface is deeply covered by glacial drift and vegetation, and it is only where the great streams, rushing down off the mountain slopes, have cut through this drift that the coal beds are exposed. In this way they are known at many localities, and it is probable that they are present in the intermediate covered areas, but no one is willing to say so until more prospecting has been done. When that occurs it is probable that the recognized area of the coal fields of Washington will be greatly increased. The known coal fields of Alaska seem to be comparatively small, having approxi-



Coal Areas of the United States.

Black shows anthracite and bituminous coal; shaded, lignite.

*Abstract of an address by Marius R. Campbell, of the United States Geological Survey, to the National Geographic Society.

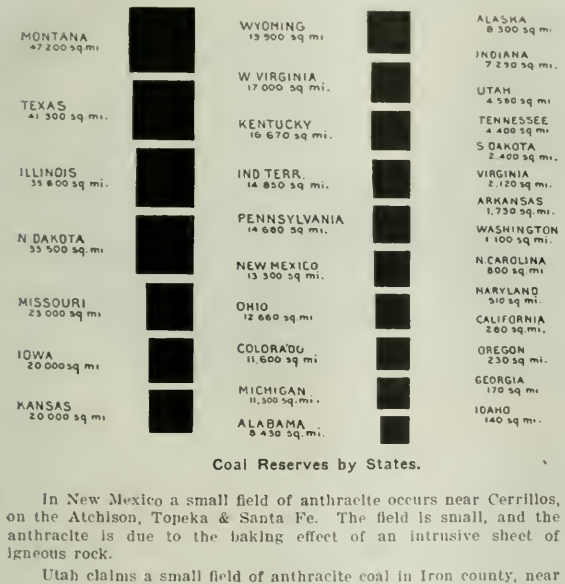
mately the same area as the bituminous field of Alabama. Here again exploration may, and probably will, increase the area materially, especially that of the low-grade lignites of the Arctic slope.

The area given for the coal fields of Alabama includes only the bituminous coal of carboniferous age in the northeast part of the state. In addition to this, as shown by the accompanying map, there is a wide band of lignite-bearing tertiary rocks crossing the southern part of the state. These rocks are known to contain beds of lignite, but in the presence of high-grade bituminous coal the lignite has never been explored, and consequently the number of beds, their thickness and extent, are not known. It is possible that when the supply of better fuel is exhausted, or has fallen below the demand, the lignite field may be found to contain an important supply of fuel.

So far as our present knowledge goes, the distribution of the various classes of coal in the western states is as follows:

Anthracite.—Only small areas of anthracite coal have been found in the western states and Alaska. Generally these are the direct result of volcanic activity and hence are of limited geographical extent.

The largest field of anthracite coal in the western states is in Gunnison county, Colorado, in the Crested Butte region. Apparently the anthracite in this field is the result of immense intrusions of igneous rock, which have baked the coal and thus driven off its volatile matter. The same coalbeds only a short distance away are either bituminous or sub-bituminous in character. One other occurrence of anthracite is known in Colorado, in the Yampa coal field, in the northern part of Routt county. In this locality the coal has been changed to anthracite by dikes and sheets of igneous rock. This field is very limited in extent.



Coal Reserves by States.

In New Mexico a small field of anthracite occurs near Cerrillos, on the Atchison, Topeka & Santa Fe. The field is small, and the anthracite is due to the baking effect of an intrusive sheet of igneous rock.

Utah claims a small field of anthracite coal in Iron county, near the southwestern corner of the state. It has not been developed and little is known of its extent or value.

In Washington a very small field of anthracite occurs in the vicinity of a large mass of igneous rock on Carbon river, southeast of Tacoma.

The largest anthracite field outside of Pennsylvania occurs near Controller bay, Alaska. In this field the change in the character of the coal is said to be not directly related to volcanic activity, but to be due to the intense folding to which the rocks have been subjected.

At present, anthracite is mined in the West only in Gunnison county, Colorado, and near Cerrillos, New Mexico.

Coking Coal.—Good coking coal is scarce in the Western fields. The principal source of supply is the Raton, or Trinidad, field, in southern Colorado and northern New Mexico. Of the coke produced in the western fields, 70 per cent. comes from this region. Some coke is also produced in Colorado, on the west side of the Front range, at Durango and in the vicinity of Glenwood Springs. Other important centers of coke production are Castle Gate and Sunnyside, in Utah, and along Carbon river southeast of Tacoma, Washington. Coke is also made to a limited extent in Wyoming near the Black Hills and in southern central Montana. There are several other coals that will coke with difficulty, which may be developed in the future, but the present [illegible] not particularly promising.

Bituminous and Sub-bituminous Coal.—This class of fuel is much more abundant than either of the two preceding classes. In New Mexico the largest deposit of such coal is in the Raton field, in the north central part of the territory. Similar coal also occurs in the northern part of the great Durango-Gallup field, in the northwest corner of the territory, and in several small fields south of Santa Fe.

In Colorado good bituminous coal occurs in the field just mentioned, at Trinidad and about Durango. It is also present in the small field south of Canyon City and in Gunnison county. As shown on the map the latter field occupies the southeastern point of a large synclinal basin which extends as far west as Castle Gate, Utah. The coal outcrops on the south limb of this basin in the Book Cliffs west of Grand Junction and along the "Great Hogback" from Gunnison county northwestward through Glenwood Springs and Meeker. Throughout the whole line of outcrop around this basin the coals are of the bituminous class, although in places they belong to the lowest group of the class. Good bituminous coal also abounds in the Yampa field, in Routt county. Thus it will be seen that Colorado has a large supply of this class of coal.

Utah is also well supplied by the same basin and by its extension southward from Castle Gate along the Wasatch Plateau. There is also a small field at Coalville, east of Salt Lake City, and a field of unknown extent in Iron county, occupying the Colob plateau.

Wyoming has bituminous coals along the line of the Union Pacific at or near Hanna, Rawlins, Rock Springs, and Kemmerer, and also in small areas about the Black Hills. It is possible that other areas of bituminous coal exist in this state.

Montana has considerable bituminous coal in the fields along the Northern Pacific west of Billings, about Great Falls and in the Crazy mountains, but by far the largest areas in the state carry coal of an inferior grade.

Washington has several bituminous coal fields along the western foothills of the Cascade mountains and at least one local basin at Roslyn, on the eastern side.

Most of the coals of California are of low grade, but one bed has been developed in Stone canyon, in the southeast corner of Monterey county, that is good bituminous coal. So far as known, this is the only coal of this class in the state.

Sub-bituminous Coal.—This class of coal is abundant in the western fields. Most of the coal in the south part of the Durango-Gallup basin is of this class. It is the only coal found in the Denver basin and in North and South Parks of Colorado. The great fields in the northeastern part of Wyoming, the Bighorn basin, and most of the fields in Uinta county contain sub-bituminous coal. All of eastern Montana is supposed to be underlain by it, as is also the big field in the north-central part of the state around the Bearpaw mountains. A number of small fields lying west of Butte, Helena, and the main front range contain coal of this character, but generally they are of small extent and probably have little commercial value. In Washington this class of coal is abundant, but as a rule it occurs some distance west of the Cascade mountains.

Lignite.—This class of fuel is found only in the fields of southern Alabama, Mississippi, Arkansas and Texas on the Gulf slope and North and South Dakota at the north. It is mined commercially only in North Dakota and Texas.

Up to the present time we have used our fuel without question as to possibility of its exhaustion. Of late, however, more far-seeing people have been thinking deeply on this subject, especially since the recent order of the President withdrawing temporarily from coal entry 64,000,000 acres of coal land, and his recommendation to Congress that the time has arrived to begin the conservation of our mineral fuels, and urging upon that body the passage of laws upon the subject.

In the older fields of the east, with the exception of Indian Territory, practically all of the coal land has passed to private ownership. Therefore the President's order and the interest of the people generally, centers about the coal fields of the Rocky Mountain region and the Pacific slope. The former contains an area estimated at 134,800 square miles, and the latter, including Alaska, 10,000 square miles, or a total of 144,800 square miles out of a total for the whole country of 400,500 square miles.

Of this area of 144,800 square miles of coal fields of the western states, it is estimated that 50 per cent. has passed to private ownership, leaving about 72,000 square miles of coal fields yet belonging to the government. It must be remembered, however, that more than half of this area is included in the lignite fields of eastern Montana, North Dakota and South Dakota, and when this is deducted from the figures given above, it leaves an area of only about 33,000 square miles of fairly good coal, the title to which is still vested in the United States.

The estimated amount of coal in the coal fields of the United States, not including Alaska, is 2,200,000,000,000 short tons, enough,

if it were moulded into a block, to form a cube with a side $7\frac{1}{2}$ miles long, or spread out flat to make a layer $6\frac{1}{2}$ ft. thick over the 400,000 square miles of coal fields of the United States. Is not this amount, to all intents and purposes, inexhaustible? In order to judge about this, it is necessary to know the rate of consumption.

The total production of the United States in 1906 was over 414,000,000 short tons. The United States leads the world in coal production by over 100,000,000 tons, Great Britain, and next Germany, being the only countries which produce more than about 50,000,000 tons a year. If the present rate of coal consumption should be maintained from now on, the coal of the United States would last nearly 4,000 years. On the other hand, the increasing rate of coal consumption in the United States is an alarming factor in considering the future supply. The rate of increase is enormous, the amount produced in each decade since 1816 being equal to the entire previous consumption. The amount of coal consumed in the 10 years from 1816 to 1825 was about 315,356 short tons. In the 10 years from 1896 to 1905 the consumption was over 2,832,599,452 short tons. If the consumption of coal continues to increase in the future as fast as it has during the last 90 years, the coal supplies of the United States will be exhausted in about 100 years. Since there is every prospect of a constantly increasing demand for coal, it seems probable that the rate of consumption will increase at nearly the same ratio as in the past, and hence that the life of the coal fields of the United States will probably be about 200 years.

New Southern Pacific Passenger Station at Tucson, Ariz.

The accompanying illustration shows the general style of a new passenger station which is just about to be opened for use by the Southern Pacific at Tucson, Ariz., a division point on its main line from San Francisco to El Paso and New Orleans. This is one of the first adaptations of the old Spanish mission architecture to a Southern Pacific passenger station. The building is arranged not only to accommodate the traveling public, but also the division officers and staff.

New Passenger Station at Tucson, Ariz.; Southern Pacific.

Southern Arizona is very hot during most of the year, therefore the building was so planned that the waiting rooms on the ground floor are protected from the sun's rays by wide arcades on each side of the main part of the building. The main building is flanked at each end by a low one-story wing. Each end of the main building itself on the street front shown in the photograph has a shallow pavilion. Similarly the track side of the station has a gable. At each end of the main building, which is two stories high, is a low one-story wing. The building is 218 ft. by 60 ft., with solid brick walls, finished outside in cement stucco. The ornamentation is of cast cement stone placed in the walls during construction. Level with the second floor is a low, deep loggia covered with a wide sweeping roof of red terra cotta Spanish tile.

The foundation and basement floor containing a heating plant is built of concrete. The second floor and roof timbers are wood. In the center of the main building on the first floor is the ticket office, with the general waiting room and women's room on one side and the smoking room and waiting room for Mexicans on the other side. The baggage room is in the smaller one-story wing at the end of the main building. In the wing at the other end is an emergency hospital and the offices of the commercial agent and roadmaster. The whole second floor is to be used by the division force.

The interior of the building is in keeping with the style of the exterior. The walls of the smoking room are paneled up to the height of the doors with wood; above this a low, ornamental cornice runs around the whole room. The frieze between this cornice and the ceiling is filled in with a dark leather, in the center of each panel of which is a shield, representing in colors the great seal of one of the states through which the Sunset Route of the Southern Pacific runs. In the entrance vestibule are four Tympanum arches, which are to be filled with oil paintings by Maynard Dixon of subjects typical of Arizona or taken from its history. The general waiting room and smoking room will have tile floors. There are especially designed electroliers for lighting the building which is equipped throughout with electric fans and steam heating. The cost of the new station is about $65,000. The plans were made in the office of J. H. Wallace, Assistant Chief Engineer of the Southern Pacific, by D. J. Patterson, Architect for the company.

Association of Transportation and Car Accounting Officers.

The semi-annual meeting of this association was held at St. Paul June 25 and 26. The principal reports were printed in the *Railroad Gazette* of June 28, page 923.

The membership of the association now represents 215,000 miles of road. The committees on per diem and on car service were consolidated and a new committee on "Conducting Passenger Transportation" was created. This committee proposes to consider the advisability of restricting baggage to certain trains (in suburban service), the effect of electrification on passenger business, standard speeds of trains for different degrees of curvatures, and using half-minutes in reporting trains.

The committee recommendation concerning Per Diem Rule No. 5 was recommitted. The report on office methods was adopted substantially as presented. The report of the committee on conducting transportation brought out a long discussion, the views of the committee being very generally approved.

The rules for handling cars, recommended by the committee on car service, were adopted, with the exception of Rules 9, 10 and 17, which were recommitted.

The next meeting will be held at Chicago, December 10, and the next summer meeting will be held at Atlantic City June 23, 1908. The President of the association for the ensuing year is Fred Clark (C., B. & Q.), Chicago; Secretary, G. P. Conard, 24 Park Place, New York City.

Standard Time on the Canadian Pacific.

Mr. W. J. Camp, Electrical Engineer of the Telegraph Department of the Canadian Pacific Railway, read a paper on this subject at the annual meeting of the railroad telegraph superintendents at Atlantic City. The circuits of this road being very long, time signals are sent by hand. The speaker describes the arrangements of the repeaters at Montreal, where the time is taken from McGill University. The company sends time regularly to islands in the Pacific ocean, also to the Azores, in the Atlantic, and other distant points. The true longitude of Montreal was fixed several years ago by a long series of observations by astronomers at Montreal and in Nova Scotia, Ireland and England. Mr. Camp says that on several occasions the time given on railroad lines in the United States has been as much as three seconds in error. The standard clocks on the Canadian Pacific are made the subject of daily records, and the reports are examined and compared every month. The time inspector visits every standard clock once, twice or thrice a year. The watch inspectors of the company examine every watch twice a year, and all watches are twice a month brought to them to be compared. An employee who has neglected to visit the inspector in the first and third weeks of each month is not eligible for duty without an order from the superintendent. Each employee must keep with him the card showing the rating of his watch. All watches must be cleaned at least once in 15 months. All inspectors have seconds pendulum clocks and are required to ascertain the error thereof at least once a day. At Montreal the Canadian Pacific has 81 clocks on five circuits worked by one master clock.

Five More New York Public Service Commissioners.

Last week we published the photographs of four of the members of the New York Public Service Commissions. The accompanying photographs are of five more Commissioners, of these Mr Keep is a member of the Commission for the Second district, consisting of all New York state except New York, Kings, Queens and Richmond counties. The other four are on the Commission for the First district.

Charles H. Keep, of Buffalo, was born in Lockport, N. Y., in 1861. He graduated from Harvard University in 1882, and from Harvard Law School in 1885. He practiced law in Buffalo until 1903. From 1890 to 1901 he was Secretary of the Lake Carriers' Association, and from 1898 to 1901 was Secretary of the Buffalo Chamber of Commerce. In 1903 he was appointed Assistant Secretary of the United States Treasury, where he remained until January, 1907, when he was appointed Superintendent of Banks of New York state.

C. H. Keep.

William McCarroll, of Brooklyn, was born in Belfast, Ireland, in 1851. He was educated at Russell's Academy, Brookville Academy and at the Royal Academical Institution and then came to this country, where, in 1869, he began to work in the leather manufacturing business. In 1878 he formed a company of his own and in 1902, when the American Leather Company was organized, he was made Vice-President and General Manager. He is now President of this company and also President of the Hide and Leather Association, the New York Board of Trade and Transportation and the Morocco Manufacturers' National Association. Mr. McCarroll is also Chairman of the National Committee for the Promotion of Foreign Commerce and a Director of the National Manufacturers' Association, as well as being a member of several other organizations.

William McCarroll.

M. R. Maltbie.

E. M. Bassett.

Edward M. Bassett, of Brooklyn, was born in that city in 1863. He was educated at Hamilton College, Amherst College and Columbia Law School. After graduating from the latter he was admitted to the bar in 1886. He spent the next six years in legal work connected with a contracting firm in Buffalo, and then returned to New York and began the general practice of law. He is now the senior member of the firm of Bassett, Thompson & Gilpatrick. He was on the Brooklyn Board of Education from 1889 to 1901, and on the Flatbush Local School Board from 1901 to 1902, when he was elected to the United States Congress, where he served for two years. Mr. Bassett has worked on the improvement of the United States bankruptcy law and the New York state law regarding eminent domain.

Milo R. Maltbie, of New York, was born at Hinckley, Ill., in 1871. He graduated from the Upper Iowa University in 1892, from the Northwestern University the next year, and from Columbia University in 1897, after having acted as Professor of Economics and Mathematics at Mount Morris College from 1893 to 1895, and as a fellow in administrative law at Columbia from 1895 to 1897. He was Secretary of the Reform Club Committee on municipal affairs from 1897 to 1902 during which time he was also editor of *Municipal Affairs*. He was prize lecturer on municipal government at Columbia in 1900, and has been Secretary of the Municipal Art Commission since 1902. Mr. Maltbie has been on several other commissions; he has investigated civic art and municipal conditions in Europe and has also investigated the municipal ownership of public utilities in Great Britain, the street railway franchises of Chicago and the Ramapo water contract in New York City.

J. E. Eustis.

John E. Eustis, of the Bronx, was born in Limerick, N. Y. When he was 17 years old he enlisted in the 20th New York Cavalry in which he served for two years, and then went to Wesleyan University, where he graduated in 1871, having taken a scientific course. He then came to New York and was appointed City Surveyor. The next year he began to study law and graduated from Dwight Law School in 1877. In 1880 he began practice and is now a member of the firm of Eustis & Foster. He served as School Trustee of the Twenty-fourth Ward until 1885 and was then made a School Inspector, which position he held for five years. In 1896, he was appointed Commissioner of the Board of Education. He was Park Commissioner for the Bronx in 1902, and he has been Vice-President of the Citizens' Union, and a member of its City Committee, of the Bronx West Side Association, of the Civic League, of the West Side Board of Trade, of the Bronx Bar Association, and of the Bar Association of New York county.

Electric Railways.*

SUBJECT FOR DISCUSSION:

(*a*) What are the factors which determine the maximum economical grade for electric railways?

(*b*) In establishing direct lines with heavy grades, under what conditions will it be found practicable to use electric locomotives and gas-engine generating stations, rather than traction by steam locomotives?

It is difficult to furnish material for discussion of a question having such scope as the first part of this topic, except in the shape of generalities, which are either obvious or of little use in the special case which the engineer may have in mind. The length of line, the character and density of traffic, the location and length of grades, all have important bearings upon the economies, constructing and operating, in any railway proposition. It is probable, therefore, that the proposer of the question had in mind a discussion of the factors peculiar to the method of traction, rather than those effecting the location of rail-

*An informal discussion at the annual convention of the American Society of Civil Engineers, by George Gibbs. From advance pages of the *Proceedings* for August, 1907.

way lines in general. These factors result from the method of application of the power to the trains and from the interconnected character of the apparatus which makes up the motive power system.

On a steam railroad the power plants are the locomotives; an electric road has its power system jointly in the locomotives (or the motor cars), in the continuous power conductor along the line, and in the central power-house. In the steam railroad, therefore, the first cost of power equipment is fixed by the number of locomotives, independently of the location, or the length of line, or other outside considerations; with the electric proposition the first cost of the power system is affected, not only by the number of locomotives or motor cars, but also by the magnitude of the other items of power equipment, and these items depend largely upon the grades, their length and possibly their position. For instance, we can readily imagine a line with grades located in such a way that, with a given train interval, all trains may be ascending simultaneously; in such a case the line equipment and power-houses must be designed to supply all trains taking power simultaneously, even if this maximum power is only needed for a small percentage of the total time. A location with the grades differently selected, even if the maximum gradient is not altered, might readily result in a much lower maximum demand at the power-house, and a consequent reduction in cost of the power system. Length and position, as well as rate of grades, therefore, are of much importance in an electric railway proposition.

The quantitative importance of these factors, of course, depends upon the character of the business; thus, where the traffic is very dense, requiring the operation of trains at short intervals, the relative location of grades is not as important as with infrequent train units, because, as the number of trains is increased, those ascending and descending the grades at any one time tend to balance, resulting in a relatively steady load on the power-house. The length of grade in an electric proposition has a peculiar importance because of the fact that electric motors have a rating in which the time limit comes in. Thus, for short maximum grades, the limit of motor capacity is in the commutation of the current; with long grades the limit is in the heating of the motors, due to the cumulative effect of passing current through the motors, the resulting heat being not entirely dissipated by radiation.

As to maximum practicable gradients. This factor is generally a less limiting one in electric traction than in steam. For trains composed in whole or in part of motor cars, the question of adhesion may generally be dismissed, because the limiting grade, from the standpoint of safety, is generally less than that dictated by the adhesive limit. Even with locomotive trains the problem is less serious in electric than in steam traction, because of the large proportion of the electric locomotive weight available for adhesion, and because of the facility with which trains may be double-headed with electric locomotives. This arises from the fact that by multiple control two or more locomotives become in effect a single unit, and are not open to the objections of dual control, as in operating two or more steam locomotives on one train.

From the two factors, namely, the higher adhesion ratio and the selection of grade locations, it may result that, with an electric railway line, the economic grade may be greater than that possible with steam traction. For certain kinds of electric railways in a flat country, for instance the interurban trolley road, this facility for surmounting short but very heavy grades without reaching the adhesive limit is of great importance in separating steam and electric grades at crossings, without excessive cost, either for grading or for power plant.

The effect of gradient upon operating cost cannot well be discussed for the general case; in some cases the grades may have little or no effect, if they are short and the traffic is heavy; in other cases their length and location may have an important effect upon the quantity of fuel required and the economy of power-house operation. Of course, the cheaper the fuel the less the importance of this factor in determining the line location.

Summing up, therefore, some important points to be considered in laying out an electric traction proposition are:

1. The effect of density of traffic in averaging the load requirements at the power-house.

2. The effect of location of grades, especially in infrequent service, in averaging load requirements at the power-house.

3. The wider latitude in fixing the maximum grades because of the greater adhesion ratio.

4. Limiting commutating effects on short grades.

5. The motor heating effects on long grades.

6. The less effect of grades on speeds because of the greater accelerating rate possible.

In order to use gas-engine stations successfully for any electric traction project it is necessary, of course, first, that gas engines and generators be obtainable of the proper characteristics for such work, and, second, that they will prove advantageous and economical. The form of the question appears to limit the subject to gas-engine prime movers for electric lines, rather than consideration of electric traction versus steam traction. In laying out the project in question, however, it is presumed that it would first be essential to determine whether electric traction of any kind would be advantageous, and then whether gas engine would be better than steam or water-power prime movers.

A general discussion of electric versus steam traction, of course, opens up a vast subject, and to indicate even the treatment would be beyond the limits of a brief opening discussion. Generally stated, for heavy grade work it may often be advantageous to adopt electric traction, not only because of economy of operation, but because of an increase in the capacity of the line consequent upon the use of exceptionally powerful electric locomotives which will enable the ruling loads to be taken over the grade without doubling; also because of the convenient application and control of electric locomotives, and because of the factors mentioned in connection with the discussion of the previous question.

Having determined that it will be economical or advantageous to use electric traction, it does not necessarily follow that gas engines would be the best means for producing power. Where water-power is available, and may be developed at moderate cost, on the line or within reasonable transmission distance of it, it will be found that such power will be more economical than either gas or steam. Where water-power is ruled out, and where the railroad is located within a short distance of coal mines, it may be that a steam generating station would be more economical than a gas-engine station, because of the lower first cost of the steam generating plant.

In order that the gas-engine plant may be used economically, it is necessary that, as before stated, the machinery be available in units of proper size, that the details be worked out practically, and that they compare favorably with steam or water in first and operating costs. Doubtless these questions will be discussed in connection with the subject of gas engines, and, therefore, it may be stated here, that, from the point of view of economy of power, the gas-engine plant promises well, but from the view of availability there appear to be at the present time two important limitations: The first is in the small over-load capacity of the gas engine, which is disadvantageous for fluctuating railroad loads, and the second is in the fact that gas engines and producer plants, up to this time, have been developed in relatively small units. Of course, it is true that some large gas engines have been built, but they can hardly be called a commercial article yet for general application to railway purposes.

The Railroads of Mexico.*

BY ERDIS G. ROBINSON, C. E.
Formerly of the Engineering Department of the Mexican Central.

The national history of the Republic of Mexico is of such surpassing interest that one writing only of the railroads of that country can with difficulty confine his thoughts, and therefore his pen, strictly to his subject. The temptation to wander is strong and ever present. If at times the following remarks may seem to depart somewhat from the stated subject, the writer would suggest, in addition to the above, that in making a study of railroads it is necessary to a proper understanding of the subject to know somewhat about the physical character of the country served, as well as its commercial activity and political stability, since the prosperity of the one is dependent upon that of the other.

Soon after the conquest in 1520 by that intrepid explorer and courageous adventurer Cortes, Mexico became the source of much traffic in precious metal exportation. The Spanish conqueror and explorer was most keen after the riches of the earth and but little concerned with the welfare of the people or the future of the country he was despoiling; wherein, we are led to believe by certain radical sheets of to-day, he resembled greatly the commercial *conquistadores* of the present age. Those early prospectors covered the entire land; mineral deposits were discovered and worked by slave labor, and the precious metals mined were sent to Spain in vast quantities. For the transportation of these precious cargoes from the interior to the seaport at Vera Cruz, roads and trails were built with a thoroughness attested by the present use of many of them still in good condition.

But a nation conceived in greed and selfishness, and nurtured in tyranny and injustice cannot become the home of a peaceful people and prosperous enterprise. For 300 years the seeds of discord sown by the early Spanish colonizer, though lying dormant during certain long periods, finally harvested crops of internal rebellion and foreign invasion which prevented the country during all that time from enjoying the real prosperity which comes only with national peace. It was not until the present ruler of Mexico, by means of a successful revolution, established himself as president of the republic, that an era of peace was inaugurated which promised to endure. This happy condition made possible the development of

*When it is necessary to refer to values or costs the writer has used the words *dollar* and *cent* to refer only to the money of the United States. When values are given in Mexican units, the words *peso* and *centavo* are used. This course is not only the proper one, but seems to lead to less confusion than to be referring frequently to "*dollar, Mexican currency*," or "*dollar, gold*," or "*dollar, United States currency*," etc., as is often done. It is easy to remember that the Mexican peso has a fixed gold value, and is worth 50 cents.

the railroad interests, which forms the greatest guaranty of the continuation of peace and prosperity since it furnishes employment for the people, facilitates the operation of other industries and strengthens the hold of the government upon all the districts of the state.

Accordingly, with peace thus established, the natural riches of the country and the special inducements offered by a wise government attracted the alert mind and opened the pocket of the far-seeing investor, and the final foreign invasion of Mexico was begun by the commercial conquest and the inauguration of the railroad era.

RESOURCES.

It is to be expected that a country with a great variety of climatic conditions will have a very diversified production. From the tropical and humid coast lands of Mexico to its high, cool and dry plateau may be found nearly all of the possible weather conditions, and the products vary accordingly. The plains of the temperate plateau are naturally dry and therefore unproductive. These areas are largely covered by extensive mesquite growth, very valuable as sources of fuel, as well as many varieties of the not invaluable cactus. In some favored localities where nature has provided springs or running streams beautiful garden spots are found, where fruits, grains and vegetables are grown in abundance. The Mexicans, urged by necessity, have developed a high order of skill as hydraulic engineers, and have in successful operation many irrigating plants led from the reservoirs located in the hills. At the advantageous physical positions on the plains and in the mountains are located towns and haciendas which become the centers of much business. Near Torreon are large areas planted in cotton, the yield of which is all fabricated in the country. Further to the north are found some of the largest cattle ranges in the world. To the northeast, on the line of the Mexican International, are located the only considerable coal fields of Mexico. Further to the south, in and around Mexico City, as well in other centers of population, are large tracts planted with maguey, from which is produced the prodigious amount of intoxicating liquor consumed in the country, this traffic amounting to nearly one-half of the total agricultural tonnage of the Mexican Railway. From the different districts over the country come many important crops, nearly all of which are consumed at home. In Monterey there has recently been finished a high-grade steel plant; in several cities there are smelters for reducing the vast amounts of ore mined in the country, and in other cities miscellaneous industries are located. All these industries are carefully fostered and guarded by a high protective tariff law, the good effect of which on the internal development of the nation is plainly evident.

In the mountainous regions there are many large tracts of fine timber land of almost untold value to the country at large, and to the railroads in particular, as sources of construction timber and fuel. Many miles of roads have been built to exploit these rich timber lands.

On the lower coast lands are grown the usual tropical and semi-tropical crops—rubber, tobacco, henequin, cane, coffee, chicle, etc., as well as crops found further north.

In naming the resources of Mexico as the basis of its railroad industry, the mining business must be given the greatest prominence. The history of Mexico is a story of its mineral development. With the discovery and opening of the mines came cities located near those centers of wealth. As time passed mining methods improved; the cities grew, railroads were necessary, and engineers were given the task of reaching by rail these cities which had been located with no thought of future rail connections. Later, as the mining business prospered, all other lines of industry increased in proportion. It became necessary to communicate with the outside world and railroads to the seaports were needed.

The important relation of the mineral resources to the railroad business can be no better shown than by studying the table giving classification of the railroad traffic (shown elsewhere), from which it will be noted that the products of mines make up 54 per cent. of the tonnage of the Mexican Central, 75 per cent. of that of the Mexican International, 46 per cent. of that of the Mexican National and 26 per cent. of that of the Mexican Railway. Expressed in round numbers and in the Mexican peso, the gold mines yield annually 22 million, the silver mines 80 million and the copper mines 25 million. The entire exports of the country amount to something over 200 million pesos, the imports to 160 million pesos and the corn crop to 75 million pesos.

TOPOGRAPHY.

A large part of the area of Mexico is a high tableland, with considerable width at the northern part and narrowing to a point south of the City of Mexico, where the mountain ranges converge. Across the northern part, along the United States boundary, the elevation is between 2,000 and 4,000 ft., and at the city, 7,500 ft. This rise in elevation is not made gradually, however, but over a series of plateaus separated from one another by intervening ranges of hills. At Torreon, about midway from the northern line to the City of Mexico, the elevation is almost the same as at El Paso, although the separating ridges passed over have reached an elevation of 5,000 ft. on the north and over 8,000 ft. on the south of that centrally located city.

Along each coast line is a strip of low land less than 100 miles wide, which has the good and bad qualities common to the truly tropical climates. At the least unfavorable points along these coasts are seaports, some located at natural harbors formed at the rivers' mouths, and some built up on the open coast line. Tampico is of the former and Vera Cruz of the latter class, for nature has not blessed Mexico with numerous and well-sheltered natural harbors, and in securing those in service the government and the railroads have had to help. At Tampico an excellent harbor is secured by means of jetties at the mouth of one of Mexico's large rivers, these jetties forming as fine an example of such construction as will be found in any country. They were built for the Mexican Government by the Mexican Central, E. L. Corthell being the consulting engineer. The deep water assured by these jetties and the excellent wharves recently completed by the government at a cost of nearly 4,000,000 pesos, as well as other wharves, and the connection by rail to Mexico City and to Monterey by two lines of the Mexican Central, may well account for the large tonnage handled at this port. At Vera Cruz, until recently, there was no good harbor protection nor wharf facilities for handling of the cargoes, which were transferred to land by lighters from the vessels anchored in the open. This city, however, had been the principal seaport since the time of the Spanish conquest. The vast quantities of precious metals in transit to Spain were brought here for shipment, and the importance of the port was thus early established, and it still ranks first in importance in value of imports and exports. Two lines of railroad now connect it with the Mexico City, and it also has connection with the Isthmus of Tehuantepec, on the south. The importance of this port gradually made better harbor protection imperative, and this was secured by great breakwater construction, which has resulted in a sufficient depth of water and a well-protected anchorage.

There are a number of harbors along the Pacific coast, notably at Acapulco, Manzanillo, Mazatlan and Guaymas. These harbors are as yet without rail connection with the interior of the country, although, prompted by prospects of good business and by liberal government subsidies, many lines have been projected and surveys made. At the present time the Mexican Central is completing its line from Guadalajara to Manzanillo (to be described later), at which point the government has recently made very important and costly harbor improvements.

The harbors named above, as well as others of less importance, have long accommodated a valuable coastwise trade, serving as natural outlets for the products of the low coast lands, but largely barred from handling the business of the interior until railroads were built crossing the two mountain barriers which, rising abruptly from the low elevations, divide these strips of coast lands from the great plateau areas. Almost from the level of the sea the mountains rise to heights which easily rank them with the loftiest ranges on this continent and furnish scenery of surpassing grandeur. In the eastern range, and in direct line from Vera Cruz to the City of Mexico, is Mt. Orizaba, rising from almost the sea level in one grand cone to an elevation of over 17,000 ft. Slightly southeast of the City of Mexico and plainly visible from it as beautiful snow-capped peaks are the two mountains, Popocatepetl and Ixtaccihuatl, the former rising to a height about the same as Orizaba. Further to the west, in the beautiful state of Michoacan and surrounded by vast areas of dense forests, is Mt. Patamban (elevation 13,000 ft.), while still farther west is the mountain of Colima. All these mountains are volcanic peaks; Orizaba and Popocatepetl were reported in eruption at the time of the Spanish conquest, while Colima is still doing business as a volcano, its frequent eruptions of ashes and lava being an unique and grand spectacle which furnishes a good bid for tourist travel in the hands of the passenger agents of the Mexican Central, whose Pacific extension skirts the base of this interesting mountain. The mention of these few mountains will serve to indicate the general character of the ranges separating the low from the high lands; lofty volcanic peaks with all the rugged topography that can accompany such mountains.

In order to exploit the mineral and timber riches of these lands, and to convey to and from the seaports the products and supplies of the engineer, as well as the faith and confidence of the capitalist, necessary to cross by railroads these forbidding mountain areas and to penetrate into their very hearts.. The slopes and passes among these mountains are deeply cut by barrancas of most forbidding topography, which while they offer the only means of crossing, still seem to have been designed by nature to test the patience and skill of the engineer, as well as the faith and confidence of the capitalist. These barrancas are too wide and deep to be bridged and too sharply cut by tributary barrancas to be easily turned, and therefore must be overcome by heroic means.

To an engineer the nature of this country can be appreciated best by a study of the character of the lines already built. In a later paragraph will be given such information as the writer has been able to gather concerning the grades, curves, etc., of the lines that have been completed over these precipitous divides.

(To be continued).

Progress of the Pennsylvania Tunnels Under Manhattan Island.

In our issue of November 2, 1906, through the courtesy of the Pennsylvania, New York & Long Island Railroad and The United Engineering & Contracting Company, contractors for the work, we gave a general description of the plant and organization used in driving the Manhattan crosstown tunnels of the Pennsylvania extension into Manhattan and Long Island, being that portion of the line under 32d and 33d streets, between the east end of the terminal station at Seventh avenue and the East river, where the contractors are using the west half of the shafts sunk by S. Pearson & Son, who have the contract for driving the sub-aqueous tunnels eastward under the East river.

The plans for the tunnels under 32d and 33d streets, as originally made, showed three tracks from the terminal station to the west building line of Fifth avenue under each street, the third, or center track, to be used for storage purposes. The grade of the tunnel through this length was therefore made such that trains would remain at rest without setting the brakes.

From the west building line of Fifth avenue eastward the tunnels were designed for two tracks; those under 32d street for eastbound express and local use; those under 33d street for westbound service, and the grade was made 1½ per cent., descending to the level of the tubes below the bed of the East river. Under Fifth avenue and somewhat to the eastward these two grades were joined by a long, easy vertical curve.

The profile of the tunnels showed the base of rail an average probability of causing considerable settlement of the front walls of the old residence structures on either side of the street. Such structures as the larger hotels and business buildings would have caused no trouble, as the foundations of these buildings rest on the solid rock.

After careful review of the situation, it was determined to make application for permit to do the work by open cut under a temporary street surface, after the front walls of the buildings not resting on rock, had been carried down thereto, as shown in Fig. 1. This permission was ultimately granted by the Rapid Transit Commission, as it seemed to be to the best interests of the city and the property-holders.

At the time the application was before the Rapid Transit Commission, the railroad company having modified its trackage arrangements within and west of the station, found that it was reasonable to do away with the storage track east of Sixth avenue, and made plans by which the section from Fifth avenue to Sixth avenue could be changed to two-track tunnels, and the vertical curve shifted to Sixth avenue.

In the previous article standard sections of three-track and two-track tunnels were shown, and by reference to these it will be seen that the height of the three-track section was some 8 ft. greater than that of the two-track section. The change to the two-track section lowered the top of the roof 8 ft., and the change in grade gave 5 ft., thus lowering the grade of the roof below the bed of the old stream a total of 13 ft.

At this new grade of roof exploration drifts were sent for-

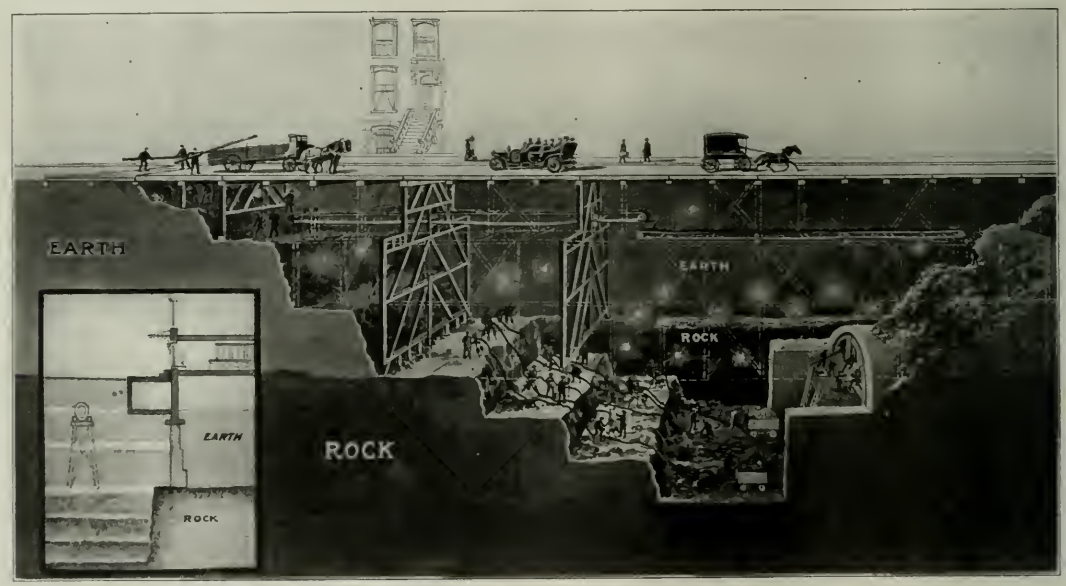


Fig. 1—Proposed Method of Excavating Pennsylvania Crosstown Tunnels West of Fifth Avenue.

of 85 ft. below the surface of the streets, and the accurate preliminary survey of the top of rock indicated that the roof of the tunnel, practically throughout its entire length, would lie 40 ft. below the surface of the rock.

On the west side of Fifth avenue, however, the bores passed under the bed of an old stream, flowing, in general, in a southeasterly direction through a trough of rock that was either the reason for its presence, or cut out by the action of the stream; and at this point the roof of the three-track section cut through the rock into soft material.

When this point was reached with the excavation going westward, the section was advanced by driving three separate small headings, one at the elevation of the roof in the middle of the cross-section and the other two the full height of the perpendicular sides of the tunnels.

Had the ground been dry, as had been expected, because of the elimination of surface water by buildings and pavements, it would not have been difficult to have driven these small headings forward through the soft ground, and to have constructed the sidewalks and thrown the masonry of the roof across from wall to wall by alternate sections. But the conditions of the sewers, built back forty years ago, and possibly also of the Croton water pipes, kept the ground saturated, and it was found to be of such a nature that it was being carried into the tunnel in suspension by the seepage.

Therefore, while it was quite practicable to build the tunnel by this method, it could not have been carried out without the ward, with the result that ample depth of solid rock was found over the tunnels, making it unnecessary to resort to open cut. It is, therefore, probable that the lower grade will be adopted, and that there will be no open cut, except for a short distance at the west end of 32d street, where it is impossible to change the grade, and where the structures are of such a nature that they can be readily protected and the work done, without great inconvenience, from the surface.

The only other change in the plans for the excavation of the tunnel consists in sinking shafts at the west end for the purpose of hastening the completion of the work by driving eastward to meet the drifts on their way west from Fifth avenue. It is expected that the excavation will be entirely completed by November 1.

These tunnels have now been driven for 80 per cent. of their length, through solid rock, under the most thickly inhabited district of Manhattan, without damage to the buildings on either side of the street, and with an inconvenience so slight that the property-holders and tenants have expressed their high appreciation of the way in which the work has been handled, no serious complaints have been made.

At present the work of lining with concrete is well under way, and precisely as in the case of the excavation, the plant is driven entirely by electricity. The materials (cement, sand and broken stone) are received at the dock at the foot of East 35th street, furnished the contractor by the railroad company for his sole use.

The sand and gravel are unloaded by means of clam-shell

Fig. 2—Heading of Double Track Tunnel in Solid Rock.

Fig. 3—Completed Excavation for Two-Track Tunnel in Solid Rock.

buckets, two men, one operating the electric hoist and one the traps of the hopper under which the wagons drive to be loaded, being the only labor necessary to clear the boats. Both materials are unloaded at the rate of 50 cu. yds. an hour. The material is carted to the shafts, where it is dumped into bins constructed in the shafts, the top being at the ground level, and the bottom about 20 ft. above the grade of the tunnels.

The cement is also fed down to this level through a gravity device similar to the Louisville type of spiral fire-escape. Just beneath the hoppers of the bins are the charging platforms of the mixers. The batches are measured in boxes fed from the hoppers and dumped into the loading chutes of the "Smith" mixers, which in turn dump the material into the concrete cars, in which the mixed concrete is carried to the point of placement in the walls.

The operation of placing the concrete is as follows: The floors are first brought to the final level of the under side of the ballasted tracks, the idea being to obtain a smooth graded floor to give perfect drainage. On this floor of concrete are placed the rails of a 16-ft. gage track, on which the frames for the side walls and roof arch are run. When these rails are once lined and graded there is no further bother with engineering instruments in completing the tunnel masonry, since the forms are substantial and the tunnel section uniform throughout. The floor concrete is shown in place for half the tunnel, in Fig. 3.

The first operation for the side forms is to smooth up the walls for the waterproofing. These forms are shown in place in Fig. 4. When the waterproofing is finished the forms for the side walls complete are set up to a point somewhat above the spring of the arch. These forms are shown in place in Fig. 5.

It should be noted here that the cross-section of the twin tunnels shows a concrete central wall. However, as the two-track sections advance toward the East river, where the two tunnels of two tracks each are broken up into four sub-aqueous tubes passing under the river, the two tracks under each of the streets gradually separate, so that ultimately they are sufficiently far apart to leave a core of rock between. The point where the core of rock is left in place is shown in Fig. 5.

Fig. 7 shows the completed arches of the tunnel, which is the standard section across town.

The forms are made in 32-ft. sections, and follow each other in close sequence as the work progresses. The arch concrete and the upper portion of the central wall is placed by an ingenious belt conveyor designed by the contractor and constructed for them by the Robins Conveying Belt Company. By the system adopted the labor of placing concrete is reduced to a minimum, although the investment in plant is large.

Fig. 4—Placing Forms for Concrete Side Walls.

Much work has been accomplished in the 13 months of actual tunnel digging. Several records in tunnel work have been made. For several successive months after the plant got working a greater yardage was taken out of the six headings that were being driven simultaneously than has ever been taken out of six headings in any other tunnel. This is partly due, of course, to the unusual size of the drifts, but a record for linear feet of progress has been made on this job.

The great width of the headings was a peculiar advantage, owing to the necessity to pull the cuts in such a way that no damage would be done to the structures lining the streets when blasting. Three, and even four, relieving cuts have been used in order to maintain the desired daily progress and still keep within the limitations imposed by city ordinance and good judgment.

No material damage has been done by blasting. The absence of damage has been due primarily to an expenditure by the contractor that would startle a cross-country railroad tunnel builder; not only in the actual excavation below the surface, but in the headhouse plant and top charges made necessary in order to avoid noise and interference with the full enjoyment of their property by the neighboring house-holders.

So great a work could not, of course, be carried out without some annoyance. There has been arranged a regular hour for the receipt and consideration of complaints, and some of these have been more or less amusing.

For example, a young man in a large retail house, who had a contract to maintain the incandescent gas-burners, came in and promised dire punishment unless the blasting was altogether stopped, on the allegation that it was breaking his mantles.

It is curious to note how universal is the habit of not noticing cracks in the ceilings and walls until some attention is called to them. To avoid just this complication, examination was made of every house in the zone of influence of the work, and complete diagrams were made, with affidavits of the examining engineer at-

Fig. 5 View in Tunnel near East River Shaft Showing Central Rock Wall.

Following the completion of the sidewalks, shown in Fig. 6, comes the placing of the arch forms. These may be freed from the concrete by being lowered, since the sidewalks are carried above the spring line of the arch. The steel forms for the arch are shown in place in Fig. 6.

tached, showing all the cracks and faults existing before the work was undertaken. In practically every complaint that is filed a reference to the diagrams shows that the cracks complained of

Fig. 6—Steel Forms for Tunnel Arch.

existed, and in many cases the plaster was down before a blast was fired.

That no damage has been done to structures in good condition is clearly shown by the fact that the tunnels have been driven under the subway station at 33d street, built in the same rock and only 35 ft. above, without shaking loose any of the [illegible]

George S. Rice, Chief Engineer of the [illegible] Railroad Commissioners, had installed in the station a specially constructed seismograph to determine the effect of the blasting. This was kept in position for five months, and while the tunnel was being driven from 400 ft. west of the station to 400 ft. east. The effect of the blasting was shown on the records as a momentary movement of the needle perpendicular to its travel when at rest. The record was merely a straight line about $\frac{1}{16}$ in. long, perpendicular to the line of rest. The seismograph happened to be in position at the time of the San Francisco earthquake, and the record made by that phenomenon extended over a period of 13 minutes. The record consisted of a wavy line, passing both sides of the line of rest, with a maximum versed sign of $\frac{3}{16}$ in. This shock was recorded simultaneously with the record made at the state house in Albany.

Another interesting situation developed with regard to a public school along the line. Here the woman principal, as well as her staff of teachers, were alarmed lest the children should become excited through the effect of blasting. The contractor asked that a committee of teachers be organized to make a visit to the tunnel for the purpose of seeing what was going on, and be reassured that no damage could result. This committee visited the tunnel, and were so impressed with the way the work was being conducted that all timidity disappeared, and no further complaint has been registered.

The excavation is now about 80 per cent. complete, and about 20 per cent. of the concrete has been placed. It is expected that the excavations will be entirely completed by the first of the coming year, and that the concrete will be practically finished by the end of the present season. What there is left to be done will take but a short time the early part of next season, and the work will be completed on contract time, early in 1908.

We are indebted to D. L. Hough, President, and Paul G. Brown, Managing Engineer, of The United Engineering & Contracting Company, for the information; to J. P. Gillette for the photographs, and to Capt. G. A. Coffin for the drawing, from which Fig. 1 was made.

Fig. 7—Completed Section of Standard Twin Tunnels.

Strength of Red and Yellow Douglas Fir Bridge Stringers.*

The terms red and yellow fir are not thoroughly defined. By some only close-grained, bright yellow sticks are designated yellow fir and all other sticks called red fir, while others call only close-grained sticks of a pronounced red color red fir and all other material yellow fir. Both red and yellow fir are secured from the same species—Douglas fir—and often from the same tree.

An analysis of the strength tests made by the Forest Service on Douglas fir stringers is shown in the attached table. These stringers were graded according to the export grading rules of the Pacific Coast Lumber Manufacturers' Association, and in the table are grouped by grades. In classifying the stringers according to color all timbers of a reddish tinge were called red fir and all of a yellowish tinge were called yellow fir. The rings per inch shown in the table indicate that yellow fir is of slower growth than red fir. It also ranges higher in grade. Of the 94 yellow fir stringers tested 47.8 per cent. were selects, 40.4 per cent. were merchantables and 11.8 per cent. seconds. Of the 162 red fir stringers tested 29.8 per cent. were selects, 43.8 per cent. were merchantables and 26.6 per cent. seconds, but, grade for grade, these tests show that there is practically no difference in the strength and stiffness of red and yellow fir in bridge stringer sizes:

Strength of Red and Yellow Douglas Fir Bridge Stringers.
(Yellow fir expressed in per cent. of red fir.)

New York Central Freight-Yard Policemen.

A recent issue of the *New York Herald* contained an interesting account of the desperate contest which the New York Central & Hudson River has waged for the past few years with freight-car thieves in New York City, from which we quote as follows:

When A. H. Smith came from the West to become general manager he sent for Chief Inspector Humphreys and began to study the question. R. F. Humphreys, brother of the inspector, and like him, a veteran policeman, was called to the city and placed in charge. He went at it confidently and slowly. He used special care in picking his men. They had to be men who would be useful in emergencies, able to take care of themselves on and off moving trains. They had to be able and willing to stand off the attack of a half-dozen men in a lonely aisle of cars, with assistance far away. They had to be able to "hop" a freight, grab their man, throw him off and jump after him; they had to be alert and capable of long hours of duty. Above all they had to be honest. What use would the "force" be if a policeman could be bought to be at the other end of his post when there were valuable cars to be "ripped," or what further use would it be if a policeman could be induced to fail in his identification of the prisoner when on the day of trial?

It took something like three months to get the men, and when they were selected every one of them came from "up the state." All were young, all were lusty and all had proved their courage. Some had been policemen, others had been soldiers and several were active young college athletes who went into it because of the possible dangers of it. The twenty-seven of them were brought to the city a year ago last month and installed at the pier at the foot of West 49th street.

They were provided with everything any man would want. Their sleeping quarters were given to them, a gymnasium, shower baths, lounging and reading rooms and good salaries. A man that joins the force gets first $60 a month, but he works into a $125 salary if he shows the right spirit. If he does not deserve a raise he gets out; they don't want him. The long district is divided into three posts, or precincts—one at the milk station at 33d street, another at 59th street and the third at Spuyten Duyvil. Down around 33d street the milk thieves were working. This was a large band, usually working with company employees. Many a can of milk would be reported missing in the morning and no one could tell where it went.

Fifty-ninth street was the car thief district. That extended up above 99th street, and in this district there were a half-dozen well-organized bands, with some hundreds of independent operators. There were regular landing places along the Hudson river for the marine fleet, "fences" for disposing of property of all kinds, secret cuts, private ways and escapes. The district was divided by the bands impartially, and there was a "gentleman's agreement" among the thieves that made the rights sacred.

There was one band for the "new yards," as they were called, which begin at 60th street; there was the 69th street band, the band in 74th street, the "Bath House band," and so on up every few blocks. Spuyten Duyvil was the "yegg" clearing house. Through that point had to pass all the criminal tramps beating their way to the city.

This police force had been in existence just one year on May 17, 1907. During that period they made 1,351 arrests, and of this number there were a few more than 1,200 convictions. One-half of those arrested were charged with theft, larceny, robbery, burglary and highway robbery; a third more were for trespass and attempts at the same; others were for stealing rides and the like. The members of the force shot at least three men during the year, and two of their men were shot in return. One man was killed, Peter Michaels, a member of the 69th street band. There were at least three pitched battles, in which shots were exchanged, and the personal encounters were without number. Every man on the force was shot at, and often heard volleys of stones come whizzing by.

Of all the bands in existence a year ago, May 17, but one survives, the 69th street band, and out of that eight members are now serving terms of imprisonment. Michaels was shot and the leader dare not show his face across the tracks. The powerful political backing the band had a year ago is weakening, and visits to see "if something can be done to settle it" are not so frequent, nor is bail forthcoming so quickly as it was.

The men work twelve hours at a stretch and seventeen are on duty at night. F. D. Hunter is a graduate of Colgate University. Hunter, who is very quiet, tells about the work: "The Chief (and by the Chief he means Wilson A. Humphreys, at Albany) won't have a man who drinks, who has a spot on his record or who loses his head. He wants men, also, who are very good pistol shots. It is around 10 o'clock and the sergeant tells you it is time he made his rounds. He is compelled to do this just as in real police stations. If he finds a roundsman derelict there must be charges preferred and a policeman goes through the same ordeal. He starts out and is soon plunging ahead between a row of freight cars on one side and a moving train on the other. It is not pleasant walking for the visitor. Every one of our men along the track has his post, but he does not patrol it as a regular policeman would. You will usually find him hidden between cars or lying flat on a roof in a bad locality. He does not need to walk around, for the reason that there never has yet been made a car door that did not rattle or squeak when it was opened. He waits for that rattle, and when he hears it he runs.

"We've caught them trying to get away with sewing machines and machinery parts. They'd ruin $1,000 worth of machinery for $10 worth of brass."

To the left or river side of the track now spring up low sheds, bathhouses and heavy houseboats. "This is where Michaels was killed," says Hunter. "We got into the place this spring and got a carload of stuff. The keeper is now doing time. You've got to keep watch on all these places. Over there," pointing to a small dump pier, "is where the boats come in. They come from over in Jersey, and they are a bad crowd. We got eight of them and one of their boats this spring. They are pretty well scared now."

"This is where the park begins. That was their best hold. They could rush a trainload of stuff over in there and get away with it. We have had some good fights up along here. They usually work in bands of four or more, so they are ready for a fight. Usually a boy acts as their scout, and he comes on the track, as if he were going over to the river. If the coast is clear he whistles or coughs, and the men are over the wall into the car in half a minute. * * *"

Foreign Railroad Notes.

The Prussian State Railroads call for bids for 700 locomotives, to be delivered between April 1 and Oct. 31, 1908. The call is addressed only to those works which have heretofore received orders from these railroads.

At the beginning of the summer traveling season this year the Prussian Minister of Public Works issued a circular to his railroad subordinates in which he enjoined the strictest attention to maintaining passenger cars in good condition; to see that at terminal points they are kept cool and provided with cold water. Conductors and guards must see that the doors close tight and do not stick, that the door fastenings are in order, that the window blinds do not rattle, that windows open and close easily, that the window curtains are in order, that the lamps burn properly, that the lavatories are clean and provided with plenty of water. Well founded complaints of passengers should be attended to, when possible, during the trip, without waiting till the terminal station is reached.

*Bulletin of the U. S. Department of Agriculture, Forest Service

GENERAL NEWS SECTION

NOTES.

In the Federal Court at Rochester N. Y., July 5, the New York Central & Hudson River was fined $15,000 for carrying oil, shipped by the Standard Oil Company, at a secret rate.

The Mexican Central is to put cupolas in the roofs of the baggage cars of all through trains, in order to make it easier for the conductor to keep watch of the movement of his train.

Suits have been filed in the Federal Court at Des Moines, Iowa, to enjoin the Minneapolis & St. Louis and the Iowa Central from adopting the 2-cent fares prescribed by the Iowa law.

The Atchison, Topeka & Santa Fe has notified the Attorney General of Missouri of its compliance with his request to cease issuing passes in that state; and it is said that the Burlington, the St. Paul and some other roads will comply.

The Delaware & Hudson Company is receiving 450,000 ties from the South. The company bought but few ties last year because of the high prices. The ties arrive in New York by the Mallory line and are transferred to canal boat and barges of the Myers line for Albany.

Cattlemen of western and northwestern Texas say that since last March the railroads have been unable to supply more than half the cattle cars that shippers need, and that consequently thousands of animals are dying for want of water. Claims are being presented for damages due to delay in furnishing cars.

Since the fire of April, 1906, the ferries of the Southern Pacific between San Francisco and Oakland have carried 2,000,000 passengers a month, as against an average of 1,300,000 before the fire. These boats have carried in 40 years about 300,000,000 passengers. Of this number only three lost their lives while using the ferry.

Following a loss of travel in consequence of increased competition from street railroads, the Philadelphia & Reading has taken off a number of passenger trains between Philadelphia and Chestnut Hill; also some from the Glenside division. At Tioga (about three miles from the terminal), where trains of several divisions pass, the number of trains stopping each day is now 40 less than under the last time-table.

The United States Civil Service Commission, Washington, is to receive applications August 1 for positions in the Department of Accounts in the Interstate Commerce Commission. The positions to be filled are those to be established in connection with the inspection of railroad companies' accounts under the revised Interstate Commerce law. Applicants must have railroad experience and must know at least as much as a traveling auditor.

At Catalla, Alaska, July 4, a fight with clubs and pistols between rival railroad construction forces was accompanied by a novel feature, a "go-devil." The go-devil is something like a battering ram. It is erected at the point of intersection of the two lines and is kept in motion in such a way as to prevent the enemy from doing any work within its range. This machine was put up by the Brunner forces but it was captured by the Guggenheim forces.

The Mayor of Philadelphia has signed the ordinance under which the Philadelphia Rapid Transit Company receives limited street railroad franchises throughout the city for 50 years with a provision that the city is to have half of the income from operation in excess of 6 per cent. on the capital paid in. The city is to be represented in the board of directors by three persons—the Mayor and two selected by the councils. This arrangement was proposed by the Retail Merchants' Association, but it was opposed by the Reform Party.

Governor Comer, of Alabama, in his message to the Legislature last Tuesday complained that the state railroad laws are "held up" by injunction in the Federal Court the same as in Iowa. He said: "Discrimination has been proved, and it is a great hardship for Alabama to be forced to go through court processes on a case already pioneered and worked out and demonstrated." The Governor advocated biennial sessions of the Legislature and the passage of an anti-lobby bill.

The record for May shows the greatest aggregate movement of freight cars in the history of the Pennsylvania road. The total freight car mileage for the month was 122,770,303. The number of freight cars moved on the Pennsylvania's eastern lines during May averaged 146,476 a day; average daily movement of each car 27.07 miles. These figures do not include cabooses. On May 24 the interchange between the eastern and western lines at Pittsburg totaled 8,784 cars, which was 670 more cars than had ever passed between the lines before in one day.

The New York Central has issued on the Pennsylvania division an order doing away with a third brakeman on all road freight crews except way freights, pick-up and through trains. Hereafter one brakeman, one flagman and a conductor with the engineer and fireman will constitute a full crew. Owing to the great amount of construction work going on and the extra work trains on the road the third man has been thus far retained though with every car in a train equipped with automatic couplings and air brakes, only two brakemen are ordinarily deemed necessary.

In the United States Circuit Court at Chicago the Federal District Attorney has asked for injunctions to restrain five prominent express companies from granting franks to their employees and others. One of the defendants, the United States Express Co., in its answer contends that it is not a common carrier. The revised Interstate Commerce law, under which the provisions of the act now apply to express companies, has a long section containing a list of exceptions to that clause of the law which forbids free transportation, but the exception as regards employees applies only to the transportation of persons, not property.

The Cincinnati Chamber of Commerce has issued a circular to its members, requesting them to load cars to their marked capacity. It is pointed out that in view of the increased capacity of cars, averaging now nearly 60,000 lbs., the loading of cars to the minimum limit of 24,000 lbs., 30,000 or 40,000 lbs. is a waste of space which is an injustice to the commercial public, both railroads and shippers. This should be laid before certain legislatures and railroad commissions, which, though supposed to be fountain heads of justice, issue laws and rules perpetuating the injustice here mentioned.

Electrification in Australia.

It is proposed to electrify the suburban lines about Melbourne, Australia, for which purpose the government is prepared to spend $15,000,000. The system to be adopted is now under discussion.

St. Louis Railroad Terminals.

The Municipal Bridge and Terminals Commission of the city of St. Louis, which is a board of nine public spirited citizens, appointed by the municipal assembly, with Mr. Rolla Wells as chairman, says in its fourth report, recently submitted, that plans are being made for the improvement of the extensive tracts of land recently acquired by the Terminal Railroad Association for the enlargement of its freight yards, and will soon be laid before the Municipal Assembly. The commission reports that the executive officers of the railroads centering in the city have worked with the commission in a friendly spirit. Indeed, the marked success of this commission during its two years' life appears to have been due largely to the reasonable attitude of mind evinced by its members. Unlike some bodies of municipal representatives, these gentlemen evidently do not invariably approach the railroads with a demand for every possible improvement that can be thought of. In securing the abolition of the differential rates between St. Louis and East St. Louis on all freight from the east, except from points within 100 miles, the commissioners have secured reductions aggregating many hundred thousand dollars yearly for the business men of the city, but in modestly stating this in the report they admit some of the points made by the railroads and frankly declare that from points within the 100-mile radius the existing rates are entirely fair to all interests. In the matter of passenger fares, also, the commission for the present keeps its hands off, believing that there is nothing in the situation which will not probably adjust itself in the near future to the satisfaction of the city.

The commission still has much work before it and asks for an appropriation to continue its investigations. The elaborate plans for a new bridge across the river and the arrangements for a large number of new freight houses are yet to be worked out. The commission believes that the different railroads doing business in the city should each deal with the public through its own agents. The public is jealous of any appearance of monopoly and the prejudice against the Terminal Railroad Association cannot be extirpated. To give, on the joint terminals, really satisfactory service the agent of each road must be able to act as though he were working on a part of his own road; and, while there can be no objection to an

agent serving two or more roads, he should do business in the name of the individual railroad company.

Washington Railroad Commission's Rules.

The Railroad Commission of the state of Washington has issued a code of eleven rules governing passenger and freight traffic which the railroads of the state are directed to print on large cards and post in their passenger stations. Rule 1 makes all regular tickets good for 30 days. Rule 2 requires railroads to redeem unused tickets within six months at any general passenger office or at the station where sold. Rule 3 requires the three principal roads of the state to sell at all coupon stations 2,000-mile tickets at $50. Unused parts of mileage books must be redeemed after one year at 2½ cents a mile. Before the end of the year, unused parts may be redeemed allowing 3 cents a mile for the part used. A firm having bought a ticket for an employee may return it and have the unused portion credited on the purchase of a new book for another employee.

Rule 5 requires clean and comfortable waiting rooms and toilets. Rule 6 requires bulletin boards for delayed passenger trains, and rule 7 requires notice to be given at stations and on cars when a train is likely to meet an obstruction delaying it more than 30 minutes.

Rule 8 requires every station agent to keep a record, open to inspection, of applications for cars and how they are filled, etc. Rule 9 requires a similar record in the superintendent's office, and a monthly abstract of this must be sent to the railroad commission. Rule 10 requires every passenger train to be fitted with a hose and valve at the rear end so that in moving the train backward the rear brakeman can control its speed.

The New Commissions in New York State.

The Public Service Commission of New York State, Second District (headquarters at Albany), has announced the retention of the following employees of the old Railroad Commission, at the same salaries for the present: Steam railroad inspector, J. D. Schultz; inspector of electric railroads, C. R. Barnes; expert on accidents, E. F. Vanhoesen; locomotive inspector, G. P. Robinson; superintendent of grade crossings, A. H. Sutermeister; inspector of grade crossings, J. E. Brazee.

The Commission has been too busy organizing to attend to specific complaints. All matters relating to railroads have been referred to a committee of which Commissioner Sague is chairman, and Commissioner Decker is to attend to all matters relating to tariffs. All roads must file tariffs by November, 1907.

The commission has set hearings for each of the first three days of next week on applications for new security issues and proposed extensions and improvements to various railroads.

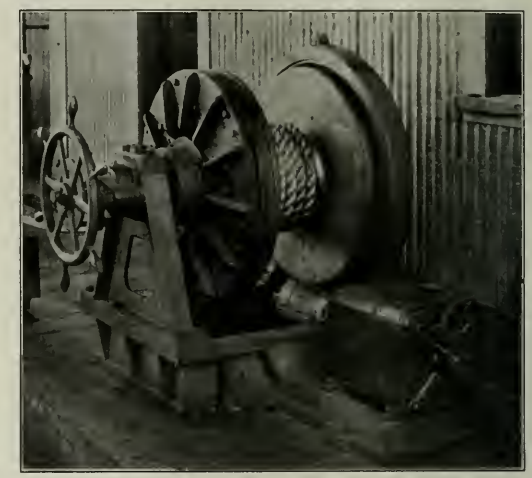
The commission has created a division of light, heat and power and appointed Henry C. Hazzard, former secretary of the gas commission, as the chief clerk at a salary of $4,000 a year. Mr. Hazzard's salary as secretary of the gas commission was $3,000 a year.

On the suggestion of the commission of the first district a conference between the two public service commissions will be held to formulate uniform rules of procedure.

The commission for the first district (New York City) has ordered all railroad companies within that district—steam and electric, subway, surface and elevated—to send to the Commission memoranda of their accounts, showing their systems of bookkeeping; also to furnish a complete record showing the movement of traffic, a schedule of all cars and trains in commission on the first day of July, giving the exact scheduled starting time of each car or train on every trip; the exact time of its scheduled arrival at destination, with the incidental statistics concerning distances, number of runs for each car and the headway. The same order calls for each company's estimate of the number of cars it expects to have in use on September 1 of this year, with the total seating capacity, and, for purposes of comparison, the number of cars, with total seating capacity, in commission on September 1, 1906, and September 1, 1905.

Lidgerwood Slip-Drum Electric Winch for Car Ferries.

At the three car ferry transfer bridges of the Pennsylvania at the Greenville, N. J., terminal yards there have been in use for nearly three years a number of motor-driven slip-drum hauling-in winches of novel construction made by the Lidgerwood Manufacturing Co., New York. These bridges are operated entirely by electricity and the winches are controlled from a cab or tower by the same operator who manipulates the raising and lowering mechanism. The winches were designed to overcome the difficulty and danger of hauling in by hand power and to prevent the parting of the mooring lines in rough weather or under the shock of running cars on the floats.



Lidgerwood Slip-Drum Electric Winch.

Transfer Bridge at Greenville Yard, Showing Lidgerwood Slip-Drum Hauling-In Winch.

Each winch is moved by a 10 h.p. General Electric d.c. motor geared to develop 5 h.p. at 900 r.p.m. The motor turns the drum through a steel worm running in oil. Each end of the worm shaft is provided with a roller thrust bearing. The drum is 14 in. in diameter and has a 14-in. face. It carries a manila hawser 2 in. in diameter which it hauls in at a speed of 10 ft. a minute. The winch complete with motor occupies a space 56½ in. long, 44 in. wide and 52½ in. high.

The slipping drum friction is of the type developed by Spencer

Miller for maintaining a constant tension on the cables used in the Lidgerwood cableway for coaling ships at sea. It is designed to slip continuously under full pressure for an hour at a time without destructive wear or heating and to maintain a constant tension on the hawser of any desired amount. The friction can be adjusted by the operator to give any strain. The winches at Greenville are adjusted to exert a pull of 11,000 lbs. before slipping and a continuous pull of 9,000 lbs. while slipping. The drum is normally loose on its shaft and is lined with bronze bushings to take up wear while slipping. At its ends the drum is provided with steel friction rings rubbing against soft steel and soft cast-iron friction blocks mounted in the surrounding casing. The surfaces of the rings and blocks are brought together with the required degree of pressure by means of a threaded screw and a combination of springs. The friction produced is of peculiar quality. The coefficient is high and varies only slightly between a state of rest and movement.

In operating the winches the mooring lines are made fast and the motors started. While bringing the float in, if it rebounds or is bumped by a tug or high wave the drums slip before a breaking strain comes on the hawsers, but continue to exert a pull sufficient to check the movement of the float. If for any reason the float should break away while loading or unloading cars the winches check the movement and are ready immediately to haul in again before any damage is done. During the three years they have been in use at Greenville they have been subjected to many severe tests and have been satisfactory in every way.

Two-Cent Passenger Fares in Many States.

Reports from Chicago to the effect that passenger fares are to be reduced to 2 cents a mile on many roads even where not required by law continue, and the air of authenticity is maintained; but no official announcements are yet given out. An Assistant General Passenger Agent of the Burlington at Omaha is reported as saying that his road will within 10 days announce rates of 2 cents a mile between all points on the entire Burlington system, extending into 11 states. Notices sent to the Interstate Commerce Commission—which of course deal only with interstate rates—are said to indicate that all of the prominent roads expect within the present month to adopt the 2-cent rate throughout Illinois, Wisconsin, Minnesota, Iowa and Missouri.

At Richmond, Va., July 10, Judge Pritchard, in the United States Circuit Court of Appeals, continued the restraining order against the enforcement of the uniform 2-cent passenger rate ordered by the State Corporation Commission.

INTERSTATE COMMERCE COMMISSION RULINGS.

Equal Facilities for Negroes.

The Interstate Commerce Commission on July 8 decided the case of Georgia Edwards v. the Nashville, Chattanooga & St. Louis, which involves the right of interstate carriers to discriminate between negroes and whites in facilities furnished.

Immediately after the Rate Law took effect the complainant, a colored woman, purchased a first class ticket from Chattanooga, Tenn., to Dalton, Ga. She entered the car assigned to the use of white passengers but was removed to the car assigned to colored people. She filed a complaint, alleging discrimination in the facilities furnished to her as against those provided for white passengers. The opinion is rendered by Commissioner Lane, who holds that where a railroad provides certain accommodations for first class white passengers it is commanded by the law that like accommodations shall be provided for colored passengers of the same class. The following statement of facts precedes the conclusion of the opinion:

The train in question was defendant's No. 93, which leaves Chattanooga at 6:36 a. m., and arrives at Dalton at 7:38 a. m. The distance from Chattanooga to Dalton is 38 miles. This train started from Nashville, 151 miles northwesterly of Chattanooga, and before it left Nashville, all the cars were thoroughly cleaned inside. They were again cleaned to some extent at Chattanooga. Both at Nashville and at Chattanooga the cleaning process applied equally to both the passenger coaches in the train. These two cars are of the same quality, having seats of the same size, upholstered in a like manner and with exactly the same quality of goods. One of them is used by white passengers and is provided with towels and washbowls, while the other is without such conveniences. The latter is constructed as follows: A partition placed in the middle of the car divides it into two compartments, and entrance from one to the other is had through a swinging door which, after being opened, closes automatically. Negro passengers are required to occupy one of these compartments, while the other is occupied by other passengers who wish to smoke.

In one end of the other passenger coach there is a compartment for smokers which will seat seven persons, but defendant does not provide any separate smoking compartment for negroes. It is also true that while only one toilet is provided in the negro compartment, the car which is entirely used by other passengers [illegible] one is to be used by [illegible] and the [illegible] only partially enforced. The principal [illegible] case and only one [illegible] the other is that the [illegible] the negro compartment is very much less than [illegible] transported in the other car. Defendant [illegible] sengers about one-sixth of the space in its [illegible] passengers, while the number of negroes transported [illegible] about one-fifteenth of the total. When there are [illegible] compartment, smoking there is allowed, but not otherwise. [illegible] happens that a car provided by defendant for the use of white [illegible] no washbowls and only one toilet and no smoking compartment [illegible] smoking is allowed in such cars if there are no women present.

On the whole defendant's Nashville-Atlanta passenger trains are among the best in the country, so far as equipment is concerned. The [illegible] are manufactured by the Pullman Co., and vestibuled. The cost of the car allotted to negroes was about $8,100, while that of the other passenger car in train No. 93 was about $8,800. The expense of the small smoking compartment in the latter accounts for nearly all the difference in cost.

Commissioner Lane holds that the broad question of the right under the thirteenth and fourteenth amendments of the Constitution to segregate white and colored passengers has been upheld by the Supreme Court of the United States and the Interstate Commerce Commission in previous decisions. The opinion concludes:

While, therefore, the reasonableness of such regulations as to interstate passenger traffic is established, it by no means follows that carriers may discriminate between white and colored passengers in the accommodations which they furnish to each. If a railroad provides certain facilities and accommodations for first-class passengers of the white race, it is commanded by the law that like accommodations shall be provided for colored passengers of the same class. The principal that must govern is that carriers must serve equally well all passengers, whether white or colored, paying the same fare. Failure to do this is discrimination and subjects the passenger to "undue and unreasonable prejudice and disadvantage." In this case it is manifest that defendant has unduly and unjustly discriminated in some particulars against colored passengers, and it will be ordered therefore that where the defendant carrier provides a washbowl and towels in coaches devoted to the use of white passengers and also a separating smoking compartment for such passengers, that similar accommodations shall be provided for colored passengers paying first-class fare.

Application for Rehearing Denied.

The Interstate Commerce Commission has announced its decision, rendered by Commissioner Clark, on the motion of the Missouri Pacific and the Chicago, Burlington & Quincy for rehearing in the case of the City Council of Atchison, Kansas, against those companies and others. In the original decision the Commission held that defendants should abstain from withholding the same or equivalent elevator allowances or free services in connection with elevation and transfer of grain at Atchison which are at the same time granted or furnished at Kansas City, Mo., and Kansas City, Leavenworth and Argentine, Kan.

The motion for rehearing contained various reasons for its being granted, which are discussed, but held not sufficient for granting a rehearing. In denying the motion the Commission says: "While the power to grant a rehearing is discretionary, it is not believed that the petition presents a situation which makes it necessary or advantageous so to do. The petitioners had an opportunity to fully present their case, but the counsel of the Missouri Pacific did not submit any testimony and did not show enough interest in the proceeding to remain throughout the hearing. Full hearing was had and briefs were filed. No allegation has been made that the case was not completely submitted. It is not alleged that the decision of the Commission is erroneous or that since the hearing evidence has been discovered which was not at that time known. It is not asked that some matter not previously presented or considered should be now brought to the attention of the Commission."

Relation Between Wheat and Flour Rates.

The Interstate Commerce Commission, in an opinion by Commissioner Prouty, has announced decision in the case of Howard Mills Co. vs. the Missouri Pacific and other carriers. The complainant alleged that the defendant carriers unduly discriminated against Kansas millers in favor of California millers by exacting rates for transportation of flour which were 10 cents greater per 100 lbs. than the rates for transportation of wheat from Wichita and other shipping points in Kansas to points in California known as "Pacific coast terminals," and also by exacting rates for transportation of flour which were 35 cents per 100 lbs. greater than the rates for transportation of wheat from these shipping points to Phoenix, Ariz. The Commission decides that the flour rates between the said shipping and destination points should not exceed the wheat rates by more than 7 cents per 100 lbs.

The Commission says that there is no inflexible requirement that rates on grain and the products of grain should be under all circumstances the same, but rather that carriers may, in just regard for their own interests or to meet special conditions, vary those rates within narrow limits. When, however, the relation has

been established, business developed and money expended on the strength of it, then the carrier cannot, in the absence of some sufficient reason, change that relation, nor would the Commission direct such a change.

Commodity Rates to Amarillo, Tex., Reduced.

In an opinion by Commissioner Prouty, the Commission has decided the case of Nobles Brothers Grocery Company and others against the Fort Worth & Denver City and others. It appears in this case that a certain defined territory in the northern part of Texas, commonly known as the Burnt district, takes from Kansas City and other Missouri river points lower rates than are made to the balance of the state, in recognition of greater proximity to these Texas points; the class rates from Kansas City to Fort Worth, representative of the Burnt district, are higher than from Kansas City to Amarillo (where complainant does business) though Amarillo is less than the average distance to the Burnt district; and that the Santa Fe is rebuilding its road to Amarillo, which will soon be situated on its main line. The Commission decides that the present class rates from Kansas City to Amarillo are unreasonable and unjust, and that the commodity rates between said points should not exceed those from Kansas City to Fort Worth; but that the class rates from St. Louis to Amarillo may properly be higher than from St. Louis to Fort Worth.

MANUFACTURING AND BUSINESS.

The Pittsburg Steel Company, Pittsburg, Pa., is to issue $4,000,000 first mortgage 6 per cent. bonds to pay for building at Monessen eight 60-ton open hearth furnaces, a blooming mill and three billet mills.

J. W. Williams has been appointed sales agent in southern states for the Carbon Steel Co., Pittsburg, Pa., with office at 426 Lincoln Trust building, St. Louis. Mr. Williams continues to represent Brown & Co., Inc., Pittsburg.

Solomon Ginsburg has been elected President of the New York Car Wheel Company, Buffalo, N. Y., succeeding Joseph H. Berry, deceased. W. G. Smith has been elected Vice-President and J. A. Venable, Secretary and Treasurer.

The Westinghouse Electric & Manufacturing Co., Pittsburg, Pa., has sold to Kuhn, Loeb & Co., New York, $6,000,000 three-year, 6 per cent. notes, dated August 1, 1907. They were issued to retire an issue of the same amount of 5 per cent. notes maturing August 1.

A special meeting of the stockholders of the Safety Car Heating & Lighting Company, New York, has been called for July 15 to act on a proposal to increase the capital stock from $5,000,000 to $10,000,000. The new stock is to be issued to present holders as a 100 per cent. stock dividend. The annual dividend rate has been 18 per cent. for the last two years.

MEETINGS AND ANNOUNCEMENTS.

(For dates of conventions and regular meetings of railroad conventions and engineering societies, see advertising page 24.)

National Association of Railroad Commissioners.

The annual meeting of this organization is to be held at Washington, D. C., October 8, and not in the state of Washington, as had been announced.

ELECTIONS AND APPOINTMENTS.

Executive, Financial and Legal Officers.

Delaware, Lackawanna & Western.—The general offices in New York City have been moved to 90 West street.

Grand Trunk.—William Wainwright, General Assistant and Comptroller, has been elected Fourth Vice-President, with office at Montreal, succeeding F. H. McGuigan, who went to the Great Northern last March. Mr. Wainwright's former office has been abolished.

Randolph & Cumberland.—Ira A. McCormack, Assistant to the General Manager of the New York Central & Hudson River, has been elected President and General Manager of the Randolph & Cumberland, with office at New York.

Operating Officers.

Chicago, Rock Island & Pacific.—See Houston & Texas Central.

Delaware & Hudson.—C. E. McKim has been appointed Superintendent of Car Service, with office at Albany, N. Y.

Houston & Texas Central.—J. F. Sugrue, formerly Superintendent of the Chicago, Rock Island & Pacific at Dalhart, Tex., has been appointed Assistant Superintendent of the Houston & Texas Central at Ennis, Tex., succeeding D. Black, resigned.

Illinois Central.—Patrick Laden, Assistant to the Assistant Chief Engineer, has been appointed Superintendent at Mattoon, Ill., succeeding Otto Schilling, resigned.

Mexican Central.—A. F. Chreitzberg has been appointed Trainmaster at Gomez Palacio, Durango.

New York Central & Hudson River.—See Randolph & Cumberland under Executive, Financial and Legal Officers.

Norfolk & Western.—G. W. Merrell, Assistant to the General Superintendent, has been appointed Assistant to the General Manager, with special duties in connection with maintenance of way and accounts.

Southern Pacific.—A. B. Stickney has been appointed Superintendent of the San Joaquin division, with office at Bakersfield, Cal., succeeding W. H. Averell, promoted.

Texas & New Orleans.—D. T. Wacther, yardmaster at Beaumont, Tex., has been appointed Trainmaster, with office at Jacksonville, Tex., succeeding A. K. Frye, resigned.

Traffic Officers.

Buffalo, Rochester & Pittsburg.—R. W. Davis, General Freight Agent, has been appointed Freight Traffic Manager, with office at Rochester, N. Y. F. W. Bale succeeds Mr. Davis, with office at Rochester.

Colorado Southern, New Orleans & Pacific.—George A. Hill, Industrial Agent, has been assigned to other duties and his previous position has been abolished.

Philadelphia & Reading.—R. L. Russell, freight claim agent, has been appointed Assistant General Freight Agent in charge of through and export freight traffic, with office at Philadelphia, Pa., succeeding E. B. Crosley, who has been appointed Coal Freight Agent.

St. Joseph & Grand Island.—C. T. Hummer, city passenger agent and chief clerk to the General Freight and Passenger Agent, has been appointed to the new office of Assistant General Passenger Agent.

St. Louis & San Francisco.—W. R. Powe, Assistant General Freight Agent at Memphis, Tenn., has been appointed Chairman of the Southern Freight Classification Committee, with office at Atlanta, Ga., succeeding P. J. McGovern, deceased. E. T. Willcox, division freight agent at Birmingham, Ala., succeeds Mr. Powe.

Union Pacific.—W. S. Basinger has been appointed Assistant General Passenger Agent at Omaha, succeeding Gerritt Fort, resigned.

Wabash, Chester & Western.—W. S. Easton has been appointed General Freight and Passenger Agent, with office at Chester, Ill., succeeding C. E. Kingsbury, who remains Auditor.

Wheeling & Lake Erie.—H. S. Bradley, commercial agent at Pittsburg, has been appointed General Agent at Canton, Ohio, succeeding C. C. Wilson, transferred.

Engineering and Rolling Stock Officers.

Chicago, Burlington & Quincy.—William Baird has been appointed General Car Inspector of the lines west of the Missouri river, with office at Lincoln, Neb., succeeding E. S. Barstow.

Grand Trunk.—Joseph Hobson, Chief Engineer, has been appointed Consulting Engineer. Howard G. Kelley, Chief Engineer of the Iowa Central and of the Minneapolis & St. Louis, succeeds Mr. Hobson. William McNab, Assistant Engineer at Montreal, has been appointed Principal Assistant Engineer. The offices of all are at Montreal.

Illinois Central.—L. A. Downs, roadmaster at Chicago, has been appointed Assistant Chief Engineer of Maintenance of Way. See this company under Operating Officers.

Peoria & Eastern.—W. P. Feeley, Assistant Engineer, has resigned to go into other business.

LOCOMOTIVE BUILDING.

The Canadian Pacific, it is said, has decided to build 50 heavy freight locomotives.

The Pennsylvania Lines West, it is said, have decided to order five passenger locomotives and 45 freight locomotives.

The Iroquois Iron Company, Chicago, has ordered one saddle tank locomotive from the Baldwin Locomotive Works.

The Portland & Seattle denies being in the market for five switching locomotives, as reported in the *Railroad Gazette* of July 5.

CAR BUILDING.

The Illinois Traction Company, it is said, has recently ordered 10 cars from the American Car & Foundry Company.

The Missouri, Oklahoma & Gulf, as reported in the *Railroad Gazette* of July 5, has ordered 200 coal cars of 80,000 lbs. capacity from Barney & Smith.

The Rochester, Syracuse & Eastern has ordered, through J. G. White & Co., from the Niles Car & Manufacturing Company, 15 combination passenger and baggage cars and two express cars; each car has four 75 h.p. motors.

The Buffalo & Susquehanna has ordered, it is said, 500 steel gondolas of 100,000 lbs. capacity from the Pressed Steel Car Company, and is in the market for 1,000 additional steel gondolas, 200 box cars and 100 coke cars.

RAILROAD CONSTRUCTION.

New Incorporations, Surveys, Etc.

ALASKA ROADS.—About 20 miles of railroad has been built by the Guggenheimer interests (American Smelting & Refining Company) from Catalla, Alaska, towards the Copper river district. Between 800 and 1,000 men, it is said, are at present building the line. At Catalla the company is building a breakwater, and it is also doing a large amount of bridge work near that place. A branch is to be built from a point about 18 miles from Catalla into the coal fields. M. K. Rodgers, of Seattle, Wash., is in charge of the work.

ATCHISON, TOPEKA & SANTA FE.—There are to be extensive improvements to the line through Wellington, Kan. Contracts for the work are to be let in a few days. About 150 miles of the line beginning at Cicero, a few miles north of Wellington, is to be rebuilt. It is thought that the contract for the work will be let to Bancroft & Doty, of Topeka, who offered to do it for $440,000.

BUCKHANNON & NORTHERN.—This company, which started grading about four years ago on a line from Bellington, W. Va., north to New Brownsville, in Monongahela county, about 60 miles, and suspended work some time ago, has recently started surveys and will resume work on the line. About 45 miles is graded. S. T. Brady, Parkersburg, W. Va., Chief Engineer. (March 15, p. 380.)

CAIRO TERMINAL TRACTION.—The Illinois Traction System, otherwise known as the McKinley Syndicate, has organized a company under this name with a capital of $500,000, and office at Cairo, Ill., to build an electric line from Cairo north about 20 miles to the northern boundary of Pulaski county. It is said the company intends to eventually extend the line north to a connection with the McKinley lines at St. Louis and East St. Louis, and to build other extensions to connect with electric lines in the southern part of Illinois. The incorporators include: L. E. Fisher, D. H. Sawyer, W. S. Dewey, B. F. Vogel and D. Hogan.

CANANEA, YAQUI RIVER & PACIFIC.—See Southern Pacific.

CANYON CITY & NORTHWESTERN.—Incorporated in Texas with a capital of $100,000 to build a line from Canyon City, Tex., northeast to Yarnell, in Carson County, about 36 miles. The general offices are at Canyon City. The incorporators include C. T. Ward, L. G. Conner, J. M. Black, W. F. Weller, R. W. O'Keefe, D. M. Stewart, all of Canyon City.

CAPE FEAR, SOUTHPORT & ATLANTIC.—Incorporated in North Carolina, with $1,000,000 capital and office at Southport, to build a line from Southport, N. C., west to the North Carolina state line, 40 miles; also from Southport north to Wilmington, 25 miles. The incorporators are A. J. Fahnestock, F. S. Pusey and C. F. Anck, of Philadelphia, Pa.

CARTHAGE RAILROAD.—See Randolph & Cumberland.

CHICAGO & ALTON.—The cut-off from Iles, Ill., to Murrayville, on the Kansas City division, 35 miles, is to be opened for traffic about August 1. See article on page 33.

CHICAGO, ROCK ISLAND & PACIFIC.—A contract is reported let by this company to John J. Fox, of Fort Worth, Tex., for ballasting work on lines in Texas.

CHICAGO SOUTHERN.—This road is to run from Chicago Heights, Ill., where it connects with the Chicago Terminal Transfer, south 114 miles to the Indiana state line, where it connects with the Southern Indiana, which runs to Terre Haute. Track has been laid for 11 miles from the state line north and for 65 miles from Chicago Heights south. It is said that work has been started toward completing the gap. Arrangements for the reorganization of the company's finances are well under way.

CHICAGO SUBWAY [illegible] & T[illegible] COMPANY.—[illegible] which was organized in 1904 and of which William [illegible] is President, [illegible] that it is going to take over the Arnold subway project for which plans were made by Bion J. Arnold. The company has applied to the city government for [illegible] to build a double-deck subway system, to consist of three north and south lines from the northern boundary of the city of Chicago to its southern boundary, and three west side lines from the central district to the western city limits. S. D. Gos[illegible], S. M. H[illegible] and John M. Ewen are interested.

DEFIANCE, HICKSVILLE & FORT WAYNE (ELECTRIC).—Incorporated in Ohio with $10,000 to build electric lines. The incorporators include W. E. Golding, H. C. Eplert, M. O. Topliff, E. E. Murphy and M. I. Brown.

FAIRMONT & MANNINGTON (ELECTRIC).—Contract is reported let to the Blodget Construction Company, of Wheeling, W. Va., by this company, which is being promoted by New York capitalists, to build an electric line from Fairmont, W. Va., west to Mannington, 15 miles.

LONG ISLAND.—Final consent having been obtained from the New York City Board of Estimate and Apportionment, work on the change of line of the Manhattan Beach line will begin at once. This work, being done under the direction of the Brooklyn Grade Crossing Commission, is part of the Bay Ridge improvement. It will remove, altogether, about 80 grade crossings on the Long Island Railroad between Bay Ridge and East New York, and between Manhattan Beach Junction and Manhattan Beach. The contract has been let to Walter H. Gahagan. Construction forces are ready and filling will begin at once. The Brighton Beach improvement, under direction of the Grade Crossing Commission, has been finished, so far as highway crossings are concerned. Two tracks are already in operation and the other two will probably be ready by autumn. It is estimated that it will take about a year for the Long Island Railroad's tracks to be laid on the new elevated grade. Work on the Bay Ridge line from the shore of the bay to East New York is being pushed to completion. At several points trains are already running on the new grade. (See Brooklyn Rapid Transit, March 15, p. 380.)

MEXICAN ROADS.—R. S. Towne, of New York, and associates are projecting a line from the city of Zacatecas, Mex., northwest to Durango, 250 miles. Mr. Towne is interested in the Mexican Northern and in the large smelter at San Luis Potosi.

MISSOURI, KANSAS & TEXAS.—This company, it is reported, is moving three miles of track between Ada and Konawa, Ind. T., from the Canadian river embankment to a new grade along the rock cliff. The work includes some new bridges at Tyrola. It will both shorten the line and eliminate danger from floods.

MORGANTOWN & KINGWOOD.—Local reports state that this road has finished the 20-mile extension to Rowlesburg. The line now extends from Morgantown, W. Va., southeast to Rowlesburg, 50 miles. (May 17, p. 695.)

NEW ORLEANS GREAT NORTHERN.—Track on the branch from Rio, La., northwest via Franklinton to Tylertown, Miss., 41 miles, has been laid, and it is expected that the branch will be put in operation this month.

NEW YORK CITY RAILWAY.—This company has begun the work of changing the First avenue horse car line from Fifty-ninth street north so that it can be operated by the underground trolley system. Later a similar change is to be made below Fifty-ninth street.

OMAHA, LINCOLN & BEATRICE (ELECTRIC).—Work, it is said, is to be resumed on this line, building from Omaha, Neb., southwest to Lincoln, 56 miles. About 14 miles is finished. E. C. Hurd, General Manager, Lincoln.

ONTARIO ROADS (ELECTRIC).—Plans, it is said, are under way to build an electric line from Fort Francis, Ont., southwest, about 150 miles to Duluth, Minn. W. H. Elliott, of Fort Francis, and other local capitalists are interested.

PENSACOLA, ALABAMA & GEORGIA.—Application has been made in Florida by a company under this name to build a line from Pensacola, Fla., northeast to Andalusia, La., 75 miles. The project is being promoted by residents of Pensacola, and is supposed locally to be backed by the Central of Georgia.

RANDOLPH & CUMBERLAND.—This company, operating the old Carthage Railroad from Cameron, N. C., northwest to Hallison, 18 miles, is planning to extend the road southeast to Southport, 216 miles. (March 15, p. 390.)

SACRAMENTO VALLEY & EASTERN.—This company, it is said, has finished 10 miles of road between a point on the Southern Pacific near Kennet, Cal., and the works of the Bully Hill Copper Company at De Lamar. When finished the road will be 18 miles long. (March 15, p. 391.)

Shawnee Central.—This company, recently incorporated in Oklahoma with $10,000,000 capital and office at Shawnee, has surveys made and rights of way secured for about 50 miles on its proposed line from Shawnee, Okla., east to Muskogee, Ind. T., about 90 miles. Contracts for the work, it is said, will shortly be let. J. M. Aydelotte, President, and F. H. Peckham, Chief Engineer, Shawnee, Okla. (May 31, p. 760.)

Sikeston & Southeastern.—An officer writes that contracts will be let this fall for building this proposed line from Sikeston, Mo., north via East Prairie to Hickman, about 30 miles. A. J. Matthews, President, Sikeston, and J. E. Warner, Chief Engineer, Benton.

Southern Indiana.—See Chicago Southern.

Southern Pacific.—The Mexican Engineering & Construction Company of Mexico City has a contract for building the first 32 miles of road of the Cananea, Yaqui River & Pacific west from Orendain, Mex. Connection is to be made with the Mexican Central at Orendain.

Spokane & Inland Empire (Electric).—This company, which recently opened its line from Spokane, Wash., south as far as Oakesdale, announces that the road, originally intended to be built only as far as Moscow, Idaho, is to be extended further south to Lewiston.

Utica & Mohawk Valley (Electric).—Announcement is reported made by General Manager C. Loomis Allen that an electric road is to be built from Rome, N. Y., to Oneida. The necessary franchises have been obtained, and the work will be started as soon as financial arrangements can be made.

Valley River.—Incorporated in West Virginia with $50,000 capital to build a line from Mill Creek, W. Va., southwest to Clovercreek, Va., about 40 miles. The office of the company is at Mill Creek. The incorporators include: J. G. Huffman, Jr., and F. C. Huffman, of Wheeling, W. Va.; N. Heuch and W. A. Donnell, of York, Pa., and L. E. Schull, of Mill Creek.

Western & Atlantic.—Application has been made to the state legislature for permission to extend the terminals of this company at Chattanooga, Tenn., to the Tennessee river.

RAILROAD CORPORATION NEWS.

Atlanta, Birmingham & Atlantic.—N. W. Harris & Co., New York and Boston, are offering at a price to yield 6⅜ per cent. $1,720,000 5 per cent. equipment trust notes dated July, 1907, and falling due in 20 equal semi-annual instalments beginning January 1, 1908. The bonds are secured on 1,200 coal cars, 500 box cars, 300 flat cars, 30 cabooses and 25 locomotives costing approximately $2,145,000.

Baltimore, Chesapeake & Atlantic.—A semi-annual dividend of 2 per cent. on the $1,500,000 cumulative 5 per cent. preferred stock has been declared. The annual rate was 2 per cent. in 1905 and 3 per cent. in 1906.

Baltimore & Ohio.—See Washington Terminal Company.

Boston & Lowell.—The Massachusetts Railroad Commission has approved an issue of $250,000 stock of this company to reimburse the Boston & Maine for improvements and additions. The new stock, which will make $6,849,400 outstanding, being the total authorized issue, will be sold at public auction for not less than par value.

Boston & Maine.—See Boston & Lowell.

Buffalo & Susquehanna.—N. W. Harris & Co., New York and Boston, are offering, at a price to yield 6 per cent., $540,000 5 per cent. equipment bonds, series "B" dated April 1, 1907, and falling due in 20 semi-annual instalments beginning October 1, 1907. The bonds are secured on 500 steel gondolas, four passenger cars, two combination passenger and baggage cars and five consolidation locomotives costing about $640,000.

Chicago & Eastern Illinois.—Speyer & Co., New York, have agreed to underwrite $3,085,000 general consolidated and first mortgage, 5 per cent. bonds of 1937, which are to be issued to retire $2,376,800 first mortgage, 6 per cent. bonds maturing next December and $150,000 first mortgage, 7 per cent. bonds of the Indiana Block Coal Railroad, maturing next July. The general consolidated and first mortgage bonds are part of an authorized issue of $30,000,000, of which $16,583,000 is already outstanding. The present issue is part of $6,403,000 reserved to retire prior lien bonds.

Chicago, Peoria & St. Louis.—The January 1 interest on the 2,000,000 consolidated mortgage 5 per cent. 30-year bonds was paid on June 25. The payment of the preceding semi-annual interest was similarly delayed.

Chicago, Rock Island & El Paso.—See El Paso & Southwestern.

Chicago Southern.—The July 1 interest on the $4,000,000 two-year, 5 per cent. notes has been paid. About 75 per cent. of the issue has been deposited with the Girard Trust Company of Philadelphia under the terms of the plan for exchanging them for their par value in first mortgage, 5 per cent., 30-year, together with 25 per cent. par value of common stock of the Southern Indiana, which is owned by the same interests. See construction column.

Denver City Tramway Company.—See Denver, North-Western & Pacific.

Denver, North-Western & Pacific.—The President of this company is said to have sold his holdings in the Denver City Tramway Company to Eastern interests, including D. C. Clark and W. L. Bull, of New York, and Marsden J. Perry, Benjamin A. Jackson and Samuel M. Colt, of Providence, R. I. The proceeds of the sale are to be used toward paying for the completion of the D., N-W., & P.

El Paso & Southwestern.—It is understood that this company has taken over the Chicago, Rock Island & El Paso line from Santa Rosa to Tucumcari, 59 miles.

Mexican Central.—Some of the income bondholders, including Alexander Morton, of London, and certain New York bankers, have demanded an examination of the books of the company in order to find out the amount of income properly applicable to interest payment on these securities. There are three classes of income bonds, aggregating $32,179,900 outstanding, on which no interest has been paid for 15 years. See National Railways of Mexico.

National Lines of Mexico.—See National Railways of Mexico.

National Railways of Mexico.—This is the name of the company in which the National Lines of Mexico and the Mexican Central are to be merged. It will have $30,000,000 4 per cent. non-cumulative preferred, $125,000,000 5 per cent. non-cumulative second preferred and $75,000,000 common stock. The common and second preferred are to share equally in dividends after the regular dividends on both first and second preferred have been paid. There are to be issued $231,000,000 4½ per cent. preferred mortgage bonds and $186,000,000 4 per cent. general mortgage bonds. The principal and interest of the last named securities are to be guaranteed by the government. The terms on which these securities are to be exchanged for old securities are not yet announced. A syndicate headed by Ladenburg, Thalmann & Co., New York, has been formed to bring out the bonds. The Mexican Central has outstanding $59,454,300 stock and $142,173,000 bonds and notes, and the National Lines of Mexico have $93,403,000 stock and $96,029,000 bonds and notes. The Mexican Central has about 3,350 miles of road and the National Lines about 3,500. The Tehuantepec National is not included in the merger.

Philadelphia, Baltimore & Washington.—See Washington Terminal Company.

Southern Indiana.—See Chicago Southern.

Topeka & Northwestern.—This company, which built 38 miles of the cut-off on the main line of the Union Pacific from Menoken, Kan., to Marysville, 70 miles, has made a mortgage securing $6,000,000 6 per cent. bonds of 1957. It is understood that the bonds are to be turned over to the Union Pacific in payment of the cost of the cut-off.

Union Pacific.—See Topeka & Northwestern.

United Railways Investment Company.—At a meeting to be held July 23, the stockholders are to be asked to authorize the issue of $3,000,000 three-year, 6 per cent. notes and the acquisition of the $1,000,000 ten-year, 5 per cent. notes of the United Railroads of San Francisco.

United Railroads of San Francisco.—See United Railways Investment Company.

Wabash.—The directors have declared an interest payment of 6 per cent. on the $3,500,000 debenture "A" 6 per cent. bonds and 1 per cent. on the $26,500,000 debenture "B" non-cumulative 6 per cent. bonds. No interest had been paid on the debenture "A's" since July, 1904, and no interest had ever been paid on the debenture "B's." The plan for retiring both classes of debentures was agreed on last December. (Dec. 28, 1906, p. 184.)

Washington (D. C.) Terminal Company.—Brown Bros. & Co. have bought $1,575,000 two-year 5 per cent. notes to be dated August 1, 1907. They are secured on $2,000,000 first mortgage 4 per cent. bonds of 1945, and are guaranteed principal and interest by the Baltimore & Ohio and the Philadelphia, Baltimore & Washington.

RAILROAD GAZETTE

ESTABLISHED IN APRIL, 1856.

Published Every Friday by The Railroad Gazette at 83 Fulton Street, New York
Branch Offices at 376 Old Colony Building, Chicago, and Queen Anne's Chambers, Westminster, London.

EDITORIAL ANNOUNCEMENTS.

THE BRITISH AND EASTERN CONTINENTS edition of the Railroad Gazette is published each Friday at Queen Anne's Chambers, Westminster, London. It contains selected reading pages from the Railroad Gazette, together with additional British and foreign matter, and is issued under the name Railway Gazette.

CONTRIBUTIONS.—Subscribers and others will materially assist in making our news accurate and complete if they will send early information of events which take place under their observation. Discussions of subjects pertaining to all departments of railroad business by men practically acquainted with them are especially desired.

ADVERTISEMENTS.—We wish it distinctly understood that we will entertain no proposition to publish anything in this journal for pay, EXCEPT IN THE ADVERTISING COLUMNS. We give in our editorial columns our own opinions, and these only, and in our news columns present only such matter as we consider interesting and important to our readers. Those who wish to recommend their inventions, machinery, supplies, financial schemes, etc., to our readers, can do so fully in our advertising columns, but it is useless to ask us to recommend them editorially, either for money or in consideration of advertising patronage.

OFFICERS.—In accordance with the law of the state of New York, the following statement is made of the office of publication, at 83 Fulton St., New York, N.Y., and the names of the officers and editors of The Railroad Gazette

OFFICERS:

W. H. Boardman	Ray Morris, *Secretary*
Pres't. and Editor	H. S. Crosby, *Treas.*
E. A. Simmons	I. B. Riner, *Cashier*
	L. B. Sherman
Vice-President	*Western Manager*

EDITORS:

Ray Morris, *Man'g Editor*	George L. Fowler
Braman B. Adams	Frank W. Krueger
Charles H. Fay	Hugh Rankin
Rodney Hitt	Bradford Boardman

CONTENTS

Vol. XLIII., No. 3. Friday, July 19, 1907.

The report of the demise of the freight car clearing house and pooling experiment appears to be "greatly exaggerated." The Alton has decided to withdraw and the St. Paul has not been a supporter for some time, but the other roads do not seem to have yet lost courage. Nevertheless it was not reasonably to be expected that even the most limited car pool would succeed at the first attempt, or the second. Such an arrangement has all the disadvantages of a gentleman's agreement on the one hand and of an unwieldly machine on the other. A Mallett compound locomotive with 40-ft. boiler tubes and eight groups of drivers would be simpler. The mere expense of keeping the necessary records, with or without the attempt at an actual or modified pool, staggers the railroad officer who is not farsighted and bold. Freight car records have always been trouble breeders. No car accounting scheme ever supplanted another by a strong vote; it has always been carried by arguments which on slight provocation would reverse themselves. Some roads are now declaring that any equalization of cars as between different roads must be given up because under the present Federal law it becomes illegal. This argument is useful as talk, but, we believe, as talk only. The Interstate Commerce Commission has taken uniformly sensible views on economical use of freight cars and can be depended on to block any arbitrary or narrow construction of the law. The silver lining to this car pool cloud is the fact that nothing can hinder any road from hunting up its own cars, nor from taking proper measures against those who misuse them. A pool might be five years in getting successfully under way, but in five months with a sufficient force of tracing agents a single road could make a long stride toward reform, provided it were not itself too big a sinner.

Mr. Wilgus' resignation from the New York Central has something more than personal interest to those who have watched the development of railroad officers to meet the peculiar demands of exacting modern conditions. The day of the grand old man of keen, observant eye and a memory for the face and name and personal quality of every division officer and of most foremen is long past. Time was when the science of railroading was crude, when the appliances and uses of power were few, when the loads were light and the speeds were low, and when memory, rules of the thumb and stern but parental watchfulness of subordinates were the only requirements for the man who ran the road. We need those men now to maintain discipline, but with the use of electricity, compressed air and oil, as well as steam; with many safety appliances making speed, weight, shorter space intervals and luxurious comfort possible and necessary; with decreasing rates and increasing costs; with trade union, socialistic and governmental domination; with these, the satisfactory officer at the head of a department of a great railroad must be an earnest student and must become a scholar with full knowledge of the sciences involved in his administration, and, of equal importance, of character and with a judgment of men. Mr. Wilgus is simply one of this modern type and it happens that his field of usefulness has been that of designing engineer. But the requirements of this age must develop the same type of scholarly, devoted men in the operating, traffic and financial departments. The "scholarly" officer need never to have seen the walls of a university, but he must have an insatiable appetite for facts which pertain to his work, and keep busy in digesting them. A man cannot operate successfully a machine which he does not thoroughly understand, and it is becoming more and more plain that the ideal officer in charge of operating, contracting for transportation, or financing a great modern railroad must be capable of a thorough understanding of its locomotive and electric power, its signals, track and structures, their uses and limitations; and this with an ability to train and judge subordinates. A livery stable or a stage route has in its management some of the problems of a great railroad with electric terminals, but these problems vary in size and difficulty.

W. F. M. Goss has resigned as Dean of the Engineering Schools of Purdue University to become Dean of the College of Engineering of the University of Illinois. His name has long been identified with Purdue University, but his fame comes rather from his services to railroad science and his help to motive power officers. His going will be a loss to Purdue and a gain to the University of Illinois, but his wide field of influence among railroad officers will not be narrowed. He will have equal opportunities in his new position to continue the work by which he has become so well known in the past. Railroad officers, particularly those of the motive power department, all over the world are familiar with his work in investigating the problems of the locomotive. It was he who conceived

the idea of a stationary locomotive testing plant and who, after a number of years of patient waiting and planning, saw the first plant wiped out by fire almost before any experiments with it had been made. He was not discouraged and soon had another and better experimental plant with a large modern locomotive ready for testing. The results of his investigations during the last ten years have made great changes in locomotive design. Perhaps more than to any other man he may be given the credit for inspiring the monumental work of the Pennsylvania Railroad in building its own elaborate locomotive testing plant for the St. Louis exposition, work in which is now continued in a permanent and progressive way at Altoona. The experimental work at Purdue under Prof. Goss has not been confined entirely to the locomotive, however. Largely through his efforts the Master Car Builders' Association built and installed there its brake-shoe testing machine, its drop testing machine for couplers and axles and its air-brake test rack. His boys, his old students, will all feel a sense of personal loss when he leaves the post where he was so long their friend and counselor.

ELEMENTARY ESSENTIALS IN RAILS.

The railroads are not asking for the impossible when they demand rails that are tough and strong and hard enough to stand a reasonable amount of wear under heavy wheel loads. They want rails made of sound homogeneous steel free from segregation and pipes, toughened and hardened by proper physical and heat treatment during rolling and not by simply increasing the hardening elements, carbon and phosphorus and then passing the metal at too high a heat through the rolls. High carbon and phosphorus make hard rails—which break because they are brittle—and the method costs nothing. Because this gets wearing qualities under present methods of rolling, these hardening elements have been gradually increased to beyond the danger point. It takes more time to roll rails thoroughly at a low temperature and reduces the output a little.

The lower the temperature to which steel is worked the finer the structure and the greater the hardness and toughness. If the work stops at a high temperature the steel in cooling assumes a coarse crystalline structure, and becomes brittle. On the other hand, if the rolling or forging is continued until the steel cools down to the so-called "critical temperature," about 1,600 deg. Fahr., the fine, strong texture produced by the physical work is retained on further cooling, and a hard, tough steel is produced. With rapid and continuous rolling the finishing temperature is therefore a good indication of the amount and efficiency of the work done on the rails. Kept low enough it insures that the steel has been thoroughly worked under the best conditions, and that in cooling it will not deteriorate. It is not practical to work too close to the critical temperature, but it is easily possible to finish rails at much lower temperatures than at present employed.

The method of checking the finishing temperature almost universally used is to measure the shrinkage in a rail length from the time it leaves the last pass until it cools completely. It is an accurate thermometer. The committee of the American Society for Testing Materials recommends "a shrinkage allowance at the hot saws for a 30-ft. rail of 100-lbs. section, of 6 11/16 in., and 1/16 in. less for each 5-lb. decrease of section. These allowances to be decreased at the rate of .01 in. for each second of time elapsed between the rails leaving the finishing rolls and being sawn." This is a more liberal allowance than was made a few years ago, when we got good rails, and it does not unduly limit the mill's tonnage. The limit to be placed on the shrinkage allowance is a matter to be agreed on, but it should be much lower than it now is in any specifications in force.

While the chemical requirements are important they need not be defined too closely or insisted upon too strongly. Given the proper heat treatment and sufficient work in the rolls the rails will be hard enough, even though the chemical composition of the steel varies widely. The greatest danger from bad chemical composition is in making brittle rails due to too much phosphorus and carbon. To guard against brittle rails the drop test, if properly conducted, is a sufficient check. It is not enough, however, to make a drop test from every third heat or every fifth heat of steel. There are inevitable variations in the action of the Bessemer converter and these variations may be sudden and extreme. One heat may make good rails, and the next heat bad rails. Nor should there be any provision for retest of heats which fail under the drop. If the test rail fails it is reasonable to suppose that other rails in the same heat may be weak and dangerous to put in track. Dr. C. B. Dudley, in a recent address, said:

> "If a shipment made under specifications has been tested and does not fill the requirements, all of the material covered by the test should be rejected. None of the specifications of the Pennsylvania Railroad provide for a second or third sampling in corresponding tests. Our theory is that the material ought all to be of the grade called for by the specifications. One sample then is as good as 50. If a specification is so severe that only two-thirds of well-made material will stand test, the specification should be changed. On the other hand, if a manufacturer can only make a product, two-thirds of which will stand test, he should either learn how to improve his product, or go out of business."

Rail specifications then to meet present needs resolves itself into firm insistence on three points; sufficient discard from the top of the ingot to give sound homogeneous steel, limiting the shrinkage to insure low finishing temperature and adequate physical work during rolling and a drop test made frequently enough and severe enough to detect brittle rails. These features of the specification the railroads have a right to determine for themselves, always, of course, within reasonable limits; but it is a fact that rails furnished to American railroads during the past four years have not been made to specification—this with possibly a few exceptions. Orders with specifications as to quality have been refused during these flush times. Quality has deteriorated, sacrificed to increased output and increased profits. The conditions are changing. Orders are now solicited, but orders are held back in the hope that the publicity given to bad manufacturing may result in a decent regard for the rights of the railroads and the people who use the railroads.

MEXICAN GOVERNMENT RAILROAD HIGH FINANCE.

The principal railroads of Mexico are shortly to be consolidated in one great system under control of the national government. Complete plans of the merger have not yet been made public, but certain facts have lately been reported from the city of Mexico. The National Railways of Mexico, the new company, is to include, with the exception of the Tehuantepec National and the Vera Cruz & Pacific, the various railroads in which the government has a controlling interest, amounting in all to nearly 7,000 miles of line. The new company is to be capitalized at $230,000,000 in stock, of which $30,000,000 is first preferred, $125,000,000 second preferred and $75,000,000 common stock. Bonds are to be limited to a maximum of $417,000,000, of which $231,000,000 are to be preferred mortgage 4½ per cent. bonds, and the remaining $186,000,000, 4 per cent. general (second) mortgage bonds, the latter guaranteed principal and interest by the Mexican government. This makes a total capitalization (stock and bonds) of $647,000,000.

The railroad development of Mexico has been different from that of the United States, in that it has been by north and south rather than by east and west lines. To be sure the first railroad in Mexico, the old Mexican Railway—the most important, by the way, of the lines still independent of government control—was built to carry an existing traffic between Vera Cruz, the principal seaport, on the east coast, and Mexico City, the capital. But even to this day, owing to the difficulties of crossing the Sierra Madre range which runs parallel to and not far from the west coast, with the exception of the Tehuantepec National, which crosses the narrow isthmus at the southern extremity of the republic, there is no east and west line in operation across the country from coast to coast. The two most important railroads, the Mexican Central and the National of Mexico, connect points on the United States boundary with the capital city. These roads were so built because the principal mountain ranges of Mexico run north and south, and because the promoters of these roads were men from the United States who looked to the interchange of traffic between the two countries as the principal source of future profit.

Up to 1880, the Mexican government made no effort to encourage railroad building. Up to nearly that time the uncertainties of Mexican politics made railroad construction especially difficult and expensive through the exactions of the party which happened to be in power. The cost of the Mexican Railway, the only road built previous to 1880, was estimated by A. M. Wellington to have been doubled by such means. In 1887, Porfirio Diaz, then 47 years old, was first elected President of the republic. Ever since that time he has been in power, directly or indirectly. He brought order out of disorder because of his success in developing the material welfare of the country. In particular he realized the efficacy of railroads in uniting the political and upbuilding the commercial interests of the nation. In 1880, three years after his election, a law was passed which, while expressly reserving the right of gov-

ernment regulation, provided for government subsidies and other favors to new railroads. Most of the railroads of Mexico were built under this law. It was superseded in 1899 by a new law which amplified the old one and also made possible more efficient methods of railroad operation, in particular by legalizing pooling arrangements and prohibiting construction of unnecessary parallel lines. It also provided that all railroads built under succeeding concessions should revert to the government at the end of 99 years. This law therefore marked a strengthening of the railroad policy of the government.

In 1903 it was rumored that interests allied with the Standard Oil group of capitalists in this country, who already had a large interest in the Mexican Central, were about to acquire the National and consolidate the two roads. The government thereupon bought control of the National of Mexico, thus preventing the threatened merger. It also secured the Mexican International and the Interoceanic of Mexico, two small but important roads. These three roads were more or less formally combined under the title National Lines of Mexico. Although the government held virtual control, it did not undertake the actual management, which was left largely in charge of the other owners. In other words, this was not government operation or strictly even government ownership, but simply government control by stock ownership.

Last December it was announced that the government had bought securities of the Mexican Central sufficient for control, and was planning to consolidate that road with the National Lines. The three main arguments for this consolidation were summed up as follows by Minister of Finance Limantour to the Mexican Congress: First, to avoid friction between competing lines; second, to prevent absorption of the Mexican Central by one of the great railroad systems of the United States, and, third, because of the prospect of realizing economies through consolidation.

The first reason is shown by the accompanying remarks of the Minister to refer particularly to the inequalities of a situation in which it is to the interest of the national government to favor one of two competing roads at the expense of the other. A concrete instance is the concession granted to the National Lines soon after their acquisition by the government, allowing them and them only to build new railroads across a stretch of territory about 30 miles wide on the south bank of the Rio Grande, thus preventing the Mexican Central from building a projected cut-off to give it a shorter route for international traffic than its present roundabout route via El Paso. It does not seem as if this could have been an important reason from the government's point of view because the hardship falls, not on the government's own road, but on its competitor. But there is another possible reason for this desire to avoid competition. The Mexican Central is heavily over-capitalized. It has about $100,000,000 in mortgage bonds and collateral trust notes falling due within four years. It is by no means certain that the road, left independent, could have come through this trying financial period without a receivership. Hence with the Mexican Central independent there was the possibility of the government system's having to face the ruinous competition of a bankrupt road.

The second reason is probably the one which was most important in bringing about the acquisition of the Mexican Central. The strong federal government of Mexico has for some time looked with alarm at the prospect of having its principal railroads controlled in the United States. Yet to prevent the reported absorption of the Central by a United States system, the government has undertaken the very consolidation which three years earlier it entered upon its large policy of railroad ownership to prevent, and has brought to an end the useful competition in railroad rates and service which it then attempted to preserve.

The third reason, the economies of consolidated management, though actually important, probably was incidental. There is no doubt, however, that there are many economies to be gained, particularly in centralization of management and more economical routing of through traffic.

Not only has the Mexican government in making this consolidation adopted the very principle which it was unwilling to see established under private ownership in Mexico, and at which it looked askance as carried out in the United States, namely, consolidation of parallel and competing lines, but in the formation of the merger it has followed still other methods evolved by American railroad financiers. As already mentioned, the stock capitalization of the new company is $230,000,000. Considering the consolidated system to have 7,000 miles of line—in reality it has a little less than that—this is at the rate of $32,857 stock per mile. The total bond issue of $417,000,000 similarly works out at $59,571 bonds per mile. This is a total of $[illegible] per mile, comprising [illegible] of the bonds are to be issued at once or sold to refund outstanding issues. The present capitalization of the Mexican Central, National of Mexico, Mexican International and Interoceanic of Mexico together is about $21,[illegible] stock and $[illegible],000 bonds per mile.

Even though the new funded debt per mile be no heavier than at present, the new company would have a total capital (stock and bonds) of $[illegible] per mile. The average stock and bond capitalization of all United States railroads is $66,583. But, in Mexico, of the less than 7,000 miles of line included in the merger, 1,315 miles are narrow gage, and, furthermore, maintenance expenditures on standard and narrow gage alike have been much lower than the average on United States roads, with the resultant fact that the Mexican roads are reported to be in great need of repairs and improvements. The figures for the United States, on the other hand, cover, with unimportant exceptions, standard gage railroads, many of them with large amounts of second, third and in some cases fourth track, and with exceedingly valuable terminals. More than this, the typical United States railroad has of late years, instead of holding back on maintenance expenditures, been appropriating large sums out of earnings for betterments and improvements. It is obvious therefore that even the probable minimum capitalization of the National Railways of Mexico is very high, in comparison with the present value of the roads. It is to be observed further that the maximum proposed bond issue of the consolidated company is 80 per cent. larger per mile than the existing bond issues of the separate companies. A part of the bonds, however, are no doubt to be reserved for betterments and additions to existing lines and acquisition of other roads which may sooner or later come under control of the government. The explanation given by the Minister of the $230,000,000 of stock capitalization is that the issue is large in order to give the government control of a majority of the shares, their value being a matter of secondary consideration; in other words, that part of the stock is issued for purposes of control only.

The National Railways of Mexico in short is a splendid example of the modern highly capitalized holding company. It has all the elements of that institution as developed during the last few years in the United States. A number of properties, most of them already capitalized at an amount far exceeding their actual value, are merged in a central company which issues its securities in exchange, in amounts not only large enough to repeat the overcapitalization of the constituent units and to cover the economies of consolidation, but to provide for all the growth which can at best be expected for many years in the future. The operation appears to be on a par with the Chicago & Alton reorganization and the formation of the Rock Island Company. The striking and original thing about it is that it is being carried out by the government of the country in which the consolidated properties are situated; this at the very time that the United States government is considering the advisability of trying to break up similar mergers. It is only natural to wonder whether the evil effects of such "high finance" methods, as recognized in the United States, will appear when such a consolidation is carried out by a government. What effect, for instance, will the existence of $200,000,000 second preferred and common stock, part of which will be in the hands of the public, have on railroad rates in Mexico? When it is argued by American railroad officers that capitalization has no effect on rates, the existence of competition is always given as proof of the assertion. But in Mexico there will be no competition to overrule the natural incentive to pay dividends on all outstanding stock. This is only one of the interesting questions for the future brought up by the recent railroad policy of the Mexican government.

NEW PUBLICATIONS.

American Street Railway Investments. Issued in connection with the Street Railway Journal. 1907 edition: 462 pages, 9½x12¾ in.; cloth; price, $5.00. The McGraw Publishing Co., 114 Liberty Street, New York.

The current volume contains the usual full statistical data about street railways in the United States, giving a brief statement of the history, capitalization, earnings, expenses and traffic statistics of each company together with a statement of plant and equipment, a list of officers and a date for the information about each company. The book is illustrated this year with 44 maps and covers the reports of more than 1,400 operating and controlled companies in the United States and Canada. In the beginning of the book, compilations are made as in previous years of companies arranged in groups according to their gross earnings, and it is interesting to note that in the 1906 fiscal year there were 63 companies which earned over $1,000,000 each, as against 53 companies in 1905. The

five companies having the largest earnings in 1906, as in 1905, were the Interborough Rapid Transit Company of New York, which earned $20,411,097; the New York City Railway Company, which earned $19,092,385; the Brooklyn Rapid Transit Company, $18,797,264; the Philadelphia Rapid Transit Company, $17,676,249, and the Boston Elevated, $13,634,612. There were also two other companies which earned more than $10,000,000 in 1906, the Pittsburg Railways Company and the Chicago Union Traction Company. In all, there were 15 companies which earned more than $5,000,000 in 1906, as against 14 in 1905. There were 20 companies which earned over $4,000,000, as against 16 in 1905, and 29 companies which earned over $3,000,000, as against 22 in 1905. There were 44 companies which earned between $500,000 and $1,000,000, 184 companies which earned more than $100,000 and less than $500,000, and 190 companies which earned less than $100,000. The most interesting part of the showing is that decreases were practically nonexistent, while each of the groups showed a very substantial gain over 1905; thus the gain of the companies in group one, having gross receipts of over $1,000,000, was 16 per cent. in 1906 over 1905; the gain in group two, having gross receipts between $500,000 and $1,000,000, was over 31 per cent.; that of the third group, having receipts between $100,000 and $500,000, was over 24 per cent., and the gain of the group having gross receipts between $50,000 and $100,000 was 29 per cent. This is probably the best argument that could possibly be given for the stability of American street railway enterprises.

CONTRIBUTIONS

A Radical Change in Rail Design.

68 William St., New York, July 10, 1907.

To the Editor of the Railroad Gazette:

It seems to us that the present is the time for a radical change in design of rails. It must be evident to any engineer that the design of a section for use on a railroad with heavy rolling stock and good roadbed calls for a different distribution of material from that required by a new road with much lighter cars and locomotives and poorer permanent way.

Railroad engineers have heretofore been limited in their designs by the ability or unwillingness of the rolling mills to produce other than standard sections. The introduction of very broad flanged beams as rolled on the Grey Universal Mill has opened up new possibilities, and we would suggest that railroad engineers should design new rail sections, which in their judgment are most suitable for the different divisions of their roads, and in so designing cut loose from all preconceived ideas as to what, in their minds, it is possible for the rolling mills to produce and simply show what would be ideal for their conditions. There is no necessity to retain any of the old characteristics, height (area of head, web and flange), and widths need not be restricted to measurements approximating those heretofore in use; all that need be considered is what is most desirable for their own individual purposes. The effort to standardize various weights of rails and induce railroads to use such, regardless of their climatic and other conditions, has brought about unsatisfactory results. The railroad man defers to the rail-maker, instead of the latter endeavoring to meet the views of the former. The railroad engineer should design his section and the rolling mill should roll, as near to his requirements as their outfit will allow. It should not be that the rail-maker tells the railroad what it will give and the railroad engineer has to accept. This has been the condition and the results have been disastrous. The situation needs a thorough overhauling, and it is up to the railroad engineer to show what he would like to have without regard to what he has had to use. If he wants higher rails and wider flanges, this need not mean heavier rails. If the railroad first determines what is ideal, it is then up to the rail-maker to see how near he can come to producing such ideal. We are convinced that better service can be obtained by changing the method of rolling rails. We are also of the opinion that the time is ripe for changing the whole plan of railroad permanent way. The wooden tie is a costly relic of bygone days, and a relic which costs untold millions to perpetuate. The rail as now designed has two separate and distinct functions calling for two diametrically opposing qualities, one to resist the positive bending moments, resulting from the wheel loads, and the other to resist the abrasion and crushing effect of heavy and repeated wheel pressures. The first requirement might be satisfied by a permanent section of structure which would support for its entire length the frictional resisting section, which must be so carried as to allow its being quickly replaced when worn sufficiently to call for removal. By having one section for the load-bearing medium and another for the frictional resisting medium two separate qualities of steel can be used, and each can be so graded as to meet the requirements for which it is designed.

Railroads are in a rut and no one seems disposed to get out of it. Why should they continue to demand from the rail-maker what he cannot make, or rather, what he has so far failed to satisfactorily supply—namely, a single bar of steel which has at the same time the maximum wearing qualities and the highest efficiency of load-bearing characteristics? If they have one bar suited for one function and another for the other function and each designed both as to shape and quality to best serve its individual purpose, they will get better service, cheaper renewals and greater safety. The time is ripe for getting out of the rut and for dispensing with both the wooden tie and the old T-rail, the former necessitating almost continuous renewals and the latter necessitating the renewal of not only the part that is worn out by reason of oft-repeated heavy wheel contact pressure, but also that part which is designed to transmit such wheel loads to the roadbed.

Henry Grey & Son,
Consulting Engineers.

The Block-Signal and Train-Control Board.

This is the title of the board which has been appointed by the Interstate Commerce Commission under the acts passed by the last two sessions of Congress, to investigate and report on the subject of automatic stops and other questions connected with block signaling. The members of the board are: Professor Mortimer E. Cooley, Dean of the Department of Engineering, University of Michigan, chairman; Azel Ames, Jr., Signal Engineer, Electric Zone of the New York Central; Frank G. Ewald, Consulting Engineer of the Illinois State Railroad Commission, and B. B. Adams, Associate Editor of the *Railroad Gazette*.

The immediate purpose in establishing this board appears to have been to give suitable publicity to the present "state of the art" of automatic apparatus for stopping trains, as called for in the communication which was sent to Congress by the Interstate Commerce Commission on January 3 last, wherein the commission advised Congress that it was credibly informed that such devices had been sufficiently perfected to justify the government in testing them. The clause in the appropriation bill which authorizes the commission to expend money in this direction was, however, drawn so as to cover not only the investigating and testing of automatic stops, but also investigation in regard to the use of and necessity for block signals on railroads. The functions of the new board will, therefore, include the examination of any or all of the subjects which were dealt with in the report on the block system which was made to Congress by the commission last February (*Railroad Gazette*, Vol. 42, pages 277, 479, 507 and 544). That report, it will be remembered, spoke of the need of further investigation of signaling under the following four heads:

(1) The telegraph block system on the larger roads (mainly double track) as regards the personnel and the routine, the use or non-use of distant signals, and the practice of permissive block signaling.

(2) The telegraph block system on single track lines and minor roads as regards the personnel, the routine, distant signals and permissive signaling, and also as regards the use of time rules and despatchers' orders to make up for incompleteness in the block signaling arrangements.

(3) The automatic block system should be investigated on all roads with respect to the efficiency of the apparatus and of the methods of inspection and care and the integrity of the records of signal operations in respect to their completeness.

(4) The automatic block system on single track lines should be investigated with respect to the features named in the foregoing paragraph, and also as regards the use simultaneously with the block signals of despatchers' orders and other measures designed to prevent collisions irrespective of the block signal system.

Prof. Cooley, who is appointed chairman of the board, was graduated from the United States Naval Academy in 1878, but resigned from the service in 1885, since which time he has held the chair of Mechanical Engineer in the University of Michigan. Prof. Cooley made a valuation of the physical property of the railroads of Michigan ordered by the legislature in connection with taxation a few years ago, and has done other similar work for that state. Last year he was employed by the city of Chicago in connection with the valuation of the street railroads of that city, and he was one of the authors of the valuable report on that subject which was noticed in the *Railroad Gazette* of December 28, 1906, page 567.

Captain Ames is a graduate of the Massachusetts Institute of Technology and was an officer in the engineering corps of the United States army during the Spanish-American war. He was Supervisor of Track on the Hudson division of the New York Central, then Signal Engineer of the Boston & Albany, and subsequently of the Lake Shore & Michigan Southern before being promoted to his present place.

Frank G. Ewald has been Consulting Engineer of the Illinois Railroad and Warehouse Commission for the past ten years, prior to which he was employed by the city of Chicago in charge of tunnel work for the water system of that city. Before that he was employed in the engineering department of the Atchison, Topeka & Santa Fe.

B. B. Adams has for 20 years been one of the editors of the *Railroad Gazette*. He has had long experience in railroad work and is the author of "The Block System." He was for two years Secre-

tary of the Railway Signal Association. He has had charge of the preparation of the accident bulletins of the Commission for the past five years, and, with Mr. C. C. Anthony, performed the technical work in connection with the block signal report which the Commission made to Congress last winter.

W. P. Borland, Secretary of the Board, is a railroad man of long experience who has been employed by the Commission for the past five years.

The headquarters of the board will be at the office of the commission in Washington, and the Secretary is Mr. W. P. Borland. The commission has requested the co-operation of the American Railway Association in the conduct of any tests which may be made and the signal committee of the association, in response to this request, has appointed a sub-committee to take up the matter consisting of Messrs. F. C. Rice (C., B. & Q.), A. M. Schoyer (Pennsylvania Lines); W. G. Besler (C. of N. J.), A. T. Dice (P. & R.), E. C. Carter (C. & N.-W.), and H. C. Moon (L. S. & M. S.).

New Passenger Station at Evansville for the Evansville & Terre Haute.

The Evansville & Terre Haute Railroad has begun work on a new station at Evansville, Ind., on the site of the old one at the corner of Eighth and Main streets. In order to put the waiting room in the most convenient relation to the tracks, the station building will front on Eighth street and be built across the ends of the tracks. The [illegible] of the building [illegible] street, the distance from the [illegible] of the building to any track is as short as could be secured. The [illegible] distance from the property line in order to give plenty of room for vehicles in Eighth street.

The main waiting room is at the center of the building with the ticket office, baggage office, smoking room and women's waiting room around it. The [illegible] room is at the [illegible] end of the building at the corner of Main and Eighth streets, and opens off the waiting room. The sizes of these rooms are as follows: Waiting room, 50 ft. square; ticket office, 17 ft. x 11 ft.; smoking room, 19 ft. x 16 ft.; women's room, 19 ft. x 19 ft.; lunch room, 20 ft. x 20 ft.

Between the main building and the track [illegible] is a passenger concourse 25 ft. wide and 166 ft. long. The baggage room opens directly on this concourse on the track side, and the concourse has an exit porch on Main street. This latter gives direct communication between the concourse and the street so that passengers do not have to pass through the main building—a convenient and effective arrangement, especially when there are large crowds. The concourse entrance porch has a marquise, so that passengers arriving at or leaving the station by carriage or motor need not be exposed to the weather.

Express, mail and baggage are received and delivered by teams in a special courtyard on the Main street side, separated from the street by a brick wall. The baggage, mail and express, therefore, will be handled with the utmost convenience, out of sight of

Proposed Station at Evansville, Ind., for the Evansville & Terre Haute.

the public and in such a way as not to conflict in any way with the passenger service.

Besides the rooms on the first floor of the station already mentioned, there is a room at the east end, 40 ft. x 47 ft., for the general freight agent. The second and third floors, each with an area of 12,000 sq. ft., will be used for the general offices of the company.

The style of the exterior of the building is that of a freely interpreted classic on Colonial lines. There are round-headed windows below and an unbroken frieze formed by the windows of the third story, this frieze running around the whole building below the heavily overhanging roof. The main body of the wall surface will be red brick with stone trimmings. The frieze of the windows will match the stone in color and the roof will be of gray-green tile which contrast well with the red of the wall surface. In order to make the buildings most easy of access the front and back of the waiting room open out through three large doorways toward the street and toward the concourse respectively. This triple entrance on Eighth street is marked by monumental stone columns. In adopting the classic forms, the overhanging roof and the colorings mentioned, the idea was to produce a building which would be in sympathy with the architectural traditions of the South.

The auxiliary building for baggage, mail and express will be across the passenger concourse from the station building, 63 ft. long,

General Plan of Evansville Station.

one-story high, and parallel to the tracks. The five tracks will be protected by a train shed, and beyond this there will be umbrella sheds for unusually long trains. To avoid smoke and dirt, the heating plant will be placed under the nearby freight house.

The architects for the station are D. H. Burnham & Co., Chicago. The principal contract was let to August Ohm, Terre Haute, Ind. It is expected to have the station ready for service in the fall.

The Interstate Commerce Commission's Report on the Harriman Investigation.

The report of the Interstate Commerce Commission on the investigation into combinations of carriers' generally known as the "Harriman inquiry" was made public on July 14. After summing up the expansion of the Harriman system and influence and reviewing the reorganization of the Chicago & Alton, which is said to be "rich in illustrations of various methods of indefensible financing," by a syndicate in which Mr. Harriman was one of the members, the Commission sums up as follows:

A.—The effect of the control of the Southern Pacific by the Union Pacific has been to unify and amalgamate the management of these two railroad companies and their steamship lines and to eliminate competition between them in transcontinental business and in business to and from Oriental ports.

B.—The Union Pacific, as has been shown, controls the San Pedro, Los Angeles & Salt Lake, the stock of which is deposited in the hands of a trustee. This line was originally intended as an independent road, extending from Salt Lake, where it connects with the Union Pacific and with the Denver & Rio Grande, to Los Angeles and San Pedro, Cal. There is therefore no competition between this line and the Union Pacific and Southern Pacific.

C.—It appears that the Union Pacific also owns $10,000,000 par value of the stock of the Atchison, Topeka & Santa Fe, and about $30,000,000 more is owned by individuals connected with the Union Pacific, making $40,000,000, or substantially 17 per cent. of the entire capital stock of the Santa Fe company. Who owns this stock outside of the $10,000,000 Mr. Harriman declined to state. Two directors of the Union Pacific are also directors of the Santa Fe company, and there is now a division of the Oriental traffic by the Pacific Mail Steamship Company between the Union Pacific and the Santa Fe systems. It appears that there has also been a division of the fruit traffic between certain California territory and the East, each taking a certain percentage, and that north of San Francisco the Union Pacific and the Santa Fe have joined and amalgamated their interests in the Northwestern Pacific Railroad and that a joint control has been inaugurated similar to that of the Chicago & Alton.

D.—Prior to the acquisition of the Southern Pacific by the Union Pacific the Denver & Rio Grande system, extending from Denver, where it connects with various lines to the east, to Salt Lake and Ogden, was given equal facilities over the Central Pacific, and thereby practically formed another transcontinental line. Since the amalgamation of the Union Pacific and Southern Pacific and the construction of the San Pedro road this line has been denied equal facilities in the receipt and transportation of freight over the Central Pacific and the San Pedro lines. Its business, therefore, has decreased, and its ability to compete with the Union Pacific and Southern Pacific impaired. On this account the Gould lines are aiding the construction of another line from Ogden to San Francisco.

E.—The joint control of the Chicago & Alton by the Union Pacific and the Chicago, Rock Island & Pacific has undoubtedly eliminated competition between the Alton and the Rock Island between Chicago, St. Louis and Kansas City.

F.—These are conspicuous illustrations of the development of the theory of "community of interest" and "harmony of management," which Mr. Harriman suggested when he demanded representation upon the Santa Fe board.

G. If the policy of purchasing and controlling stocks in competing lines is permitted to continue, it must mean suppression of competition.

The Commission concludes by making the following three recommendations:

First—The function of a railroad corporation should be confined to the furnishing of transportation. Railroads should not be permitted to invest generally in the stocks, bonds and securities of other railroad and of steamship companies, except connecting lines, for the purpose of forming through routes of transportation, including branches and feeders. It is in the interest of the public to facilitate the consolidation of connecting lines.

The credit of a railroad company is founded upon the resources and prosperity of the country through which it runs. Its surplus funds and credit should be used for the betterment of its lines and in extensions and branches to develop the country contiguous to it. The testimony taken upon this hearing shows that about 50,000 square miles of territory in the state of Oregon, surrounded by the lines of the Oregon Short Line Railroad Company, the Oregon Railroad & Navigation Company, and the Southern Pacific Company, is not developed; while the funds of those companies which could be used for that purpose are being invested in stocks like the New York Central and other lines having only a remote relation to the territory in which the Union Pacific system is located.

Railroad securities should be safe and conservative investments for the people. To this end the risks of the railroad should be reduced to a minimum. Everyone knows that railroad securities fluctuate more or less, according to the prosperity of the times, and also by reason of the wide speculation in such securities. It, therefore, adds an element of hazard to a railroad's capital and credit to have its funds invested in the stocks of other companies, thereby endangering its solvency and its ability to pay reasonable dividends upon its own capital stock. It is a serious menace to the financial condition of the country to have large railroad systems fail to meet their obligations or go into the hands of receivers, and the object of legislation and administration should be to lessen the risks of railroad investments.

Second—It is contrary to public policy as well as unlawful, for railroads to acquire control of parallel and competing lines. This policy is expressed in the Federal laws and in the Constitutions and laws of nearly every state in the Union. We have examined the Constitutions and laws of all the states, and find in about 40 of them prohibitions against consolidation of capital stock or franchises of competing railroads, of the purchase and acquisition by a railroad of competing lines. Competition between railroads as well as between other industries is the established policy of the Nation. And while the acquisition of a small minority of the stock of a competing line might not decrease the competition, yet the acquisition of any considerable amount of stock, with representation on the Board of Directors of such railroad, unquestionably has the effect of diminishing competition and lessening to that extent its effectiveness. So long as it is the policy of the General Government and of the states to maintain competition between naturally competing lines, the ownership of any stock by one railroad in a competing railroad should not be permitted, and such lines of railroad should be prohibited from having any common directors or officers.

Third—The time has come when some reasonable regulation should be imposed upon the issuance of securities by railroads engaged in interstate commerce. We are aware that in the construction of new lines of railroad, developing new territory, as it has been necessary in many instances to sell railroad securities at large discount, and to sell bonds with stock bonuses, and even in such cases it has many times been difficult to raise the necessary capital. Men will not invest their money and take the risk for small rates of interest.

But this principle does not apply to old established railroad systems having good credit. Such railroads should be prevented from inflating their securities for merely speculative purposes. Railroads should be encouraged to extend their systems and develop the country. It is of the utmost importance also that railroad securities should be safe and conservative investments for the public, and should yield good and ample return for the money invested. Reasonable regulation will tend to make them safer and more secure investments, and thereby benefit not only the railroad companies but the public.

Socialism and the Railroads.*

BY COL. H. G. PROUT.

We stand face to face with a situation in our national life of great gravity. We are at this moment in full movement of an historical epoch of deep significance to us as individuals, to our nation and to the human race. The situation which I have in mind is created by the attitude of the American people toward aggregations of capital. Great individual fortunes, corporations, trusts so-called, any devices by which a few men can control large amounts of money, have become objects of suspicion and of active hostility to a great part of our fellow citizens.

AN HISTORICAL PARALLEL.

The situation has a close historical parallel in the French Revolution. Then the sense of injustice became intolerable and the plain people cut off the heads of the king and the nobles and burned their palaces and confiscated their lands. The Texas editor who wants us to hang the bankers would have sent his thrifty neighbors to the guillotine if he had lived in France in 1793. Will the resentment of the mass of the American people go as far as to destroy great property values, to impoverish those who have been so wicked as to make a little money and to invest it in the securities of productive enterprises? They have begun the process without knowing what they are doing. Will they go on with it?

This is the most solemn question that has confronted this nation since the Civil War. If we stand aside and allow the answer to the question to be determined by that great class of politicians

*An address delivered before the Traffic Club of Pittsburg.

and editors who try to sit on the top of the wave of popular feeling and drift with it, in the hope of being landed high and dry on some sunny slope of personal prosperity; if, I say, we allow the answer to this solemn question to be determined by that selfish and irresponsible class we deserve the calamity that will no doubt overtake us.

I have tried briefly to state in general terms, the situation now before this nation. Let us try to bring it a little nearer home. Let us see how it especially affects the railroads. I speak as a railroad man, because I have got most of my living from the railroads, and for years I have been a friendly and sympathetic student and observer. Some folks say I have been a partisan of the railroads.

The attitude of the people of the United States toward the railroads of the United States is one of the strangest social phenomena within my observation or reading. Consider for a moment what the railroads have done in the history of this nation. The building of the United States was the most colossal real estate enterprise the world ever saw or ever dreamed of. Nothing like it can ever happen again; nothing approaching it. It would be impossible to estimate the value of the part played by the railroads in this real estate operation which we call the building of the nation. It would be almost impossible to overstate it. With pride and with amazement I think of the enterprise, the courage, the genius of the men who risked reputation and fortune in pushing railroads over the uninhabited lands or the thinly peopled areas of our country in the second and third quarters of the century just closed. Those were the heroic days when men had dreams and saw visions. Those were the glorious days of the youth of the nation. States and counties and towns stood and beckoned to the railroad builders, and gave them franchises and rights of way and local bonds. That is why to-day a four-track railroad runs trains at sixty miles an hour over a street crossing at grade through a great city. It is not because the railroad man is depraved or reckless, but because the pioneers said, "Come, help us build the city; help us to get rich"; and the men and women of this land and of England and of Holland, who had saved up a little money, ventured their savings in this colossal speculation, lost their savings very often, and made it possible to build us the cities to cover our continent with a network of railroads.

RAILROADS AND THE PUBLIC.

It is not strange that under the conditions of our railroad building unwise things and wicked things were sometimes done. We are all foolish and wicked, more or less, and the measure of our folly and of our sin is largely a question of opportunity and of the moral atmosphere in which we live. The building of the railroads and of the cities and of the villages of this continent, the building up of the great industries in steel and oil, in packing and in milling gave abundant opportunities, and the builders did not have very much time to stop and think. It was not strange that indiscretions should have been committed in finance and in the relations of the railroads to the traders and the manufacturers of the nation. It is not strange that certain somewhat crude notions should have been established as to the correct relations of railroads to society.

Twenty years ago last March the Interstate Commerce act went into effect. At that time most railroad officers took a very simple view of their obligations toward the public. It was commonly held that a railroad belonged to its stockholders; that the stockholders had put their money into the property and were responsible for its debts; that the duty of the hired man, viz., the president, the vice-president, the general manager, the traffic manager, the division superintendent, and so on down, that the duty of this hired man was to make money for the stockholders, to enable them to pay interest on the bonds, to eventually clear off the debts resting upon the property, and to gradually increase the value of the equities in that property. In brief, the general view taken was that a railroad property should be managed just as a mill is managed, or a dry goods store, or any other large property. It was held by the thoughtful railroad man of twenty years ago that the relations of the railroads to the public would be properly established and maintained through the action of enlightened selfishness. It was believed that in the long run the interests of the railroads and of the public were the same; that the railroad's officers would appreciate this fact, and that the public would appreciate this fact, and that just and harmonious relations would work themselves out exactly as they do in all other human affairs. My instincts and my habits of thought tempt me to still believe that to be the sound view of the relations of the railroad to society; but in the twenty years that have elapsed since the Interstate Commerce act went into effect there has been a great change in the public conception of what we may call the political economy of railroads, and there has been an important change in the minds of a considerable number of railroad officers. This change has come about very largely through the incessant discussion of railroad matters that has been stimulated by the constant activities of the Interstate Commerce Commission.

RAILROADS AND THE GOVERNMENT.

The notion has now become very prominent that the railroads are not to be treated as private properties, but as public institutions at least as much public institutions. A great number of our fellow citizens, including therein many of the most intelligent railroad officers, now believe that railroad affairs should be subjected to Government control. I should say that a majority of our fellow citizens believe this. The question of difference is simply as to the degree of control that the States or the Federal Government are permitted to exercise. Personally, although I am a Republican in politics, in political economy I am a Democrat of the old school and I have a thoroughgoing and fundamental belief in the doctrine that the Government is best which governs least. I contemplate with dread an enlargement of the functions of Government and particularly the invasion of the field of railroad control by the officers of the State and Federal Governments. But I recognize that control of the railroads by the various governments within our country is bound to be tried on a very considerable scale. I still believe that it will fail, except in some broad and simple way; but I am quite sure that we shall go through a good many years of experiment with railroad control. This theory of the control of railroads is only one manifestation of the wave of socialism which is sweeping over the country and which has one of its principal fountains in the White House. It is the oncoming of that great wave which alarms me for the future of our country, and which has such special menace for those who are responsible for the prosperity of the railroads.

I have spoken of the attitude of our people toward the railroads as a strange phenomenon. This is true when you think of the part which the railroads have had in building the country, and when you think further of the part that the railroads play in our daily life. Outside of agriculture, railroading is the most important industry in the country. It employs more men than any other industry except agriculture. It pays out about eight hundred and fifty millions of dollars a year in wages, being 60 per cent. of the total operating expenses. It pays in dividends $238,000,000. The wages and taxes paid by the railroads amount to nearly four times as much as the dividends paid on railroad stock; in fact, the dividend payments amount to only about three and six-tenths per cent. on the stock; ten years ago the dividends paid amounted to but one and seven-tenths per cent. A little more than 37 per cent. of all the railroad stock of the country pays no dividends. Ten years ago about 70 per cent. of the railroad stock of the country paid no dividends. These few figures give a notion of what the prosperity of the railroads means to the working people and to the manufacturers and traders of the country, and they give us a notion also of the really very small returns which railroad properties make to their owners.

IMPORTANCE OF RAILROADS.

I shall not trouble you with any recital of the well-known figures of ton-miles and passenger-miles by which we measure the public service of railroads, but I will call your attention to the fact that there is not a human being in our nation, there is hardly a civilized human being in the world, whose life is not every moment affected by the railroads of the United States. The prosperity and the happiness of every man, woman and child in the civilized world depends more or less on the prompt, cheap and regular movement of freight over the railroads of the United States. Here in the United States, the prompt, cheap and regular movement of freight is, excepting the crops, the most important element in our daily happiness and in our continued prosperity. The appreciation of this fact is one important element in the intense popular feeling against the railroads.

But people do not know how light is the burden of the transportation tax. They do not know that we have the cheapest freight rates in the world and the best freight service. They do not know that the free play of commercial forces uncontrolled by governments has given us a flexibility and an adaptation of rates and service such as no other country has ever seen. They do not stop to think that an eight-cent loaf of bread has paid one-third of a cent for transportation from the wheat fields of Dakota to the freight station in New York; that is, one twenty-fourth of its cost to the consumer is transportation tax. They do not stop to think that a mechanic, working one day, earns enough to pay for the transportation from Chicago to Liverpool of his food for one year. A long time ago Abram S. Hewitt said that Sir Henry Bessemer was the great apostle of Democracy, that he had done more than any other one man to destroy the power in Great Britain of the privileged classes. He meant that Bessemer's discoveries and inventions had reduced the cost of transportation and so brought down the cost of living and enabled the poor man to cut himself loose from the soil of the little parish or county in which he had been reared. Cheap transportation had opened up to the poor man the markets of the world from which to draw his food and clothes, and had given to him the markets of the world in which to sell his labor.

These are elementary facts that I am reciting, but it is well for us to get back now and then to elementary facts, in order that

we may see our way more clearly through the complex conditions that surround our daily lives.

RAILROADS MUST HAVE MONEY.

If the railroads are going to continue to do their part in the further development of our country and in the further progress toward liberty, happiness and prosperity of all the people of the earth, it is obvious that they must not be hampered or crippled. This principle applies to their administration and to their financial credit. That their administration may be the most efficient, the freest play must be given to the operation of the great elements of ambition, energy and enterprise; and that they may be able to finance their future requirements, their credit must be sustained. You will remember that Mr. Hill has lately said that the money requirements of the railroads of the United States to meet the natural demand of our growing population will be about eleven hundred million dollars a year for five years. Mr. Loree, a clear-headed man with a gift for analysis, has lately told me that he had gone through his own estimate, independently of Mr. Hill, and had arrived at nine hundred million dollars a year as the natural requirements of the railroads.

RAILROADS MISREPRESENTED.

I have already told you that the railroads of the United States are paying now only about two hundred and thirty-eight millions a year in dividends, and that over 37 per cent. of railroad stock pays no dividends, and that ten years ago 70 per cent. paid no dividends. It is obvious that they cannot earn the money to extend and improve road and equipment to meet the proper requirements of our people. Where are they to get it?

I shall not stop here to consider the debated and debatable question as to who is the most powerful in destroying the credit of the railroads—the financier who represents what the President calls predatory wealth, or the President himself as representing the wrath of the people. I merely point out that at this moment the railroads are between the devil and the deep sea; and, further, that anything which cripples the railroads is a calamity of the first magnitude for the nation.

It is a national misfortune that the railroads are so generally and systematically misrepresented in the public press. Fair discussion, discussion in the spirit of justice and truth, is almost never seen in the daily newspaper treatment of railroad matters, whether it be of accidents, of freight rates, of passenger rates, of whatever may be the subject under discussion. The consequences of this attitude are most serious. Indeed, I go so far as to say that the malicious wrecks that have occurred lately should be charged to the editorial offices of the daily newspapers. By those newspapers the railroads are treated as outlaws. People of feeble reasoning powers and of emotional temperament are easily led to think that it is proper to attack an outlaw in any way that amuses them or gratifies their hatred or envy.

That predatory wealth of which the President is so fond of talking has really very little to do with the policy of the railroads of the country in general. Perhaps the President himself would be surprised to know how little, although I am inclined to think that he does know, and that he says more than he really believes, as a part of his general scheme of keeping the Republicans in power and keeping the Democrats out of power. It has been suggested that when Bryan went in swimming the President stole his clothes and ran off with them. At any rate, the President has maneuvered Bryan and his followers out of all their really strong positions.

PREDATORY WEALTH AND RAILROADS.

But predatory wealth has very little to do with the policy and conduct of the railroads. You know and I know that the great mass of the owners of the railroads are honest and law-abiding citizens. You know and I know that the directors and administrative officers of the railroads are just like the rest of us—no better and no worse. In intelligence and executive capacity they rank high, because they are disciplined in an exacting school, and they are selected because of their capacity to carry responsibility. In moral character they are probably above rather than below the average. The assumption that they are scheming to cheat their neighbors, that they are trying to contrive ways to annoy their patrons, that they are indifferent and incompetent in practical operation of their railroads, would sound childish if it were not so serious and so far-reaching in its consequences.

Of course, we know that wrong things are done by railroad officers. We have heard, for instance, a great deal about rebates; but if we reflect, we discover that rebates are not new, simply they have been made illegal. We know that they have been used for years, and even for generations, as a means of building up communities and industries along lines of railroads. Probably, in the primitive times many of those railroad managers who granted rebates thought that they were doing a correct and public-spirited thing. Unfortunately, correct notions about these matters are almost never presented in the daily press. It is unfortunate, too, that there are so few men having exact information and correct judgment on these matters who have time and disposition to write or speak for the education of the public. In that respect the death of Mr. Samuel Spencer was a great loss to the railroads. He was one of the few railroad officers of high rank and of great experience who had the faculty of analysis, and clear, simple and attractive presentation, and, who, joined to that faculty, had the consciousness that it was his duty toward the railroads and toward the public to speak and write on the social science of railroads, as opportunity offered.

I am afraid that what I have been saying sounds a good deal like the Lamentations of Jeremiah; and I am afraid that, like Jeremiah, I can suggest no very practicable and easy way of bettering the conditions that I have tried briefly to put before you. Some things do appear to me, however, as being quite practicable and useful.

BUILD UP CORRECT PUBLIC OPINION.

It seems to me that it is a duty of the officers of the railroad companies, and those who are closely related to railroad companies, and who have means of special information, to try to build up correct public opinion. This some of us can do by talk with our neighbors; some of us by occasionally writing for publication here and there; some of us by an occasional public speech; some of us by direct personal contact with our Senators and Representatives in Congress and the members of our State Legislatures. It seems to me that this is an obvious and neglected duty that all of us can perform, and, in the aggregate, with a good deal of profit, and it is a duty, not to the railroads alone, but to the nation.

Beyond this, there is a good deal that every railroad man can do in his daily business life. Much of the public feeling against railroads has its root in little disagreeable things in the relations between subordinate officers and employees and the public. Quite a number of years ago it became my duty to spend three or four weeks among the railroads in England. As I was coming away, I went to say good-by to the general manager of the Great Northern Railway, to whom I was under obligations for courtesies. I told him that I had been running about in yards and stations and railroad warehouses and a lot of places where I had no business to go, that I had practically lived on the railroads for three weeks, and that, from the time when I set my foot on the British Islands until the moment of leaving, I had not had an uncivil word or act from any British railroad servant. This did not seem a very surprising thing to the general manager, but it was a very rare and surprising thing to me. In our own country it is the exception to get civility from the minor officials and employees. Every time that a man buys a ticket he runs the risk of more or less gross incivility. It would be hard for us to overestimate the accumulated influence of the display of bad manners toward the public, so characteristic of the minor officials of the railroads of our country. I have not the slightest doubt that this has been an influence of very great importance in creating the widespread hostility of which we see so many signs and which is expressing itself now in costly and disastrous legislation.

CLAIM DEPARTMENT OBSTRUCTION.

I wonder how many of you ever thought of the relation between the claim department and hostile legislation. To the outsider, it seems as if the claim department of a railroad was a highly efficient organization for obstruction. The desire to ascertain the truth and to help the shipper, or the consignee, or the person who has suffered damage or injury, to get justice, is apparently no part of the duty of the claim department. Of course, I am aware of the fact that the railroads must protect themselves against swindling claims; but I do protest that it is contrary to the instincts of the Anglo-Saxon to be considered a swindler until he proves himself an honest man. Do you wonder, when you think of these things, that the great, self-respecting, proud American public, with a keen sense of its own rights and dignity, should resent that sort of treatment?

I told you at the outset that I consider myself a railroad man, and that I speak with the greatest friendliness; in fact, these little matters of discourtesy, injustice and arrogance slide off from me like water off a duck's back, because I know that the men who do these things do not properly represent the gentlemen above them, and it has been one of my principles of conduct to try to cultivate a sense of humor and not give undue importance to little things. But I have ventured to remind you of these little things by way of showing you one way in which you can help your railroads and your country, namely, by incessantly instilling in the minds of your subordinates the prime duties of courtesy, patience and fair mindedness in dealing with the public.

The railroad ticket tax imposed a year ago by the German Empire was estimated to produce about 24,000,000 marks the first year. The Secretary of the Treasury recently announced that the prospect is that only about 12,000,000 marks will be realized by it. The diversion of travel from the higher to the lower classes has been greater than was estimated.

New Top-Mast Motor Signal.

The General Electric Company, Schenectady, N. Y., is now bringing out after a long and severe test under all weather conditions a new two-position electric motor signal of the top-mast type, similar in outward appearance to its three-position signal, with which the reader is familiar. This signal, shown in Figs. 1 and 2, and known as the M-113, embodies several new and interesting mechanical and electrical features.

Figure 3 is a back view of the signal mechanism in the position corresponding to the proceed indication of the blade. The supporting frame of this mechanism, carrying the bearings for the shaft and gearing, also forms the case, which is weather proof. The bottom of the case *A* forms a socket by which it is secured to the top of the mast, and inside this socket is a removable insulating bushing *B* which eliminates possibility of grounding, even if the wiring comes in contact with the case or an insulation is broken down. A similar socket *C* is provided at the top of the case to hold the pinnacle, or for an extension of the mast, in case one or more signals are to be placed above it.

The form of the case is such that, with a suitable bracket (*D*) for supporting the lamp, any of the present standard semaphore spectacles may be used. The whole external design presents a symmetrical and graceful appearance. The motor is similar to that used in the other type of the General Electric Company's signals, except that it is provided with both series (*E*) and shunt (*F*) field winding, and with a ball ratchet to prevent backward rotation of the armature. The object of this modification is explained below.

The high speed gear and the motor pinion are protected by a case attached to the inside of the frame, while the intermediate

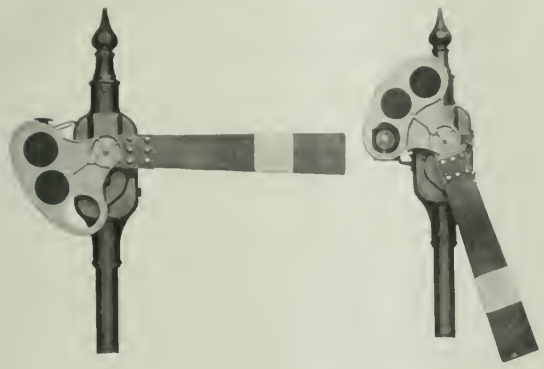


Fig. 1. *Fig.* 2.

General Electric Top Mast Signal.

gear and its pinion are protected by a gear case made of a single piece and bolted to the outside of the frame, with which it makes a weather-proof joint. To the face of the main gear *G* are attached driving pins of case-hardened steel, which move the signal from stop to proceed position by engagement with the pawl *H* of the slot-arm. The slot-arm *J* is mounted on a squared portion of the signal shaft by means of a broached hole in its hub, and carries a magnet *K*, the armature *L* of which is attached to one end of a bell crank lever, which by a pawl at its other end engages with the driving pins whenever the slot-magnet is energized. The series coil of the slot-magnet is connected in the motor circuit, and the shunt or high resistance coil is connected outside of the control contacts which break the motor circuit. Current is carried to the slot-magnet without the use of flexible moving wires, segmental collector rings and brushes being employed as in other G. E. signals.

On the signal shaft, directly back of the main gear, is mounted an eccentric *M*. The strap of this eccentric is cast in one piece with the cylinder of the dash-pot, or buffer, *N*. In front and also connected to the main shaft is a counting device *O* for registering the number of signal movements.

When the signal circuit is closed, current will flow through the shunt coil of the slot-magnet, and in another circuit through its series coil, and thence through the motor control sector *P* and its contact fingers *Q* to the motor. The slot-magnet being energized, the pawl *H* is held in the path of the driving pins, and as the motor revolves one of these pins is forced against the pawl, thereby turning the slot-arm and the signal shaft to which it is connected, thus carrying the signal arm toward the proceed position. When the arm of the signal comes almost to its extreme "proceed" position, the motor current is broken by means of the controller *P*, but this breaking of the current does not arrest the movement of the signal, for the inertia of the revolving armature and other parts keeps it going. While the armature is thus driven by its own inertia it becomes a generator, maintaining the field excitation. Immediately after the current between the motor and the battery is broken, a low resistance circuit is closed between the motor brushes, thus converting the armature into a powerful magnetic brake to arrest further movement of the signal. As soon as the motor stops the ball ratchet above mentioned prevents any backward rotation of the armature and the signal is thus held in its clear position until the main circuit between the signal and the battery is opened. The circuit-closer for electric brake control is shown in the cut at *R*. At *S* are a number of fingers for extra circuits. The glass cover of the compartment is shown removed at *T*.

It will be understood that the higher the voltage of the battery and the less the friction of the machine the armature will be the speed of the motor at the time the battery current is cut off, and the greater will be the inertia of the moving parts. It is also evident that the greater the speed of the motor the higher will be the E. M. F. generated in its armature, and the greater will be the

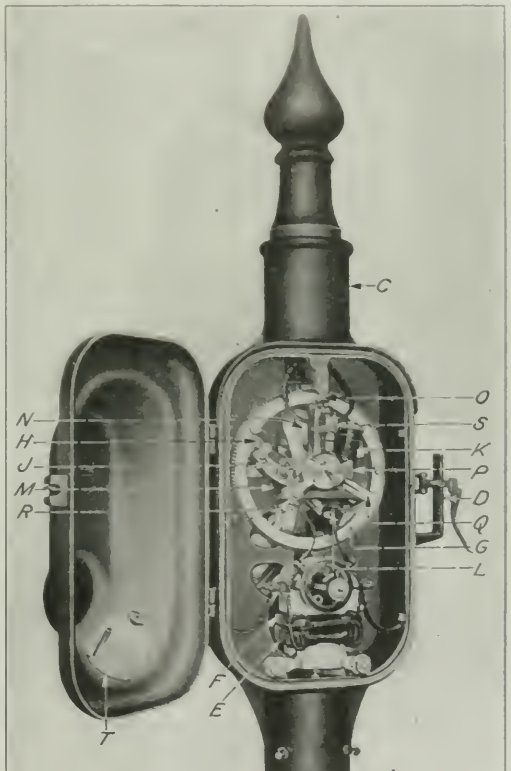

Fig. 3—General Electric Company's Top-Mast Semaphore Mechanism.

current opposing its forward movement when it is acting as a generator. Therefore the motor will make approximately the same number of revolutions after its current is broken, stopping the signal arm at the same position under all conditions; so that a friction brake is not needed.

When the main signal circuit is opened and the slot-magnet de-energized, its heavy armature falls away from the poles, this movement being also assisted by the pressure of the driving pins against the pawl. The pawl being thrown back from engagement with the driving pin, the signal is free to assume the position to which it is normally carried by gravity. As the signal arm comes to its stop position, the rotation of the slot-arm causes its armature to swing back against the poles of the magnet, so that it is in position to be held firmly in place when current is again applied.

While this signal was specially designed for use in two positions only, it can be operated as a three-position signal when an extra circuit controller is used, and a back contact provided on the line relay. When used as a three-position signal, and when indi-

cating a train backing into the section of track for which the signal gives distant indications, the arm will go from proceed to stop before assuming the caution position. Where such a movement is not objectionable this signal is applicable.

The design of this signal is such that all parts are readily accessible, and they are easily removed from the case, when necessary. The motor and other parts are readily reversible to provide for moving the signal either up or down from the horizontal position.

Progress in the Philippines.

The following are quotations from an interview, published in the *Journal of Commerce*, with Charles A. Conant, one of the directors of the Manila Railway, a New Jersey corporation, through which the Speyer syndicate is building new railroads in the Philippines. The Manila Railway has taken over the Manila & Dagupan, the only steam railroad now in operation in the islands. In regard to the proposed extensions of the Manila Railway, Mr. Conant said:

About 428 miles of new line will be built on the island of Luzon. The existing line, which was opened some 14 years ago with English capital, runs for about 120 miles from the outskirts of Manila to Dagupan, almost due north, and also includes 88 miles of branches. It is now proposed to extend this line some 35 miles farther north to San Fernando de la Union, and to build a number of spurs and branches connecting with Manila the principal towns of the western part of the island. There will also be a detached line of considerable length built at Albay Province, the southeast peninsula of Luzon, which will connect with the steamship line and open up territory which could be reached only by a very circuitous route if it were all rail from Manila.

The railroad receives no grants of money or property, directly or indirectly, in connection with this construction. The United States Congress authorized the Government of the Philippine Islands to guarantee 4 per cent. interest for 30 years on bonds issued for the construction of lines in the Philippines. The Philippine Commission advertised for bids under this law, and bids for construction with guaranteed bonds were accepted for certain detached lines in some of the other islands. In the island of Luzon, however, the Manila Railway was so firmly established that it was not easy for any rival syndicate to cut the ground from under its feet, even with Government aid. Mr. Speyer, therefore, after offering to build some aided lines in connection with others which were to be unaided, decided finally to ask simply for franchise rights for the proposed extensions, without asking any financial aid from the Government. He felt that under such a grant the railroad would have greater freedom in choosing its routes and conducting its operations, and that with entire responsibility for its finances it would not be tempted to enter upon projects which did not commend themselves to its own engineers.

The Manila Railway originally received a subsidy from the Government. There is a curious story about that. The Spanish Government was so eager to encourage railroad building that they provided in the charter of the Manila Railway for a regular annual payment of interest on a part of the cost of construction. Such payments were suspended by the American Government. An effort was made to set up the claim that it was not a continuing obligation of the governing power, since the sovereignty had changed hands. It is doubtful if the courts would have sustained the repudiation of an official contract on this ground alone; but it was contended that the road had allowed its tracks and rolling stock to be used by the insurgents, and especially for carrying on trade, in violation of the orders made against trading with provinces which were in revolt. The railroad, on the other hand, put in a claim for heavy damages to its property and loss of revenue by the seizure and use of its cars and locomotives for Government purposes. While the road had large claims against the Government under these heads, there was a clause in the original contract which might have hampered the road materially if it continued to grow. This was a stipulation that when the gross receipts exceeded a certain amount a large payment was to be made into the public treasury. The road has been so successfully conducted since the insurrection terminated in 1901 that considerable amounts have accrued under this obligation to the Government. Thus there was a condition of claims and counterclaims. The railroad cut the Gordian knot by renouncing all claims against the Government in return for a renunciation by the Government of its claim to a share in the earnings of the road. The road, however, will pay into the public treasury a percentage of its gross receipts. This percentage will increase at fixed dates.

The extension of the railroad is the one step needed to put the islands on the high road to commercial prosperity. We have become so accustomed to railroads that we hardly realize their economic importance. They not only open up new sources of production, but they afford a safeguard against starvation in times of uneven crops and protection against political revolution, which are very important. A railroad corrects the variability of the crops by permitting the surplus product of one province to be taken to another where the crop may have failed. Millions of lives have been saved in British India through this one fact. In China in the great famines it has often been the case that thousands have perished because the transportation facilities did not exist to bring to them the contents of the bursting granaries of other sections. From a political point of view the railroad and the telegraph render attempted revolution difficult, because they permit prompt transmission of news and prompt despatch of troops to the center of disturbance.

Railroad development has been slower than some anticipated when the American occupation began. It is still less than six years, however, since Governor Taft superseded the military authorities with the full powers of civil government. Six years is but a day in the life of a nation, and it could not be expected that everything would be accomplished in so short a time. Much has already been done, however, to develop the island commercially and more undoubtedly will be done in the near future. The new breakwater at Manila, which is now practically completed, will make the city, with the proposed new piers, the best equipped port in the Orient. A contract has recently been awarded for about $443,000 for two large steel and concrete wharves, one 600 by 70 ft., the other 650 by 110 ft. The military authorities have already completed a wharf for their own use, and on September 12 last the transport 'Logan' lay alongside it to unload—the first large transpacific liner to lie beside a pier in the Philippines. All harbor dues have been abolished in the islands, and as tonnage and light dues had already been done away with, Manila is now a free port, so far as shipping is concerned. The American warehouse system permits the free transshipment of goods destined for delivery in other Oriental countries, and should aid in making the city and bay of Manila a great distributing center. The harbor has been dredged to the depth of 30 ft. wherever such a depth is desirable. Within a year transportation has been put on a healthy commercial basis by doing away with the Government inter-island steamers, which were absolutely essential for military and civil purposes when the islands were in a state of confusion, and letting the mail and transportation contracts to commercial companies.

American capital has been going into the islands. This subject is discussed in the annual report of the Philippine Commission for 1906. Among the cases there cited of the employment of American capital are the contracts for the harbor works let to Americans, not only at Manila, but at Iloilo and Cebu; the adoption of a modern telephone service in Manila, which will be gradually extended throughout the island of Luzon; electric lighting plants at Iloilo and Cebu; the traction system in the city of Manila, which has been substituted for the dirty little horse cars in which no European or American would ride, a modern electric service; contracts for new water-works and sewer systems for the city of Manila; one of the inter-island transportation companies, and large companies for getting out lumber, for printing, for the manufacture of cocoanut products, for distributing American machinery, and for many other purposes. It is declared by the commission that all this progress has been made, not by depriving Filipinos of industries that before were theirs, but by the introduction of new capital and new business sagacity that have enabled Filipinos in nearly every case to obtain greater and larger remunerative employment and greater prosperity than ever before.

The Harriman Lines and Reciprocal Demurrage.

The following is a letter addressed to officers and agents of the Union Pacific signed by A. L. Mohler, Vice-President, and General Manager of the Lines East of Green River:

Agitation in favor of the enactment of state and national laws embodying that which is misnamed "reciprocal demurrage" is based to a very large extent upon a misunderstanding of present conditions and the results which would follow such legislation. It is important that employees of this company, coming in contact with the shipping public, should be posted upon the underlying principles of the subject in order that they may be able to present to the advocates of such legislation the unfairness as well as the consequence thereof. The question of adequacy of car supply naturally divides itself under the following headings:

(A) Freight locomotives and cars represent about one-fifth of the total capital invested in a railroad, and are practically the only portion of the property which provides revenue; the value of the remaining four-fifths depending entirely upon the use made of this one-fifth.

(B) Locomotives and cars can only be of value to their owners when moving under load or towards the loading point. Promptness of despatch in transit and methods adopted by railroads to secure increased daily loaded movement of cars.

(C) Cars are at times very valuable to consignees for storage purposes on the basis of the present low demurrage rates.

One of the most important questions that has engrossed the attention of the entire country during the past few months has been the inadequacy of freight car supply to meet the extraordinary

demands made upon our railroads to move a freight traffic unprecedentedly heavy by reason of bumper crops and the prosperous condition of all lines of industry throughout the country. Whilst this unusual state of affairs has taxed even the financial resources of the government in furnishing funds required through activity in money centers, and has resulted in congestion and overworking of existing facilities in all branches of trade, with shortage of labor, higher wages and higher cost of living, etc., it has been to railroad transportation to which inquiry has been practically alone directed. Yet, it can be truthfully said that the railroads, of all others, because of their past experience and their close touch with the pulse of business progress, long ago anticipated the present increased traffic, as well as anticipated what would naturally follow leading up to a shortage of cars, as it was self-evident with the tremendous growth of prosperity consignees' and consignors' warehouse and storage facilities would be overtaxed, resulting in more cars being tied up for storage purposes, which alone contributed more to and stimulated more the shortage of cars for the movement of traffic than anything else.

While this is true of the railroads in general, we can more confidently speak of what has been done by the Harriman lines as a whole, with which we are connected, operating about 15,000 miles of main line westward from Omaha, Neb., Kansas City, Mo., and New Orleans, La., to Los Angeles and San Francisco, Cal., and Portland, Ore., traversing states whose area is half that of the entire United States. During the past year on no part of the line has there been an insufficiency of equipment to move traffic. The San Francisco fire of April 18, 1906, completely destroyed the facilities for receiving and storing freight at by far our greatest traffic center, causing an aggravated blockade, tying up at its maximum over 6,000 cars, or 9 per cent. of our entire equipment. As it was impossible to reproduce the destroyed facilities, we had, under the circumstances, to be extremely lenient with consignees, and the congestion continued in greater or less degree for nearly six months. During this time local points along the line of the Union Pacific proper were largely dependent upon receiving empty car equipment from California, which had moved west under load, and as sufficient empties could not be sent east, this contributed its portion to the car shortage in the Middle West.

During the past five years the Harriman Lines have anticipated, perhaps, as much or more than any other system, the increasing development of the territory they serve, and have made vast additions to their rolling stock, the expenditures for which in this period have amounted to over $60,000,000. In the five years, 1902 to 1906, including equipment under contract, we have purchased 1,194 new locomotives and 40,196 new freight cars, most of these being steel cars which require less repairs, will be less time out of service, and therefore capable of handling a greater traffic than the wooden ones. Our car orders for this year alone amounted to 14,000 cars, or 20 per cent. of our entire equipment.

All of the engines are of the heaviest hauling capacity used anywhere, bringing our locomotive standard to as high an average condition and efficiency as exists on any road in the United States, whilst the cars added were principally of 50 tons carrying capacity with steel underframing. This new equipment is equal in tonnage carrying capacity to over 70,000 cars of the standard type used only a few years ago, and is far greater in tonnage capacity than the entire equipment owned only four years ago. In this time we have added over five tons to the average carrying capacity of every car we own. This great activity in car construction has been carried on during a time of extremely high material and labor prices, extra cost being added for steel construction to lessen damage from accident, the cost of our new cars being nearly double that prevailing 10 years ago.

To show how our lines have increased their equipment in advance of traffic requirements, below is given a statement going back four years to 1902 and looking forward to 1907 when we shall have received the equipment really ordered in 1906, but which will not be delivered until the spring of this year:

Thus in the heaviest period of 1906, we had only 6 per cent. greater traffic than in 1904 and [illegible] had [illegible] to [illegible] on account of new equipment provided 18 per cent. more locomotive traction and 14 per cent. more freight car capacity.

The average speed of freight trains on the Harriman Lines excluding stops is about 16 to 18 m.p.h. To meet competitive conditions and to market perishable products, the speed of trains has been increased on our lines and we have established a manifest system under which the movement of a large part of our traffic is vastly expedited and delays eliminated. As a result cars are being handled more expeditiously and moved a much greater distance per day than on the average road, as per the following comparison:

	Miles run per car per annum.		
	Loaded.	Empty.	Total.
All railroads of United States	5,820	2,[illegible]	[illegible]
Union Pacific system	8,861	2,985	11,8[illegible]
Southern Pacific Company	7,312	2,910	1[illegible]

These averages for our cars are for owned cars only. Foreign cars, which are largely confined to long haul business, we move faster and average 50 miles per day, or at the rate of about 18,000 miles run per annum.

As an aid to more efficient use of equipment we on June 1, 1901, established on the Harriman Lines a car clearing house, whereby all freight cars owned by all our separate lines are pooled and handled as a common ownership. Under this system cars are expeditiously moved from parts of the system where there may be a surplus to districts where most needed. Our officers everywhere are held to strict accountability for failure to properly watch car movement and utilize equipment capacity. By a rational system of tonnage rating, based on speed requirements as well as tractive power, locomotives are properly loaded to obtain their full value as traffic movers, whilst loading of cars is closely watched and their tonnage capacity utilized to its fullest possible extent. Shipments are combined to save car equipment where it is an object for this purpose on long hauls and where no material delay to freight will result. Elaborate statistics are kept of the use made of cars and locomotives, and officers making a poor record are held to strict accountability. Large capacity cars are kept in long haul business where greatest ton mileage can be handled. Car tracers are employed to check up car movement, and in various other ways we are seeking the maximum efficiency of our equipment, both for economy's sake and to render the best possible service to the public, as manifestly it is to the interests of any road to handle every ton of freight it can. Our equipment is always kept in the highest standard of condition, repairs being made as occasions offer, preferably in the lighter seasons. Our locomotives and freight cars were never in better condition generally than they are to-day. During 1906 we made repairs on 4,344 locomotives and 340,115 freight cars as compared with 329,230 cars in the previous year. For these repairs we expended $17,000,000. All these details, thoroughly suggestive to the mind of any practical railroader of to-day, have resulted in the excellent showing made by the Union Pacific and Southern Pacific Lines as compared with "All railroads of United States" on "Miles run per car per annum" shown in the foregoing tabulated information.

The statement is often made that yard facilities for handling cars have not been increased in proportion to the increased traffic. This is certainly not true for the lines of the Union Pacific and Southern Pacific systems. With each new car ordered computations are made and estimates prepared for additional tracks and terminals to hold the entire equipment ordered, although, of course, only part of it is in terminals at any one time. For example, in the four and a half years since June 30, 1902, with an increase of 15 per cent. in number of cars owned, an increase of 16 per cent. in car mileage and an increase of 17 per cent. in train mileage, we have increased our mileage of double main train 214 per cent. and have added 1,100 miles, or 30 per cent. to the length of yard tracks and sidings. For each car owned we now have 362 ft. of yards and sidings as compared with 322 ft. four years ago.

	June 30, 1902.	June 30, 1906.	Increase over 1902	June 30, 1907.	Increase over 1902.
Tons of freight carried one mile, thousands	10,339,057	3,738,198	33 per cent.	14,587,958	41 per cent.
Tonnage capacity freight cars owned	1,638,410	2,177,293	33 "	2,721,776	66 "
Total hauling capacity of locomotives as expressed by total w't on drvrs, tons.	98,720	145,340	47 "	166,505	69 "
Freight train miles	29,576,176	31,579,901	7 "	32,238,032	9 "
Total freight car miles	785,584,562	913,429,442	16 "	945,390,661	20 "

Thus estimating an average increase of traffic for 1907 as prevailed in previous years to move 41 per cent. of traffic, we will have available 66 per cent. more car capacity and 69 per cent. more locomotive capacity than we had five years ago.

The measure of the tax on railroad facilities is the traffic moved during the busiest season. Selecting the heaviest month out of the past three years, we have the following:

Tons of Freight Moved One Mile.

October, 1904	1,201,000,000
October, 1905	1,261,000,000
October, 1906.	1,279,600,000

With the car shortage agitation, the most important question to all railroads has been the detention to cars by shippers and consignees. We have endeavored to clearly show that the increased traffic has been anticipated by the Harriman Lines by the purchase of new equipment, and we might add that long ago anticipating the increased traffic, experience, which proves to be the best teacher, called forcibly to our attention the fact that during the wave of prosperity there would, as before stated, naturally follow a further growth of laxity on part of the commercial world, whose warehouse and storage facilities were overtaxed, to release cars promptly,

preferring to hold and utilize them for warehouse purposes. Stringent and positive instructions were issued long in advance of the heavy movement, impressing upon the minds of our agents and all concerned that they must force consignees to release cars promptly. Only one-eighth of a day is actually required to move a freight car the average distance it is hauled, the remaining time being consumed in terminal yards awaiting movement in trains, on sidings after being unloaded, on yard tracks at disposition of shipper awaiting loads, and, perhaps, more important of all, delayed at stations under load waiting to be released by consignees who are holding to unload or holding on re-consigning orders.

In order to increase the efficiency and promote their own earnings, railroads are always endeavoring to reduce delays for which they are responsible, and if their patrons would lend their aid to do likewise, vast good would be accomplished. The limitation of every railroad system in times of heavy traffic is the terminal situation, and the proper terminal situation depends upon the exertions of every shipper and consignee to unload cars with the least possible delay. Some consignees have ample facilities for the prompt handling of their maximum business, but the reverse is the rule. Many consignees order freight in large amounts expecting to sell it before it arrives, in which effort they are frequently unsuccessful in whole or in part. Much freight is consigned to brokerage or commission houses, the prompt disposition of which depends upon future market conditions. Some consignees with ample facilities delay cars badly by neglect and poor business methods.

These conditions have made necessary the present demurrage rules. The consignees know that the carriers would greatly prefer the cars to the demurrage charges—but unfortunately their preference is the same and the company must perforce permit them to exercise their preference regardless of the interest of the carriers,

A New Monorail Car.

and to the detriment of all other shippers. No railroad company can get any benefit from the prompt loading, unloading and handling of cars without, at the same time, benefiting shippers and consignees, hence the claim of the carriers that existing rules are non-discriminating, reasonable, and in the highest sense "reciprocal."

But the proposed reciprocal demurrage bill includes a provision for penalizing the carrier for failure to furnish cars as called for within a specified time. Legislation to fine a corporation for omitting to do that which is imperative with the self interest of the corporation, is as unique as it is unjust, and could not obtain an audience except under the extraordinary political, commercial and industrial conditions now prevailing. Demurrage is collected from a shipper on account of his converting to individual use facilities furnished by the company for the benefit of the shippers as a whole. Reciprocal demurrage, as planned, is a penalty to be paid by a carrier, not for something it receives or unduly retains, but for failure to supply that which it does not and cannot possess, and from the possession of which it is to a considerable extent debarred by the failure of its patrons as a whole to realize and fulfill their obligations to other shippers and to the railroad company. If the carriers are to be so penalized, actual reciprocity would require shippers to furnish loading at all times for all cars available.

It should be remembered that penalizing a railroad for not furnishing equipment is equivalent to a rebate to a large shipper who has a large holding in manufacturing and elevating interests, thereby defeating the purpose of the Hepburn bill to prevent rebates. Why should railroads be penalized for not furnishing equipment to any greater extent than consignees for not furnishing storage facilities to adequately provide for the business and necessary storage? The consignee feels justified in paying $500 or $600 per year for demurrage in preference to enlarging his facilities at a cost of say $20,000 per year, thereby eliminating the responsibility of interest, taxes and depreciation on the investment which, in a few years, with a decline in business, would be a burdensome one.

The great majority of shippers located on the Union Pacific Company's lines are broad-gaged, intelligent and fair-minded men, and are not in sympathy with any proposed legislation which has for its effect the restriction of prosperity and the discouragement of increases in investments in the way of improved facilities and terminal enlargements. Every large city must have terminal facilities to provide for the growth of such cities, and when such municipality by malicious and unfair advisers prevents the enlargement of terminal facilities by a legitimate and equitable franchise, to that extent the rapid development of that city is retarded.

The officers and employees of the Union Pacific will, at all times, co-operate with patrons and shippers along its lines. The prosperity of shippers is absolutely essential to the successful operation of its property; therefore, there can be no question as to the importance of dividing prosperity between the transportation lines and their patrons; and this company will at all times be found on the side of aiding increased prosperity rather than to encourage conditions which are certain to result in the withdrawal of marvelous prosperous conditions at the present time existing, and which all enjoy, and which, to the writer, appears as the poorest time to grumble.

A New Monorailway.

A working model of a new monorail car which has created much interest in Great Britain, where it has been exhibited, is shown in the accompanying illustration. It is the invention of Louis Brennan, well known as the inventor of the torpedo which bears his name. Equilibrium is maintained by gyroscopic action and the car is balanced on a single rail at all times, whether moving or standing still and under all conditions of wind pressure, shifting load or centrifugal force. The gyroscopic mechanism consists of two flywheels mounted on special bearings in a case from which the air has been exhausted. The air and journal friction is thus reduced to a minimum, and only small power is required to keep them in motion. They are rotated in opposite directions at very high speed by small electric motors taking current from a storage battery placed in the car. The use of two gyroscopes overcomes the tendency toward excessive inclination or variations when running backward or forward. The mechanism occupies only a small space and weighs about 5 per cent. of the total weight of the car.

The model car is mounted on two bogies, each having a pair of wheels. These bogies are designed for free radial and vertical movement to permit the car to round sharp curves and ride easily on rough track. The two wheels of each bogie are coupled, and they are driven by electric motors geared to one wheel. The track consists of a single rail laid on blocks, and for crossing gullies a heavy cable. An experimental track of this kind with steep grades and sharp curves has been built and the model car successfully run over it with loads as high as 150 lbs.

The War Department of the British Government has begun the construction of a large car of this kind. It will be propelled by a gasoline-electric generator set. The motors on the wheels will be provided with change gears for ascending steep grades. This car will be tested for its availability in military railroad work where the monorail track construction would be especially valuable.

Foreign Railroad Notes.

There is pending in the French Parliament a bill providing for old age pensions to railroad employees. This bill was introduced ten years ago, and five years ago was submitted to the President of the Senate. In order to hurry him up a little, on the 8th of June last 400,000 postal cards were addressed to him by as many railroad men in all parts of France, asking his early attention to the matter.

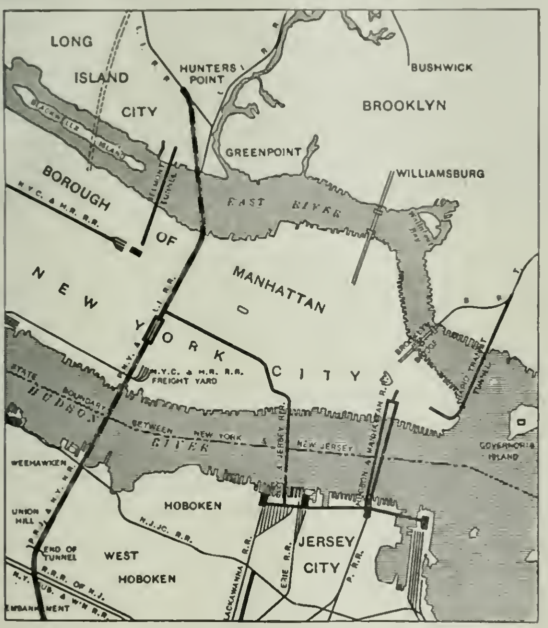
A committee of the Italian Parliament reported a plan for the reorganization of the state railroad administration which has one novel feature. There is to be a "traffic council" to advise as to the public needs in the way of transportation, apparently something like the advisory railroad councils in Germany, and one of its members is to be a journalist. The committee urged that the most important traffic questions are and must be discussed in the press and decided with its co-operation. The Minister of Public Works declared that he would not be willing to select the journalist councillor, and it was thought the appointment would be left to the Italian Associated Press.

Tunneling Operations in New York City.

The accompanying map showing the location of all the tunneling operations in New York City and vicinity is reproduced from a paper by H. T. Hildage, read before the American Institute of Mining Engineers. The following is a brief summary of recent progress on all of these tunnels:

Pennsylvania Tunnel & Terminal (Pennsylvania Railroad).—Double-track approach embankment west of Bergen Hill under construction. Twin tunnels in rock under Bergen Hill to Weehawken shaft about two-thirds excavated; work in progress. Twin tubes under North river to Eleventh avenue, Manhattan shaft, completed and work of sinking foundation piles and putting in concrete lining in progress. Excavation of approach tunnels from Manhattan shaft to station site at Ninth avenue about one-half completed. Excavation for station between Seventh and Ninth avenues nearly completed, erection of steel work in progress. Double-track cross-town tunnels under 32d and 33d streets excavated from East river shafts to a point near Sixth avenue, and work of lining in progress. Four East river tubes under way and about one-half completed. Long Island City tunnels in soft ground completed to portal near Borden avenue.

Hudson & Manhattan.—Both tubes completed under North river between Hoboken and Greenwich street; to be ready for experimental operation by Sept. 1. Open cut extension from Greenwich street under Sixth avenue to 33d street under construction. Tunnel connection between Hoboken and Jersey City under construction. Twin tubes between Cortlandt street and Jersey City under construction. Foundations completed for terminal station at Cortlandt and Church streets and erection of steel work in progress.



Tunneling Operations in New York.

(Tunnels under construction are shown in heavy black lines.)

Interborough Rapid Transit.—Brooklyn extension from Battery loop under East river to Joralemon street, Brooklyn, is partially completed. Both tubes are joined, but work is in progress to reinforce them with pile foundations before concrete lining is put in. Will not be ready for operation for some months to come.

Belmont Tunnel.—From 42d street and Park avenue under 42d street and East river to Long Island City. Work still going on in one tube. Other tube has met and tunnel is nearly completed under 42d street.

New York Central.—Reconstruction of Park avenue tunnel about completed. Work in progress on excavation of west half of new Grand Central Station yard.

Delaware, Lackawanna & Western.—Driving a second double-track tunnel parallel to present tunnel under Bergen Hill, Hoboken. About one-half completed.

For fighting fire in its anthracite coal mines, the Delaware, Lackawanna & Western is using a new form of chemical fire engine. It is built on a truck and can be attached to an electric mine locomotive and rushed to the point of danger at high speed. When a chemical engine plays upon [illegible] the heavy gases [illegible] cling to the floor and smother the [illegible]. Men are not annoyed by fumes and can [illegible] effective work. The complexities of mine working [illegible] in every direction as the thinner and less accessible [illegible] are being [illegible] so that increased attention to fire fighting is necessary.

Rest Requirements on French Railroads.

The Minister of Public Works of France has sent a circular to the railroad managers setting forth the requirements as to the time allotted to employees for rest. This must be at least 52 days a year, and it is desirable that these days should fall on Sunday. Employees whose work cannot be interrupted on Sunday must be granted at least three full days of rest a month. To these three days there must be added at least enough supplementary rest either in whole days or, if Sunday is cut out, in half days, to make up the balance. The days off may be separate or together according to the exigencies of the service and the convenience of the employee. But even where his duties are most exacting, there must be 52 days of rest a year. Where half days are taken, every effort should be made to have them fall on Sunday; and the same rule holds regarding full days; for this reason the managers are urged to reduce Sunday work of all kinds as much as possible.

The New York Central's Electric Lines.

Early in 1905 there was incorporated in New York state the Mohawk Valley Company, a holding company which controls the electric and street railway investments of the New York Central & Hudson River. Its $20,000,000 stock is held, 60 per cent. by that company and 40 per cent. by a syndicate, made up largely of Cleveland and New York men, and headed by Horace E. Andrews, President of the Cleveland Electric Railway. The directors of the Mohawk Valley Company are. Horace E. Andrews, William K. Vanderbilt, Jr., Walter N. Kernan and the following vice-presidents of the New York Central: W. C. Brown, E. V. W. Rossiter, John Carstensen and W. J. Wilgus. The executive organization is: Horace E. Andrews, President, John Carstensen, Vice-President of the New York Central in charge of accounting, and W. K. Vanderbilt, Jr., Vice-Presidents; Dwight W. Pardee, Secretary, and Edward L. Rossiter, Treasurer of the New York Central, Secretary and Treasurer, respectively, and A. L. Linn, Jr., General Auditor.

It is the plan of the Mohawk Valley Company to eventually have a continuous electric line parallel to the New York Central main line all the way from Albany to Buffalo, giving frequent local passenger and express service. Although this will be a continuous line between those points, there is no intention to operate through electric service over it. The fact that it will run through the streets of the principal cities is one reason against this, but the deciding reason is that the very purpose of having a parallel electric line is to leave the tracks of the steam road (which itself will in all probability within a few years be electrified) free for freight and fast through passenger service. The plan is to have the electric line take over, so far as possible, the short distance local passenger travel of the steam road. The superiority of an electric line in offering frequent service and carrying passengers directly to the central streets of the cities makes this possible. To put it concretely, one car every half hour furnishes vastly more satisfactory service for local travel than six cars every three hours. An electric line can offer such frequent service more cheaply than a steam line can run infrequent local trains.

One of the accompanying maps shows the present holdings of the Mohawk Valley Company and the large gaps still left in the ultimate continuous line across New York state. The company controls the whole trolley systems of Schenectady, Little Falls, Utica, Rome and, with one or two small exceptions, Syracuse and Rochester. The Schenectady Railway which, besides giving local service in that city, operates fast through service to Albany and Troy, is controlled jointly with the Delaware & Hudson, each company owning one-half the stock. The Delaware & Hudson owns also the United Traction Company operating the city systems of Albany and Troy and controlling the entrance of the Schenectady Railway into those cities, and the Hudson Valley Railway, running north from Albany and Troy with nearly 100 miles of line. The Mohawk Valley Company owns all or a controlling proportion of the stock of its other trolley companies.

It will be observed by this map that the longest through electric line now owned parallel to the New York Central main line is the Utica & Mohawk Valley Railway's line from Little Falls west to Utica. The West Shore line between Utica and Syracuse, 44 miles, has recently been electrified, thus extending the electric system to Syracuse and making a line from Little Falls to Syracuse, 75 miles, of New York Central auxiliary lines under electric operation. A map of this electrified section of the West Shore is also shown. This

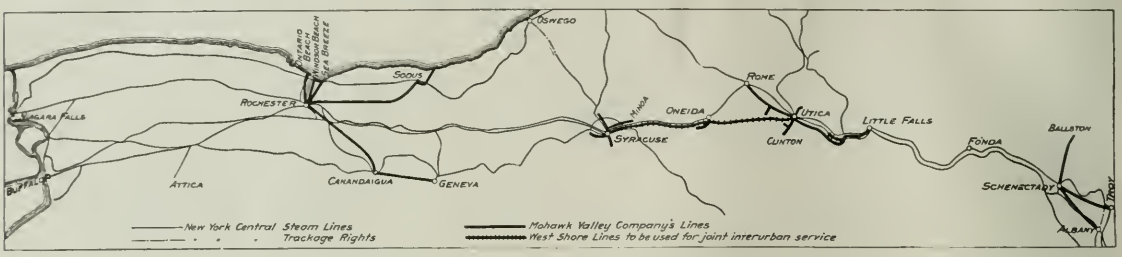
electrification was paid for by the Oneida Railway, which before its purchase was projected to be extended west to Syracuse. The work was done by the Oneida Construction Company. On June 15 this stretch of electrified line was officially opened and regular service over it is now in operation. Besides this, one track on a small section of the West Shore between Mohawk and Frankfort, five miles, was earlier electrified, giving the Utica & Mohawk Valley, which is double tracked all the rest of the way between Little Falls and Utica, a second double track between these points.

The work of electrification of the West Shore for the 44 miles between Utica and Syracuse for joint interurban service was carried out under C. Loomis Allen, Vice-President and General Manager of the Oneida Railway; W. J. Harvie, Electrical Engineer, and M. J. French, Jr., Engineer of Maintenance of Way. An agreement was made with the New York Central under which the Oneida Railway, besides electrifying the line, is to conduct the passenger business over the West Shore between Utica and Syracuse. The New York Central on its part agreed to abandon the local passenger trains on this stretch of track, but will continue to operate freight trains and through passenger trains by steam locomotives. Before electrification there were only two local passenger trains each way a day over this line, the only other passenger trains being two night through trains with sleepers. Yet this is a well populated territory. Besides other smaller places, the three towns of Oneida, Vernon and Canastota traversed have together 17,000 people. Here, then, was a local territory in need of better passenger transportation facilities but whose possibilities of larger traffic were not sufficient to justify increased operation of steam passenger trains. Electric traction offered the advantages of frequent service at small cost per unit. Also an electric line between Utica and Syracuse was needed as part of the Mohawk Valley Company's plan.

There are to be two kinds of electric passenger service over these West Shore tracks. Fast limited electric cars or trains will run hourly between the two cities, making only two other stops. This limited run will be made in 88 minutes for the 44 miles, but 28 minutes of this time will be used within city limits of the terminal cities. There are also to be hourly local cars or trains which are to run at the rate of 21 miles an hour and make the complete run in 118 minutes. These cars will make frequent stops, at every highway if necessary. Besides these two kinds of electric service there will be the regular steam service as at present, except for the steam local passenger trains.

To provide for passing the express trains around the local trains a third track has been laid between Clark's Mills and Vernon, 8½ miles, with cross-over connections to both outside tracks. It will be used by both east-bound and west-bound trains and will be protected by block and interlocking operators at both ends. A fourth track has also been laid between Oneida and Canastota, 5½ miles, where there are water stations and freight yards which might delay the movements of electric trains.

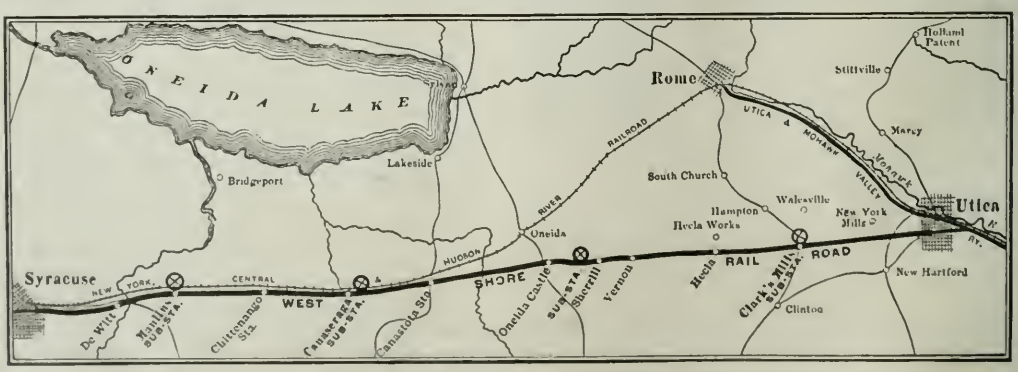
Power for operating the line is bought from the Hudson River Electric Power Company, which has hydraulic power plants at Spiers Falls and Mechanicsville. The transmission line for 60,000 volts is now being extended to Utica, but pending its completion the power company has installed in Utica a temporary steam plant equipped with Curtis turbines and delivering three-phase 60,000-volt current at 40 cycles to the railway. In the 44 miles between Syracuse and Utica there are four sub-stations approximately 10¾ miles apart. Each sub-station contains a 330-k.w., 60,000:370-volt oil-cooled transformer and one 300-k.w., 370-volt a.c. and 600-volt d.c. rotary converter, together with the necessary switches and other accessory apparatus.



The New York Central's Auxiliary Electric Lines.

The line is built for third-rail operation. The same type of third rail as in the electric zone of the New York Central in the New York terminal territory is used. The third rail is placed 32 in. out from the gage line and the contact surface is 2³⁄₁ in. above the top of the track rails. New York Central electric equipment can be run over the line without changing the position of the contact shoe. The third rail is normally located between the tracks on tangents and on the high side of the track on curves.

In order to operate over the street railway lines in both Utica and Syracuse a different type of car was adopted than would have been for the West Shore tracks exclusively. One of the cars is shown herewith. The main dimensions are: Length over end panels, 40 ft.; length over vestibules, 48 ft.; width over sills, 8 ft. 4 in. The underframing consists of two intermediate and two center sills of 6 in. I-beams extending under the vestibules, with malleable iron caps and supports for the main truss rods; which are 1¼ in. in diameter. The interior is finished in laid mahogany; the ceilings are full Empire decorated. The floor is covered with interlocking elastic tile, while a rubber mat is furnished for each vestibule. Storm sashes are furnished for the side windows, which replace window guards in winter. The cars are equipped with 24 reversible and 2 stationary plush seats with high backs and head rolls. Each car is also fitted with a toilet.



Electrified Line of the West Shore between Utica and Syracuse for Joint Interurban Service.

To provide for passing the express trains around the local trains a third track has been laid between Clark's Mills and Vernon, 8½ miles, with cross-over connections to both outside tracks. It will be used by both east-bound and west-bound trains and will be protected by block and interlocking operators at both

In the extension of the Mohawk Valley Company's electric

service the Falls Road of the New York Central—the second steam line shown on the larger map south of Lake Ontario between Rochester and Niagara Falls—is later to be electrified. Other gaps in the through line will be filled in, either by electrifying one of the existing steam lines or building new parallel electric roads, so that within four or five years the complete plan for an electric line, relieving the through steam line of local passenger traffic, will be in operation all the way between Albany and Buffalo.

The Mohawk Valley Company controls directly 331 miles of electric line, of which 166.6 miles are double track. The electrified West Shore lines for joint interurban service make up 49 miles more, a total of 380 miles of line under electric operation. The following table gives the names of the different controlled companies and their mileages in detail:

Table of Mileages.

	Miles of line			Miles of track

*Miles of line. †Miles of track.

The 10 lines are operated as follows: The Schenectady Railway, of which E. F. Peck is General Manager, and the Rochester & Eastern Rapid Railway, running from Rochester to Geneva, of which J. H. Pardee is General Manager, are each operated separately. The other eight roads are in two groups, the eastern one made up of the Utica & Mohawk Valley, the Syracuse Rapid Transit, the Rome City Street Railway and the Oneida Railway, under C. Loomis Allen, Vice-President and General Manager; and the western group made up of the Rochester Railway, the Rochester & Suburban, the Rochester & Sodus Bay and the Rochester Electric Railway, under R. E. Danforth, Vice-President and General Manager. The different companies maintain their separate corporate organizations. They are not merged in the Mohawk Valley Company, but simply controlled by it.

Stretch of West Shore Electrified Three-Track Line.

In acquiring a through line such as that described, it was, of course, most important of all to secure entrance into the large cities. In consequence the entire local street railway systems of Utica, Syracuse and Rochester had to be taken over. This gives an added value, however, to the electric service to outlying points, as passengers arriving by the through lines outside the city can transfer to local cars which will take them direct to their particular destination within the city. Arrangements have already been made for through ticketing over both steam and electric lines. Passengers can now in New York city buy a through ticket over the steam road to the next large city nearest their point of destination and over one of the Mohawk Valley's electric roads to the outlying town where they wish to go. Joint tickets are also now sold in the opposite direction. On such tickets, in either direction, baggage can be checked to or from points on the Mohawk Valley lines, a matter of great convenience. This auxiliary electric service makes outlying towns on the electric lines much more accessible both in through and local service. Thus the parallel electric lines fulfil a valuable service as feeders and helpers of the steam lines, to the advantage both of the railroad and of the local territory served. The extension and successful carrying out of this idea is the moving force behind the Mohawk Valley Company's plan.

Type of Car for West Shore Electric Interurban Service.

New Blacksmith Shop of the Union Pacific at Omaha.

The new blacksmith shop of the Union Pacific at Omaha, Neb., was designed with particular reference to economical operation. The route of the iron from box cars to storehouse, thence to the shears and through the blacksmith shop, was determined in advance, and the machines located to give the most economical movement. In working up the preliminary designs of this shop, as is customary in the mechanical department of the Union Pacific, W. R. McKeen, Jr., Superintendent of Motive Power, acting as chairman, called together a committee to map out and discuss the methods of doing work in this shop. The committee consisted of the mechanical engineer and some of his draftsmen, the blacksmith shop foreman, assistant superintendent of motive power and superintendent of shops. The general foreman of the car department, general foreman of the machine shop, boiler shop foreman and storekeeper were all called into consultation as the work of their respective departments was discussed. Thus the requirements of all departments were carefully considered. The exact method of handling the iron through the blacksmith shop was decided on at that time.

The proportion of output to size of the shop is believed to equal if not excel any similar shop in existence; also it is thought that there are less hand forges in this shop than in any other in the country. Special use is made of the Bradley hammer, of which

Material cars serving machines, in foreground.

there is a battery of five on car work. Work on track tools, etc., is done with economy. The hand forges are grouped, with steam hammers working in conjunction with each group, thus facilitating the work of hand forging and decreasing helping labor. By the use of mechanical forging machines, bulldozers and other modern iron-working tools, material can be turned out much more cheaply than before.

One source of great economy has been the systematizing of work so that parts for cars and locomotives are carried through the blacksmith shop on store orders, the parts being made in large numbers and carried in stock, instead of manufactured by hand, one at a time, as formerly. All of the furnaces use crude oil for fuel. The large furnaces are equipped with modern water-tube boilers, which not only furnish steam for running the steam hammers and heating the buildings, but supply considerable steam for the power plant.

It is the policy to provide the most healthful possible conditions for employees. To that end the Sturtevant system for carrying off smoke from the forges and furnaces has been installed in the blacksmith shop; also a lantern in the top of the building for ventilation in the summer, and the suction or exhaust system of ventilation in the roof for relieving the inside of the shop of any smoke which may escape from the other system. With this triple system of ventilation the atmosphere is always clear and agreeable.

The drop-forging department has been developed to a wonderful extent and a great many locomotive parts which for years have been made by hand are now made under the drop hammers much more cheaply. The method of working up the scrap and of forging old axles and heavy iron by the regular furnace or hammer gangs is a great economy.

In connection with the blacksmith shop is the nut, bolt and stud machinery in an annex to the shop, where all threaded articles are manufactured. This bolt shop, which is shown in one of the photographs, is equipped with bolt cutters, nut tappers, screw-cutting machines, stud machines, staybolt drills, etc., and delivers the finished product from the blacksmith shop direct to the storehouse.

Material is conveyed from the iron house to the different machines on 24-in. gage push cars. From a machine it passes to a second push car, and so on, being handled through the shop without touching the ground. The cars are moved in trains by a storage-battery truck.

The foreman of the Omaha blacksmith shop is R. A. Mould. He has an assistant and a clerk.

Progress on the Western End of the St. Paul's Pacific Extension.

The route of the western end of the Pacific coast extension of the Chicago, Milwaukee & St. Paul from Butte, Mont., to Missoula, parallels in a general way the existing main line of the Northern Pacific. From Missoula the route parallels the Coeur d'Alene branch of the Northern Pacific to a point near St. Regis, Mont., where it turns southward and crosses the Bitter Root mountains through a new and hitherto almost unknown pass. The work in this district is in charge of Winston Brothers Company of Minneapolis. This firm has the contract for a big tunnel west of St. Regis. Very little active construction has taken place. The work now being done consists mainly of preparation and organization. Active work on the big tunnel will begin shortly.

From the Bitter Root tunnel to Tekoa, Wash., the new line follows the valley of the St. Joseph river, crossing the south end of Lake Coeur d'Alene near Chatcolet and paralleling the operated line of the Oregon Railroad & Navigation to Tekoa. This stretch has a light, water grade, with heavy rock cuts and fills necessary along the bluffs and cliffs of the river. This division is being built by H. C. Henry, of Seattle, Wash., who is general contractor for all of the line west of the Bitter Roots. At present it is largely in the initial stages of organization. The engineers are busy cross-sectioning, while the contractors are clearing the right-of-way and getting ready for active construction. At the same time most of the heavy cuts have been opened and station men are at work on the light grading. No bridge work has been done. This is probably the least completed section of the new line.

The construction from Tekoa, Wash., to Ellensburg is in a more advanced state. The general route is from Tekoa directly southwest through Whitman and Adams counties, crossing the Northern Pacific at Lind, Wash. Thence the line goes southwest to the village of Othello in the southwestern corner of Adams county; then follows Crab creek to the Columbia river. From the Columbia river crossing to Ellensburg the general direction is northwest through the Poisoned Spring district. Several townsites in this district, in Adams and Douglass counties, have been platted and will shortly be on the market. The region is literally covered with contractors and the work is well under way; most of it has advanced beyond the line-changing stage. Considerable progress has been made on bridges.

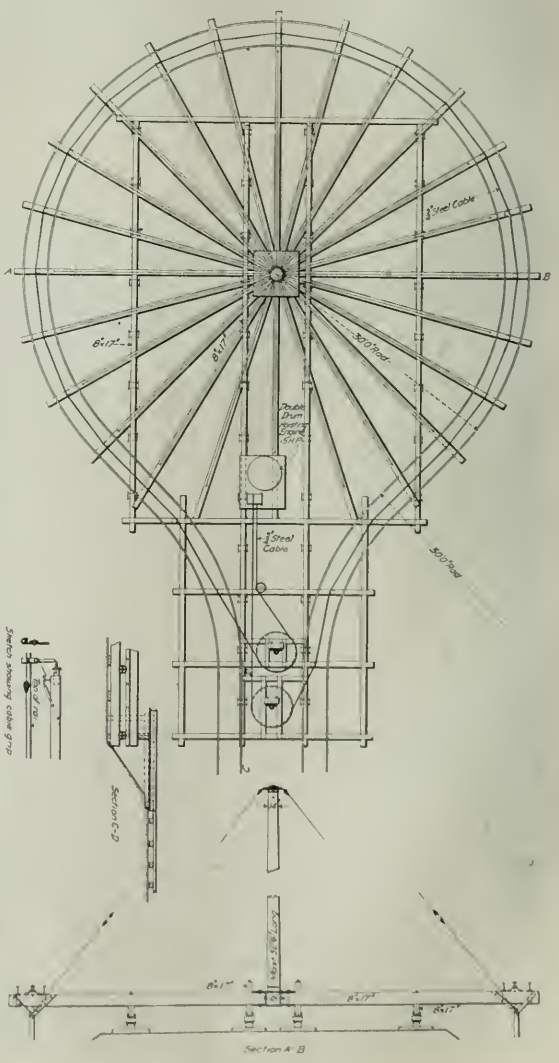
From Ellensburg, Wash., to the Cascade mountains the line parallels the Northern Pacific. A great deal of grade has been finished between Ellensburg and Easton, but there yet remains several months' work on the heaviest cuts and fills. The line crosses the Cascades through a long tunnel under Snoqualmie Pass at the north end of Lake Kilchelos and goes down the west slope through the North Bend region. Near the tunnel the work is in its first stages; in some sections the right-of-way clearing has just been begun. West of North Bend construction is much further advanced; miles of grade and considerable bridge work have been finished. This district will be the first to be ready for track laying. Between Seattle and Tacoma the grade is half completed but no bridge work has been done. No work has been done on either the Seattle or Tacoma terminals.

In general, the line has been finally located, and throughout the whole stretch from Butte to Seattle actual construction has begun. Some sections will shortly be ready for the track, but it will be at least 18 months before many parts of the heavy solid-rock work is finished.

An Unloader for High Fills.

The E. B. & A. L. Stone Company, of Oakland, Cal., is one of the contractors who are building the Western Pacific Railway. It has been necessary for them to make a number of high fills, and to expedite these a machine has been designed which is shown at work in the accompanying photographs and in detail in the accompanying drawing.

The machine consists of a circular track supported on 8 in. x



Unloader for High Fills.

17 in radials, with the additional support of rods suspended from a mast. A cable, which is held in place by rollers, leads around between the rails. A train of contractors' cars loaded with earth is hauled around this circular track by the cable which is operated by a donkey engine located on the machine, as shown. While the cars are being pulled around, the locomotive engine switches from the delivering to the receiving track. As the cars are unloaded while in motion, the empty train is in place by the time the engine has made the switch. The cars can be dumped inward or outward at any point on the machine.

When sufficient earth has been dumped, the unloader is moved forward 10 ft., a process which requires about an hour or an hour and a half. This is generally done at noon or in the early evening. The base of the unloader is carried about 4 ft. below grade, and the fill is brought up to grade at the back end as the machine is moved forward. Four stringers 16 ft. long are attached to the machine and are dragged forward when it is moved ahead. Rail sections 10 ft. long are used to fill in the space behind, resting on these stringers. The first trainload of dirt, after the machine has been moved, is used to fill in the open space behind over which the stringers stretch. While filling, the settlement is taken care of by raising the machine with jacks and blocking up. This requires one carpenter and two laborers continually. Five men on top of the machine, including the man who runs the donkey engine, attend to the dumping of the cars and chalking up. The timbers and iron of the machine are of such lengths that they can be loaded on an ordinary flat car. The machine is all bolted together and can be taken apart by a small gang of men in two days.

High Fill on Line of Western Pacific; Unloader at Work.

Unloader Used on High Fills; by E. B. & A. L. Stone Co.; Western Pacific.

This unloader has for the past four months been in use on a 112-ft. fill near Altamont, Cal., working day and night. Previous to that it was successfully used on a 125-ft. fill, now completed. It has not yet been possible to determine the number of cars that can be handled, as a 70-ton Bucyrus steam shovel in good digging has not been able to keep the unloaded busy more than half the time. The machine was designed for the special purpose of making high fills by F. F. Lloyd, who is connected with the E. B. & A. L. Stone Company.

The Mt. Blanc Tunnel.

According to the *Revue Industrielle* the construction of a tunnel under Mt. Blanc is needed in order to place the French railroads on an equality with those of Germany in the transportation of passengers and freight between the north and Italy. The recent completion of the Simplon tunnel and the approaching opening of the Loetschberg has placed France in a very unfavorable position commercially in comparison with Belgium and Germany. Communication between France and Italy is limited to two lines, those of the Littoral and Mt. Cenis, and it is for the purpose of protecting the railroad interests of the country that the Mt. Blanc tunnel is required. By means of this route Paris and Dijon will be in direct communication with Milan and Genoa, and the whole commercial, industrial and agricultural territory of the basin of the Loire and the Saone will be able to ship direct to the two great commercial centers of Italy.

It appears that this Mt. Blanc proposition is not a new one, but even preceded the creation of the railroad system, for as early as 1836 M. Vaguer proposed a route from Courmayeur to Chamounix by way of a gallery beneath Mt. Blanc. Eight years later, in 1844, the idea was revived by an advocate, M. Martinet, and an engineer, M. Alby. In 1846 it was discussed by the Casuel canton and in 1862 by the canton of Gorret. Again in 1870, 1873 and 1879 the project was discussed and abandoned because of the hostility of rival interests. The route now proposed starts from Chamounix and shortly afterwards enters a tunnel 13,500 meters (44,280 ft.) long beneath the crest of the mountain, which runs to Courmayeur. This is really the only logical route. In fact, the dominant question is that of driving the tunnel, for after leaving the tunnel there is a choice of approaches.

The Mt. Blanc Railway will be built half on French and half on Italian territory. It is expected that Italy, which contributed so largely to the construction of the St. Gotthard and the Simplon, will not refuse its assistance to the Mt. Blanc, especially as this last will be of such great importance to it.

Passenger Locomotive for the Duchy of Oldenburg Railroads.

The Hannoversche Maschinenbau-Actien-Gesellschaft of Hanover, Germany, has recently celebrated, with festivities appropriate to the occasion, the delivery of the 5,000th locomotive built by these works. On that occasion there were present representatives of the governments of the towns of Hanover and Linden and other public authorities of numerous administrations of German and foreign railroads, as well as representatives of neighboring industrial firms.

These works were brought prominently before the American public ten or a dozen years ago, in that they were largely instrumental in the construction and development of the compound locomotive as designed by the late August von Borries, who was at that time the head of the locomotive department of the State Railroads of Hanover. They were founded in 1835 by Georg Egestorff, who was succeeded by the present firm. It was not, however, until 1846 that the first locomotive was delivered, and it was ten years later before 100 had been built. The 500th was built in 1870; the 1,000th in 1873; the 2,000th in 1888; the 3,000th in 1897, and the 4,000th in 1903. Of the 5,000 locomotives built up to the present time, about 1,100 were built for roads outside of Germany, and of these by far the larger number were sent to Russia. Deliveries have also been made to Roumania, Japan, Java, Denmark, Turkey, India, Austria, Portugal, Italy, Bulgaria, Holland, China, Siam, Finland, Argentine, Sweden, Greece and Chili; so that the firm is widely known not only because of its connection with important works but from the wide territory over which its engines are running.

The locomotive that is the subject of this sketch has been built for the railroads of the Grand Duchy of Oldenburg. It is of the 4-4-0 type with a bogie in front, and is of the standard type used on the State Railroads of Prussia. It is a two-cylinder compound with cylinders having a ratio of 1 to 2.25. In connection with these, the Lindner starting device is used, by which live steam is allowed to enter the low-pressure cylinder when the reverse lever is at either one of the extreme positions. Staby's smoke consuming device is also used and the second dome on the boiler is the one from which steam is drawn for the working of the apparatus. Again, in accordance with the prevailing practice upon the Prussian State Railroads, a superheater is used. It is of the Ranafier smokebox type and is formed by the sub-division of the receiver into 46 seamless iron tubes of 1⅝ in. diameter each,

and so arranged as to act as a spark arrester at the same time. The heating surface of these tubes is 154 sq. ft. measured upon the outside, and their capacity is 1.75 times the volume of the high-pressure cylinder. Six express locomotives have, thus far, been fitted with this type of superheater on the railroads of the Grand Duchy of Oldenburg, and it will be placed on 11 more now in course of construction.

As compared with the engines to which American eyes are accustomed this one appears low. Its design is distinctively German and the peculiarities of the arrangement of certain of the parts in detail are such that they would attract immediate attention. For example, the exhaust from the Westinghouse brake pump is carried up outside the boiler jacketing and the stack. This arrangement has been used to but a limited extent in this country, probably because of the unsightliness of the pipe, though it does possess the advantage of not fanning the fire when the engine is standing. In addition to this it is quite probable, though there are no figures at hand to support the statement that the interposition of this extra exhaust into the stack must interfere with the efficiency of the main exhaust by introducing eddies in the steam jet that interfere with its proper action.

The Walschaert valve gear is arranged for an outside admission, and with the radius rod lifted direct by the lifting shaft arm instead of through a hanger as in the usual practice in the United States.

The practice of covering the bolts, and the saving of heat by radiation losses also puts the base sheets out of the running. These are a few of the items that are deserving of attention and consideration in this design. Some might well be copied while others do not appear to be as efficient or simple as similar details that are to be found in American engines.

The following are some of the principal dimensions of this engine, and in these attention is called to the large proportion of the total weight that is upon the trucks:

Cylinder, diameter, high-pressure	18 in.
Cylinder, diameter, low pressure	27 "
Piston stroke	23½ "
Wheels, diameter, driving	69 "
Wheels, diameter, truck	40 "
Wheel base, truck	7 ft. 3 "
" rigid	8 " 6½ "
" total	24 " 3 "
Heating surface, tubes (fire side)	1,188.0 sq. ft.
" " firebox	96.7 "
" " total	1,284.7 "
" " superheater	154.0 "
Grate area	24.6 "
Tubes, number	231
" diameter (outside)	1¾ in.
" length	12 ft. 9½ in.
Diameter boiler shell	55 "
Steam pressure	176 lbs.

Passenger Locomotive for the Railroads of the Grand Duchy of Oldenburg.

No brakes are put on the truck wheels, but the drivers are fitted with two shoes for each wheel. This is a practice that was strongly urged in this country at one time, but which has not received an extensive application except on a single road. The advantages claimed for the arrangement are that it relieves the boxes and rods of all strain due to brake pressures; that it secures a more uniform wear on the wheels and can be made much lighter than where the pull is all in one direction. In the case of these German engines a double connection is used, a rod running on each side of the wheels, with vertical equalizers below each brake lever so that with the exception of the use of horizontal equalizers and a single pull rod on the engines in America, the principle underlying the foundation rigging of this brake is the same as that of the Beals brake that has been used for so many years on the New York, Ontario & Western Railroad. The double shoe is also used on the tender wheels of these engines.

It will be noticed, in the reproduction of the photograph, that the staybolts of the firebox apparently come through the lagging and jacketing. Of course this is not the case but those markings are thimbles that are placed through the covering at each staybolt, making it possible not only to inspect each staybolt but to remove and replace any one of them without disturbing the jacketing in any way. This is not an uncommon requirement in Europe but is quite unknown to American practice. The advantages are apparent upon first sight and the only disadvantage lies in the additional first cost, but this would be met in part at least by the first occasion that should arise necessitating the renewal of a staybolt. As for the safety thus insured there can be no comparison with the

GENERAL NEWS SECTION

NOTES.

Three thousand Japanese laborers are being brought to British Columbia for the Grand Trunk Pacific.

In Ohio it is reported that both the New York Central and the Pennsylvania are making reductions in the forces of their men in their city freight soliciting offices.

The Electric Express Co. has been organized at Boston to do the express business on the electric city and interurban railroads controlled by the New York, New Haven & Hartford.

Vice-President Fay, of the Southern Pacific, expects to have the whole of that company's line from New Orleans, La., to Houston, Tex., equipped with automatic block signals within three months.

The Department of Agriculture on July 15 sent to the Department of Justice 41 cases on which to bring suit against railroads for keeping live stock in cars beyond the legal length of time.

The new State Railroad Commission of Montana has held a meeting and declared that the freight and passenger rates now in force shall be deemed the maximum lawful rates, except as regards coal on the Great Northern and lumber on the Northern Pacific. The rates on these commodities will be considered by the commission.

The Supreme Court of Georgia has sustained the right of the State Railroad Commission to prescribe through rates over the lines of the Central of Georgia and the Wadley Southern the same as though both roads belonged to the same company, the commission having found that the Wadley Southern is controlled by the Central of Georgia.

The Governor of Wisconsin has signed a bill making an eight-hour day for telegraphers, and one to prevent watering stocks. The new law requires public service corporations to get permission from the State Railroad Commission before issuing any stock or bonds and prohibits selling stock for less than par or bonds for less than 75 per cent. of par.

At El Paso, Tex., recently 30 employees in the freight yard of the Galveston, Harrisburg & San Antonio were discharged for having struck, and the dismissals are sanctioned by the union to which the men belonged because they took action without first reporting their grievance to the union headquarters. The cause of the strike was the dismissal of a yardmaster.

In the United States Court at Chicago last week the Atchison, Topeka & Santa Fe was indicted on a charge of granting rebates aggregating $12,000 to the United States Sugar & Land Co., of Garden City, Kan. The indictment contains 65 counts, all having to do with shipments of building material carried by the road when the sugar company was building its refinery.

Surprise tests of enginemen appear to be growing in favor, and the fashion of giving the results of the tests to the public also seems to be spreading. The latest aspirant for public notice is the Lehigh Valley, on which road a number of tests were made on April 12 and 27, May 1, 9 and 23, and June 7, 10 and 14, all the tests showing complete obedience to the rules.

By vacation of a stay order last week in a preliminary injunction issued a year ago 54 ticket scalpers in Chicago are compelled to quit business or fight their way in court against 17 complaining railroads, assuming the burden of proof as to the legality of their business. This issue is involved in a case before the United States Supreme Court, but a decision is not expected for a year.

The State Railroad Commission of Wisconsin has ordered that the grain elevators at Superior owned by the railroads be opened for the use of the general public at reasonable rates. The grain dealers have long wanted this privilege because of an expected advantage in having grain inspected under the law of Wisconsin instead of under the law of Minnesota as is necessary at Duluth, across the river.

A. F. Dillinger, reporting on the condition of the Canadian Northern after the tie-up of that road last April, tells the Canadian Railway Commission that the causes of the breakdown were lack of motive power and cars and of roundhouses and repair shops; the severity of the winter; want of proper apparatus to keep tracks clear of snow, and complete absence of systematic organization. The report recommends that 15 snow plows and 10 flangers be purchased, that five more roundhouses and five more repair shops be built in the West, and that the company adopt a systematic organization.

The Interstate Commerce Commission announces that a final hearing on the proposed uniform bill of lading will be held October 15. A joint committee of representatives of the carriers and shippers has reported to the Commission that practically all of the carriers in the official classification territory and the original petitioners have agreed to the proposed form of bill of lading submitted to the Commission, and have requested the Commission to approve and prescribe that form.

The Canadian Railroad Commission has ordered that the trunk lines of that country cease discriminating against Windsor and other points in western Ontario in favor of Detroit and other points west of the St. Clair river. The rates from Detroit and Port Huron to eastern cities must be the maximum rates from Windsor and other points in that region. An order with a similar purpose is issued in regard to rates from points in Ontario near Niagara which it is declared have been too high as compared with rates from Buffalo.

The Pennsylvania Railroad has issued revised rules for handling explosive and inflammable freight. The large yellow label which must be put on boxes, barrels, etc., does not read "*Dangerous*," etc., but has been changed to, "Notice to Pennsylvania Railroad employees. CAUTION. This package must be carefully handled," etc. The words at the end of the old notice, "Fire or other danger or loss may result if these directions are not followed," have been omitted at the request of a large number of shippers, who were troubled by some consignees being afraid to accept goods which they deemed so dangerous.

Judge Thomas G. Jones, in the United States Circuit Court at Montgomery, Ala., July 13, declared unconstitutional the law recently passed in Alabama intended to prevent railroads from going to the United States courts when sued by the state for non-compliance with its law. According to the law in question, the mere act of beginning a suit in the Federal Court would work the abrogation of the license of the road to do business in Alabama. Judge Jones holds that such legislation violates the contract made between the state and the corporation, and therefore is invalid under both the state and the United States constitutions.

The terms of the agreement between the New York Central & Hudson River and the New York, New Haven & Hartford, as to the New Haven's purchase from the New York Central of electric current to be used between Wakefield and Grand Central Station, were settled some time ago. A memorandum to that effect was initialed by the presidents of the respective companies some time before the daily newspapers began a series of stories of the progress of the negotiations and the difficulties and disagreements, with general suggestions that these were responsible for the delay of the New Haven in using electric power to reach Grand Central Station. The price to be paid has not been made public, but the basis for the terms was the cost of production, together with the proper allowance for interest and depreciation on the New York Central plants.

Two Cents a Mile in Wisconsin.

The people of Wisconsin appear to have taken a second thought on the question of passenger fares in that state and to have rescinded what was supposed to be their approval of the decision of the State Railroad Commission when it held that 2½ cents a mile was a proper maximum on the principal railroads of the State. The legislature has now passed a law, which has been signed by the Governor, limiting all fares to 2 cents a mile on every railroad having yearly gross receipts of $3,500 a mile.

Rock Island Employees' Magazine.

Publication of a magazine for employees of the Chicago, Rock Island & Pacific has been begun. It will be issued the latter part of each month, and it is intended that every person on the Rock Island payroll shall receive it regularly, free of cost. The first number contains an announcement by President Winchell, of the Rock Island Lines, beginning with a statement substantially as above, and explaining the scope and objects of the publication. The magazine is to be a 64-page publication beginning with No. 3, by which time it is expected to have it fully organized. The current number contains 16 pages and No. 2 will have 32 pages. It will also have a suitable cover design, to be chosen from drawings which the employee readers have been asked to submit. The first issue contains some good reading,

giving promise of a publication of real value and excellence when the full purpose, as set forth by the president, has been incorporated into its columns. The editor and manager is H. E. Reisman, 323 La Salle Street Station, Chicago.

Canadian Fire Precaution Rules.

The Dominion Railway Commission has issued new regulations to govern all Canadian roads in protection against fires. There must be a fire extinguisher at each end of each passenger coach, of a pattern approved by the board, under penalty of $25. A watchman must be provided for every 2½ miles of track, or, if furnished with a track bicycle, for each five miles of track. A barrel of water must be provided at every trestle and one at every 100 ft. Companies are required to keep the whole width of the right of way near any trestle free from brush. The use of lignite coal is prohibited.

A New Paulus Track Drill.

The Buda Foundry & Manufacturing Co., Chicago, has produced a new style of Paulus track drill, which is illustrated herewith. It is much like the older style but has a number of improvements. These are briefly as follows:

The frame, which can collapse backwards to allow trains to pass without disturbing the setting of the drill, is heavier and stronger than before, being of T section, which secures comparative lightness with greater stability, and makes it possible to do heavy work without racking the frame. The variable-feed arrangement shown in Fig. 2 is simple. The pawl which operates the feed-screw ratchet wheel is actuated by a rocker shaft. This rocker shaft is kept in motion by the eccentric which revolves with the spindle. The arm that rests on the eccentric has a small roller bearing which relieves friction and wear. Over the feed-screw ratchet wheel is a small semi-circular shield which is slotted at the end hid from view and held in position by the thumbscrew at the side of the base. When in the position shown, the pawl slides along the top of the shield and drops into only one notch, but if the shield is allowed to slip back, the pawl will drop into the notches sooner and thus give a feed of one, two or three notches as desired. The ball-bearing thrust is placed between the feed screw and the spindle and is dust proof.

Another feature is the simple arrangement to feed the bit up to the work and return it quickly. This is done by a small crank handle at the rear of the frame. The spindle does not revolve while being moved to or from the rail. By the adjustable-handle arrangement, while using large bits with heavy feed in hard rail, a greater leverage can be obtained by the operator. When smaller bits are used with lighter feeds it is more desirable to have the handles shortened up, thus giving greater speed. The gearing has been changed, as compared with the former design, so that the work of the operator is lightened.

While either twist or flat bits may be used, the drill is shown equipped with the Rich spindle and chuck, and Rich flat high-speed steel bit. The makers claim that the flat bits will drill 10 to 15 times as many holes as other kinds before requiring to be re-sharpened. Also there is double the usable steel. The chuck is designed to permit only enough of the bit to project to penetrate the work, thus increasing the torsional strength.

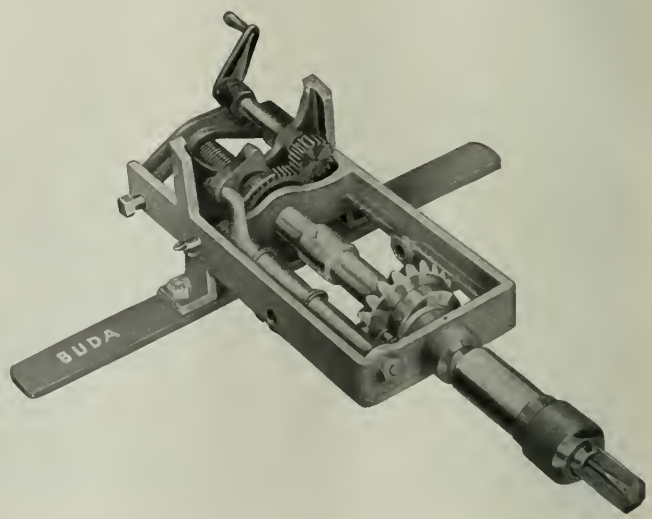

Fig. 2—Detail View of Base; New Paulus Drill.

Progress on the St. Paul Extension.

The point at which the St. Paul's Pacific extension crosses the Missouri river has been named Mobridge. Work is under way on the bridge but slow progress has been made as the temporary bridge has been washed away three times since the breaking up of the ice last spring, the last time by an unusually heavy June rise. The bridge is being built with caissons of which as yet only one has been sunk. The stone work on this pier is up to the water line. The new line west of the river is nearly finished to the point where it crosses into North Dakota at the northeast corner of Butte county, South Dakota. See article on page 72 covering progress on the western end.

Reduced Passenger Fares in the West.

The substance of the fragmentary unofficial statements given to the newspapers in Chicago concerning changes in passenger rates appears to be that between Chicago and the Rocky Mountain states rates on the principal roads, both interstate and intrastate, are to be put on the basis of 2 cents a mile as soon as the tariffs can be prepared; and that east of Chicago a similar change is contemplated but will not be made for two or three months yet. West of Chicago a 2,000-mile interchangeable book is to be sold at $40 and the mileage bureau will be abolished. East of Chicago the 1,000-mile book at $25, good only for the purchaser, with a rebate of $5, will be continued.

Doing Away With the Call Boy.

It is announced at Altoona, Pa., that the enginemen, firemen and trainmen of the Pennsylvania living in that city are to have telephones put into their houses at the expense of the railroad company so that they can, by that means, be called when they are wanted for duty, thus putting the time-honored peripatetic caller out of business.

The Stickney Tract.

Railroads centering in Chicago find it impracticable to utilize the joint car clearing yard, established 15 years ago by H. H. Porter and his friends on what is known as the Stickney tract, at a cost of $5,000,000, with accommodations for 5,000 cars. The yards have been idle for several years. About six months ago a movement was started to give them another thorough trial and the formulation of a plan was entrusted to a committee, but it has done

[illegible] The yards are [illegible] and the expense involved in their [illegible] prohibitive and the [illegible] dead. Miles of [illegible] rails are [illegible] are going into decay and a big investment [illegible] yielding no returns.—*Press Despatch.*

INTERSTATE COMMERCE COMMISSION RULINGS.

The Commission has postponed to October 1 all further action on the question of posting tariffs in stations. On that date a hearing will be held at Washington, and the order made June 10, designed to secure a better compliance with the law requiring the posting of two tariffs in every [illegible] temporarily suspended.

Wheat Rate from Oklahoma to Texas Reduced.

In an opinion by Commissioner Prouty decision has been announced in the case of W. O. Mitchell v. Atchison, Topeka & Santa Fe and others. The complainant, a resident of Oklahoma City, Okla., and a shipper of wheat, alleged that the rates charged by defendants for transportation of that commodity from Oklahoma City to Gainesville and Fort Worth, Tex., are excessive. The short-line distances are 140 miles to Gainesville and 202 miles to Fort Worth, and the rate in both cases was at the date of the hearing 28½ cents per 100 lbs. The Commission held that this rate on wheat is unreasonable, and required defendants to establish in lieu thereof a rate of 20 cents to Gainesville and of 22 cents to Fort Worth.

Estimated and Actual Weights of Shipments.

In an opinion by Commissioner Lane, the case of W. N. White & Co. v. Baltimore & Ohio Southwestern and Baltimore & Ohio, is decided. The complaint alleged that defendants' carload rate on apples from certain points in Illinois to New York City was unreasonable in that an arbitrary weight greater than the actual weight was imposed. Subsequently the railroads amended their tariffs so as to make them apply only to actual weight on such apples. On this showing the complaint was dismissed. In this decision the Commission said that it has recognized the right of carriers, in order to facilitate the movement of business, to fix an estimated weight on certain standard packages on which a rate is based. This estimated weight is taken into consideration in making the rate itself, and of such estimated weights shippers have the right to complain before the Commission and secure relief. But the facts in this case did not justify a finding that the estimated weight complained of was a violation of the Rate Law, therefore the claim for reparation is denied.

Rates on Staves Through East St. Louis Upheld.

In an opinion by Commissioner Lane the Commission has announced decision in the case of Omaha Cooperage Company v. Nashville, Chattanooga & St. Louis and others. Rates on oak staves and headings from Hollow Rock, Tenn., to East St. Louis when destined to South Omaha were claimed to be unreasonable compared with the rates from the same points of origin to East St. Louis when destined for Alexandria, Mo., or Keokuk, Iowa. The South Omaha rate is a combination of the 14-cent rate of the N., C. & St. L. and Illinois Central plus the "local" rate of 10 cents of the C., B. & Q., whereas the Keokuk or Alexandria rate is a joint rate of 19 cents, 14 cents to the two first carriers and 5 cents to the C., B. & Q. The complainant made no complaint against the C., B. & Q. rate. It appears that some years ago the division gave the C., B. & Q. its full "local" from East St. Louis to Keokuk or Alexandria, and the two eastern carriers 2 cents less than their joint rate to East St. Louis; but the division as now made gives these two roads the same earnings on cooperage products carried from Tennessee points to East St. Louis, whether destined to South Omaha, Alexandria or Keokuk. The complaint is dismissed.

Embargoes Against Individuals Unlawful.

The Interstate Commerce Commission has announced decision, in an opinion by Commissioner Lane, in the case of E. L. Rogers & Co. v. Philadelphia & Reading. It appeared that in July, 1906, defendant issued a special embargo on complainant's shipments of hay and straw destined to the Reading's 23d and Arch streets station in Philadelphia. The Commission holds that such embargo was an unlawful discrimination. Whatever may be said of an embargo against one commodity only in a time of congestion, nothing can be said for an embargo which refuses transportation facilities to some establishments while according such facilities to their competitors. If the exercise of such a power were to be at all tolerated, carriers would be able to issue sentence of commercial death against some of their patrons, while continuing to serve others. The Commission also holds that it has jurisdiction to forbid such [illegible] rates and to award reparation [illegible] and [illegible] resulting from [illegible] as [illegible] in the [illegible] fails to show that the shipments [illegible] were [illegible] claim for [illegible] injury [illegible] tained by the [illegible].

Railroad Ordered to Make Through Route and Rate With Steamship Company May Secure Itself.

The Commission, in an opinion by Commissioner Prouty, has announced decision in the case of the Enterprise Transportation Co. v. Pennsylvania Railroad and New England Navigation Company. The purpose of the proceeding was to compel the Pennsylvania to make a through route and joint rate with the complainant from Jamestown, Rhode Island, to Philadelphia, Pa., for transportation of fish.

The Commission holds that no satisfactory through route exists from Jamestown to Philadelphia within the meaning of the language of the Rate Law. Even if the present arrangement should be regarded as a satisfactory through route, complainant's right to maintain this proceeding would not be affected thereby, since, at the time the complaint was filed, through route from Jamestown by defendants' lines had been abandoned and for a time thereafter was not in operation.

The Commission ordered the Pennsylvania and the complainant to establish, for the transportation of fish, from Jamestown to Philadelphia, a through route, and apply thereto a joint rate of not more than 31 cents per 100 lbs., except that the Pennsylvania may, if it wishes to do so, apply to the Commission for an order requiring complainant to indemnify it against any loss it may suffer in the premises by reason of the financial irresponsibility of complainant.

Connections with Industrial Road Must Be Made; Divided Opinion of the Commission.

The Interstate Commerce Commisson, in an opinion by Commissioner Prouty, has announced decision in the case of McRae Terminal Railway v. Southern Railway and Seaboard Air Line. The complainant, owning a railroad about one mile long, from a point near the Southern in McRae, Ga., to a point near the Seaboard Air Line, alleged that these roads decline to make with it physical connections at its termini. The Commission holds that as such connections are practicable, can be made without hazard to the public, and the complainant's prospective business is sufficient to justify the connections, the defendants should give complainant the physical connections asked for, but they should be made at the expense of complainant. Definite order is withheld pending action of the defendant carriers and taking of further testimony. In deciding this case, the Commission refers to the decision of the Supreme Court of the United States in the case of Wisconsin, Minnesota & Pacific v. Jacobson, holding that an order of the State Commission of Minnesota directing a physical connection between two railroads of that state in pursuance of a statute of the state was a valid exercise of authority, and the Commission sees no reason why Congress may not, as it has done, exercise the same authority over a railroad handling interstate traffic which the state can exercise with respect to state traffic.

Dissenting opinions are filed by the Chairman and Commissioners Clark and Harlan.

Through Rate Reduced to Sum of Locals; State Legislation No Bar to Power of the Commission.

The Interstate Commerce Commission, in an opinion by Commissioner Harlan, decides the case of Hope Cotton Oil Co. v. Texas & Pacific and St. Louis, Iron Mountain & Southern. The complaint alleged that defendants' joint through rate of 67 cents per 100 lbs. on cotton seed, carloads, from points north of Shreveport, La., on the Texas & Pacific, via Texarkana to Hope, Ark., on the St. L., I. M. & S., is unreasonable, and that a reasonable rate would be a through rate equal to the sum of the present local rates in and out of Texarkana, which is 17.5 cents per 100 lbs. After complaint was filed, defendants put in effect between the points of origin in Louisiana and Hope a joint through rate of 30 cents per 100 lbs. on cotton seed in carloads with a minimum weight of 30,000 lbs. per car. The Commission holds, upon the record, that the present through rate of 30 cents is unreasonable and that it should not exceed 17.5 cents, the sum of the locals, with a minimum carload weight of 30,000 lbs. The carriers are ordered to put the reduced rate in force on or before August 26.

The Commission further says that while a rate fixed by a state statute or a state commission is naturally and properly entitled to respectful consideration, it has no greater sanctity, as applied to interstate traffic, than a rate established by a railroad; and the Commission will not hesitate, on proper evidence that a rate so

established would be unjust either to a carrier or to a shipper, to refuse to accept it as a basis for fixing an interstate rate.

Compression Privileges on Cotton.

The Interstate Commerce Commission, in an opinion by Commissioner Lane, has decided the case of Muskogee Commercial Club and Muskogee Traffic Bureau v. Missouri, Kansas & Texas. In this case it appeared that defendant's rule for compression of cotton in transit allows uncompressed cotton, on demand of shippers, to be taken out of Muskogee, Ind. T., and points north, including the Tulsa division, for compression at South McAlester, Ind. T., but does not allow uncompressed cotton to be taken out of or through South McAlester for compression at Muskogee. A large part of the cotton grown in the territory tributary to Muskogee is sold in the East, and is always compressed before being loaded for the long haul. Under the practice of compressing at South McAlester, uncompressed cotton originating at Muskogee and points north is hauled by defendant to South McAlester, unloaded at that compress, compressed, reloaded and then hauled back over the same line of railroad, passing again through Muskogee to defendant's eastern terminus, involving an extra service of 124 miles for which defendant receives no compensation. The Commission held, upon these facts, that defendant's rule for compression of cotton results in undue prejudice against Muskogee, and that defendant should grant all the privileges to one compression point herein considered that it grants to the other.

The Commission also held that the fact that a compress company at South McAlester has another compress at Fort Smith and threatens, unless the foregoing preference is given to its compress at South McAlester, to divert its cotton traffic to another railroad, does not justify discrimination in the rules or practices of defendant, as the competition described is not the character of competition that relieves from the operation of the statute.

The question of compression of cotton in transit, says the Commission, is not one with which a railroad may deal entirely as it sees fit and without respect to the effect which its practices have on the transportation of cotton. Either the carrier must publish a rate on uncompressed cotton and another rate on compressed cotton and divorce itself entirely from the matter of compression, or else such compression as is given by the railroad becomes subject to the jurisdiction of the Commission. Where a railroad company declares a policy which allows compression of cotton in transit at the nearest point it cannot vary that rule so as to give certain shippers the opportunity to avoid it and thereby receive an advantage which is not given to shippers generally.

Toll by the Coast Line Route to San Francisco Abolished.

The Interstate Commerce Commission on July 12, in an opinion by Commissioner Lane, decided the San Francisco Toll Case, which involved the right of the Southern Pacific to charge as a part of its rate to San Francisco a state toll of 5 cents a ton. The Southern Pacific enters San Francisco by two lines, one from the northeast, known as the Ogden route, which reaches San Francisco bay at Oakland; and traffic by this route is ferried across the bay, landed on the wharves in San Francisco, and hauled thence to its station and yards. The second route, known as the Coast Line, comes from the southeast, following generally the line of the ocean shore, and enters San Francisco by the all-rail peninsular route, landing its traffic at the railroad company's station. The Ogden line is much the older of the two, and was, until merged with the Southern Pacific, the Central Pacific. The Coast Line, by which freight is transported to and from San Francisco without crossing San Francisco bay or the wharves or water front of San Francisco, has been open only since June, 1901.

The title to the land which constitutes the water front of the city and county of San Francisco is in the state of California, and the general charge and management of this water front, and of the docks and wharves erected along the same, are in the board of state harbor commissioners, which is vested by law with the right to collect charges for dockage, wharfage and tolls, and to fix and regulate the rates of dockage, wharfage, cranage, tolls and rents for their use. In accordance with this power, the board has fixed a schedule of tolls on merchandise passing over these state premises, ranging proportionately downward from 5 cents a ton to 1 cent on 400 lbs. or less.

Commissioner Lane continues: Traffic moves from the east via the Coast Line to San Francisco, and is there delivered to the consignee, to whom is presented an expense bill showing, among other items, the articles carried, their weight, the rate of transportation, total freight charges, and, in addition, under the heading "Toll," the amount which the consignee would have been required to pay upon the shipment had the shipment moved by the transbay route instead of by the Coast Line. In other words, the rate to San Francisco is exactly the same by both routes; but when the traffic moves across the bay from Oakland to San Francisco the Southern Pacific collects a toll which it in turn pays to the state for the use of its wharves; whereas if the shipment moves by the Coast Line and enters San Francisco without crossing the bay, an expense bill of precisely the same character, and including a charge for toll, is presented to the consignee. Thus the question arises, Why should the railroad be allowed to charge a toll on Coast Line shipments which it is not required itself to pay, and which is not in any way a charge which the railroad has to meet, and for which it renders no service?

The theory on which transcontinental rates are made is that the rail carriers are compelled to meet the competition of the water carriers doing business out of San Francisco bay. Prior to the time of transcontinental rail carriage transportation from the Eastern states to San Francisco was wholly by water or by the Panama or Nicaragua routes; and when the first transcontinental railroad line reached tide water it found itself compelled to meet this competition. On this theory the transcontinental lines have justified, and properly so, lower rates to San Francisco than to intermediate points. The rate to Pacific Coast Terminals is designated by railroad men as a compelled rate—one which the carriers themselves would not make were they not required to do so by water competition.

When the Ogden line reached San Francisco bay at Oakland it found that to deliver goods in San Francisco it was compelled to pay an arbitrary toll fixed by the state for crossing the state lands abutting the bay upon which the wharves surrounding San Francisco were built. It therefore inserted in its tariffs a note to the effect that, in addition to the regular transportation charges, freight arriving at San Francisco would be required to meet an additional toll charge—a charge which the freight brought to San Francisco by ocean carriers was also compelled to meet. Later, when the Coast Line was built, the same tariff was made applicable to freight carried by that route, and thus it results that freight into San Francisco by the coast route bears an arbitrary charge of 5 cents a ton for crossing a wharf which it never crosses.

The Southern Pacific's contention, however, is that it is entitled to make this charge on a shipment which does not cross the bay, because it may properly impose on transcontinental business any rate, not unreasonable in itself, which it can get in competition with water carriers, and therefore may include in its rate an amount equivalent to the state toll, because the water competition which it has to meet must always be compelled to meet the toll charges of the state.

This argument is adroit, but does not appeal to us as conclusive. The tariff would make it appear that this toll charge was actually imposed on all freight entering San Francisco. This, we perceive, is not the fact. Moreover, all eastbound freight leaving San Francisco is not subject to this charge, at least as a toll charge, no matter by what route it goes. The toll, it is contended, when toll is paid, is in fact included in the rate itself—is absorbed by the carrier and not specifically and separately charged as in the case of westbound business.

If the rate to San Francisco by the Coast Line, including the additional toll charge, is in and of itself reasonable, there is no reason why the tariff applicable to the Coast Line cannot be made to state, as the law requires, the full rate via that route to San Francisco. But it is to be noted that Sacramento, Stockton and other cities farther inland than San Francisco are given the benefit of terminal rates without such additional toll charge, although the one reason that is assigned for supporting such rates is their proximity to San Francisco, through which city alone they have the advantage of water competition.

The history of this toll provision leads to the conclusion that it was never intended as a part of the transportation rate; and certainly if the Coast Line had been first built its tariff would not have contained any such provision. Why, then, should we now regard it as properly inserted in a Coast Line tariff? Moreover, the law does not contemplate that a rate shall be made by including charges which the carrier does not in fact meet; and a tariff or schedule of transportation rates which makes the rate charged dependent upon one or more factors which do not enter into the transportation as it is actually conducted, does not conform to the law. To illustrate: A rate over the New York Central into New York city from the West could not properly be stated as $1 per 100 lbs. with a notation elsewhere in the tariff stating that all goods destined to New York city would bear an additional charge equivalent to the cost of lighterage from Jersey City to New York, which all rival carriers entering New York are compelled to pay.

It will be ordered, therefore, that the Southern Pacific shall cease from making any charge for toll at San Francisco when such toll charge is not actually paid by the carrier.

TRADE CATALOGUES.

Hicks Locomotive & Car Works.—A book illustrating the plants, equipment and products of this company has just been issued. It is a 100-page volume, 9¼ x 12, printed on calendered paper, with board covers. The company has two plants at Chicago Heights,

III. The West works include the locomotive and passenger car departments, the East works are the freight car shops. General and detail views of each plant are shown, also typical views of new and rebuilt locomotives turned out by the locomotive department and of locomotives overhauled for different large railroads. All kinds of cars from private and dining to baggage and express and freight equipment of all classes, are illustrated, also some special equipment, such as ballast spreaders and gasoline-electric motor cars. All the illustrations are excellent half tones, made from photographs. Their arrangement and the general make-up of the volume reflect credit on its compiler.

Railroad Track and Other Scales.—Bulletin No. 111 of the Huda Foundry & Manufacturing Co., Chicago, deals with scales. Railroad track scales, coal mine, depot and warehouse, wagon, elevator, portable and other scales, recording beams and quick weighing devices, are described and illustrated, and lists of parts given for each.

Structural Steel.—The Interstate Engineering Co., Cleveland, Ohio, is distributing advance sheets from Bulletin No. 8, soon to be issued. The circular, No. 101, illustrates some examples of structural steel work recently done by this company.

MANUFACTURING AND BUSINESS.

The Seaboard Air Line has given the contract for the oil-burning furnaces for its new shops at Jacksonville, Fla., to Tate, Jones & Co., Inc., Pittsburg, Pa.

Atwood Paxson & Company has been formed to deal in iron and steel products and railroad equipment and supplies, with office at 120 Liberty street, New York. Mr. Paxson was for some years with L. J. Buckley & Company, of New York city.

P. G. Ten Eyck, hitherto Treasurer and Chief Engineer of the Federal Railway Signal Co., Troy, N. Y., has been appointed Vice-President, with office at Albany, N. Y. The officers are now: J. T. Cade, President; Lawrence Griffith, Vice-President; P. G. Ten Eyck, Vice-President; Frederic Pruyn, Treasurer; C. E. Newman, Secretary.

Gilbert Greenbusch, C.E., of London, England, is in New York for a few weeks with address at 17 Battery Place. He is an American engineer, graduate of Stevens Institute, with ten years' residence in London, where he is an associate member of the British Institute of Civil Engineers. He has just completed his work as engineer in charge of construction of the lifts in the London underground electric railways and now proposes to introduce American mechanical and electrical specialties in Europe. He is well equipped in character, knowledge and acquaintance.

Hermann von Schrenk, well-known to readers of the *Railroad Gazette*, has resigned as Pathologist in charge of investigations of timber diseases and methods for their prevention in the United States Department of Agriculture, and has associated himself with E. B. Fulks and Alfred L. Kammerer, Consulting Timber Engineers, with office at Tower Grove and Flad avenues, St. Louis. Mr. von Schrenk has been appointed Timber Engineer of the Rock Island, the St. Louis & San Francisco and the Chicago & Eastern Illinois railroad systems. His new office will be prepared to carry on investigations and make reports on all problems dealing with the best methods for handling and using timbers. It would seem that this is a field of great usefulness, since work of this character is highly important now and must constantly become more so as the timber reserves of the country become cut off.

Iron and Steel.

The Atchison, Topeka & Santa Fe has ordered 30,000 tons, and the Delaware, Lackawanna & Western 7,500 tons of rails from the Bethlehem Steel Co. for 1908 delivery. They are to be rolled in the new rail mill now nearly completed at Bethlehem and will be made from open hearth steel with a maximum of .04 phosphorus. The Santa Fe specifications require 25 per cent. crop on the ingots and the Lackawanna 20 per cent. It is reported, though it cannot be confirmed, that the price is $35 a ton, an increase of 25 per cent. over the pool price.

OBITUARY NOTICES.

Charles H. Nye, formerly and for a number of years Superintendent of the Cape Cod division of the Old Colony Railroad, now part of the New York, New Haven & Hartford, died at his home at Hyannis, Mass., on July 9. Mr. Nye was 85 years old.

W. H. Hayden, Advertising Manager of the Boston & Maine, died at Littleton, N. H., on July 8, a few hours after being thrown out of a carriage. Mr. Hayden went to the Boston & Maine at the end of last year, after having been in charge of advertising on the Central of New Jersey for five years. He was 35 years old at the time of his death.

Charles H. Rockwell, General Traffic Manager of the Chicago, Indianapolis & Louisville, died on July 6 at Indianapolis, Ind., of heart failure. Mr. Rockwell was born in 1852 at Terre Haute, Ind., and began railroad work in 1869 as an assistant yard clerk on the Cleveland, Columbus, Cincinnati & Indianapolis, now part of the Big Four. He worked his way up through several positions, on roads which are now part of the New York Central lines, until 1884 when he was made Auditor of the Cincinnati, Hamilton & Dayton. After serving as General Passenger and Ticket Agent of that road he went to the Pullman Company in 1888 as Secretary to the President, but a few months later was made General Superintendent of the Columbus, Hocking Valley & Toledo, now part of the Hocking Valley. Two years later he was appointed General Superintendent of the Chicago & Eastern Illinois, and in 1893 was made Assistant to the President of that road. Later in the same year he went to the Cincinnati, Akron & Columbus as General Passenger Agent. From 1895 to 1897 he was Auditor of the Western Passenger Association and then took the office which he held at the time of his death.

MEETINGS AND ANNOUNCEMENTS.

(For dates of conventions and regular meetings of railroad conventions and engineering societies, see advertising page 24.)

International Railroad Master Blacksmiths' Association.

The fifteenth annual convention of this association is to be held at Montreal, Canada, August 20, 21 and 22. Headquarters will be in the Bath Hotel, where accommodation can be had at a rate of $2.50 a day for each person, including all meals.

The subjects to be presented are: Flue Welding, John Conners, Chairman;

Tools and Formers for Bulldozers and Steam Hammers, G. M. Stewart, Chairman;

Piece Work, Grant Bollinger, Chairman;

Discipline and Classification of Work, S. Uren, Chairman;

Case Hardening Methods, Time Taken and Samples, Geo. Masser, Chairman;

Best Fuel for Use in Smith Shop, Jos. Jordan, Chairman;

Frame Making and Repairing, Grant Bollinger, Chairman;

Thermit Welding, Geo. Kelly, Chairman.

Master Car and Locomotive Painters' Association.

The thirty-eighth annual convention of this association is to be held at St. Paul, Minn., September 10-13. Arrangements have been made for hotel accommodation on the American plan at the Hotel Ryan, at prices ranging from $3 to $4 a day for each person. The subjects for discussion are as follows:

Painting of Steel Passenger Cars, a composite paper by John D. Wright (B. & O.), H. M. Butts (N. Y. C. & H. R.), and R. J. Kelly (Long Island);

Disinfecting Passenger Cars at Terminals, H. E. Smith (L. S. & M. S.), R. W. Mahon (N. Y. C. & H. R.), A. J. Bruning (L. & N.);

Cleaning, Coloring and Lacquering of Metal Trimmings, B. E. Miller (D., L. & W.), Geo. Warlick (C., R. I. & P.), C. A. Cook (P., B. & W.);

Painting Locomotives and Tenders, J. H. Kahler (Erie), W. A. Buchanan (D., L. & W.), E. Daly (C., C., C. & St. L.);

Linseed Oil Substitutes and Drying Oils, W. O. Quest (P. & L. E.), W. H. Smith (Southern Ry.).

There is also to be an essay on Problems of the Present-day Paint Shop, by Chas. E. Copp (B. & M.).

There will also be a number of queries as follows:

Have you found any coating that will resist rust? Discussion opened by Chas. E. Becker (C., C., C. & St. L.).

Denatured Alcohol—Is it a satisfactory substitute for grain alcohol? Discussion opened by W. J. Orr (Erie).

Is it advisable to apply three coats of body color to a car? Discussion opened by J. Gearhart (Penn.).

Can light colored freight car stencil paints be improved? Discussion opened by W. Bailey (B. & M.).

Is pressed fiber as durable as a three-ply wood veneer? Discussion opened by O. P. Wilkins (N. & W.).

What should be the nature of a detergent? Discussion opened by B. E. Miller (D., L. & W.).

ELECTIONS AND APPOINTMENTS.

Executive, Financial and Legal Officers.

Alabama & Vicksburg.—See New Orleans & North-Eastern.

Ashland, Odanah & Marengo.—The officers of this company are as follows: President, L. K. Baker, with office at Odanah, Wis.; Vice-President, J. Stearns, with office at Ludington, Mich.; Secretary and Treasurer, E. B. Hill; General Freight Agent, F. J. Darke; Superintendent, E. Mercier, and Auditor, D. J. McMahon, all with offices at Odanah.

Boyne City, Gaylord & Alpena.—The office of Traffic Manager has been abolished. C. J. Wilson has been appointed General Freight and Passenger Agent and Assistant Superintendent. G. W. Laing, Purchasing Agent, has been appointed also Auditor. W. L. Martin has been appointed Superintendent. Frank Butler has been appointed Trainmaster.

Brinson Railway.—The officers of this company are as follows: President and Superintendent, G. M. Brinson; Vice-President and Traffic Manager, Charles Neville, heretofore General Freight and Passenger Agent of the Georgia Coast & Piedmont; Auditor, E. K. Bonney, all with offices at Springfield, Ga.

Cairo Northern.—The officers of this company are as follows: President, W. T. Whiteman; General Manager, E. M. Decker; Traffic Manager, T. Tilford; General Freight Agent, C. P. Bowen, and General Passenger Agent, W. S. Bowen, all with offices at Cairo, Tex.

Central of New Jersey.—F. T. Dickerson has been appointed Assistant Secretary, succeeding Joseph James, Jr.

Charlotte Harbor & Northern.—The officers of this road, which will be opened for traffic on August 1, are as follows: Second Vice-President and General Manager L. M. Fouts, with office at Jacksonville, Fla.; General Freight and Passenger Agent J. L. de Treville, with office at Arcadia, Fla.; Superintendent C. B. McCall and Auditor W. J. Gilligan, both with office at Hull, Fla.

Chicago & Calumet River.—F. N. Hoffstot, President, and J. W. Friend, Vice-President, of the Pittsburg, Allegheny & McKee's Rocks, have been elected also to these offices on the Chicago & Calumet River.

Corvallis & Eastern.—G. W. Talbot, Vice-President and General Manager, has resigned to go to the Oregon Electric with the same title.

Georgia Coast & Piedmont.—W. R. Basset has been appointed Auditor, succeeding W. B. Scott. See Brinson Railway.

Mississippi Eastern.—Walter Stone has been appointed Auditor, with office at Quitman, Miss.

Mobile, Jackson & Kansas City.—L. S. Berg, formerly President of the New Orleans Terminal, has been elected President of the Mobile, Jackson & Kansas City, succeeding B. M. Robinson, resigned.

New Orleans & North-eastern.—L. A. Jones, Auditor, has been elected also Vice-President of this road and of the Alabama & Vicksburg and the Vicksburg, Shreveport & Pacific, succeeding D. D. Curran, who was recently elected President.

New York Central & Hudson River.—William J. Wilgus, Vice-President, has resigned and his service with this company will end on October 1 next. He does not expect to enter other railroad service; it is probable, rather, that his future work will be in an advisory capacity. He leaves indelible marks on the property of the company of which he has been a general officer only eight years. He became Chief Engineer in May, 1899, and began at once to standardize the roads, track and structures. His large blue print volume of standard drawings of ballast, track signs, signal posts, culverts, bridges and structures of all kinds is a monument of industry and skill. He fulfilled the instruction of the then President, Mr. Callaway: "Make it so that I can wake up anywhere on the line and look out of the window and know I am on the Central." His far-seeing advocacy, as well as construction, of the Beech Creek extension, which insures the company's supply of bituminous coal, was much to his credit. He will long be best known for having planned, designed and executed the electrification of the New York City terminal, an engineering work of the first magnitude and made difficult by the necessity for keeping the terminal open for the heavy traffic of two great railroads while it is being entirely reconstructed, both under and above ground. Of his most startling innovation in engineering methods, comparatively little has been said. His entirely novel method of tunnel construction is now being carried out under his own supervision for the Michigan Central's traffic under Detroit river, and the cost of it, as contracted for, is just one-half the price bid by Sir Weetman Pearson's contracting firm. There is no reason to expect that the ambitions of this engineer, less than 42 years old, are at all satisfied, or that there will be any considerable intermission in his activities.

William J. Wilgus.

See Toronto, Hamilton & Buffalo.

New York Public Service Commissions.—John S. Kennedy, of Corning, N. Y., has been appointed Secretary of the Commission for the Second district. Mr. Kennedy had been for several years Secretary of the New York State Railroad Commission. T. H. Whitney is Secretary of the Commission for the First district, the office of which is at 320 Broadway, New York City.

Pittsburg, Allegheny & McKee's Rocks.—See Chicago & Calumet River.

Rio Grande, Sierra Madre & Pacific.—The authority of the officers of this company have been extended over the Sierra Madre & Pacific.

Shreveport, Houston & Gulf.—The officers of this company are as follows: President, W. T. Carter, with office at Houston, Tex.; Vice-President and General Manager, G. A. Kelley; Secretary and Treasurer, C. C. Gribble, and Auditor and Traffic Manager, L. D. Garrison, all with offices at Manning, Tex.

Sierra Madre & Pacific.—See Rio Grande, Sierra Madre & Pacific.

Silver Lake Railway.—L. S. Ward has been appointed Treasurer, with office at Rochester, N. Y., succeeding G. L. Eaton, resigned.

Southern.—J. S. B. Thompson, General Agent of the Executive Department at Atlanta, Ga., has been appointed Assistant to the President, with office at Atlanta.

Toronto, Hamilton & Buffalo.—D. W. Pardee, Secretary of the New York Central & Hudson River, has been elected also Secretary of the Toronto, Hamilton & Buffalo.

Vicksburg, Shreveport & Pacific.—See New Orleans & North-eastern.

Operating Officers.

Atchison, Topeka & Santa Fe.—A third grand division has been created and H. W. Sharp, Superintendent at Kansas City, Mo., has been appointed General Superintendent of it, with office at La Junta, Colo. D. Farley succeeds Mr. Sharp.

Atlantic Coast Line.—The First division is to be divided into two divisions, to be known as the First division and the Second division. The new First division will consist of the lines between Richmond, Va., and Florence, S. C., and the Second division of the lines between Florence and Savannah, Ga. The present Second division, from Savannah, Ga., to Jacksonville, Fla., will hereafter be known as the Third division, while the present Third division, consisting of the lines in Florida, will become the Fourth division. A. W. Anderson, General Superintendent of the present First division, has been appointed General Superintendent of the new Second division, with office at Florence. W. H. Newell, Superintendent of Transportation of the present First division, has been appointed General Superintendent of the new First division, with office at Rocky Mount, N. C. J. C. Murchison, Superintendent of the Wilmington district, succeeds Mr. Newell, with office at Wilmington, N. C. All appointments are effective August 1.

Brooklyn Rapid Transit.—W. S. Menden, Chief Engineer, has been appointed General Superintendent, succeeding D. S. Smith, resigned.

Central of Georgia.—J. J. Cotter has been appointed Superintendent at Cedartown, Ga., succeeding R. J. Armstrong, resigned.

Chicago & Illinois Western.—H. Bates, foreman of locomotive and car repairs, has been appointed General Superintendent, succeeding D. P. Plummer.

Colorado & Northwestern.—C. M. Williams has been appointed Superintendent, with office at Boulder, Colo.

Colorado Southern, New Orleans & Pacific.—G. Kennedy has been appointed Trainmaster at Eunice, La.

Illinois Central.—T. L. Dubbs, Superintendent at Nashville, Tenn., has been appointed Superintendent of the Birmingham division. L. E. McCabe, Trainmaster at Louisville, Ky., succeeds Mr. Dubbs.

Interoceanic of Mexico.—See National Lines of Mexico under Engineering and Rolling Stock officers.

Lehigh & New England.—J. V. Lyddon has been appointed Trainmaster at Pen Argyl, Pa., succeeding J. E. Curry, resigned.

Malheur Valley.—See Oregon Short Line.

Minidoka & Southwestern.—See Oregon Short Line.

National Lines of Mexico.—H[illegible] Taylor, who was recently appointed Assistant General Manager, was born at Montgomery, Ala., in 1870. He graduated from the Alabama Polytechnic Institute in 1889 and immediately began railroad work as a draftsman on the Birmingham Mineral division of the Louisville & Nashville. He worked his way up on this road until he became resident engineer in charge of construction of the Coosa river bridge near Shelby, Ala. In 1891 he went to the National of Mexico as engineer and supervisor; he served as brakeman, conductor and yardmaster until 1895, when he was made Trainmaster at Laredo. Five years later he was made Division Superintendent, and in 1902 Superintendent of Construction of the Mexico-Gonzalez line. In [illegible] he was appointed General Manager of the Interoceanic of Mexico, where he remained until his recent appointment as Assistant General Manager of the National Lines of Mexico in charge of engineering and maintenance.

National Railroad of Mexico.—See National Lines of Mexico under Engineering and Rolling Stock officers.

Oregon Short Line.—C. M. Hunt, Superintendent of the Pacific & Idaho Northern, has been appointed to the new office of Trainmaster of the Third, Fourth and Fifth districts of the Idaho division and the Boise branch of the Oregon Short Line, the Minidoka & Southwestern and the Malheur Valley, with office at Nampa, Idaho.

Pacific & Idaho Northern.—See Oregon Short Line.

Rio Grande Western.—A. B. Apperson, Assistant Superintendent at Helper, Utah, has been appointed Assistant Superintendent at Salt Lake City, Utah, succeeding H. J. Roth. R. R. Sutherland succeeds Mr. Apperson.

St. Louis, Brownsville & Mexico.—G. B. Huestis, General Superintendent, has been appointed Superintendent of the First division, consisting of the line from Brownsville to Kingsville and the Hidalgo branch, and the office of General Superintendent has been abolished. Oliver Rowe has been appointed Superintendent of the Second and Third divisions, consisting of the line from Kingsville to Algoa and the joint track from Corpus Christi to Robstown. E. T. Gibson has been appointed Trainmaster of the whole road. W. B. Upp has been appointed Car Accountant, succeeding C. J. Crane. The offices of all are at Kingsville, Tex.

Trinity & Brazos Valley.—W. A. Allison, who was recently appointed Superintendent of Telegraph, was born at Glade Spring, Va., in 1875, and began railroad work in 1891 as a telegraph operator on the Norfolk & Western. He was appointed train despatcher in 1897, and soon after went to the Baltimore & Ohio in the same position. He was later appointed to the same office on the Missouri, Kansas & Texas, and in 1899 went to the Illinois Central as despatcher at McComb, Miss. He was made chief train despatcher at that place in 1903 and in 1905 was appointed Trainmaster of the Memphis division of the Yazoo & Mississippi Valley, where he remained until he resigned in June of the current year to go to the Trinity & Brazos Valley.

W. A. Allison.

Traffic Officers.

Atlantic Coast Line.—A. C. Kenly, Freight Claim Agent, has been appointed Superintendent of Freight.

Bedford Stone Railway.—J. G. Ray has been appointed General Freight Agent, succeeding H. W. Walters, resigned.

Brookhaven & Pearl River.—W. J. Helmick has been appointed General Freight and Passenger Agent, with office at Brookhaven, Miss., succeeding Alfred Mead, resigned to go to another company. See Tremont & Gulf.

Chicago, Rock Island & Pacific.—H. C. Battles has been appointed to the new office of General Agent at Peoria, Ill.

Delaware & [illegible].—A. M. White has been appointed General Freight and Passenger Agent, with office at New York, succeeding W[illegible] Harrison, resigned.

Michigan Central.—H. R. Daly has been appointed General Agent at Grand Rapids, Mich.

Minneapolis, St. Paul & Sault Ste. Marie.—J. S. Carter has been appointed General Agent at Spokane, Wash.

Missouri Pacific.—J. B. T[illegible], General Agent at [illegible], has been appointed General Agent at Pittsburg, Pa., succeeding John Walsh.

National Lines of Mexico.—The territory to be covered hereafter by the General Eastern Agent at New York will include Pennsylvania, New England and the Atlantic states, as well as Nova Scotia, New Brunswick and that part of Ontario east of a north and south line passing through Port Huron, Mich. The territory of the General Western Agent at Chicago includes all the rest of the United States and Ontario except Texas, Oklahoma and Indian Territory, which will be in charge of the General Agent at San Antonio, Tex., who, however, will not have charge of the Texas-Mexican Railway.

St. Joseph & Grand Island.—H. C. Mitchell has been appointed General Agent at Pittsburg, Pa.

Sierra Valley Railway.—W. H. O'Neill has been appointed Assistant Traffic Manager.

Somerset Railway.—F. V. Berry has been appointed Assistant General Freight and Passenger Agent, with office at Oakland, Me.

Tremont & Gulf.—Alfred Mead, General Freight and Passenger Agent of the Brookhaven & Pearl River, has been appointed General Freight and Passenger Agent and Assistant Superintendent of the Tremont & Gulf.

Western Maryland.—F. M. Howell, General Passenger Agent, has been appointed General Passenger and Ticket Agent, succeeding to the duties of James D. Whittington, General Ticket Agent and Ticket Auditor, who has resigned on account of ill health, and whose former position has been abolished.

Engineering and Rolling Stock Officers.

Colorado & Northwestern.—Leonard Ruhle has been appointed Master Mechanic, with office at Boulder, Colo., succeeding M. Fitzgerald.

Colorado & Southern.—H. W. Ridgway, Master Mechanic at Trinidad, Colo., has been appointed Master Mechanic at Denver, Colo., succeeding D. Patterson, resigned.

Manitoulin & North Shore.—C. M. Colburne has been appointed Chief Engineer, with office at Sault Ste. Marie, Ont.

Mexican International.—See National Lines of Mexico.

National Lines of Mexico.—G. P. De Wolf, Superintendent of Terminals of the National Railroad of Mexico at Mexico City, has been appointed Assistant Chief Engineer of the Mexican International, with office at C. Porfirio Diaz, Coahuila, Mex., succeeding C. J. Carroll, resigned to go into other business. E. W. Bowans, Trainmaster of the Interoceanic of Mexico at Pueblo, succeeds Mr. De Wolf.

Purchasing Agents.

Georgia & Florida.—J. M. Turner, General Manager, has been appointed also Purchasing Agent.

LOCOMOTIVE BUILDING.

The Southern is about to buy 50 light locomotives.

The Central Vermont is said to be figuring on 10 locomotives.

The Grand Trunk Pacific, it is said, is about to buy 50 eight-wheel locomotives.

The Grand Trunk, it is understood, is to buy 100 locomotives within the next two months.

The Yosemite Valley has ordered one eight-wheel locomotive from the American Locomotive Company.

The Green Bay & Western has ordered one mogul locomotive from the American Locomotive Company.

The Santa Fe, Raton & Des Moines has ordered one ten-wheel locomotive from the American Locomotive Company.

The Hanyang Steel & Iron Works has ordered one four-wheel tank engine from the American Locomotive Company.

The Burden Iron Company has ordered one four-wheel switching locomotive from the American Locomotive Company.

The Carnegie Steel Company has ordered one six-wheel switching locomotive from the American Locomotive Company.

The Memphis Warehouse Company has ordered one six-wheel switching locomotive from the American Locomotive Company.

The Intercolonial has ordered 22 locomotives from the Kingston Locomotive Works and the Locomotive & Machine Company of Montreal.

The Louisville & Nashville has ordered eight consolidation Baldwin and switching locomotives from the American Locomotive Company.

The Savannah, Augusta & Northern, which is to build a road in Georgia, has ordered two mogul locomotives from the American Locomotive Company. W. J. Oliver, Knoxville, Tenn., is understood to have the contract for building the road.

CAR BUILDING.

The Dayton & Troy Electric, Dayton, Ohio, will buy two large interurban cars.

The Central of Georgia is said to be preparing specifications for 1,000 freight cars.

The Missouri, Oklahoma & Gulf has ordered from 50 to 100 cars from Barney & Smith.

The Cold Blast Transportation Company, Chicago, is asking prices on 200 stock cars.

The Hanover & York has ordered six cars from the Niles Car & Manufacturing Company.

The Central of New Jersey has ordered 1,000 freight cars from the Cambria Steel Company.

The Pittsburg, Shawmut & Northern is said to be preparing plans for a number of coke cars.

The Chicago, Burlington & Quincy has ordered 1,000 steel gondola cars from Barney & Smith.

The Intercolonial has ordered 3,000 freight cars, mostly from the Crossen Manufacturing Company and Rhodes, Curry & Company.

The Illinois Central has ordered 3,000 steel underframe box cars of 100,000 lbs. capacity from the American Car & Foundry Company.

The Storz Brewing Co., Omaha, Neb., is said to be building four refrigerator cars at the Plattsmouth, Neb., shops of the Chicago, Burlington & Quincy.

The Southern is about to buy 75 passenger coaches, four dining cars, six combination mail and baggage cars, six combination passenger and baggage cars and 200 cabooses.

The Las Vegas & Tonopah, as reported in the *Railroad Gazette* of June 28, has ordered three standard 60-ft. coaches and three standard 60-ft. baggage cars from the Pullman Co., for October delivery. The special equipment for both includes:

Heating system	Safety
Light	Pintsch
Paint	Murphy System

The Marquette & South Eastern, as reported in the *Railroad Gazette* of July 5, has ordered 20 flat cars of 80,000 lbs. capacity from the Hicks Locomotive & Car Works, for July 25 delivery. These cars will be 41 ft. long and 9 ft. wide, over all. The special equipment includes:

Bolsters	Bettendorf
Brake-beams	Simplex
Brakes	Westinghouse
Couplers	Tower
Draft rigging	Miner
Journal boxes	Symington

The Connecticut Company, which buys the equipment for the electric lines of the New York, New Haven & Hartford, has ordered the following cars:

New Haven Line	16	double truck,	30 ft.	closed cars.
Hartford Line	24	" "	30 ft.	" "
Bridgeport Line	10	" "	30 ft.	" "
South Norwalk Line	3	" "	30 ft.	" "
Derby Line	10	" "	30 ft.	" "
New Britain Line	2	" "	30 ft.	" "
Millidale Line	2	" "	30 ft.	" "
Waterbury Line	11	" "	30 ft.	" "
Stafford Springs Line	4	" "	30 ft.	" "
New York & Stamford	12	" "	30 ft.	" "
Norwich Line	1	" "	33 ft.	" "
Middletown Line	8	" "	33 ft.	" "
Rhode Island Lines			30	" "

The company has also ordered snow plows from the Wason Car Co. as follows:

Hartford Line	3	Bridgeport Line	1
Stafford Springs Line	1	Derby Line	3
N. Y. & S. Line	1	Waterbury Line	2
Middletown Line	1	Millidale Line	1
Norwich Line	1		

Special Equipment.

Bodies	Wason
Brakes	Allis-Chalmers
Heaters	Consolidated electric
Motors for New Haven Line, Hartford Line, Stafford Springs Line, New York & Stamford and Rhode Island Lines	General Electric Co.
Motors, for all other cars and for all snow plows	Westinghouse
Registers	New Haven
Trolleys	Sterling-Meaker
Trucks	Standard Motor Truck Co.'s
Wheels	Schoen rolled steel

RAILROAD STRUCTURES.

Alfalfa, Tex.—Surveys, it is reported, are being made by the Galveston, Harrisburg & San Antonio for a new yard here.

Birmingham, Ala.—The new passenger station, built at a cost of $1,500,000, was recently opened for traffic.

Columbus, Ga.—The Columbus Railway Company is planning to put up a two-story brick car barn.

Frankfort, Ind.—The Toledo, St. Louis & Western, it is said, will spend about $150,000 in the enlargement of its shops here.

Garden City, Kan.—The Atchison, Topeka & Santa Fe will build a new passenger station and additional tracks here to cost about $25,000.

Havre de Grace, Md.—The Baltimore & Ohio has given the contract for construction of the substructure of the new double-track bridge over the Susquehanna river at this place to Eyre-Shoemaker, Inc., of Philadelphia, Pa., and it is expected that the work will be started at once. The contract for the superstructure was let about six weeks ago to the American Bridge Company. This bridge will be double-track throughout, require about 45,000 cu. yds. of masonry in the substructure and between 14,000 and 15,000 tons of steel work in the superstructure. It will be 7,000 ft. long and the largest bridge on the Baltimore & Ohio system. It will take about three years to build the bridge and the cost will be about $2,000,000. The masonry work will consist of a new abutment at the west end and a pier on the west bank, four new intermediate piers in the west channel, 21 piers on Watson's Island and one new pier in the east channel.

Kansas City, Kan.—The Atchison, Topeka & Santa Fe, it is said, has given a contract to H. G. Douglas, of Topeka, Kan., for putting up shops to replace those recently destroyed by fire.

Kansas City, Mo.—The Kansas City Southern, it is reported, has bought land between Second and Third streets and Broadway and Wyandotte streets, on which additional tracks are to be laid and other improvements made to increase terminal facilities.

Lima, Ohio.—The Lima & Toledo Traction Company is planning to put up a new passenger station to cost $50,000.

Memphis, Tenn.—A permit has been given to the Illinois Central to put up a brick freight house, at a cost of about $50,000, to replace the structure destroyed by fire some time ago.

Mobile, Ala.—Local reports state that the Louisville & Nashville will not use the new union passenger station, but will build a station for its own use.

St. Louis, Mo.—The Missouri Supreme Court in a recent decision upheld the validity of the St. Louis $3,500,000 bridge bond issue. This will make possible the issuance of $1,000,000 of the bonds, so that work on the proposed bridge over the Mississippi river can be started.

Sherman, Tex.—Work has been started rebuilding the Frisco shops recently destroyed by fire. The four brick buildings to be put up are to cost about $60,000, and the machinery $55,000.

Sunbury, Pa.—The Pennsylvania, it is said, is planning to build a bridge over the Susquehanna river to carry four tracks.

Teague, Tex.—The Trinity & Brazos Valley machine shops, roundhouse and terminals to be built at this place will cost about $500,000.

Valdosta, Ga.—The Georgia Southern & Florida has plans ready for putting up a brick passenger station 74 ft. x 104 ft. to cost $30,000. Platforms, with umbrella sheds, will be 460 ft. long.

Vancouver, B. C.—The Canadian Pacific announces that extensive additions to its wharf facilities is to be made. Bids are wanted for dredging and the building of stone walls. The proposed wharf is to be 670 ft. long x 162 ft. wide.

West Chester, Pa.—Contract reported let by the Pennsylvania to Corcoran Brothers, for grading and improving its yards at this place. New tracks are to be added and the terminal facilities increased.

Winnipeg, Man.—A sub-committee has recommended to the Board of Works that the City Engineer be instructed to prepare plans for a subway for both the Canadian Northern and Grand

Trunk Pacific Railways at the Main street crossing near the Norwood bridge. It is also recommended that in the agreement with the Grand Trunk Pacific provision be made for two overhead steel bridges over the tracks between Cambridge and Pembina streets, and for a subway at Cambridge street.

RAILROAD CONSTRUCTION.

New Incorporations, Surveys, Etc.

Adirondack & St. Lawrence.—This road is in operation from De Kalb Junction, N. Y., south to Hermon, four miles.

Ashland, Odanah & Marengo.—This road has been opened for business from Odanah, Wis., to Echo [illegible]n, 26 miles.

Brandon, Saskatchewan & Hudson's Bay.—See Great Northern.

Brinson Railway.—This road has been opened for business from Savannah, Ga., north to Springfield, 25 miles.

Butte, Anaconda & Pacific.—Freight trains are now running on this road from Anaconda, Mont., to Browns, six miles.

Cherryvale, Oklahoma & Texas.—This company, which was incorporated to build about 700 miles of line from Cherryvale, Kan., to El Paso, Tex., has had its charter amended to provide for building branch lines as follows: Caney, Kan., southeast to Fayetteville, Ark., 150 miles; Pawhuska, Okla., southeast to South McAlester, Ind. T., 200 miles, and Childress, Tex., southeast via Abilene to Aransas Pass, 600 miles. The offices of the company are at Caney and Independence, Kan., and at Perry, Okla. The capital stock of the company is $18,000,000. S. M. Porter, of Caney; A. W. Shiltise, F. D. Brewster and J. H. Brewster, of Independence; R. E. Wade and J. H. Masters, of Perry, incorporators. W. R. Stubbs, of Kansas City, is also interested in the project. (March 15, p. 381.)

Caro Northern.—This road has been opened for business for 16½ miles between Caro, Tex., and Mount Enterprise.

Chesapeake & Ohio.—The Guyandotte Valley district has been extended from Logan, W. Va., to Ethel, five miles.

Chicago & Illinois Midland.—This road has been extended from Pawnee, Ill., east to Taylorville, 16 miles.

Chicago & North-Western.—The extension from Bonesteel, S. Dak., west towards the Rosebud Indian Reservation, finished to Herrick last year, has been extended from Herrick west to Gregory, 14.9 miles.

The Pierre, Rapid City & North-Western, building from Pierre, S. Dak., west to Rapid City, 165 miles, is reported finished.

Chicago, Milwaukee & St. Paul.—The White River Valley, Railroad from Chamberlain, S. Dak., west to Rapid City, 219 miles, is reported finished.

El Paso & Southwestern.—On the Western division a new branch called the Warren line has been opened for business from Lowell, Ariz., via Warren to Corta, 4.3 miles.

Eureka Hill.—This company has given a contract to Baxter, Straw & Stove, of Provo, to build a five-mile line from Silver City, Utah. C. W. Nibley, President, Salt Lake City, and R. B. West, Chief Engineer, Silver City.

Grand Trunk Pacific.—According to reports from Montreal construction work on this line between Saskatoon, Sask., and Edmonton, Alb., is being pushed. About 1,700 men are now at work on this section. It is expected to have 150 miles graded by the first of next month so that rails can be laid.

Great Northern.—The Brandon, Saskatchewan & Hudson's Bay on the Minot division has been opened for business from St. John, N. Dak., north to Brandon, Man., 73½ miles.

Gulf, Colorado & Santa Fe.—The Jasper & Eastern has been opened for freight and passenger traffic from De Ridder, La., to Cravens.

Indian Territory Roads (Electric).—J. C. Cameron, of New York City, has submitted a plan to residents of Ada, Ind. T., to build an electric line, including a branch, south for 13 miles.

Kansas City, Mexico & Orient.—Surveys are reported under way for extending this road from San Angelo, Tex., to San Antonio.

Laramie, Hahns Peak & Pacific.—This company, which has built a line from Laramie, Wyo., on the Union Pacific, west 30 miles to Centennial, will, according to local reports, shortly begin grading on a proposed extension from Centennial to Walden, Colo., about 70 miles. Financial arrangements have been made to finish the line to the coal fields in North Park.

Macon, Americus & Albany (Electric).—According to local reports bids are asked for to build this proposed electric line from Macon, Ga., southwest to Albany, 150 miles. (April 19, p. 565.)

Malheur Valley.—See Oregon Short Line.

Michigan Roads.—Bids are wanted [illegible] by J. E. [illegible], Engineer of Construction of the Vans Harbor Land & Lumber Company of Gladstone, Mich., for grading and laying tracks on [illegible] of road for a steam railroad from Cooks Mills, Mich., to Vans Harbor, Delta county.

Mississippi Central.—O. A. Gibson, of Natchez, who has a grading contract for some of the work on the extension of this road from Brookhaven, Miss., west to Natchez, has been given an additional contract to lay tracks on a 22-mile section of this extension. (May 17, p. 695.)

Nevada Roads.—A line from Las Vegas, Nev., south via Eldorado canyon to Searchlight, 60 miles, it is said, will be built by George P. Spittall, of Searchlight.

New York City Roads.—Bridge Commissioner Stevenson reports to the Public Service Commission that the Williamsburg bridge will within the present year be fitted for the operation of elevated railroad electric trains over the structure.

Norfolk & Southern.—The Pamlico division has been extended from Washington, N. C., south to New Bern, 35 miles.

The Eastern district of the Raleigh division has been opened for business from Washington, N. C., west to Farmville, 30 miles.

North Yakima & Valley.—This road has been opened for business from North Yakima, Wash., west to Naches, 14 miles.

Oregon & Washington.—See Oregon Railroad & Navigation Co.

Oregon Railroad & Navigation Co.—Plans have been finally completed for building the Oregon & Washington northward to Seattle and Tacoma. At Seattle there is to be a tunnel a mile long to enable the line to reach the business center of the city without causing congestion of traffic on the water front streets. At Tacoma also there will have to be a tunnel, to avoid steep grades. This tunnel will be 8,700 ft. long. At the Tacoma terminus the company has bought seven blocks of land, two of which will be the site for the passenger station.

Oregon Roads.—A company is being formed in Oregon, with Steven Carter, of Eugene, as the principal promoter, to build a line from that place west to the Pacific coast at the mouth of the Siuslaw river, about 60 miles. It is proposed to begin work at once on the first 30 miles.

Oregon Short Line.—The Malheur Valley has been opened for business from Ontario, Ore., west to Vale, 15 miles.

On the St. Anthony branch the Yellowstone Park Railroad has been extended from Marysville, Idaho, north to Mesa, 14.4 miles, thence north 6.8 miles.

Pierre, Rapid City & North-Western.—See Chicago & North-Western.

Public Belt Railroad.—Additional contracts for building this line around New Orleans, La., to consist of a double-track main line, with a single-track line along the river front, a total of about 20 miles, are to be let shortly. Work is under way by Thomas Egan, of New Orleans, who has a contract for some of the work. Mayor Martin Behrman is President, and Hampton Reynolds, Engineer.

Rio Grande, Sierra Madre & Pacific.—The Temosachic-Bacerac branch of the Sierra Madre & Pacific has been opened for business from Temosachic, Mex., via Rincon to Madre, 32 miles. (March 15, p. 396.)

Shreveport, Houston & Gulf.—This road has been opened for business from Prestridge, Tex., to Manning, nine miles. (March 15, p. 391.)

Sierra Madre & Pacific.—See Rio Grande, Sierra Madre & Pacific.

Spokane & Inland Empire (Electric).—This company has extended its line from Oakesdale, Wash., south to Palouse, 22.7 miles.

Tacoma Eastern.—This company has extended its main line from Tilton, Wash., to Glenavon, three miles.

Tampa Northern.—This road has been opened for business from Tampa, Fla., north to Brooksville, 48½ miles.

Taylor, Somerville & Gulf.—Incorporated in Texas with $100,000 capital and office at Taylor. The company proposes to build a line from Taylor, Tex., east to Somerville, about 60 miles. The incorporators include: J. A. Thompson, R. C. Briggs, Howard Bland, A. A. Wheatley, J. R. Lyon, Charles Parke and J. A. Jones.

Tecolote Valley.—An officer writes that this company has finished surveys, and will let bids about September 1 for its proposed narrow gage line from Las Vegas, N. Mex., north via Mineral Hill mining district, passing within five miles of Mora, the county seat of Mora county, to Black Lakes, thence west to Taos, about 80 miles. All of this, with the exception of 22 miles, will be in the

mountain, and will necessitate the piercing of a number of tunnels. At Las Vegas the company's shops will be built, and a line is projected from that point south to the Tecolote mining district. Frank J. Buck, Chief Engineer, Elizabethtown. The offices of the company are at Las Vegas.

Texas Interurban.—Incorporated in Texas with $400,000 capital to build a system of interurban lines from Austin, Tex. The incorporators include: T. Moore, of Elizabeth, N. J.; E. Miller, of White Plains, N. Y., and W. W. McKay, of Hempstead, L. I.

Texas Roads.—Residents of Waco, Tex., are interested in a project to build a line from Waco, west via Hamilton to Brownwood, about 120 miles.

Toledo, St. Louis & Western.—Vice-President George H. Ross is reported as saying that the work of relaying 75-lb. rails between Toledo and St. Louis, which has been under way for about 2½ years, will be finished this month. About 120,000 yards of ballast at various points on the line is being added and orders have been given for six steel bridges to be built this year. Contracts have also been let for extensive ditching and widening of banks.

Virginia-Carolina Railway.—This line has been extended from Taylor's Valley, Va., eight miles, to Konnarock.

Virginian Railway.—Press reports state that this company, the successor of the Tidewater and the Deepwater Railways, which is building a line from Norfolk, Va., west and north to a point in West Virginia, has plans made for building a branch from a point on the main line in Virginia north to Richmond. The old roadbed of a line which was projected from Manchester to the mines at Midlothian, about 13 miles, is to be widened and extended into Powhattan to connect with the Tidewater & Western, which it is said has been bought by the Virginian Railway. The Tidewater & Western, formerly the Farmville & Powhattan, is a narrow gage line operating about 89 miles of road in Virginia. From Manchester entrance is to be made over the James river above Belle Isle, at the west end of the city.

Waco, Hamilton & Brownwood.—Incorporated in Texas with $120,000 capital and office at Austin. The company proposes to build a line from Waco, Tex., west through McLennan, Bosque, Hamilton, Comanche, Mills and Brown counties to Brownwood, 120 miles. J. B. Baker, J. S. McLendon, H. S. Shear and S. Sanger, of Waco; J. A. Austin, B. S. Smith and O. F. Johnson, of Brownwood, and J. L. Spurlin and J. T. James, of Hamilton, are incorporators.

Western Pacific.—Track is reported laid from Salt Lake City, Utah, west to a point 21 miles beyond the Utah-Nevada state line, 143 miles. Track-laying is being pushed from that point west, and will also be started this month at Winnemucca, Nev., and at Marysville and Stockton, Cal.

White River Valley.—See Chicago, Milwaukee & St. Paul.

Wichita Falls & Northwestern.—This road has been extended from Burkburnett, Tex., north to Kell, Okla., 14 miles.

Yellowstone Park Railroad.—See Oregon Short Line.

Yosemite Valley.—This road has been extended from Bagby, Cal., east to the Yosemite National Park at El Portal, 30 miles.

RAILROAD CORPORATION NEWS.

Atchison, Topeka & Santa Fe.—It was announced last week that the subscriptions to the $26,000,000 10-year 5 per cent. convertible bonds offered to shareholders at par would, it was estimated, amount to about $10,000,000. The issue was not underwritten.

Bald Eagle Valley.—The Pennsylvania is to exchange three shares of its capital stock and $50 in cash for each share of the outstanding 33,463 shares of the Bald Eagle Valley. The Bald Eagle Valley runs from Vail Station, Pa., to Lockhaven, 51 miles, with 43 miles of branches. It is leased to the Pennsylvania, which owns nearly half of the stock. The annual dividend rate has been 10 per cent., and in May, 1906, an extra dividend of 9 per cent. in stock was paid.

Bangor & Aroostook.—Brown Bros. & Co., New York, are offering at a price to yield about 5½ per cent $900,000 5 per cent. series D car trust notes, dated April 1, maturing in 20 semi-annual instalments beginning October 1 1907. The notes are secured on 300 flat cars, 706 box cars, 40 stock cars and 6 cabooses.

Buffalo Terminal Association.—See Wabash.

Chicago Railways Company.—A hearing on the following plan will be held on July 29 and the discharge of the receivers of the Chicago Union Traction and of its subsidiaries and the turning over of their property to the Chicago Railways Company will then be asked. The new company will make an issue of first mortgage 25-year 5 per cent. bonds to provide funds for rehabilitation, additions, etc. The amount of these bonds is not limited; the only restrictions are those as to the purposes for which they can be issued under the mortgage. There will also be $32,800,000 consolidated mortgage 20-year 4 per cent bonds, of which series A, $15,000,000, will be prior to series B, $17,800,000; also, $5,000,000 20-year 4 per cent. sinking fund income debentures, $4,500,000 5-year 6 per cent. collateral notes and $5,000,000 10-year 5 per cent. collateral notes. Income participation certificates of three classes aggregating $23,250,000 will also be issued. Immediate cash requirements are to be supplied by two syndicates; the first to furnish $12,000,000 for rehabilitation and the second $4,000,000 to cover the receivers' certificates, car trust and other notes, and organization expenses.

Chicago Union Traction.—See Chicago Railways Company.

Delaware & Hudson.—See Troy & New England.

Fort Dodge, Des Moines & Southern (Electric).—The common stock of this company has been increased from $1,500,000 to $5,500,000 and the preferred stock from $1,000,000 to $1,200,000. There have been authorized $6,500,000 refunding mortgage bonds, of which $3,500,000 is reserved to retire an equal amount of authorized first mortgage 4½ per cent. bonds of 1931. The company expects to open by September 1 a line from Des Moines, Iowa, to Fort Dodge, about 80 miles. It will be operated by electricity for passenger service and by steam for freight. A part of the road consists of trackage rights over the Newton & Northwestern line, from Kelly to Lanyon, 37 miles, which has been electrified. A branch is being built from Kelly to Ames and a four-mile branch from Colfax to Doddard is in operation, being leased to the Newton & Northwestern. The Newton & Northwestern runs from Newton, Iowa, to Rockwell City, 102 miles, and has been acquired by the F. D., D. M. & S.

Lake Shore & Michigan Southern.—See Mahoning Coal Railroad.

Mahoning Coal Railroad.—A dividend of 6 per cent. on the $1,500,000 common stock will be paid August 1, to stockholders of record July 18. This is the same rate as was paid February 1. The company is leased to the Lake Shore & Michigan Southern, which holds $865,900 of the common stock. In 1906 the company paid 10 per cent.

Minneapolis, St. Paul & Sault Ste. Marie.—The directors have authorized an increase of the common stock from $14,000,000 to $28,000,000 and of the 7 per cent. non-cumulative preferred stock from $7,000,000 to $14,000,000. Only about $4,000,000 of the new stock will be issued now.

Mobile, Jackson & Kansas City.—Control of this company, it is understood, has passed to L. S. Berg, the new President, and associates, the Yoakum interests having decided not to use the option which they held on the property.

Newton & Northwestern.—See Fort Dodge, Des Moines & Southern.

Norfolk & Ocean View (Electric).—This company, the successor of the Bay Shore Terminal, which was sold under foreclosure a year ago, has made a mortgage to the Baltimore Trust Company securing an issue of $1,500,000 5 per cent. bonds; of this amount $1,000,000 is to be issued at once to pay for the Bay Shore Terminal and for improvements, while the remainder is to be issued as needed for further improvements, extensions or rolling stock.

Pennsylvania.—See Bald Eagle Valley.

St. Louis, Brownsville & Mexico.—Whitaker & Co., St. Louis, are offering, at a price to yield 6.10 per cent., a block of the $1,600,000 5 per cent. notes due November 1, 1910, being part of an authorized issue of $3,000,000. The proceeds will be used for additional equipment, spur tracks and other facilities.

Troy & New England (Electric).—Control of this company, which runs from Troy, N. Y., to Averill Park, nine miles, has been acquired by the Delaware & Hudson.

Union Pacific.—It is understood that about $1,000,000 of the $75,000,000 20-year 4 per cent. convertible bonds were subscribed to. The issue was underwritten.

Wabash.—This company has arranged to extend for one year, at 5 per cent., $350,000 of the $835,000 6 per cent. Buffalo Terminal Association first mortgage bonds, which fell due on June 29. These bonds are secured on the Hamburg Canal strip, which the Wabash bought from the city of Buffalo for terminal purposes. They are guaranteed principal and interest by the Wabash.

White Pass & Yukon.—A semi-annual dividend of 4 per cent. on the £1,375,000 ($6,875,000) stock was paid on July 15. Previous dividends have been as follows: 2½ per cent. in 1903, 5 per cent. in 1904, 3½ per cent. in 1905, 5 per cent. in 1906 and 3 per cent. last January.

RAILROAD GAZETTE

ESTABLISHED IN APRIL, 1856.

PUBLISHED EVERY FRIDAY BY THE RAILROAD GAZETTE AT 83 FULTON STREET, NEW YORK
BRANCH OFFICES AT 375 OLD COLONY BUILDING, CHICAGO, AND QUEEN ANNE'S CHAMBERS, WESTMINSTER, LONDON

EDITORIAL ANNOUNCEMENTS.

THE BRITISH AND EASTERN CONTINENTS edition of the Railroad Gazette is published each Friday at Queen Anne's Chambers, Westminster, London. It contains selected reading pages from the Railroad Gazette, together with additional British and foreign matter, and is issued under the name Railway Gazette.

CONTRIBUTIONS.—Subscribers and others will materially assist in making our news accurate and complete if they will send early information of events which take place under their observation. Discussions of subjects pertaining to all departments of railroad business by men practically acquainted with them are especially desired.

ADVERTISEMENTS.—We wish it distinctly understood that we will entertain no proposition to publish anything in this journal for pay, EXCEPT IN THE ADVERTISING COLUMNS. We give in our editorial columns OUR OWN opinions, and these only, and in our news columns present only such matter as we consider interesting and important to our readers. Those who wish to recommend their inventions, machinery, supplies, financial schemes, etc., to our readers, can do so fully in our advertising columns, but it is useless to ask us to recommend them editorially, either for money or in consideration of advertising patronage.

OFFICERS.—In accordance with the law of the state of New York, the following announcement is made of the office of publication, at 83 Fulton St., New York, N.Y., and the names of the officers and editors of The Railroad Gazette:

OFFICERS:

W. H. BOARDMAN, *Pres. and Editor*
E. A. SIMMONS, *Vice-President*
RAY MORRIS, *Secretary*
H. S. CHISOLM, *Treas.*
I. B. JONES, *Cashier*
L. B. SHERMAN, *Western Manager*

EDITORS:

RAY MORRIS, *Man'g Editor*
BRAMAN B. ADAMS
CHARLES H. FRY
RODNEY HITT
GEORGE L. FOWLER
FRANK W. KRAEGER
HUGH RANKIN
BRADFORD BOARDMAN

CONTENTS

VOL. XLIII., No. 4. FRIDAY, JULY 26, 1907.

The state of New York is to regulate the working hours of railroad telegraph operators beginning October 1, or five months before the Federal law on that subject goes into effect. The New York act, given in another column, is so clumsily drawn that in parts it is difficult to make sense of it; but its main features appear to be: 1. Eight hours a day's work, except in extraordinary emergency, for all telegraph and telephone operators who have to do with the movement of trains, including despatchers at headquarters and towermen at interlockings. 2. Ordinary block signalmen communicating solely by bell code seem not to be included. 3. The penalty for violation lies against the railroad company, not the employee. 4. Half of any penalty recovered goes to the informer. 5. A road or part of a road running less than eight passenger trains each way each week day is exempt, unless it usually runs 20 freight trains each way each week day. The purpose of this law is commendable, but, like that already in force in Maryland, it may easily do much harm. On the Baltimore & Ohio some of the operators who had their hours reduced by the benevolent legislature for the purpose ostensibly of increasing the safety of trains, employed their freedom to work as operators for the Western Union, or in other outside business, thus increasing instead of diminishing the strain on their bodies and minds. This condition, and the impossibility of regulating by statute the management of operators in times of emergency, make plain the futility of a law of this kind, except as a lever to raise the operators' wages, which, no doubt, was its chief purpose. With suitable relief arrangements for Sundays and holidays, a ten-hour day is reasonable in the great majority of offices, and an eight-hour law is simply a crude measure for punishing those railroads which have paid stingy wages or have not employed enough relief operators. In the future as in the past the railroad superintendent who desires reliable service must depend, not on laws but on his own judgment and vigilance. To keep men from sleeping on duty, or from wasting their energies when off duty he will be obliged, first, to find operators with consciences and, second, to keep himself constantly informed as to how they habitually spend their time, for they will impair their efficiency by reason of bad judgment as well as from defective moral character. With roads as important as parts of the Delaware & Hudson main line exempted from this law, and with the different exceptions and hour limits in the Federal law, the situation on New York roads, after the Federal law goes into effect will be confusing. The most immediate and practical problem which an eight-hour law presents to the railroad manager is that of securing a supply of telegraphers. Good operators are scarce enough now. Unless we are going to use automatic block signals everywhere, or depend wholly on electric bells and telephones, it will be necessary to establish telegraph schools; and not only that, to also take the necessary measures to get competent young persons to enter the schools.

"It will be a sad day for the people of North Carolina when its citizens are prohibited by acts of the legislature from asserting any right guaranteed to them by the Constitution of the United States." *Justice Pritchard.*

The law passed by the last North Carolina legislature forbidding the larger railroads to charge passengers more than 2½ cents a mile went into effect July 1. The Southern Railway applied to the Federal Circuit Court at Asheville for an injunction, on the ground that this law was confiscatory and therefore repugnant to the Constitution of the United States. This injunction was granted, the court at the same time ordering that, pending a decision, the railroad should with each ticket issue a refund coupon representing in each case the difference between the existing rate and the rate proposed by the new law. This the railroad proceeded to do, charging for tickets at the old rates. Because they continued to sell tickets at the old rates the District Passenger Agent and the City Ticket Agent of the road at Asheville were arrested by the state authorities, indicted, tried in a state court and sentenced each to thirty days in the chain gang. Two days later Judge Pritchard, of the Federal court, issued writs of habeas corpus, under which the two passenger men were discharged, and the whole matter will be determined by the United States Courts. This action of the Federal

judge is suggestive of the protection which the United States courts can be depended on to give to corporations or individuals who are unconstitutionally oppressed by the operation of a state statute. It is particularly important, in view of the numerous cases in which the railroads are now facing serious reductions in earnings as a result of recently enacted state laws. Justice Pritchard in his opinion said:

"The penalties [$500 for each violation] prescribed by the state statute for charging more than the statutory rate are so enormous that if permitted to be enforced they would practically bankrupt the railroads in an exceedingly brief time and before a final hearing could be had in the case, and thus place the carrier in a position where it would be powerless to assert the right guaranteed to it by the constitution of the United States. If the criminal prosecution against the agents, conductors and employees is permitted to continue, the managers of the railroads cannot successfully operate their trains, carry the mails or continue their usefulness in interstate commerce . . . Any system of penalties which is intended to have the effect and which is so framed as to have the effect of closing the doors of the courts to a judicial inquiry as to rates, is, in consequence of that fact, unconstitutional and void. The penalty section of the act in question clearly attempts to do this. It imposes upon the company as a penalty for an unsuccessful attempt to appeal to the court, no matter how bona fide its bill is made, such enormous fines and penalties . . . as to burden the challenger of the act in the courts so as to make it, if the penalties were valid, practically impossible for such an appeal to be made."

There is nothing new or startling in this stand of the Federal court. The instance is only one more example—a gratifying one—of the value of the Federal courts as checks on hasty action of local officers. The people of North Carolina are entitled to have the low-fare question tested, but only in an orderly way. If 2½ cents is too low a rate, the state may, by arbitrarily enforcing it, bankrupt its servants, the railroads, which make living in that state possible. The final decision will probably be referred with all possible despatch to the United States Supreme Court. In Alabama the low-rate law had a clause punishing every railroad which should even attempt to have its rights adjudicated by a Federal court by taking away its right to do business. This clause was promptly condemned by the Federal court. North Carolina has been equally fatuous and has been halted with equal suddenness.

THE NEW EXPENSE ACCOUNTS.

In our issue of June 21 we commented on the new classification of operating expenses ordered by the Interstate Commerce Commission to go in effect as compulsory on July 1. We criticised this accounting system, primarily on the ground that while the proposed system provided well for one primary use of statistics, it provided quite imperfectly for the other, that is to say, it gave a very good check on income and expenditures but did not afford executive officers the best possible measure with which to control the operation of their property. Besides this defect the requirement that a specific charge be made each year for depreciation of equipment and the likelihood that this compulsory depreciation allowance would be extended to way and structures, while theoretically correct, in actual practice is sure to do a great deal of harm to undeveloped or only partially developed properties which have always believed, in accordance with American railroad tradition, that it was better to expend money on the property when you had it and say nothing about it than to advertise to all the world that you were not spending money on the property because you did not have it to spend.

We urged in our brief comment on this subject that the enforcement of these regulations be postponed for a year. The Commission has shown no interest in this proposal, however, although it has received letters on the subject from a very considerable number of railroad executives. The situation as it stands, therefore, is that the railroads must keep a very elaborate set of primary expense accounts exactly in accordance with the forms set for them by the Interstate Commerce Commission. If they desire to keep other sub-divisions of these accounts besides those indicated by the Commission they may do so, subject to the Commission's approval, but they must at all events keep a mass of records, which, we must frankly say, have not been drawn up with the skill and thought which should have been given to a subject so important. The first revised issue of the classification of operating expenses took effect July 1, 1894, and the second revised issue became effective July 1, 1901. We think that the Interstate Commerce Commission will be the first party at interest to admit that these two previous classifications were imperfect, since, if the Commission did not consider them imperfect, it would presumably not have sought to change them. We are of the opinion that the errors in the new system are on the whole more hurtful than those in the old, and we believe it to be a matter of the greatest regret that at the time a change is made, to the very severe inconvenience of all concerned—a change, moreover, which works permanent injury to the continuity of records—that this change should not embody the very best thought of the day and generation.

The railroad accounting officers who co-operated with the statistician of the Interstate Commerce Commission in preparing these accounts did their work well so far as regards the function of account keeping with which they themselves were interested, but it is rather a ridiculous situation that the executive officers in charge of the property should be forced to accept a defective system of accounting which their own subordinate officers approved without acting or being empowered to act for their respective companies. A president or a general manager or a general superintendent, who is accustomed to use statistics with the skill and with the results obtained therefrom which have for many years occasioned American railroad statistics to excel those of all other nations in their scope and usefulness, ought surely to have a voice in a proposed change.

We believe that in spite of some individual hardships, the statistical systems of American railroads have been greatly improved since the Interstate Commerce Commission took hold of the matter in 1894. We believe that these statistical systems needed change, and that it is quite possible that the statistical systems of 1907 can be made to improve upon them materially in a number of particulars, but we are sure that the systems as now outlined by the Commission do not so improve upon the existing methods of record. In the good name of American railroad operation, therefore, why cannot the Commission leave it to be understood that its new orders, as promulgated, are experimental orders, and during the next year why can it not give earnest thought to the suggestions which have been made, and confer, not exclusively with one branch of statistical users, but with the other branch as well; that is to say, with the presidents and vice-presidents and general managers and general superintendents of American railroads? What is the use of violently overthrowing an existing statistical system to set up an inferior one in its place?

TRACK CIRCUITS IN RAILROAD SIGNALING.

The track circuit was put into practical use in automatic block signaling for the first time about the year 1879, having been experimented with for several years previous. These experiments appear to have consisted mainly of installing test sections and observing the results obtained from the use of various relays and track insulations. In this manner some information was gained as to the apparatus best suited to the usual conditions under which track circuits must work. If, along with these experiments or at any time since then, any series of tests were made, under the various climatic and physical conditions to which track circuits are subjected, to determine the electrical and insulation resistance of the track rails, the electrical resistance of bond contacts, the insulation resistance of insulated joints, the resistance of wheel contacts etc., such data seems never to have been given out for the public benefit.

Experience thus far seems to have taught us that a relay, with an electro-magnet having proportions and weight within certain limits, wound to a resistance of about four ohms and operating for pick up and release of armature at a minimum of about .065 and .030 amperes respectively, is the most satisfactory with the usual track circuit.

As track circuits equipped with such relays are credited with giving good service and as a series of tests to determine the characteristics and behavior of track circuits would entail not only considerable labor and expense but the use of some instruments which most signal engineers do not have, it is easy to understand why this subject has not been more thoroughly investigated.

Every signal engineer at times has track circuit failures, some of them serious, which he cannot understand and which he cannot find a reason for. Take, for example, the case reported by an engineman the other day where an automatic signal did "queer stunts" after the train had entered a 3,000-ft. track section at the battery end. Had the signal engineer known that the maximum resistance of the track circuit with its 80-lb. rail could be as much as .9 of an ohm; that the probable insulation resistance of the rails from the ground during the weather existing at the time was about five

ohms, and that the insulation resistance of the insulated joints at the relay end of the section had dropped to four ohms each, he could have readily figured the probable cause of the unruly behavior of the signal as leakage of current to the four-ohm relay of the section in question from the adjacent track circuit battery.

The track circuit does not seem to have received its full share of the investigation and improvement that have been under way in signaling during the last few years, and particularly so since it is now considered an essential factor in block signaling. It is doubtful if many signal engineers in planning their installations give it much consideration other than, perhaps, to fix a limit on its length and to make special provision for protection where a foreign current is known to exist.

It is apparent that the track circuit is regarded by many as a fixed institution in signaling, and that the positiveness of its operation under almost any condition or circumstance is beyond question or need of study. In view of the information and data on the subject available, ought this idea to prevail?

At the last meeting of the Railway Signal Association the following questions were presented for consideration, but provoked little discussion:

"1. It is noticed that when track relays are shunted, current is not entirely absent with a train in the block. What current does the relay receive under such conditions?

"2. Would a relay, able to pick up at .030 ampere and release at 50 to 75 per cent. of the pick up, be desirable, also, with such a relay, could longer blocks be used?

"3. What would the ideal pick up and release points be for a 4-ohm relay?"

These questions might well have engaged the attention of the members present, and along with them the following might have proved profitable:

(*a*) Are long track sections as safe, as efficient and as economical as short ones?

(*b*) Is not the pick up current of .065 ampere and the release current of .030 ampere, as lately adopted by the Railway Signal Association for track relays, too low for safe working under usual conditions?

(*c*) Should track circuits be installed with the expectation of as safe operation with trains entering from the battery end as from the relay end?

(*d*) Would not two bonds of No. 6 B. W. G. iron wire give better results in track circuit operation than two of No. 8?

(*e*) Should not the cross-section of the ballast grade and the kind of ballast used be given more consideration in the installation of track circuits than at present?

(*f*) Would not two relays, one a four-ohm and the other approximately 16 ohms, the latter placed, in multiple with the track battery, at the incoming end of the section, be better than one relay?

(*g*) If when track relays are shunted, current is not entirely absent with a train on the track circuit, is there a point in such section where the shunt by the train is equally effective at both ends of the section?

All of these are questions affecting the behavior of the track circuit which a committee of the Railway Signal Association, aided perhaps by the signal companies, would do well to investigate.

THE EVOLUTION OF STATE RAILROAD COMMISSIONS.

Mid-summer of the present year finds all the state legislatures adjourned, most of them after extended sessions prolonged very largely by railroad questions. The railroad legislation mania—most of it anti-railroad—has been far and wide. It has reached the East with hardly less violence than the West and the South; and, in a large number of cases has been attended either with the creation of new state railroad commissions or the equipping of existing commissions with fresh powers. About 40 states now have railroad commissions, strong or weak. Sometimes heretofore they have been strong in powers while weak in practice; in other cases weak by statute but strong by their intelligent leadership of public opinion. Taken as a whole, the result of the last six months of state lawmaking and, even more, of the popular attitude, has been positive and decided evolution of state railroad commissions. For better or for worse, they will, in the immediate future, be more assertive bodies.

The obvious tendency of the season's lawmaking has been to make the advisory into the regulating commission—and the word "regulating" must here be used in a very strong sense. It has extended not only to regulation of rates but to regulation of other matters too numerous to cite. One need only go to the Public Service Commissions Law of New York state to see what it means; though this is one of the most extreme examples. In some of the states also, if we are not mistaken, where the powers of the commissions have previously been so extensive as to be almost farcical, they have been still further overloaded with functions. With existing problems of railroad regulation as the while growing more intricate it would seem as though railroad matters alone would give a state commission enough to do and more. But when to railroads is added warehousing, and to warehousing, the express business, and to the express business, the telephones and to the telephones, taxation and to all these in some cases general purview of corporations, it would seem as though legislators might have passed in the overloading process. The inevitable effect of this overburdening of a commission is to make it a jack of all trades and master of none. Yet in some states the revision of the commission laws makes one think of courts and legislatures rolled into one and vested by law with omniscience.

A bad feature of this radical evolution of the state commissions has been a kind of compulsory demagogism. That which is created, by the inexorable law of human nature, must reflect the spirit and policy of the creator. It is too much to expect that commissions, most of them made up of politicians, will set themselves against a tide of hostile popular and legislative sentiment, even though transitory. In the past, some commissions have been too subservient to the railroads. In most cases now and for some time to come, the railroads are likely to find such commissions hostile, not as an expression of real feeling, but as a matter of personal policy in order to hold their places. Sympathy in such cases with railroad corporations is not unqualified. In the past they have been content with the "political" commission as being one that could be "handled," if not otherwise, by the infirmity of its own ignorance. Would it not have been better if, in years gone by, the railroad influence had been more freely used for infusing intelligence in the railroad commissions even at the price of their greater independence? This moral default of the railroads heretofore, to a considerable degree spells demagogism now. Corporation foresight might have averted some of the present sad reflections of hindsight.

But in the radical evolution of railroad commissions we front a condition, not a theory, and the primary question is the extraction from that condition of the final equities. Here there is solid ground for hopefulness. Remembering that it is the *personnel* of a state railroad commission that counts, it requires no excess of optimism to discover in present radicalism an ultimate residuum of good. Nothing tries out incompetency like responsibility. It is the overdoing of a bad system or bad thing that brings its ultimate correction. The wider and more ramified the functions of a state commission that is inefficient or invertebrate, the surer is its exposure and the louder the call for brains and courage. Again, as the functions of the commissions grow more and more technical, the more conspicuous to both public and legislative vision becomes the need of the trained mind. A force working toward the same end is the advance into debatable ground of the state and interstate questions relating to public service, where the demand for intelligence and special knowledge on both sides is imperative. Finally there are the courts in their double office of nullifying bad commission rulings and exposers of commission weakness; while, as regards demagogical drift of the public and its law makers, it can hardly survive any really serious railroad calamity that touches the pocket nerve and the means of livelihood. It will not be surprising if next year's sessions of the state legislatures, as concerns the railroads, prove as tame as those of the past six months have been fierce.

Deeper searched and tried, that period beginning with the opening of the present year, though one of storm, will probably in the outcome be deemed a clarifying tempest in its development of the railroad commissions. They are now bodies in transition and it rests partly with them, partly with the public and partly with the railroads to determine whether the transition shall be upwards or downwards and whether the personality of the political officeholder shall or shall not give way to character and training. Without these last, railroad law may be piled on law and powers be amplified or restricted, but all in vain. Toward that higher ideal of state commissions better qualified than now, it looks as though events were trending under the urgency and gravity of the railroad problem. Two or three years hence—perhaps earlier—there will be sharper light on the subject after we begin to see clear water below the weltering foam of the railroad legislation of the last half year.

Train Accidents in June.[1]

Our record of train accidents occurring on the railroads of the United States in June includes 16 collisions and 27 derailments, 38 accidents in all. This record is not published in full, as was formerly done, except in the cases of the few accidents which are especially prominent—in the present instance two collisions and one derailment. The record of "ordinary" accidents—which term includes, for our present purpose, only those which result in fatal injury to a passenger or an employee or which are of special interest to operating officers—is given in the shape of a one-line item for each accident, showing date, location, class and number of deaths and injuries.

This record is based on accounts published in local daily newspapers, except in the cases of accidents of such magnitude that it seems proper to send a letter of inquiry to the railroad manager. The official accident record published quarterly by the Interstate Commerce Commission is regularly reprinted in the *Railroad Gazette*.

The most serious accident in the present list is the collision which occurred at Hartford, Conn., on the 23d, killing eight employees. The next most serious is the collision near Pittsford, N. Y. There are only three others in the list which caused the death of more than two persons each.

The Hartford collision, which happened about 7 p.m., appears to have been within or near the yard limits. The main line of the Highland division of the New Haven road from Hartford westward consists of two tracks, but it is operated as two separate single-track lines, one of the tracks being used exclusively by frequent short-distance passenger trains which formerly were propelled by electricity. It appears that one of these passenger trains backed through a cross-over track on to the other main track in entire disregard of the fact that a work-train had the right of way on that track; and it collided with the caboose of the work-train, wrecking the car and killing or injuring nearly all of the 40 men who were in it. The wreck took fire but the flames were quickly extinguished by the city firemen. Two of the injured men subsequently died, making the total number of fatalities 10.

The collision at Pittsford occurred about 11 p.m., and the persons killed were a station agent, one passenger, a brakeman, an unidentified man, and a boy who was riding on one of the locomotives. The trains were an eastbound passenger train and a westbound freight; both engines were wrecked and the smoking car of the passenger train demolished. The wreck took fire but the damage from the flames was not great. The freight train was wrongfully running on the time of the passenger train.

In the derailments on the Southern Railway the 5th and the Great Northern the 15th, passenger trains were thrown down embankments with much damage. In the Great Northern accident the whole train of nine cars took fire and was burned up, with the exception of a mail car. In the derailment on the Southern Pacific on the 2d, the passenger cars were overturned while running at full speed at 3 a.m. The derailment on the Baltimore & Ohio Southwestern on the 20th at 4 a.m. was due to the fall of a rock in a tunnel which occurred at the precise moment that the mail car of this train was passing the spot.

The persons recorded as killed and injured in connection with the derailment at Reddick, Ill., on the 4th were by-standers who were killed or injured by the explosion of a car of gasolene some little time after the cars had run off the track. The heated journal which caused the derailment set fire to the wreck and as one of the cars was loaded with gasolene, the explosion was inevitable. It broke windows and chimneys in houses throughout the village.

One accident, not prominent by reason of cost or fatality, was notable for its novelty. It was a derailment at Suspension Bridge, N. Y., on the 15th. Three freight cars broke from a Grand Trunk train of 11 cars in the middle of the steel arch bridge and plunged into the Niagara Rapids, 250 ft. below. In leaving the track the cars did considerable damage to the upper and lower decks of the bridge. When they struck the water they were not badly injured, but the current of the rapids carried them to the whirlpool, where they were broken into pieces. A brakeman had a narrow escape.

[1]Abbreviations used in Accident List:

rc.....Rear collision.
bc.....Butting collision.
xc.....Other collisions; as at crossings or in yards. Where only one train is mentioned, it is usually a case of a train running into a standing car or cars, or a collision due to a train breaking in two on a descending grade.
b.....Broken.
d.....Defective.
dr.....Defect of roadway.
eq.....Defect in car or engine.
n.....Negligence
unf.....Unforeseen obstruction.
unx.....Unexplained.
derail.....Open derailing switch (negligence of engineman or signalman).
ms.....Misplaced switch.
acc. obst..Accidental obstruction.
malice....Malicious obstruction of track or misplacement of switch.
boiler....Explosion of boiler of locomotive on road.
fire.....Cars burned while running.
Pass.....Passenger train.
Ft.....Freight train (includes empty, engines, work trains, etc.).
*Wreck wholly or partly destroyed by fire.
†One or more passengers killed.

Of the electric car accidents reported in the newspapers in June, four—two collisions and two derailments—resulted fatally; the total deaths reported in the four accidents being six and the total injuries 50.

Robert J. Bailey, of the Monongahela River Consolidated Coal & Coke Co., which company owns 600 coal cars, has invited other private car owners to attend a meeting in Cleveland next Thursday with a view to presenting a united demand upon the railroads for greater compensation for the use of private cars in freight service. Formerly the rate paid for private cars was the same as that paid by the railroads to each other for the use of cars owned by the railroads, namely three-fourths of a cent a mile. Later the interchange rate between railroads was reduced to six-tenths of a cent, but the rate for private cars was left unchanged. Five years ago the railroads adopted the per diem system for their own cars, but continued the mileage rate for private cars, most or all of the private car owners finding that the per diem basis (20 cents a day at first and later 25 cents) was less profitable to them than the mileage rate. But now, with the per diem rate for railroad companies' cars raised to 50 cents, the boot is on the other foot; or at least it appears that it is so in some cases. Fifty cents a day is likely to average a good deal better than 7½ mills a mile, or even 1 cent a mile, and so, of course, the private car owners will now go in strong for reform. And how can the railroads refuse? Quite likely many of them will not want to refuse; but whatever the inclination of any road may be, the only reasonable and just stand to take is to approve a change to per diem. The per diem principle was adopted by the railroads as between themselves, not because it was more profitable—though to lenders it usually was profitable—but because it was rational and because by its use it is possible to do away with the opportunity for injustice and error that is inherent in the mileage system. If there is any difference between the railroads and the private car owners it should be one of rates and not one of methods. Fifty cents a day may or may not be a fair price—as between railroads the rate is supposed to be unimportant, as both sides are or should be lenders and both sides borrowers—but any mileage rate is unfair because it is not based on the actual service of the car.

A Criticism of the Salt Lake City Union Station.

Pittsburg, Pa., July 15, 1907.

To the Editor of the Railroad Gazette:

The *Railroad Gazette* of July 12 contains an article describing the new union station to be built by the Harriman Lines at Salt Lake City. Presumably the publication of such an article is an invitation to your readers to criticise the lay-out. If so, it seems permissible to remark that it is a conspicuous illustration of inef-

ficiency per unit of cost. The passenger station, which is to cost $450,000 seems intended to provide for a very large business. Seven through passenger tracks with island platforms and two local or terminal tracks are shown behind the station. This indicates a large contemplated passenger train movement. It is probable that the station is to be used by passenger trains in both directions, yet all baggage must be handled at the western ends of the platforms. This means that baggage to and from eastward trains—having the baggage car in front—must be conveyed almost the entire length of the various platforms, apparently at grade with great delay, expense of handling and inconvenience to passengers.

Just how the express and mail matter is to be handled between the rooms at the easterly end of the building and the trains is not clear. Apparently it is to be conveyed across the tracks at grade and then along the island platforms, like the baggage. It looks as if an additional tunnel or subway across the tracks near the east end of the station with lifts at the island platforms and a longitudinal subway to the basement should be added, even at the expense of cutting out some of the æsthetic features of the building, if necessary to reduce the cost. Another alternative would be to build a tunnel for baggage, express and mail opposite the center of the station with a longitudinal tunnel and lifts at both ends of the building. We think there would be no doubt of the adoption of one or the other of these alternatives east of the Mississippi river.

The arrangements for handling passengers between the station and trains are apparently quite as archaic as those for handling baggage, mail and express. The communication between the waiting room and the trains is apparently by a grade crossing of the tracks in front of the waiting room and by the island platforms. This practically restricts the station to handling one, or not more than two, trains at a time, unless the trains are quite short, not exceeding 440 ft. long. It is not clear why seven passenger tracks are needed at a station where but one train at a time can be handled. The inefficiency of such an arrangement may be seen daily at the Mount Royal station of the Baltimore & Ohio in Baltimore, at the Union Station of the Pennsylvania Railroad in Baltimore, and at the Pennsylvania station in Altoona, although at none of these points, if I recollect correctly, are there more than five tracks. A similar lay-out formerly existed at the Pennsylvania station at Harrisburg, but several years ago it was found necessary to change it by installation of overhead bridges from the waiting room to the island platforms, so that trains could be handled on all of the tracks simultaneously. The fact is that such a lay-out is at least 20 years behind the times.

I must confess to a feeling of some astonishment that the management of the Harriman Lines, whose reputation for efficiency is high, should have adopted such a lay-out, and that the *Railroad Gazette* should publish a description of it without an explanation of its necessity or a word of warning that it was intended to instruct the public as an example of how not to do it. S.

Proposed Southern Pacific Hospital at San Francisco.

The Southern Pacific is about to build a new railroad hospital in San Francisco to replace the one last year destroyed by fire. The site is the block north of the entrance to Golden Gate Park bounded by Fell, Hayes, Baker and Lyon streets. The new hospital will have 225 beds and will cost $600,000.

The building, which will be built largely of reinforced concrete, will be in the form of an H. There will be an east and a west wing with an administration building in the center connected with the wings by wide corridors. The main front of the building will be 220 ft. 8 in. on Fell street. Each wing will be 86½ ft. x 150 ft., with the administration building 72 ft. x 168 ft. There will be four stories. The frame will be reinforced concrete with the outside walls brick and the outside surface finished in white stucco. All partitions will be made of steel studs with metal lath and plaster and the floors of glazed ceramic tiles of different patterns. The only woodwork in the building will be the doors and windows. The different floors will be connected by easy inclines, thus avoiding the necessity of stairs, and there will be two elevators, one for general passenger service and the other to be used in connection with the ambulances and the operating room. A vacuum and cleaning plant is to be installed and all food rooms are to be cooled with a brine system of refrigeration. On each floor above the basement the corridors connecting the wings with the central part of the building have been widened so as to form sun rooms with large glass windows.

Proposed Southern Pacific Hospital at San Francisco.

On the lower or basement floor is the kitchen, with all necessary store and refrigerator rooms, dining-rooms, bath-rooms, drug-room and chemical laboratory, X-ray, hot and steam rooms, machinery room, and foreign wards with their dining-rooms in connection. In each wing on the first floor are to be two 12-bed wards with their service kitchen, bathrooms and rooms for nurses and internes, while the administration building on this floor has two large general waiting rooms for men and women, a library, offices for the chief surgeon and staff, with consultation, examination and dressing rooms. Each wing on the second floor is like the first floor, having two 12-bed wards, with service kitchens in connection, while the administration building on this floor has two 8-bed and three 2-bed wards, three single rooms with bath and nurses' rooms.

On the third floor there are two 8-bed and two 12-bed wards and 17 private rooms, with private room for visiting doctors, all equipped with service rooms, baths, nurses' rooms, etc. In the rear of the administration building, on this floor, are two large operating rooms connected with the sterilizing and anesthetic room, nurses' rooms and baths for doctors and nurses. The floors and wainscot of the operating, sterilizing and anesthetic room will be of ivory white unglazed vitrified tile, with wide plate glass windows, giving ample light.

In the rear of and directly opposite the center of this main building will be a four-story building 52 ft. x 116 ft. 9 in.,

and of the same construction, detail and finish. This to be used for the accommodation of the entire hospital staff. On the second and third floor of this annex will be four 6-bed wards, isolated by solid brick walls, to be used for contagious diseases.

The ideas and plans for the systematic operation of this large hospital plant are the work of Dr. F. K. Ainsworth, Chief Surgeon of the Southern Pacific. All details have been carried out according to his instructions. E. H. Harriman, President of the Southern Pacific, enlisted the services of Carrere & Hastings, architects, of New York City, in suggesting a design for the exterior. All plans for the work were prepared in the office of J. H. Wallace, Assistant Chief Engineer, and D. J. Patterson, Architect, of the Southern Pacific.

The Symmetrical Masonry Arch; Analysis According to the Elastic Theory.

BY MALVERD A. HOWE.

It has been established experimentally that the deformations of a masonry arch under a given loading correspond to those determined theoretically by means of formulas based upon the theory of elasticity. It may be concluded from this that the stresses within the arch ring vary according to the same theory. Only recently has the elastic theory been applied to masonry arches. A complete analysis is seldom made and quite often none is attempted, the dimensions of the arch ring being simply guessed or copied.

Much the same method was employed by the old builders of wooden bridges. They, to a certain extent, were excusable, as the theory of stresses was not commonly known in their time. But the designers of masonry arches in the present time have no such excuse as the elastic theory has been thoroughly worked out. It is true that the formulas and graphical methods have not, as yet, been made so short that anyone not familiar with the subject can in a few moments pass upon the correctness of a given design submitted for approval.

It requires time to check a design for an ordinary truss bridge, and there appears to be no good reason why the same amount of time should not be willingly spent in checking a design for a masonry arch. It is not necessary to determine the stresses for every possible loading upon an arch in order to be reasonably sure that the design is safe.

Assume that a design has been submitted and that its safety is questioned. The following method enables one to answer the question in a comparatively short time. Divide the span into 20 equal parts δx, and at the center of each division draw vertical lines cutting the axis of the arch ring. Beginning at the left, number the points so found on the axis 1, 2, 3, etc., up to the crown and number the symmetrical points upon the right of the crown 1^1, 2^1, 3^1, etc. Scale the co-ordinates of these points and call them x and y, the origin being taken at the left support. At each point scale along the axis to the right and to the left to a point half way to the adjacent points and call the sum of these distances $\delta \varsigma$. Or, if the arch axis is a curve of known radii the angle Φ from the crown to each point may be computed and then $\delta \varsigma' = \delta x$ secant Φ. Compute the moment of inertia I at each point and let $\Delta = \delta \varsigma \div I$ for each point. This will usually have a different value for each of 10 points on the left of the crown. The same values will, of course, obtain for the corresponding points upon the right of the crown.

If H_1 represents the horizontal thrust produced by vertical loading then

$$2\,H_1 = \frac{\Sigma\, m_x \Delta \left(y - \frac{\Sigma\, y\, \Delta}{\Sigma\, \Delta}\right)}{\Sigma\, y\, \Delta \left(y - \frac{\Sigma\, y\, \Delta}{\Sigma\, \Delta}\right)}$$

in which all of the factors are known quantities depending upon the dimensions of the arch ring, the shape of the axis, etc., and entirely independent of the loading, *with the exception of* m_x. The sign of summation indicates the sum of the factors for all points of the axis. In this case 20 in number. For example

$$\Sigma\, y\, \Delta = y_1 \Delta_1 + y_2 \Delta_2 + y_3 \Delta_3 \ldots\ldots\ldots\ldots\ldots\ldots y_{1'} \Delta_{1'}$$
$$\Sigma\, \Delta = \Delta_1 + \Delta_2 + \Delta_3 + \ldots\ldots\ldots\ldots\ldots\ldots\ldots \Delta_{1'}$$

etc., etc.

In Form A, columns 1 to 6 inclusive show the computations to be made. These are made but once as they are constant for the given arch ring. The factor m_x depends upon the loading. The loadings which should be considered are as follows:

(a) Load points, 1—1' inclusive.... } With a concentration
(b) " " 1—8' " } equivalent to uniform
(c) " " 9—1' " } moving load per ft. of
(d) " " 1—8' & 8—1' " } span multiplied by
(e) " " 8—9' " } Δx.
(f) Dead or fixed load alone.

Only (a), (b) and (f) need to be considered in computing H_1, as the values for the remaining loadings can be found by proper combination of the results obtained for (a), (b) and (f). These combinations are given in Form A.

The value of m_x at each point is simply the common bending moment produced by the given loading on a straight beam supported at the ends and having a span equal to that of the arch axis, *plus the common bending moment produced by an equal and symmetrical loading.*

In case of the dead load m_x is equal to *twice* the common moment as found from the ordinary equilibrium polygon. For a uniform load covering the entire span the same is true. In Form A the values of these moments divided by $\frac{1}{2}\ \delta x$ for each point are given for a unit load at each point. For any other load, multiply by the load. The values of $m_x \frac{2}{\delta x}$ are also given for unit loads at 1-8 inclusive in Form A. The sums of columns 10 and 12 must be multiplied by $\frac{1}{2}\ \delta x$ before substituting in the expression for 2 H_1 as indicated.

When the computations according to Form A are completed the values of H_1 for six different loadings are known and at an expense of but little time and labor. Any other loading such as a road roller can be considered in a like manner, remembering the significance of the factor m_x.

The next step is the determination of the moments at the left and right supports. Let them be represented by M_1 and M_2 respectively, then for all symmetrical loading such as a uniform load covering the entire span or the dead load in a majority of cases,

$$M_1 = H_1 \frac{\Sigma\, y\, \Delta}{\Sigma\, \Delta} - \frac{\Sigma\, m_x \Delta}{\Sigma\, \Delta} = M_2$$

in which m_x is the common moment at each point produced by the given loading on a beam supported at the ends.

All factors in the first term of the second member of this equation are known in computing the quantity $\Sigma\, m_x\, \Delta$. The values of m_x for each pair of symmetrical points may be combined and the sum multiplied by the common value of Δ for these two points. Table B gives the values of m_x so combined for a unit load at each point 1—1^1 inclusive. The computation of $\Sigma\, m_x\, \Delta \div \Sigma\, \Delta$ is a very short process. Having H_1 and M_1 for any given symmetrical loading and since $V_1 = V_2$ = one-half the loading, the equilibrium polygons can be readily constructed in their true relation to the arch axis. The ordinate between the arch axis and the equilibrium polygon at the support equals $M_1 \div H_1 = y_1$.

The equilibrium polygon may be located in another way. Above the spring line a distance $\Sigma\, y\, \Delta \div \Sigma\, \Delta$ and parallel to the chord of the arch axis draw a straight line A B. Construct the equilibrium polygon with a horizontal closing line, using the true H_1 as a pole distance. Above this line a distance $\Sigma\, m_x\, \Delta \div \Sigma\, \Delta$ draw a line A^1 B^1 parallel to the closing line. If now the two figures be superimposed so that these two lines A B + A^1 B^1 coincide

Form A.—To be Used in Computing H_1.

	1	2	3	4	5	6	7	8	9	10	11	12
			(1)x(2)		(3)x(4)	(2)x(4)		(6)x(7)		(6)x(9)		(6)x(11)
Point	y	Δ	$y\Delta$	$y - \frac{\Sigma y\Delta}{\Sigma\Delta}$	$y\Delta(y - \frac{\Sigma y\Delta}{\Sigma\Delta})$	$\Delta(y - \frac{\Sigma y\Delta}{\Sigma\Delta})$	Dead Load	$m_x\Delta(y - \frac{\Sigma y\Delta}{\Sigma\Delta})$	Unit load at 1-8 inclusive m_x	$m_x\Delta(y - \frac{\Sigma y\Delta}{\Sigma\Delta})$	Unit load at 1-1' inclusive m_x	$m_x\Delta(y - \frac{\Sigma y\Delta}{\Sigma\Delta})$
1							Insert TWICE the common moment for the G. L. on a beam supported at the ends		8		20	
2									22		56	
3									34		88	
4									44		116	
5									52		140	
6									58		160	
7									62		176	
8									64		188	
9									64		196	
10									64		200	
Sum												
		$\frac{1}{2}\Sigma y$	$\frac{1}{2}\Sigma\Delta$	$\frac{1}{2}\Sigma y\Delta$	$\frac{1}{2}\Sigma y(y - \frac{\Sigma y\Delta}{\Sigma\Delta})$			$\frac{1}{2}\Sigma m_x\Delta(y - \frac{\Sigma y\Delta}{\Sigma\Delta})$		$\frac{1}{2}\Sigma m_x\Delta(y - \frac{\Sigma y\Delta}{\Sigma\Delta})\frac{2}{\delta x}$		$\frac{1}{2}\Sigma m_x\Delta(y - \frac{\Sigma y\Delta}{\Sigma\Delta})\frac{2}{\delta x}$

$$2H_1 = \frac{\frac{1}{2}\Sigma m_x \Delta(y - \frac{\Sigma y\Delta}{\Sigma\Delta})}{\frac{1}{2}\Sigma y\Delta(y - \frac{\Sigma y\Delta}{\Sigma\Delta})} \qquad \frac{\delta x}{2} = \frac{1}{40}$$

H_1 for loads 1-8 and 8'-1' = $2H_1$ for loads 1-8
H_1 for loads 9-1' = H_1 for loads 1-1' minus H_1 for loads 1-8
H_1 for loads 9-9' = H_1 for loads 1-1' minus H_1 for loads 1-8 and 8'-1'

then the equilibrium polygon is in its correct position relative to the arch axis. For unsymmetrical loading

$$\left.\begin{matrix} M_1 \\ M_2 \end{matrix}\right\} = H_1 \left\{ \frac{\Sigma y \Delta}{\Sigma \Delta} - \left\{ \frac{\Sigma m_x \Delta}{\Sigma \Delta} + \frac{\Sigma m_x \Delta \left(x - \frac{l}{2} \right)}{\Sigma \Delta \left(n - \frac{\Sigma z^2 \Delta}{n \Sigma \Delta} \right) \frac{\delta x}{2}} \right\} \right.$$

The factors in the first and second terms of the second member have the same significance as for symmetrical loading. In the third term m_x is the simple moment for the given loading on a beam supported at the ends. As $\Delta \left(x - \frac{l}{2} \right)$ has two equal symmetrical values but *opposite in sign* for each pair of symmetrical points, the symmetrical values of m_x may be combined and the *difference* multiplied by the common value $\Delta \left(x - \frac{l}{2} \right)$. This is shown in Form B for loads 1-8 inclusive. In the denominator of the third term, n is 20 the number of the equal divisions into which the span was divided. $z = 2x \div \delta x$ and has the values 1, 3, 5, 7 .... 39. Since Δ is the same for a pair of symmetrical points, the symmetrical pairs of values of z^2 have been combined in Form B. Form B is quickly filled, and as a result the values of M_1 and M_2 for six different loadings are known.

Form B.—To be Used in Computing M_1 and M_2.

Point	1	2	3	4	5	6	7	8	9	10	11	12	13
				Dead Load		Unit Loads 1-1'		Unit Loads 1-8					
			(1)x(2)		(1)x(4)		(1)x(6)		(1)x(8)		(3)x(10)		(1)x(12)
	Δ	$x - \frac{l}{2}$	$\Delta(x - \frac{l}{2})$	m_x	$m_x \Delta$	m'_x	$m'_x \Delta$	m''_x	$m''_x \Delta$	m'''_x	$m'''_x(x - \frac{l}{2})\Delta$	z^2	$z^2 \Delta$
1				Moments produced by D.L. on beam supported at ends		20		8		4.8		1522	
2						56		22		12.4		1378	
3						88		34		18.0		1250	
4						116		44		21.6		1138	
5						140		52		23.2		1042	
6						160		58		22.8		962	
7						176		62		20.4		898	
8						188		64		16.0		850	
9						196		64		9.6		818	
10						200		64		3.2		802	
Sum					$\frac{1}{2}\Sigma m_x \Delta$		$\Sigma m'_x \Delta \frac{\delta x}{2}$		$\Sigma m''_x \Delta \frac{\delta x}{2}$		$\Sigma m'''_x \Delta (x - \frac{l}{2}) \frac{\delta x}{2}$		$\Sigma z^2 \Delta$

For symmetrical loading $M_1 = H_1 \frac{\Sigma y \Delta}{\Sigma \Delta} - \frac{\Sigma m_x \Delta}{\Sigma \Delta} = M_2$

For unsymmetrical loading $\left.\begin{matrix} M_1 \\ M_2 \end{matrix}\right\} = H \left\{ \frac{\Sigma y \Delta}{\Sigma \Delta} - \left\{ \frac{\Sigma m_x \Delta}{\Sigma \Delta} \pm \frac{\Sigma m_x \Delta (x - \frac{l}{2})}{\Sigma \Delta (n - \frac{\Sigma z^2 \Delta}{n \Sigma \Delta}) \frac{\delta x}{2}} \right\} \right.$

M_1 for loads 1-8 and 8'-1' = M_1 + M_2 for loads 1-8
M_1 for loads 9-1' = M_1 for loads 1-1' minus M_1 for loads 1-8
M_1 for loads 9-9' = M_1 for loads 1-1' minus M_1 for loads 1-8 and 8'-1'

For any loading the left reaction is found from the expression

$$V_1 = \frac{M_2 - M_1}{l} + R_1$$

where l is the length of the span and R_1 the common reaction for the given loading on a beam supported at the ends. Knowing H_1 M_1 and V_1 for any loading the true equilibrium polygon can be readily constructed.

The moving loads employed in Forms A and B produce maximum moments at the supports, the crown and in the vicinity of point 6' with a close approximation.

Thirty-three Passengers Killed in Michigan.

On the Pere Marquette Railroad near Salem, Mich., July 20, 33 passengers, nearly all of them employees of the railroad company, were killed in a butting collision between an eastbound passenger train and a westbound freight, and about 75 others were injured. These people were employees of the company, chiefly at Ionia, who were taking their annual excursion to Detroit, the special train being run for their accommodation. The passenger train met the freight in a cut on a sharp curve about one mile east of Salem. Two of the passenger cars were completely wrecked. The only explanation of the accident is that the conductor and engineman of the freight, who had received an order from the despatcher giving the times of the excursion train at the successive stations, misread the order. The engineman and fireman of both trains jumped off and, it appears, escaped without very serious injury.

A press despatch from Detroit says that Receiver Hannah, in charge of the operation of the road, has given orders that all the victims of the wreck be settled with the same as if they were passengers who had paid their passage.

The conductor of the freight train, it is said, has acknowledged that he read his orders wrong. He was arrested. Press despatches say that the engineman, fireman and one brakeman also read the orders wrong, reading that the time for Salem on the order was 9.25, when it was really 9.10. The engineman is at his home confined to his bed by injuries.

The Passing of the Pay Car.*

Republished from The American Magazine for July. Copyrighted, 1907, by The Phillips Publishing Co.

Railroading isn't any fun any more. Sordid commercial folk in Wall street, with never an idea in their noggins but to invest money and make it pay dividends, have improved all the romance out of life on the rails.

They have reduced grades and straightened kinks and eliminated low joints and high centers and wooden culverts and crazy bridges until a ride over the division is about as thrilling as walking to church. Air-brakes have so thoroughly crowded out the good old Armstrong kind that a brakeman has no use for skill or judgment or muscle or even a vocabulary in stopping a train. The engineer does all that is necessary with a slight twist of the wrist.

As for making a coupling, a brakeman no longer mines in the cinders on the back of the tank until he digs up a rusty old link and a couple of pins and, taking these in one hand and his life in the other, sprints down the center of an unballasted track and over unprotected frogs and guard rails 6 inches ahead of a string of cars rolling back at the rate of 15 miles an hour. No; in these days of slavish adherence to M. C. B. standards he just stands around smoking cigarettes and lets the cars couple themselves. No more does he fracture the handle of the fireman's coal hammer and his own peace of mind in vain endeavors to pound a stub switch open after a grilling summer sun has expanded the rails until they are stuck as tight as if they were welded. A fellow in a dog house on a pole away off yonder, by manipulating a few dainty levers, throws the switches for him.

They have replaced the little old eight-wheel engines, with their ear-splitting, staccato bark, with compound steel mountains, with cylinders like hogsheads and nozzles so big that the exhaust is gentle as a lover's whispered nothings, for no better reason than a desire to keep down coal consumption. Trains, instead of being made up of a dozen or so of pill boxes, now consist of a string of warehouses on wheels so long that when the front end is arriving at its destination the hind end is just pulling out at the other end of the division.

No more do engineer and conductor, watches in hand, make nice calculations on the time they can steal to make a meeting point that has a siding long enough to avert the necessity of sawing past. Roads are double-tracked and four-tracked and block-signaled till all a man has to do is to trundle along from block to block until his run is ended and repeat the process until he is retired on a pension.

Ah, no! Railroading isn't what it used to be. But if those Wall street money grubbers had only left us the pay car all else could have been forgiven. Do you remember how, in the good old days, the decrepit jokes about what was to be done when the pay car came were taken out of the moth balls along about the 10th of the month and dusted off and put through their paces? How, toward the 15th, a feeling of sprightliness gradually stole over every one from the wipers in the roundhouse to the lucky dogs who had passenger runs? How this exuberance swelled in volume as anticipation became more keen, until toward the 18th everybody went about with a broad grin and nerves all a-tingle the way you feel when the orchestra is playing the creepy music to accompany the villain's midnight assault with intent to kill? How, still later, everybody drifted down to the depot about four times a day to ask the station agent if he had heard anything about the pay car, until he grew as crabbed as a setting hen? How, about the 22nd, the waiter girls at the Depot Hotel would give you a saucy wink and bring you a great, juicy, melting, extra special wedge of pie you didn't order, for dessert, along with the ice cream and nuts and raisins and fruit and pudding and shortcake you did order? Those girls knew how to work a fellow for tips about pay day, didn't they?

At last, one day as you were letting 'em down the hill into the junction, the operator pulled his train order signal on you. Your heart leaped into your throat because you knew—— Well, you just felt it in your bones. You went down the side of the car without knowing how you did it and sprinted for the switch to

*By C. F. Carter.

head 'em in on the passing track, and then flew to the station on winged feet, leaving the engineer to hold 'em with the driver brakes or let 'em run out at the lower end as he chose. And the grumpy old curmudgeon stopped 'em beautifully, without so much as saying "boo," when on any other occasion he would have unloosed a torrent of vituperation that would have set the ties on fire, and would have followed it up by heaving a monkey-wrench at you if you had been in range.

There behind the counter was the Old Man looking over the shoulder of the operator, who was spelling out the order without breaking oftener than every second word:

"Train No. 7, Conductor Flatwheel, Engineer Poundem, will meet Pay Car special, Conductor Linkenpin, Engineer Moriarty, at Emerson."

Such an air of nonchalance as Old Man Flatwheel did assume as he turned away to discuss with the hind man the advisability of making a switch of that through car of corn next the engine to get it behind the way cars so we wouldn't be bothered with it at Lyons in doing our work on those heavy grades, and affected to forget that he was getting orders until the operator called him over to sign them. He was so slow about his signature that before the despatcher's O.K. was received you looked out of the big bay window and saw the section gang that was working just beyond the Y throw down their shovels and run down the track like a herd of stampeded steers.

There, just coming around the curve, was a glittering vision of brass and varnish half hidden in a nimbus of smoke and dust. Two short blasts on a whistle greeted the gang, the vision hesitated for a minute, while the section men disappeared in the nimbus and reappeared as suddenly as if they had been shot out of a gun, and here came the vision gliding up to the platform with bell ringing and pop valve sputtering *sotto voce*, like a young lady trying to suppress a ticklish cough. It was the pay car. At this point you lost consciousness.

Some time later, while still as one in a dream, you realized that your numbed senses, beginning at the pilot, had taken in every detail of this romantic visitation of opulence. Never was there such an engine as the one which pulled the pay car. At each joint in her jacket was a band of brass 4 in. wide. Dome, sand box, steam chests and cylinders were encased in brass, polished until you could have seen to shave in it. Her front end and her dainty straight stack were rubbed with plumbago until they shone like a small boy's heel. All her bright work was smooth and spotless and glittering, while all the rest of her surface was striped and curlicued with all the colors the general shops could mix.

Moriarity, the lucky runner of this paragon, in a clean checked jumper left open at the neck to show a gorgeous red tie in which a diamond glittered, a hard boiled cady cocked jauntily over his left ear, was lolling out of the cab window in such a way that all the world might see that he wore kid gloves while on his engine. Moriarity was something of a swell and he didn't care who knew it. His only rival in sartorial effulgence was Pete Swanson, his Swede fireman, who was leaning out of his cab window with a stony glare fixed on vacancy, affecting to watch for signals. Of course he knew that all the signals which concerned him would be given with the bell cord; but his zealous attention to duty relieved him of the necessity of recognizing his humbler fellow mortals. No plebeian overclothes eclipsed Pete's glory. There was the square-cut black coat that no one but a railroad man ever wore —you know the kind—a vest of fancy red cloth, trousers with stripes that you could hear ten car-lengths away, square-toed shoes with soles half an inch think, and a stiff-bosomed shirt with red and white stripes. On this foundation reposed a black satin puff tie held together by a locomotive done in gold. On his head at a rakish angle was one of those soft hats of the peculiar block affected exclusively by railroad men a score of years ago. No, you didn't need to read the tag to discover that Pete was a railroad man.

Coupled to the engine was a wheeled palace built on graceful lines in freshly varnished yellow paint which rivaled the brass work on the engine in brilliance. The plate-glass windows were curtained with bright-hued brocade. Not a speck nor a flaw was to be seen. Even the yellow wheels bore only so much dust as had been gathered on the day's run. Through an open window came fragrant odors, while in the background a white jacket surmounted by a black face vibrated at intervals.

All this time Old Man Flatwheel was heading a little procession bound toward the rear platform of the pay car at a gait which he assumed but once a month. Flatwheel had conscientious scruples against undue exertion. He always had the caboose stopped at the station platform so that without dissipating his energies he could saunter in to gas with the agent until the hind man announced that the work was all done and that we were ready to go. Then he would get his orders or a clearance and tell the hind man to give 'em the sign and saunter back to the caboose before they got to rolling. But to have seen the animation with which he swung himself aboard the pay car would have created the impression that he was the only working railroad man on the division.

At his side stalked Panhandle Dan, the engineer, his face actually wreathed in smiles. Panhandle Dan had a chronic grouch from 12.01 a.m. January 1 to 11.59 p.m. December 31, except for three minutes once a month. On the way to the pay car he always perked up a bit and was even known to crack a joke with Old Man Flatwheel. After these two came the hind man talking incessantly with the fireman. Charles always was talking that way. He had an automatic tongue which never ran down. Half the time he didn't know he was talking. His was what the doctors would diagnose as a reflex conversation. Frank, the fireman, was the only sober one. He, poor fellow, was doing sums in mental arithmetic, trying to figure out how on earth $58.60 could be made to pay all necessary bills for a helpless father and mother, a wife and four kids, besides board bills for a man who was obliged to be away from home half the time.

Then there was the operator, in shirt sleeves and careworn air, hoping he could get back to his key before the despatcher lost his temper; the agent, placidly smiling; and the two coal heavers from the coal shed with an expression of almost human intelligence struggling up through numberless strata of grime and whiskers. After 30 days of humping over a scoop shovel in a choking smother of dust they were now about to be recompensed with 30 seconds of bliss in which they could fondle real money with their own hands. After that the storekeeper would do the fondling and feel bad because there wasn't more.

You had presence of mind enough to float into the pay car in the wake of the others. There were nine in the little party and you knew by experience that the average time required to pay nine men was 60 seconds; also that Moriarty would have 'em rolling before the last man had scooped his allotted coin into his trembling palm. But in the presence of death or the paymaster one may live an eternity in 60 seconds. How glad you were that you had not been rude and rushed in ahead of anybody, even the coal heavers! Now your hungry soul could have the uttermost second in which to revel in——

Great Mackerel! Just look at it! A metal coin rack crammed to the muzzle with three denominations of yellow boys, flanked with silver, and on the desk behind it a very large wooden tray on which were long columns of yellow coins. D'ye ever see anything so pretty in all your life? No wonder your eyes stuck out until you could have used 'em for hat pegs. And all the time an exquisitely musical "tinkle, tinkle, clink-clink" welled up from coin rack and counter in response to the calls of the assistant paymaster. Talk about Beethoven's symphonies!

If it were not for that strong wire screen you could have touched that fascinating tray. For the infinitesimal fraction of a second a wicked thought flitted through your brain. Then you almost fainted as your roving eye stared down the barrel of a monstrous revolver. It was only in a rack, but it was within easy reach of the paymaster's hand and most eloquent for all that. Half a dozen of its fellows lay in the handiest places, while as many Winchesters lying on tables and settees, came in strong on the chorus. Hurriedly your vagrant wits busied themselves with all the Sunday-school lessons you had ever learned. As your subconsciousness perceived that the head of the road's secret service department stood on the platform with his eyes intent on every man in the car at once, while Conductor Linkenpin stood on the ground outside very much alert, with his coat tail bulging suggestively, your bosom swelled with pride over the watchful care the company had exercised to bring its honest toilers their hard-earned money.

From the lithograph of Caroline Miskel Hoyt on the wall to the little hollows in the hard mahogany counter worn out by the attrition of the $128,000,000 in wages the paymaster had plunked down on that spot since this first pay car ever built had been commissioned, you kept on absorbing details until your name was called. A still greater rush of blood to your head caused you to gulp violently. Mechanically you lifted your hand to touch the pen as the others had done, and turned to go.

"Here! Come back and get your money."

When you came out of your trance you were standing in the middle of the track, your eyes wandering from some yellow objects in your hand to a nimbus of smoke and dust which was just tipping over the hill to the accompaniment of the diminuendo flutter of Moriarty's exhaust.

But now! Oh, well! After you have washed up on a certain day in each month you trudge drearily down to the station all alone, walk in, and lolling on the counter, affect to look indifferent and say: "Hello, John!" And the agent, after going over a column of figures three times, replies, "Hello, Bill," and gets up and goes to the safe and fumbles over some papers and hands you——

A check! No jokes, no infectious sprightliness, no uncertainty to put a wire edge on anticipation, no fleeting vision of brass and varnish and opulence wreathed in a halo of romance to leave a golden taste in your mouth for a day, nothing but a measly old check handed over a commonplace counter by a man who lives next door to you.

Why couldn't they have left us the pay car?

Increase in Weight of Locomotives.

At the recent annual meeting of the American Society for Testing Materials, H. V. Wilson of the Baldwin Locomotive Works, contributed to the discussion on rail a number of diagrams showing the increase in weight of locomotives of various types during the last 22 years beginning in 1885. Some of these diagrams are reproduced herewith, the weights being the averages of the output of the Baldwin Locomotive Works for each year. Fig. 1 shows the increases in total weight, weight on drivers and average weight per axle for eight-wheel locomotives. It will be seen that the maximum figures were reached in 1904, since which time there has been a decided falling off owing to the practical abandonment of this type of locomotive in favor of Atlantic, Pacific and Prairie locomotives for passenger service and those of heavy freight. The highest driving axle loads are 41,000 lbs.

Fig. 2 shows the same data for 10-wheel (4-5-0) locomotives. The average total weight has increased from 87,000 lbs. to 161,000 lbs., or 85 per cent., and the average weight on drivers has increased from 65,000 lbs. to 122,000 lbs., or 88 per cent. The average weight on each driving axle was 32,500 lbs. in 1885 and 40,000 lbs. in 1907.

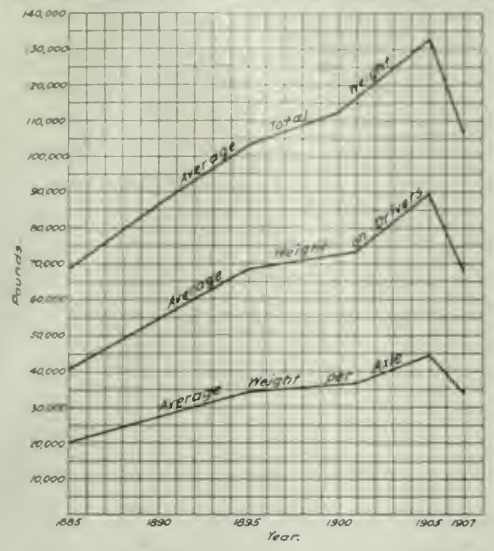

Fig. 1—Increase in Weight of 8-Wheel Locomotives.

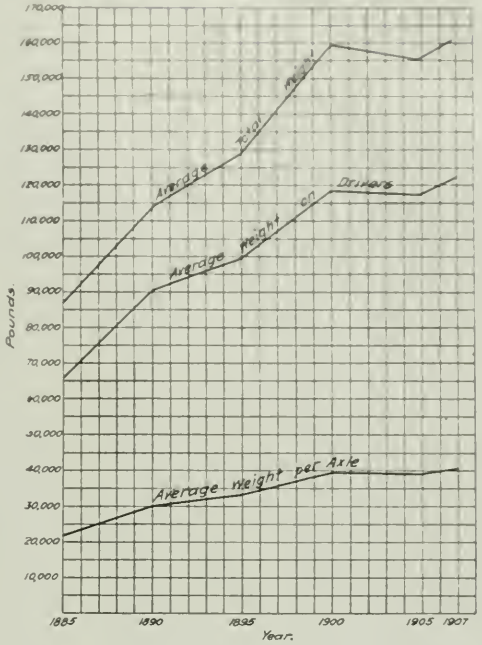

Fig. 2—Increase in Weight of 10-Wheel Locomotives.

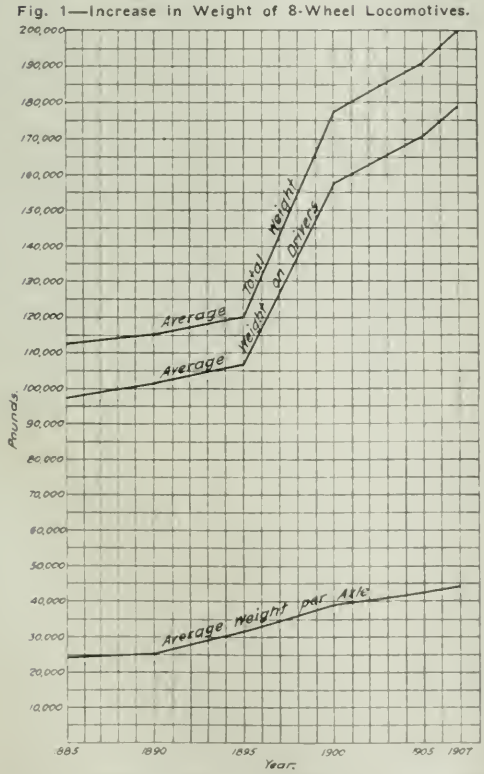

Fig. 3—Increase in Weight of Consolidation Locomotives.

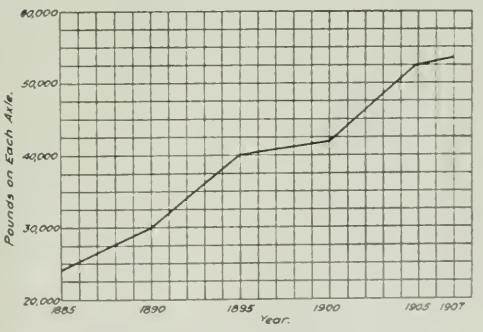

Fig. 4—Increase in Maximum Axle Loads.

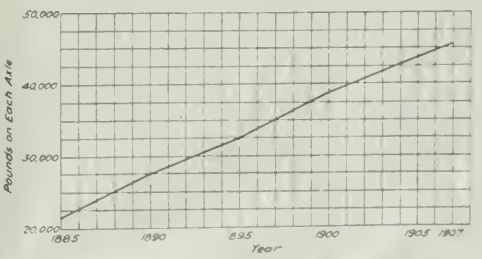

Fig. 5—Increase in Average Axle Loads.

Fig. 3 is for consolidation (2-8-0) locomotives. The average total weight increased from 112,000 lbs. to 200,000 lbs., or 79 per cent., and the average weight on drivers increased from 97,000 lbs. to 179,000 lbs., or 85 per cent. The driving axle weights rose from 24,250 lbs. in 1885 to 44,750 lbs. in 1907.

Fig. 4 shows the increased maximum axle loads, the highest in 1885 being 24,000 lbs. and the highest in 1907 being 53,500 lbs.

The increase is 123 per cent. Fig. 5 shows average axle weights for all types of locomotives, the increase in 22 years being from 21,500 lbs. to 45,500 lbs., or 112 per cent.

New York Telegraphers' Hours-of-Labor Law.

The Governor of New York has just signed a law, passed by the last legislature, to limit the working hours of railroad telegraph operators. The law is in substance as follows:

It shall be unlawful to require or permit any telegraph or telephone operator who spaces trains by the use of the telegraph or telephone under the "block system" * * * or whose duties pertain to the movement of trains by the use of the telegraph or telephone * * * to be on duty for more than eight hours in a day of 24 hours, except in cases of extraordinary emergency caused by accident, fire, flood or danger to life or property; and for each hour of labor so performed in any one day in excess of such eight hours, by any such employee, he shall be paid in addition at least one-eighth of his daily compensation. Penalty not less than $100 or more, one-half to go to the informer. The provisions of this act shall not apply to any part of a railroad where not more than eight regular passenger trains in 24 hours pass each way; provided, moreover, that where 20 freight trains pass each way generally in each 24 hours then the provisions of this act shall apply, notwithstanding that there may pass a less number of passenger trains than hereinbefore set forth, namely, eight. The act takes effect October 1, 1907.

Three Cent Fares in Cleveland; A Favorable View of Mayor Johnson's Projects.*

The fight for lower fares in Cleveland dates from 1898, when ordinances were introduced in the City Council to reduce fares on certain lines. These ordinances proceeded on the theory that the right to regulate fares and service had been reserved to the Council. In the elections which preceded these ordinances the political activity of the railroad companies had been notorious, and the use of money to influence the elections and to control councilmen was a matter of common gossip and scandal. The street railway companies met these ordinances with injunction suits. Thus began the first of a long line of litigation, which has extended over the intervening eight years, and which has been fought through every state and federal court. In the meantime grants were nearing expiration. Two considerable main line grants expired in 1905. This has been decided by the United States Supreme Court. Other grants, covering the very backbone of the system, will expire in from one to three years. On two occasions the railroad company nearly succeeded in getting a renewal grant. If it had made an offer even approaching the one it is now making, nothing could have stopped the passage of the renewal ordinance. But the City Council, realizing that there was little hope of being able to regulate fares under the old franchises, sought to secure a reduction and readjustment by inviting competition.

In 1901, Tom L. Johnson, millionaire, successful street railway promoter and operator, became Mayor, and thus brought to the service of the city a type of ability ordinarily to be found only in private corporations. He was elected after a campaign in which the street railway question was the chief issue. His efforts induced an outside capitalist to offer to build street railway lines and operate them on a 3-cent fare. The preliminary legislation was started and in 1902 grants were made to a competing company at 3-cent fare over territory not yet pre-empted by the old company. A new line of litigation and injunctions was begun and, because the railways themselves had hitherto made most of the street railway law, this new company was finally forced out of business.

At once new establishing ordinances were introduced, in which all of the quirks and technicalities were complied with to their last absurdity. And so dangerous to the "vested interests" did this attack become that the co-operation of the Attorney-General of the state was secured, and suit brought in the Supreme Court of the state to oust the city government and declare void its charter. The end to which the Cleveland roads, under the leadership of the late Senator Hanna, went in this litigation is almost without a parallel. The company, to maintain its advantage, succeeded in destroying not only the charter and city government of Cleveland, but brought down every city government in the state, so that not one charter was left whole. The destruction of the charters throughout the state made it necessary to hold a special session of the legislature in order to supply a new municipal code. On the night of May 4, 1903, this new code, under which all cities of Ohio are governed, went into effect, and the same night the fight was renewed. New establishing ordinances were again introduced.

Under these ordinances the Forest City Railway was awarded one grant on an outlying street for a 3-cent fare road. With this as a base to extend from, there has now been built and equipped, during intervals between injunctions, a 15-mile piece of road, from one extremity of the city to the center. It will be well to explain here that, under the laws of Ohio, it is almost impossible to establish a new line, but a comparatively much easier matter to extend from an established line. In the meantime construction has commenced on isolated stretches on the other side of the city. An extension over the two main lines of the old company, the franchises for which have expired, has been granted to the Forest City Railway. When all of these pieces are connected, there will be a line from one extreme end to another through the very heart of the city. As the old franchises expire, the new company will bid for franchises over these streets on the same terms hereinafter explained. Thirteen miles of the new road have for several weeks been in actual operation, and experts who have studied the matter claim that this fragment, by itself, can be operated for 3-cent fares at a profit.

The new road is being built and equipped for less than $50,000 per mile. The capitalization of the old company is $150,000 per mile. The construction is of the most modern and heaviest kind, and the equipment the best to be had. As a matter of fact, the structural value of the 236 miles of the old company is under $50,000 per mile, although capitalized for three times this amount. This figure was at one time agreed to by the old company. The capital invested in the new project is represented by the Forest City Railway, which is the owning company. The city is represented by the Municipal Traction Company, which is the holding company. The Forest City Railway is a corporation organized in Ohio, with a present authorized capital of $2,000,000, all common stock, 6 per cent., cumulative. It can issue no bonds. Under a trust agreement, $1,900,000 of the stock has been turned over to one of the leading trust companies of the city, the largest in the state. The other $100,000 of the stock had already been issued for actual money paid in. By a fiction of purchasing franchises from the original grantee for $200,000, the stock is fully paid up when sold at 90. Of it $750,000 was offered at popular subscription and oversubscribed by nearly an equal amount. The stock may be retired at 110. The money from the sale of stock at 90 can only be paid out by the trust company, on the order of the Municipal Traction Company for actual construction cost and expenses incident thereto, and for payment of 6 per cent. interest on instalments paid in to the first day of October, 1906, after which date dividends accrue. We have here a corporation without a dollar of debt, in which every stockholder, no matter at which time he becomes one, is on exactly the same footing, and one in which every dollar paid in goes into construction. There is no ground floor, no "rake-off" for promoters.

The franchises are all granted to The Forest City Railway. They are for 3-cent fare, cash or ticket, and universal transfers. The right to regulate charges and service is explicitly reserved to the Council. The grants are revocable at the will of the Council, limited only by a clause that the property cannot be impaired as a 6 per cent. investment. They contain a municipal ownership clause, under which the city may, whenever the laws of Ohio shall permit it, take over the property for its actual cost, less depreciation, plus 20 per cent. All of the property and rights, present or to be acquired, of the Forest City Railway are leased to the Municipal Traction Company for 50 years, with a privilege in the lessee to renew for another 50 years. The lease follows the general scheme under which the Elkins-Widener Syndicate controls the underlying properties in its system of street railways.

The Municipal Traction Company can be described as a purely paper corporation. It is organized under the laws of Ohio with an authorized capital of $10,000, 10 per cent. paid in. It is composed of five selected stockholders, each one a director, each owning one-fifth of the capital stock. Its personnel consists of five leading business and professional men, the President and General Manager being A. B. du Pont, one of the leading street railway experts in this country, and its Vice-President, Frederick C. Howe, a law partner of James R. Garfield. It will never pay any dividends. The directors and officers get reasonable salaries. By a carefully drawn contract, each stockholder and director has executed to all of the others an option on his stock, under which it will only be necessary to insert the name of the newly elected director into the certificate to transfer the stock. The stock certificates have been endorsed in blank and put in safe deposit and are accessible only to a majority of any surviving members. If a vacancy should occur, the same will be filled by the survivors. If the directorates shall all become vacant at the same time, a court of equity would take care of the emergency. The body is thus self-perpetuating.

The Municipal Traction Company owns no property except the lease to it of the Forest City Railway. It has or assumes no liabilities other than the current ones growing out of the operation of the road and the rental equal to 6 per cent. on the outstanding stock of the Forest City Railway and not to exceed $2,500 per year organization expense. Under the terms of the lease the lessee constructs and equips the road out of the proceeds from the lessor company's stock, and the title to the property is in the lessor. The

*Abstract of an article by Carl H. Nau, in the *Journal of Accountancy*.

lessee operates and maintains and keeps in original good repair the property of the lessor out of the earnings from operation. The lessor company cannot issue bonds or execute any mortgage or make any charge upon its lines or property without the written consent of the lessee. The lessee, of course, cannot in any way put any charge upon the property, the title to all of which is vested in the lessor. The lessee can, out of its surplus earnings, buy the property of the lessor at any time, in whole or in part, for a price 10 per cent. in excess of part on the stock, and the rental to be paid ceases on such portions so bought. Any portion of the property so paid for out of earnings, or any extensions to it built out of earnings, will not have to be paid for when the city exercises its option to purchase under the municipal ownership clause in the franchise. All of the books and records of both companies are open to the inspection of the City Council or any citizen and the utmost publicity has been provided for concerning all of their transactions.

The crux of the holding company plan is the question of trusting the five directors of the Municipal Traction Company to administer their trust faithfully and to elect equally faithful successors. As already shown, the stock of the Municipal Traction Company is so safeguarded that none of it can pass into the estate of a director in case of death, nor into the hands of a receiver in bankruptcy in case of financial trouble. All vacancies will be filled by the surviving members. The efficient checks upon the good faith and rectitude of the five men composing this holding company for the public are:

1. Their high character, the public pledges they have given and the obligations they have assumed.

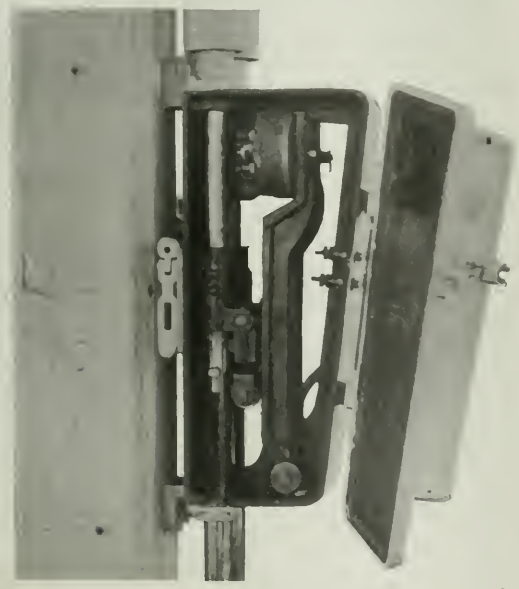

Fig. 1—Double Electro-Mechanical Slot.—Doors Open on Both Sides.

2. The utmost publicity. They and their every act are at all times open to public scrutiny.

3. The city's right, under the option reserved in the franchises, to appropriate the property at a small percentage over structural value.

4. The right to revoke the franchises at any time and grant them to another, who will compensate the stockholders of the owning company for their actual investment only.

Since this new project was financed and the holding company formed, the old company has made a new offer, which for the past six months it has been strenuously urging on the city by the expenditure of over $1,000 a day in advertising in the newspapers and by the attempted creation of favorable sentiment through discussions in churches, clubs and other organizations of the city.

This offer for a renewal franchise for 20 years is seven tickets for a quarter and universal transfers, including all of the other burdens now imposed, such as paving, sprinkling, licenses, etc. The present rate is 11 tickets for 50 cents. In its advertisements the company claims that this means a saving to its patrons of over $1,000,000 a year.

The fight for 3-cent fares in Cleveland has now, however, progressed so far that there seems to be a growing disposition to compromise on nothing less, and moreover to insist on no franchise being granted, at any rate of fare, that is not revocable and that does not reserve the future to the city. As the most valuable franchises expire in a comparatively short time the disposition seems to be to wait until they do expire, and then grant them to the Forest City Railway. In the meantime, a truce has been entered into whereby all construction by the new company and all adverse activities and litigation by the old company has been stopped, while a representative of the city and one of the company are fixing the value of the old company's property, with a view to leasing it to a holding company controlled by the city. The basis for the leasing value is to be physical value, plus unexpired franchise value plus one-ninth.

The Hall Electric Slot.

The Hall Signal Company's electro-mechanical slot for semaphore signals combines in a marked degree reliability, simplicity and accessibility. To reduce failures to a minimum such an apparatus should be easily understood, and easy to inspect and repair. A slot placed at or near the arm of a high signal is not, under the most favorable circumstances, easy of access. A small case, necessitating excessive compactness aggravates this condition. The placing of moving parts, such as levers and dogs, behind any other part, necessitating the removal of the latter to make repairs to the former, is a nuisance, and wires connected to moving magnets are liable to cause failure. This slot, shown in the accompanying illustration, is free, to a remarkable extent, from the evils mentioned. It is designed to be mounted near the base of the signal post, where it will be easily accessible to the maintainer. All movable parts can be plainly seen and easily inspected or removed without dismembering the entire mechanism. The case is roomy but not over large, and the magnet is fixed. The details and construction are shown in Fig. 2. In this drawing A represents the cast-iron case; B is the lower operating rod and C the upper operating rod carrying the dash pot Q, attached in the usual way. D is a powerful iron-clad magnet mounted on a stand which is rigidly fastened to the case; E is the armature secured loosely to the lever F by the threaded pin G. G is slightly smaller than the hole in F, through which it passes, and has a semi-spherical head, after the manner of a ball and socket joint. This is to allow E to make good contact with D despite any small lack of adjustment in F. Lever F is pivoted at O. H is a phosphor bronze spring used to restore lever F to its normal position, but exerts no appreciable pressure otherwise. I is a cast-iron sleeve riveted to the lower rod B, and carries the latch J pivoted to the lug K, which is part of the sleeve I; J carries a roller L to reduce friction when traveling against lever F. The lower end of C extends within B and carries a pin M working in slot N cut in B. This is to allow the signal to be pulled to danger, as M projects beyond the edge of B on both sides. Both rods are notched at P to allow the projection of latch J to engage with upper rod C.

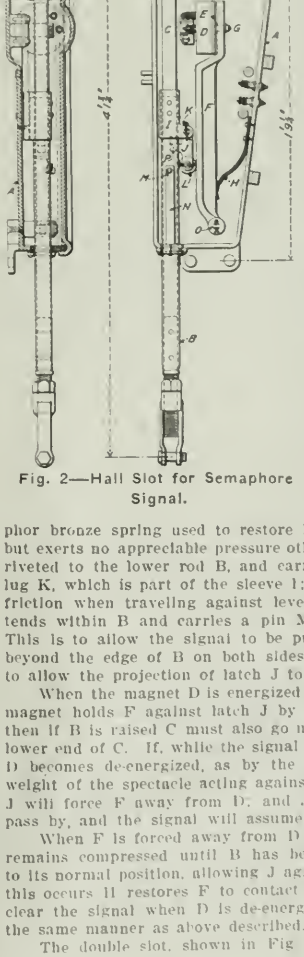

Fig. 2—Hall Slot for Semaphore Signal.

When the magnet D is energized the signal can be cleared. The magnet holds F against latch J by pressing against roller L, and then if B is raised C must also go up for latch J will engage with lower end of C. If, while the signal is in the clear position, magnet D becomes de-energized, as by the opening of a track relay, the weight of the spectacle acting against lever F, through C and latch J will force F away from D; and J, in tripping, will allow C to pass by, and the signal will assume the stop position.

When F is forced away from D it compresses spring H, which remains compressed until B has been restored by the signalman to its normal position, allowing J again to enter the notch P; when this occurs H restores F to contact with D. If it is attempted to clear the signal when D is de-energized, F will be forced back in the same manner as above described.

The double slot, shown in Fig. 1, is used where two arms of

a signal are slotted, and is much more compact and convenient than two single slots. This slot consists essentially of the mechanisms of two single slots mounted side by side in one case, and it operates exactly as above described. The principal dimensions of both slots are shown in Fig. 2. The single slot weighs approximately 85 lbs., and the double slot approximately 145 lbs. These slots will operate on 0.12 watts, and are highly efficient.

The Chemical Composition of Steel Rails.*

In the discussion on a paper which I presented to the institution nearly 40 years ago, manufacturers suggested matters of specification and composition in connection with rails should be left entirely to them; but the late Sir John Fowler, past-president, upheld the claims of his profession, and stated that "in his opinion it was not desirable in the interests of railroad proprietors or the public that engineers should abdicate their functions; but he would advise them to draw up specifications and to take pains to ascertain the process of manufacture. However, he thought it would be admitted that no rule could be laid down for the manufacture of rails which would be applicable to all localities."

In spite of the great amount of subsequent study, and of discussions on this subject, I still retain my opinion that a universal specification or composition for rails which would suit all cases cannot be satisfactorily arrived at. The varying conditions, such as ores available, process of manufacture, weight of rail, climatic and traffic conditions, differ in almost every case and all of them should be taken into account, in order to obtain the best results.

It will easily be realized how difficult a problem faced the Engineering Standards Committee when drawing up a general specification with fixed limits of chemical composition, to be applicable to the various processes of manufacture and other conditions.

All I can do in introducing this subject is briefly to mention the effect of each element according to my experience.

Beginning with phosphorus, I think engineers have suffered enough from fractures due to a high percentage of this element, especially in cold climates, to make it necessary to limit it as far as possible, in spite of the good wearing results of high-phosphorus rails. It is possible to work to a lower phosphorus limit with the basic than with the acid processes, especially with the basic open-hearth process; but starting with a pure ore, as in the acid processes, must always be attended by less risk of an accidentally high-phosphorus than the basic processes of purification.

Sulphur will probably present more trouble to the manufacturer than to the user, because if a high percentage is present the rails will be red-short. Sulphur is also liable to cause incipient flaws, which, although not apparent at the rolling, may develop under continuous wear into serious flaws, and in the interests of both the manufacturer and the railroad excessive sulphur should be avoided.

Manganese was stated by the late Sir William Siemens to have the effect of atoning for many evils in steel by healing it up and producing a smoothly rolled surface, which, after all, is of great importance, as many fractures commence with a small surface crack or flaw. At the same time, no more manganese should be allowed than is absolutely necessary for clean rolling, as I have found many cases of rail-fractures attributable chiefly to high manganese.

Silicon.—It has been found in the past that rails containing a high percentage of silicon, although giving excellent wearing results, have not been satisfactory, owing to their brittleness and irregularity of percentage. This has been due to the silicon being left in the steel from the pig-iron during the conversion, or added in the form of pig-iron. As a result of this experience, engineers now generally limit the maximum percentage of silicon to 0.1 per cent. or even less. I have for many years experimented with silicon in rails with a view to obtaining soundness and solidity without brittleness, and I gave some results of my experiments in a paper read before the Institution of Mechanical Engineers in Sheffield, in 1890.

I have found that for rail-steel the effect of silicon added is very different from the effect of silicon left in from the pig iron. When silicon is left in, the percentage varies considerably, depending on the heat of the charge, thus causing great irregularity, and as the iron has not been completely converted into steel the metal is of a brittle character. As a rule silicon, if left in, is an indication that the metal has been blown too hot, which is well known to lead to great irregularity in the finished steel. But when the silicon from the pig-iron has been eliminated as far as possible and a known quantity of silicon is added, in the form of high-percentage silico-spiegel or ferro-silicon, I obtain regularity in the percentage of silicon, and moreover, the silicon then toughens the steel instead of making it brittle, this being largely due to the more complete removal of gases and oxide from the steel. I thus obtain a harder, and at the same time, tougher rail, which as far as mechanical tests indicate should be able better to withstand both the wear and the crushing at the ends caused by the present day heavy axle loads. Very thorough tests on large quantities of these rails have been made at various works, but tests, although of great interest, could not be taken as final until they were confirmed by actual experience in the road. I have laid this question before many engineers who have witnessed the tests at the works, and who have now had the rails in the road for some time, and I think it would be of general interest if some of them would give their experience as far as it goes.

Carbon.—In general it is desired to obtain a rail as hard as is compatible with safety, and carbon is the most suitable hardener. In my practice I do not specify carbon limits, merely stating that it shall be as high as the safety or drop-test will allow. Although not absolutely a criterion, the drop-test is still the best safety-test we have.

Another point that has of late years attracted considerable attention is the modern high speed and temperature of rolling. Efforts have been made by various means to remedy the evil effects of this, such as using larger ingots, allowing the whole rail to cool before the last pass and other methods. I have preferred to obtain cold rolling of the rail-head only, by applying sprays of water to this portion of the partially rolled rail at the various passes of the rolls. This should at any rate improve the wearing surface, and has the advantage of neither delaying the manufacture, decreasing the output, nor appreciably increasing the cost. The rails of which tests are shown in a table (to be exhibited at the meeting) have all been treated in this way.

Considerable trouble has been experienced on electrified railways owing to the excessive side wear of the rails on curves. Apart from the question of better wearing steel for their rails in general, one of these railways has introduced the novelty of using a considerably harder steel for check-rails. This has shown surprisingly good results, about which I hope we shall hear more during the discussion.

Regarding special qualities of steel, such as manganese, nickel or chrome-steel rails, I have not, in the short time now at my disposal, touched upon these, because, owing to their high price they can generally be employed only for exceptional purposes.

* A paper read before the Engineering Conference of the Institution of Civil Engineers by Christer Peter Sandberg.

Local Freight Agents' Association.

The annual meeting of the American Association of Local Freight Agents' Associations was held at New Orleans June 18, 19 and 20, representatives being present from 60 cities. Membership in this association consists of Local Freight Agents' Associations located in cities of the United States and Canada having 50,000 inhabitants or over with three railroads, 100,000 inhabitants or over with two railroads or any city with five railroads, and the American association is formed of such associations situated in 86 of the largest cities of the United States and Canada. The topics discussed at this association are labeled with the name of the city which presents them at the meeting. We give below a condensed statement of the most important business done at New Orleans.

Stray freight was discussed in communications from three different cities, and it was voted the sense of the meeting that stray freight should be forwarded to the marked destination by the shortest route, billed free, the agent at destination to see that the roads interested receive their proper share of the revenue.

Toledo presented a paper written by C. H. Newton, formerly Local Freight Agent but now Freight Claim Agent of the Wabash, on the necessity of loading cars to their full capacity; and the meeting voted to have 10,000 copies of the paper printed. Kansas City proposed that waybills of freight received should remain permanently in the hands of the receiving agent and the matter will be taken up with the Accounting Officers' Association. Louisville proposed and the association agreed that freight houses ought to be closed from 12 noon to 1 p.m.

On the suggestion of St. Louis it was the unanimous opinion that one complete file of tariffs should be kept at each station, and only one; this to be the working file of the office, and to be accessible to the public.

Peoria.—The conference committee was instructed to try to secure the adoption of rules under which detachable parts of traction engines, agricultural implements and such like freight, when carried on open cars, should either be boxed or be fastened to the car by iron bands or bolts.

On the suggestion of Memphis a committee of five was appointed to draft a set of uniform blanks for use in local office business.

Cleveland.—In view of the great difficulty experienced in getting competent office help, every railroad should have an officer to be in immediate charge of agencies, keeping in close touch with their wants.

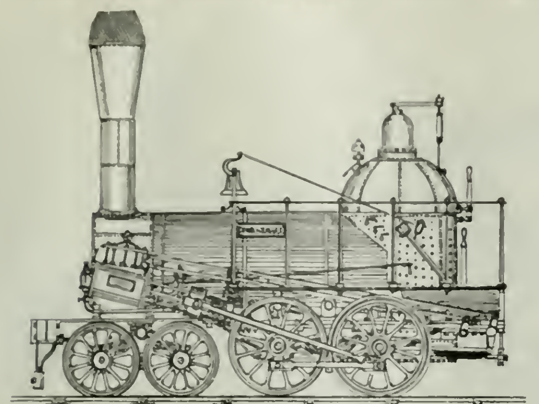
The President of the association for the ensuing year is W. W. Alexander, Louisville & Nashville, Cincinnati, Ohio; Secretary, G. W Dennison, Pennsylvania and Hocking Valley, Toledo, Ohio. The place and time for the next meeting will be decided by the executive committee.

Early Years of the Philadelphia & Reading.

BY C. H. [illegible]

The desire of the people of England to provide a speedy means of carrying coal from the mines to the more distant points of consumption or distribution formed the primary incentive to building railroads at the time of their origin in that country, and to the same motive can be attributed the construction of the Philadelphia & Reading Railroad, one of the [illegible] railroads, not of Pennsylvania alone, but of the whole United States.

Tiring of the slow and somewhat uncertain methods of bringing



Freight Engine "Gowan & Marx," 1839.

Built by Eastwick & Harris. Fuel, anthracite coal. Cylinders, 12½x18 in. Drivers, 42 in. Weight, 11 tons. Weight on drivers, 9 tons. Gurney draft box.

to market the products of the vast deposits of coal in the anthracite regions of Pennsylvania, the promoters of this road built it from Philadelphia to Port Carbon and Pottsville, passing, of course, through Norristown and Reading. Thus, although much of the line was located in fine agricultural districts and passed through manufacturing towns of considerable importance, even at that early day, the chief object in view was the heart of the anthracite coal regions of the state.

The first part of the road to be completed extended from Reading to Norristown, and the first train was run over it on July 16, 1838, when 11-ton engine, "Gowan & Marx," burning anthracite coal, drew a train between the points just named. This train, according to the company's report for the year 1838, consisted of 80 small four-wheel cars containing [illegible] of flour, [illegible] of bloom, [illegible] tons of coal, [illegible] and 6[illegible] persons. The [illegible] of the train, [illegible] of engine and tender, was [illegible] or a net weight of [illegible]. The [illegible] and arrangement of [illegible] exactly as [illegible] in the report. After the train had covered a distance of 1[illegible] miles from Reading the "water pipes" (by which the [illegible] who [illegible] the report probably meant the pipes [illegible] with the pump) gave out and caused a delay until engine "Delaware" (the [illegible] of that name) came up and pushed the outfit to Pottstown. Here the trouble appears to have been rectified and the "Gowan & Marx" drew her train the remainder of the distance to Norristown, assisted at a few points by second-class engine [illegible]. The weight of the "Delaware" is stated to have been "[illegible] tons, including water and fuel." Passenger traffic between Reading and Pottsville was established soon afterward, and also between these points and Harrisburg by way of the Schuylkill Valley and the state road of Pennsylvania. The freight traffic, however, was small, but was not expected to be otherwise until the entire line would be ready for operation from Port Carbon to Philadelphia. This important event took place on January 13, 1842, and hauling of anthracite coal by rail then began in earnest. The cost of the road is placed at $5,000,000, with an additional $521,000 for the extensions to Pottsville, and from the Philadelphia terminus to the Delaware river. As an indication of the business done after the final opening, the report for 1842 shows that the company at that time owned 12 eight-wheel passenger cars, 2 four-wheel passenger cars, 1,130 four-wheel coal cars, 176 four-wheel freight cars, 3 eight-wheel freight cars and 5 four-wheel baggage cars. It is most probable that the capacity of these four-wheel freight and coal cars was little, if any, over three tons. Contracts had also been entered at this time for 14 locomotives and 450 four-wheel coal cars.

From this beginning of 96.9 miles of road, the company from time to time absorbed the following lines: Atlantic City Railroad; Catasauqua & Fogelsville; Cape May, Delaware Bay & Sewells Point; Chester & Delaware River; Dauphin & Susquehanna; Gettysburg & Harrisburg; Lebanon Valley; Middletown & Hummelstown; Mine Hill & Schuylkill Haven; North Pennsylvania; Perkiomen; Philadelphia & Chester Valley; Philadelphia & Frankford; Philadelphia, Newtown & New York; Port Reading; Philadelphia, Germantown & Norristown; Reading & Columbia; Rupert & Bloomsburg; St. Clair, Tamaqua & Hazelton, and Wilmington & Northern. It also added a line of sea-going steamships, sailing from its Port Richmond wharves and carrying anthracite coal to many seaports.

In the few years which intervened between the phenomenal success of the "Rocket" at Rainhill and the date of the opening of the Philadelphia & Reading Railroad, the steam locomotive had so thoroughly established the claims of its supporters as the only satisfactory means of drawing railway trains (excepting, of course, the use of stationary engines on inclines of unusually heavy grades) that no allusion appears in any of the printed matter consulted in

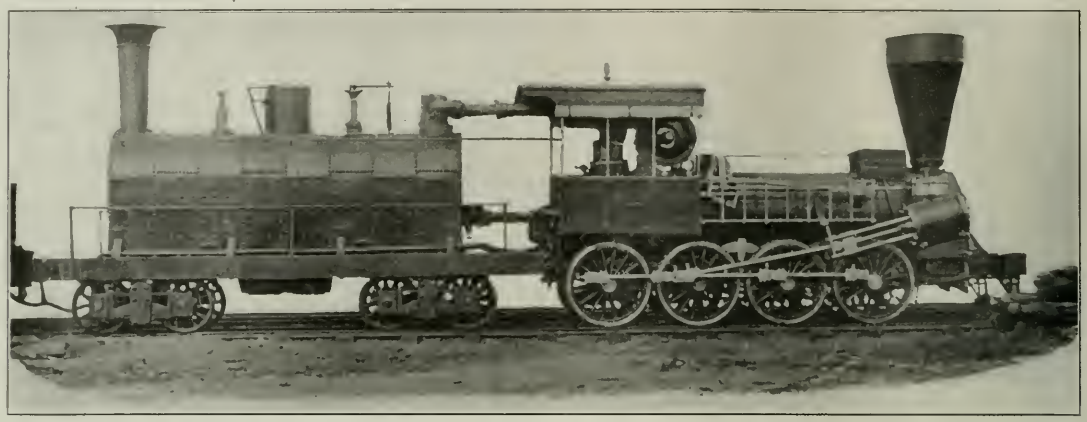
The "Delaware"; Philadelphia & Reading.

connection with this article to indicate that any other method had been considered.

It is probable that the "Gowan & Marx" and the Winans' "crabs" were the only engines of the early equipment which used anthracite coal as their fuel, and that on account of the abundance of wood then available at low prices, together with the limited grate area of the other engines, the use of anthracite in them was not attempted to any extent. Naturally, however, the officers of the company realized the importance of using in all their locomotives a fuel with which the interests of the company were so closely allied. The "Gowan & Marx" already referred to had a firebox 60 in. long, and the large grate surface in comparison to that of their other engines

standard on the line, and with some modifications has not only continued to be so ever since, but has also been extensively adopted on other roads using anthracite coal in their engines, and in a few instances has been applied to a number of engines on roads where soft coke coal is used.

As we have already referred to the fact that the Reading Railroad was built and opened but a few years after the "Rocket's" achievements in Europe, and the impetus given to locomotive construction in this country by the final successful operation of M. W. Baldwin's "Old Ironsides" on the Philadelphia, Germantown & Norristown Railroad, therefore it is but a natural sequence that we should find a great variety of types of locomotives on the road in the

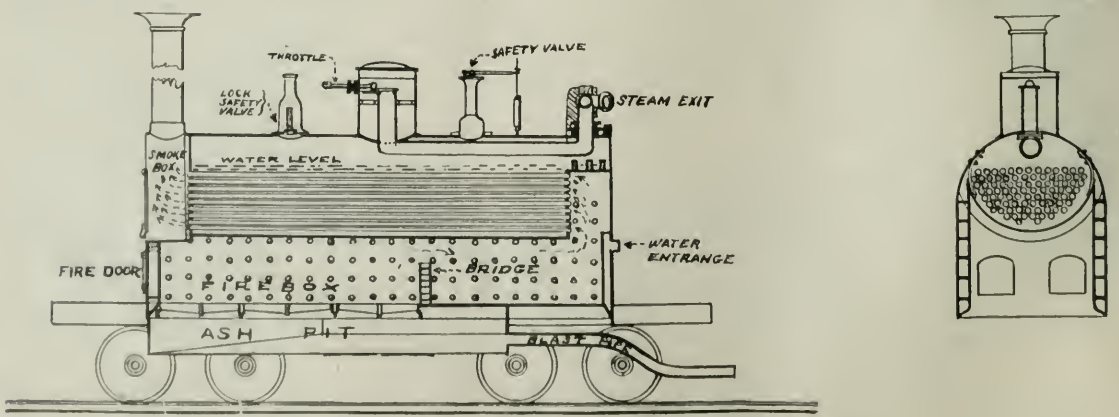


Engine "Novelty", Built in 1847 at Reading, Pa., from Designs of G. W. Nicholls, Engineer and Master Mechanic.

undoubtedly produced results which impressed both officials and locomotive builders with the necessity of large grate era in engines using anthracite coal. Even with this engine the desired degree of efficiency in the use of fuel does not seem to have been obtained; in fact, the solution of the problem appeared rather remote until 1846, when Ross Winans placed his engine "Baltimore" on the road. The firebox of this engine had a grate area of 17 sq. ft. It also had a variable exhaust which proved satisfactory, and the favorable results obtained from this engine doubtless induced the designing and building of the "Novelty" in the following year, with a grate surface of about 44 sq. ft. In 1850 Ross Winans delivered the "camel" engine "Patapsco" to the road, with a firebox of 19½ sq. ft. grate area, and in 1852 James Millholland brought out his "Pawnee," with a grate surface of 24½ sq. ft., following it with the passenger engine "Hiawatha," which also had a grate surface of 24½ sq. ft. These last three engines were practically the standard engines of the road during the next ten years, or until about 1862, when freight engines of the "gunboat" type and passenger engines with similar boilers were built. Both of these types were larger than their predecessors, and both had a greater grate area. During the ensuing fifteen years but little change was made in the locomotive practice of the company. Then, in 1877, the first Wootten boiler was applied to an engine numbered 408. This engine was exhibited at the Paris Exposition the following year. The Wootten boiler at once became the

earlier years of its existence, especially when we consider that American builders soon cut away from the somewhat similar designs of the various English builders, and each man became "a law unto himself" in his efforts to improve the design and efficiency of the steam locomotive. The English engines in use were all practically of the "Planet" type, which will be recognized by those who have seen the famous "John Bull," now in the National Museum at Washington, D. C. Among the earlier engines were four Winan's "crabs," of which the men running them in 1840 say: "They are pulling like elephants."

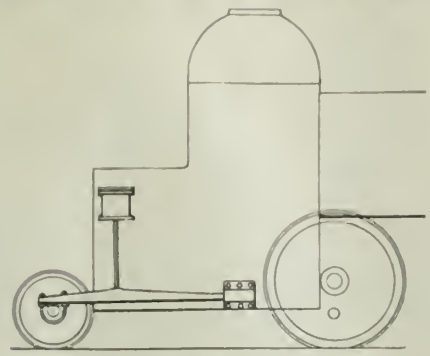
As tabulated data of the engines does not appear in the company's reports until 1846, it is possible that some very interesting machines have passed out of existence and "left no trace behind." These reports show that in 1845 the company owned equipment consisting of 47 locomotives, 2,456 four-wheel coal cars, 265 four-wheel freight cars and 19 passenger and baggage cars. The names of the firms which built the locomotives are: Braithwaite & Co. (England); M. W. Baldwin; Norris Brothers; Eastwick & Harrison, Locks, Canal & Navigation Co.; Lowell Machine Co.; Dotterer & Co., and Ross Winans. By the close of 1847 the locomotive equipment had increased to 72, and the annual report for 1857, ten year later, gives a total of 141. In the report for 1872 we find the names Boston Locomotive Works (Hinckley & Drury); Hayward, Bartlett & Co.; John Brandt; Taunton Locomotive Works; Davenport, Bridges &



Side and End Views, Engine "Novelty", 1847; Philadelphia & Reading.

Kirk, Danforth, Cooke & Co. and Lehigh Railroad Co. added to the list of builders for the road.

Until 1872 all the engines were known by names, but in that year numbers were substituted, although the annual report of that



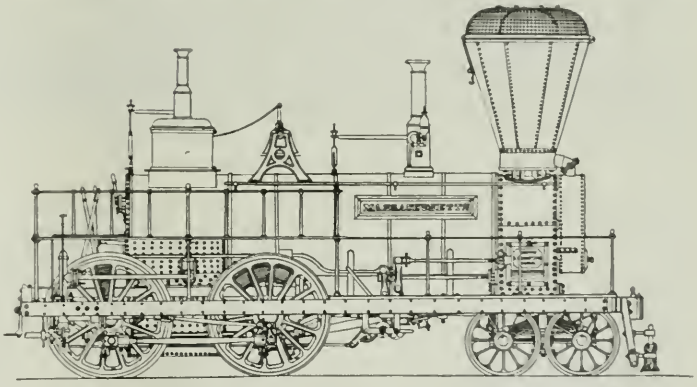
Trailing Wheels and Connections Added to Winan's Locomotives of 1847.

date gives both names and numbers in the tabulated statements of the locomotives, which had then reached a total of 377. All subsequent reports use numbers only. That of 1879, which practically marks the advent of the more modern types of engines on the road, places the total number at 495, and contains the name of one more builder, Smith & Jackson, in addition to those of 1857.

Referring to some of the more prominent types of engines used at various times on the road, the "Gowan & Marx" first attracts our attention. This machine was built by Eastwick & Harrison, of Philadelphia, Pa., and its prominent features, in addition to the large grate surface already alluded to, are the position of the wheels, which were placed in such a manner as to allow the drivers to carry 9 of the 11 tons of its maximum weight, and its reversing valve-seat, which was placed upon the regular seat, carried the slide-valve on its back, and contained ports which regulated the admission and exhaust for forward or backward motion as it was moved backward or forward. On first examination of a drawing of the "Gowan & Marx" one would suppose it to be one of the "old-timers," with full-stroke and cut-off valve-rods, but the preceding description of the reversing-plate will make it clear that the lower rod controls this plate, while the upper one is that which actuates the ordinary slide-valve. The cylinders were $12\frac{1}{2}$ by 18 in., and the four driving-wheels were 42 in. diameter. The forward end was carried on a four-wheel truck. A peculiar form of nozzle, or exhaust-box, was used; the invention of Eastwick & Harrison. This consisted of a sort of drum which the exhaust steam entered on the under side and emerged through a large number of small tubes on the top. This arrangement was supposed to have a more continuous and uniform effect on the fire than the common form of nozzle, and was used on a number of engines built by the same firm for other roads.

Of the English engines on the road at that time the "Spitfire" was afterward sold to the Delaware, Lackawanna & Western, and became the No. 1 of that road. It, like its sister engines, was from the shops of Braithwaite & Co., and was of the "Planet" type. A six-wheel connected engine without truck wheels, named "Richmond," was built and placed in service by Norris Brothers in 1844, but exploded its boiler not long afterward. It was afterward rebuilt by the railroad company and the name changed to "Philadelphia."

The Ross Winans engine "Baltimore" of 1846 required some changes in the way of looping off a part of the cylinder flanges at the sides, and a slight readjustment of some other parts to enable it to clear all objects along the line before it was permitted to go into service. A man who was at that time, or nearly afterward, connected with the motive power department of the road informed me some years ago that "thereby hangs a tale." As has been mentioned, the attempts to use anthracite coal had been of an adverse nature until this engine of Winans came and appeared to make a "howling success" of it. Thereupon, my informant stated, it was quietly decided that this engine must be "downed," if at all possible. After close scrutiny it was found that the cylinder on one side had "slightly scraped" against something on the line, and the engine was declared unsuited for service and was run into the roundhouse at Schuylkill Haven as a companion to two Winans' "crabs" which had been retired from service. The "man from Baltimore," however, was not to be put out of the race in such a manner, and soon appeared on the scene and cut off sufficient of the flanges to furnish the necessary clearance. The "trouble hunters" next "discovered" that the engine had too much "overhang" at the rear. Again was the objection met, this time by the addition of a pair of small trailing wheels placed behind the firebox, and attached to it by springs extending from the journal boxes to pads on the sides, while steam cylinders, one on each side of the engine, were also attached to the sides of the firebox above the springs. These cylinders were open at their lower ends and took steam at their upper ends through pipes without cocks or valves. The ends of their piston rods rested in seats on the backs of the springs, and all worked fairly well unless the engine left the rail. Then the pistons usually blew out and a goodly proportion of the steam in the boiler followed, causing trouble and strong language on the part of the engine crews. After the "Baltimore" was finally considered up to the company's requirements through the addition and subtraction mentioned, Ross Winans



The "Massachusetts." Built by Hinkley & Drury in 1849

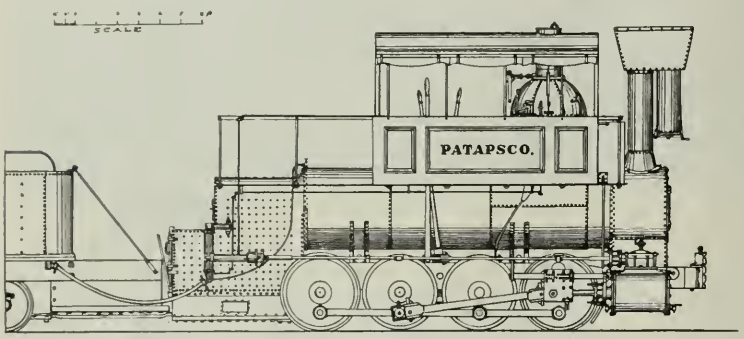
The "Perry". Built in 1849 by M. W. Baldwin. Owned First by the Pennsylvania, Then by the Reading.
Weight, 50,975 *lbs.* *Cylinders*, 17x22 *in.* *Drivers*, 44 *in.*

quickly followed it with three more of the same type, completing the number specified in the order, of which the "Baltimore" was the first. The three were named "Ohio," "Chesapeake" and "Maryland," but through some inadvertance the "Chesapeake" bore the name of an engine already in service, and the Winans' engine was then renamed "Delaware." It appears rather strange that although the "Baltimore" was the first of the type, and the one which first proved their ability to burn anthracite coal successfully in continuance service, that the "Delaware" should usually be the machine referred to in this connection both in descriptive matter and in illustrations. These engines had cylinders 18 by 22 in. and 46-in. drivers; also the drop-book valve gear with a half-stroke cut-off driven by a cam, all of design followed on the "camel" engines of the same builder. At a later period J. Milholland rebuilt the "Maryland" and added another dome and changed the cab of the "Ohio" to the same position as those on the "camels." He also placed a cylindrical water heater in the smoke-box. This heater contained a number of small tubes, through which the exhaust passed and heated the feed-water in so doing. The arrangement heated water well enough, but affected the exhaust to some extent, yet the use of the device was continued for several years, until one day the old "crab" "Delaware," which had stood out of service for many years, was dismantled and the boiler taken to the shop to be put in order for pumping service. When the tube cover was removed, lo! there was found the same



Ross Winans' Short Firebox "Camel" "Patapsco", 1850.

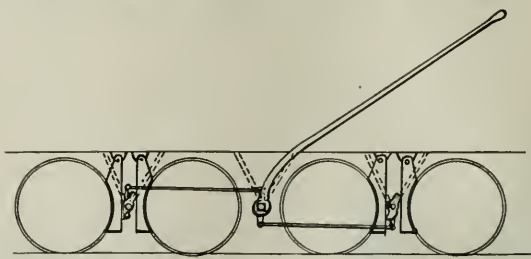
arrangement of a heater, and, worse still, covered by letters patent in the name of Ross Winans. Then the Milholland heaters were hustled out on short notice.

The success of the Winans' engines referred to, preferably suggested to G. W. Nicholls, the engineer and superintendent of the company, the designing and construction of the "Novelty," which was certainly no misnomer. This engine came out on June 21, 1847, and in the annual report for that year Mr. Nicholls writes in the following sanguine manner: "The locomotive 'Novelty' alluded to in my last report, as then building on a new principle for the purpose of burning anthracite coal has been completed and in operation since June of the present year. Her performance has been very satisfactory, fully equaling my expectations and showing no injury from the use of coal as her exclusive fuel after five months' trial and a duty of 9,357 miles run with coal trains. With such results and from her great economy in fuel, I feel confident that the main difficulties in using anthracite coal in locomotives have been overcome, and with further improvements which experience has suggested, now in progress, this road will shortly be able to use as its exclusive fuel the coal of its own region."

It is to be regretted that such high hopes failed of their realization, but in the report for 1848 the "Novelty" appears in the tabulated record of engine performances as "in shop undergoing repairs," and in the report for the next year, 1849, the entry opposite its name reads: "Boiler used for stationary engine," and its name does not appear thereafter; nor can I find any reference to it in any reports of Mr. Nicholls after that already quoted. As the "Novelty" has been so often described in various publications, it will suffice to mention that it consisted of three units, first, the usual running-gear, frames, etc., of an ordinary eight-coupled locomotive having a drum, or cylinder, substituted for the boiler; second, a boiler mounted on a separate frame which rested on two four-wheel trucks, and third, an ordinary tender.

The drum was used as a receptacle for the exhaust steam and feed-water, and was supposed to serve the double purpose of a condenser and heater. It was surmounted at its forward end by a French & Baird smokestack, probably more for appearance sake than for any other reason, as nothing passed out of it except the surplus exhaust steam from the drum.

The boiler was practically of the return flue type and had a grate surface of over 12 sq. ft. Its steam connection to the cylinders was by means of a pipe passing above the head of the engineman and fitted with swiveling metallic joints. The check-valve was on the end next to the foot-plate, and was connected to the lower part of the drum by pipes also fitted with joints similar to those of the steam connections. On account of the constant danger of these connections breaking, especially if the engine should leave the track,

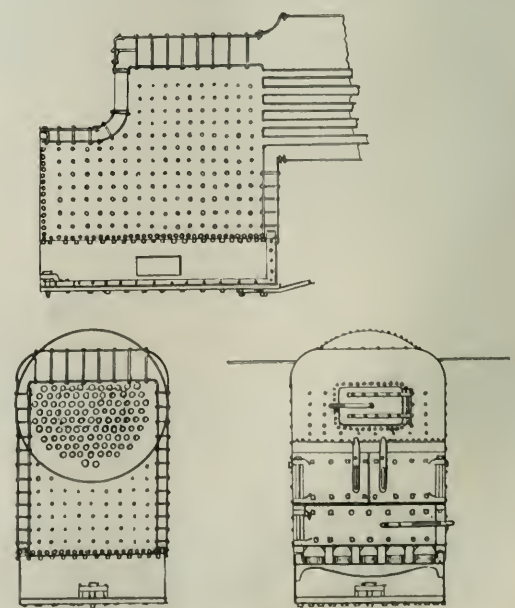


Eight-Wheel Tender Brake, 1850-1860; Philadelphia & Reading.

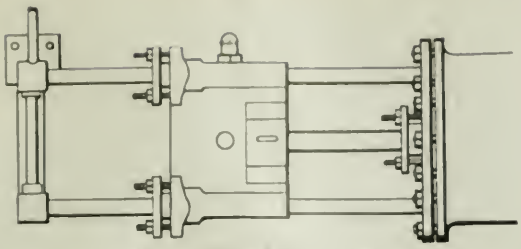
as it was very liable to do in those days of comparatively imperfect construction of roadbeds, an old employee of the Reading once said that he thought it was a very brave man indeed who would risk either running it or riding on it. Its principal dimensions were: Cylinders, 18 by 20 in.; drivers, 46 in. diameter; weight of engine proper, 43,000 lbs.

As the "Novelty" was a digression from the path of improvement which the locomotive was following, and may fitly be designated a freak, we can return to the beaten way and notice that in 1846 M. W. Baldwin built 17 eight-wheel connected engines for the company, all of which had his flexible truck on the first two pairs of drivers. Except that the capacity of the boilers was somewhat deficient, the engines were good in all other respects and continued in service for many years. Fifteen of these engines had 15 in. x 20 in. cylinders and 46 in. drivers, and two had 17½ in. x 18 in. cylinders and 42 in. drivers. Their average weight was 48,000 lbs. They were the first engines built by M. W. Baldwin with a roof over the footplates, and the first built by anyone with sandboxes.

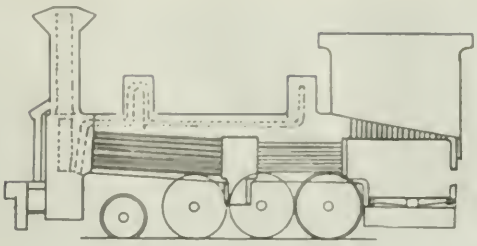
Probably but a short time previous to the building of the first of these engines, a 4-4-0 passenger engine named "Champlain" had been placed on the road by the same builder, and had his first independent half-stroke cut-off which he placed on all subsequent engines built at his shops until 1853. Both Baldwin and Norris had



Firebox of the "Patapsco."



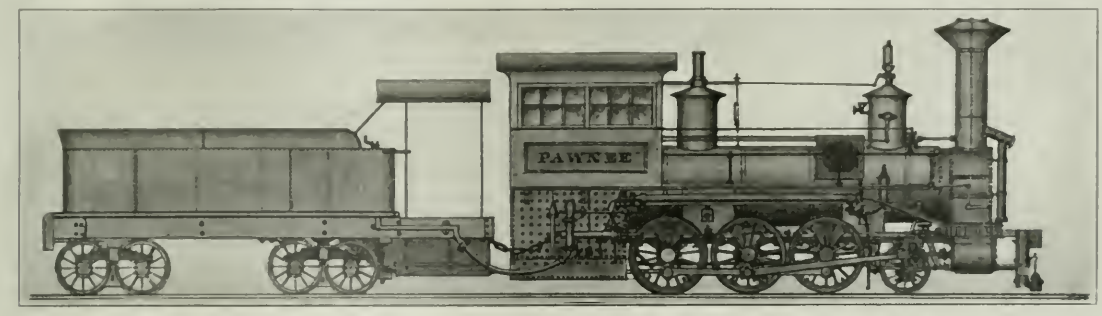
Milholland's Guide, 1851-1874.



Section, Engine "Pawnee".

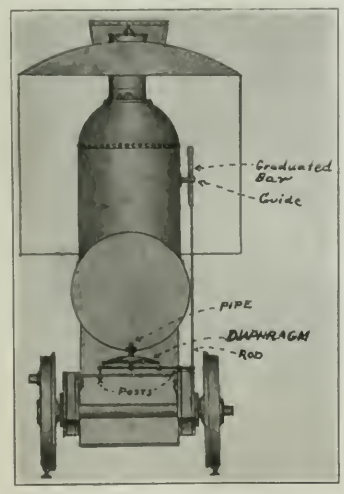
also furnished some 0-6-0 freight engines beside the Richmond already mentioned.

Simultaneously with the building of the four Winans engines just described, the Norris firm built the "Chesapeake," and placed it in service in April, 1847. It was the first 4-6-0 engine, or 10-wheeler, and was built under the patent granted to Septimus Norris. I have seen a number of engines built in 1862-3 with a cast iron plate on the base of the dome-casing bearing the words, "Septimus Norris Ten-wheel Patent," and a date somewhere in the late forties, but if the description generally given of the "Chesapeake" is correct, it must have required considerable ingenuity to extend the protection of this patent over these later engines, as they had the Bissell truck of that day, while we are informed that the "Chesapeake" used no center-plates but simply a large pin which passed through a part of the truck prepared to receive it; the idea of the truck being merely to guide the engine, the weight being all thrown upon the drivers, the front pair of which was very close to the cylinders. The "Chesapeake" had a Bury dome, 46 in. drivers, 14½ in. x 22 in. cylinders, and weighed 20 tons, and in addition to using a sort of composite parallel-rod rather favored by Norris, had that one which coupled the second and third pairs of drivers carried on the pins as close to the face of the wheels as possible, while that uniting the first and second pairs was placed sufficiently far out on the pins to enable the connecting rod to grasp the main pin between the two parallel rods. This arrangement was adhered to by the Norris people for at least 15 years after the building of the "Chesapeake," although the composite form of rod does not appear on their engines after 1851.



The "Pawnee". Built in 1852 for the Philadelphia & Reading.

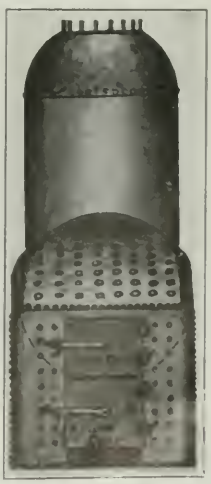
Cylinders, 18x22 in. *Drivers*, 46 in. *Pony wheels*, 30 in. *Steam pressure*, 110 lbs. *Firebox*, 42x84 in. = 24½ sq. ft. grate area.



Early Steam Gage on a Winans "Camel", Probably between 1852 and 1855.

In 1850, two 0-8-0 engines built by Baldwin for the Pennsylvania Railroad were sold by that company to the Reading, as it was feared they were too heavy for the bridges on the road of the original owner, although some other reason must have been the true one, as the selling company retained an exactly similar engine built at the same time. These engines had 17 in. x 22 in. cylinders, 44 in. drivers, and weighed 50,975 lbs. They had Bury (haystack) domes, deep horse-shoe fireboxes, a small additional dome on the waist of the boiler, and all the driving wheels between the firebox and front of smokebox. One of the same design was built at the same time by M. W. Baldwin for the Reading. All had a peculiar arrangement of the Baldwin hook motion, having both rockers carried in one set of boxes, one rocker being hollow and thus serving as the journal for the other.

The "Massachusetts" was a 4-4-0 engine built for the company in July, 1849, at the "Boston Locomotive Works" of Hinckley & Drury. It had inside cylinders 15 in. x 18 in., 54 in. drivers, and weighed 20½ tons. It had a peculiar form of drop-hook valve-gear with an independent half-stroke cut-off, all so arranged that the reversing of the engine and the control of the cut-off were effected from the same lever. This gear was also used on one Wiimarth engine which came under the writer's notice during the later years of its existence. The "Massachusetts" not only had inside frames, but also composite outside frames, these latter consisting of two broad plates of iron with wood centers, all being riveted firmly together. Another peculiarity is a sort of extension front into which the cinders passed from the smoke-stack through a pipe attached to the usual "dust hole." This same arrangement is shown on a drawing in my possession of an engine built in 1851 for a New England railroad by the Amoskeag, N. H., company.



Furnace End of "Camel" as Remodeled by James Milholland in 1863.

The "Patapsco" was a "short firebox" "camel" built for the Reading by Ross Winans in October, 1850, and with one or two more of similar design which followed it, gave such good results with anthracite coal and in other respects, that it was followed in succeeding years by other "camels" of the "long firebox" type until by 1859 the number of these engines on the road had reached 42.

This number was afterward diminished by the scrapping of one or two and the entire remodeling of others, until it dropped to 31 by 1864, but in 1868 was increased to 38 by the purchase in that year of the Dauphin & Susquehanna Railroad and its equipment. The "Patapsco" had 18 in. x 22 in. cylinders, and weighed 24$^{6}/_{10}$ tons. The long firebox "camels" had 19 in. x 22 in. cylinders; firing chutes on the sloping roof of the fireboxes; grate surfaces of about 23½ sq. ft. each., and ranged in weight from 50,200 to 55,000 lbs. With the exception of the fireboxes, of the first three, the general features of all were alike. In 1863-4 James Millholland substituted link motion for the hooks; two round guide-bars placed one above the other, for the single square bars used by Winans, and crossheads with glands on the outer ends where the guide-bars passed through. These glands are variouly stated to have been packed with Babbitt metal, rubber, hemp, lead and leather. As I believe my informants to be reliable, it is just possible that all of these materials may have been used singly at different times or on different engines. This type of guide and crosshead had been used on other engines of the company after 1851, and was the standard for many years. A few are still in use, I believe, or at least were very recently, on a number of the older engines yet in service.

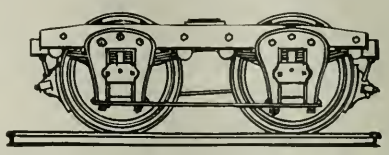
Probably the first pressure gage ever used on a locomotive in America was on engine "Minnesota," one of the first three "camels" referred to. The "Minnesota" had been built for a railroad in the New England states, and was meant to use anthracite coal, but the employees of the line were unfamiliar with the use of this fuel, and as the performances of the engine were therefore unsatisfactory, it was sold to the Reading, coming on the road soon after the "Patapsco," and also was the smallest "camel" owned by that company, its cylinders measuring 16½ in. x 22 in.; drivers 42 in., and its weight being but 22½ tons.

The steam gage referred to consisted of a diaphragm attached to a cross brace between the frames directly under the dome and attached to the boiler on its upper side by a pipe which extended up through the sheet about 5 or 6 in., in order to prevent the entrance of mud or other sediment. Its under side, which was of flexible metal, was attached to a compound lever extending horizontally across the frames. This lever was connected by short posts to the frames, and at its outer end was attached to a vertical rod which extended upwards into the cab and through a guide on the side of the dome. The upper part of this rod was flattened and contained a graduated scale from 0 to 120 lbs., which was an ample limit as the maximum pressure carried on the engine was but 100 lbs. One edge of the guide formed the point from which the pressure was indicated.

When the long-furnace camels came on the road the furnace-ends were of Winans' standard type without any water space, but of course covered by two large firing doors on their upper half, and on the lower part with a large single door to afford access to the grates and for cleaning the fire. In their later years, Millholland altered some of these, if not all, by adding a water space at each side of these ends, which then left an opening of about 18 in. in width, extending from the top to the bottom, for access to the grates.

About 1869 some one thought that he had discovered an inherent and dangerous weakness in the boilers of these engines, and 17 were put out of service within a short time. The "scare" soon assumed such proportions that a sweeping order was issued to take all the rest off the road as rapidly as possible. As a result, by the end of 1870 only four remained, and these vanished into the obscurity of the scrap heap before 1871 had ruled the calendar for very many moons. Their memory, however, was perpetuated in the adoption of many of their features in subsequent engines. While this was noticeable to an extent on some other lines, it was especially so on the Reading; probably because the success of these engines in using anthracite coal made them favorites and thus impressed the other features upon the officials.

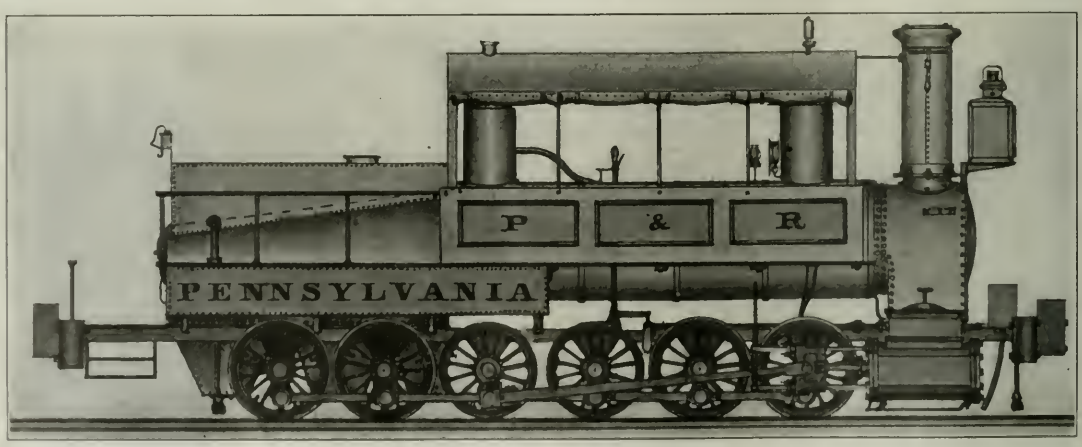
In some one of the years not far from the advent of the "camels," Lewis Kirk, who had been master mechanic of the company from 1844 to 1848, and during that time had rebuilt many of the small 0-6-0 freight engines on heavier lines, became a partner in the firm of Davenport, Bridges & Kirk at Cambridgeport, Mass., and as he was supposed to know the requirements of the Reading, an order for a 4-4-0 engine was given that firm. This engine when it came was named "Cambridge," and had 15 in. x 22 in. cylinders, 54 in. drivers, and was a close imitation of the Hinckley engines with one exception. Its weight was 24 tons, and 15 of these were on the truck. A standing joke among the employees thereafter was that



Tender Truck, 1860-1874.

they had to put the heaviest engineman and fireman in service on the footplate to "keep her down"!

The "Pawnee" was built in 1852 by Jas. Milholland at the company's shops in Reading, and shows many earmarks of the "camel," among which are the solid end rods and sloping top firebox placed behind the frames. Its pump, however, was original in having a heater between it and the point of admission to the boiler. It also had two combustion chambers, one at the firebox end of the boiler barrel and the other about midway between the smokebox and the firebox. The flues connecting the latter with the smokebox were smaller in diameter than those leading from it to the back chamber. The "Pawnee" had three pairs of 46 in. driving wheels and one pair of 30 in. leading wheels, all set in pedestals rigidly attached to the engine frame, and all placed between the cylinders and the firebox, an arrangement which for some unaccountable reason seemed to meet the approval of some locomotive builders and railroad officials of that period, and was followed in two Norris engines and in the Smith & Perkins engines built for the Pennsylvania soon after. M. W. Baldwin also caught the "fever" slightly and built

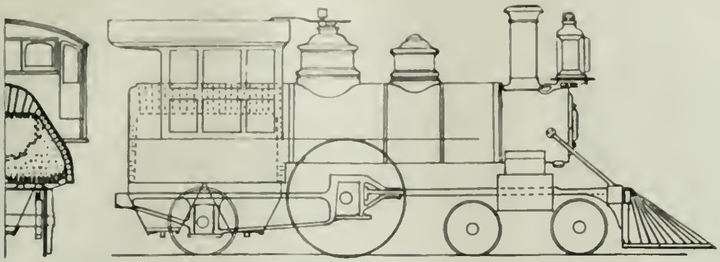


Engine "Pennsylvania," 1857; Philadelphia & Reading.

12 for the Pennsylvania with three pairs of drivers and one pair of leading wheels in rigid pedestals on the engine frame, but with the drivers spread widely apart, the rear pair being behind the firebox. Returning to the "Pawnee," the engine of that name was the second of the class built at Reading, but as the "pony" wheels were new to the men, I have been informed that some of them thought the names Pony and Pawnee were synonymous and styled all of the class "Pawnees" as they were built, and the officials, unwittingly perhaps, adopted the same nomenclature. They were probably the first engines with the Milholland guides and crossheads already described. Galvanized sheet-iron was just becoming popular at the time of their advent, and at least one had a boiler

jacket of this material used without the addition of any paint or varnish. These jackets soon rusted away and were replaced with the orthodox Russia iron. The "Pawnee" engines continued to be the standard for freight service for about 10 years, although a few of the later ones were built with main rods attached to the second pair of drivers. All had the Gooch suspended links.

In 1857 Milholland built a 12-wheel connected locomotive, without truck wheels, to be used as a pushing engine on heavy coal trains between Falls of Schuylkill and Port Richmond wharves at Philadelphia. It was named "Pennsylvania," and had a boiler somewhat like that of the "Pawnee," a cab like the Winans "camels," even to the canvas curtains instead of glazed sash, one water tank on top of the firebox, and two more placed one on each side of the boiler at the rear. No coal was carried and the firing was done at either end of the run, which was not long but strenuous. The cylinders were 20 in. x 26 in., and the drivers 43 in. in diameter, and grate surface $31\frac{1}{2}$ sq. ft. The total weight of the machine was 50 tons. It is said to have performed very satisfactorily, though in later years two pairs of the drivers were removed and replaced by a four-wheel truck. In this shape it was still reported in service, bearing the number of 1149. While this engine was practically of saddle-tank type, the first saddle-tank engine as we now understand them, came on the road in 1860.



No. 507, Built by Baldwin Locomotive Works in 1880.

Cylinders, 18x24 in. Drivers, 78 in. Firebox, 94x96 in. = 56 sq. ft. grate area. Auxiliary cylinders under waist of boiler enabled weight on drivers to be varied from 35,000 lbs. to 45,000 lbs.

Engine No. 14.

Built in 1866 at the locomotive works of Norris Bros., Lancaster, Pa., to working drawings of the Philadelphia & Reading's "Gunboat" type for another company which wished to experiment with this kind of locomotive.

In 1862, the "Gunboat" type of freight engine used for so many years until supplanted by the larger engines after the advent of the Wootten firebox, were first built. While retaining a few of the features of the "Pawnee," they were larger and better in every way. The drivers, six in number, were 48 in. in diameter, and the cylinders 19 in. x 22 in. The weight was about 66,000 lbs. The four wheels of the truck were 28 in. in diameter. The pumps were driven by return cranks from the rear parallel-rod pins, and were of a double-action type. The frames were of composite type. Each consisted of two bars of iron about 6 in. wide set vertically about 3 or 4 in. apart, and united by thimbled distance pieces. The pedestals were separate and fastened between the bars of the frames. A number of 0-8-0 engines similar in all other respects to the "Gunboats" were also built about the same time, and many passenger engines with practically the same type of boiler. Quite a number of the "Gunboats" and passenger engines are yet running, and I have seen at least one of the 0-8-0 type within three or four years in the yard at Tamaqua.

In the latter part of 1877 the first Wootten firebox was built and put into service, and later was taken to the Paris Exhibition of 1878, where it attracted considerable attention. The barrel of the boiler of this engine, 408, was almost like that of a "Gunboat," and the cab was perched high on the sloping top of the "Wootten." After the close of the exhibition the engine was taken to the Northern Railway of France and put into service, but not until the cab had been removed to a position forward of the firebox, and thus made the engine the forerunner of the host of Wootten engines of today with their cabs but a short distance behind the smoke-stacks and called by many "Camelbacks."

The advent of this type of firebox marked a decided change in the locomotive equipment of the company. All new engines except a few 2-8-0 built at the Baldwin works within the early years of the last decade, received Wootten fireboxes and the corresponding arrangement of cabs and other parts, and a number of old engines were rebuilt on these lines. The exceptions mentioned were intended to use soft coal, an innovation in the company's practice which occasioned no little comment in railroad circles at the time. The sloping tops of the first Wootten fireboxes was superseded in later engines by perfectly straight tops. Although consuming anthracite coal, and especially coal of inferior grade admirably, the type has never met with ardent supporters on railroads outside of the anthracite coal district, chiefly, perhaps, on account of its necessitating the separation of the engineman and fireman during much of the time the engine is running, and thus increasing the danger of accident through the engineman missing signals on account of sudden illness or death while at his post.

In 1880 the growing demand for increased speed on passenger train schedules induced the Reading Company to design and build engine No. 507 from which great results were expected, but which, like the "Novelty," failed to meet such expectations. This engine was a 4-2-2 with 18 in. x 24 in. cylinders and 78 in. drivers. It had a Wootten firebox and a steam cylinder was placed under the boiler in front of the firebox and so connected to the equalizing beams as to enable the weight on the drivers to be increased or diminished as might be required. It was built by the Baldwin Locomotive Works, and was No. 5,000 of their manufacture. After a brief service on the Reading it was sold to the Eames Vacuum Brake Co., and was taken, after a few changes to adapt it to the lines, to England to show the working of the Eames brake to the railroad officers and employees of that country. It was followed in 1895 by another 4-2-2, which gave much better results. Yet only one more of the type was built, and both were followed by many

4-4-2 and some 2-4-2, from all of which good results in speed on heavy trains were obtained.

In recent years the company has had numerous engines built for suburban trains which appear to be well adapted to the service. They are of double-ender, tank type, 2-6-4, with 20 in. x 24 in. cylinders, 61⅝ in. drivers, and weigh 201,700 lbs.

The tenders used during the existence of the company have differed little from those of other roads. When eight-wheel types first came into use the first two pairs of wheels were arranged in a swinging truck and the last two pairs were carried in pedestals attached rigidly to the frame. Brakes were used only on the first two pairs of wheels, as it was feared that if applied to all there would be a tendency to derailment when drawn. They consisted of wooden shoes or blocks, suspended between the wheels from the frame, and actuated by short arms on a shaft which extended crosswise between the blocks, and had a long operating lever attached to the end on the right hand side. When brakes were afterward applied to all wheels, this lever was removed to an additional transverse shaft which was placed midway between the trucks and connected by short arms and rods to the shafts on the trucks. The simple type of truck used on the Winans "camels" was a favorite in the early days with the company, and was used on the "Pawnee" class and other engines. After that, a wooden frame somewhat like that of a passenger car truck was used for many years. Although some of these were very recently in use, the diamond-bar and, later, various forms of stamped-steel trucks have taken their place. A number of the small 0-4-0 saddle-tank shifting engines use a small four-wheel tender without water space to carry a moderate supply of coal.

The car equipment of the company has been referred to, and it may be added that at one time it ran its own parlor cars, but later changed them to ordinary day coaches and fell back upon the Pullman Co. for a supply of "elegance."

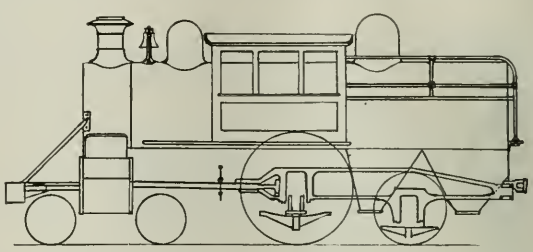
When the Philadelphia, Germantown & Norristown Railroad came into possession of the Reading it brought with it a lot of passenger coaches which were provided with gratings of about $^{5}/_{16}$ in. round iron bars placed about 3 in. apart, vertically, over the windows. This grating was probably meant to prevent injury to passengers from putting their arms or heads out of the windows; nevertheless it gave the whole outfit the appearance of Black Marias carrying their loads of prisoners to the penitentiary.

Another odd feature obtained by this purchase was the railroad station at the end of the Chestnut Hill branch. Here the engines were turned at the end of each trip, and as the turntable was too short to hold both engine and tender at the same time, they were always uncoupled and turned separately.

The passenger stations in Philadelphia previous to the building of the present terminal were at Broad and Vine streets for the first station in the city after the opening of the road, and removed later to Thirteenth and Callowhill streets; that of the Philadelphia, Germantown & Norristown Railroad, which became a part of the Reading system, at Ninth and Green streets; and the New York division station at Third and Berks streets—three widely separated points.

The Reading is peculiar in many respects. It, more than any other railroad, dominates the mining, hauling and shipping of the unique fuel to which it owes its origin. It has at present a mileage of 2,122, and a trackage of 4,686, the greater part of which is situated in a comparatively small portion of the eastern part of Pennsylvania. Much of this traverses what would rank among the grandest mountain scenery of the state, were it not that this same fuel which plays so important a part in the existence of the road, has changed the whole region to a region of desolation, covering it with leaden-hued culm banks and polluted streams. Even the cities and smaller towns are dingy and forbidding, the whole uniting to form a veritable black country differing in many ways from the outside world.

The road has also drawn largely for its employees on a community where "Pennsylvania Dutch," a strange patois formed of about equal parts of English, Dutch and German, is extensively used by the farmers and other descendants of the earlier settlers, and therefore by many of the employees of the railroad. Within four years I have heard an entire crew of a local freight train on the road conducting all their conversation in this tongue, as I watched them drilling cars for 20 minutes at a town within 25 miles of Philadelphia. Even the orders given to them verbally by the rather intelligent young station master were couched in the same, to me, unintelligible jargon.



P. & R. No. 385. High-Speed Passenger, Vauclain Compound, Built in 1895 by the Baldwin Locomotive Works.

Cylinders: High-pressure, 13x26 in.; low-pressure, 22x26 in. Drivers, 84½ in. Firebox, 114x96 in. = 76 sq. ft. grate area. Weight, 115,000 lbs.; on drivers, 48,000 lbs.; on truck, 39,000 lbs.; on trailer, 28,000 lbs.

The company also possesses a record of interest in the fact that a former president, Franklin B. Gowen, was able to cope with, and end forever, the fearful career of the "Molly Maguires," an organization which in the early seventies attained such a hold upon the anthracite region that operators and miners of any reputation at all conducted the plants at the risk of their lives, and too often formed the subjects of mysterious disappearances, or brutal assaults and murders committed with most extraordinary boldness; and when even people from other places, and having no connection with the coal companies, were openly insulted on the highways and streets.

Type of Suburban Tank Locomotive Now in Use on the Philadelphia & Reading.

This article must not close without reference to the valuable aid so cheerfully accorded the writer while collecting the data contained therein during past years, by L. B. Paxson, former Superintendent of Motive Power of the Reading; E. J. Rausch, who was with the locomotive department of that company during many years at the time most of the earlier engines referred to were in service; H. F. Colvin, who is also very familiar with the early equipment of that road; the Baldwin Locomotive Works; J. Snowden Bell, and an old volume prepared by E. Reuter, who was a draftsman in the service of the Reading, and from whose excellent work the drawings of the "Delaware" and "Massachusetts" have been reproduced.

GENERAL NEWS SECTION

NOTES.

The Baltimore & Ohio is to establish a police force throughout its lines, to be organized like that of the Pennsylvania lines west of Pittsburg.

On the lines of the Southern Pacific, near the Great Salt Lake, Utah, water from the lake is now regularly used to destroy weeds in the roadbed.

The railroads running east from the Missouri river have decided to apply the new and higher freight tariffs to the grain, estimated at 6,000,000 bushels, which was in elevators at Missouri river points on July 1, when the advance in the tariffs took effect. The owners of the grain had expected that it would be carried forward at the old rates.

It was announced this week in New York that the Southern Pacific had once more brought the Colorado river under complete control, and that the property in the Imperial valley and thereabouts, which was damaged or endangered by the break in the river, had been turned over again to the control of the California Development Company.

The Union Pacific and the Oregon Short Line, having received the approval of the Interstate Commerce Commission, announce, for the period between July 19 and September 1, a reduction of 25 cents a ton on coal shipped to points in Washington, Idaho and Nevada, this action being taken to stimulate the movement of coal at this season with a view to preventing a congestion in the winter.

It is announced in Madison, Wis., that Chairman John Barnes, of the State Railroad Commission, has resigned his office. The reason for this, according to the press dispatches, is the fact that the Legislature has passed a law limiting passenger fares to 2 cents a mile, in disregard of the fact that the Commission has published a decision that 2½ cents is a fair rate to be charged by the roads of the state.

The Pennsylvania Railroad publishes the following comparison of prices paid last year (1906) with those paid the current year, all of them being increases: Steel angles 31 per cent., bronze journal bearings 25 per cent., copper 22 per cent., freight car wheels 21 per cent., and malleable iron castings 20 per cent. Brass and tin have each increased 16 per cent., car axles and cross ties 12 per cent., rail braces 8 per cent., white pine lumber 8 per cent., and air-brake hose 7 per cent.

On Wednesday last the New York, New Haven & Hartford began the use of electric motors on a few of its passenger trains between New Rochelle and the Grand Central Station, New York. New Rochelle is about four miles from the junction with the New York Central and 16 miles from New York. Five regular westbound trains begin their trips at this point and these are the first to be propelled by electricity. It is expected to use the electric power farther east within a week or two.

The State Railroad Commission of Missouri has issued a voluminous report on the condition of tracks of the Missouri Pacific in that state and has ordered a reduction in the maximum rates of speed on certain sections of the road as follows: Thirty miles an hour between Jefferson City and Kansas City; 12 miles an hour on the Colorado line between Kansas City and the Kansas state line; 25 miles an hour between Kansas City and Cole Junction, and 25 miles an hour between Pleasant Hill and Joplin.

Chicago newspapers say that railroads west of that city recently declined to comply with a request to expedite shipments of agricultural machinery from the International Harvester Company, which had been delayed on the road and which were urgently needed for use in gathering the crops in Nebraska, Kansas and other Western states. The legal advisers of the roads decided that to thus favor particular shipments would be an illegal discrimination; and they declared, furthermore, that any such favor, if granted, would be subject to special odium because it would be a favor done for a "trust."

The Public Service Commission of the second district of the State of New York announces that about September 1 it will begin the investigation of car service and demurrage charges. It is the intention to give public hearings, and all shippers, consignees and railroads are asked to present in concise and orderly form any facts they may have bearing on the grievances of shippers and consignees and the best ways of curing them. Persons having grievances are reminded that vague or general statements will be of no assistance to the Commission. The railroads will be required to furnish all necessary detailed reports concerning the way in which demurrage rules now work.

The New York State Public Service Commission, second district, has appointed Frank Barry Chief of the Division of Traffic at a salary of $4,000 and Walter E. Griggs of Jamestown Chief of the Division of Tariffs at a salary of $3,000. The Commission for the first district has appointed Abel E. Blackmar Chief Counsel at the statutory salary of $10,000 a year. The same board has appointed William J. Norton, First Assistant Secretary, and J. O. Hammett Second Assistant Secretary. Mr. Norton is a mechanical engineer and Mr. Hammett has been an Albany newspaper correspondent.

The railroads leading west from Chicago expect to issue complete tariffs of reduced passenger rates this week. Through rates to points beyond the Missouri river will, in most or all cases, be made up on the basis of 2 cents a mile to the Missouri river, with the addition of the existing rate west of that river. The new rate to Kansas City is $9.20, as compared with $12.50. This difference of $3.30 is the difference between the old and the new rates to Denver and other points in the far West. Since the tariffs have been practically finished the State of Wisconsin has ordered a reduction of local fares in that state to 2 cents a mile, so that for points in the Northwest the rate clerks will have to do their work all over again. An officer of the Chicago, Milwaukee & St. Paul, denying the report that 2 cents a mile would be the rate from Chicago through to points in North and South Dakota, says that his company will make no reductions not forced upon it by the law. Rates to points in North and South Dakota are figured at 2 cents to the border of those states and 2½ cents beyond. In North Dakota the rate of 2½ cents is now prescribed by law and in South Dakota the State Railroad Commission has power to prescribe that rate.

An Advance in Rates and Reasons for It.

The Great Northern and the Northern Pacific announce that on October 1 the rates on lumber and shingles from the Pacific coast will be advanced—to St. Paul 25 per cent. (from 40 cents to 50 cents), to Chicago 20 per cent., and to Missouri river points 10 per cent., and in the announcement they say:

"The conditions that influenced the reduction in rates on lumber from the Pacific coast to the East in 1893 on completion of the Great Northern Railway no longer exist.

"(1) At that time the cut of white pine in Minnesota and Wisconsin was at its height and Pacific coast lumber could not have paid higher freight rates in competition with lumber from these nearer sources of supply. Since then the forests of Minnesota and Wisconsin have been rapidly depleted, and the consequent enhancement in value of the white pine has materially limited its competition with the Pacific coast lumber.

"(2) In 1893 the preponderance of traffic on the transcontinental roads was westbound, and without the lumber it would have been necessary to return many cars empty. To-day this condition is absolutely reversed. Cars have to be sent west empty for lumber.

"(3) The cost of operation and maintenance of the railroads has materially increased, occasioned principally by demands of the public for better service (both freight and passenger), higher wages to employees and the additional cost of supplies. In three years fir ties have increased in price 86 per cent.; fir car sills, 67 per cent.; fir car siding, 24 per cent., and fir timber, 81 per cent.

"In view of the foregoing and considering the large reductions in their gross revenue recently forced upon them by legislative action in various states, it is obvious that the present abnormally low rates are no longer warranted."

New Record Around the World.

In an interesting letter to the London *Times* Lieut.-Colonel Burnley-Campbell has been describing how to beat the record of his prototype in Jules Verne's "Round the World in Eighty Days" by circling the globe from Liverpool westward to Dover in not much more than half that time. Traveling by the Canadian Pacific route, he left Liverpool at 7.20 p.m. on May 3 and reached Vancouver at 5 a.m. on May 14 and Yokohama at 5 a.m. on May 26. Departing thence at 7 p.m. next evening he traveled across the island by rail to Tsaruga, and sailing from that port, a few hours later landed at Vladivostok at 2.15 p.m. on May 30. Then he caught the trans-Siberian train at 7 p.m. for Moscow, where he arrived at 2.38 p.m. on June 10, and finishing the journey via Warsaw, Berlin, Cologne and Ostend, landed at Dover at 2.50 p.m. on June 13. The

time consumed on the journey was thus 40 days, 19½ hours. Of course, in strictness he did not quite complete the circle, but seven hours more would have sufficed him to do so, since he could have reached London soon after 5 p.m., in time to catch the 5.55 from Euston due at Liverpool at 9.30. On the whole he had very good luck with his connections, and the only place where there was any serious waste of time was at Yokohama, where he had to stay 38 hours; but to have avoided this would not have done him any good, since there was no earlier train that he could have caught out of Vladivostok. His most anxious moment must have been in the Japan sea, when his steamer ran ashore in a fog, but in spite of this delay he had the sufficient margin of 3¾ hours at the last-named port, though if his steamer had remained aground four hours longer than she did, the result, in the absence of a train on the Siberian railroad, would have been an increase of four days in his time. The journey is a striking example of what the Siberian railroad has done in increasing rapidity of communication, for so recently as the beginning of this century, before that line was constructed, the feat would have been quite impossible.

Atchison Merits.*

Merit marks placed to the credit of various employees in the month of June:

J. W. Wright, section foreman, 10, on account of best attention being given to switch lights.

William Walck, sealer, and Charles Coleman, flagman, 10 each, for discovering parties stealing merchandise from a car.

A. H. Hill, engineer, and W. D. McCeery, fireman, 15 each, for discovering fire in car at Argentine and taking it across the main line, thus saving other cars from burning.

C. A. McKneeley, brakeman, 10, for prompt action in reporting telephone wire across track and too low to clear a man on a car, thus possibly preventing a personal injury.

W. O. Russell, agent, Duke, Texas, 15, for diving into water tank through 14 ft. of water, repairing valve and putting water tank into service without making it necessary to empty it.

W. M. Riggs, engineer, and C. D. Hill, conductor, 10 each, for extraordinary efforts put forth to keep engine alive and get freight into terminal. In this case engine on local freight had burst a flue, but by liberal use of bran and sawdust the engine was taken to terminal with but slight reduction in tonnage.

T. P. Guilfoyle, conductor, 10, for lifting four tickets on train No. 8, June 11, in the hands of wrong party. Mr. Guilfoyle is probably the most skilful conductor on the system in detecting scalped tickets.

H. G. Hadler, operator, Woodward, Kan., 10, for moving Pecos Valley trains when wires were down. Mr. Hadler started a train sheet at Woodward and handled trains for the Pecos Valley Lines until their wires were working.

New Barge Canal Engineer.

Governor Hughes of New York has appointed, subject to confirmation by the Senate, Mortimer G. Barnes, of New York city, a member of the Board of Advisory Engineers for the Barge Canal, succeeding Elmer L. Corthell, resigned. Mr. Barnes is a graduate of the University of Michigan, and has worked on the construction of many waterways, including the Birmingham Canal, the Sault Ste. Marie Canal, the Illinois & Mississippi Canal and the Panama Canal. He is at present connected with the work on the new Catskill reservoir.

The Art of Handling Men.

President Winter, of the Brooklyn Rapid Transit Company, says there are three principles. Before men will work for you they must understand: first, that you are going to be boss; second, that you know your job and theirs; third, that you are square. He is an experienced railroader, a westerner, and now has 14,000 men under him, operating more than 250 miles of street railway. One of the penalties of a high corporation position, he says, is that you lose the close contact with men - for ten years he hasn't been as close as he wanted to be.

Introduce a new head or sub-head into any working force, from a half-dozen bindery girls to a railroad division, and that force instinctively braces itself for a trial of strength with the newcomer. Then follows a shock, and one or the other wins. There can be no compromise. "When I was in the railroad business," says one corporation executive, "I kept an eye out for trouble and adjusted it." Being an acute "trouble man" is a large factor in management. Many an executive is treating symptoms, never finding the seat of the disease.

Being square with employees is important and difficult. It is easy enough to deal out justice to men under your eye. But how can it be managed over a system of 11,000 miles of railroad, or in a department store where the distance between the proprietor and some of his people is so great that one of them may starve to death without his knowing it until the newspapers begin to castigate him? Such a case happened in New York a few years ago, and to-day every employee of that merchant is required to keep at home a postal-card, addressed to the store, upon which a report of sickness must be mailed.

How are petty bosses to be controlled? President Vreeland, of the New York surface-car lines, says that wonders may be worked through firmness and intelligent sympathy with men by an executive who knows the kind of lives they lead, the anxieties that they carry about, the ambitions they have for themselves and their families. But to find petty bosses with this sympathy is a crucial matter. For lack of them many a system breaks of its own weight. * * *

In a Boston store where a board of arbitration sits on the appeal of every discharged employee, two-thirds of those who appeal are reinstated because it is found that subordinates have been unjust or worked out a grudge.

The Brooklyn Rapid Transit Company investigates even the appeal of the man whose application for employment has been denied. President Winter took up such an appeal from his desk the other day to illustrate this point, and found that it was the application of a Hebrew who charged that he had been excluded on racial lines. The real cause lay in his physical disability. But his appeal was not denied until that had been made certain. An employee with a grievance can sometimes take his case right up to the president, and even past the president to the board of directors. But good judgment must be exerted, or subordinates would be weakened in authority.

One railroad officer says he can't do much with men until he knows them, and can't know much about a man until he has seen his wife and family. This spirit seems to be growing among executives, and accounts for the social features that sprout out of welfare work, such as dinners, dances and lectures. One industrial president in the Middle West carries a photographer with him when he goes on a foreign vacation, has stereopticon slides made when he comes home, and lectures to his employees on "The Homes of the Pharoahs" or "Europe as I Found It." Probably nobody would care to pay to get into one of his lectures. But that isn't the point.

President Ralph Peters, of the Long Island Railroad, holds a reception in his office the first week in the year, and any worker on the road who can arrange his schedule is welcome to come in and shake the "Old Man's" hand.—*James H. Collins in Saturday Evening Post.*

British Comment on Hot Water Boiler Testing.

American boiler practice does not accord in many ways with British ideas, and we have several times called attention to what appear to us to be very antiquated views. Any boilermaker who here advocated that hydraulic tests should be made with hot water, on the ground that it is not so likely to injure the boiler, would be pretty generally suspected of turning out poor work, and if he urged that such a test enabled leakages or fractures to be more easily discovered, the majority of persons familiar with the subject would think he was trifling with their intelligence. Yet both these suggestions were made in a report presented by T. W. Rowe, of the Canadian Pacific Railway, at a recent convention of the International Railway Master Boilermakers, Cleveland, Ohio. The writer of the report remarks he has had little experience with cold-water testing worth relating, and is strongly in favor of hot-water in preference to cold-water testing, as being the nearest to the working conditions yet provided; and "as the material with which we construct a boiler becomes stronger up to about 600 deg. temperature, the hot-water test is not so likely to develop an injury to the boiler, and leaks or fractures are less likely to pass undiscovered." Leakages from a hot boiler are much more likely to evaporate without leaving a trace than when the water is at normal temperature. At least, this is the view which engineers here universally accept, and how the writer of the report can arrive at a distinctly opposite conclusion is beyond our comprehension.—*The Mechanical Engineer.*

Overwork in England.

Responding to an order of the House of Commons, the British Board of Trade has issued a statement showing all instances during the past eight years in which the inspectors in reporting on railroad accidents in the United Kingdom have spoken of excessive working hours. The list would appear insignificant when compared with a similar list in regard to train accidents in the United States, there being only 34 items in all. When comparing it with cases like Terra Cotta and others which have appeared in the United States Government Accident Bulletins it becomes of still less apparent consequence,

*Extracts from a long list, in the Santa Fe Employees' Magazine.

as most of the cases refer to men who had been on duty only 12 or 13 hours. Eighteen railroads appear in the list, but of the 34 items there are nine which occurred on a single road. One other road has five items. In a hasty glance through the report we find only two or three cases which would have been forbidden by a 16-hour law such as has been passed recently in this country by Congress and by a number of state legislatures. Only eight of the items, however, refer to train accidents, all of the rest being cases of men injured by other causes.

The Logic of the Situation.

"So you are in favor of government ownership?"

"Emphatically," answered the disinterested citizen.

"I suppose you have studied the subject thoroughly?"

"No, I can't say I have. But I fancy it is something the railroads wouldn't like." *Washington Star.*

Heavy Bail.

Following a slight collision on the Third Avenue Elevated Railroad at 106th street, New York city, on July 16, the conductor and motorman of the train at fault were arrested and held in $10,000 bail each, pending hearings before the court on charges of assault, or manslaughter, about 20 persons having been injured by broken glass, two of them seriously. There was a crowd of boisterous men on the leading car of the second train and, according to the reports, the presence of these men, some of whom cut off the view of the motorman, was the occasion of the negligence by which this train was allowed to run into the one ahead of it.

On Monday of this week Mr. Eustis, of the state Public Service Commission, having made an investigation, laid before the Commission a report on this collision holding that it was due to the riotous action of the passengers, for which the motorman was not to blame.

A Great Shrinkage at Pittsburg.

Atlantic City is not the Mecca of Pittsburgers this year. Instead of there being 30,000 at the resort at this time of the year, as has always been the case before, the number of Pittsburgers there at the present time will not reach 1,000. And all because the Pennsylvania, along with other railroads, has shut off free passes. In years past the Pennsylvania people required from three to four sections of the special trains that they ran for their Atlantic City excursions. This year one excursion was arranged, and the usual special train was provided. But it was not needed. Just two persons showed up with tickets. Not only is the man who rode on a pass remaining at home, but many of those who formerly paid their fares are doing likewise. This is accounted for by the fact that the man who paid his fare usually accompanied a man who rode on a pass. Because he had a pass, this man would be willing to help pay the traveling expenses of the man who didn't have a pass.—*Philadelphia Press.*

INTERSTATE COMMERCE COMMISSION RULINGS.

Grain Rates from Kansas Producing Points Adjusted.

In an opinion by Commissioner Prouty decision has been announced in the case of Farmers, Merchants and Shippers' Club, of Kansas v. Atchison, Topeka & Santa Fe and Gulf, Colorado & Santa Fe, and in the case of the same complainant against the Chicago, Rock Island & Pacific and others. These cases involved rates on grain from various points of production in Kansas. The district of origin is the same in both instances and the destinations are identical. The two cases were heard together and were disposed of in one report.

The complaint put in issue the reasonableness of defendants' rates on grain from Wichita and other shipping points in Kansas to Kansas City, Mo., and Galveston, Tex., for export and to various destinations in Texas for domestic consumption. The Commission found that the rates to Galveston for export and to the various destinations in Texas for domestic consumption are unreasonable of themselves and ordered reductions of from 3 to 5 cents per 100 lbs. to be made. It appeared that the rates from these shipping points must be the same to Kansas City, Mo., and to Kansas City, Kan., and that after the complaint was filed, the legislature of Kansas reduced by 15 per cent. the rates to the latter point, whereupon defendants, after accepting said reductions, reduced correspondingly the rates to Kansas City, Mo. For these reasons the Commission took no action concerning the latter rates. The destination points in Texas are divided into groups numbered 1, 2, 3 and 4, at the hearing, representatives of the city of Lancaster contended that that city should be transferred from group 2 to group 1, and the Commission upheld this contention. Other defendants against the shipping points in favor of Kansas City, Mo., were merged, but the Commission refused to modify the orders of the complaint.

Rates to New Mexico Points Reduced.

In an opinion by Commissioner Prouty the case of the Roswell Commercial Club and others v. the Atchison, Topeka & Santa Fe and others is decided. The complaint put in issue the reasonableness of rates between various points in the western states and Roswell, Artesia, Hagerman and Carlsbad, New Mex. The Commission held that the present class rates from Kansas City and St. Louis, Mo., Galveston, Tex., and Denver, Colo., to these points in New Mexico are unjust and unreasonable and reductions were ordered. Certain commodity rates to the same points in New Mexico were held to be excessive. The commodity rates on grain and grain products from points in Kansas and Oklahoma were ordered reduced from 47 cents on flour and 45 cents on wheat to 42 cents on flour and 40 cents on wheat per 100 lbs. The commodity rate on lumber from points in Texas and Louisiana was ordered reduced from 45 cents to 32 cents per 100 lbs., and that on salt in sacks from Hutchinson, Kan., was ordered reduced from 35 cents to 30 cents per 100 lbs. The commodity rates on apples, alfalfa and alfalfa meal from said points in New Mexico to Fort Worth, Tex., were held to be unreasonable and were ordered reduced from 50 cents on apples and 34 cents on alfalfa and alfalfa meal to 45 cents on apples and 30 cents on alfalfa and alfalfa meal per 100 lbs.

Parcels Express for Suburban Patrons.

In an opinion by Commissioner Prouty the case of J. E. Walker v. Baltimore & Ohio and United States Express Co. has been decided. These two companies operate, for the convenience of suburbanites, a parcels express from Philadelphia, Pa., to certain points on the B. & O. This is done by affixing stamps, which are sold at the railroad stations. The charges for these stamps are: For a package under 10 lbs., 5 cents; for a package from 10 to 25 lbs., 10 cents; for a package from 25 to 50 lbs., 15 cents. A person desiring to use this service puts the proper stamp on the package and delivers the package to an agent of the express company at the 24th and Chestnut street station of the Baltimore & Ohio in Philadelphia. The express agent cancels the stamp, bills the package to destination and turns it over to employees of the railroad company, who carry it in baggage cars. For its services the express company receives from the railroad the entire receipts from the sale of these stamps. The services of the railroad company in handling the packages are without compensation.

Previous to 1890 the Baltimore & Ohio carried without charge in its baggage cars parcels from Philadelphia to outlying stations in the vicinity. Its purpose in so doing was to increase the convenience of suburban life and stimulate suburban travel. As the amount of this business increased, much confusion and dissatisfaction resulted; whereupon the present system was adopted. The purpose of the railroad in handling packages without compensation is similarly to stimulate suburban travel. In general such packages are sent either by or for the benefit of patrons of the railroad. Packages of eatables are carried in the baggage cars of the company free up to a certain weight and at a small compensation when over that weight, provided the package is for a commuter or is carried on the train with a passenger.

The complaint in this case was brought by a person who desired to send packages from Philadelphia to Hockessin, Del., but who was, previous to August 28, 1906, refused the privilege on the ground that he was not a regular patron of the road, in spite of the fact that this privilege was in most cases open to the public generally. Since August 28, 1906, the day on which the Rate Law went in effect, the privilege has been extended to complainant and the public, but defendants insist that it is their right, if they wish, to restrict the privilege to the patrons of the road, for whose benefit it is intended. The Commission holds that on the facts previous to August 28, 1906, the complaint was well founded. To select the complainant and apply to him a particular rule not applied to the public generally was clearly an unjust discrimination. No opinion is expressed on the lawfulness of the Baltimore & Ohio's practice in transporting packages of a certain kind free only when they belong to commuters or to a passenger on the train; nor is any opinion given on the right of the defendants to restrict the privileges of the parcels express service to patrons of the road, although the defendants asked the opinion of the Commission on that point. The Commission rules, however, that it is the duty of the United States Express Co. to establish for the benefit of the public an adequate service over this same territory at a reasonable compensation. Whether the charge for the stamps affords such compensation is not now considered.

TRADE CATALOGUES.

Traction Couplers and Draft Rigging.—The Edwin C. Washburn traction devices, made by the Washburn Steel Castings & Coupler Co., Minneapolis, Minn., are described and illustrated in a 111-page catalogue just issued which is claimed to be the first catalogue devoted entirely to a complete line of couplers for traction service. The couplers are divided into three types: (1) The M. C. B., able to work on curves as sharp as 45 deg.; (2) type K, called a rigid coupling joint, and (3) type M, a simple link and pin arrangement. One hundred and fifty cars recently built by the St. Louis Car Co. for the Pacific Electric Co., of Los Angeles, Cal., are equipped with the first type mentioned. The other types are described and illustrated in detail, also traction draft riggings. The second half of the book shows a number of standard Washburn M. C. B. couplers that are considered as being peculiarly adapted to the requirements of traction service as used on steam roads; and also a design of cast-steel bolster or transom.

The Rotary Snow Plow.—In time of peace prepare for war. It is probably on this principle that a pamphlet illustrating and setting forth the merits of a rotary snow plow is issued in July by the American Locomotive Company. The value of the pamphlet lies not so much in anything new that it contains as in its reminder to those who may have forgotten that this type of plow can be driven through the deepest drifts at a speed impossible to rival by any other means of snow removal. The pamphlet contains a sketchy account of some of the performances of the rotary and their cost, a description of the machine and complete instructions about its use. It is interesting to note that the Walschaert valve gear is used. To those who are confronted with the problem of keeping a railroad open through deep snow this pamphlet should prove more than interesting.

Car Trucks, Bolsters, Underframes, Etc.—The 1907 catalogue of the Bettendorf Axle Co., Davenport, Iowa, describes the trucks, bolsters, tank cars, underframes, etc., made by this company. The Bettendorf truck with cast-steel side frame and journal boxes in one piece is well-known and has been described in the *Railroad Gazette*. The different standard and special designs are shown as well as their application to locomotive tenders and different kinds of cars. Different capacity body and truck bolsters made from standard shapes of open-hearth steel are shown. Underframes and tank cars fill the second half of the book, designs of underframes and principal parts and a number of designs of tank cars built for various users being illustrated.

Wyoming & North-Western Railway.—The Chicago & North-Western has prepared a folder on its new route to the Yellowstone National Park through Wyoming—the Wyoming & North-Western Railway. The folder tells of the resources and attractions of this "big-game" country and is illustrated with colored half-tones. There are relief maps of the part of Wyoming traversed by the new route and of Yellowstone Park. The opportunities for fishing, hunting and camping are set forth at length.

Pneumatic Tools.—A new 47-page catalogue has been issued by The Dayton Pneumatic Tool Co., Dayton, Ohio. The first half is devoted to hammers, the various styles being illustrated and described. A table gives the sizes and other essential facts about the different hammers and their work. Sand rammers, drills, hoists, holders-on, air hose, electrical drills, etc., are included in the latter half of the book, also "Climax" air compressors, which are accompanied by tables giving essential information about the different sizes.

Vises.—Catalogue No. 7 of the Emmert Manufacturing Co., Waynesboro, Pa., describes fully the company's wood workers' and pattern makers', and machinists' and tool makers' universal vises, as well as the "Tiger" parallel vise for machinists and iron workers. The illustrations show the universal vises set at different angles so as to hold the work in the most convenient positions. The catalogue gives dimensions, weights and prices of different sizes of each style of vise, as well as a price list of parts.

Track Drills.—The latest improvements in track drills manufactured by Cook's Standard Tool Co., Kalamazoo, Mich., are shown in a 12-page pamphlet just issued. The standard track drill of this company is illustrated in its various details and applications. The standard grinder and drill, and standard tool grinder are included, also lists of repair parts and prices of twist drill bits.

MANUFACTURING AND BUSINESS.

The Pullman Company has ordered applied to all its private cars Bliss axle light equipments, made by the Bliss Electric Car Lighting Company, Milwaukee, Wis.

The Central Inspection Bureau, 17 State street, New York, is inspecting 56 cars for export to South America and also a number of cars for Porto Rico, which are now being built by J. G. Brill Company, Philadelphia, Pa.

Otto Dieckman, Jr., representative at St. Louis of the Atlas Engine Works, Indianapolis, Ind., has been appointed Manager of the company's direct sales office at St. Louis. His office will be, as heretofore, in the Chemical building.

The Rostand Mfg. Co., Milford, Conn., maker of the McCarthy rack for passenger coaches, is now putting on the market a rack for parlor cars, the design of which follows closely the basic principles of the McCarthy patents with suitable additional ornamentation.

D. W. Ross, who recently resigned as Chief Purchasing Officer of the Isthmian Canal Commission, has been appointed Managing Director of the Magnus Metal Company, 111 Broadway, New York. W. H. Croft has been appointed Manager of the sales department and W. S. Bostwick General Manager.

L. W. Jones resigned on July 8 as President and Director of the Pittsburg Filter Manufacturing Company, Pittsburg, Pa. Mr. Jones had been with the company since 1903. He intends to open an office soon in Pittsburg as a consulting engineer, taking up municipal and industrial filtration plants, water softening and sewage disposal plants.

The entire issue of $13,000,000 5 per cent. 10-year convertible bonds of the General Electric Company, Schenectady, N. Y., has been subscribed to. The first payment of 50 per cent. was made on July 20 and the payment for the remainder falls due in six months. Since many of the subscribers have already paid in full, the company has, so far, realized from the new issue between $7,000,000 and $8,000,000, which is available for construction and other purposes.

The Cincinnati Planer Co., Cincinnati, Ohio, has increased its capital stock from $200,000 to $400,000. The proceeds will be used to cover the cost of the company's new plant now being built at Oakley, Ohio, a suburb of Cincinnati. This plant will be equipped with new machinery throughout and will be used exclusively for making large planers from 6 ft. to 12 ft. square. The present plant will continue to be used for the smaller sizes. Work on the new plant is now well under way and will be finished some time in September.

Gilbert Rosenbusch, C.E., of London, England, is in New York for a few weeks with address at 17 Battery Place. He is an American engineer, graduate of Stevens Institute, with ten years' residence in London, where he is an associate member of the British Institute of Civil Engineers. He has just completed his work as engineer in charge of construction of the lifts in the London underground electric railways and now proposes to introduce American mechanical and electrical specialties in Europe. He is well equipped in character, knowledge and acquaintance.

Iron and Steel.

Bids are in for about 7,000 tons of fabricated steel for freight sheds on piers 54 and 56, New York.

The New York, New Haven & Hartford is in the market for bridge steel for a lift bridge at Providence, R. I., which will require about 1,500 tons.

There are inquiries for about 7,000 tons of rails for electric lines in the Cleveland district, and sales are reported of from 1,000 to 2,000 tons of light sections.

It is thought that the Pennsylvania will re-let the contract for about 20,000 tons of fabricated steel, which was originally ordered from Milliken Bros. It is understood that the American Bridge Company has made the lowest bid, but the matter may still be adjusted between the Milliken receivers and the railroad.

The National Transcontinental Railway Commisson (Canada) has given contracts for rails and fastenings for the Grand Trunk Pacific aggregating about $1,850,000. The Algoma Steel Works, of Sault Ste. Marie, has a contract for 23,000 tons for the Abitibi section, half of which is to be delivered by November 1, 1908, and the other half in 1909. The Dominion Iron & Steel Company, of Sydney, N. S., has an order for 43,000 tons, half to be delivered before November, 1907, and the other half by July, 1908. Deliveries to be made at Edmundston, N. B., at Quebec, and at Levis, Que.

The United States Steel Products Export Company, of New York (United States Steel Corporation) has orders for 10,000 tons of 80 to 100-lb. rails to be used on extensions of the Victorian State Railways, Australia. The rails are to be rolled at the Homestead

mills of the Carnegie Steel Company. According to the terms of the contract delivery is to be begun within 90 days. Orders have also been given to the same company for 12,000 tons for the Imperial Government Railways of Japan, 6,000 tons for the Cananea, Yaqui River & Pacific, Mexico, and for about 1,000 tons of heavy girder rails for the Municipal Electric Traction lines of Christchurch, New Zealand.

OBITUARY NOTICES.

Augustus R. Macdonough, formerly Secretary of the Erie, died on July 21 at his home in New York City. Mr. Macdonough was 86 years old. He was born at Middletown, Conn., and graduated from Yale in 1839. He studied law and practiced for a short time in St. Louis and then came to New York. He was Secretary of the Erie for 25 years, resigning about six years ago.

ELECTIONS AND APPOINTMENTS.

Executive, Financial and Legal Officers.

Central of Georgia.—James A. Blair has resigned from the Board of Directors.

Chihuahua & Pacific.—Philip Baber has been appointed Auditor, with office at Chihuahua, Mex.

Illinois Central.—A. G. Hackstaff, Vice-President, has been elected a Director, succeeding John C. Welling, deceased.

Maine Central.—Arthur P. Foss has been appointed Auditor of Disbursements, with office at Portland, Me.

Mobile, Jackson & Kansas City.—Ambrose Monell, Thomas Morrison and John McLeod have resigned from the Board of Directors. R. D. Scandrett, of Pittsburg, has been elected a Director.

New York, New Haven & Hartford.—John F. Stevens has been appointed Vice-President in charge of operation, with office at New Haven, Conn., effective August 1.

Pennsylvania.—George T. Smith, General Agent at New York, has been elected Chairman of the Lighterage Committee of the Trunk Line Association, succeeding W. B. Pollock, resigned.

St. Louis, Brownsville & Mexico.—John D. Finnegan, Treasurer, has been elected also Assistant Secretary, with office at Kingsville, Tex.

Operating Officers.

Boca & Loyalton.—H. H. Griffiths, Superintendent of the Western Pacific, has been appointed General Manager of the Boca & Loyalton, succeeding W. S. Lewis, resigned.

Canadian Northern.—M. H. Macleod, Chief Engineer, has been appointed General Manager, with office at Winnipeg, Man., succeeding E. A. James, resigned.

Corvallis & Eastern.—George F. Nevins, Assistant General Manager, has been appointed General Superintendent, and his former position has been abolished. The office of General Manager, formerly held by G. W. Talbot, who recently resigned to go to another company, has also been abolished.

Mobile, Jackson & Kansas City.—W. F. Owen has been appointed General Manager and Assistant to the President.

Oregon Railroad & Navigation Company.—W. M. Gleason has been appointed Assistant Superintendent at Starbuck, Wash., succeeding L. F. Pennington, assigned to other duties.

Western Pacific.—George A. Brown has been appointed Superintendent, with office at Stockton, Cal., succeeding H. H. Griffiths, transferred. See Boca & Loyalton.

Engineering and Rolling Stock Officers.

Baltimore & Ohio.—E. Conniff, general foreman at Holloway, Ohio, has been appointed Master Mechanic at Benwood, W. Va., succeeding F. C. Scott, resigned.

Buffalo, Rochester & Pittsburg.—E. J. Govern, Assistant Engineer of Bridges, has resigned.

Illinois Central.—L. A. Downs, who was recently appointed Assistant Chief Engineer of Maintenance of Way, was born in 1872 at Greencastle, Ind. He graduated from Purdue University in 1894, and began railroad work on the Vandalia. He then went to the Illinois Central, where he has been ever since, serving first as Assistant Engineer and then as roadmaster on, successively, the Amboy, the Louisville, the Louisiana, the Springfield and the Chicago divisions.

New York Central & Hudson River.—W. O. Thompson, Division Superintendent of Motive Power at Oswego, N. Y., has been appointed Master Car Builder at East Buffalo, N. Y., succeeding James Macbeth, deceased.

Traffic Officers.

Chicago & Alton.—Jared M. Adee has been appointed General Agent at Pittsburg, Pa., succeeding T. C. Frew, resigned.

Colorado Southern, New Orleans & Pacific.—C. C. Cary has been appointed General Agent at Opelousas, La.

Las Vegas & Tonopah.—George F. Knight has been appointed General Agent at Goldfield, Nev.

Louisville & Nashville.—See Missouri Pacific.

Missouri Pacific.—Charles L. Stone, General Passenger Agent of the Louisville & Nashville, has been appointed to the new office of Passenger Traffic Manager of the Missouri Pacific, with office at St. Louis, Mo.

Western Maryland.—Thomas G. Smiley, Assistant General Freight Agent, has been appointed General Freight Agent, with office at Baltimore, Md., succeeding W. T. Hunter, transferred. W. A. Cox, General Agent at Baltimore, Md., succeeds Mr. Smiley.

Buffalo, Rochester & Pittsburg.—Robert Ward Davis, who was recently appointed Freight Traffic Manager, was born at Union Square, N. Y., in 1857. After a common school education he began railroad work in 1872 on the Syracuse Northern, now part of the New York Central & Hudson River. He was station agent at Union Square from 1876 until 1880, when he went to the Rome, Watertown & Ogdensburg as train despatcher. He was later made ticket agent at Watertown and then Traveling Auditor. He was appointed train despatcher in 1882 and two years later was made traveling freight agent. After a few months he was made also chief clerk in the general freight office, holding both positions until 1892. He then went to the Rochester & Pittsburg as General Freight Agent and held the same office on its successor, the Buffalo, Rochester & Pittsburg, until his recent promotion.

R. W. Davis.

LOCOMOTIVE BUILDING.

The Public Belt Railroad (New Orleans) is asking bids on locomotives.

The Michigan Central is said to be contemplating the purchase of 30 locomotives.

The San Antonio & Aransas Pass, it is understood, is about to order some locomotives.

The Great Northern has ordered two locomotives from the American Locomotive Company.

The Northern Pacific has ordered five switching locomotives from the American Locomotive Company for the Portland & Seattle.

The Tunisian Government has been authorized to buy from abroad 38 narrow-gage locomotives. For information apply to Bureau of Manufactures, Washington, D. C., referring to Foreign Trade Opportunity No. 1220.

The Pennsylvania Lines West, as reported in the *Railroad Gazette* of July 12, have ordered five class E-2b (Atlantic) locomotives from the Altoona-Juniata shops. The 45 freight locomotives mentioned have not been ordered.

CAR BUILDING.

The Duluth & Iron Range is about to order 800 ore cars.

The Grand Trunk is asking prices on 5,000 freight cars.

The Canadian Pacific is asking prices on 1,000 box cars.

The Oklahoma Central is to order new equipment within 60 days.

The Public Belt Railroad (New Orleans) is asking bids on cars.

The Western Maryland is said to be in the market for 1,000 freight cars.

The Illinois Tunnel Company, Chicago, is asking prices on 500 small dump cars.

The Chicago, Burlington & Quincy is said to have ordered 1,300 additional steel cars.

The Kansas City Southern, it is said, is considering the purchase of some freight equipment.

The Oklahoma Central is said to be in the market for 500 coal cars of 80,000 lbs. capacity.

The Lake Superior & Ishpeming is considering the purchase of 150 ore cars of 100,000 lbs. capacity.

The San Antonio & Aransas Pass is understood to be about to order some passenger and freight cars.

The Toledo & Ohio Central has ordered one combination mail and express car from the Pullman Company.

The Detroit & Toledo Shore Line, it is said, has ordered 400 coal cars from the American Car & Foundry Company.

The Western Maryland denies being in the market for 1,000 freight cars, as reported in our advance sheet of July 17.

The Washington, Idaho & Montana, it is understood, has ordered 50 flat cars from the American Car & Foundry Company.

The Southwest Missouri (Electric) has, it is said, ordered three single and three double truck cars from the Jewett Car Company.

The Duluth & Iron Range is in the market for four passenger coaches, two combination and two combination baggage and mail cars.

The Tampa Northern, it is said, has ordered 75 flat and 75 box cars of 60,000 lbs. capacity from the Baltimore Steel Car & Foundry Company.

The Central Railroad of New Jersey has ordered 1,000 hopper bottom coal cars of 100,000 lbs. capacity from the Cambria Steel Company. These cars will measure 30 ft. long and 9 ft. 5⅝ in. wide, inside measurements, and 31 ft. 6 in. long, 10 ft. wide and 10 ft. 4 in. high, over all. The bodies and underframes will be of steel. The special equipment includes:

Brake-beams	Diamond adjustable
Brake-shoes	Am. Brake-Shoe & Fdry Co., steel back
Brakes	Westinghouse
Brasses	Magnus metal
Couplers	R. E. Janney
Door fastenings	Simonton hopper door rigging
Draft rigging	Miner
Journal boxes	Symington
Springs	Simplex Railway Supply Co.
Trucks	Andrews cast-steel side frame, Barber lateral device

RAILROAD STRUCTURES.

Beaver, Pa.—The Pittsburg & Lake Erie bridge over the Ohio river is to be replaced with a new structure. The plans call for a bridge over the river starting 200 ft. east of the old structure on the Beaver side, with a shore pier on the West Virginia bank of the river 500 ft. above the old bridge. The channel span is to be 767 ft. long, and for 531 ft. of this span it will be 90 ft. above low water. The War Department has been asked to grant the necessary permission to put up the structure.

Brookhaven, Miss.—The Illinois Central, it is said, will put up a brick passenger station, 32 ft. x 196 ft., to cost about $25,000. Contract reported let to George P. Swift & Co., of Chicago. The work to be finished within 90 days.

Buffalo, N. Y.—Contractor John Johnson, of Buffalo, is said to have been the lowest bidder for the stone and concrete work on the elimination of grade crossings for the New York Central & Hudson River at East Buffalo. The bids were in two sections. The first for the work at Bailey avenue and Broadway crossings, on which the bids were: Stone masonry, $149,261, monolithic concrete, $139,373, and reinforced concrete $135,026. The second section was for crossings on the line between Kensington avenue and Amherst street. They were: Stone masonry, $129,822; monolithic concrete, $122,262, and reinforced concrete, $112,785. The city is to pay part of the cost, aggregating about $200,000, and the Grade Crossing Commission has voted to ask the Common Council to authorize an issue of bonds for that amount.

Butler, Pa.—The Baltimore & Ohio, it is said, is planning to put up a new freight house also a passenger station here, and increase its yard facilities.

Glendon, Pa.—Bids will soon be asked for building a steel and concrete bridge over the Lehigh river, to replace the old covered bridge. The cost is to be borne by the county of Northampton, the Lehigh Coal & Navigation Company and the Lehigh Valley Railroad. The borough of Glendon is to do the grading on the approaches.

Vancouver, B. C.—Contracts are reported let by the Canadian Pacific for putting up a pier 670 ft. long and 166 ft. wide to cost about $300,000. A number of similar piers are to be built at the C. P. terminals here.

Washington, Pa.—J. W. Sheldon, of Fayette county, one of the promoters of an electric line from Masontown to Waynesburg, is negotiating with the Greene county and Fayette county commissioners to build a bridge over the Monongahela river at a cost of about $150,000. The electric line is to pay one-third of the cost.

West Albany, N. Y.—Bids were recently asked for by G. W. Kittredge, Chief Engineer of the New York Central, Grand Central Station, New York city, for putting up a steel, concrete and brick boiler shop 125 ft. x 430 ft. and 40 ft. high. Separate contracts are to be let for the structural steel to be used in the construction.

RAILROAD CONSTRUCTION.

New Incorporations, Surveys, Etc.

Alexandria, Zimmerman & Northwestern.—Incorporated in Louisiana, with $230,000 capital, to build a line from Alexandria, La., northwest to Zimmerman, 35 miles. J. A. Bentley, President; E. W. Zimmerman, Vice-President; A. F. Sharpe, Secretary, and P. Lisso, Treasurer.

American Midland.—Local reports say that this company has been incorporated in Oklahoma with a capital of $20,000,000 and office at Guthrie. The company proposes to build a north and south line from Langdon, N. Dak., south through the Dakotas, Nebraska, Kansas, Oklahoma, Indian Territory and Texas to Galveston, 2,100 miles; also a branch from Winnsboro, Tex., east to Shreveport, La., and one from Coalgate, Ind. T., east to Poteau. The Incorporators include: Henry Oppenheimer, C. F. Senkowsky, F. Jerome, H. Meyer and L. Linden, of New City; B. F. Hagler, Jr., U. C. Guss and C. R. Havinghorst, of Guthrie.

Arkansas Anthracite.—This company, incorporated in 1904 with a capital of $1,500,000, to build a line from Fort Smith, Ark., east to Clarksville, in Johnson county, about 65 miles, has been granted an extension of 18 months to begin the work. The directors include: R. M. Remmel, C. McKee, G. Heim and others. The Arkansas Anthracite Coal Company is also interested in the project. (See Arkansas Anthracite & Western, May 4, 1906, p. 136.)

Atlanta & Carolina Construction Company (Electric).—Incorporated in Georgia with $5,000,000 capital, to build an electric line from Atlanta east to Augusta, 160 miles. Surveys made from Atlanta to Conyers and from Athens to Augusta, leaving about 50 miles to be surveyed. J. W. English, President, Atlanta; Mathew Mason, Vice-President, and M. T. Edgerton, Secretary.

Atlantic Northern & Southern.—Contracts are reported let to the Engineering Construction & Securities Company, of Chicago, Ill., for building this proposed line from Manning, Iowa, south to Villisca, about 75 miles. Surveys made and rights of way obtained from Kimballton south to Atlantic. (May 24, p. 726.)

Beaumont, Sour Lake & Western.—See Colorado Southern, New Orleans & Pacific.

Charleston, Westfield, Marshall & Terre Haute Interurban.—Incorporated in Illinois, with office at Marshall, to build an electric line from Charleston, Coles county, east via Westfield, to the Illinois-Indiana state line, 35 miles. The incorporators include: James Dawson, S. Hurst, N. Bennett, M. L. Briscoe, W. B. Scholfield, T. M. Berkley, E. T. Pinnell and W. R. Patten.

Charlotte Harbor & Northern.—This company announces that its line from Arcadia, Fla., south via Hull, Fort Ogden and Liverpool to Boca Grande, 53 miles, is completed and is to be opened for traffic August 1. From Arcadia to Liverpool, 17 miles, the line has been in operation for freight only for some time past. (March 15, p. 381.)

Chesterfield & Lancaster.—This road is said to be in operation to a point 20 miles west of Ruby, S. C., and the company plans to extend it northwest towards Charlotte, N. C., or to Concord.

Chicago & North-Western.—It is reported that contracts will soon be let for grading an extension of the line from Bellefourche,

S. Dak., north about 10[illegible] miles to the northern border of South Dakota.

CHICAGO, BURLINGTON & QUINCY.—Work, it is said, is to be started at once on an extension of the line from Guernsey, Wyo., northwest to a connection with the Chicago & North-Western at Orin Junction, about 40 miles.

CHICAGO, ROCK ISLAND & GULF.—Track is reported laid for about 3½ miles on the extension this company is building from Irving, Tex., which is on the Fort Worth-Dallas line of the Rock Island, north to Carrollton, on the St. Louis & San Francisco, 11 miles.

CINCINNATI (OHIO) BELT LINES.—Surveys are to be made for a proposed belt line around Cincinnati. John E. Bleekman represents the interests which will finance the project. If the survey is satisfactory steps will be taken at once to begin the work. (See Cincinnati Intersecting, March 29, p. 467.)

COLORADO SOUTHERN, NEW ORLEANS & PACIFIC.—The Beaumont, Sour Lake & Western extension from Sour Lake, Tex., west to Houston, 64 miles, is reported finished, and the old line from Beaumont to Sour Lake, 22 miles, has been reconstructed to form part of the through line from New Orleans, La., west to Houston, 360 miles. Work is under way on the section from Baton Rouge to De Quincy, 137½ miles. The tracks of the Kansas City Southern are to be used from De Quincy to Beaumont, 47 miles, and the tracks of the Yazoo & Mississippi Valley from Baton Rouge to New Orleans, 89 miles. It is expected to have the whole line in operation early in September. (March 15, p. 382.)

COLUMBUS, MEMPHIS & PENSACOLA.—This company proposes to build a line from Aberdeen, Miss., on the Illinois Central, the Mobile & Ohio and the St. Louis & San Francisco, south to Columbus, on the Mobile & Ohio and the Southern, about 25 miles. H. E. Reynolds, President; C. Y. Reynolds, Vice-President; B. L. Reynolds, General Manager, Aberdeen, and C. B. Hopkins, Secretary and Treasurer, Columbus.

DEFIANCE, PAULDING & FORT WAYNE (ELECTRIC).—Reports state that this company is to be incorporated in Ohio to build an interurban line from Defiance, Ohio, southwest to Fort Wayne, Ind., with a branch from the main line a few miles south of Defiance south to Paulding. It is intended to eventually extend the line from Defiance northeast via Toledo to Detroit, Mich. H. F. Schnelker and W. S. Rogers, of New Haven, Ind., and Fort Wayne are interested.

DOLGEVILLE & SALISBURY.—This company is building an ore line from the mines of the Salisbury Iron Company at Salisbury, N. Y., southeast to a connection with the Little Falls & Dolgeville at Dolgeville, N. Y., about five miles. W. H. Switzer, President and General Manager; E. L. Wells, Vice-President, and F. R. Switzer, Secretary and Treasurer, all of Utica. The directors include E. Fairchild, of Salisbury; A. M. Mills, of Little Falls, and C. Sullivan, of Dolgeville.

ELYRIA SOUTHERN (ELECTRIC).—Incorporated in Ohio with $100,000 capital and office at Cleveland. The company proposes to build an electric line from Elyria, Ohio, south through Lorain, Medina, Wayne, Ashland, Richland and Knox counties, about 60 miles. The incorporators include W. E. Elliot, F. W. Carpenter and F. L. Sargent.

FLORIDA CENTRAL.—Incorporated in Georgia to build a line from Thomasville, Ga., south to the Georgia-Florida state line, about 13 miles. J. L. Phillips, of Thomasville, and associates are incorporators.

GAINESVILLE, TEXAS & SOUTHWESTERN.—Incorporated in Texas, with office at Gainesville, to build a line from Gainesville, Tex., southwest to Mineral Wells, about 80 miles. The incorporators include: E. C. Bell, of Toledo, Ohio; E. M. Wickey, of East Chicago, Ind.; W. W. Newberry, of Chicago, Ill.; J. M. Lindsay and John King, of Gainesville.

IDAHO NORTHERN.—Contract reported let by this company for building 35 miles of its proposed line from Kingston, Idaho, which is on the Oregon Railroad & Navigation Company's line, northeast to Murray, about 22 miles, thence south to Wallace, on the O. R. & N. and the Northern Pacific, 20 miles. B. F. O'Neill, President of the State Bank of Commerce at Wallace, is President. E. P. Spaulding, of Spokane, Wash., is also interested.

ILLINOIS & NORTHWESTERN (ELECTRIC).—Incorporated in Illinois with $10,000 capital and office at Chicago. The company intends to build an electric line from Lyons, in Cook county, south to Bloom, about 15 miles; also a number of branches. The incorporators include: A. B. Konsberg, E. J. Cady, C. P. Chamberlain, H. S. Martin and W. E. Phillips.

KENTUCKY NORTH & SOUTH.—Surveys are nearing completion and plans made to soon start work on this proposed line. The route is from Fullerton, Ky., on the Ohio river opposite Portsmouth south to Bristol, Tenn., about 200 miles, where connection is to be made with the Southern Railway. (June 21, p. 917.)

LOUISIANA & PACIFIC.—See Shreveport, Alexandria & Southwestern.

MADISON COUNTY (LOUISIANA) BELT.—Incorporated in [illegible] with $35,000 capital and office at Highland. The company proposes to build an electric line from Scranton, in Mississippi county, southeast via New Douglas, Dean, south through Grantfork to Highland, and thence southwest via St. Jacobs and Troy to Collinsville in Madison county, about 45 miles. W. P. Watt, J. Gebrig, J. Wild, J. L. Rhein and J. Pardu are incorporators.

METTOWEE VALLEY.—Incorporated in Vermont to absorb the Manchester, Dorset & Granville Railroad. The M., D. & G. was organized to build from Manchester, Vt., northwest via Dorset to Granville, N. Y., 25 miles, and the road finished to Dorset, eight miles. It is now proposed to extend the road from South Dorset to Granville. C. L. Leach, President.

MEXICAN INTERNATIONAL.—This road, it is reported, is to be extended from Tepehuanea west via the Topia mining district to Culiacan, 225 miles, where connection is to be made with the Western Railway of Mexico, operating a line from Culiacan west to Altata on the Pacific coast, 38 miles, recently reported bought by the Mexican government. The latter road is to be rebuilt and extensive improvements made at the port of Altata, which is midway between the ports of Topolobampo and Mazatlan.

Surveys reported made for a branch from Durango south to Guadalajara, 400 miles. (March 15, p. 396.)

MEXICAN ROADS.—The state of Chihuahua, Mex., has granted a concession to Jose Batello to build a line from Parral to San Jose Delsito, 60 miles.

A concession has been granted to Pablo Olivas, of Prieto, by the state of Chihuahua, Mex., to build a line from Allende northeast to Jiminez, about 75 miles.

MIDLAND VALLEY.—The branch building from Jenks, Ind. T., to Glen Pool, 6½ miles, is nearing completion, and trains will be run soon. It is reported that this is to form part of an extension from Jenks, Ind. T., southwest to Shawnee, about 100 miles.

MISSOURI, KANSAS & TEXAS.—Local reports state that work is under way on a second track from Parsons, Kan., south to Muskogee, Ind. T., on the Cherokee division. This division, which is 117 miles long, is to be shortened to about 100 miles. It is estimated that the work will take three years to finish, and cost about $2,000,000.

MOBILE, JACKSON & KANSAS CITY.—President L. S. Berg, of this company, is reported as saying that the road is to be extended from its present northern terminus at Middleton, Tenn., north about 100 miles to a point on the Ohio river.

NASHVILLE, CHATTANOOGA & ST. LOUIS.—Contract reported let to Toney & Lawler, of Chattanooga, Tenn., for grading a five-mile branch from Tracy City, Tenn., to coal mines at Pryor Ridge.

NEVADA & CALIFORNIA.—See Southern Pacific.

NEW YORK, AUBURN & LANSING.—Application has been made by this company to the New York Public Service Commission for permission to make a new mortgage for $2,000,000, half of which is to cover the cost of double-tracking the 37 miles of road from Auburn to Ithaca and installing a third-rail electric service. (March 15, p. 387.)

OAXACA & EJUTLA.—This company, operating a line from Oaxaca, in the state of Oaxaca, Mex., south 43 miles to Ejutla, is reported planning to build an extension south to the Pacific coast, about 60 miles.

OVERTON COUNTY.—This company, operating 19 miles of railroad from Algood, Tenn., northeast to Livingston, is planning to build an extension northeast to a connection with the Cincinnati, New Orleans & Texas Pacific at Burnside, Ky., 75 miles.

PARAGOULD & MEMPHIS.—This company, which proposes to build an extension from Cardwell, Mo., north to Poplar Bluff, 50 miles, and one from Cardwell west to Paragould, Ark., 17 miles, has located the line for the last named. Extensions are also projected from Manila, Ark., southwest to Marked Tree, 30 miles; also from Manila southeast to Osceola, 16 miles. (March 15, p. 389.)

PENNSYLVANIA.—This company, it is said, is planning to build a branch from the Indiana branch at Twolicks, Pa., east to a connection with the Cherrytree & Dixonville at Clymer, about 15 miles.

PEOPLES RAILWAY CONSTRUCTION COMPANY.—Organized in Texas to build a line from Tyler, Tex., northwest to Canton, about 40 miles. B. B. Caill, President; J. Durst, of Tyler, Vice-President; T. Butler and S. Brack, of Tyler, and D. F. Clark, of Canton, are interested.

PEORIA & ST. LOUIS.—It is reported that a company under this name is being formed in Illinois to build a line from Dixon, Ill., northeast to Belvidere, about 50 miles. The names of the promoters are not given.

Perla Northern.—This company, operating a logging road from Perla, Ark., northwest to Whittington, 18 miles, is said to be building an extension northwest, also an extension from Perla southeast to a connection with the Wyandotte & Southeastern.

Sacramento Valley & Eastern.—An officer writes that this company is building a line with its own forces from Pitt, in Shasta county, Cal., three miles east of Kennett, along the north bank of Pitt river to the mouth of Squaw creek, thence via Copper City to Delamar, 16 miles. About five miles has been graded. The work is heavy, being mostly through rock. Maximum grades 4 per cent. and maximum curves 20 per cent. There are to be two bridges; one over Sacramento river and the other over McCloud river. Some of the work may be let if bids from contractors prove satisfactory. D. W. Riordan, President, New York, and F. J. Dearborn, Chief Engineer, Wintbrop, Cal.

St. Francis.—Incorporated in Arkansas to build a line from Parkin, Ark., on the St. Louis, Iron Mountain & Southern, south about 20 miles to Round Pond, on the Chicago, Rock Island & Pacific. E. E. Taenzer, W. D. Darnall and others, of Memphis, Tenn., are incorporators.

St. Louis & San Francisco.—This company, it is said, has recently appropriated funds for double-tracking work on its road between St. Louis, Mo., and Springfield. Surveys are reported made for building a cut-off from Crocker, Mo., east to Rolla, so as to shorten the line between these two towns from 36 miles to 30 miles.

Shreveport, Alexandria & Southwestern System.—The Louisiana & Pacific extension from Fulton, La., is in operation south to Banks, 16 miles from Fulton, and it is said work is under way from Banks south to Lake Charles, eight miles. Plans are reported being made to build an extension from the northern end at De Ridder to Cravens, 10 miles. (June 14, p. 879.)

Southern Pacific.—An officer writes that preliminary surveys are being made for an extension of the Nevada & California from its southern terminus at Keeler, Cal., south to Mojave, about 120 miles.

Tennessee & Georgia Interurban.—Incorporated in Georgia with $500,000 capital to build an electric line from Rossville, Ga., southeast via Ringgold to Catoosa Springs, about 25 miles. J. R. Jones, J. C. Brayn and J. W. Clark, of Catoosa county, and W. H. Payne, of Chattanooga, Tenn., incorporators.

The Suffolk Syndicate Co.—This company, which has mortgaged its property for $200,000, is believed to intend using the proceeds to build an electric railroad from Patchogue, N. Y., westward through the villages and towns along the south shore of Long Island. John W. Wells, of New York city, is President.

Union Pacific.—Contracts, it is said, will soon be let for laying a new second track from Hanna, Wyo., west to Rawlins, 40 miles, to cost about $1,000,000. The work also includes the elimination of curves and the building of a number of cut-offs to shorten the line. Similar work is also to be carried out from Wamsutta, Wyo., west to Robinson, 20 miles, and from Rock Springs to Green River, 16 miles, at a cost of about $1,000,000. Surveys are reported made and work is to be started at once on a cut-off from Robinson, Wyo., west to Point of Rocks, 27 miles. The line is to be seven miles shorter than the existing road.

Western Railway of Mexico.—See Mexican International.

RAILROAD CORPORATION NEWS.

American Light & Traction Company.—A quarterly dividend of 1½ per cent. on the outstanding $6,738,700 common stock has been declared payable August 1. The annual rate was 5 per cent. during the fiscal year ended June 30, 1907. In the first half of 1906, 2 per cent. was paid; 1905, 3½ per cent., and in 1904, 1½ per cent. The company owns or controls gas, lighting, power and traction companies in Wisconsin, Minnesota, Michigan, Texas, New Jersey, New York, Colorado and Canada.

Baltimore & Ohio.—See Chicago Terminal Transfer.

Buffalo, Rochester & Pittsburg.—This company has applied to the New York Public Service Commission for permission to issue $1,300,000 additional equipment trust notes.

Chicago, Burlington & Quincy.—See Chicago Terminal Transfer.

Chicago Terminal Transfer.—The Baltimore & Ohio is said to have offered $30 a share for the preferred stock held by minority stockholders. There is outstanding $17,000,000 4 per cent. noncumulative preferred stock, of which the Burlington is believed to own over 70 per cent.

Chicago Union Traction.—This company has sold about $4,000,000 first-mortgage 5 per cent 25-year bonds to the First National Bank of Chicago. It is said that probably $6,000,000 more will be sold at once. The proceeds are for rehabilitation. (July 19, p. 84.)

Detroit & Charlevoix.—See Michigan Central.

Florida East Coast.—This company, which operates 484 miles of road from Jacksonville, Fla., south, has sold to Harvey Fisk & Sons, New York, $3,000,000 three-year 6 per cent. notes; they are secured by bonds of the railroad company and also, it is said, by the endorsement of H. M. Flagler, President of the company, who owns the road. It is supposed that the notes were sold to raise money to pay for the extension from Homestead along the Florida keys to Key West, about 125 miles, on which work has been under way for the past two years.

Kansas City Southern.—Earnings and expenses for the month of June, 1907, and for the year ended June 30, 1907, were as follows:

Month of June, 1907.			
Gross earnings	$870,428	Inc.	$208,448
Operating expenses	508,606	"	25,900
Net earnings	$361,822	Inc.	$182,548
Taxes	15,583	Dec.	437
Net earnings, taxes deducted	$346,239	Inc.	$182,985
Year Ending June 30, 1907.			
Gross earnings	$9,284,884	Inc.	$1,531,993
Operating expenses	5,486,539	Dec.	157,991
Net earnings	$3,798,345	Inc.	$1,689,984
Taxes	190,925	"	16,884
Net earnings, taxes deducted	$3,607,420	Inc.	$1,673,100

Michigan Central.—According to press dispatches, this company has bought the Detroit & Charlevoix, which runs from South Arm, Mich., to Frederick, on the Michigan Central, 44 miles, with an eight-mile branch. The Detroit & Charlevoix is a logging road and has $520,300 stock outstanding.

Milwaukee Electric Railway & Light.—This company has increased its authorized common stock from $15,000,000 to $20,000,000. A subsidiary, the Milwaukee Light, Heat & Traction Company, has increased its authorized common stock from $1,000,000 to $30,000,000. The parent company owns 103 miles of road and controls all the gas and electric lighting companies in Milwaukee.

Mobile, Jackson & Kansas City.—L. S. Berg and associates have bought half of the controlling interest heretofore held by Alexander McDonald, W. D. Stratton and E. K. Stallo. (July 19, p. 84.)

New York, Auburn & Lansing.—This company has applied to the New York Public Service Commission for permission to make a mortgage for $2,000,000, of which $1,000,000 is to refund outstanding bonds and the rest is for double-tracking and electrifying the company's road from Auburn, N. Y., to Ithaca, 37 miles.

Santa Fe Central.—It is understood that finances of this company are to be reorganized and the road consolidated with a coal and iron company and several real estate companies. The road runs from Santa Fe, N. Mex., south to Torrance, 117 miles, and had a 47-mile branch from Moriarity Junction to Albuquerque under construction at the beginning of the present year. It was reported over a year ago that C. W. Tallmadge, of Chicago, had bought the road. It has outstanding $2,500,000 stock and $2,000,000 first-mortgage 5 per cent. bonds of 1941.

Southern Pacific.—The estimated income account for the year ended June 30, 1907, is as follows:

Gross earnings	$124,861,440	Inc.	$19,215,326
Operating expenses	82,578,907	"	11,992,257
Net income	$42,285,533	Inc.	$7,253,069
Other income	3,665,365	"	211,220
Total income	$45,950,898	Inc.	$7,464,289
Fixed charges and rentals	19,423,833	"	2,497,937
Available for dividends	$26,527,065	Inc.	$4,966,352
Dividends, preferred stock, 7 per cent.	2,769,879		.....
Available for common	$23,757,186	Inc.	$4,966,352
Dividends, common stock, 5 per cent.	9,892,463	"	4,946,217
Surplus	$13,864,723	Inc.	$20,135

Union Pacific.—The estimated income account for the year ended June 30, 1907, is as follows:

Gross earnings	$75,781,115	Inc.	$8,499,573
Operating expenses	42,222,464	"	5,258,691
Net earnings	$33,558,651	Inc.	$3,240,882

RAILROAD GAZETTE

ESTABLISHED IN APRIL, 1856.

PUBLISHED EVERY FRIDAY BY THE RAILROAD GAZETTE AT 83 FULTON STREET, NEW YORK.
BRANCH OFFICES AT 375 OLD COLONY BUILDING, CHICAGO, AND QUEEN ANNE'S CHAMBERS, WESTMINSTER, LONDON.

EDITORIAL ANNOUNCEMENTS.

THE BRITISH AND EASTERN CONTINENTS edition of the Railroad Gazette is published each Friday at Queen Anne's Chambers, Westminster, London. It contains selected reading pages from the Railroad Gazette, together with additional British and foreign matter, and is issued under the name Railway Gazette.

CONTRIBUTIONS.—Subscribers and others will materially assist in making our news accurate and complete if they will send early information of events which take place under their observation. Discussions of subjects pertaining to all departments of railroad business by men practically acquainted with them are especially desired.

ADVERTISEMENTS.—We wish it distinctly understood that we will entertain no proposition to publish anything in this journal for pay, EXCEPT IN THE ADVERTISING COLUMNS. We give in our editorial columns OUR OWN opinions, and these only, and in our news columns present only such matter as we consider interesting and important to our readers. Those who wish to recommend their inventions, machinery, supplies, financial schemes, etc., to our readers, can do so fully in our advertising columns, but it is useless to ask us to recommend them editorially, either for money or in consideration of advertising patronage.

OFFICERS.—In accordance with the law of the state of New York, the following announcement is made of the office of publication, at 83 Fulton St., New York, N. Y., and the names of the officers and editors of The Railroad Gazette.

CONTENTS

VOL. XLIII., No. 5. FRIDAY, AUGUST 2, 1907.

THE NOTABLE OPERATION OF THE KANSAS CITY SOUTHERN.

The Kansas City Southern, in saving for net earnings more than its entire increase in gross during the fiscal year just ended, has made a record which is probably unique among the more important roads during recent years. It was to be expected that, other things being equal, the company would this year be able to decrease its operating ratio because last year's maintenance expenses included large amounts spent for rehabilitation. The road was left in bad shape at the end of 1905. But this chance to improve its showing was more than offset by the higher costs of material and work which, during the past fiscal year, have greatly increased the operating ratio on most roads. The results under consideration are, therefore, to be credited to the management of the road and not to general conditions.

How these results were obtained is worth studying in some detail. The methods followed are perhaps not uncommon, but their success is uncommon. In June, 1906, estimates of the amounts to be spent on maintenance and conducting transportation, based on experience in 1906, were made. Then, throughout the year, close track was kept by watching detailed monthly reports and whenever any item was larger than the standard that had been set, inquiries were made until the waste was stopped or a satisfactory explanation found. The probable cost of maintenance could be figured closely, after several weeks of careful inspection had furnished data for estimating how much rolling stock, track material and supplies would be needed for renewals. The chief element of uncertainty was the cost of labor, usually amounting to about 30 per cent. of maintenance expenses. In 1906 maintenance cost 29 per cent. of gross earnings. The estimates did not call for reduction of this percentage, but a system was put in force looking toward getting better results from the same amount of money. The maintenance of way engineers were allowed the usual margin of 10 per cent. over the estimated cost of the work to be done and were then told that what they saved could be spent on some improvement they particularly wanted but which had not been approved. This form of "bonus system," which has worked out well in the East, was new to the Kansas City Southern engineers, but results were noticeable as soon as the men got used to it. Conducting transportation cost, in 1906, 38 per cent. of gross earnings. The management saw no reason why this should not be reduced to about 30 per cent.; as a matter of fact it was brought down to 33 per cent. The big saving was made by increasing the average train load and the car mileage. The road has no low grade operating division, gradients of about 1 per cent. being scattered over the whole line and opposing about equally both the north- and southbound traffic. The reduction of these grades has been figured on, but nothing has been done yet because of the financial situation. The train load was increased not by using heavier locomotives but by getting a larger backhaul. The great bulk of the traffic had been northbound, consisting mostly of lumber from Louisiana, Texas and the southern part of Arkansas for shipment to Kansas City. The traffic department has directed especial energy toward getting a backhaul south, and it has succeeded in getting enough more manufactures and grain, particularly the former, to greatly increase the southbound train load, although this is not yet as large as the northbound. The average car movement was about 20 miles a day a year ago; this increased to 34 miles in October, 1906, but has since fallen off to about 29 miles. The responsibility for the small car movement in previous years rests on the transportation officers, who failed to make the shippers handle the cars faster. When the requisite activity was infused into this department, the resulting quicker movement of freight attracted southbound traffic and had a gratifying effect on gross earnings. The monthly statements of earnings which have been made public throughout the year show that after the first few months the improvement was steady and rapid. The yearly results are surprisingly close to the original estimates. Gross earnings for the 12 months ended June 30, 1907, were $9,290,000, an increase of $1,530,000, or 20 per cent.; operating expenses, $5,490,000, a de-

crease of $160,000, or 3 per cent., leaving net earnings of $3,800,000, an increase of $1,690,000, or 80 per cent.

THE COLLISION AT SALEM, MICHIGAN

The terrible butting collision near Salem, Mich., July 20, in which 33 persons were killed, reported in the *Railroad Gazette* of July 26, was due to a mistake in reading the schedule of the special train. This schedule was in the shape of a written train order, a slightly reduced fac-simile of which will be found on another page. The schedule was delivered to the freight at Plymouth. The error in reading "Salem.....9:25" instead of "Salem.....9:10" was due evidently to the failure of the person reading to follow the line of dots connecting the word with the figures. It would appear that in the first writing of the order, the time at Brighton (8:39) was omitted, and that it was inserted afterward, and the dots then put in to guide the reader.

As both conductor and engineman are required by rule to know the correct reading of an order, it will be seen that the cause of this collision was careless reading by two or more men of an imperfect order. The order is imperfect, not only because the time for Plymouth is on a level with the word Salem, but also because the dots making up the lines are insufficient. The dots should be larger and there should be more of them. Indeed, a strict construction of the rules for writing orders would require that in a case like this the order should be torn up and then be resent by the despatcher to enable the operator to make a new and correct copy. But, as everyone knows, it would require unobtainable vigilance by the superintendent to enforce such a high degree of care. A cautious conductor would have taken special care with an order of this kind. Any conductor of experience would see that it was not a satisfactory order. A document involving the safety of lives and property when presented in this shape challenges its reader to extreme caution. A conductor determined to avoid any chance of mistake would not be satisfied to read the Salem line alone by itself. He would read the whole order with sufficient care to grasp the entire schedule of the extra train. In doing this he would by force of habit see that "9:25" at Salem indicated abnormally low speed. This would lead him to re-examine the other items in the schedule.

The order was received by the night operator, a young man 22 years old, about 2:27 a.m. and was delivered by the day operator about 8:40 a.m. The day operator says that he remembers the conductor's reading it aloud to him correctly. If this is so, the conductor's fault evidently must be classed as mechanical reading. He read it, but did not give thorough attention either with his eyes or with his ears. Once the wrong impression is made, it is easy to make the same error in reading to the engineman or the fireman or the rear brakeman. If we may judge by what has been brought out in similar cases before. The freight was to stop at some point between Plymouth and Salem and unload two carloads of cinders. The day operator says that he reminded the conductor that he had not time to do that work and still reach Salem in time to clear the extra. If this is so it is one more evidence that the conductor was not giving sufficiently careful attention to the order.

The newspapers have made much of the alleged fact that the train despatcher had been early informed that the freight had left Plymouth without sufficient time to reach Salem, and yet that he did nothing to prevent the collision. If this is so, and if some means existed by which the despatcher could have communicated to one train or the other, the fact may have some bearing on the alertness of the despatcher; but it has no value as a lesson. The prevention of collisions is not to be accomplished by educating despatchers to perform lightning calculations and to do unheard of feats in emergencies. It is a fine thing to have despatchers who can do such things, and we all praise them when we hear of such strokes of genius, but to talk of prescribing in advance that such procedures shall be carried out or that any despatcher shall be held accountable for not using every possible opportunity to do something, is idle.

The causes of this collision have been given in detail; not because it is proposed to discuss the faults in the details and the means of correcting them, but simply as an interesting exhibit of how the time-honored American train despatching system breaks down. The only way to cure these faults is to abolish the system and use in its place the block system. We must accept as an incurable defect in American railroad operation the continued employment of men who will occasionally make such mistakes as were made in this case. In setting forth what an ideal freight conductor would have done in this case we have implied a standard of proficiency which must be regarded as unattainable. That is to say, no superintendent of a large road can assure himself that he can attain it in all of his men all of the time. Our train-despatching system is, indeed, time-honored, but it is not worthy of confidence. The non-automatic block system is suitable for roads of the lightest traffic and cannot reasonably be objected to because of its cost. It is not free from chances of error, but it is simplicity itself compared with the despatching system, and simplicity tends to enhance safety.

If we may judge by the action of a number of other roads during the past ten years, the road on which this collision occurred will now proceed to install the block system on a considerable part of its lines. In our list of notable disasters we can at a glance pick out 40 collisions which have occurred within the past 20 years, killing an average of 20 persons each, or 800 in all, all due to causes of the same general nature as those which figured in this case; and a psychologist, desiring to estimate the influence of collisions on railroad directors' minds, could, if he had the inside facts of these 40 cases, make out an instructive exhibit of cause and effect—collisions as causes and orders for block signals as effects; with possibly as a side light an estimate of the number of lives sacrificed to establish each hundred miles of block signals. The failure of the Federal Government and of most of the state governments to establish competent inspectorships or any suitable and authoritative means of giving to the public correct statements of facts and rational lessons therefrom is an invitation to anybody and everybody to propose remedies for railroad disasters. This particular disaster will, no doubt, bring out at least a dozen amateur cures for everything, from boiler explosions to sleepy brakemen.

Is this country so big, and is our collision problem so scattered, that American railroad officers will never concentrate their energies on its effective settlement?

TAKING RAILROAD PROPERTY WITHOUT DUE PROCESS OF LAW.

"The Constitution of the United States declares that no individual shall be deprived of his property without just compensation, or without due process of law. . . . If a law were passed by a legislature contrary to the Constitution, taking from a man his home or interfering with his lawful enjoyment of it, there is no one, thus deprived, who would not ask, through the courts, the protection of the Constitution for his lawful rights. Every good man would applaud his action and would uphold his hand. If, however, legislation is enacted contrary to the Constitution taking from a railroad company its property or interfering with its lawful enjoyment of it and an effort is made by those charged with the responsibility for the property, to obtain for it in the courts constitutional protection, there are those who declare that this is a defiance of the popular will . . . an arrogant refusal to accept the popular verdict. Instead of a firm and determined insistance on Constitutional protection, the railroad manager is confronted with denunciation, with obstruction, with threats of reprisals and with efforts at intimidation."—*President Finley, of the Southern Railway, to the Board of Trade of Nashville, Tenn., July* 17, 1907.

"If this kind of obstruction should prevail and citizens are thus to be denied the rights guaranteed them by the Constitution of the United States, then those provisions of the Constitution [providing that no person shall be deprived of property without due process of law] would become a dead letter, as there would be no means of enforcing them."—*Justice Pritchard, July* 29, 1907.

The first of these quotations, from President Finley's speech at Nashville a little more than two weeks ago, is peculiarly apt in describing, prophetically, the latest developments in the dispute over the new passenger-rate law in North Carolina, of which we spoke last week. Then the situation was that two agents of the Southern Railway, arrested and sentenced to the chain gang for selling tickets at a rate of more than 2½ cents a mile, the rate established by the last North Carolina legislature, had been released on writs of habeas corpus issued by the United States Circuit Judge. In his opinion accompanying this action, Justice Pritchard took occasion to condemn the heavy penalties prescribed by the state statute and the methods of the state authorities in instituting criminal prosecutions against the railroad's agents. In spite of his sensible words, the state authorities, headed by the Governor, besides arresting Mr. Finley himself, who had come to the scene of action to help straighten out the tangle, threatened to call a special session of the legislature to annul the charter of the old North Carolina Railroad, which runs from Goldsboro to Charlotte, 224 miles, and is one of the constituent parts of the Southern Railway lines. A compromise plan suggested by one of the assistant attorney generals of the United States sent by the Department of Justice to North Carolina on this special mission, was rejected by the Governor, who insisted that no compromise would be entertained

until the railroads agreed to immediately adopt the new rate. On July 27 a compromise was reached between the Governor on the one hand and the Southern Railway and Atlantic Coast Line on the other containing the following agreements:

(1.) The railroads to put the 2 cent rate in effect not later than August 1, 1907.

(2.) The State to appeal from the decision of Judge Pritchard discharging parties in Asheville on writs of habeas corpus.

(3.) The Southern Railway to appeal to the Supreme Court of North Carolina in the Wake County case and if the case is there decided against it, to take the case by writ of error to the Supreme Court of the United States.

(4.) Both sides to cooperate to have both of these cases advanced, argued together and speedily determined.

(5.) The State at its option to dismiss the Atlantic Coast Line in one case.

(6.) All indictments and prosecutions now pending to be dismissed and no other indictments or prosecutions to be instituted for any alleged violation of the law up to the time the new 2 cent rate is put in effect under this arrangement so far as lies within the power of the Governor.

(7.) The Governor to advise all people against bringing any penalty suits pending final determination of the questions involved and to ask the people as a whole to acquiesce in this arrangement.

(8.) The suit pending before Judge Pritchard to be diligently prosecuted, without, however, the State's waiving any question of jurisdiction.

Later in the day, the Governor made public a statement in which he referred to the acceptance of this agreement by the railroads as a victory for State rights and the people's rights against "the oppression of the railroads [and] the interference of the Federal courts." It is a victory, but there is nothing to be proud of in the methods by which it was gained. In the same petitions in which they surrender the protection of the Federal court, the two railroads declare that the agreement was assented to under duress, because of threats that if they did not assent, worse things would happen to them. They point out that by similar methods of "coercion and intimidation" the state could fix the passenger rate at 1 cent and compel the railroads to put it in force, although obviously unconstitutional. The state's present victory was gained by threats of retaliation in entirely different fields than the one under dispute, a method which in the case of an issue between individuals would be called blackmail.

It will be observed that in this whole controversy the real point at issue was whether or not the railroads should put the reduced rate in force while its fairness was being judicially determined. At the direction of Justice Pritchard, who had also earlier issued the injunction suspending the operation of the law, the railroads were giving with each ticket sold at the old rates a refund coupon, representing in each case the difference between the existing rate and the rate proposed by the new law. These coupons were to be valid if the law were finally upheld. This is a much fairer method of procedure than the one which the railroads, under pressure of threats from the state officers and unwilling to suffer the odium of what would be alleged as law breaking, have finally agreed, though under protest of duress, to adopt. The case of the fare from New York City to Coney Island clearly brings out this point. In August, 1906, a New York judge, in an obiter, announced it as his opinion that the fare of 10 cents charged by the Brooklyn Rapid Transit Company to Coney Island was illegal and that 5 cents was all that should be charged. Rioting followed, and the company sought determination of this question in the courts. Pending decision of the legality of the 10-cent fare, the company issued for each fare paid a rebate coupon good for 5 cents if the 10-cent fare were overthrown. Five months later, the highest court in New York State decided that a 10-cent fare to Coney Island was legal.

Under this method of procedure no one suffered. Both the railroad company and its passengers were protected. On the other hand, if the Brooklyn Rapid Transit had been forced to charge only 5 cents while the law was being passed upon by the courts, it would have had no means of recovery for the difference between the 5 cents paid and the 10 cents which should have been paid during the intervening five months before the law was declared void. To sue hundreds of thousands of passengers, each for a small sum, is impracticable; a railroad corporation is a responsible party. The North Carolina passenger-rate dispute as now compromised is an example, first, of the loss which will unjustly fall on the railroads in that state if the reduced rate is overthrown in the United States Supreme Court; and, second, of the sort of inconsistent hostility to railroads described by President Finley at Nashville. The whole incident is important, not so much because of its conflict between State and Federal authority, as because the railroads have not been able to obtain the protection which would have been granted, as a matter of course, to any citizen.

NEW PUBLICATIONS.

[redacted]

It is refreshing to take up a work dealing with electric traction on a large scale and find that one must be constantly on guard against overstatement and exaggerated estimates and in which the main idea of the author is not to depreciate the steam locomotive but to tell what really can be done. The authors of this book have evidently gone on the principle that "good wine needs no bush," and so in the first words of their preface they say that "the considerations which have led to the adoption of electric traction on the larger steam railroads have generally been peculiar to the local circumstances," and that "in the application of electricity to long distance lines, it is to be steadily borne in mind that the steam locomotive has demonstrated itself to be the most efficient self-contained machine, considering its varying functions, that the engineer has yet devised. To compete with this machine, every appliance entering into the electric traction installation must compare from every point of view, as regards efficiency, with this most highly developed and perfect mechanism. The electric locomotive installation duplicates, in many respects, the steam locomotive installation." These quotations are given to show the mental attitude of the authors, and that they are not among those who have donned their funeral habiliments or festal dress—according to the point of view—to attend the obsequies of the old iron horse.

While the book is issued from the press of an American firm it has an English viewpoint throughout, which perhaps accounts in part for its conservatism. The first chapter deals with the old problem of traction and acceleration. This it does thoroughly and at some length, entering carefully into details of tests and results, giving tables of factors and data required for the solution of its formulae; but, on the whole, it considers that the formula evolved by Aspinall is as reliable as any because "little interest attaches to tractive resistance at speeds of less than 10 miles per hour," while, for speeds greater than that, this formula "leads to very trustworthy results." This covers tractive resistance at constant speed. Then follows a chapter on acceleration. This has many diagrams, showing curves of resistance and speed, and these serve "to bring out very forcibly the limits of attainable average and 'schedule' speeds and to show that for a one-mile run between stops an average speed of 45 miles an hour is practically unattainable." With these diagrams comes consideration of the part that can be played by various types of equipment in obtaining results, and how the weight of this equipment rises if a high rate of acceleration without undue heating is to be maintained.

The book then goes on to give an analysis of the tractive force and the power and energy at the axles, and then takes up the characteristics of railroad motors. Here again a word of caution is sounded in reference to the fact that high schedule speed involving frequent stops and rapid acceleration can only be obtained "at very disproportionately increased cost." The discussion throughout the chapter hinges about the a.c. single-phase motor, and the conclusion that is dispassionately drawn is that the d.c. motor is superior. The electric power generating plant is taken up in detail and its working analyzed; and the designer is warned against a too great refinement, lest he may find to his cost that "thermal gains are not always commercial gains."

High tension transmission, sub-stations and the distributing system follow and after them a fully illustrated chapter on locomotives and motor cars, special attention being given to the work on the New York Central, the Baltimore & Ohio and the Valtellina Line in Switzerland, as well as the apparatus used in the Berlin-Zossen trials. In this chapter there is another criticism of the single-phase system, in the statement that "from the standpoint of its technical merits, the single-phase commutator motor is at present a factor in the railroad electrification problem only in so far as the possibility of its further improvement at an early date entitles it to consideration. Although the last three years have witnessed the advent of several types of single-phase commutator motor, each of which constitutes a great step in advance of the old induction type single-phase motor without commutator, there is still a wide gap to be bridged before it can, on the basis of its engineering merits, rival the continuous-current motor. The single-phase motor has the non-technical advantage that it is now fully realized that some radical innovation is essential to the success of railroad electrification. It appeals to the speculative instincts of human nature to take up a promising novelty rather than undertake radical but comparatively uninteresting modifications of a well-tried and reliable system, especially as there is a prevailing belief that this would only postpone the inevitable, ultimately successful, introduction of an alternating current railroad motor. It will, however, not be denied that a treble or quadruple increase in the traditional continuous-current trolley voltage would greatly increase the practicability of introducing electric traction on main railroads without discarding continuous-current railroad motors." This certainly is a clean-cut non-partisan statement of the present situation. Con-

tinuing this subject it is said: "The preparation of a rigid quantitative comparison is, in such a case as this, beset with difficulties, but it should be evident from the data set forth, that pending considerable further development, the continuous current motor has as yet no rival for city and suburban work.

"For interurban work, it is believed that the 600-volt continuous-current motor can generally hold its own; nevertheless there appears insufficient reason why advantage should not be taken of the higher economies incident to employing higher voltage at the motor."

The last chapter of the book is devoted to trucks and many of the more prominent types are illustrated and described in detail. The authors express a decided preference for the European type of truck as compared with the American, and doubt the desirability of equalizing between the wheels. In this they state, however, that the preference for the European model is confined to European engineers for they have no record of any adoption of the type in the United States.

There is at the end an exceptionally good index, which, as the book is to be used for rapid and ready reference, is most essential.

Wrentmore's Batter Tables. By C. G. Wrentmore, C. E. New York: Engineering News Publishing Co. 8 in. x 9½ in.; 197 pages; cloth. $5.00.

This is a book of tables for determining the length of braces, diagonals and rivet spacing when the batter or inclination of the part to the base is known. There are 192 tables for batters ranging by sixteenths from 1/16 in. to 12 in. to the foot, a page being devoted to each, and each of these tables are given in two sections. One gives the length of the hypothenuse for any base from 1/16 in. up by sixteenths, and the other gives the altitude for the same base dimensions. All dimensions in the tables are given in decimal fractions of a foot, and these are readily converted to nearest sixteenths for use on drawings by means of a conversion table on the inside of the front cover that gives the equivalent decimal fraction of a foot for all measurements from 1/32 in. to 12 in., increasing by increments of 30 seconds. The tables will undoubtedly be a great convenience, especially to those who are working out details of structural iron and steel.

CONTRIBUTIONS

Fuel Consumption of Gasolene Motor Cars

Omaha, July 26, 1907.

To the Editor of the Railroad Gazette:

Referring to editorial in the *Railroad Gazette* of June 7:

The figures as to the relative cost of gasolene and steam cars must have been based on some old style, impractical gasolene car. These statistics show the cost of gasolene as $7.50 per 100 miles as against oil at $4.90 per 100 miles and coal at $2.69 per 100 miles, making it appear that gasolene motors are highly expensive to operate as compared with steam. As far as the Union Pacific is concerned, this figure for gasolene is wrong, as accurate statistics show that Union Pacific motor cars are being operated at a cost of $3.36 per 100 miles for fuel. This figure covers a period of operation of more than two years and shows the cost to be less than one-half the amount shown in the table printed with the article in question.

W. R. M'KEEN, JR.,
Supt. M. P. & M.

The Salt Lake City Union Station.

Chicago, Ill., July 29, 1907.

To the Editor of the Railroad Gazette:

Referring to the criticism of the Salt Lake City union station by "S" in your number of July 26th: Your correspondent evidently does not understand the plans, or the operating conditions at Salt Lake City, which are not at all similar to the way stations he refers to. That city, in common with many such locations in the West, is a terminal point from which trains, many of them short locals, originate in both directions—east and west. There are, however, a few through trains, and it is intended to take care of these on the last track or two from the building proper. The other trains originating here will stand with their rear ends at the platform designated in the drawing as "train shed," for which there is ample track length, as is shown in the general yard plan.

It is true that the umbrella sheds are 440 ft. long, but this does not mean that the trains themselves are restricted to this length, because the climatic conditions include no intense heat, and a very short winter season, during which time only it is necessary to protect passengers going to and from trains, which are then shortest, and an umbrella shed 440 ft. long, which allows accessibility under cover to the platforms of about seven cars, is sufficient for this purpose. It would seem to be absurd to compel passengers to climb stairs and go over bridges, or through tunnels, when all trains are perfectly accessible on the "archaic" level. This would seem to dispose of the objections raised to the arrangements for handling passengers.

There are no "island" platforms shown in this plan in the sense of platforms elevated above the rail between the tracks; but the entire floor of this building, as shown in the end elevation published, is level with the top of the rails.

Regarding the handling of baggage: It is both feasible and intended at this place to handle most of the baggage by setting baggage cars on the spur track shown in the plan opposite the baggage room, which gives a minimum of trucking and handling. It is true that there will be some little late baggage which will have to be trucked, and to avoid crossing tracks which may be occupied by trains, the tunnel, with lifts as shown, is provided. It is expected that practically all of the mail and express will be similarly handled to and from cars set in on the spur provided for that purpose; and it may be noted that at present this is the arrangement satisfactorily used at this place. It is true that some little trucking may be necessary with this as with any arrangement of depot. Complete tunnels for handling baggage, express and mail have been discussed but are regarded as unnecessary under the conditions.

The reasons given above are so obvious that this explanation seems hardly necessary to any one at all familiar with this subject.

JOHN D. ISAACS,
Consulting Engineer, Bridges, Buildings & Structures, Harriman Lines.

Government Accident Bulletin No. 23.*

The Interstate Commerce Commission has issued Accident Bulletin No. 23, containing its report of railroad accidents in the United States during the three months ending March 31, 1907. The number of persons killed in train accidents was 421, and of injured 4,920. Accidents of other kinds bring the total number of casualties up to 20,563 (1,293 killed and 19,270 injured). These reports deal only with (*a*) passengers and (*b*) employees on duty. Under "passengers" are included postal clerks, express messengers, employees on Pullman cars, newsboys, live-stock tenders, men in charge of freight, etc.

Table No. 1.—*Casualties to Persons.*

	Passengers.		Employees		Tot'l persons reported

Total (other than train accidents)	58	862	814	13,488	872	14,350
Total, all c'asses	184	3,336	1,109	15,934	1,293	19,270

The number of employees killed in coupling accidents in this quarter shows a diminution of 25 per cent. as compared with the quarter last preceding or with that of one year ago. This is a gratifying indication of an improvement in safety appliances, which it is to be hoped will be maintained. The other principal items in the present record show no important changes as compared with the last preceding quarter, which was marked by large aggregates of both killed and injured. The number of passengers now reported killed in train accidents (126) is, indeed, 30 per cent. smaller; but the record includes two collisions (Table 2*a*, Nos. 30 and 31) killing 41 persons and two derailments (Nos. 1 and 18) killing 41; and the total of 126 is more than twice the total of this quarter in 1906.

The principal items in the present bulletin, compared with the last preceding quarter and with the quarter one year ago, appear as follows:

		Bulletin No. 23.	Bulletin No. 22.	Bulletin No. 19.
1	Passengers killed in train accidents	126	180	62
2.	Passengers killed, all causes	184	234	111
3.	Employees killed in train accidents	295	291	212
4.	Employees killed in coupling	62	84	81
5.	Total passengers and employees killed, all causes	1,293	1,439	1,126

Table No. 2.—*Collisions and Derailments.*

	No.	Loss.	Persons Killed.	Persons Injured.

Total	2,078	$1,835,259	215	2,780

*The five most serious accidents are collisions 30 and 31, and derailments 1 and 18, in Table 2*a*, and the explosion noticed in the last paragraph of the report. These accidents may be identified by reference to the *Railroad Gazette* records as follows:

Collision No. 30, Alta Vista, Kan., Jan. 2.
Collision No. 31, Fowler, Ind., Jan. 19.
Derailment No. 1, Williamsbridge, N. Y., Feb. 16.
Derailment No. 18, Colton, Cal., March 28.
Explosion at Sandford, Ind., Jan. 19.

In the cases of the two collisions the Government's report contains some interesting details concerning the causes which were not given in the earlier accounts.

Derailments

Following is the usual list of Class A train accidents—all in which the damage is reported at $10,000 or over, notable cases in which passengers are killed, and those doing damage less than $10,000 and down to $2,000, whenever the circumstances or the cause may be of particular interest

TABLE No. 21.—*Causes of Fifty-one Prominent Train Accidents (Class A)*

[NOTE.—R, stands for rear collision, B, butting collision, M, miscellaneous collisions, D, derailment, P, passenger train, F, freight and miscellaneous trains.]

COLLISIONS.

No.	Class.	Kind of train.	Killed.	Injured.	Damage to cars, engines, roadway.	Reference to record	Cause.
1	M	F. & F.	7	20	$800	34	Employees killed and injured in a caboose, being pushed on yard track; butting collision, both trains disregarded yard speed limit.
2	M	P. & F.	0	1	1,250	64	Freight train moving from side track to main track at night struck by following freight. Markers had not been turned from green to red, and brakeman had turned switch without looking at electric indicator connecting with automatic block signal.
3	B.	F. & P.	0	2	3,600	98	Empty engine started from interlocking station on wrong main track; intended to run through crossover and signalman had cleared the signal, but did not throw crossover switch; signal had but one arm, which is cleared for either of the two routes; engineman on duty 17 hours.
4	M	P. & F.	0	1	3,200	67	Switch out of order; signalman gave clear hand signal, assuming, erroneously, that switch had been spiked by repair man.
5	B.	F. & F.	0	7	4,118	19	Illegible train order, order written 3d 73; taken to read 2d 73, operator failed to check order when it was read aloud in his presence; despatcher caused unnecessary confusion by putting two orders in one.
6	B.	P. & F.	0	1	4,582	33	Engineman misread despatcher's order. (See note in text below.)
7	B.	P. & P.	1	18	4,700	23	Engineman misread name of station in despatcher's order; order legibly written; conductor had not properly delivered order to engineman; gave order to brakeman; brakeman gave it to fireman and he to the two enginemen of the two engines.
8	R.	F. & F.	2	2	5,250	16	Engineman ran past 2 automatic block signals set against him.
9	B.	F. & F.	0	0	5,970	5	Despatcher sent order to 2d and 3d No. 50 when it should have been sent to 1st and 2d No. 50. (See note in text below.)
10	B.	P. & F.	1	26	6,262	101	Freight train backing into side track; rear part broke loose and ran back down grade into head of passenger train. Conductor set hand brakes but could not stop cars until too late. Air brakes had been bled because of the bursting of a hose.
11	B.	P. & P.	4	107	7,745	97	Regular eastbound passenger train ran past meeting point.
12	M.	P. & F.	1	42	8,000	4	Misplaced switch. Switch had been opened by man in charge of freight train, intending to enter main track thinking that the passenger train (No. 4) had passed. The train which had passed was No. 2.
13	B.	F. & F.	3	2	8,500	53	Conflicting train orders, 12:30 a. m. Despatcher at fault was 39 years old, experienced in train and telegraph work, but had served only 1 night as despatcher. He forgot an order which had been issued by the other despatcher about an hour before. Had not receipted for this outstanding order.
14	M.	P.	0	6	9,567	29	Misplaced switch at station. Target of switch covered with snow.
15	R.	P. & P.	1	15	10,100	30	Approached station (8 p.m.), not under control; faulty flagging.
16	R.	F. & F.	2	5	11,000	21	Excessive speed, and failure of standing train to flag.
17	R.	P. & P.	0	11	11,025	9	False clear block signal. (See note in text below.)
18	B.	F. & F.	0	3	11,100	88	Eastbound ran past signal at meeting point at 4 miles an hour.
19	B.	P. & F.	0	11	11,170	31	Westbound passenger train disregarded wait order. (See note in text below.)
20	B.	P. & F.	2	12	11,300	63	Westbound extra freight (2 a.m.) neglected to head in at entrance to side track; engineman asleep.
21	R.	P. & F.	6	1	11,900	6	Freight followed passenger train from station (4 a.m.) within 5-minute time limit and ran into passenger train unexpectedly stopped; weather very cold.
22	R.	P. & F.	0	16	12,000	55	Passenger train unexpectedly stopped (3 a.m.) run into at rear by freight. (See note in text below.)
23	M.	P. & F.	5	3	12,100	58	Extra freight entered main track in face of fast train, disregarding automatic indicator at switch. (See note in text below.)
24	B	P. & F.	[illegible]	1[illegible]	1[illegible]	[illegible]	[illegible]
25	M	P. & F.	[illegible]	[illegible]	[illegible]	[illegible]	Freight [illegible] passenger [illegible] main track [illegible]
26	B	F. & F.	1	[illegible]	1[illegible]	[illegible]	Northbound train disregarded meeting order. [illegible] As the [illegible] was on the side track and [illegible] was taken for [illegible] the northbound train passed without stopping
27	M	P. & F.	1	1	18,844	18	Runaway on steep grade; engineman continued using steam too long after passing summit.
28	M	P. & F.	0	3	21,900	66	Passenger train disregarded distant and home automatic block signals, ran into side of freight train. Fireman had called clear signals to engineman without seeing signals; engineman also ignored rule requiring an all right hand signal at this point
29	B.	F. & F.	1	3	27,102	8	Runaway on grade. See note in text below.)
30	B.	F. & P.	32	75	31,100	11	Operator failed to deliver order. (See note in text below.)
31	R.	P. & F.	9	8	48,500	10	Passenger train ran past block signal and freight disregarded time limit. (See note in text below.)
32	M.	P. & F.	0	15	73,625	27	Maliciously misplaced switch, damage largely due to fire.
33	B.	P. & F.	5	11	75,300	1	Misplaced switch. (See note in text below.)
Total......			87	504	$516,843		

DERAILMENTS.

No.	Class.	Kind of train.	Killed.	Injured.	Damage	Reference to record	Cause.
1	D.	P.	19	149	$2,600	79	Unexplained. (See note in text below.)
2	D.	P.	2	15	.....	106	Broken rail.
3	D.	P.	0	12	5,650	77	Derailing switch thrown under train by repairmen testing interlocking apparatus.
4	D.	P.	0	2	6,700	78	Broken rail. One passenger car destroyed by fire which started in oil lamps.
5	D.	P.	3	3	8,747	73	Engineman (who was killed), disregarding slow order, ran into side track at 50 miles an hour. Engineman thought to have been asleep; fireman had spoken to him about excessive speed, but not with the necessary determination and energy.
6	D.	F.	1	0	9,350	76	Open draw.
7	D.	P.	2	49	10,500	121	Maliciously misplaced switch.
8	D.	P.	1	5	11,260	82	Broken rail.
9	D.	P.	6	11	15,119	38	Misplaced switch; occurred 4 a.m., no lamp on switch. (See note in text below.)
10	D.	F.	0	3	16,000	37	Runaway on 3 per cent. grade; negligent management of brakes; hand brakes were in use, power brakes alone being deemed unsatisfactory for so steep a grade.
11	D.	F.	1	1	16,750	117	Roadbed washed out at side by flood in river; engineman is said to have been keeping good lookout and to have thought roadbed intact. Track inspected one hour before and traversed by a train 30 minutes before.
12	D.	F.	0	1	17,055	42	Unexplained.
13	D.	P.	3	35	18,700	47	Unexplained.
14	D.	P.	1	1	21,500	75	Switch out of order; rod maliciously loosened, switch new and in good condition 2 days before. Wreck mostly destroyed by fire, which started from heater in car or train lamps.
15	D.	F.	3	0	22,000	118	Middle pier of bridge gave way as train passed over, undermined by flood believed to have been caused by cloudburst. The dam caused by the wreck divided the stream in such a way as to destroy both abutments.
16	D.	P.	1	23	29,430	69	Unexplained, believed some part of engine broke and fell to the ground, speed, 28 miles an hour.
17	D.	P.	0	14	60,000	81	Brake beam on rear truck of tender fell on track and derailed cars.
18	D.	P.	22	116	28,685	115	Misplaced switch, engineman failed to keep good lookout and approached yard at too high speed. (See note in text below.)
Total....			65	470	$299,846		
Grand total			152	974	$816,689		

Collision No. 30, killing 32 persons and injuring 75, was caused by the mistake of a telegraph operator. Westbound passenger train No. 29, running from A to B, C and D, etc., had orders to meet eastbound passenger train No. 30 at C and eastbound train No. 14 at B. No. 29 train arrived at B and entered a side track opposite the station, and eastbound train No. 14 proceeded on its way. While No. 29 was on the side track, the operator was called upon by the despatcher to take an order changing the meeting point with No. 30, making it B instead of C. According to his own statement, the operator, on receiving notice of this order to make a change, and while continuing to give his attention chiefly to the receiving of the message, went through the motion of striking the signal lever at his elbow so as to change it from the clear to the stop position, but

he did not make sure that the signal actually went to that position; and whatever he did or did not do to the lever, the signal was not caused to indicate stop. Before he had finished taking the message No. 29 backed out of the side track and proceeded westward along the main line past the station.

When the train passed his window the operator picked up his lantern and ran out in the attempt to stop it, though not so promptly as he otherwise would have done, because he thought that the train would stop for water a short distance west of the station, as was often or usually done. In giving the stop signal he swung his lantern so violently that the flame was soon extinguished. He then ran to the pump house near by and picked up the pumpman's lantern and tried to use it, but that also went out. He then ran back to the office and found that his signal was not in the stop position. The operator then decamped, first telling the despatcher that he felt certain that a collision would occur, and that he was afraid of being mobbed. Train No. 29 went on, and a short distance west of the station collided with No. 30. The operator subsequently came back, or was brought back, and made a statement to the county attorney.

According to the rules the despatcher should not issue an order, as, for example, to a westbound train at B, requiring it to wait at B for an eastbound train of the same class, if avoidable. When unavoidable, an order may be thus issued if the superior train (the westbound) has already stopped or is scheduled to stop at that station, or has received a previous order to stop there; and provided the weather is clear and the line is sufficiently straight and level to give an approaching engineman ample time to bring his train to a stop before reaching the signal; and provided further, that in case of a passenger train two torpedoes have been placed on the rail by the operator. As No. 29 was already stopped at B, the despatcher is held by the superintendent blameless so far as this rule is concerned, though the operator, knowing the rule, should either have put down the torpedoes or else have called the conductor into the office before finally accepting the order. The operator had been in the service of the company only five days and at this station only two days (nights). He was 18 years of age, though in applying to the company for employment (and also to another company at the same time) he gave his age as 23 and averred that he had had several years' experience, when, in fact, he had worked as an operator only 18 months. The report says that his size and general appearance indicated a man much older than 18. The collision occurred about 4.25 a.m., and the operator had been on duty about 10 hours. He stated that he had been awake all night, and there is no evidence of anything like intoxication.

Collision No. 31, occurring about 2.14 a.m., killing nine persons and injuring eight, was between an eastbound passenger train and a westbound freight, the freight being at the time partly in a side track, which it was entering. The passenger train ran past a block signal set against it at F, and the collision occurred a few rods east of the signal. The passenger train was running at high speed, although there was a dense fog at the time which made it impossible to see the signal light more than a few hundred feet; and the signal which was disregarded was on a post 40 ft. high and 25 ft. to the left of the track. The engineman chargeable with this neglect was a man of experience and his record was one of the best on the road. He asserted that the block signal indicated clear and that his speed was low—about 25 or 30 miles an hour; but these statements are both disproved by conclusive evidence to the contrary. The men in charge of the freight train are also held blameworthy in connection with this collision, as, notwithstanding the protection afforded to their movement by the block signal at F, the rule required that freights should in all cases be clear of the main track five minutes before the time for the arrival of any passenger train.

Collision No. 6, occurring about 2 a.m., was due to the engineman of a freight train misreading a despatcher's order. He was running in the inferior direction and received an order making his train superior from A to C. Subsequently he received another order modifying this. This second order contained instructions concerning five meeting or waiting points and mentioned two trains besides his own. It contained four complete sentences. The engineman, in reading, ran the second and third sentences together and wrongfully assumed that two superior trains were to wait for him at a certain station, when the order in fact named only one of those trains as being required thus to wait. This second order was not delivered to the conductor of the train. It was on Form 19, not requiring signatures, and was delivered by the operator to a man on the engine of the train as it slowly passed his station, but it was not delivered to the conductor, who was on the rear end of the train, because neither the conductor nor the rear brakeman was in position on the step of the caboose to receive the order as the station was passed. The engineman, though having received his copy of the order, should not have continued on his journey beyond that station without a hand signal from the conductor to proceed. This he did not receive, the conductor and rear brakeman having ignored the stop signal.

Collision No. 9 was due to the error of a despatcher in sending an order to the wrong train. He sent the order to station A and to station D, giving an extra westbound train right over the first and second sections of an eastbound regular train from A to D, but in sending the order to D he addressed it to the conductor and engineman of the second and third sections of the regular train. The first section had already left D and the despatcher was aware of the fact. He seems to have assumed that the address of the order as sent to D corresponded with the statement in the body of the order, when in fact it did not correspond. The station operator who received the order at D did not discover the discrepancy, nor was it noticed by the operator at A.

Collision No. 17, occurring in the middle of the night, took place on a line worked by manual block signals, communication from cabin to cabin being by bell code. The signalman at A, 45 years old, and in the service of this company eight months as signalman (and formerly as brakeman), appears to have given a clear signal to the second train when he was not certain of the information he had received from station B. He claims to have received "four bells," meaning "block clear," but the signalman at B claims that he sent five bells, meaning block not clear. The signalman at A appears to have been in doubt concerning the bell signal and yet he did not ask B to repeat it. Both signalmen are reported as of good habits and good records. A large part of the damage incident to this accident was caused by a fire which was started by coals from the firebox of the locomotive.

Collision No. 19 was due to negligence on the part of both the conductor and the engineman of a passenger train. They had received an order to wait at S until 8.45 a.m., but passed that station at about 8.38, although the order had been given to them only about 13 minutes before. The conductor entirely forgot the order and he was dismissed. The engineman had misread the order and thought that he had a right to go to another station farther on. As he was passing S the fireman looked at his watch and spoke to the engineman; but the engineman, in response to this, simply pulled the order out of his pocket and handed it to the fireman without looking at it, evidently having no doubt that his reading of the order had been correct. Before the fireman had time to finish reading the order the collision occurred. Both the conductor and engineman were men of long experience. They had been on duty about three hours.

Collision No. 22 was due to the inefficiency of the flagman of a passenger train. This flagman, 24 years of age, who had been in the service about three months, started out to flag the following train, but took neither torpedoes nor fusees. After going a short distance he returned to his train to get his overcoat, and before he could again go out a sufficient distance for his signal to be of any use the following train was upon him.

Collision No. 23, between a fast first class train and a switching freight, was due to the carelessness of a brakeman of the freight train, who turned the switch from the main track to a siding without heeding the indication of the electric visual signal, which would have warned him that the fast train was approaching. The line at this point is equipped with automatic track-circuit block signals, and the fast train had already passed the point at which it set the switch indicator when the switch was turned. This train occupied only about 1 minute and 36 seconds in running from the signal at the entrance of the block section to the misplaced switch, and when it came on, at full speed, the freight had just fouled the main track. The brakeman at fault had been in the service of the road about 14 months. The enginemen had told him particularly to look at the indicator before turning the switch. It is possible that he looked at the indicator, but allowed considerable time to elapse after looking before turning the switch, the fast train meantime passing the block signal showing clear. Another collision in this quarter (No. 2 in the table) was due to the neglect of a trainman to make proper use of an automatic indicator at a switch.

Collision No. 25 was due to inefficient management of brakes. The freight train, westbound, running slowly along a passing track while waiting for a passenger train moving in the same direction, was allowed to run a few feet too far at the end of the passing track and so fouled the main line. The passenger train, coming along just at that moment at full speed, struck the freight, and the passenger engine was overturned. The freight train consisted of 23 cars, but had air-brakes in use on only four cars. The engineman asserted that he was ignorant of the fact that the other 19 cars had been disconnected. At a station about four miles back a non-air car had been put in the fore part of the train with the view of saving time at the next station, where that car was to be left. One of the brakemen claimed to have informed the engineman about the change in braking power.

Collision No. 29 was due to a freight train becoming uncontrollable on a steep grade about 2 a.m. The men in charge of the train were experienced, but appear to have exercised poor judgment. It is believed, though not proved, that an angle cock had been shut at the third car from the engine, so that the air-brakes were not effective on that part of the train behind the third car, and

for this misplacement of the track the conductor and engineman are held responsible. Aside from this, however, these men had allowed the train to attain too high speed before taking action to check the speed, and in addition to this the brakeman at the rear of the train, who should have opened the conductor's brake valve when the engineman sounded the alarm whistle, neglected to do so.

Collision No. 33 was due to a misplaced switch and occurred about 9 p.m. A northbound passenger train running at full speed, entered a siding and struck a southbound freight train which was standing there. Both engines were demolished and from their fireboxes the wreck took fire, three Pullman cars and 11 freight cars being completely destroyed. The switch had been left wrong by an employee of another road, the side track being used in common by the two roads as a connecting track.

Derailment No. 1, killing 19 persons and injuring 149, is reported as "cause unknown," the railroad company stating that its investigation into the circumstances of the accident has not yet been completed. The train derailed consisted of five passenger cars, drawn by two electric motors. It was running at full speed on a curve of 3 deg., the outer rail of which was superelevated 4½ in. Two cars were overturned. The track consisted of rails weighing 100 lbs. to the yard, laid on 21 ties to each 33 ft., with tie plates. The ballast was stone and the whole track was well built and maintained. In the cab of the leading motor were four men, the engineman, his helper, an electrical inspector, and the assistant superintendent of the division. These men estimate the speed of the train at the time of the derailment at 45 to 50 miles an hour, which estimate is corroborated by the record at the last block signal station, compared with that at the power house, where note of the time was made when power was automatically shut off by the breaking of the third-rail electrical conductor at the moment when the cars jumped the track. The report of the railroad company further says that in making a test run some time after the accident, with a train made up like that which was wrecked and with all conditions similar, the speed proved to be 48 miles an hour at the point of the accident. A careful examination was made of the track and wreckage immediately after the derailment, but although indentations were found on wheels and rails, it was impossible to determine whether these marks had anything to do with the cause of the derailment, or were only effects.

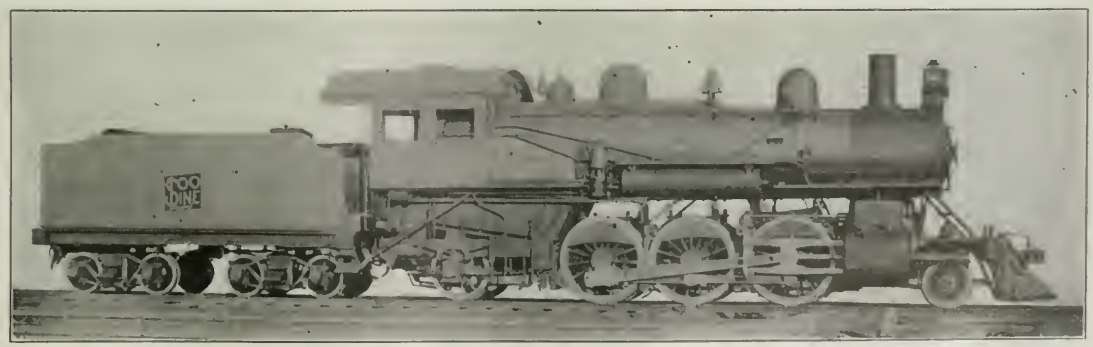
Derailment No. 18 appears to have resulted from gross negligence on the part of a number of different persons. A passenger train approaching an important station at high speed was derailed at a misplaced switch. The train was run not only in disregard of a rule requiring trains to be run within the yard limits with speed under control, but also apparently with recklessness as regards the switch which was misplaced and which caused the derailment; for it appears that the air-brakes on the train which, according to all the available evidence, were in good order, had not been applied before the engine ran off the track. The engineman was fatally injured, dying 11 days after the accident, and he made no intelligible statement. The train consisted of an engine and 14 cars. Six of these cars were completely broken up, and three others were badly wrecked. Most of the passengers who were killed were riding in two ordinary cars, not vestibuled, which were the first two cars in the train, while the cars behind these were not only heavier but were, most of them, vestibuled. The train, running at from 50 to 65 miles an hour, ran over the misplaced switch and entered the side track at such high speed that the engine was overturned at a point a few feet beyond the point where it left the main track. This switch was 1,585 ft. within the yard limit. There was a good view of the switch from the approaching train. The engineman of the passenger train was an experienced employee of this road, but the men in charge of the switching engine, who had left the switch set in the wrong position and abandoned, were comparatively new to their work. The foreman of the crew had been employed at this point only four weeks, though he had had railroad experience before. The switchman who was immediately responsible had worked in the yard about six weeks, but had had several years' experience in railroad work. The engineman and fireman of the switching engine had worked in the yard only three days.

Derailment No. 9, occurring about 4 a.m. and causing the death of four passengers and of the engineman and fireman, happened at a misplaced facing-point switch, the speed of the train at the time being about 35 miles an hour. The switch was found locked in position for the side track. It had been used by a freight train about 40 minutes before, but the question who was blameworthy for the misplacement has not been settled. The switch had no lamp, being a new one. The lamp had been received for it, and it was to have been put in position the next day. The engine was equipped with an electric headlight, by the aid of which the engineman could undoubtedly have seen the position of the switch target in season to stop the train before reaching the switch, but from the position in which the dead body of the engineman was found after the derailment it is concluded that he was not keeping a good lookout. There is evidence that he had crouched down behind the boiler head to light a cigar.

Explosion.—One of the most serious train accidents occurring in the quarter under review was due to an explosion. It is not classed either as a collision or a derailment, and therefore does not appear in Table 2*a*. In this accident 14 passengers and two other persons were killed and 33 passengers and six other persons were injured. The victims were on a passenger train approaching a small station, at low speed, and the deaths and injuries were due to an explosion of powder in a car of a freight train standing on a side track. The explosion, from some cause unknown, occurred just at the moment that the express car of the passenger train passed the powder car. The passenger cars were wrecked and the total amount of damage to the cars and locomotive was $11,300. The freight car in question contained 500 kegs of powder. It was stationary at the time and had been so for at least 12 minutes. There had been heavy continuous rains for several hours previous. The car containing the powder was comparatively new. After an exhaustive investigation by officers of the road the cause of the explosion still remained a mystery.

Prairie Locomotive for the Minneapolis, St. Paul & Sault Ste. Marie.

The American Locomotive Company has recently built 10 two-cylinder compound prairie (2-6-2) locomotives for the Minneapolis, St. Paul & Sault Ste. Marie. For a number of years the two-cylinder cross compound locomotive has been successfully used in both freight and passenger service on this road; but, heretofore, the fast freight work has been done by moguls. These are the first prairie engines that have been put in service. The reason for this change was that as it was desired to use them for both freight and passenger work, the prairie, with its wide firebox, offered a better opportunity to get a large grate and the necessary ample steaming capacity for passenger service, than the mogul.



Prairie Locomotive Built by the American Locomotive Company for the Minneapolis, St. Paul & Sault Ste. Marie.

In working order the engines have a total weight of 191,500 lbs., of which 133,000 lbs., or 69½ per cent., is carried on the driving wheels. The engines are compounded on the Schenectady principle, the high-pressure cylinders being 22½ in. in diameter by 26 in. in stroke and the low-pressure 35 in. in diameter by the same stroke. This gives a cylinder ratio of 2.42. The high-pressure cylinder is equipped with a piston valve and the low-pressure with an

Allen-Richardson slide valve, the valves being actuated by the Stephenson link motion.

The boiler is of the extended wagon top type with sloping back head and throat sheet, and is made in three courses, the outside diameter of the first and smallest ring being 60¼ in. The tubes, of which there are 266, are 2 in. in diameter and 15 ft. long, which gives a heating surface of 2,077 sq. ft., the total heating surface of the boiler being 2,243 sq. ft.

These locomotives, like so many others, show the wide variation in practice in the location of the injector check. The photograph shows that it is set well to the front. As a matter of fact, its center line is just 10 in. from the inside face of the front tube-sheet. As the hole is 2½ in. in diameter the edge of the stream of entering water is only 8¾ in. from the plate. This is quite contrary to the practice on other roads. A comparative determination of effects of different locations on tubes and steaming capacity would be interesting. The firebox is 90 in. long and 62¼ in. wide, giving a grate area of 39 sq. ft. The water spaces are large, being 5 in. wide at the mud-ring and increased to 7 in. at the crown-sheet at the sides and to 6 in. at the back end.

There is here a further variation in practice in the use of flexible stays. By comparing this boiler with others that have been made recently by the same company it will be found that one boiler with a length of 108 in., had a double row of flexible stays up each side and across the top, with clusters in the upper corners. The fireboxes in these prairie engines have a grate length of 90 in. and a length at the door of about 103 in. Yet here no flexible bolts are used at all. It is quite true that this corresponds with older practice, but the question arises why one firebox should need four vertical and two horizontal rows of these bolts and another, only 5 in. shorter, should need none at all. It does not seem that the difference can be wholly either in the difference in the length or the degree of forcing to which the fire is subjected. Possibly the matter is worthy a more thorough investigation than it has yet received. The frames are of cast-steel with double front rails and a separate slabbed section at the rear for the trailing trucks.

In the matter of weight equalization a departure has been made from the ordinary practice in equalizing the front and main driving wheels with the front truck and the rear drivers with the trailing truck, instead of equalizing the two rear drivers and the trailing truck together as is usual in this type.

The following are some of the principal dimensions and ratios of these engines:

The Maximus Brake.

The accompanying drawing shows the construction of an ingenious accessory mechanism applied to the foundation brake gear of a car to automatically produce a pressure on the brake shoe inversely proportional to the varying coefficient of friction at different speeds and thus to give a uniform retarding effect throughout the stop. The apparatus is an English invention and has been developed in connection with both the vacuum brake and the Westinghouse brake. Referring to the drawing, Fig. 1, which shows the application of the apparatus to one end of a four-wheel truck, it will be seen that the right-hand brake shoe is suspended by a rigid hanger in the ordinary manner. The left-hand shoe, however, is suspended by a link from a bell crank rigidly attached to a square shaft which extends across the end of the truck outside of the end piece. To this square shaft are also rigidly fastened two short lever arms which have pins at their ends working in circular slots in the casting bolted to the end piece and shown partly in section. This casting forms a seat for the spiral spring, the stem of which is also attached to the square shaft. The tension in this spring can be adjusted by the double nuts on the outer end of the stem. Below the spring is shown a ratchet slide which engages with a toothed pawl which is pivoted and which is normally disengaged by the pressure of the square shaft against the vertical leg. Power is transmitted from the brake cylinder through the pull rod shown at the top to the truck lever which is supported by the fixed hanger shown just to the left of the axle. This truck lever carries a roller which works in a V-shaped cam slot in the connecting yoke attached to the left-hand brake shoe and passing under the axle. The right-hand brake shoe is connected with the truck lever by a short link passing over the axle. When the brakes are applied the truck lever is pulled to the left by the pull rod in the usual way and draws the two brake shoes up tight against the circumference of the wheel. As soon as the friction is sufficiently great to cause the left-hand brake shoe, which is hung from the bell crank, to stick and begin to move down, the square shaft moves to the right against the spring pressure, pivoting about the end of the short lever arm extending downwardly. The initial tangential retarding effect at the brake shoe is thus made a constant quantity depending on the tension on the spring. At the high speeds when the coefficient of friction is low the pressure exerted by the truck lever is made correspondingly high. At the instant that the brake shoe begins to drag and to move the square shaft to the right against the spring pressure the toothed pawl is released and engages with the ratchet slide. This slide is connected back to the cylinder lever by a rod, and when it engages with the pawl all further movement of the cylinder lever and, therefore, any further increase in pressure at the brake shoe through the truck lever is arrested. In making a stop at high speed the brakes are applied with the maximum force which continues to be exerted until the tangential pull on the brake shoe releases the stop pawl and checks any further increase in braking power. As the speed falls, due to the retarding action of the brakes, the coefficient of friction increases. This causes the left-hand brake shoe to tend to drag farther and farther downward. As it moves downward the roller on the truck lever goes up in the slot of the connecting yoke and in effect opens out the toggle joint connection between the two brake shoes, thereby relieving automatically the pressure on the shoes without altering the pull at the upper end of the truck lever. If the car is moving in the opposite direction the movement of the apparatus is in the reverse direction to that described. The left-hand brake shoe moves up instead of down and the bell crank pivots about the end of the upper short lever arm. The yoke rises instead of falling and the roller on the truck lever moves downward in the cam slot, accomplishing exactly the same effect. The drawing shows the arrangement

of the apparatus at one end of the truck only. The locking mechanism however is applied only at the end of the truck nearest the center of the car. The brake shoes on the other pair of wheels on the truck are suspended from two links but are connected together with the same arrangement of brake levers. Their action

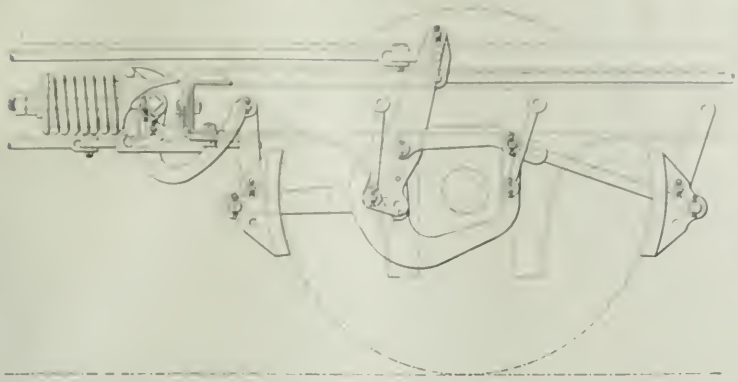

Fig. 1—Maximus Brake Apparatus Applied to Four-Wheel Truck.

under the constantly increasing coefficient of friction as the speed is reduced is precisely the same as that already described.

Figure 2 shows the apparatus as applied to a four-wheel truck on the North Eastern Railway of England. The square shaft extends across the end of the truck and the bell crank hangers with the regulating springs are mounted at each end of the truck end piece directly in line with the wheel treads. The ratchet and pawl are in the center line of the car, the connecting rod extending back to the brake cylinder levers.

The value of this apparatus is chiefly in making stops from high speed. With the ordinary brake apparatus the pressure on the brake shoe is constant, being limited to about 80 or 90 per cent. of the weight on the wheel in order to prevent skidding at the end of the stop. At very high speeds the coefficient of friction is less than one-third the coefficient of friction at low speeds and consequently an arrangement of brake apparatus employing a constant braking pressure from the beginning to the end of the stop has an efficiency when first applied of not more than 26 per cent., at medium speeds 52 per cent. and near the end of the stop 80 per cent., or an average of but little over 50 per cent. With the Maximus brake the initial braking power is increased to 160 per cent. or more of the weight of the car either by changing the foundation brake leverage or by increasing the size or pressure in the brake cylinders. This braking power is effective at the beginning of the application, but it is gradually and automatically eased off in the manner described to 80 or 90 per cent. of the load as the train comes to a stop, giving an average

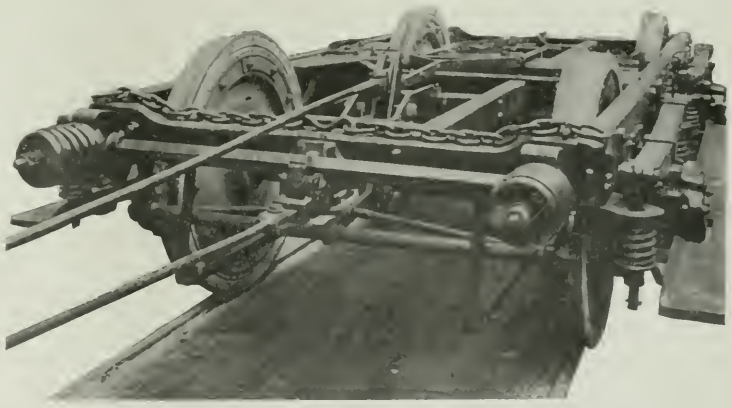

Fig. 2—Application of Maximus Brake to North Eastern Railway Four-Wheel Truck.

diagram shown in Fig. 3. These tests were made on a strip of straight track between York and Pilmoor during January and February, 1906. The stops shown for the ordinary brake were made by slipping one six-wheel coach braked on the four end wheels only to 62 per cent. mathematically of its weight. The same coach was then taken into the shop and fitted with the Maximus brake apparatus with the same percentage of weight braked. The tests were then repeated under the same conditions, both tests being made on days which were clear and dry. The highest initial speed

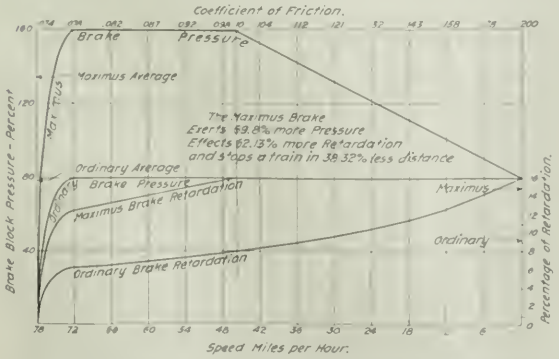

Fig. 3—Comparative Pressure and Retardation of Maximus and Ordinary Brakes.

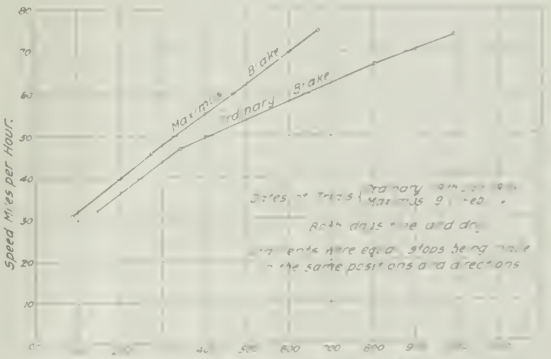

Fig. 4—Diagram of Brake Trials on the North Eastern Railway.

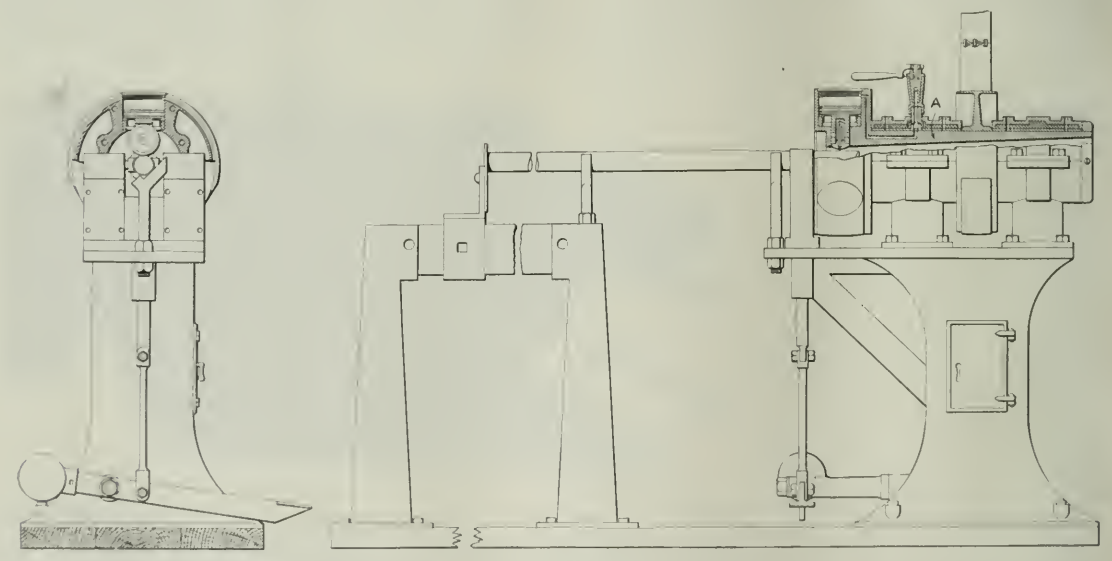
attained was 74 miles an hour with the ordinary brake and 75 miles an hour with the Maximus brake. With the Maximus brake the car was stopped from 75 m.p.h. in 2,010 ft. The coach, fitted with the ordinary brake, was stopped at 74 miles an hour in 2,970 ft. Equating the two steps for equivalent speeds the saving was 34 per cent. At 60 miles an hour the saving was 26.5 per cent. More recent tests have shown even greater saving in distance in making stops.

The action of the brake being entirely automatic the engineman does not need to be careful in making emergency or service applications. Full braking power can be thrown on at either high or low speed without danger of skidding the wheels or making uncomfortable stops. The action of the brake is said to be very smooth and uniform at both high speeds and low speeds. So successful have the trials been in England that the Great Western has already bought the rights to apply the apparatus to all of its passenger stock. It is controlled by the Maximus Brake Syndicate, Limited. Queen Anne's Chambers, Westminster, London. The licensees for Great Britain are Taite & Carlton, 63 Victoria street, London. Harvey E. Brown, Managing Director of the Maximus Brake Syndicate, with headquarters at the Southern Hotel, St. Louis, Mo., is introducing the device in the United States.

Pneumatic Tube and Pipe Cutter.

A pneumatic tube and pipe cutter designed by S. H. Lewis, assistant general foreman, is in use at the shops of the Seaboard Air Line at Portsmouth, Va. It can be easily operated by one man. With an air pressure of 50 lbs. per sq. in. it can cut three 2-in. locomotive tubes per minute, including the handling. If the air pressure is increased, the capacity increases also. Furthermore, the cutter is very economical in air consumption.



Pneumatic Tube and Pipe Cutter; Seaboard Air Line Shops.

The machine consists of a sleeve A turning in long bearings and driven by a pulley keyed near its center. At the end of the sleeve is an enlargement containing three cylinders to which pistons are fitted. These cylinders stand on radial lines and the pistons have roller cutters attached. There are ports through the sleeve as shown that lead to the outer end of the cylinders, through which air is admitted by means of the three way cock. Stops for the tube and Y supports are provided beyond the end of the machine and the tube is firmly clamped in position by pressure on a pedal.

After the machine is started the tube is placed in position to be cut, resting on the supports and shoved back against the stop. It is clamped by the pedal and the handle of the three-way cock is turned to admit air to the outer ends of the cylinders. This forces the pistons in and the cutters against the tube. As the circular head revolves the cutters roll around the tube and are forced in and cut off the piece in a few revolutions.

The piece cut off passes out at the back end through the hollow tapered spindle. When the tube is cut, the air valve is moved to exhaust and the cutters open by centrifugal force to receive another tube. As the tube is clamped by the pedal it can be fixed and released instantly without loss of time, and as the tube does not revolve, the machine is practically noiseless. In addition to these advantages the boiler maker does not have to mark each tube where it is to be cut, as the length is fixed by the adjustment of the stop. This is of value in cutting new tubes into safe ends, as the work of handling the tubes is materially lessened.

The cutters are of steel ⅛ in. thick and 3 in. in diameter; they are cheap, and their life is long. One set of cutters in the Seaboard Air Line shops has been in service for four months and has made 24,000 cuts without grinding on 2-in. tubes, approximately ⅛ in. thick.

Previous to building this machine the number of engines that could be turned out of the shop was dependent on the tube work; but since its installation the amount of tube work to be done is not considered in deciding upon the number of engines to be turned out. At the present time, with an output of six engines that are receiving a general overhauling per week, and notwithstanding the fact that other facilities have been greatly increased, the one tube cutter in service is idle a large part of the time.

An American State Owned Railroad.*

Instances of government ownership and operation of railroads have been rare in America. The Western & Atlantic Railroad furnishes perhaps the most important example in our history. That road was begun under a legislative act of 1836, built with public funds, and operated by the state government during periods of prosperity and depression, of peace, war and political reconstruction until 1870, when it was finally leased to a private corporation.

In 1826, Wilson Lumpkin, afterwards Governor of Georgia, made a survey through central Georgia and the Cherokee territory to the northwestward and reported that a route could there be had for a railroad. At this time steam locomotion was hardly contemplated for railroads in America, and Lumpkin proposed that the motive power should be furnished by teams of mules.

The idea upon which Lumpkin had acted in his survey was never abandoned. The revised charter of 1835 of the Georgia Railroad recites in its preamble: "The people of the West have in contemplation to make a communication between the city of Cincinnati and the South Atlantic coast by means of a railroad, and the best route for such communication is believed to be through the state of Georgia. The building of the Georgia Railroad is now in progress and will be an important link in the line of said communication." Among the projects was one for the state of Georgia to build a large part of the desired communication as a distinctly public enterprise. The legislature which met in December, 1836, passed a law which directed the survey and construction of a railroad from a point near Rossville to some eligible point on the southeastern bank of the Chattahoochee river, and provided funds not to exceed $350,000 a year, unless a future legislature should otherwise enact. The road was named the Western & Atlantic. A year later an increased provision of funds was made by authorizing the sale of state bonds

*Abstract of an article in the *Yale Review* by Ulrich B. Phillips, of the University of Wisconsin.

in amounts not more than $200,000 in any one year. By an act of 1838 an appropriation of $1,500,000 in 20-year 6 per cent state bonds supplemented and superseded the earlier provision.

Under the Act of 1836 the survey for the Western & Atlantic was pushed rapidly forward and by the end of 1837 specifications for the first 50 miles of the road were ready. In April the contracts for the grading of 50 miles were let and in October 50 miles more. By February, 1839, the contractors were working about 2,000 men on the road, and fair promise was given for the completion of the first 100 miles by the autumn of that year. In some sections, however, cuts and fills were exceedingly heavy, and some cuts which ran through rock formations were necessarily slow and expensive.

But financial troubles now came in a flood. The contractors on the road were informed of the state of finances and authorized to suspend work or carry it on with the prospect of delayed payment as they should see fit. In the dearth of other opportunities for their labor in the stagnation of business most of the contractors were disposed to complete the work on their sections, and even to secure additional contracts on the northern end of the line, and proposed to accept payment in the unsalable scrip of the state. The contracts for grading the remainder of the route were let at the end of 1839, with the one important exception of the section which was to include a tunnel a quarter of a mile long—the only tunnel on the route. The continued strain on credit, however, caused such severe decline in the market rates for state scrip, that most of the contractors, by the spring of 1842, suspended work.

The delay in the progress of the road, it happened, was not a cause of general regret. The depression of credit, each month more severe, had forced the stoppage of work on all the roads which were expected to connect with either end of the Western & Atlantic. The importance of that road lay in its becoming a connecting link of a general system. It would be of no use to forge the link until the chain was approaching readiness. Furthermore, neither of the railroads from the ocean gateways had reached within 60 miles of the beginning of the Western & Atlantic, and it would be an extravagance to haul rails and rolling stock over the wretched country roads to the isolated state railroad, which, if built, would begin on a vacant hill-top and run through ravines and forests to no terminus of consequence. The completion of the roadbed, without the laying of the superstructure, would entail a loss through the washing of the soil in the cuts and fills. The continued depression of state credit, meanwhile, made it inexpedient to attempt to buy rails.

The commission advised, in February, 1841, that the lower 52 miles of the route alone be prepared for the superstructure, and work on the northern part of the route be neglected; that as soon as one of the railroads from Macon or Augusta should reach the connecting point, the superstructure should be laid on the 52 miles and the road be put in operation for that distance; that meanwhile, the state should give financial aid to the company roads and enable them to make the Western & Atlantic connection. The state government approved most of these items and an act of December, 1841, dissolved the commission, replacing it with a disbursing agent, ordered the completion of the road for 52 miles when it should become feasible, and the suspension of work on the upper part of the route. The laying of rails for the 52 miles was in progress from 1843 to 1845; and thereafter, under an act of 1842, the road was gradually extended through the application of the net earnings from its operation. Active work was resumed under an act of 1847, and the road was completed to Chattanooga, May, 1851. Meanwhile, after 1845, times were growing much better; cotton prices rose again to satisfactory levels, business in general revived, and state scrip could be sold at par. An act of 1847 ordered the completion of the road, providing $375,000 in state bonds as the limit for the work.

The prospect for profitable traffic became much brighter. In 1845 and 1846 lines from Augusta and Savannah had reached the Western & Atlantic terminus. During 1848 the Nashville & Chattanooga Railroad was organized and put under contract. The branch from the main stem of the Western & Atlantic at Kingston was soon afterwards completed to Rome, and, aided by a steamboat on the river, attracted trade from the valley of the Coosa in Alabama. At the same time building of the Etowah flouring mills on the line of the road stimulated the production of wheat to an unprecedented extent.

With the piercing of Tunnel Hill, October 30, 1849, the completion of the road became easy. The last rails were laid in the spring of 1851. In May of that year the first train ran to Chattanooga. The road was 138 miles long and graded through much of its length for a double track, though equipped with only a single one, of 5 ft. gage. It crossed three river valleys and the dividing watersheds. Its track was a patchwork of strap rails and flange rails laid on wooden stringers, and "bridge rails," of the shape of an inverted U, spiked directly to the cross ties. Its rolling stock consisted of 13 engines, four passenger cars, two baggage cars, four box cars and six platform cars. The epoch of operation and its problems had begun.

In 1852 Governor Cobb secured as Superintendent William Wadley, who had [illegible] as Superintendent of the Central of Georgia. W[illegible] was at once felt with [illegible]. During the spring and [illegible] were [illegible] the substitution of T rail for the [illegible] and the rolling stock was rapidly increased. The [illegible] of the road advanced from less than $[illegible] and $[illegible] in 1851 to $77,170 in 1852 [illegible] $176,[illegible] in 185[illegible]. S[illegible] of these amounts as exceeded the expenses of operation were applied to betterments and charged to account of construction.

Wadley was succeeded in January, 1853, as Superintendent of the Western & Atlantic by George Yonge, and he in 1854 by Thomas F. Cooper. The position was later held by James M. Spullock from the summer of 1855 until the end of 1857, when the accession of Joseph E. Brown to the Governorship and his appointment of John W. Lewis brought a distinctly new régime in Western & Atlantic affairs. Until the business-like administration of Brown and Lewis began, the commonwealth had continually felt that it had a white elephant on its hands. The people were anxious lest the road and its money should become the instrument of political tyranny and corruption, but feared, on the other hand, that a still greater power would be established for possible evil if the road were sold or leased to a private corporation. The *Federal Union* in an editorial January 31, 1851, which in its dread of corporation control has a very modern tone, spoke as follows:

"The road has never yet had a fair trial. within the last two years large improvements have been made on some parts of it, and great additions to its equipment; several branch roads have also been built which will add greatly to the business of the main trunk; and now, just as the proudest hopes of the friends of the road are about to be realized, it is proposed to turn over this great work with all its splendid prospects to a company of speculators. But the pecuniary loss would not be all that the people would suffer by this transaction. A large corporation, like a mighty Colossus, with one foot at Savannah and the other at Chattanooga, will bestride the state, whilst its iron fingers will be felt in every election and will direct the future legislation of the state. No matter what guards and checks this legislature may throw around such a corporation, when they once get control of such immense resources they will elect a legislature to suit themselves and will break all these bands like cobwebs. We are willing to entrust the management of the road to the people, whether the Whigs or Democrats are in power, for we believe that the large majority of both parties are honest men and their agents are always responsible to the people for their conduct, but a gigantic corporation has neither soul nor conscience and owes no responsibility to any tribunal whether in heaven or on earth. The influence of corporations is already felt in every fibre of our legislation; it can be seen in every vote that is taken on this subject, and if ever these corporations get control of the State road, they will govern the state."

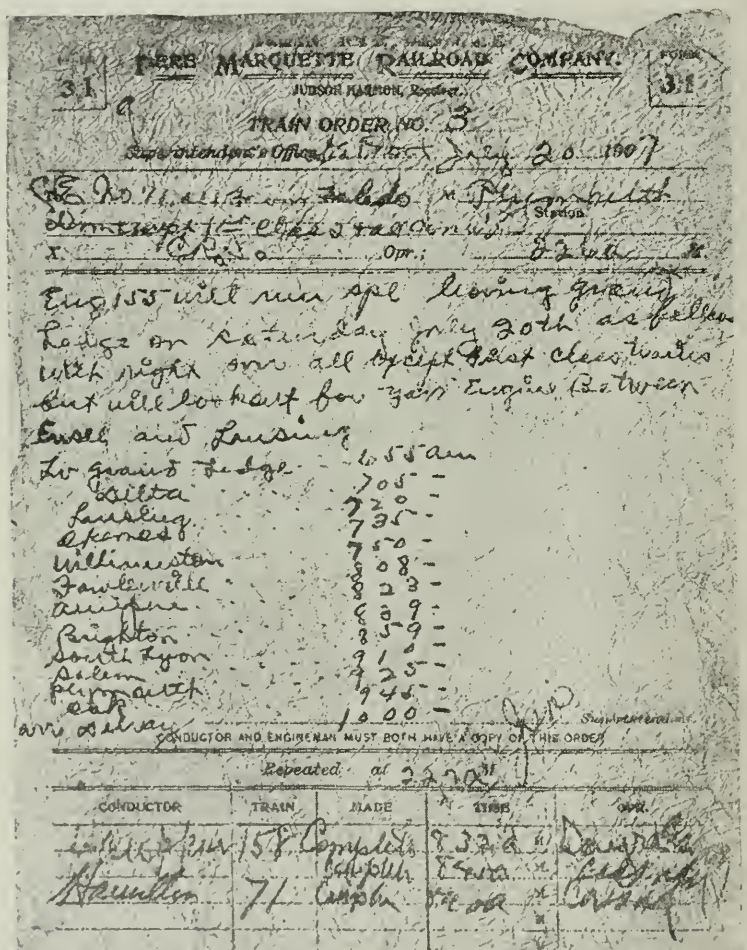
A vital problem was that of freight rates. Here the crux was in the question of whose interests the state road ought primarily to subserve. Ought rates to be high for the sake of large returns to the treasury, or low to benefit the citizens who were consumers of western produce? Ought local tariffs to be on the lowest basis, so as to increase the prosperity along the route of the road in Georgia, or ought the through rates to be at the minimum so as to attract business from afar and cheapen the food supply throughout the cotton belt? Ought the rates on goods for transfer to the connecting lines in Georgia to be on a reduced basis for the benefit of the established towns like Macon and Augusta, or ought the tariff to be absolutely uniform and thus promote the growth of a distributing center of food supplies for the cotton belt at the Western & Atlantic terminus? The actual policy as to freight rates was based on a few substantial principles: the road ought to yield a reasonable return on the investment; it ought to promote the welfare of the people of the state at large; it ought to subserve the special interests of the people along the route when they did not conflict with those of the state at large, but in case of such conflict the larger interest ought to prevail. These doctrines, of course, were easier to formulate than to apply in concrete cases with general satisfaction. Indeed freight rates seem to have been altered with some frequency to allay clamor.

The fact that the road was for a period incomplete and operated for strictly local business, caused the rise of local enterprises which shortly led to vigorous demands on the ground of protection to vested interests. The growing of wheat and corn along the route yielded large returns so long as the road was unfinished, but was thereafter embarrassed by the western competition. There was also phenomenal growth at the southern end of the road of a town first called Terminus, then Marthasville, and finally Atlanta. The grain raisers, of course, objected to any reduction of rates for western cereals, while Atlanta protested against any tariff which would encourage shippers to send cars past her depot unbroken. These protests were at times of some avail. For example, in November, 1855, a rule was put in force that all down traffic on the Western & Atlantic should bear the same charges whether bound for Atlanta or points below. At the same time rates on corn were fixed on a strictly distance basis, the road was laid off into seven divisions of distance, and the rate for corn in sacks fixed at five cents a bushel for one unit of distance, six cents for two units, seven cents

for three, and so on to 11 cents for the whole length of the road. Four cents a bushel was included in this tariff for terminal charges and one cent for carriage over each unit of distance.

The disproportion of down traffic and up traffic was enormous. No tonnage tables are available for the ante bellum period, but the figures from the report of 1868-1869 are perhaps a fair illustration of this characteristic feature of the road. In that year the through tonnage southward from Chattanooga to Atlanta was 233,022,932 lbs., and the through tonnage northward between the same stations was 6,089,500 lbs. The total freight southward was above 350,000,000 lbs., while the total northward was below 30,000,000. This meant that 11 cars out of every 12 had to go back empty, and the profit on the downward load was diminished in all such cases by the cost of hauling back the empty car.

From 1861 to 1863, there is to be noted the heavy traffic on



Schedule of Special Train Wrecked at Salem, Michigan.

government account, the large nominal earnings in depreciated currency, and a great deterioration of track and rolling stock. In 1864, Sherman's army destroyed much of the track and equipment, a destruction which was crudely restored, in part only, by the Confederate government and the state before the end of the war. The road was operated by the United States military authorities and was restored to the commonwealth on September 25, 1865, a rough patchwork of damaged and crooked rails, laid on rotten crosstles and on rough poles and other makeshifts; eight miles of track at the upper end were entirely missing, while the rolling stock was fit for the scrap heap. In 1866 1867 there followed a period of vigorous rehabilitation; there was an immense press of traffic to supply the exhausted country, a pressure increased by delay in reopening the seaboard lines; the gross earnings for 1865-1866 were $1,315,756.40, and for 1866 1867 $1,273,191.35; net, $360,655.69 and $585,729.13; large sums were devoted to rebuilding.

In 1870 there ensued a travesty of administration with wholesale mismanagement, extravagance and plundering, shared in by numerous politicians. Blodgett, the Superintendent, is said to have stated, with grim humor, that he took charge of the road to manage its "public and political policy." N. P. Hotchkiss, the Auditor, when asked how he had managed to save up 20 or 30 thousand dollars in a year or two out of a $2,000 salary, explained that it had been done "by the exercise of the most rigid economy." Blodgett and others were afterwards indicted for various crimes, but were pardoned by Conley, the last Republican Governor. By the autumn of 1870, the officials of connecting lines began to protest against the Western & Atlantic track as too dangerous to trust their cars on. Blodgett was robbing the road of all it was earning and of all he could borrow in its name, and now demanded an appropriation of $500,000 from the State for repairs. The condition of things had now become intolerable for the people, and a great cry arose for the road to be taken out of politics.

At the meeting of the legislature in October, 1870, a law was passed providing for the lease of the road, on adequate security, for 20 years, at not less than $25,000 a month. A company headed by ex-Governor Joseph E. Brown at its head, and including railroad presidents and politicians, Democrats and Carpet-Baggers, made a bid of $25,000 a month, furnished acceptable security and received the award of the lease. At the end of 1870 the Western & Atlantic accordingly passed out of state operation. When the term of the lease expired in 1890, a new lease, which now has some years yet to run, was made of the state road to the Nashville, Chattanooga & St. Louis at $420 000 a year. The existing status of the road as public property under private operation continues to be viewed in the state with general satisfaction.

The Salem Train Order.

We print herewith a fac-simile, slightly reduced, of the train order which figured in the disastrous collision at Salem, Mich., July 20, made from a plate for which we are indebted to the *Detroit News*. This copy of the order was made at Plymouth by the night operator, and the copy for the freight train (Train No. 71) was delivered by the day operater about 8.40 a.m. Further particulars are given in the editorial on page 114.

Earnings of German Roads.

At the beginning of the year 1906 there were 34,124 miles of standard gage railroads in Germany, 21 per cent. more than there were 10 years ago. The area of the German Empire is 208,780 square miles and the population is 62,125,000. The receipts from passenger traffic for the year 1905 were $163,773,750, 63 per cent. more than in 1895. The passenger and baggage traffic contributed 28 per cent. to the total receipts. There are four class rates for passengers. The first class averaged but 4 per cent. of the passenger traffic; second class, 21 per cent., and third and fourth class, 75 per cent. The average earnings per passenger per kilometer (0.62 miles) was about six-tenths of a cent, 12 per cent. less than in 1895. Freight earnings were $376,585,020, an increase of 57 per cent. over 1895. The receipts per ton per kilometer were about 8 cents. Ninety-two per cent. of the standard gage road is owned and operated by the governments of either the confederacy or the separate states; the balance is owned by private joint-stock companies. The net income on the capital invested in all the roads averaged 6.4 per cent. a year. There were 606,612 employees and officials in the service in 1905. Salaries, wages, etc., including $12,278,120 devoted to institutions and other expenses for their benefit, amounted to $209,618,500, an increase of 17 per cent. over the expenditure per person in 1895.

The Trans-Andine Railroads.

BY LEWIS B. FLEMAN.

The present year has been marked by two events which are important in the history of South American railroads. The first was the completion of the Chilean Trans-Andine, after many years of construction in the face of heavy difficulties, to a point where, at an elevation of 10,500 ft., nothing intervenes between it and the Argentine Trans-Andine Railroad but a mile of granite mountain through which a tunnel is being driven as fast as possible. The other event was the discovery, 500 miles south of the Transandine route, of a pass through the Andes whose highest point is at an elevation of only 2,260 ft., and so open that a broad gage line can be run through from the coast of Chile to Bahia Blanca and Buenos Aires without building a single tunnel.

The west coast of South America, as far as freight, mail and passenger services are concerned, is as remote from New York and London as Australia, and twice as remote as South Africa. The people of Chile, Peru and Ecuador, when voyaging to Europe, sail down the coast, around Cape Horn and then north again to Buenos Aires or Montevideo, where a direct European connection is made. The time required is from five to eight weeks, and the expense

Grading for the Chilean Trans-Andine.

is almost as much as making a direct first-class trip around the world following the usual northern hemisphere routes. The much shorter Panama route is no less expensive and, owing to the slow and irregular coasting steamer service, usually takes as much or more time than the all-water route by the Horn.

Mail to Peru and Ecuador usually comes by Panama, but the great bulk of the freight to these countries as well as Chile, pays the high insurance covering the passage by the Horn rather than meet the expense of the double trans-shipment at Panama and the delays to freight by that route on account of the overcrowded condition of the isthmian railroad. For the people of Chile, and for many Peruvians, the completion of the first transcontinental railroad will cut down the expense of the European voyage 30 per cent., and save in time of transit of both passengers and mail almost 50 per cent.

Chile will obtain favorable freight rates over the broad-gage line building by the newly discovered low-grade pass of San Martin, which is now breaking all South American records for rapid construction. Trans-shipment of goods to train will be made at Buenos Aires, La Plata or Bahia Blanca, from where they may be carried to destination without further transfer. The cost of trans-shipment will be more than met by the saving in insurance. There will be avoided the passage of the tempestuous Horn and also, for six months of the year the even greater danger of exposure in the unprotected Chilean harbors to the "northers," storms of great violence which occur on the southern Pacific coast during the winter season. A second handling at Chilean ports would probably prove too costly to warrant shipping freight to Ecuador and Peru across the continent by rail, and relief for these countries will be deferred until the completion of the Panama Canal.

The historic Uspallata Pass, on the line of the Trans-Andine Railroad, has formed the principal land route of travel between the Pacific and Atlantic coasts of South America ever since the Spanish conquerors of Peru first crossed by it when descending into Chile to found the present cities of Santiago and Valparaiso. The highway discovered and opened up by these early "makers of empires" was the same one over which the Argentine patriot, San Martin, poured the troops that struck the death-blow to Spanish power in South America at Chacabuco. The population center of the southeastern part of the continent is in the vicinity of the Rio Plate where the three cities of Buenos Aires, Rosario and Montevideo contain between them nearly 2,000,000 inhabitants. On the west coast Valparaiso and Santiago are in almost the same latitude as the mouth of the Plate, and a line drawn between these two centers cuts the Andes almost exactly at Uspallata Pass.

Long before a railroad over the mountains was considered feasible 700 miles of direct line was built across the Argentine pampa to the rich and populous wine-growing province of Mendoza, at the foot of the Andes and on the line of the old approach to Uspallata pass. On the Chilean side the extension of the government road up the fertile valley of the Rio Aconcagua to Los Andes penetrated for some distance the outer ranges of the mountains and approached even nearer than the Argentine road to the summit of the divide. The terminals of these two roads were only about 60 miles apart in an air line and, when the Trans-Andine Railroad was proposed, a survey showed that they could be connected by rail with something like 110 miles of track.

Clearing Snow on Rack Section of Argentine Trans-Andine.

The 70 miles of the Argentine section of this line—from Mendoza to Las Cuevas, where the summit tunnel is now being driven—follows the open valley of the Rio Mendoza for nearly all of its length and involves no difficult construction. It was completed several years ago and has been in operation ever since, doing a good business in the summer months in carrying mail, passengers and light freight. On the Chilean side, however, where only 40 miles had to be built, the physical obstacles to be overcome in building a line that would be protected at all exposed points from the snow-slides that every spring sweep down the steep slopes of the Andes, have made progress so slow that only this spring have the rails been laid up to the portal of the summit tunnel.

The last 13 miles of the Chilean section presented to the engineers the most difficult problems. The snow that causes all the

Approach to Uspallata Pass on the Chilean Side, Showing Railroad Grade on the Right and Government Wagon Road on the Left.

trouble in winter is partly the result of natural precipitation and partly the result of slides from the slopes of the 20,000-ft. mountains that hem in the pass. This snow is from 10 to 60 ft. deep by spring time, and when an accumulation of seven months begins to slide in the thaws of November and December, whole faces of the mountains often break away. The coach road running up to the pass is rebuilt each spring at an expense of $60,000 by the Chilean government. During the summer it is one of the best mountain highways to be found in any part of the world, but it is so completely ground down and scoured out by the slides that its reconstruction involves both regrading and resurveying.

The engineers who built this section of the railroad had to conform to the limiting grades, and also protect the track from the onslaughts of the spring slides and the winter snow to permit operation all the year round. The heaviest snow-sheds of the North American transcontinental railroads would be about as useful here as canvas wind shields in preventing the track from being carried off down the mountain. The method adopted of tunneling deep into the sides of the mountains at all exposed points was a heroic measure, but undoubtedly the only one that would have succeeded under the circumstances. The last 13 miles leading up to the divide is broken by 15 tunnels, all through the solid rock, and some of them over a quarter of a mile long.

The summit tunnel, which is being driven at an altitude of 10,500 ft., will be a little over two miles long. It is the longest tunnel ever attempted at so great a height. The international boundary line between Chile and Argentina cuts the tunnel almost in the middle, 3,000 ft. below the base of the colossal statue of Christ, which, as shown in one of the photographs, crowns the summit of Uspallata Pass. Work has been in progress for 18 months and about half a mile has been driven from each end. Little headway was made at first because all the native laborers were inexperienced in the use of the special machinery employed, but from the present rate of progress it is expected that the headings will meet some time in the latter part of 1908.

Up to this time passengers and light mail and baggage have been carried over the pass by stage three times a week during five or six months of the summer, the time from Buenos Aires to Valparaiso being from 40 to 60 hours, depending largely on whether snow was falling on the summit. Though the schedule calls for the trip over the pass between Los Andes and Mendoza between daylight and dark of the same day it usually happens that delays force the passenger to spend a night in one of a group of stone huts at Las Cuevas, near the summit. With the completion of the tunnel, trains will be run from coast to coast on a 30-hour schedule every day of the year. At the present time the boats carrying mail to and from the west coast leave Valparaiso every two weeks and take about two weeks in the passage to Montevideo, so that mail or passengers missing a boat must wait 13 days, or a total of 27 days, before reaching the east coast. The railroad will save from 12 to 26 days in either direction for mail and passengers.

The International Boundary Line Between Chile and Argentina at the Summit of Uspallata Pass.

This Uspallata line, however, cannot hope ever to do an ex-

The Argentine Trans-Andine Railroad Approaching Uspallata Pass.

tensive freight business because of the heavy grades, some of which, where the rack system is employed, run as high as 8 per cent. This together with the high price of coal in that part of South America will make the carrying of anything but light packages too expensive to permit competition with the steamship lines. For this reason the recent discovery of a favorable location for a broad gage line through the hitherto practically unknown southern pass of San Martin is most important.

The pass of San Martin lies in a region until lately unexplored. Because of the determined stand made by the warlike Arauco Indians, the early Spanish conquerors of Chile were never able to extend their influence beyond the broad river Bio-Bio, which, at about the 38th parallel, cuts transversely across the country from the Andes to the coast. These Indians long ago became peaceful agriculturists, but Chileans still refer to the Bio-Bio as the "frontier," and though the extension of the government railroad to the south has done much to encourage settlement, the country is still wild and forbidding.

The announcement of the discovery of an open pass through the Andes at an extreme altitude of 2,300 ft. was received with incredulity in all parts of South America. The Oroya Railroad in Peru, which penetrates only the first range of the Peruvian Andes, had to climb to an elevation of 18,000 ft.; the railroad to Quito, the Ecuadoran capital, from Guayaquil its port, ascends to more than 13,000 ft. In Colombia, the capital, Bogotá, while a short day's journey to the Pacific coast if a railroad could be built to scale the lowest of the lofty passes that exist in that region, on account of the difficulty of building such a road, still has to depend on the tedious two weeks' trip to the Carribean down the Magdalena river. From one end of the continent to the other, from the 22,000-ft. Chimborazi in the north to the 23,500-ft. Aconcagua in the south, is a continuous chain of great peaks 20,000 ft. above the sea. The famous Pass of Uspallata has always been considered the most favorable for travel on account of its comparatively low altitude of 13,000 ft.

The commission which settled the boundary dispute between Argentina and Chile traversed a part of the San Martin Pass several years ago, and it seems almost incredible that the men composing it could have neglected to note the favorable conditions for a main route of transcontinental travel. An enormous pile of green bottles which was pointed out to me in the rear of the cabin in which the commission made its headquarters in this region may furnish an explanation of the carelessness of these men.

A little more than a year ago a trader, William Angemeyer, a German by birth, an American by citizenship and a Chilean by residence, traveled through the pass on horseback, and realizing its many advantages for obtaining through it by for a railroad survey. Even before the survey was finished a company of French and Chilean capitalists with European backing had begun the construction of a line that will be extended through the pass to San Martin in Los Andes on the Argentine pampa, where connection will be made with the Buenos Aires Southern, which began extending simultaneously from its terminus at Neuquen. Trains are now running over several miles of both extensions and a through service will be begun not long after the opening of the Uspallata line.

Chilean Portal of Summit Tunnel under Uspallata Pass.

The rainfall at the latitude of San Martin—about 40 deg.—is nearly double that at Uspallata, and the snowfall in the higher mountains is proportionately heavy. The pass, however, at its highest point hardly touches the snow belt, and the snowfall is very light, rarely lying for a week at a time. No one of the four lakes that wind their way through this break in the mountains has ever been known to freeze over.

Lake Lacar, at the Eastern End of San Martin Pass.

In a recent trip through San Martin Pass from the Chilean coast to Argentina and back again, during the coldest days of midwinter, no temperature lower than 23 deg. Fahr. was recorded, and no snow was encountered of a greater depth than 14 in. Most of the way was entirely clear of snow, that met with having been at the top of the temporary bridle trail 1,000 ft. above the pass proper.

The pass is formed by a chain of lakes, each from 20 to 40 miles long. They run nearly east and west and empty successively into each other until their waters ultimately reach the Pacific at Valdivia through the Valdivia river. There are several favorable routes of approach to the pass for a railroad, but that which is being followed is up the Rio Valdivia and the Calle-Calle and San Pedro rivers. The government railroad extends to Collilelfu, where the new line begins. The 20 miles from Collilelfu to Lake Rinhue, the first of the four lakes, has just been put in operation.

Through the pass the line will skirt the open stretches along the lakes, heavy cutting being necessary only at three or four points where the mountains rise sheer from the water. It is a fortunate circumstance that, while each of the lakes lies in a great crack in the mountains, there is enough open space along at least one side to permit of comparatively inexpensive railroad building.

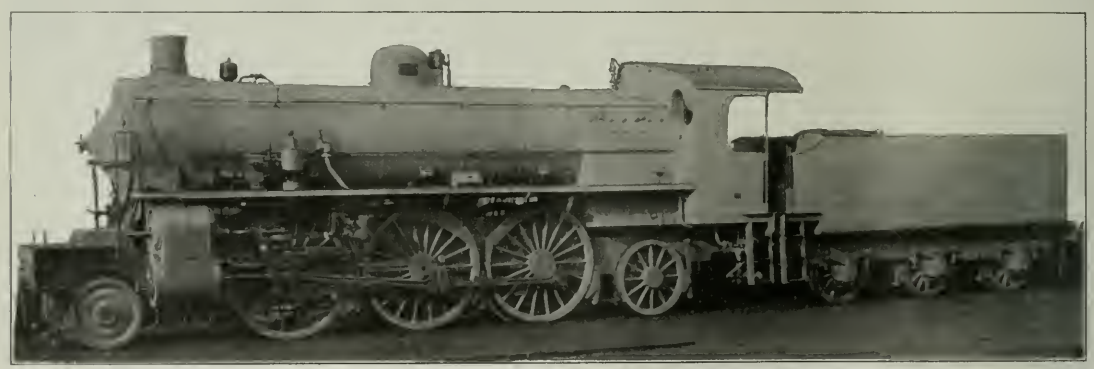
There are no new engineering problems to be solved on this route and only one piece of construction that is likely to prove costly. This is the 10 miles of grading between the lakes Panguipulli and Perihuelco, which have a difference of elevation of about 1,000 ft. Some heavy rock cutting will be necessary here; also the construction of at least two, and possibly four, very high

but short bridges. On the Choshuenco river, which connects these two lakes, there is a 200-ft. waterfall of sufficient volume to furnish power to operate the railroad for 150 miles in each direction and to supply abundant power for local use.

Until the completion of the railroad, traffic through the pass is to be handled by small steamers, one of which is already in service on each of the lakes. Navigation will be shortly opened between the two upper lakes, Perihueico and Lacar, by a lock on the connecting river, and the two lower lakes may also be thus united. The traffic at present is principally cattle and foodstuffs going from Argentina to Chile.

A Balanced Compound Locomotive for the Italian State Railroads.

The accompanying drawings illustrate a locomotive embodying several features novel in express locomotive design, such as the equalized connection of the driving and pilot axles in place of a four-wheeled truck; the permissible oscillation of every axle-box in the engine about a longitudinal axis in such way as to relieve frames and axles of all strain due to diagonal movements of the one in respect to the other through the deflexion of the springs or in traversing curves; in the engine proper, the use of two piston valves distributing steam to four cylinders, each valve being independently variable in its travel by means of a duplicate reversing gear for suiting the ratios of expansion, high-pressure to low-pressure, to the widely-varying conditions of gradient and service for which these engines are intended. This ability to vary the cut-off in a balanced compound having only two valves—so differing from any two-valved engines constructed in America—is a point of great importance, for it enables machines to be set, either periodically in the shops, or by means of a second reversing gear (and in the hands of an adept engineman) to the average requirements of any section of the line. Once these requirements are ascertained by practice the duplicate reversing gear may be abandoned. Experience in nearly all the countries of Europe has shown that once the most economical working of the compound system has been determined on various sections, and a mean struck between extremes, it is safer to remove any possibility of interference with this mean at the hands of enginemen, whose duties might often interfere with a timely attention to the ratios of expansion from high to low pressure.



High Pressure Side of Four-Cylinder Compound; Italian State Railroads.

The utility of the duplicate reversing gear for operating the two valves will be appreciated from a knowledge of the fact that these engines are to work the traffic over all the most important trunk lines of Italy from Chiasso, on the Swiss frontier, to Milan, to Bologna, over the Apennines to Florence, thence to Rome and to Naples and also on the line from Florence to Pisa (Mediterranean division). The passage of the Apennine north of Florence comprises gradients of from 2.5 to 2.27 per cent. So far, it has been usual to detach the express engines at either side of the mountain and to couple at the train-head the most powerful freight engine available and to run another powerful freight engine, tender forwards and uncoupled from the cars, behind the train.

The old freight engines have just been replaced by some remarkably powerful balanced compound freight locomotives having two cranked axles, and with these aiding there is a possibility of a greatly accelerated mountain passage. It is true that it is proposed to electrify this mountain section; but in view of the fact that the electric service may break down at any time, as recently occurred for a period of three weeks on the Simplon tunnel railroad, it would be impossible to do without a powerful reserve of self propelled locomotives at Pistoja—the foot of the mountain. Again, on the line from Florence to Rome there are continuous grades 44 miles long and gradients as great as 64.4 ft. between Orvieto and Chiusi, this rise being 6.2 miles long. Consequently, a two-valved engine, whose high and low-pressure cylinder volumes were similar to the Italian, and whose admissions were quite fixed and invariable from the very construction of the machine, as in certain American examples, could not be employed economically on the extremely variable profiles of Italian lines. By the employment, however, of greater ratios between cylinder volumes it is usual to make no difference in the cut-off of the two groups, but at very high piston speeds the total atmospheric back pressure on exceptionally large l.p. pistons may be somewhat prejudicial to free working.

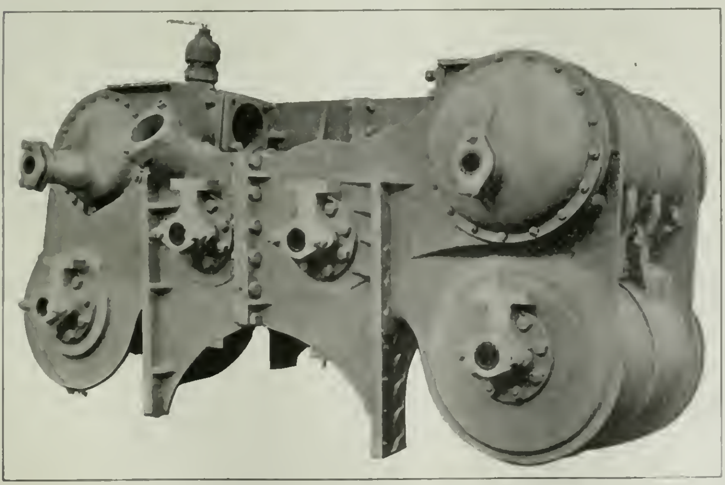
It will be seen from the drawings that the variable cut-off is made possible by the special arrangement of the cylinders: two high-pressure on one side and two low-pressure on the other side of the engine, one valve serving each group, and the opposite ends of each group of cylinders being in constant communication between themselves by means of crossed passages, so that the pressure exerted by the opposing forces of the two pistons in the same group is always and constantly equal in respect to the two cranks keyed at 180 deg. in connection with those two pistons. The balancing of the engine forces has been found to show a marked superiority by the equilibrium of steam pressures thus maintained, which is alike conducive to a regular turning moment in starting heavy trains, to a notable stability and smooth motion when speeding, and to a saving in track maintenance costs through the reduction of the wheel weights here rendered possible for the balancing of the revolving masses. The other advantages of two valves in the place of four are found also in the Vauclain compounds—that is, the passage through two valves of double the weight of steam that must traverse four valves, tending thus to efficiency in reducing variations of temperature and resulting condensations. Their internal loss by mechanical friction is naturally less than in four-cylinder single-expansion engines having four valves, and this, especially when superheated steam is employed in these latter, represents more power available for traction or for speed, and in such case the single-expansion engine becomes inferior in simplicity to the compound in consuming more steam without including the amount extra needed to overcome its own greater internal friction.

The Italian engine always works compound. It has no intercepting valve. For starting purposes there is a momentary admission of boiler steam to the low-pressure cylinders. This is entirely automatic and can only occur while the throttle is in the first stage of its opening, and only when the engine is set in full forward gear, as customary when starting a train. It just suffices to enable the high-pressure valve to obtain full admission; when the machine at once becomes quite capable, as a compound, for starting slowly any load up to 1,000 tons, or of 350 to 400 tons with rapid acceleration. The main throttle is of the Zara type, having a self-balancing action as soon as the throttle handle is moved for relieving it, first of all, of the full pressure of the boiler steam on its single seat. The lower portion of the valve is a loose-fitting piston, around the disc of which the preliminary admission of steam leaks away to the engine with the object of gradually applying the pressure, automatically, and so starting the wheels without slipping them. The succeeding phases of admission are graduated up to the moment when the throttle valve attains that full opening which is usual, from the first lifting, in all valves as ordinarily designed. The pilot valve for live steam admission to the low-pressure cylinders is connected by pipe to an extended cover on the high-pressure valve chest in which the extension spindle of the h.p. valve forms a sort of slide-valve which, when in full travel, opens the way to the receiver. From this it is obvious that back pressure from high-

pressure steam, as common in some systems of auxiliary admission, is here avoided.

The receiver referred to is a copper pipe carried around the walls of the smokebox close to the tube sheet for the purpose of reheating the steam before entering the low-pressure valve. A "Coale" anti-vacuum valve is fitted on the top of this pipe and a relief-pressure "Coale" valve, regulated to the proper pressure, is fitted over the receiver—see left hand side. Relief valves are also applied to all the cylinder covers.

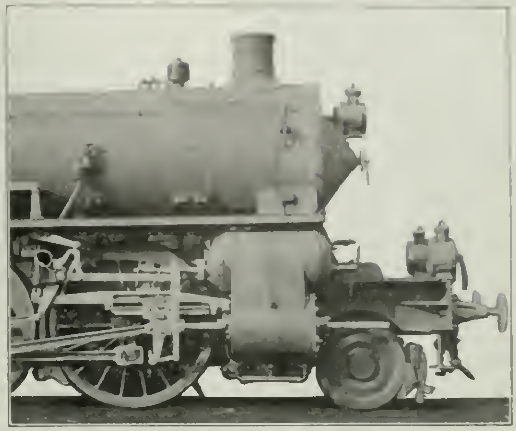
All the main driving rods work on the same axle, to effect which the inside cylinders are slightly inclined from horizontal. There can be no question that such arrangement effects a more perfect balancing than is practicable by balancing through the intermediary of side rods (or 2 x 0.5 = 1, system), and that it involves no more strain upon the cranked axle than in "divided engines" of the Webb or de Glehn order. The late Professor von Borries maintained that the efforts of the outside engines were absorbed almost entirely by the side rods and the driving wheels in connection with them. None the less, according to popular notion, "divided-engine" axles may be made of about half the strength of the single-driver axles—a fallacy at once apparent when it is considered that in the moments of the greatest stress, that is when starting a train, both single and double driver axles are equally liable to the full stress of all four pistons on one axle, and that if the divided-engine axles are really not designed to resist the torque of four pistons simultaneously then they are at a great disadvantage compared with the unicentric balanced engine. When the rear wheels of a divided-engine slip, all the power of four pistons minus that lost in skidding is applied on the front motor axle, direct or else through the side rods; and, when the front wheels alone slip, nearly the whole power is transferred to the crank pins of the rear motor axle. The same concentration of cylinder power occurs with unicentric balanced engines under the same accidental conditions, consequently it is impossible to attribute any superior equalization of the work in two-motor axles than in one-motor axles—if those axles be coupled together by side rods. In the old Webb engines and in the de Glehn engine, "No. 701," there was unquestionably an absolute division of the work at all times because their motor axles were not connected by side rods; but since rods were employed for connecting divided-motor engines no claim to any advantage over one-motor axles could be substantiated for the former. In other respects the double motor locomotive labors under real disadvantages: by the distance often separating the h.p. and l.p. cylinders as in the Webb-de Glehn-Cole types and in the constructive complication ensuing therefrom. In the Italian engine the crank axle is of the Z type of square section, forged in nickel steel, bored out hollow in all parts save the oblique arm. The mechanical details are best studied in the drawings given, but it may be remarked here that all the riding springs in the locomotive are compensated with levers from the third to the fifth axle while the leading driver has a single traversing spring.



Perspective View of Cylinder Casting.

The pilot truck frame is connected or equalized with the leading pair of driving wheels so as to form, with these latter, a four-wheeled truck, which is said to be practically equivalent in function to the ordinary four-wheeled pilot for high speeds. The arrangement is based upon the Krauss-Helmholtz equalized truck which has been in use for many years for fast [illegible] trains in Bavaria. The Italian arrangement for fast express engines differs from the Krauss in that, by the use of a swing [illegible] of a fixed pivot, any difference which may arise between the pilot and leading driving wheels [illegible] so to which shall yield at either end of the [illegible], is decided by the action of the swinging bolster which [illegible] such difference.

The designer of this locomotive, Signor G. Zara, first applied this arrangement to the [illegible] locomotives which he designed for



Front End of Low Pressure Side of Four-Cylinder Compound; Italian State Railroads.

the Valtellina electric railway [electric equipment by Ganz, of Budapest], and the Zara model was afterwards copied in the electro locomotors now operating in the Simplon tunnel by Brown, Boveri & Co. This form of equalized pilot truck, having proved successful for the electrical motors, has now been adopted extensively for Italian locomotives.

The right-hand photographic view shows one of the reversing rods, the position of the other being visible in the cross section showing the cranked axle. The left-hand view is a little more complicated by the addition of the Westinghouse air pump and the oil-feed pump. The compressed air reservoirs are concealed by the deep frames, near the firebox, and the sand boxes have the form of a saddle below the boiler and are readily accessible from both sides of the engine. It is worth notice that the brake blocks are only applied at the backs of the wheels where they relieve the strain on the axle boxes when in use.

In addition to the dimensions figuring on the plans the following may be given: Boiler pressure, 227 lbs. per sq. in.; grate area, 37.63 sq. ft.; total heating surface, 2,537 sq. ft.; weight, empty, 135,300 lbs., loaded, 151,250 lbs.; maximum for adhesion, 95,700 lbs. This latter is the maximum driving-wheel load allowable on Italian express engines until the roads are reconstructed. Any additional adhesion would call for a novel type of express locomotive having eight connected drivers. The present engines represent the power limits for such light wheel loads, and in this respect are instructive as showing the maximum of power obtainable in a minimum weight, and in a short length adapted for existing turntables throughout the Italian railroad system. They are designed for express speeds of up to 75 miles per hour with trains of up to 400 metric tons, or with fast accommodation trains of 450 tons. With the International trains-de-luxe they are found to pick up, easily, 30 minutes, and more, lost in delays during a run, and their boilers generate an abundance of steam in respect to the very economical steam consumption by the engines, although the Welsh coal employed in these new boilers—not reversed on the frames as heretofore—only evaporates, on the best average, 7.5 lbs. of water for each pound of fuel.

The new locomotives were built by the firm, Società Italiana Ernesto Breda, of Milan, and the delivery of the engines was made in the presence of the Director-General of Italian Railroads with exceptional attention and formality. Some of the more important

New Union Station for Three Roads at Waco, Tex.

The new union station recently built by the St. Louis Southwestern at Waco, Tex., is shown in the accompanying illustrations. The other roads which use the station are the International & Great Northern and the San Antonio & Aransas Pass. The St. Louis Southwestern and the International & Great Northern previously used jointly a small one-story frame station on Third and Mary streets, on the north end of the block which the new terminal now occupies. The San Antonio & Aransas Pass had a separate station of its own about half a mile away.

The new station is at the corner of Fourth and Mary streets, in the business center of the city, and four blocks from the Brazos river. It is 145 ft. x 70 ft. outside, the long dimension being on Mary street, and a covered platform 60 ft. wide extends through to Third street over the site of the old station.

The building material is red brick faced with buff brick, the trimmings being gray stone. The tower is 19 ft. square and 70 ft. high. The roofs are covered with black Bangor slate and all ridges and hip rolls are trimmed with buff terra cotta. The interior has two general waiting rooms, for whites and negroes respectively, each 41 ft. x 49 ft.; ticket office, 16 ft. x 16 ft.; ticket lobby, 19 ft. x 25 ft.; women's retiring room (white), 17 ft. x 22 ft.; men's smoking room (white), 17 ft. x 24 ft.; and smoking and retiring rooms for negro men and women, 12 ft. x 17 ft. each. The baggage room, at the north end of the building, is 26½ ft. x 41¾ ft., and adjoining it is the express room, 21 ft. x 23 ft. 10 in.

Union Passenger Station Built by the St. Louis Southwestern at Waco, Tex.

Main Waiting Room (Negroes' Waiting Room Beyond); Waco Station.

The two general waiting rooms are connected with plastered arches and colonial columns. The walls in the general waiting rooms are wainscoted 8 ft. high with Tiffany white enameled brick. Above the wainscot the walls are plastered with Acme cement tinted gray. The ceilings over the waiting rooms are plastered and have heavy beams and cornices in 12-ft. squares. The height of the ceilings in the waiting rooms and ticket lobby is 25 ft. and in the other rooms 14 ft. The floors in the waiting rooms, lobby, toilet and smoking rooms are Venetian mosaic, finished around the walls with a sanitary base of terrazo marble. The building is heated by steam and lighted by electricity.

The street, driveways and inter-track spaces are all paved with vitrified brick on a foundation of concrete. The cost of the terminal, including street paving and necessary track changes, was approximately $60,000. The plans were prepared in the office of J. S. Berry, Superintendent of Bridges and Buildings of the St. Louis Southwestern, and all work was done by company forces. We are indebted to F. H. Britton, President of the St. Louis Southwestern of Texas, for the information.

Chinese authorities have decided that all railroads built by Chinese shall revert to the government 25 years after they are opened.

GENERAL NEWS SECTION

NOTES.

The legislature of Alabama has appropriated $50,000 to pay the expenses of resisting the suits which have been begun in the courts by the railroads to secure the annulment or modification of the rate laws recently passed.

The Railroad Commissioner of Michigan has sent to all of the roads in the state a letter calling attention to the necessity of good locks on switches. He has found many unlocked switches and some which have no locks.

Complying with a recent state law, the Pennsylvania Railroad has remeasured its main line, and the distance between Philadelphia and Pittsburg will hereafter appear on the time tables two or three miles less than heretofore.

According to a press despatch from Cleveland, a strike of union boilermakers in the shops of the Lake Shore & Michigan Southern Railway at Elkhart, Ind., has been settled by the company's agreeing to entirely abolish the piecework system.

An order recently issued by the Texas State Railroad Commission, requiring the Southern Pacific to run double daily passenger trains between San Antonio and Victoria, has been suspended by a restraining order from the District Court.

Somebody in Texas has estimated that the more elaborate accounts which must henceforth be kept by the railroads in compliance with an order of the State Railroad Commission, will cost the companies $300,000 additional yearly for clerical help.

Western papers say that the railroads between Chicago and Kansas City have decided to reduce the time of their through express trains from nine hours to eight hours 30 minutes. The time of these trains was lengthened from eight and one-half hours to nine hours a few months ago.

The Public Service Commission of the Second District of New York State has ruled that railroads may sell round trip excursion tickets to the state fair at Syracuse, with a coupon giving admission to the fair grounds; but a passenger must not be compelled to buy the admission ticket in order to secure the excursion rate.

The legislature of New York has passed a bill, which has been signed by the Governor, repealing the clause in the franchise tax law under which railroad grade crossings in first-class and second-class cities are exempted from liability to the franchise tax. This means that the right of a railroad to cross a street is to be regarded as property and may be assessed for taxation.

The presidents of a number of important railroads met at the office of President Underwood of the Erie in New York City last week and discussed the question of abandoning excursions in order to increase their income, with a view to counteracting in some degree the reduction caused by the recent enactment of 2-cent rate laws by several states; but no action was taken, each road being left to act for itself.

The state of Connecticut has passed a law, similar to the federal law, limiting the working hours of railroad telegraph and telephone operators. At offices which are not open at night the operator may work 12 hours, but at other places the ordinary limit is eight hours a day. The only exception to this is in cases of "sickness, death, wrecks or washouts." The penalty for disobedience is $1,000 fine, or ten times as much as the fine prescribed in New York State.

A new line of steamers from Vancouver, B. C., to the west coast of Mexico, subsidized by the Canadian and Mexican governments jointly, is now in operation. The steamship Georgia has made one voyage from Vancouver south to Salina Cruz, the western terminus of the Tehuantepec National Railway, stopping at intermediate ports. There was little or no cargo at Vancouver for this first voyage, so that the vessel was loaded at Puget Sound ports.

The new laws of the State of Texas, requiring a certain number of brakemen on trains and requiring the use of electric headlights on locomotives, and regulating the working hours of trainmen and telegraphers, went into effect July 12. Mr. Van Vleck, of the Southern Pacific, is reported as saying that on his road the headlights alone will cost about $200,000; while the increase in wages and the cost of changing terminals, in consequence of the limitation of working hours of trainmen, will for the whole state and for all the roads run up into the hundreds of thousands.

The Wabash has reconsidered its decision to establish a passenger rate of 2 cents a mile in all territory east of Chicago. As the only road having lines both east and west of Chicago, the Wabash is a member of both the Western and the Central Passenger Associations. It found itself making 2-cent interstate rates in the territory west of Chicago and 2½ and sometimes 3 cents east. This led to a notice of intention to make a uniform rate of 2 cents a mile, but it is now announced that interstate rates are not to be disturbed, except in cases where the through rates exceed the sums of the local rates.

The committee on car efficiency of the American Railway Association has issued a statement showing surpluses and shortages of revenue freight cars on July 10 on all of the principal roads. These figures show the conditions as to over and under supply of cars as reported to the committee without regard to the number of cars owned. By comparison with February 6 last, the date showing minimum surpluses and maximum shortages since such figures have been compiled, it is found that July 10 shows an increase in surpluses of 37,459 and decrease in shortages of 85,739 cars, or a net improvement of 123,198 cars for an average of 79 roads.

An advance of 20 per cent. in freight rates recently announced by the Metropolitan Steamship Co. has raised the level of water rates between Boston and New York to a parity with the all-rail rates. It is said that the tendency in the last few years among coastwise steamship companies has been to lessen constantly the margin of difference between competitive rail and water rates. The New Haven water lines for several years have been gradually increasing the rates on the Providence and Fall River boats to New York, until at present there is no practical difference in the cost of freight between the rail and water lines. It is said that the advances in water rates have been due to the increased cost.

A lumber manufacturer in the Northwest says that his inability to promptly fill orders for carload shipments, which, a few months ago, was due to a scarcity of cars, is now due to a scarcity of cars of the right kind; that is to say, the railroad, according to this shipper, has enough cars standing around his station to take all of his lumber, if only they could be used; but the road will not allow its own cars to be sent off its own line, and the other cars which are standing there empty cannot be sent to the points to which the lumber is destined. In other words, the railroad has begun to comply with the rule which forbids sending foreign cars in a direction opposite to that which will take them home—a refreshing revival of conscience.

Out of 1,196 surprise tests on the Union and Southern Pacific in a recent month, in only 16 cases did enginemen fail to observe signals. Eighteen different tests were applied, besides special tests. All red flags, crossing, station and block signals were observed. This is the fourth year of surprise tests on the Southern Pacific and the third year on the Union Pacific lines. Tests are made in person by each division superintendent and his subordinates, and the general superintendents and general managers are required to make a number of surprise tests every month. Two or more of each of 18 different kinds of surprises must be made on each division each month. These tests cover the use of torpedoes, fusees, slow and red flags, switch lights out and at danger, and all semaphore signals.

According to a press despatch from Chicago, the Post Office Department has decided that on the railroads west of that city it can save $1,000,000 a year by occupying less room in the mail cars on the railroads; and the railroads have been notified of the purpose of the department to make this change. Railroad officers are complaining of this, and also of the severe enforcement recently of penalties for delays. One officer says that the fines levied by the Government against his road, in one quarter, amounted to $40,000. The Department now adheres, it is said, to the rule providing that if mails are late 10 times on any route during a period of 90 days the road shall be assessed 15 per cent. of the pay of that route for the quarter. Under the speed standards as now established it will be a marvel if any of the big Western roads escape having their important mail trains late more than 10 times in 90 days. As to car room, it is said that the Post Office Department is preparing in many cases to insist upon one size car westbound and an entirely different car eastbound. One of the Government inspectors is quoted as telling a railroad official that this was being done because of the knowledge that, rather than deadhead cars over their routes, the railroads would in all such cases use the larger car both ways, whereas the Government would have to pay for the larger size car in only one direction.

English Excursions.

An excursion run from Burton-on-Trent to Blackpool, England, on July 19, for the employees of Bass, Ratcliff & Gretton, brewers, filled 17 special trains, all of them starting between 4 and 6:45 a.m. The distance traversed was 121 miles, the journey covering parts

of four different railroads. The whole expense of the excursion was borne by the employers, including side trips in steamers and admission to all the Blackpool shows.

On the excursion of the employees of the Great Western Railway from Swindon, the first week in July, over 25,000 people left that town for a week's holiday, the employees taking their wives and families and the town being nearly deserted. On the fifth of July 22 special trains left Swindon, all before 7 a.m. Three of these trains, carrying 4,500 passengers, went to London; five to Weymouth and the Channel Islands, with 6,000 passengers, three for Plymouth and the West, with 5,500, and four for Weston-super-Mare, with close on 5,000 holiday makers. In addition, more than 3,000 people visited South Wales, and 2,500 the North of England. The traveling arrangements were conceived in the most generous spirit, the company providing free passes for employees and their families over its own road, and tickets at reduced rates for journeys over foreign lines. The only restriction imposed was that each man must decide on his holiday resort a fortnight beforehand, in order to simplify the arrangements for transporting the vast number of travelers. The special time table issued for this occasion fills 16 pages.

Welding Locomotive Frames with Thermit.

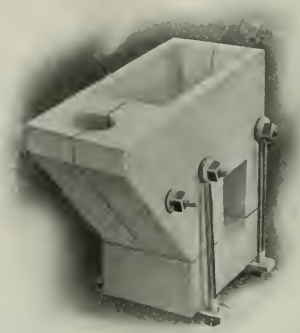
The Goldschmidt Thermit Co., 90 West street, New York, has recently developed a new and simple method for welding locomotive frames which employs fire brick moulds instead of the usual sand mould. These moulds are shown in the accompanying illustrations. They are made in three parts, two side pieces and a bottom piece, the necessary gate and riser being formed in the moulds, as well as the collar around the fracture. They are made in four sizes for frames from 3 in. wide and 4 in. deep to frames 5 in. wide and 6 in. deep. For intermediate sizes the bricks can be cut to fit. In welding frames the fracture is prepared in the usual way by drilling 1 in. holes along the line of the break and jacking the

Parts of Firebrick Mould for Welding Locomotive Frames.

Mould and Crucible Ready for Pouring.

parts open from $\frac{1}{16}$ in. to $\frac{1}{8}$ in. The contact surfaces of the right-hand and left-hand bricks are covered with a thin layer of fire clay and then bolted together around the fracture. The contact face of the lower brick is coated with clay and squeezed up against the side bricks and then the openings around the frame are carefully luted by squeezing in fire clay. The mould is surrounded with a sheet iron or wooden box which is filled with sand and thoroughly tamped as an additional precaution against the escape of molten steel. The crucible is placed in position over the pouring gate and the charge melted and poured in the usual way after the mould and frame have first been heated red hot. The use of these standard moulds eliminates much of the preliminary work which was formerly necessary and allows the welding to be done quickly and accurately. The moulds are furnished at the uniform price of $5 a set of three pieces. They can only be used once.

Where the fracture is located in a part of the frame which makes it impossible to use these standard moulds a simple process of making the mould out of green sand has been developed. Yellow



Frame Mould Assembled.

wax is used as a pattern or matrix for the casting and is shaped around the fracture in the form of the collar desired. The mould box is then placed in position and moulding sand, consisting of a mixture of fire clay and sand, is tamped around the matrix in the usual manner except that a small hole is left in the lowest part of the mould. The patterns for gate and riser are made of wood and placed in the mould in the usual way. After the mould box is filled and tamped the gate and riser patterns are withdrawn and a torch applied through the riser. The intense heat melts the wax matrix which runs out through the opening at the bottom. The heat is continued until the metal is red hot and the mould is thoroughly dry, after which the opening at the bottom is closed with a sand core. Pouring is then performed in the regular way.

Test of Holmes Rod Packing.

A thorough test of Holmes' metallic packing, made by the Holmes Metallic Packing Co., Wilkesbarre, Pa., was recently completed by the Philadelphia & Reading. An eight-wheel switch engine, No. 1,356, built by the Baldwin Locomotive Works, was equipped on February 11, 1906, with Holmes' metallic packing applied to the left piston rod and right valve stem and the opposite rod and stem were packed with other packings. The locomotive was worked 24 hours a day for seven days in the week with a steam pressure of 205 lbs., and, during the 16 months ending June 8, 1907, made over 75,000 miles. At the end of that time the rod and stem packed with the Holmes' metallic packing was absolutely steam tight and both the rods and the packing were in perfect condition. The piston rod had been reduced less than $\frac{1}{64}$ in. in diameter. The packings on the opposite rod and stem during the same period were renewed 41 times, eight new sets of packing being applied during one month, December, 1906. The rod required turning with a reduction in diameter of $\frac{1}{64}$ in.

The Yale & Towne Triplex Hoist.

It will be observed in the upper photograph on page 71 of the *Railroad Gazette* of July 19, 1907, illustrating an article on "The New Blacksmith Shop of the Union Pacific at Omaha," that a Yale & Towne triplex chain block is in use holding a locomotive frame in front of the frame fire. These hoists are made by the Yale & Towne Manufacturing Co., New York city.

New Warehouse at Newark for the Central of New Jersey.

On August 1 the Newark Warehouse Company, a subsidiary company of the Central Railroad of New Jersey, opened a large new building at Mechanic, Lawrence and Ward streets, Newark, N. J., for handling freight coming to and from the city on the New Jersey Central. Cars will be switched into the ground floor of the building, where their contents will be unloaded and raised by a complete elevator system of 11 elevators and eight gravity conveyors

to the floors above or unloaded directly onto trucks. The whole building is made of reinforced concrete. It occupies a city block, is six stories high and has 370,000 sq. ft. of floor space. Six thousand tons of steel were used in its construction. Fifty freight cars can be accommodated on the tracks inside the building, which has room for the storage of 12,200 carloads of freight.

Exports Through Atlantic and Gulf Ports.

The *Wall Street Journal* publishes the following figures of grain exports through the Atlantic and Gulf ports, compiled by the traffic department of the Chicago Board of Trade. The figures are for the years ended June 30, 1906 and 1907.

Grain Exports for Two Years.

	Corn		Wheat.	
	1906.	1907.	1906.	1907.
Boston and Charlestown	6,769,128	4,693,998	297,542	2,622,505
Portland and Falmouth	401,148	149,742	967,767	1,189,815
New York	24,528,389	21,761,363	7,504,594	18,679,225
Philadelphia	11,684,063	6,368,221	1,201,980	8,394,150
Baltimore	26,237,722	19,917,037	1,669,578	5,026,578
Newport News, Norfik, Prtsmth	4,421,561	1,940,544	160,000	943,359
Total	74,042,011	54,820,895	11,741,461	36,852,632
Galveston	13,643,529	5,663,301	3,816,916	14,172,021
Mobile	1,901,491	2,307,570	110	862
New Orleans	18,881,433	8,236,918	1,521,354	5,496,965
Total	34,429,053	16,328,192	5,338,410	19,669,818
Percentage via Atlantic ports	68.26	77.05	68.74	65.2
Percentage via Gulf	31.74	22.95	31.26	34.8

Although the proportion of wheat exports via Atlantic ports declined, the proportion of flour exports increased, being 86.83, as against 81.84 in the 1906 crop year. The flour totals in barrels follow:

	Seaboard.		Gulf	
	1907.	1906.	1907.	1906.
Exports	8,980,128	8,065,998	1,361,260	1,789,837
Per cent.	86.83	81.84	13.17	18.16

Third Class Passenger Cars in Canada.

The Canadian Railway Commission has ordered the Grand Trunk Railway to have third-class carriages put on its trains throughout the entire system in Canada. The road has the right to appeal from the order to the Supreme Court. Third-class would probably mean a general rate of 2 cents a mile.

Record Earnings of the United States Steel Corporation.

The net earnings of the United States Steel Corporation for the second quarter of 1907 (April 1 to June 30) were $45,503,705 against $41,750,125 in the previous high record quarter, which was that ended December 31, 1906. The net earnings for the six months ended June 30, were $84,626,197. This compares with the first half year's net earnings of previous years as follows:

1906	$76,750,523	1903	$61,568,235
1905	53,331,012	1902	64,377,500
1904	32,699,611		

The unfilled orders on hand June 30, 1907, amounted to 7,603,878 tons, somewhat less than at the ends of the last three quarters. The falling off in new business in July as compared with July of last year is estimated at 25 to 30 per cent.

Carrying Coals to Newcastle.

The people of Tonawanda, N. Y., had their curiosity aroused recently by the appearance at that port of a steamer flying the Norwegian flag. It was the "Polleux," loaded with 860,000 ft. of spruce lumber from St. John, N. B., consigned to a wholesale lumber dealer. This is nearly the same as carrying white pine to Michigan, and serves as a reminder that "times have changed."

INTERSTATE COMMERCE COMMISSION RULINGS.

Rate on Cotton Waste from Augusta, Ga., to New York, Reduced.

Commissioner Clements has announced the decision of the Commission in the case of Riverside Mills v. Southern Railway et al. It appeared that defendants' rate on cotton waste, a by-product of cotton goods, in bales, from Augusta, Ga., to New York, is 41 cents per 100 lbs., or the same as the rate on cotton goods between the same points, though cotton waste has considerably less value and involves much less risk and expense in transportation than cotton goods. The Commission held that cotton waste should be carried at less rates than cotton goods, and that no higher rate than 35 cents per 100 lbs. should be charged for its transportation by sea and rail from Augusta to New York.

Rate on Cotton Goods from Augusta, Ga., to New York, Upheld.

In an opinion by Commissioner Clements decision has been announced in the case of the Warren Manufacturing Co. et al. v. Southern Railway et al. The Commission held that the absorption of a competing line of railroad by another in alleged violation of the statutes of a State or of the Sherman anti-trust act can be considered by the Commission only if it results in unreasonable rates. The long-continued carriage of any article of freight at certain rates, while establishing a presumption that such rates are reasonable and remunerative, is not alone conclusive, but to carry such presumption must show a settled practice or policy. Where a rate is comparatively the lowest in its territory on a given article of freight and by reason thereof has been made the basis of reductions from competitive points, it will not be further reduced on the ground alone that it had at stated periods in the past been somewhat lower, unless it be shown that it is unreasonably high for the service performed. In this case the rate of 41 cents per 100 lbs. on cotton goods by sea and rail from Augusta, Ga., to New York was held not unreasonable, and the complaint was dismissed.

Grain Rates from Oklahoma to the Gulf Reduced.

In an opinion by Commissioner Prouty decision has been announced in the case of the Territory of Oklahoma v. Chicago, Rock Island & Pacific et al. The complaint asked reduction of the rates on wheat and corn from all stations in Oklahoma on the lines of the defendants when moving to Galveston for export. The defendants are the various railroad companies carrying this grain from points of origin in Oklahoma to Galveston, the other originating roads being the Atchison, Topeka & Santa Fe; Gulf, Colorado & Santa Fe; St. Louis & San Francisco, and Missouri, Kansas & Texas. The other defendants are railroads which receive this traffic at various junction points and carry it to destination. The Commission found that defendants' rates on wheat and corn from points in Oklahoma to Galveston for export are unreasonable and ordered them reduced.

The Basing Point System Upheld.

In an opinion by Commissioner Clements, decision has been announced in the two cases of the Commercial and Industrial Association of Union Springs, Ala., v. Louisville & Nashville et al., involving the reasonableness of rates from St. Louis, Nashville and Memphis to Union Springs as compared with the rates from the same points of origin to Columbus, Ga., and Montgomery, Eufaula and Opelika, Ala. No basis was found for a conclusion that the rates to Union Springs are unduly discriminatory, nor for a conclusion that the rates are unduly high in themselves. The Commission held that in a territory where the basing point system has been in operation since the advent of railroads, rates to a complaining point made by a combination of the through rate to the nearest trade center and the local rate beyond, need not, under the construction of the fourth section of the Act by the Supreme Court, be reduced to the basis of every neighboring point of like distance when the other points in the group whose rates are desired have the advantage of water or other competition. The complaint was dismissed.

Compression of Cotton in Transit.

The case of the Commercial and Industrial Association of Union Springs, Ala., v. Central of Georgia has been decided in an opinion by Commissioner Clements. This case involved alleged undue discrimination against Union Springs in the privilege of compression of cotton in transit. Complainant alleged that defendant refuses to apply the through rate from points of origin to points of ultimate destination on cotton shipped into Union Springs, there compressed and again shipped out, and that defendant being interested in compresses at other points favors such other points in hauling cotton there for compression. The Commission held that the testimony does not support the first alleged discrimination. The facts developed as a basis for the second alleged discrimination were conceded to be in a measure true, but whether compression of cotton in transit should be considered an incident of transportation, and therefore a matter wholly within the discretion and control of a carrier as to the instruments employed, neither the grower nor the consumer being directly interested, the Commission declined to decide without a general investigation covering the whole field of production and markets. Such a question cannot be determined on an insufficient inquiry at a single point. The complaint was dismissed.

MANUFACTURING AND BUSINESS.

J. W. Taylor, Jr., is associated with J. H. Burwell, Fisher building, Chicago, representing Edward H. Smith & Co., the Seeger-Gallasch Refrigerator Co., and the Automatic Ventilator Co.

The Vredenburg Company, 1332 Monadnock block, Chicago, was recently organized to take charge of the advertising of engineering, contracting and manufacturing companies. The manager, Clar-

ence Vredenburg, was editor and manager of *Engineering World* from its beginning until its recent sale.

The Atlantic Coast Line has installed in its shops at South Rocky Mount, N. C., a five-ton, three-motor, 72-ft. span electric Northern traveling crane made by the Northern Engineering Works, Detroit, Mich.

Iron and Steel.

The Lake Superior Corporation has taken a contract for 21,000 tons of rails for a Canadian road.

It is estimated that the mills have on their books orders for more than 2,000,000 tons of rails, over half of which is for 1908 delivery.

The New York, New Haven & Hartford and one or two other eastern roads are in the market for an aggregate of 2,000 tons of bridge material.

The American Bridge Company has orders for 15,000 tons of structural steel for the Portland & Seattle and for 350 tons for the Delaware & Hudson.

The McClintic-Marshall Construction Company has orders from the St. Louis & San Francisco for 3,000 tons of structural steel for new shops at Springwell, Mo., and from the Western Pacific for 2,000 tons of bridge material.

ELECTIONS AND APPOINTMENTS.

Executive, Financial and Legal Officers.

Corvallis & Eastern.—J. W. Newkirk has been elected Treasurer, with office at Portland, Ore., succeeding G. W. Talbot, resigned to go to another company.

New Orleans & North-eastern.—See New Orleans Terminal.

New Orleans Terminal.—D. D. Curran, President of the New Orleans & North-eastern, has been elected also President of the New Orleans Terminal.

St. Joseph & Grand Island.—See Virginian Railway.

Virginian Railway.—F. W. Russell, Secretary of the St. Joseph & Grand Island, has been elected Secretary of the Virginian Railway, with office at Norfolk, Va., effective August 15.

Wisconsin State Railroad Commission.—John Barnes, Chairman, has resigned.

Operating Officers.

Boston & Maine.—G. H. Folger, Superintendent of the Boston Terminal division, has been appointed to the new office of Assistant General Superintendent. G. L. R. French, Assistant Superintendent at Springfield, Mass., succeeds Mr. Folger. W. H. Ford, Assistant Superintendent at Lyndonville, Vt., succeeds Mr. French. George W. Cree succeeds Mr. Ford.

Chicago & Alton.—W. B. Causey, Engineer of Maintenance of Way at Bloomington, Ill., has been appointed Superintendent at that place, succeeding W. L. Derr, resigned to go to another company.

Mexican Central.—E. R. Walter has been appointed Acting Superintendent of the Chihuahua division during the leave of absence of W. T. Provence. S. J. Ross has been appointed Acting Superintendent of the Coahuila & Pacific and Saltillo divisions.

Mexican Southern.—W. L. Morkill, General Manager, has resigned, effective early next fall, to go to a company in Peru.

Union Pacific.—H. V. Hilliker has been appointed Trainmaster at North Platte, Neb., succeeding J. F. Clabaugh, resigned.

Traffic Officers.

Boston & Maine.—A. S. Crane, Export Freight Traffic Manager, has been appointed Assistant Freight Traffic Manager, with office at Boston. T. A. Dugan, Assistant General Freight Agent at Boston, has been appointed General Freight Agent, with office at Boston. George H. Eaton succeeds Mr. Dugan. F. S. Davis has been appointed Assistant General Freight Agent at Troy, N. Y.

Cleveland, Cincinnati, Chicago & St. Louis.—N. R. Johnson, General Agent at Cincinnati, has been appointed General Agent of this company and of the Peoria & Eastern at Peoria, Ill., succeeding to the duties of H. M. Griggs, division freight agent, transferred. C. O. Stimson, assistant division freight agent at La Fayette, Ind., has been appointed General Agent at that place. See New York Central Lines.

Grand Trunk.—C. E. Dewey division freight agent at Toronto, Ont., has been appointed Assistant General Freight Agent, with office at Montreal, Que.

New York Central Lines.—H. M. Griggs, division freight agent of the Cleveland, Cincinnati, Chicago & St. Louis at Peoria, Ill., has been appointed Assistant General Coal and Ore Agent of the New York Central Lines, with office at Cincinnati, Ohio.

Peoria & Eastern.—See Cleveland, Cincinnati, Chicago & St. Louis.

Engineering and Rolling Stock Officers.

Chicago & Alton.—See this company under Operating Officers.

Colorado Southern, New Orleans & Pacific.—H. M. Hensen, supervisor of bridges and buildings of the Denver, Kansas & Gulf, has been appointed Superintendent of Bridges and Buildings of the Colorado Southern, New Orleans & Pacific, with office at Beaumont, Tex.

Iowa Central.—W. D. Wheeler, Division Engineer at Minneapolis, Minn., has been appointed Chief Engineer of this company and of the Minneapolis & St. Louis, succeeding H. G. Kelley, resigned.

Minneapolis & St. Louis.—See Iowa Central.

Missouri Pacific.—A. C. Brower has been appointed Division Engineer at Wichita, Kan., succeeding E. C. Welch, transferred to the St. Louis, Iron Mountain & Southern.

Pennsylvania.—C. D. Gray has been appointed Assistant Master Mechanic at Ormsby, Pa.

Purchasing Agents.

Isthmian Canal Commission.—C. E. Dole is Acting General Purchasing Officer, with office at Washington, D. C.

LOCOMOTIVE BUILDING.

The Chicago & North-Western has ordered 10 ten-wheel locomotives from the Baldwin Works.

The Atchison, Topeka & Santa Fe has ordered 17 consolidation locomotives from the Baldwin Works.

The Wheeling Terminal Railway has ordered one locomotive from the American Locomotive Company.

The Butte, Anaconda & Pacific has ordered four locomotives from the American Locomotive Company.

The Philadelphia & Reading, it is said, is about to build 10 freight locomotives at its Reading, Pa., shops.

The Florida Phosphate Mine Corporation, Greenbay, Fla., is said to have ordered three locomotives from the Vulcan Iron Works.

The Sacramento Valley & Eastern, which is under construction, is in the market for locomotives. D. M. Riordan, 42 Broadway, New York, is President.

CAR BUILDING.

The Erie is reported to be figuring on new freight equipment.

The Louisville & Nashville is building at its own shops 3,000 freight cars.

The Louisiana & Arkansas has ordered one mail and baggage car from Barney & Smith.

The Canadian Pacific has ordered 500 box cars from the American Car & Foundry Company.

The Northwestern Elevated, Chicago, has ordered 40 cars from the American Car & Foundry Company.

The Illinois Tunnel Company, Chicago, is said to have ordered 500 cars from the Bettendorf Axle Company.

The Harriman Lines have ordered 250 50-ton tank cars of 12,500 gallons capacity, from the Cambria Steel Company.

The Georgia Southern & Florida has ordered one baggage and mail car and four express cars from Barney & Smith.

The Charlotte Harbor & Northern has ordered one passenger and baggage car and two coaches from Barney & Smith.

The Mobile, Jackson & Kansas City is in the market for 400 box cars of 40 tons capacity and 600 flat cars of 40 tons capacity.

The Northern Railway of Costa Rica has ordered 100 box and 100 flat cars from the Western Steel Car & Foundry Company.

The Delaware, Lackawanna & Western has ordered one baggage and mail car, one dining car and four coaches from Barney & Smith.

The Gulf & Ship Island has ordered three coaches, one baggage car, one mail and baggage car and one chair car from Barney & Smith.

The Sacramento Valley & Eastern, which is under construction,

is in the market for cars. H. M. Reardan, 42 Broadway, New York, is President.

The Mobile, Jackson & Kansas City has ordered thirty 36-ft. Hart convertible cars of 80,000 lbs. capacity from the Rodger Ballast Car Company.

The Higgins Oil & Fuel Company, Beaumont, Tex., has bought 25 tank cars of 80,000 lbs. capacity, or 10,500 gallons, from the German American Lines.

The Washington, Utah & Western, as reported in the *Railroad Gazette* of July 26, has ordered five 11-ft. flat cars of 70,000 lbs. capacity from the American Car & Foundry Company for October, 1907, delivery.

The New York Central Lines, as reported in the *Railroad Gazette* of May 31, recently ordered 11 baggage cars, seven mail and baggage cars and one passenger and baggage car from the American Car & Foundry Company.

The Chicago & Eastern Illinois, as reported in the *Railroad Gazette* of July 5, has ordered 2,000 steel underframe National dump cars of 100,000 lbs. capacity from the National Dump Car Company for January 1908, delivery. These cars will weigh 40,100 lbs. and will be 36 ft. 6 in. long, 9 ft. 8 in. wide and 4 ft. 6 in. high, inside measurements, and 10 ft. wide and 8 ft. 10½ in. high, over all measurements. The special equipment includes:

Brake beams	Simplex
Brake shoes	Streeter
Couplers	Janney
Draft rigging	Miner

The Isthmian Canal Commission is in the market for 500 all-steel double dump cars of 12 cubic yards capacity and 5-ft. gage, 100 cars for November 1, 1907, delivery at New York City, and 100 each month thereafter until all are delivered. These cars are to be 19 ft. long, 9 ft. wide and 1 ft. 10½ in. high, all inside measurements. The special equipment includes:

Axles	Open hearth steel
Air brakes	Westinghouse
Brake beams	Simplex
Brake shoes	Streeter
Couplers	Tower or Chicago
Draft rigging	Miner
Journal boxes	McCord
Trucks	Arch-bar
Wheels	33-in., 600-lb.

RAILROAD STRUCTURES.

Clinton, Iowa.—The Chicago & North-Western has let a contract for a double-track steel bridge to cross the Mississippi river. The bridge will cost $2,000,000 and is to be finished by February, 1910. It will be south of and adjoining the present single-track structure.

Clover Bar, Alb.—The May-Sharp Construction Company is building the piers for the Grand Trunk Pacific bridge across North Saskatchewan river.

Fort Worth, Tex.—The St. Louis Southwestern will build a new freight house at this place which, together with team tracks and storage yard, will cost $250,000.

New York, N. Y.—The Brooklyn Rapid Transit is to build a repair shop costing $300,000.

Ottawa, Ont.—The Grand Trunk has filed plans for a terminal station to cost $250,000 and a hotel north of the station to cost $1,000,000. Another hotel, on Nepean Point, may also be built.

Pittsburg, Pa.—The Pittsburg & Lake Erie, it is said, proposes to build a bridge over the Ohio river near this place to cost more than $1,000,000.

The Baltimore & Ohio, it is said, will build large storage warehouses and a cold storage plant at this place.

Vancouver, B. C.—The Vancouver, Westminster & Yukon will, according to press reports, soon begin work on the approaches to the proposed bridge over the Second Narrows. The plans for the bridge are said to have been approved by the Railroad Commission.

RAILROAD CONSTRUCTION.

New Incorporations, Surveys, Etc.

Alberta Wheat, Coal & Oil Railway.—This company proposes to build from Pincher Creek Station, Alb., on the Crows Nest Pass branch of the Canadian Pacific, to oil wells owned by the Rocky Mountain Development Company and the Western Oil & Coal Consolidated Company. The company also proposes to build a spur from Pincher Creek Station to Pincher Creek on condition that the town guarantees $10,000 of its bonds.

Atlanta, Birmingham & Atlantic.—This company has secured its right of way into Birmingham, together with land for yards in the city.

Atlantic [illegible].—[illegible] one 42-mile line from Portsmouth, N. H., to Dover, and another, Me., with a branch line to York Beach and recently completed a connecting link from York Beach north to Kennebunk, 11 miles. This connects with the company's 27-mile line from Kennebunk to Cape Porpoise. Kennebunkport, West Kennebunk, Sanford, Springvale, Biddeford and Saco. By the use of connecting lines a route is formed to Old Orchard and Portland. The new line, it is said, completes a route of [illegible] miles from Lewiston, Me., through Boston and New York to Wilmington and other points in a considerable district around Philadelphia, Pa., with the exception of the break at the ferry across the Hudson river.

California Roads.—The Spencer Construction Company, Contractor, and the Lamb Davis Company, it is said, will [illegible] a railroad in Chelan county, up the Chiwawa valley via Lake Wenatchee to the Red mountain district. The company is capitalized at $1,000,000, and it is said has $1,000,000 on hand to carry out the work.

Canadian Pacific.—It is said that the company intends to double-track its main line from Winnipeg, Man., west to Brandon, 133 miles. Work on the double-tracking of the main line between Winnipeg and Fort William, Ont., was, it was announced this spring, to be finished this year.

Clark-Rocheport Railroad.—Right of way has been secured for this line, which is to run southwest from Clark, Mo., to Rochepport, 24 miles. James D. Wade, St. Louis, Mo., is interested.

East Moline & Campbell's Island.—Incorporated in Illinois to build a belt line from East Moline, Ill., around Moline to Campbell's Island in the Mississippi river. The Directors are: Joseph F. Porter and James F. Lardner, of Davenport, Iowa; Burton F. Peek, Cyrus E. Dietz and O. E. Childs, of Moline, Ill.

Enid, Blackwell & Osage Interurban.—This company has been incorporated in Oklahoma with $1,000,000 capital stock, to build from Enid, Okla., to Pawhuska, 85 miles. Headquarters are at Enid. The incorporators are George W. Bear, Frank Bradfield, John R. Clover, S. I. Hudkins, A. W. McQuilkin, T. C. Cone and Guy S. Manatt, all of Enid.

Erie.—Preliminary surveys have been made for a low-grade cut-off on the Delaware division, which, it is said, will eliminate many curves and will shorten the present line 34 miles.

Franklin & Towamensing Street Railway.—This company, it is said, has secured all the right of way for its proposed line from Slatington, Pa., to Lehighton, nine miles, and work is to be begun at once.

Grand Trunk.—This company, it is said, plans extensive additions to its Brockville, Ont., yards.

Grand Trunk Pacific.—It is expected that, before winter, grading will be finished to Edmonton, Alb., 740 miles west of Winnipeg, and tracks laid to a point 456 miles from Winnipeg.

Gulf, Colorado & Santa Fe.—Work is under way on the rehabilitation of the old Gulf & Interstate, which runs from Beaumont, Tex., to Galveston and was recently taken over by the G., C & S. F.

See Corporation News.

Kansas City Southern.—Work was begun near Mena, July 1, on the 120-mile cut-off to secure easier grades from Siloam Springs, Ark., south along the Arkansas-Indian Territory boundary line to Cherokee Junction, Ind. T., thence to Fort Smith, Ark., and through Sebastian and Scott counties, joining the old main line near Mena. (March 15, p. 385.)

Las Vegas & Tonopah.—Preliminary surveys have been made for a line from Goldfield, Nev., to Tonopah, 16 miles. It is said that within two weeks grading will be finished on the extension from Rhyolite to Goldfield, 76 miles.

Long Island.—Work has been begun on the four-track cut-off between Glendale Junction and Woodside at the entrance to Sunnyside yard in Long Island City. (March 15, p. 386.)

Mexican Central.—The Atotonilco branch from Ocotlan, on the Guadalajara division, northeast to Atotonilco, 30 miles, was opened for traffic on July 1.

Mexican Roads.—The Guerrero Development Company has made surveys for a road from Acapulco, Guerrero, into the interior toward Mexico City, and is asking bids for building the first 150 miles. The company owns large tracts of mineral and timber lands in Guerrero.

It is said that Rafael Arodena intends to build a road from Santa Teresa, Coahuila, on the Mexican Central 65 miles to his cotton plantation.

Milwaukee Northern (Electric).—Grading has been finished on this line from Milwaukee, Wis., to Port Washington, and work

is about to begin on the rest of the line from Port Washington to Sheboygan. It is expected that the road will be ready for operation early in September.

National Lines of Mexico.—It is said the Mexican Government will begin at once the construction of a new line about 365 miles long from Durango, on the Mexican International, southwest to Mazatlan, on the Pacific coast.

Pacific & Eastern.—Surveys are reported made by this company for a line from a point in Siskiyou county, Cal., north to Crater Lake, in Klamath county, Ore., 100 miles. It is said that a length of 11 miles is already in operation and rights of way are being secured. The work is being done by the company's men. W. C. Morris, President, Portland, Ore.; G. W. Donnell, Chief Engineer, Medford, Ore.

Pennsylvania Lines West.—It is said that the gravity yard to be built near Bedford, Ohio, is to have a capacity for 2,300 freight cars, instead of 1,300 as originally intended.

Quebec & Lake St. John.—The Gosford branch, from Valcartier Station, Que., to Riviere aux Pius, six miles, was opened Aug. 1.

Spokane & Inland.—The Western division was to be opened for traffic south to Colfax, Wash., on August 1. It has been in operation to Rosalia, 30 miles north of Colfax, since March.

Texas & Pacific.—Track has been laid to Eunice on the line under construction from Bunkie, La., to Eunice, 35 miles. The road, which was the Louisiana East & West, is to be operated as part of the Avoyelles division of the Texas & Pacific.

Texas Roads.—E. W. Grove and others of St. Louis, Mo., are planning a road from Kingsville, Tex., on the St. Louis, Brownsville & Mexico, to San Antonio, 150 miles. It is said that San Antonio has been asked to give a bonus of $100,000 in money, and land for terminal facilities as a condition preliminary to building the line.

Toledo & Fort Wayne (Electric).—Incorporated in Ohio with $10,000,000 capital to build an electric line from Toledo, Ohio, southwest to Fort Wayne, Ind., about 75 miles. The incorporators include: E. J. Pinney, H. J. Nord, T. C. Willard, L. A. Goldstein and J. E. Lowry.

Western Pacific.—According to press despatches, this road will be opened for business from Salt Lake City, Utah, to Steptoe, Nev., 170 miles, early in September.

Wisconsin Central.—This company, it is said, has made surveys for a belt line around the northern part of Manitowoc, Wis., ending at Buffalo and Chicago streets, where a warehouse and a car ferry transfer bridge are to be built. It is understood that the necessary property was bought some years ago.

Yankton Southern.—This company has bought the franchise and right of way of the Houston, Sabine & Red River, on which some grading has been done. (See June 21, p. 917, and March 15, p. 385.)

RAILROAD CORPORATION NEWS.

Atchison, Topeka & Santa Fe.—J. P. Morgan & Co., New York, have bought the unsold balance of the $26,000,000 10-year convertible 5 per cent. bonds, of which about $9,000,000 were subscribed to by stockholders and about $2,000,000 disposed of to other interests. It is said that the bonds were sold to J. P. Morgan & Co. at about 98. The bankers are offering them for sale at 100¼.

Atlantic Shore Line (Electric).—This company opened for traffic on July 21 its connecting line between York Beach, Me., and Kennebunk, 16 miles. This line connects the Southern division, which was formerly the Portsmouth, Dover & York, with the Northern division, which was formerly the Atlantic Shore Line Railway, these companies having been consolidated last year under the name Atlantic Shore Line Railroad. Almost half of the connecting link is built on private right of way. The maximum grade is 4 per cent. and the numerous culverts and bridges are of concrete or steel. The opening of this link makes it possible to travel over electric railways from New York to Bath, Me., and beyond. The road carries a heavy summer passenger traffic and has three electric locomotives for hauling freight cars. It connects with the Boston & Maine at Springvale, Kennebunk, West Kennebunk and Wells. At Cape Porpoise, near Kennebunk, it has a pier and freight-house and has leased other wharfs from the town. It is planned to ultimately establish a steamship line from this port to Portsmouth and Boston. Electricity is generated by water power at Kennebunk and Sanford, and by steam plants at Kennebunk and Kittery Point. The company is controlled by A. H. Bickmore & Co., New York. It has $700,000 4 per cent. preferred stock, $2,000,000 common stock and an authorized issue of $3,000,000 4 per cent 20-year refunding bonds.

Baltimore & Ohio.—Earnings for June, 1907, and for the 12 months ended June 30 were as follows:

Month of June, 1907.			
Gross earnings	$7,196,085	Inc.,	$623,271
Operating expenses	4,747,839	"	526,525
Net earnings	$2,448,246	Inc.,	$96,746
Year Ending June 30, 1907.			
Gross earnings	$82,243,922	Inc.,	$4,851,866
Operating expenses	54,880,091	"	5,364,870
Net earnings	$27,363,831	Dec.,	$513,004

Buffalo & Susquehanna.—Fisk & Robinson, New York, have sold $900,000 5 per cent. equipment trust notes, dated August 11 and maturing in 20 equal semi-annual instalments. They are part of an issue of $1,200,000 and are secured on 20 locomotives, 800 steel coal and coke cars and 200 steel underframe box cars.

Buffalo, Rochester & Pittsburg.—A semi-annual dividend of 2½ per cent. on the $10,500,000 common stock has been declared payable August 15, a reduction of one-half of 1 per cent. as compared with the last semi-annual dividend. The stockholders, however, will receive as large a return on their holdings as formerly, because a dividend of 2 per cent. has been declared on the stock of the Mahoning Investment Company, which stock was distributed last December to holders of Buffalo, Rochester & Pittsburg stock to the extent of 25 per cent. of their holdings. The Mahoning Investment Company took over the coal properties of the railroad.

Central of Georgia.—See Wrightsville & Tennille.

Chicago Electric Traction.—This company has been sold under foreclosure for $330,000. The company operates 31 miles of line from Chicago to Harvey, Ill. It has been in the hands of a receiver since 1900, no interest having ever been paid on the $650,000 first mortgage 5 per cent. bonds of 1929. The road is ultimately to be merged with the Chicago & Southern Traction, which runs from Harvey to Kankakee, 40 miles.

Dublin & Southwestern.—See Wrightsville & Tennille.

Gulf, Colorado & Santa Fe.—This company has arranged for trackage rights over the St. Louis, Watkins & Gulf from Oakdale, La., to Alexandria, 38 miles, and over the Texas & Pacific from Alexandria to New Orleans, 194 miles. The Gulf, Colorado & Santa Fe is building an extension from Cravens, La., to Oakdale, 25 miles. It intends ultimately to build to New Orleans.

Houston & Brazos Valley.—It is said that this road, formerly the Velasco, Brazos & Northern, which runs from Anchor, Tex., to Velasco, 20 miles, and connects with the St. Louis, Brownsville & Mexico at Angleton, Tex., has been sold to Yoakum interests.

Interurban Railway & Terminal.—This company, which owns 83 miles of broad gage interurban road from Cincinnati, Ohio, to New Richmond, Lebanon and Bethel, is to issue $1,000,000 preferred stock, part of which will be exchanged for $900,000 of the outstanding $2,500,000 common stock, while the remainder will be used to pay off old obligations.

Mahoning Investment Company.—See Buffalo, Rochester & Pittsburg.

Pittsburg, McKeesport & Greensburg.—See West Penn Railways.

St. Louis, Brownsville & Mexico.—See Houston & Brazos Valley.

Southern.—Earnings for June, 1907, and for the 12 months ended June 30 were as follows:

Month of June, 1907.			
Gross earnings	$4,609,305	Inc.,	$315,735
Operating expenses and taxes	3,432,709	"	207,012
Net earnings	$1,176,596	Inc.,	$108,723
Year Ending June 30, 1907.			
Gross earnings	$56,657,994	Inc.,	$3,016,556
Operating expenses and taxes	44,699,282	"	4,926,143
Net earnings	$11,958,712	Dec.,	$1,909,587

Toledo, Ann Arbor & Detroit (Electric).—The property of this company, which has been in the hands of a receiver since August, 1906, is to be sold under foreclosure between September 3 and 17. It is partially built between Toledo, Ohio, and Ann Arbor, Mich.

West Penn Railways (Electric).—This company has bought a controlling interest in the Pittsburg, McKeesport & Greensburg, which runs from Trafford City, Pa., on the Pittsburg Railways, to Youngwood and Hunker, 29 miles, and has outstanding $1,030,000 stock and $1,350,000 first mortgage, 5 per cent. bonds of 1931.

Wrightsville & Tennille.—The stockholders of this company and of the Dublin & Southwestern met on August 1 to authorize the consolidation of the two roads, to increase the capital stock of the Wrightsville & Tennille from $300,000 to $600,000, and to authorize an issue of $300,000 bonds. The Wrightsville & Tennille runs from Tennille, Ga., to Hawkinsville, and it owns the entire $200,000 stock of the Dublin & Southwestern, which runs from Dublin, Ga., to Eastman, 31 miles. The Wrightsville & Tennille is controlled by the Central of Georgia.

RAILROAD GAZETTE

ESTABLISHED IN APRIL, 1856.

PUBLISHED EVERY FRIDAY BY THE RAILROAD GAZETTE AT 83 FULTON ST., NEW YORK.
BRANCH OFFICES AT 870 OLD COLONY BUILDING, CHICAGO, AND QUEEN ANNE'S CHAMBERS, WESTMINSTER, LONDON.

EDITORIAL ANNOUNCEMENTS.

THE BRITISH AND EASTERN CONTINENTS edition of the Railroad Gazette is published each Friday at Queen Anne's Chambers, Westminster, London. It contains selected reading pages from the Railroad Gazette, together with additional British and foreign matter, and is issued under the name Railway Gazette.

CONTRIBUTIONS.—Subscribers and others will materially assist in making our news accurate and complete if they will send early information of events which take place under their observation. Discussions of subjects pertaining to all departments of railroad business by men practically acquainted with them are especially desired.

ADVERTISEMENTS.—We wish it distinctly understood that we will entertain no proposition to publish anything in this journal for pay, EXCEPT IN THE ADVERTISING COLUMNS. We give in our editorial columns OUR OWN opinions, and these only, and in our news columns present only such matter as we consider interesting and important to our readers. Those who wish to recommend their inventions, machinery, supplies, financial schemes, etc., to our readers, can do so fully in our advertising columns, but it is useless to ask us to recommend them editorially, either for money or in consideration of advertising patronage.

OFFICERS.—In accordance with the law of the state of New York, the following announcement is made of the office of publication, at 83 Fulton St., New York, N. Y., and the names of the officers and editors of The Railroad Gazette:

OFFICERS:

W. H. BOARDMAN, *Pres. and Editor*	RAY MORRIS, *Secretary*
E. A. SIMMONS, *Vice-President*	H. S. CRITTENDEN, *Treas.*
	I. B. RINES, *Cashier*
	L. B. SHERMAN, *Western Manager*

EDITORS:

RAY MORRIS, *Man'g Editor*	GEORGE L. FOWLER
BRAMAN B. ADAMS	FRANK W. KRAEGER
CHARLES H. FAY	HUGH RANKIN
RODNEY HITT	BRADFORD BOARDMAN

CONTENTS

VOL. XLIII., No. 6. FRIDAY, AUGUST 9, 1907.

A suggestion for profitable use by the mills of the larger crop-ends of ingots from which rails are rolled in accordance with the proposed modified specifications comes from Robert W. Hunt, a good authority on rails. The reason for cutting off only 10 to 12 per cent. of the top of the ingot, instead of twice as much, is because this added discard means waste and reduced output. Perhaps these crop-ends can be converted into a profitable by-product. Captain Hunt's idea is to make angle-bars of them. Most of the angle-bars used at present are the same composition as ordinary soft wire rods, being made by the mills from the same ingots and rolled at the same time that the billets for the rods are produced. They are punched and sheared cold. Angle-bars made from rail ingot crop-ends would have nearly the same constituents as the rail steel; and at first thought high-carbon steel for angle-bars seems objectionable. But their use would not be a new departure, for the Canadian Pacific's angle-bar specifications are substantially those of its rail steel, with a carbon content of from 0.50 to 0.65. The Canadian Northern is also using high-carbon bars. The late A. Torrey was perhaps the first to recognize the economy of high-carbon steel in angle-bars and used them on the Michigan Central, of which he was Chief Engineer. He noted the rapid wear of soft bars, due to the motion of the rails, and the fact that they would take a permanent set and thus hold down the rail joint. He found that sometimes when the soft angle-bars were removed from a low joint the rails would spring back to a level surface. The high-carbon bars, especially those made from crop-ends, will break more readily than the others, of course, but a broken angle-bar is not a serious matter and with ordinary watchfulness no harm should result.

Still another suggestion for a profitable use of nearly all of the proposed 25 per cent. discard from the ingot comes from the chief engineer of one of the most important railroads of this country. It is that the ingot be not cropped but all of it made into the bloom and rolled to a finished rail section. Then cut from the rail 8 ft. lengths until strictly homogeneous steel, without piping, is reached. These 8 ft. lengths can be rolled into almost any imaginable section and shape for steel ties by the York cross-rolling process. It is believed that the amount of work put into the metal tie by this cross-rolling process will be quite enough to make a sufficiently strong tie, and especially for the reason that the larger rail sections rolled into steel ties have great excess strength, so that there would be a large coefficient of safety even if defective metal were used. There is one difficulty about this: No shape of steel tie has yet been devised to entirely fill the office of the wooden tie. It is necessary to secure a resiliency which will somewhat correspond to that afforded by the material of the wooden tie, the slight lateral movement of the spike in the wood and the slight canting of the rail due to the fact that it is not held with absolute rigidity to the tie. The steel tie must be made of such a form as to prevent its lateral movement in the ballast. It must also be capable of insulation, for apparently the electric track circuit for signaling purposes has come to stay. The steel tie also needs protection from rust. We have, therefore, clean cut problems for the designing engineer. If he can devise a form of steel tie that will satisfy the requirements, the cross-rolling process, either applied to old rail or to piped rail, is apparently cheap and effective.

The Pennsylvania is having a hard time satisfying the many demands of the city authorities in completing the plans for its terminal improvements in New York and Brooklyn. Last week, after long and apparently unnecessary delay, the Board of Estimate finally granted the franchise for building the Glendale cut-off, the last connecting link between the Manhattan crosstown tunnels and the New York Connecting belt line around Brooklyn, but on the same day the Municipal Art Commission rejected the plans for the Hell Gate bridge. The Commission was not satisfied with the attempted ornamentation of the massive towers flanking the great steel arch, and the architects will have to try again, which means more delay in starting the work. Since the time when Mr. Cassatt first announced the company's plans for an entrance in New York and an enlargement of the terminal facilities in Brooklyn and Long Island City the Pennsylvania has been met on every side with obstructive tactics. The Board of Aldermen held up the required franchises because the railroad refused to pay up the graft demanded. With the assistance of other powerful interests which were being obstructed in the same way, the company succeeded in having the Legislature transfer the right to grant franchises from the Aldermen to the Board of Estimate. Some of the required franchises

were quickly obtained from that body, but the New York Connecting plan was held up for nearly two years before the railroad gave in to the exorbitant demand for a payment to the city, aggregating $1,210,000, simply for the right to cross a few streets overhead in the outlying districts. The Sunnyside yard plans were similarly obstructed and the company was assessed a large sum for the privilege of closing some projected streets through land which is now a swamp. The Municipal Art Commission, however, cannot be accused of using obstructive tactics in rejecting the bridge plans. It is a disinterested body appointed for the purpose of rendering just such a verdict, if deserved, and its objections are aimed only at the artistic features of the design, not the engineering features. Nevertheless, it must be discouraging to the Pennsylvania to see every step of its work, which is really more of a public than a private enterprise, thus hampered and delayed.

THE COSTLY MISTAKE OF STATE RAILROADS

The advocates of governmental railroad ownership and control have recently been presented with a considerable amount of evidence damaging to their cause. Witnesses before the Viceregal Commission on Irish Railways have been forced to admit, in spite of their preliminary panegyrics, that on the state railroads with which they have been connected, the average level of rates and fares is higher, and the facilities given to the public lower, both in regard to freight and passenger traffic, than in Great Britain. This condition of affairs exists notwithstanding the often asseverated contention on the part of the administrations that the railroads in question are operated, in the first instance, for the benefit of the community, the earning of profits being relegated to the background, and regarded as merely incidental.

Now that is a widespread idea with regard to the administration of state-owned railroads, and is especially entertained by people who are, fortunately for themselves, without practical experience as to what the operation of a railroad system by the state really means. Perhaps one reason for the existence in England of a body pledged to the nationalization of the railroads is just the absence of real knowledge in the matter. In many respects, belief in the natural superiority of state-owned and operated railroads appears to be a matter of faith rather than of experience or reason, since the more one compares the operation of typical state and company-owned railroads, the more the disadvantages of governmental interference emerge. In this respect, E. A. Pratt, in his "State Railways," has performed a signal service in giving in striking form some facts about the price paid by a country for the theoretical benefit to be obtained by entrusting its railroads to the tender care of a government, instead of allowing the healthy competition inseparable from private enterprise.

The greater part of this book is taken up with a translation of some excellent recent articles on the Belgian state railroad administration. Belgium is a country that at first sight would appear particularly suited for the development of a highly successful railroad system. It is small, compact and densely populated, manufactures and agriculture are alike highly flourishing, the distribution of the population is fairly even, and from the engineering standpoint the flatness of the country offers no great difficulties to the laying out of railroads, thus enabling them to be both cheaply built and worked. The upholders of the state railroad superstition have consequently always pointed to Belgium as a country in which government control was working admirably, and it has been regarded by these individuals, including many Englishmen, as a sort of railroad paradise. As a matter of fact, the system, without exception, is defective in every detail in which a state railroad theoretically excels.

The average standard of pay, both of the uniformed staff and of the higher officers, is very low, not only as compared with English standards, but in comparison with the rest of the Continent. In spite of this, an excessive amount is spent on wages and salaries, owing to the great overstaffing that takes place in every department, which, however, does not prevent the hours being enough to make the hair of the Board of Trade stand on end. The state railroads employ approximately half as many men again per mile as the private Belgian companies. This overstaffing has invariably been one of the evils of government departments, and an interesting sidelight on the matter is provided by the statement that the red-tape regulations of the Belgian service provide for the employment of the same number of men at stations of the same class, regardless of the respective traffic handled by them.

Apart from the question of wages and hours, the Belgian state, at any rate where its railroads are concerned, is a bad employer of labor. In the matter of pensions, and traveling facilities, such as privilege tickets, it is niggardly in the extreme. The administration has even gone to the length of repudiating obligations into which it has entered when taking over the private companies, whose employees had already been contributing to superannuation and pension funds, and who apparently lost their contributions when the state acquired the undertakings by which they had formerly been employed. Should an employee bring a claim against the administration for personal injuries, it will be resisted as much as possible, and in the event of the courts deciding in favor of the employee, a loophole by which the responsibility may be evaded is always sought. These conditions are the more striking when it is borne in mind that the Socialist party is numerically very strong in the Belgian parliament, and is continually ventilating the grievances of the staff.

After this description of the treatment of its men, no one will be surprised to learn of the cavalier attitude adopted by the administration towards the general public. The passenger fares may be low, but they have to be considered in the light of the low speed of the trains, the infrequency of the service, the inadequate accommodation given at many of the stations, and the general drawbacks to "passenger comfort." No new train is ever put on except under strong pressure, and until the Minister of Railroads has satisfied himself that it will be run at a profit. This latter condition is, of course, perfectly reasonable in itself, but it must often be incompatible with the theory that on a state railroad the convenience of the public is the first consideration, and the question of profit a secondary matter.

The freight service appears to be even worse than the passenger. The conveyance of merchandise is slow and uncertain, and the shortage of locomotives and wagons so chronic that it does not excite special remark, except at times of particularly heavy traffic, when traders and the country in general are put to worse inconvenience than usual. On occasion, the administration has even been obliged to resort to the desperate expedient of refusing to receive any fresh consignment whatsoever for a period of three days, until the existing congestion had been somewhat reduced. In this particular instance it is clear that the congestion was less due to abnormal and unexpected traffic than to general disorganization and failure to make provision for the acquisition of sufficient rolling stock. A general complaint is that the red-tape regulations of the service have produced a cast-iron system under which any concession that would lead to the encouragement of a particular industry or district is practically ignored.

Glib writers on the alleged defects of private railroads have held up the low Belgian freight rates as an admirable example. Now the truth about Belgian rates is that they are only low in the case of through joint rates with foreign countries, and for journeys, such as between England and the Continent, where a certain small proportion of the total transit is made across the Belgian lines. Here low rates are compulsory on account of the competition of other Continental railroads, German, French and Dutch, and of water transport. Local rates in Belgium itself, that is the rates vitally affecting the domestic commerce of the country, are high when judged by any standard. The coal rates for distances of 9¼ to 16¼ miles are, for example, 6.2 to 10.4 cents higher on the Belgian state railroads than on the Eastern of France. This fable of the low freight rates charged in Belgium deserves to be universally recognized as only a fable.

It might perhaps be imagined that the financial results of state operation are favorable, especially as every effort is made to earn as large a profit as possible. The actual financial position of the system, like that of practically every other Continental state railroad, it is impossible to know, but it has been proved within recent years that the net earnings are appreciably less than had been assumed. Accounts, in the real sense of the word, are non-existent, although their place is taken by voluminous statistics, containing pages of perfectly unnecessary details. The railroad accounts are distributed under five separate and distinct budgets, considerable sums being charged to general public expenditure. It may be doubted whether anyone, even the Minister of Railroads, knows exactly how much the railroads cost to work, or their value as a going concern. One definite fact has been brought out by a report which has recently been drawn up by M. Hubert, Deputy of the Right, at the request of the Belgian Chamber. This clearly shows one very disquieting feature, the constant rise in the ratio of expenditure, which appears to be gradually swallowing up the profits of the system, in spite of the way in which the roads are starved by lack of adequate rolling stock and station accommodations and

notwithstanding the high rates charged. The report shows that in 1905 while the traffic receipts increased by 15,170,000 francs ($3,034,000) the rise in expenditures amounted to 15,570,000 francs ($3,114,000). M. Hubert goes on to sound a warning with regard to the future by saying that in the event of a general trade depression, which would result in reduced traffic, the cost of operating the system could not be reduced and the result would be a heavy loss from operation. According to this report, the chief causes for the increased expenditure are the lack of unity in the management of the lines and the crushing out of all spirit of initiative among the staff by the uniformity of salaries, defects which characterize most forms of state enterprise.

Possibly the worst feature of the entire administration is the interference of politics with an undertaking that should be conducted on a purely commercial basis. A very large part of the time of the Belgian parliament is taken up by members' complaints or suggestions with regard to the railroad service; the railroad budget is discussed for weeks, and every trifling question affecting the railroads is unnecessarily ventilated in parliament. The loss of time involved by this proceeding is obvious, and in spite of the great attention given by the parliament to railroad matters, it appears to be only on very rare occasions that any tangible results are obtained. Favoritism, largely due to political considerations, is rampant in the service, and the employees are practically forbidden to join political or labor unions, although the constitution expressly gives them the right to do so, unless the organization is one in harmony with the views of the government for the time being, in which case the men's political activity is winked at.

The above brief analysis of some of the most outstanding defects of the Belgian state railroad administration could be carried to much greater length, without presenting a complete indictment of the system. What must be appreciated is, not that the administration of the Belgian railroads is too expensive, that the facilities given to the public are insufficient, that the status of the employees is worse than those working for private corporations, that political considerations tend to have greater weight than the social and industrial welfare of the country, and that the accounts are so juggled with as to be absolutely unreliable, but that all these defects are the logical outcome of state interference with an essentially commercial undertaking.

Per se, no commercial enterprise has ever failed to suffer on the state assuming control. The use of a government department for purposes of party politics, the cast-iron system evolved from red tape and the lack of initiative inseparable from the average government official, the political influence that can be exerted by its employees and by labor leaders agitating for their own benefit, the disregard of the public caused by assuming that the public exists for the benefit of the department instead of being its master, the ease with which accounts can be cooked and responsibility evaded for financial or administrative blunders, and the lack of healthy competition, can all be expected to characterize a system of railroads owned and controlled by the state. On the Belgian state railroads, so long upheld as a model, these conditions have been proved to underlie every branch of the administration. It is consequently a service of some value to make public the truth regarding this system of state railroads, which may be regarded as typical.

THE SETTLEMENT OF FREIGHT CLAIMS.

W. B. Biddle, Vice-President of the Chicago, Rock Island & Pacific, in a circular to the patrons of his road, warning them that nothing is gained by employing agents to collect claims against the road, says that he and his fellow officers are making an earnest effort to improve their treatment of both local and interline claims; that many subordinate traffic officers have authority to settle some classes of claims on presentation, and that the company intends to give as careful attention to claims against it as to cases where the company has claims against other people. He admits that the railroads have not done justice to the matter of settling claims, but the managing officers of the Rock Island are now taking a personal interest in the work and hope to establish a reputation for promptness and fair dealing. Colonel H. G. Prout, Vice-President of the Union Switch & Signal Co., in an address which was printed in the *Railroad Gazette* July 19, told the traffic men some plain truths, which indicate that on some railroads the conditions are bad. To Colonel Prout the claim department seems to be a highly efficient organization for obstruction. He evidently finds little disposition by claim agents to learn the truth by judicial process, or to take a kindly attitude toward claimants. He protests against being considered a swindler until at least given an opportunity to prove himself to be an honest man.

The settlement of freight claims on a large railroad is a heavy task at best, and the tendency of the freight claim office will always be [illegible]. A claim requiring three weeks to investigate [illegible] to the claimant [illegible] that he is surprised at the delay. The [illegible] agent who merely tells the consignee that the other road is to blame for the delay [illegible] that he ought to apologize [illegible] the other road as carefully as for his own, would [illegible] satisfaction if he were polite and explanatory and [illegible] the necessary time to settle interline claims. The question which will interest railroad officers is how fully can Mr. Biddle and [illegible] disposed railroad managers carry out their purpose to cure the causes of Colonel Prout's complaint?

The interesting paper by the Freight Claim Agent of the New York Central, which is reprinted in this issue, does not throw much light on the actual work of settling claims. Mr. Calkins tells of some of the things that cause damage and the original claims, and he reminds us that the competent claim agent will be able to make friends of claimants even if they do have to wait a long time for their money, but the means of expediting the machinery he hints at: (1) Thorough system, devoid of cumbersomeness; (2) prompt investigation; (3) uniformly business-like treatment of claimants; (4) avoidance of disputes about small claims where no important principle is involved. These hints, however, suggest a number of pertinent questions.

To take the last point first, there is little doubt that a railroad could make friends whose friendship would be valued in dollars, by paying many small claims, presented by reputable people, without standing on its full rights—just as the great fire insurance companies do. This is the frequent method of settling for injuries to passengers. Of course, if such policy were followed in the freight department the fact that rights were being waived with the reason should be distinctly stated and even advertised. It is to be remembered that when the owner of damaged or delayed freight receives his full legal claim he still suffers in many cases a further loss for which the law will not allow him to recover.

Uniformly business-like treatment of claimants implies a competent agent or clerk at every station, and this is only partially attainable. In this connection we recall the highly commendable suggestion of one claim agent that every large station should have a claim clerk who has been trained in the general claim department; who perhaps should report direct to the general claim agent. Such a clerk could handle the claims presented at other stations within say 50 miles and thus save some time and possibly much friction.

Steady uninterrupted progress, almost daily progress, toward settlement is the desideratum. It requires time, but time need not be wasted in careless reading of letters or delay in answering them. A wideawake claim agent needs not much instruction or exhortation concerning the design or construction of his office machinery; but evidently a great many claim agents need to learn how to make their machinery move continuously. Do you answer all possible letters on the day of receipt? Do you know that this is easier, takes less of your time, than to allow letters to accumulate?

Much of the delay complained of is due to the dulness or inattention of men who do not carefully read letters received, or intelligently compose letters sent. They answer questions not asked and ignore the intent of inquiries. This causes additional letter writing and more days of delay in settlement. Premiums for excellence in letter writing, properly advertised among the clerks, might produce an improvement. Besides accuracy and promptness, clerks may cultivate courtesy. "Politeness is a requirement," said General Devereaux in an address to trainmen when he was President of the Big Four. It is especially useful in dealing with customers whose claims must be rejected. Mr. Calkins speaks of inducing claimants to see the railroad's side of a case, even when they are feeling disgruntled. Extreme courtesy by the company's representative is the only means to this end.

Revised Signaling Rules of the Belgian State Railroads.

The Bulletin of the International Railway Congress for July contains an article on the Convertible Semaphore Signal which is the standard of the Belgian State Railroads, and the description is prefaced by an extract from the new general signal rules of the State railroads, which are now in press. The article is by L. Weis-

senbruch, editor of the *Bulletin*, who also is Chief Engineer of Signaling and Safety Appliances of the State railroads.

The standard semaphore is a box girder made up of four angles and stiffened with horizontal lattice members. The fittings are so designed as to make all parts interchangeable for use with one or more arms, and with arms on either side of the post. For the support of the lamp or lamps a wire rope is provided, controlled by a windlass near the bottom of the post. The foundation is of cast-iron set in concrete. Provision is made for the use of indicators to show by a letter or number the track for which a signal arm is cleared. The use of indicators seems to be regular standard practice. They are to be used for speed up to 25 miles an hour. The spectacles for the night color indicators are separate from the arm, and are controlled by stops on the arms. These stops are so arranged that the light shows "proceed" a little after the movement of the arm, while it returns to "stop" a little in advance of the arm.

The new signal regulations, which, it would appear, have to do chiefly with future installations, seem to be in some respects tentative. Signal arms are always on the left of the post and signals usually at the left of the track. At a station a home signal arm with a notched end, like our distant signal, indicates a full speed or main line route, while the ordinary square end (full size) is used for movements to diverging tracks. In all new work bracket signals—called there "candle stick" signals—are to be used for diverging routes, a separate post for each route. For distant signals the arm has a pointed end, like that which has been adopted on the New York Central and some other American roads for automatic stop signals. Where two or more arms are on one post the upper arm applies to the high speed route in every case. No dwarf posts are shown, but short arms are used for low-speed movements in the normal direction, while for "back up" movements the shape of the arm is that of two triangles joined at the vertices. The upward inclination is prescribed for new semaphores, but the old signals, having downward inclination, have not been changed as "experience has shown that this difference causes no trouble whatever to the enginemen."

Green has been adopted for the night "all clear" indication and the process of taking out the white lights, heretofore used, is now going on. Back lights will, in future, be made visible only when the arm is in the stop position, and they will be either a small white light or a violet light. Block signals are to be fitted with an arrangement for automatically placing a torpedo on the rail when the arm is horizontal, but it does not appear from the present description to what extent automatic torpedoes are or will be used. At stations, as before stated, a notched arm indicates a high-speed route and a square end arm a lower speed; this difference is indicated at night by showing a double green light for the notched arm (in the proceed position).

In distant signals at night, the signal when "on" will show a red light side by side with a green light, or it will show a yellowish orange light. Where the red-and-green is used the clearing of the arm will make two green lights visible; while with the orange light a single green light is used for "all clear." With this last arrangement (an orange light and a single green light) there will be provided a fixed audible warning 227 ft. in the rear; or a repeating light will be thus fixed, to be lit only in time of fog. This light will show orange and green the same as the regular distant signal. This arrangement appears to be subject to confirmation after further experiments shall have been made.

The standard rules have a provision for putting up white posts along the side of the track a short distance apart approaching a caution signal, this to seasonably attract the attention of the enginemen.

As a rule the number of arms on any one post must be limited to three. The State proposes to rearrange all junctions so that trains will not have to slacken speed, this done, the notched arm and the double green light can be done away with. At interlocklings where necessary or desirable a semaphore is fixed at the outgoing end of the section of track for which the interlocking signals give indications. This seems to be designed chiefly or wholly as a limit mark and not an independent starting signal.

As Belgian signal engineers are careful students of English, German and American practice this new code, of which we have given the salient features, may be taken as an instructive exhibit of what unprejudiced observers have found worth copying from the devices and practices of the different countries. We are unable to make out just how far the several innovations have been decided upon for permanent use, but even as tentative propositions they will be found of interest by American railroad officers. The free use of bracket signals is an English idea that most Americans will not accept, but some of the other changes have features well worthy of consideration. The use of both upward and downward inclinations on the same railroad should reassure some nervous Americans. The distant signal improvements evidently have been taken mostly from American practice; while in the use of double green lights, warning signals in the rear of distants, and white fence posts, Americans may well learn from Europe.

The order for distributing coal cars in Ohio recently issued by the Interstate Commerce Commission, and reported in our news columns to-day, looks like a fine example of Dutch justice; and readers will be interested to see the full report on the case and learn how Commissioner Clark makes this kind of justice match with that kind which is supposed to underlie the law that a railroad must furnish all the cars necessary to do the business offered by shippers along its lines and must treat all shippers alike. Quite likely, when cars are scarce, Mine *A*, receiving 25 Pennsylvania cars to load with coal for the Pennsylvania's locomotives, can get along without any Hocking Valley cars and suffer less than will Mine *B* even when 10 or 15 H. V. cars are delivered to it. Moreover, as the coal road—the Hocking Valley, for example—pays for its use of the private or specially assigned cars there is a semblance of fairness in compelling it to treat such cars for the purpose of distribution, as though they were its own. But the other view is equally plausible. Suppose Mine *A* concludes to double its capacity, and to use the increased capacity, not for Pennsylvania Company's coal, but for the general market. Should not the railroad company provide cars for this market coal the same as it furnishes them for market coal from any other mine? Does a coal operator who buys cars in which to ship his coal thereby relinquish his right to being served by all common carriers on an equality with every other shipper?

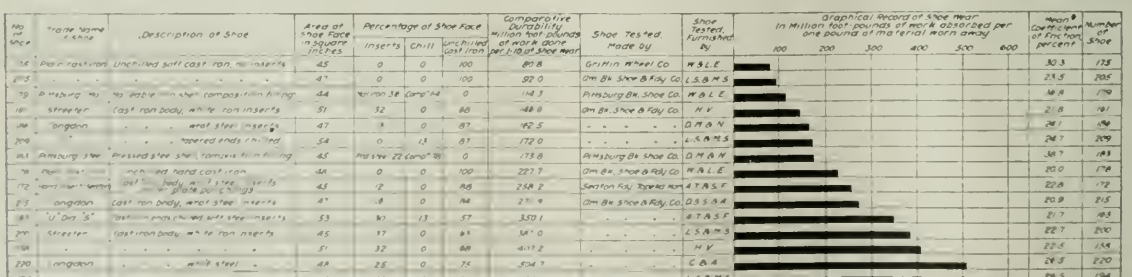
M. C. B. Tests of Brake Shoes.

Mahwah, N. J., July 30, 1907.

To the Editor of the Railroad Gazette:

The table and diagrams presented in the report of the standing committee on brake shoe tests of the M. C. B. Association at the last convention while clear to many of those who have followed closely the work and reports of the committee, do not, in the opinion of the writer, give sufficient information to enable comparisons to be made between the various shoes tested.

The table which I submit herewith is part of my discussion on the subject, and is intended to supply some information in detail to supplement the committee's report. I realize that the committee's report is in the nature of a preliminary one intended to show what the brake-shoe testing machine can do in regard to defining the relative durability and wearing qualities of brake-shoes. It is important in the study of the question to take into account not only the surface of insert and hard metal on the face of the shoe, but also the volume of each, realizing that the durability of the brake-shoe depends largely on the percentage of hard and tough material [illegible]



Comparative Composition and Durability of Brake Shoes.

the insert rather than on the surrounding body metal, which may be soft cast-iron acting as a holder for the inserts, and that 90 per cent. of the life of the shoe may be comprised within the period necessary to wear out the insert.

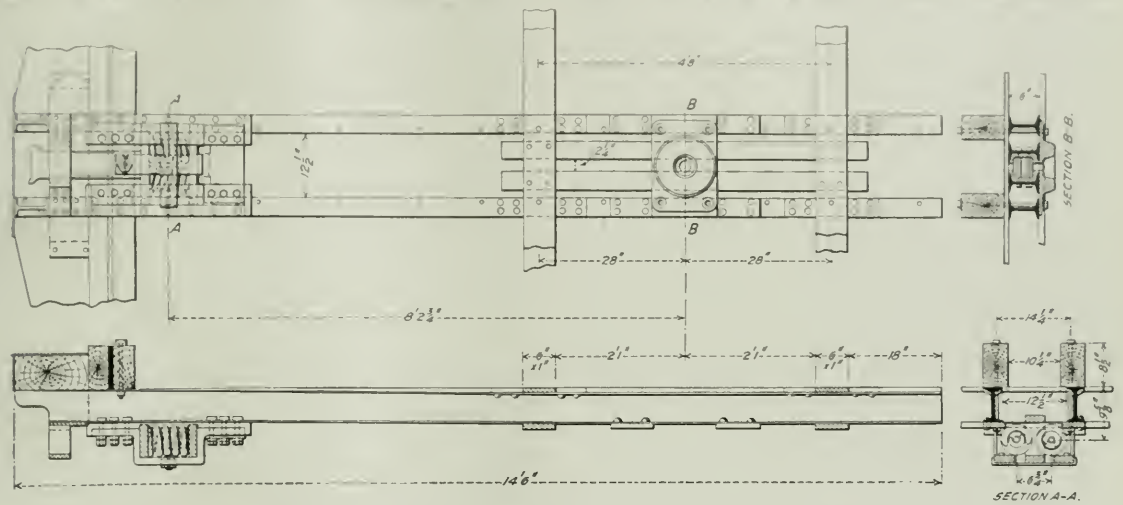
In the case of the records in question, some of the tests were made on shoes in which inserts had been worn through or had fallen out, and of course such records are not true indications of the performance of the original shoe, for that reason this new table has been prepared, which takes into consideration the actual conditions on the face of the shoe during the test. With this clearly understood, the column of comparative durability can be fairly considered.

Will you kindly publish this explanation and table for the information of those interested?

F. W. SARGENT,
Chief Engineer, American Blake Shoe & Foundry Co.

Draft Rigging for Stub-End Passenger Equipment.

The Seaboard Air Line is using a composite arrangement of steel beams for draft rigging on stub-end passenger equipment that is working well. The drawbar attachments themselves are of the twin-spring type and are riveted to and below the draft sills. The draft sills are directly below the wooden center sills of the car and are made of 6-in. I beams weighing 17¼ lbs. per foot. These beams run back 4 ft. 1 in. beyond the center plate and 1 ft. 9 in. beyond the center of the inner body bolster. There are two body bolsters of the plate type which are set 4 ft. 8 in. apart and equally spaced on each side of the center plate. The draft sills pass between the plates of the bolsters. In addition to the draft sills there are two 6-in. I beams set between them, as shown at the section on B B in the drawing, which are also riveted to the bolsters and which with the draft sills serve as a bearing for the center plate and so carry the car body. With this arrangement the end of the car framing is relieved of the buffing stresses which are carried back and distributed.



Draft Gear for Stub End Passenger Equipment; Seaboard Air Line.

Holding Power of Railroad Spikes.

BY ROY I. WEBBER, C. E.*

The determination of a proper fastening between the rail and the tie has become a matter of considerable importance. As long as the supply of suitable hard wood timber was sufficient, the ordinary spike satisfactorily fulfilled the requirements; but with increase in the amount of traffic handled and the heavier weights of cars and locomotives, and also with the use of soft deciduous and coniferous woods for ties, the common spike has proved deficient. Variations in the form of the ordinary spike have been developed, and new forms of spikes have been devised in an attempt to overcome the loss of efficiency attendant upon the use of inferior timbers. In view of these conditions, and the meager supply of published data on the holding power of spikes in ties, the writer has carried out a series of experiments to determine the resistance to withdrawal offered by the same type of spike in different timbers and by different forms of spikes in the same timber, and also to determine whether or not the preservative has any influence upon this resistance.

*Instructor in Civil Engineering at the University of Illinois. Published in Bulletin No. 6 of the University of Illinois Engineering Experiment Station.

The writer wishes to express his thanks for the hearty co-operation received from the various persons, firms and corporations mentioned in the text. He wishes also to express his indebtedness for personal aid, to Robert Trimble, Chief Engineer Maintenance of Way, Pennsylvania Lines West (Northwest System), George E. Boyd, Roadmaster of the Illinois Central; A. L. Kuehn, Superintendent of Maintenance of Way of the Cleveland, Cincinnati, Chicago & St. Louis; Dr. Octave Chanute, President of the Chicago Tie Preserving Company, Chicago, Ill., and to Prof. Ira O. Baker and Prof. C. H. Ilard, of the University of Illinois.

The ties used in these experiments were furnished gratuitously as follows: Nos. 1 to 11 and 16 to 30 by the Chicago Tie Preserving Company; Nos. 12 to 15 by the Illinois Central, Nos. 31 to 41 by the Cleveland, Cincinnati, Chicago & St. Louis. Table I gives a description of the several ties used. The ties were taken either from the stock pile of the railroad companies or from those of the treating plant. No attempt has been made to trace their history farther back than the place of growth and date of treatment. Treated ties were used in a majority of the experiments, since in the future as the inferior grades are pressed into service, the tendency will doubtless be toward the use of preserved timber.

Two distinct lines of experiments were undertaken: (1) Determination of the resistance to direct pull of several forms of spikes; and (2) Investigation of the resistance to lateral thrust.

Therefore, the paper naturally divides itself into two parts: Part I, Resistance to Direct Pull; Part II, Resistance to Lateral Displacement. All of the experiments were made in the Laboratory of Applied Mechanics, University of Illinois.

PART I—RESISTANCE TO DIRECT PULL.

The experiments were made with a Riehle 100,000-lb. testing machine. The pulling device for ordinary spikes was a Verona spike-puller threaded into a piece of steel gripped between the lower jaws of the machine; the pulling device for the screw spikes was of the same general pattern and was designed especially for these tests. A scale graduated to 1-16 of an inch was so set that the distance moved through by the lower head of the machine could be measured directly. A load of 500 lbs. was applied to insure the tie's having a good bearing before any records were taken. The machine was geared to move at the rate of $\frac{5}{8}$ in. per minute, which allowed time for carefully balancing the machine and for taking the readings of the scales. Five observations were usually taken, viz., when the lower head of the machine had moved through $\frac{1}{4}$, $\frac{1}{4}$, $\frac{1}{2}$ and $\frac{3}{4}$ of an inch, and also at the point at which the maximum fiber resistance was developed. No observations were made after the spike had been pulled $\frac{3}{4}$ in., as it would have lost its usefulness long before that point had been reached.

Further consideration of this part of the paper will be continued under the following heads: Holding Power of Ordinary Spikes; Holding Power of Screw Spikes Without Linings.

HOLDING POWER OF ORDINARY SPIKES.

The ordinary spikes were received from the following companies, the numbers in this list being the designations in the subsequent tables: Nos. 1 and 2 from the Pennsylvania Lines West; Nos. 3 and 4 from the American Iron and Steel Manufacturing Company, Scranton, Pa.; Nos. 5 to 10 from Dillworth, Porter & Co., Pittsburg; No. 11 from the W. A. Zelnicker Supply Company, St. Louis, and Nos. 12 to 14 from the Illinois Steel Company, Chicago.

The nominal dimensions of the four sizes of spikes are shown in Table II. The actual lengths varied considerably from the nominal lengths, usually being less. This was particularly true of the 6-in. spike. The actual cross sections were nearly the same as the nominal, the variation in thickness rarely being over 1-64 of an inch. As the range in thickness of the spikes was only 1-16 in., some experiments were made with plain, square and chisel-pointed bars $\frac{1}{2}$, $\frac{3}{4}$ and $\frac{7}{8}$ of an inch thick to determine the relation between the holding power and the cross section. The spikes had differently shaped points, as shown in Table II. Three spikes were used for each experiment, and these three were always of the same size and lot number. The spikes were driven by an experienced track foreman detailed for this purpose by the division engineer of the Big Four. Whole ties were used to insure freedom from splitting in driving the spikes, and care was exercised to avoid driving the spike into knots or cracks. The spikes were driven into the tie to a depth of 5 inches. In some instances, as shown in the record, holes were bored for the ordinary spikes, the hole being 1/16 or $\frac{1}{8}$ in. less in diameter than the cross sectional dimensions of the spike. The depth of the boring was not quite as great as the depth of insertion, so that the pointed end of the spike was forced into the undisturbed wood. Figures 1 and 2 show graphically the curves of average resistances of the different ties, as developed by the tests.

TABLE II.—*Description of the Ordinary Spikes.*

Record No.	Nominal length, ins.	Section, Ins. sq.	Area, Ins. sq.	Type of point.	Depth inserted.	Condtn of surface of spike.
1	6	$\frac{5}{8}$	0.372	Chisel.	5 ins.	Smooth.
2	$5\frac{1}{2}$	$\frac{5}{8}$	0.372	Chisel.	5 "	"
3	$5\frac{1}{2}$	$\frac{5}{8}$	0.372	Blunt.	5 "	"

5	6	$\frac{5}{8}$	0.372	Sharp.	5 "	"
6	$5\frac{1}{2}$	$\frac{19}{32}$	0.352	Sharp.	5 "	"
7	$5\frac{1}{2}$	$\frac{19}{32}$	0.352	Chisel.	5 "	"
8	6	$\frac{5}{8}$	0.372	Blunt.	5 "	"
9	$5\frac{1}{2}$	$\frac{9}{16}$	0.316	Blunt.	5 "	"
10	$5\frac{1}{2}$	$\frac{9}{16}$	0.316	Sharp.	5 "	"
11	$5\frac{1}{2}$	$\frac{9}{16}$	0.316	Chisel.	5 "	"
12	$5\frac{1}{2}$	$\frac{9}{16}$	0.316	Sharp.	5 "	"
13	$5\frac{1}{2}$	$\frac{9}{16}$	0.316	Chisel.	5 "	"
14	6	$\frac{5}{8}$	0.372	Chisel.	5 "	"

A study of the results to determine: (A) Comparative holding power in untreated ties; (B) Comparative holding power in treated ties; (C) Comparative holding power of the same timber, treated and untreated; (D) Effect of preservatives on holding power; (E) Relation between cross section of the spike and holding power; (F) Relation between depth of penetration and holding power; (G) Effect of the point of the spike on holding power; (H) Effect upon holding power of re-driving the spike, follows in detail:

A—Comparative Holding Power in Untreated Ties.

Table III. shows the average holding power of different untreated ties.

TABLE III.—*Average Holding Power in Untreated Ties.*

Kind of tie.	No. of Tests.	No. of Spks.	Resistance in lbs. for a pull of— $\frac{1}{4}$ in.	Resistance in lbs. for a pull of— $\frac{1}{2}$ in.	Maximum resistance: Distance pulled.	Maximum resistance: Lbs.	Resistance in per cent. of that of white oak— Inch $\frac{1}{4}$ th.	Resistance in per cent. of that of white oak— Inch $\frac{1}{2}$ th.	Resistance in per cent. of that of white oak— Maximum.
White oak	10	30	3,510	3,950	7,870	7,870	100	100	100
Elm	11	33	2,310	5,290	7,290	7,290	66	136	93
Beech	3	9	2,240	3,790	8,180	8,180	64	96	104
Chestnut	4	12	2,900	4,070	5,190	5,190	86	103	66
Loblolly pine	2	6	2,920	3,190	3,630	3,630	85	81	46

This shows the comparative holding power of five kinds of timber. The last three columns show the holding power in terms of that of white oak. It is thought that a pull of $\frac{1}{4}$ in. gives results which are of more value in comparing the holding power of the different kinds of ties than the results for either greater or less distances, since the results for the $\frac{1}{4}$-in. pull represent the resistances of the various timbers to the withdrawal of the spike for a distance which should not be exceeded in practice, and since the maximum resistance and the results for a pull of $\frac{1}{2}$ in. represent the resistances for distances which are therefore not of so much consequence as the $\frac{1}{4}$-in. pull. It is noticeable that with chestnut and loblolly pine the maximum resistance occurs at $\frac{3}{16}$ in., which is a reason for comparing their maximum resistance with that of white oak at $\frac{1}{4}$ in. instead of with its maximum resistance as in the table. If this is done, the efficiencies of chestnut and loblolly pine for a $\frac{1}{4}$-in. pull or less are 131 and 85 per cent., respectively.

The fact that the maximum resistance did not occur until the spike had been pulled from $\frac{3}{16}$ to $\frac{5}{8}$ in. is interesting. While the spike is being driven the fibers of the wood are bent downward and are pressed outward, and as the spike is withdrawn the friction between the spike and the wood tends to draw the fibers into their original position, which causes them to crowd laterally against the spike and also toward the surface of the tie, until finally the external pull exceeds the internal resistance and the spike slips. When the fiber structure is open, there is considerable cellular space for the displaced fibers to occupy, and therefore the maximum resistance is low, and is quickly attained; but when the fiber structure is compact, the reverse is true. As the loblolly pine ties should always be preserved, the results for this timber are of doubtful value. For the best results elm ties also should be treated; but as some species of elm do not absolutely require treatment, elm is properly included. Arranging these timbers in the descending order of their resistances for a $\frac{1}{4}$-in. pull, we have elm, chestnut, white oak, beech and loblolly pine. The maximum holding power for the first three timbers in Table III. is satisfactory, but that for the last two is quite low. The last fact indicates that when timber of the softer varieties or timber having loose fiber structure is used for ties, some more efficient form of fastening should be devised.

B—Comparative Holding Power in Treated Ties.

Table IV. shows the average holding power obtained with various treated ties. The average results obtained with untreated white oak are also included so that comparisons can be made. The average for the resistances for all of the treated timbers is shown at the foot of the table. Excluding the last two timbers, the average resistance for the $\frac{1}{4}$-in. pull is 5,690 lbs. The maximum resistance of the last two timbers should be averaged with the resistances of the others for the $\frac{1}{4}$-in. pull, in which case the average resistance for all of the timbers for a $\frac{1}{4}$-in. pull or less is 5,400 lbs.

TABLE IV.—*Average Holding Power in Treated Ties.*

Kind of tie.	No. of Tests.	No. of Spks.	Resistance in lbs. for a pull of— $\frac{1}{4}$-in.	Resistance in lbs. for a pull of— $\frac{1}{2}$-in.	Maximum resistance.— Lbs.	Maximum resistance.— Distance pulled.	Resistance in per cent. of that of white oak— Inch $\frac{1}{4}$th.	Resistance in per cent. of that of white oak— Inch $\frac{1}{2}$th.	Resistance in per cent. of that of white oak— Maximum.
White oak*	10	30	3,510	3,950	7,870	$\frac{5}{16}$-in.	100	100	100
Water oak	16	48	2,870	5,730	6,780	$\frac{5}{16}$-in.	82	145	86
Black oak	13	39	2,910	5,890	7,230	$\frac{5}{16}$-in.	83	149	92

Burr oak	3	9	2,670	5,750	9,210	$\frac{3}{8}$-in.	76	145	117
Ash	2	6	3,570	5,200	7,730	$\frac{5}{16}$-in.	101	131	98
Elm	5	15	2,590	5,940	7,500	$\frac{5}{16}$-in.	74	150	96
Beech	3	9	2,950	6,190	8,900	$\frac{3}{8}$-in.	84	157	113
Poplar	4	12	2,830	5,290	5,670	$\frac{5}{16}$-in.	81	134	72
Loblolly pine	4	12	2,920	3,780	4,310	$\frac{1}{4}$-in.	83	109	55
Sweet gum	5	15	3,230	5,320	5,300	$\frac{5}{16}$-in.	92	96	67
Average	..	..	2,950	5,320	7,040	.....	84	135	89

*Untreated.

The resistances of the several timbers do not differ widely and the soft timbers give results which compare favorably with those obtained for the hard woods. This table also shows that the range for the maximum resistances is much greater than that for either the $\frac{1}{4}$-in. or the $\frac{1}{2}$-in. pull. The resistances for the different species of oak are very nearly the same, the mean for a $\frac{1}{4}$-in. pull being 2,850 lbs., for a $\frac{1}{2}$-in. pull 5,680 lbs. and for the maximum 7,740 lbs. With nearly all of the timbers the maximum resistance was obtained after the spike was pulled more than $\frac{1}{4}$ in., but there is no apparent relation between the amount of holding power and the distance through which the spike has been pulled. Comparing the resistances of treated timbers with that of untreated white oak, we see that the initial resistance of the white oak is higher than any of the other woods except one; while on the other hand, the resistance at $\frac{1}{2}$ in. in white oak is less than in any of the other woods save one. The maximum resistances of all but the last three timbers are practically the same. Considering the uniformity of the results obtained with a pull of $\frac{1}{4}$ in. in the few timbers which were available, there appears to be no strong reason for much discrimination between the different treated timbers.

C—Comparative Holding Power of the Same Timber, Treated and Untreated.

Table V. is given for the purpose of studying the effect of treatment on the holding power of a timber.

TABLE V.—*Relative Holding Power in Treated and Untreated Ties*

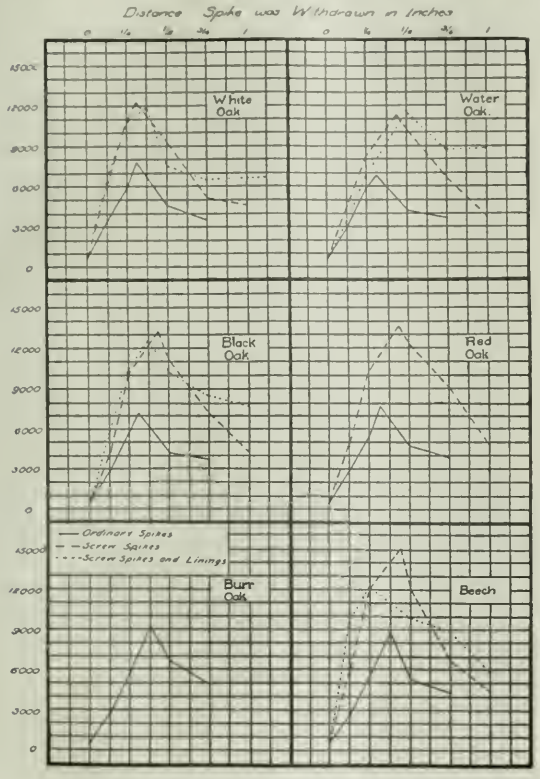
Kind of tie	No. of Ties	No. of Spikes	Condition of the	Resistance and gain in pounds due to treatment: ⅛ in pull	Gain	¼ in pull	Gain	Max resistance	Gain
Elm	3	27	Untreated	5,310		5,390		7,290	
Elm	2	15	Treated	5,500	580	5,940	550	7,500	210
Beech	1	9	Untreated	2,540		3,790		8,180	
Beech	1	9	Treated	2,950	710	6,190	2400	8,980	820
Loblolly pine	1	6	Untreated	2,820		3,190		3,650	
Loblolly pine	2	12	Treated	2,920	000	3,720	640	4,310	680
Red oak	3	15	Untreated					6,460	
Red oak	4	21	Treated					7,730	1270

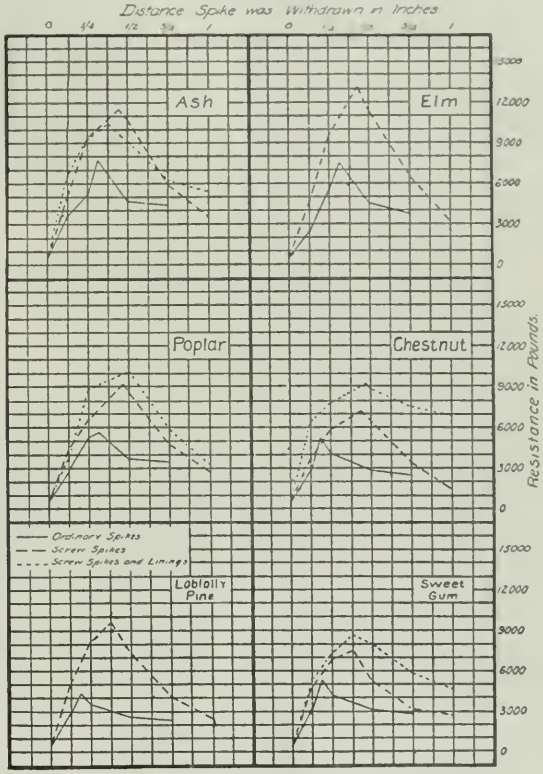
This shows that higher resistances are developed in treated than in untreated ties. The average increase due to treatment for a ⅛-in. pull was 330 lbs.; for a ¼ in pull, excluding the seemingly unreasonable increase in beech, 685 lbs., and for the maximum resistance 717 lbs. Considerable reliance is placed upon these conclusions, inasmuch as the methods of making the tests were exactly the same for the treated and untreated ties, and since the same

In those treated with zinc-creosote, but the maximum resistance is lower. If any rating were made in order of efficiency, it would appear about as follows: (1) creosote, (2) zinc-creosote and (3) zinc-tannin. However there are too many uncertain quantities involved to make such a rating reliable, and moreover the effect of the treating solution on the holding power is only one of the many elements which must be considered when choosing between the different treating solutions.

E—Relation between the Cross Section of the Spike and the Holding Power

The question to be answered here is, which size of spike will develop the highest holding power. To answer this question, Table VII. showing the relation between the cross section and the holding power has been compiled. From a study of these results it will be noticed that no general rating can be made for the various sized spikes in order of the resistances developed, since the spike which develops the lowest holding power for the ⅛ in. or the ¼ in. pull





Figs. 1 and 2—Diagrams of Resistance to Withdrawal of Different Kinds of Spikes in Different Kinds of Wood.

number of spikes, 57, was used in both cases, and also since the preserved ties were treated by different processes and at different plants.

The increased resistance due to treatment has two causes: (1) The presence of the preservative in the cells, thus reducing the space into which the fibers can crowd as the spike is withdrawn; and (2) the hardening of the fibers by the steaming, preparatory to treatment, which renders them less pliable. The movement which took place among the fibers near the surface of the tie is interesting. In the untreated ties there was a crumpling of the fibers close to the spike, while the fibers in the treated ties were torn out in deep slivers extending from the spike to the blocks which supported the tie.

D—Effect of Preservatives on Holding Power.

Three distinct kinds of preserving solutions were used in the ties tested—creosote, zinc-creosote and zinc-tannin.

Table VI. is given to show the effect produced by the treating solution on the holding power of the tie. It does not show any marked difference between resistances in ties treated with the different preservative solutions. For example, the maximum resistance of the red oak is lower when treated with zinc-tannin than when treated with zinc-creosote, but the reverse is true of the initial resistance of the red oak and also of the maximum resistance of black oak. With elm the initial resistance is higher in creosoted ties than seldom develops the highest maximum resistance. For example, in

TABLE VI.—*Effect of Different Preservatives on the Holding Power.*

Kind of tie.	Tie No.	Preservative.	Resistance in pounds for pull of ⅛ in.	Resistance in pounds for pull of ¼ in.	Max. resistance, lbs.
Comparison of Zinc-tannin and Creosote					
Water oak	4, 5, 25, 26, 29	Zinc tannin.	2,380	5,010	6,260
	34	Creosote	3,020	6,270	7,310
Red oak	6, 9, 22, 28, 30	Zinc tannin.	3,170	5,470	6,580
	11	Creosote	3,420	5,800	6,920
Comparison of Zinc Creosote and Creosote.					
Red oak	7, 8	Zinc-creosote.	2,350	4,940	8,500
	41	Creosote.	3,120	5,800	6,920
Elm.	10	Zinc creosote.	2,520	5,870	7,090
	37	Creosote.	2,600	6,350	7,210
Comparison of Zinc-tannin and Zinc creosote.					
Red oak	6, 7, 8, 9, 22	Zinc creosote.	2,350	4,940	8,500
	28, 30	Zinc tannin.	3,170	5,470	6,580
Black oak	16, 18	Zinc creosote.	2,850	5,620	7,010
	23, 24, 27	Zinc tannin.	2,830	5,620	7,550

white oak, the $\frac{13}{16}$-in. spike developed the highest resistance for the ⅛-in. pull, but the $\frac{9}{16}$-in. spike developed the highest resistance for the ¼-in. pull, and also the highest maximum resistance. In black oak the highest resistance for the ⅛-in. pull was developed by the $\frac{9}{16}$-in. spike, but that for the ¼-in. pull was developed by the $\frac{13}{32}$-in. size and the maximum resistance by the $\frac{5}{8}$-in. spike. Averaging all of the resistances for the ⅛-in. pull, the ¼-in. pull and the maximum resistance collectively, we see that the average

holding power of the $\frac{9}{16}$-in. spike is 4,990 lbs. for the $\frac{13}{32}$-in. spike 5,420 lbs. and for the $\frac{5}{8}$-in. spike 5,290 lbs. Because of the large number of spikes tested, seventy-two $\frac{9}{16}$-in., thirty-six $\frac{13}{32}$-in., and one hundred and two $\frac{5}{8}$-in., and the irregularity of the results, it was decided that no conclusions could be drawn from this table as to the relative holding power of the different sizes of spikes. However, the thickness of the spikes varied by only $\frac{1}{16}$-in. or about 10 per cent., and their areas by only 0.075 of a sq. in. or about 20 per cent.

TABLE VII.—*Relation Between the Cross-Section of the Spike and Its Holding Power.*

Kind of tie.	No. of Ties.	No. of Spikes.	Condition of tie.	Size of spike, inch.	Resistance to withdrawal, lbs. ⅛-in. pull.	¼-in. pull.	Max. resistance.

	1	3		13/32	2,550	5,400	7,660
	1	3		5/8	2,290	5,070	7,900
	1	3	Treated	9/16	2,480	5,490	9,410
Beech	1	3		13/32	3,530	6,990	8,250
	1	3		5/8	2,850	6,090	9,040
Sweet gum	1	6	Treated	9/16	2,190	3,770	4,610
	1	12		5/8	3,490	4,450	5,460

To test still further the relationship between the size of the spike and the holding power, a series of experiments was made with plain square rods with the results shown in Table VIII. Each result is the mean of 15 tests in a single kind of timber.

TABLE VIII.—*Experiments with Plain Square Rods in Beech Timber.*

Size of rod.		Area, sq. in.	Av. max. results, lbs.	Increase for each increment — Area, Sq. in.	Area, Per cent.	Resistance, Lbs.	Resistance, Per cent.
Successive increments in the size of the rod = ⅛-in.							
½-in.	square	0.250	6,280	.....	..	.....	..
⅝-in.	"	0.391	6,970	0.141	53	690	11
¾-in.	"	0.562	9,070	0.171	44	2,600	37
⅞-in.	"	0.765	9,380	0.203	35	310	3
Successive increments in the size of the rod = 1/16-in.							
8/16-in.	square	0.250	6,280	.....	.....	.....	..
9/16-in.	"	0.316	6,450	0.066	25	170	3
10/16-in.	"	0.391	6,970	0.075	23	520	8

It will be seen from these results that there is an irregular increase in the holding power as the size of the rod is increased. Notice that with increments of ⅛-in., the successive increments in the resistance are at first large, but with the last rod this increment suddenly falls to practically nothing. This drop in the increment is principally due to the tendency of the large rod to split the tie. The results with $\frac{1}{16}$-in. increments do not differ materially from those in the first part of the table. The deduction is that holding power will be increased as the size of the rod is increased, but that it is not expedient to use rods (or spikes) larger than ¾ in. unless holes are bored for them.

F—Relation between the Depth of Penetration and Holding Power.

A series of experiments was made to determine the relation between the depth of penetration and the holding power. The results are given in Table IX.

TABLE IX.—*Holding Power in a White Oak Tie with Varying Depths of Penetration.*

Depth of penetration.	Resistance, lbs. Test No. 1.	2.	3.	4.	5.	Average.
½ in.	150	150	140	160	170	150
1 in.	480	.....	500	510	490	500
1½ in.	1,440	1,000	1,760	1,320	950	1,290
2 in.	2,250	2,250	2,050	2,900	2,760	2,450
2½ in.	3,430	3,840	3,050	2,940	3,570	3,360
3 in.	3,710	3,800	4,200	4,220	4,810	4,210
3½ in.	4,760	5,980	4,210	4,500	5,860	5,060
4 in.	5,950	7,190	6,310	5,850	6,080	6,270
4½ in.	7,510	7,510	7,720	7,310	.....	7,520
5 in.	8,380	9,070	8,540	7,790	7,900	8,340

The spikes had a taper point approximately 1 in. long. Fig. 3 shows that the holding power varies directly with the penetration, not counting the taper point. It is impracticable to use a spike longer than 5½ in. in a 6-in. tie, since a longer spike would either pass entirely through the tie or sliver it on the under side. In either case the fiber adjacent to the spike would quickly decay owing to the access of water. In a thicker tie, however, a longer spike could be used advantageously. The main precaution is to keep the spike from damaging the under surface of the tie, otherwise the longer the spike the greater the holding power.

G—Effect of the Point of the Spike on the Holding Power.

There were three distinct types of points on the spikes: blunt-point, chisel-point and bevel-point, as shown in Fig. 4.

The average results obtained with spikes having these types of points are shown in Table X. The average and relative resistances of each type of spike for all timbers are shown at the foot of the table. These averages show that both the blunt-pointed and the bevel-pointed spike are higher in holding power than the chisel-pointed spike. Since the average resistances of the blunt and the bevel-pointed spikes are practically the same, and since the blunt-pointed spike develops the highest resistance for the ⅛-in. and the ¼-in. pull the greatest number of times, the blunt-pointed spike is first in point of efficiency, although the bevel-pointed spike is a close competitor under all conditions. The chisel-pointed spike is last.

The two upper figures of Fig. 5 are the two halves of a red-oak tie showing the position of the fibers adjacent to the spike; and the lower figure is a portion of the other end of the same tie split after the spikes had been pulled out. The photograph was taken immediately after the tie had been split. The figures are too small to show details clearly, but an examination of the tie showed that the blunt-pointed spike disturbed more fiber than either the chisel or the bevel-pointed spikes, the last two disturbing about the same amount. The examination also showed that the blunt-pointed spike tore rather than cut the fibers, and deposited them in unequal bundles along its faces, while the chisel-pointed spike cut the fibers and deposited them quite uniformly both across and in front of each face. The bevel-pointed spike forced a majority of the fibers to the front face and toward the corners. The relatively high holding power of both the blunt and the bevel-pointed spikes is due to this unequal concentration of the fibers.

TABLE X.—*Effect of the Form of the Point, of the Spike on the Holding Power.*

H—Effect on Holding Power of Re-driving the Spike.

In practice, when the spike is pulled out of the tie a moderate distance, it is driven back, provided the hole is not greatly enlarged. If the hole is much enlarged the spike is driven at another point. This constant re-spiking rapidly ruins the tie. A series of tests was made to determine the effect upon the holding power of re-driving the spike. The average maximum holding power of the re-driven spikes is shown in Table XI. along with the original

TABLE XI.—*Relative Holding Power of Newly-driven and Re-driven Spikes.*

Kind of tie.	No. of spikes.	Av. max. resistance, lbs. Original.	After re-driving.	Per cent. of original.
Ash	6	8,640	6,490	75

Poplar	6	4,920	3,980	81
Sweet gum	6	5,040	4,150	82

maximum holding power of the same spike. It will be seen that the holding power of the re-driven spike is much less than that of the newly-driven spike. The resistance is affected so much in some woods as to make the practice of re-driving the spike a questionable procedure if the holding power alone is considered; but as the practice of re-driving the spike helps to lengthen the life of the tie, the practice cannot be justly condemned so long as the holding power is not excessively reduced.

HOLDING POWER OF SCREW SPIKES WITHOUT LININGS.

A series of tests was made to determine the holding power of screw spikes. The tests were conducted in the same manner as those with the ordinary spikes. The screw spikes were received from the following companies: No. 1 from the Illinois Central; No. 2 from the American Iron and Steel Manufacturing Company, Scranton; No. 3 from the South Side Elevated, Chicago; No. 4 from the Oliver Steel & Iron Company, Pittsburg, and No. 5 from the Pennsylvania Lines West.

A description of the different spikes is given in Table XII.

TABLE XII.—*Description of Screw Spikes.*

Spike No.	Length.	Diameter of core.	Projection of thread.	Pitch.	Depth of insertion.	Diam. of bored hole.
1.	5 in.	21/32-in.	9/16-in.	½-in.	4½ in.	11/16-in.
2.	5 in.	11/16-in.	⅛-in.	½-in.	4½ in.	11/16-in.
3.	5¼ in.	11/16-in.	⅛-in.	½-in.	4¾ in.	11/16-in.
4.	5½ in.	11/16-in.	⅛-in.	½-in.	5 in.	11/16 in.
5.	5 in.	21/32-in.	9/16-in.	½-in.	4½ in.	11/16-in.

The shank or threaded portion of the spike was usually ⅞ in. in diameter, and approximately 1 in. of the upper portion of the core tapered from the diameter of the core to that of the shank. The hole bored for the spike was not reamed, and the result was a

tight fit between the wood and the spike. This tight contact is gained in practice by the head of the spike bearing against the base of the rail. The spike was driven by means of a wrench, the thread cutting its own path. The number of screw spikes obtainable was not sufficient to make as long a series of tests as with the ordinary spikes.

A study of the results with this spike has been made to determine: (A) Relation between the depth of penetration and the holding power, (B) Relation between the holding power of the screw and of the ordinary spikes, and (C) Influence of certain details of the screw spike upon its holding power.

The average results of the tests with screw spikes are shown in Figs. 1 and 2.

A—Relation between Depth of Penetration and the Holding Power.

A series of tests was made to determine the relation between depth of penetration and holding power of the screw spikes. The experiments consisted of pulling spikes driven to depths of 1, 2, 3, 4 and 5 in. into a beech tie, three spikes being used for each depth. The numerical results are shown in Table XIII., and their averages are shown graphically in Fig. 6 together with some additional matter which is shown for the sake of comparison.

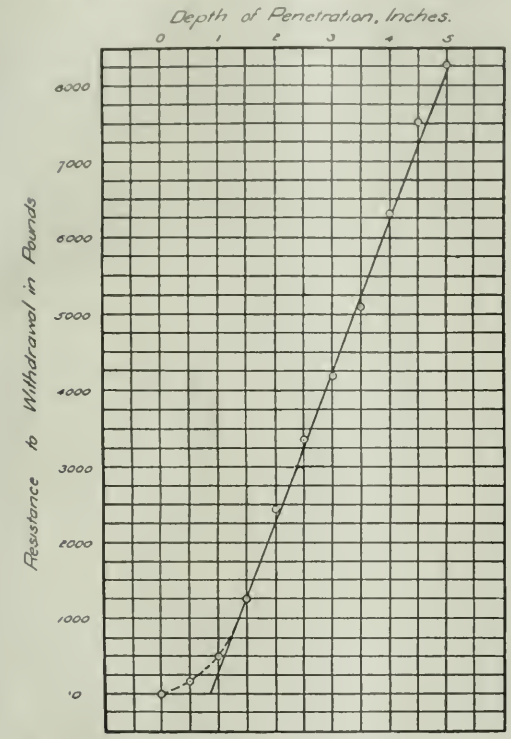

Fig. 3—Diagram of Resistance to Withdrawal of Ordinary Spikes for Various Depths of Penetration.

TABLE XIII.—*Results Obtained from Experiments on Depth of Penetration.*

	Resistance in pounds for penetration of—				
	1 in.	2 in.	3 in.	4 in.	5 in.
Test No. 1	2,770	4,560	9,610	13,100	17,360
" " 2	2,760	6,000	10,000	14,330	17,300
" " 3	2,790	4,940	8,490	13,330	16,840
Average	2,770	5,170	9,360	13,590	17,230

The results in Fig. 6 can be quite closely represented by two intersecting straight lines. The probabilities are that the actual resistances would be more nearly represented if the two straight lines were joined by a short curve near their intersection. Only the upper portion of the diagram is of interest, since penetrations of less than four inches should never be used, at least on heavy traffic railroads, the only roads likely to use screw spikes. The diagram shows that the resistance varies directly with the depth of penetration.

B—Relative Holding Power of Screw Spikes and Ordinary Spikes.

Table XIV. has been prepared to determine the relation between the holding power of the screw spike and that of the ordinary spike. As previously stated, the ordinary spikes were driven into the tie to a uniform depth of 5 in., while the screw spikes, being of different lengths, necessarily were inserted to unequal depths. On account of the relation existing between the depth of penetration and the holding power, the resistance for the screw spikes is based upon a penetration of 5 inches.

TABLE XIV.—*Relative Holding Power of the Screw Spike and of the Ordinary Spike in Several Timbers.*

Loblolly pine	Ordinary.	2,920	3,500	4,500	100	100	100
Sweet gum	Screw.	5,430	7,710	8,280	167	162	156
Sweet gum	Ordinary.	3,230	4,120	5,300	100	100	100
Loblolly pine	Screw.	5,750	9,050	10,620	197	258	247

From Table XIV. it will be seen that the holding power of the screw spike is always greater than that of the ordinary spike, and that the relation between the two varies in the several timbers. For a pull of ¼ in. in the hard woods the holding power of the screw spike is from 167 to 221 per cent. of that of the ordinary spike, and in the soft woods the range is from 117 to 258 per cent.; or the average gain in the hard woods is 76 per cent., and in the soft woods 98 per cent. It is interesting to note that the resistances in the several timbers for the ½-in. pull with the screw spike are in eight out of eleven instances nearly the same as, or greater than, the resistances for the ¼-in. pull with the ordinary spike. This signifies that the screw spike is about twice as efficient as the ordinary spike for a pull of ¼ in. or less. The curves in Figs. 1 and 2 show graphically the relative efficiency of the two forms of spikes with some information to be referred to later.

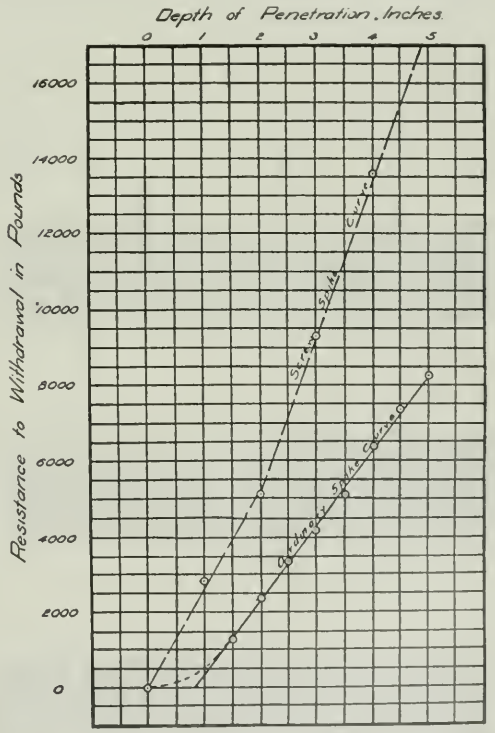

Fig. 6—Diagram of Resistance to Withdrawal of Screw Spikes and Ordinary Spikes for Various Depths of Penetration.

C—Effect of Details of the Screw Spike on Its Holding Power.

In countries where the screw spike is extensively used it has been perfected in detail until it nearly fulfills the requirements of practice. In North America the screw spike will probably be the

successor to the ordinary spike, and it may again be necessary to adjust the details to suit local conditions. Therefore, a few observations on the relation of some of the details of this spike to its holding power come within the scope of this paper. The details to be discussed are the diameter of the core, the projection and pitch of the thread and the length of the thread.

The soft steel from which the screw spike is made has an ultimate strength of about 66,000 lbs. per sq. in., so that the tensile strength of a spike $\frac{11}{16}$ in. in diameter is approximately 24,000 lbs. The ultimate compressive resistance across the grain of well-seasoned white oak is about 4,000 lbs. per sq. in., and experiments demonstrate that the thread of the spike in compacting the wood

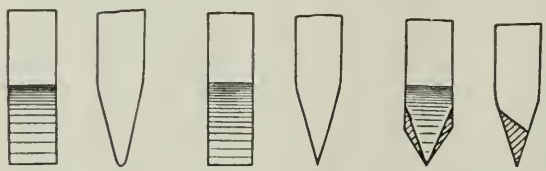

Fig. 4—Forms of Spike Points.

fibers increases the resistance about 40 per cent.* Therefore, taking 5,600 lbs. as the ultimate compressive strength of compacted white oak, and taking $17\frac{3}{4}$ in. and $\frac{1}{4}$ in. respectively as the length and projection of the thread on the 5-in. spike, and making no allowance for frictional resistance between the core of the spike and the wood, the theoretical resistance would be

$$5{,}600 \times 17\tfrac{3}{4} \text{ in.} \times \tfrac{1}{8}\text{-in.} = 12{,}430 \text{ lbs.}$$

The average actual resistance obtained in white oak ties as shown in Table XIV. is 12,630 lbs., which agrees closely with the theoretical resistance. The tensile strength of the screw spike is about 12,000 lbs. greater than the maximum resistance of white oak, which difference is greater than necessary and indicates an uneconomical use of metal in the spike. Since the ties tested are representative of

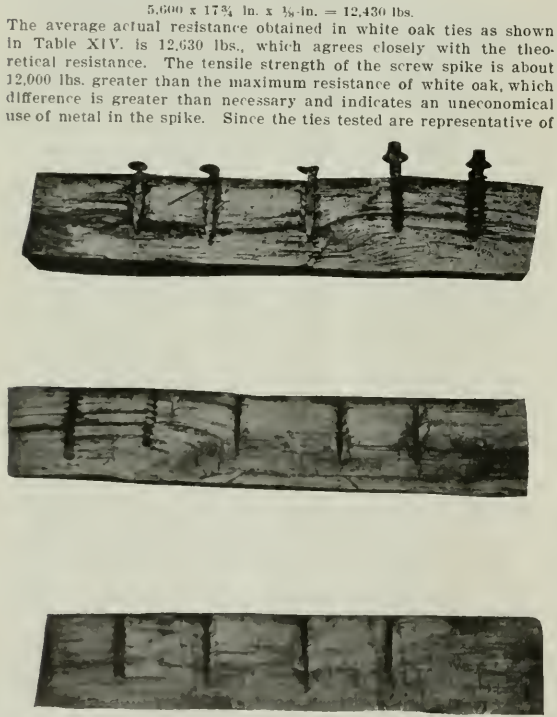

Fig. 5—Effect of Spikes in Displacing the Fibres of the Tie.

American practice, there is no apparent reason for not having the ultimate strength of the two materials in contact more nearly equal than at present, and by some slight change in the detail of the spike this could readily be accomplished. Three ways in which the ultimate strength of the materials may be made more nearly equal are: (1) increase in length of threaded portion; (2) increase in projection of thread, the length and the diameter of the core remaining the same; (3) increase in projection of thread at the expense of the core, the length remaining the same. The pitch is assumed to be $\frac{1}{2}$ in. in all cases, since it has been found in practice that this pitch gives better results than either a greater or smaller pitch.*

*Bulletin No. 50, U. S. Department of Agriculture.

(1) The length of the thread on the 5-in. spike is $17\frac{3}{4}$ in. and the width is $\frac{1}{8}$ in.; therefore, the bearing is 2.22 sq. in. If the spike is made 6 in. long two convolutions of the thread will be added, the bearing area will become 2.71 sq. in., and the holding power will be increased from 12,630 lbs. to 15,180 lbs. This leaves a difference of only 8,900 lbs. between the ultimate strength of the wood and that of the spike.

(2) If the length of the spike and the diameter of the core are not changed, and if the projection of the thread is increased $\frac{1}{8}$ in., the total resistance would amount to 15,510 lbs., leaving an ultimate strength of the spike only 8,500 lbs. greater than that of the wood.

(3) If the length of the threaded portion of the spike remains unchanged and if the projection of the thread is increased $\frac{1}{8}$ in. at the expense of the core, the maximum resistance would amount to 15,510 lbs., while the ultimate strength of the spike would be reduced to 20,200 lbs.

The diameter of the shank of the spike would have to be increased with some of the changes in the detail of the lower portion, and when the resistance to lateral displacement is taken into account, we see that this change also would be beneficial. The conclusion is that the screw spike in its present form is about twice as efficient as the ordinary spike; and that this efficiency could be increased by some slight change in the detail of the screw spike.

The following table shows the relative holding power of the ordinary spike, the screw spike, and the screw spike with helical lining in several timbers:

*Screw spike with helical lining.

PART II.—RESISTANCE TO LATERAL DISPLACEMENT.

The railroad spike is subjected not only to a direct pull by the undulation of the rail, but also to a horizontal thrust due to the lateral movement of the rail. On roads having a large amount of curvature the lateral resistance is of more importance than that of direct pull. To determine the amount of the resistance to lateral displacement which is developed by various forms of spikes the writer made a series of tests in which the lateral thrust was produced by the blows of a heavy hammer. The hammer consisted of a cast-iron weight suspended by a wooden rod from the joists of the floor above. Fastened to the joists were metal strips upon which the knife edges of the rocking arm rested. These strips were 6 ft. long, and were notched along the entire upper edge to permit the placing of the rocking arm in different positions. The length of the suspending rod was 9 ft. The weight of the hammer was 100 lbs. and the distance through which it was allowed to fall was $1\frac{1}{2}$ ft., so that the amount of the impact for each blow was 150 ft.-lbs. The hammer delivered its blow on the end of a tool-steel bar which projected beyond the end of the tie, the other end of the bar being shaped to fit under the head of the spike.

The spikes used in this series of tests were $\frac{7}{16}$ in. and $\frac{5}{8}$ in. ordinary spikes and screw spikes. Each spike was subjected to five blows and the displacement produced by each blow was carefully measured. Usually four or five spikes of each kind were tested, but when there was much lack of uniformity in the results a larger number were tested. All of the spikes were bent to a curve, the central point of which was about $1\frac{1}{2}$ in. below the surface of the tie. The ordinary spikes were pulled from the tie a short distance, but the thread of the screw spikes gripped the wood so as to prevent the spike from being pulled out even a perceptible amount.

LATERAL RESISTANCE OF ORDINARY SPIKES.

The average movement of ordinary spikes for each of the several blows is shown in Table XVI. The average total movement of the $\frac{5}{8}$ in. spikes in the first seven timbers was 0.65 in., and that of the $\frac{7}{16}$ in. spikes was 0.75 in. In the last four timbers the average total movement of the $\frac{5}{8}$ in. spikes was 0.74 in., and that of the

$\frac{9}{16}$ in spikes was 0.94 in. The total deflection of the $\frac{9}{16}$ in. spikes was usually sufficient to allow a rail to clear the head of the spike if it were overturned. The corresponding movement of the $\frac{5}{8}$ in. spikes was not usually sufficient to allow a like clearance, although it was considerably more than would be allowed in practice. The first blow is of more importance than the succeeding blows in testing the efficiency of a spike. While the distances through which the different sized spikes were deflected by the first blow differ but a small amount, the difference is sufficient to show that the deflection is less for the $\frac{5}{8}$ in. spikes than for the $\frac{9}{16}$ in. These results, together with the fact that the $\frac{5}{8}$ in. spikes were bent less by the impact than the $\frac{9}{16}$ in. spikes indicate that the $\frac{5}{8}$ in. spike is more efficient in resisting lateral displacement than the $\frac{9}{16}$ in. spike.

LATERAL RESISTANCE OF SCREW SPIKES.

The method of determining the lateral resistance of screw spikes was the same as that used for ordinary spikes. The screw spikes used were all practically alike except that they were of various lengths. In making the tests the spikes were used indiscriminately, but since they were not all of the same length some tests were made to determine the effect of impact upon spikes which were driven into the tie to different depths. The spikes used for the latter tests were all of the same make, and were cut to lengths of 3, 3½, 4, 4½ and 5 in., and were all driven into a single kind of timber. The results of these tests are shown in Table XVII. While the results for the 4- and 4½-in. spikes are the same, the averages in the last column of the table show that the amount of the lateral movement decreases as the depth of penetration increases. Also, the difference between the deflections of the 4, 4½ and 5-in. spikes is practically negligible, but for shorter lengths the difference in the deflections becomes greater. Table XVIII gives the lateral movement of the screw spikes for each blow. The number of spikes used in each kind of timber was usually three; but in case there was considerable variation in the results, more spikes were tested.

TABLE XVI.—*Lateral Movement of Ordinary Spikes for Each Blow.*

Kind of tie.	Size of spike.	Movement for each of the several blows: 1-in.	2 in.	3-in.	4 in.	5-in.	Average movement.

than that of the $\frac{9}{16}$ in. ordinary spike. In the last four kinds of timber the average total deflection of the screw spike was 0.70 in., which is practically the same as that of the $\frac{5}{8}$-in. ordinary spike, but which is 0.24 in. less than that of $\frac{9}{16}$-in. common spike. The results in the last two columns of Table XIX. show that the screw spike is superior to the $\frac{9}{16}$-in. ordinary spike in all but two kinds of timber, and that the screw spike has a higher efficiency than the $\frac{5}{8}$ in. ordinary spike in all but three kinds of timber.

The last two columns in Table XIX. show that the ordinary spike was usually displaced more than the screw spike by each blow. This should be expected since the common spike was smaller in cross section than the screw spike, and also since the latter had better bond with the wood. While the use of the screw spike is recommended to the American railroads, it is thought that the practice of Bavarian railroads could be followed to advantage. These roads have adopted the use of the screw spike on the gage side of the rail to resist overturning, but use two square spikes on the outside to resist lateral movement. This practice has been found to give very beneficial results. The figures in the last two columns show that the lateral resistance of two ordinary spikes is considerably more than that of one screw spike, and therefore if two spikes are considered as resisting the impact instead of one, the results will be in favor of the ordinary spikes. Not only is this true, but the first cost for spikes would be reduced, since the screw spike costs about 4 cents at the present time, whereas the ordinary spike costs much less. The maintenance cost of either form of spike is almost negligible.

An item of interest which is properly beyond the limits of this article is that of the 90 screw spikes used in making these tests only two were broken. One was broken under a tension of 14,000 lbs., the break being caused by an incipient crack just under the head of the spike. The other spike broke under the fourth blow of the hammer, this break being due to uncombined graphite in the metal. As the spikes were obtained from different sources, and were of different manufacture, it is thought that the test was sufficiently severe to show that the screw spike, as manufactured at present, will successfully withstand the shocks of passing trains. As the spikes were used several time during the tests, the percentage of spikes broken is very low.

SUMMARY OF RESULTS.

(1) The maximum resistance to direct pull varies from 6,000 to 14,000 lbs. for screw spikes, from 3,000 to 8,000 lbs. for ordinary spikes when driven into untreated timbers, and from 4,000 to 9,000 lbs. for ordinary spikes when driven into treated timbers.

(2) The direct pull required to withdraw ordinary spikes $\frac{1}{8}$-in. varies from 2,000 to 3,500 lbs. for untreated timbers, and from 2,500 to 3,500 lbs. for treated timbers.

(3) The direct pull required to withdraw ordinary spikes $\frac{1}{4}$-in. varies from 3,000 to 5,400 lbs. for untreated timbers and from 3,800 to 5,900 lbs. for treated timbers.

(4) Timbers having loose fiber structures have lower resistances to direct pull than timbers having compact fiber structures.

(5) The amount of withdrawal which must occur for ordinary spikes to develop the maximum resistance is less for soft woods than for hard woods.

(6) Spikes driven into treated timber offer a greater resistance to direct pull than spikes in untreated timbers, and the difference between this resistance for treated and untreated timbers is greater for soft woods than for hard woods.

(7) The difference in the resistance to direct pull for the different sized spikes in use ($\frac{9}{16}$ in., $\frac{19}{32}$ in and $\frac{5}{8}$ in.) is very small.

(8) The resistance of ordinary spikes to direct pull varies directly as the depth of penetration, neglecting the tapering point.

(9) Blunt-pointed and bevel-pointed spikes have a slightly greater resistance to direct pull than chisel-pointed spikes.

(10) For withdrawals less than $\frac{1}{4}$ in., ordinary spikes which are driven into bored holes have a little greater resistance to direct pull than spikes driven in the ordinary way.

(11) The resistance to direct pull for re-driven spikes is from

60 to 80 per cent. of the resistance of newly driven spikes.

(12) The efficiency of screw spikes to resist withdrawal is nearly twice as great as that of common spikes.

(13) The resistance of $\frac{5}{8}$-in. spikes to lateral displacement is slightly greater than that of $\frac{1}{16}$-in. spikes.

(14) The resistance to lateral displacement increases with the depth of penetration, but the increase is negligible for depths of penetration greater than 4 in.

(15) Screw spikes are more efficient than ordinary spikes in resisting lateral displacement.

Loss and Damage to Freight.*

My experience as an adjuster of freight claims has thoroughly shown that a very large percentage of the claims made against carriers have real merit and deserve expeditious adjustment. It is also my experience that the average claimant is quite as ready to consider the carrier's side of any cases which appear in doubt as we are to view theirs and, notwithstanding that the claim agent generally meets shippers and consignees at a time when they are not feeling particularly friendly toward the road, if he is desirous of establishing a reputation for fair and courteous dealing it is possible for him to make many friends, improve the standard of his profession and make known to claimants the true policy of his company.

The most frequent criticism of claim departments is for their tardiness in making claim settlements, and these complaints are not only made by claimants, but by representatives of the traffic department who are interested in making the service as satisfactory to the shipper as possible.

Wisely and progressively managed, the freight claim department may become an important factor in securing and retaining traffic, but to accomplish this it must possess a thorough system, devoid of circumlocution, for promptly investigating all claims and complaints, and in particular for treating with claimants in a uniformly businesslike manner. While carefully guarding the carriers' rights and interests it should be liberal in its consideration of claimants, avoiding a narrow policy or insistence on technicalities where important principles are not involved.

Many claim officers are to-day so equipped that they can and do promptly settle all claims in which their road alone is interested. Their efforts, however, are not appreciated by their company or its patrons, for the sole reason that claims in which other carriers are involved are delayed indefinitely because of an ill-advised and unfair practice of giving preference to the claims originating with them, inefficiency of the claim agent or an indifferent claim policy.

It is true the average interline claim cannot be adjusted as expeditiously as those in which but one road or system is interested, but that months should be consumed in the investigation of claims involving several carriers should only be necessary in exceptional cases. Both the Freight Claim Association and committees composed of progressive claim officers, are giving consideration to interline claim settlements, and several plans have been suggested from which it is expected substantial improvements will result; yet those roads which are indifferent to the need of a thoroughly effective and business-like claim policy will, to a greater or less extent, impede the operation of any improvements in this direction until they are fully awakened to a sense of their obligations to other lines.

During the past 10 years the claims which carriers have been called upon to entertain for loss and damage to freight have increased far beyond the growth of traffic, making serious inroads upon the revenues and doubling the forces employed in claim offices and elsewhere. This condition can be traced to many causes, principal among which are: Acceptance of package freight without adequate marks to insure its safe carriage and delivery; acceptance of many classes of freight when not sufficiently protected to prevent injury from the ordinary handlings it must receive; acceptance of valuable dry goods, plated ware, liquors, boots and shoes, etc., in frail boxes fastened with a few wire nails, which invite stealing by dishonest truckmen and freight handlers; shipment of perishable freight when not in prime condition, or when weather conditions make safe and prompt deliveries doubtful.

These are a few of the causes for claims which shippers make possible through reasons of economy, or lack of regard for the safety of their goods and the interests of their consignees.

Frail and second-hand boxes of uncertain strength and without erasure of old marks are used for the shipment of goods of all values, fragile articles are shipped with hardly sufficient protection to insure safety in carting to the carrier, and for the loss or injury resulting from these practices we are held accountable. If objection is made before receipt, we are informed that other lines are ready to take the goods, and if we question claims which arise from improper conditioning of goods attention is directed to our obligations as common carriers.

In opening packages which have been delivered in apparently perfect condition the consignee discovers part of his order missing, or some fragile article broken. Does the claimant say probably this is due to a mistake or accident of shippers or to theft or carelessness of their truckmen? Generally he does not. He finds it much easier to place the responsibility on the carrier, who being unable to certify to quantity or condition of contents of packages finds the claim difficult to defend. What will correct these conditions is the earnest co-operation of shippers and receivers of freight with the transportation lines in careful marking of freight shipped in small quantities and the securing of merchandise packages so that their contents cannot be readily removed, or, at least, without leaving some evidence or indication of the loss.

As to losses and damages to freight for which transportation lines are wholly responsible, the causes are without number, but for the purpose of consideration here, we will divide them into two general classes, avoidable and unavoidable; avoidable when caused by carelessness or negligence of employees, and unavoidable when ordinary and reasonable care is exercised.

As is true in respect to many other great business enterprises where large forces are employed, the negligent acts of indifferent or incompetent employees result in both direct and indirect losses, direct when the company is called on to pay the claims, and indirect when traffic is diverted to other routes because of unsatisfactory service.

Whether the average railroad employee is less regardful of his company's interests than those of large industrial concerns, or whether the growing demand for labor has influenced employees to feel less concern in the affairs of those whom they serve, are questions I will not undertake to decide, but losses clearly chargeable to avoidable causes have, during the past few years, increased alarmingly. Perhaps this can be largely attributed to the enormous increase in traffic which often taxes cars, terminal and station facilities to their utmost, requiring constant pressure on those directly concerned, as well as hurried discharge of duties; but the conclusions reached after investigating causes for loss too often remind me of the old story of the car inspector, who, being asked why he was tapping the car wheels with his hammer, replied, "D—— if I know, but thems the orders."

Enough has been said to illustrate my principal point, the development of closer relationship and co-operation between the different interests involved which will aid in removing many causes for avoiding losses and damages to freight.

In regard to overcharges the following, which is quoted from the *American Railway Journal*, published in the year 1839, may be of interest as indicating the possible origin of that class of claims in this country:

> I hope in granting charters hereafter the legislature will look closely into the question of what provisions are necessary to guard the citizen from imposition. From Philadelphia to New York the fare is $5 per head. Fifteen passengers on an average make a ton, therefore the charge is equal to $75 a ton for 100 miles. According to report, the cost of transporting coals on the road for 100 miles is 53 cents a ton. Now deduct the cost of transporting a ton of coals from the cost of transporting a ton of passengers, and it will be seen that the railroad clearly gains. Possibly some allowance should be made for the difference between the cost of passenger cars and burden cars, but it cannot be much. I hope that in any new charters which may be granted the legislature will correct this error, as it is very material to travelers.

*An address by Robert L. Calkins, Freight Claim Agent of the New York Central & Hudson River Railroad, before the New York Traffic Club.

Foreign Railroad Notes.

The locomotive works of J. A. Maffei in Munich have built for the Bavarian State Railroads a locomotive capable of hauling a train weighing 165 tons at a speed of 93 miles an hour. This engine was tested July 1 and 2, and maintained for a prolonged time a speed of 96 miles an hour, which is declared to be the greatest speed ever made in Europe by a steam locomotive. It is a four-cylinder compound with 6-ft. drivers, Schmidt superheater and Westinghouse high-speed brakes.

Freight trains on the Prussian State Railroads have heretofore been limited to a prescribed number of "car axles," for the various grades, curves, etc. The Minister in charge has now ordered that three of the directories keep accurate records of the weights of cars and loads behind tenders during the month of July as data for prescribing tonnage instead of axles as the basis of the limits of trains.

The Italian State Railroads have declined to take over the steamboat service on the lakes of north Italy. This service is something like that on Lake George, N. Y., only much more important, as the country on these lakes is thickly peopled and very productive. On the other hand, they are to maintain steamer lines between Naples and Palermo, which is the quickest route to the larger part of Sicily, and another steamer line from Civita Vecchia, the port of Rome.

Decapod Locomotive for the Buffalo, Rochester & Pittsburg.

The American Locomotive Company has recently built six decapod (2-10-0) locomotives at the Brooks works for the Buffalo, Rochester & Pittsburg. These engines have been built for pusher service between Clarion Junction, Pa. and Freeman 17 miles, with a grade of 58 ft. to the mile which is the controlling grade on northbound traffic. In addition to the wheel arrangement which, though not novel, is by no means common the engines are interesting for their great weight and high tractive power. They are the heaviest simple engines ever built by the company and have a total weight in working order of 268,000 lbs., of which 243,000 lbs. is on the driving wheels. The maximum tractive power is 55,350 lbs. Up to the present time trains on this grade, which has numerous curves up to 8 deg., are moved by two consolidation locomotives having

Decapod Locomotive; Buffalo, Rochester & Pittsburg.

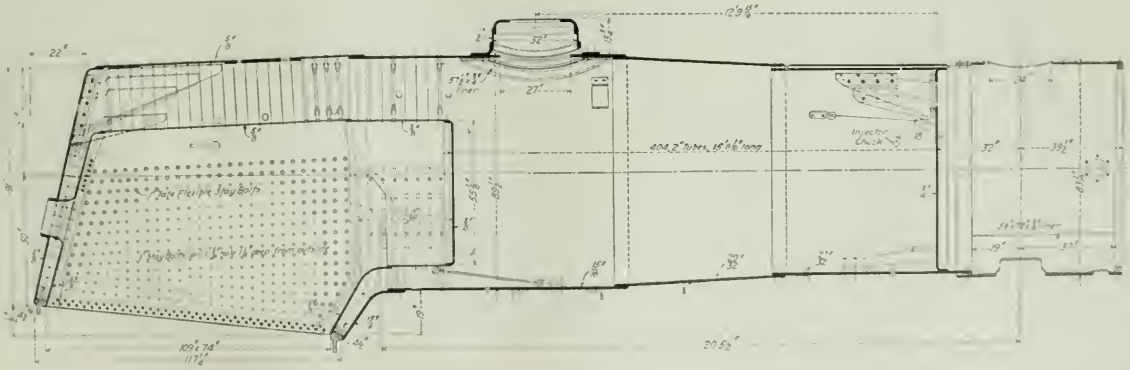
a tractive power of 38,000 lbs. each. The rated train load for the two is 3,350 tons, with one engine at the rear pushing. The rating of the same class of power (one engine) from Punxsutawney, Ernest or Dubois to the foot of the grade is 3,500 tons. With the track improvements completed, that are now in hand, it is expected that these consolidation locomotives will be able to haul 4,000 tons to the foot of Clarion Hill grade from either Punxsutawney, Ernest or Du Bois, and the decapod engines have been built to handle a train of 4,000 tons up the grade with a consolidation in the lead.

With cylinders of the size used in these engines high steaming capacity is essential, and in this case the example of the Northern Pacific has been followed and the length of the tubes cut down to 15 ft. 6 in. by the introduction of a combustion chamber. About a year ago some engines of the Mikado type were designed for the Northern Pacific with combustion chambers 3 ft. long and tubes 16 ft. 9 in. long, which were 1 ft. 9 in. shorter than the tubes in similar engines without the combustion chamber. This caused a reduction in tube heating surface from 3,339 sq. ft. to 2,737 ft., and only increased the total firebox heating surface, including the arch tubes, from 189 sq. ft. to 242 sq. ft. Equating the tube heating surface to firebox heating surface of these Northern Pacific engines by the Vaughan formula, gives 965 sq. ft. of total equated heating surface for the engine without the combustion chamber and 911 sq. ft. for the engine with it.

At the time the Northern Pacific engines were built some considered it doubtful practice to make such a reduction in tube heating surface, but the results seem to have justified it, for the work on the Northern Pacific has been quite satisfactory. The adoption of the combustion chamber on these B., R. & P. decapod engines

combustion chamber and the shell to insure a free circulation, and this is tapered down to 4½ in. at the foundation ring, which is only 19 in. below the shell. At the back, the top of the foundation ring is but 3½ in. below the same point, so that the supply of water coming back into the water legs to take the place of that evaporated has very little drop in order to reach the lowest point.

The boiler is of the wagon-top type 80 in. in diameter, and contains 3,535.5 sq. ft. of heating surface, with 404 tubes 15 ft. 6 in. long. The introduction of the combustion chamber, of course, reduces the amount of tube heating surface, but experience on the Northern Pacific has proven that the increase of firebox heating surface more than offsets this loss, and that engines with a combustion chamber and less actual or even equated heating surface, steam fully as well as those without the combustion chamber and



Boiler of Decapod Locomotive; Buffalo, Rochester & Pittsburg.

more heating surface. Assuming the Vaughan formula to be correct, the larger firebox, by causing a better rate of combustion, delivers more heat to the tubes proportionately than the ordinary firebox can do, and so raises their efficiency per foot of length.

The back head has a slope of 22 in. and the fire door is formed by the outward flanging of the two sheets and the use of a welded plate ring to connect them. The large diameter of the shell and the high steam pressure (210 lbs.) require the use of very heavy sheets, which are [illegible] in., [illegible] in. and [illegible] in. thick. In the staying of the firebox the distribution of the flexible stays is somewhat different from that used in other engines recently illustrated in the *Railroad Gazette*. The usual arrangement is a single row of flexible stays up the front and back of the side sheets, with another across the top and clusters in the upper corners. In this case, with a firebox of nearly the same dimensions, there are three rows at

the front, and two at the back and top, with a clustering in the corners. This difference may be due to a variety of causes, but it serves to show that there is, as yet, no standard of practice in this detail.

The cylinders are 24 in. in diameter, with a piston stroke of 28 in. The slide valves are outside admission, operated by the Walschaert gear. The link is supported by a casting of special shape secured to the back of the guide yoke and the reverse shaft is carried in bearings bolted to the top of a cast steel cross-tie located between the second and third pair of driving wheels by which a direct connection of the reverse shaft arm with the radius bar is made possible. This arrangement of the Walschaert gear emphasizes again the facility which it affords for the cross bracing of the frames. In this case there are five points between the cylinders and the firebox where braces are put in.

The equalization is in two groups; the front group includes the truck and the first two pairs of drivers, and the rear group includes the three last pairs. It is arranged with flat yokes over the driving boxes and semi-elliptic springs under the upper rail of the frame taking the place of equalizing levers.

Another interesting feature of these engines is the unusually large capacity of the tender. The tank is of the water bottom type and has a capacity of 9,000 gallons, which is probably the largest water capacity ever provided in a locomotive tender.

In comparing the dimensions and ratios of these engines that follow, with those of other or similar types, it must be borne in mind that the introduction of the combustion chamber introduces a wide variation in all those ratios where either tube, firebox or total heating surface is considered, as compared with engines having no combustion chamber. In order to make such comparisons, the equated heating surfaces should be used.

The principal dimensions and ratios of these engines are:

Cylinder diameter	24 in.
Piston stroke	28 "
Wheel base, driving	19 ft. 0 "
" " total engine	28 " 4 "
" " total engine and tender	65 " 3¼ "
Weight on drivers	243,000 lbs.

New Feed-Water Heater for Locomotives.

F. H. Trevethick, General Manager of the Egyptian State Railroads, has adopted a new method of heating the feed-water for locomotives working between Cairo and Alexandria, which is described in a recent issue of the *Revue Industrielle*. The water is heated by the exhaust steam in combination with the waste heat of the smokebox gases.

The feed water is forced into the boiler by a horizontal motor pump placed on the left-hand side of the firebox, and using steam at full boiler pressure. The water passes from the pump through the first heater which is formed of a cylinder set vertically between the frames below the feed pump. It is 36 in. high and contains 90 steel tubes 7/16 in. in diameter, about which the exhaust steam is made to circulate. The steam condensed by the cold feed water is collected in the bottom of the cylinder and is removed by a pipe and cock. The feed water is taken from this first heater and sent on through a pipe 2½ in. in diameter to second and third heaters which are set horizontally outside the cylinders in such a way as to receive a part of the exhaust steam on its way to the stack. The condensing surface, which is the same in the three, is formed of 42 tubes 7/16 in. in diameter and 5 ft. 6 in. long, set in a cylindrical box. The second heater, which is on the right-hand side, is divided by a partition in such a way that the water traverses it twice in going through; in the third heater there is no such partition. The water passes from the third heater into a fourth heater, formed of an annular chamber placed in the smokebox and containing 265 water tubes of 1 in. inside diameter and 18 in. long, arranged in three concentric rings, which finally deliver to the boiler on its center line directly back of the smokebox.

The successive temperatures attained by the water in the course of its circulation through the four heaters are as follows:

Initial temperature on leaving tender	68 deg. F.
Temperature on leaving first heater	82 "
" " " second heater	171 "
" " " third heater	203 "
" " " fourth heater	280 "

The estimated saving of fuel, under ordinary working conditions, is about 16 per cent.; but compared with the ordinary methods of operation, using injectors, the saving is more than 17 per cent. The averages of the results obtained in eight runs with heaters and eight without the heaters are given in the following table:

Heaters.	No. of trips.	Coal.	Weight of train (net).	Speed per hour.	Temperature of feedwater.	Point of cut-off of stroke.
Used	8	2,887.5 lbs.	251.08 tons	48.11 miles	252 deg. F.	23.6 per ct.
Not used	8	3,722.4 "	254.10 "	46.62 "	...	25.1 " "

The distance from Cairo to Alexandria is about 129 miles, and is covered by express trains making four stops in 3 hrs. 5 min.; the longest run without a stop being 74.4 miles. The coal consumption on the run from Cairo to Alexandria is about 12 per cent. more than in the opposite direction, during the summer months, because of the continual northwest winds that prevail and to which the line is especially exposed. This increase is quite marked in the detailed record of coal consumption for the several trips of the test and obtains both with and without the use of the heaters.

The consumption of coal per net ton of weight hauled was 10.45 lbs. when the heaters were used and 13.30 lbs. when they were cut out, showing that the heaters effected a saving of 21.4 per cent., or that it was necessary to burn 27.3 per cent. more coal when they were not in use. The price of coal in Alexandria is about $5 per net ton, and the cost of installing the heaters was about $1,250 per engine, representing an annual charge of about $187.50 for interest and depreciation, while the annual saving effected in 720 trips would be about 300 tons, or a net gain of about $1,300, which would be more than sufficient to pay for the equipment in a year. In an engine of this character exhibited at Milan especial provision was made in the arrangement of the smokebox heater, so that it could be used as a superheater for the steam, in case it should be desired either to cut out the heaters or use an injector instead of the pump.

Manganese Bronze Staybolts.*

The *Revue Generale* published in March, 1901, a note regarding an attempt being made by the Northern Railway of France to do away with the grave troubles due to the breakage of copper staybolts in high-pressure locomotive boilers.

Since this time the experiments have been continued, and although they have not been extended to any large number of boilers they have sufficed to justify the step, taken in May, 1904, of using manganese bronze staybolts for all locomotive boilers with a pressure of more than 185 lbs. per sq. in. One of the tests was carried out with a series of 15 locomotives, of the compound 10-wheeled type (4.6.0) designed under the direction of Mr. du Bousquet, and built in the shops of the Northern Railway for the Ceinture Railway of Paris. Mr. Koechlin, who carried out the designs of these

*Translated from a paper by M. Rodrigue, Chief Engineer of Central Service, Northern Ry. of France, printed in the *Revue Generale des Chemins de Fer*, July, 1901.

engines, described them in the *Revue Générale* of May, 1904. We will only recall at present that the boiler pressure was 227 lbs. per sq. in.

As soon as these engines went into service there were a large number of failures of the copper staybolts, and it was decided to keep a special record of this trouble. As built, the boilers were equipped with manganese bronze staybolts in the three upper rows and in the corners of the fireboxes, and on account of the large number of failures of the copper stays when the engines first went into service, Mr. du Bousquet decided to equip two of the locomotives with manganese bronze staybolts throughout.

The 15 engines were delivered during the latter half of 1902 and a careful record kept of all staybolt failures. The results are given in the accompanying table, which has been drawn up to show for each engine and for the whole series the number of staybolts replaced during each half yearly period after going into service.

It will be seen from this table that on engines 60 and 65 which were equipped throughout with manganese bronze staybolts, not a single staybolt was replaced during three years service, and that at the end of 4½ years there had been replaced only 58 staybolts of which the heads had worn down. On the other 13 engines during the same period of 4½ years the number of broken staybolts replaced was 3,978 of copper and three of manganese bronze, while 376 bronze staybolts were replaced on account of worn heads. That is to say, it was necessary to replace nearly 10 times as many copper as bronze staybolts.

This is extremely interesting from the point of view of the cost, and of the inconveniences of all sorts which attend the replacing of staybolts, but it is still more striking if one considers the breakage of the staybolts which is the most important consideration from the point of view of safety. During the period of 4½ years only three bronze staybolts broke as against 3,978 of copper.

This result would have been even more strikingly in favor of the bronze bolts if the broken copper staybolts had not been replaced by bronze. It will be seen that the number of breakages of the copper bolts, which was 983 in the first six months, fell off rapidly. If the same rate of breakage had been maintained it would have been necessary in the 4½ years to replace practically all of the copper staybolts in the 13 engines.

These figures show clearly that manganeze bronze is superior to copper for staybolts for locomotive boilers with high pressure. If the initial cost is higher it is largely offset by the savings effected during the first few months in service.

TABLE SHOWING THE NUMBER OF FIREBOX STAYS REPLACED IN HALF YEARLY PERIODS ON EACH OF 15 LOCOMOTIVES, FROM JUNE, 1902, TO DEC. 31, 1906.

No. half yearly period	1.		2.		3.		4.		5.		6.		7.		8.		9.		Total No. of staybolts replaced on each engine.

Each firebox had originally 708 (C.) copper, 176 (B.) manganese bronze, a total of 884 stays, except on Engines 60 and 65, where all the firebox stays were of manganese bronze.

[1] Manganese bronze staybolt applied Jan. 17, 1903, and broken in September, 1906.
[2] Manganese bronze staybolt applied May 3, 1903, and broken in October, 1906.
[3] Of these, one manganese bronze staybolt was applied Nov. 14, 1902, and broken in September, 1906.
[4] These 3,978 copper staybolts were replaced because of breakage.
[5] Of these, 376 were replaced because the heads were worn, and 3 because of breakage. The 376 of which the heads were worn were all in the zone below the firebrick arch.

Standard Oil Company Fined $29,240,000.

In the United States District Court in Chicago, August 3, Judge K. M. Landis imposed on the Standard Oil Company of Indiana, as the penalty for accepting unpublished rates on 1,462 shipments of oil from Whiting, Ind., to East St. Louis, fines aggregating $29,240,000, or a $20,000 fine for each offense. The Judge at the same time recommended that a special grand jury be convened to consider the question of the guilt of the Chicago & Alton Railroad, which was the other party to these offenses, and this is being done.

The trial of these cases was begun in Chicago, March 4, and was finished April 13. Arguments for a new trial were heard but were denied, and Judge Landis then called John D. Rockefeller and other officials to testify as to the relations of the Standard Oil Company of Indiana to the Standard Oil Company of New Jersey. It was found that the Indiana corporation was owned by the other. It appears that the total of the assets of the Indiana company is far less than the amount of the fines.

The offense in this case was that of accepting from the Chicago & Alton a rate of 6 cents per 100 lbs. on oil in carload lots from Whiting, Ind., to East St. Louis, Ill., when the published tariff rate was 18 cents per 100 lbs. The oil company claimed that the railroad had misled it into the belief that 6 cents was the legal rate, and that tariffs showing it had been filed with the Interstate Commerce Commission, but the court held that, as the law required freight tariffs to be posted in the freight offices for public inspection, it was the oil company's duty to know whether or not the rate given to it was lawful.

The President of the Standard Oil Company of Indiana in a statement given to the newspapers, says that the 18-cent rate was a class and not a commodity rate, and that the chairman of the Chicago and St. Louis Traffic Association, the association issuing the 18-cent class rate, under oath testified that it was never applied and was never intended to apply to oil. Continuing, he says: "Thousands of tons of freight have been shipped from these points during the past 15 years under the same circumstances as the Standard shipments, and if the Standard is guilty in this case, so is practically every other shipper in this great manufacturing territory.

"The Standard Oil Company shipped about one-third of all the oil that went from Whiting to East St. Louis over the Eastern Illinois, the other two-thirds going over the Alton and the Burlington. On the trial of the case the defendant offered to show by witnesses who were on the stand that not only during the period of time covered by the indictment, but continuously from 1895, the Eastern Illinois had a lawful published and filed rate between Whiting and East St. Louis on oil of 6 cents per 100 lbs., and that the Standard Oil Company shipped at such rate over the Eastern Illinois more than 2,000 cars of oil each year during said period. To this offer the Government through its attorneys strenuously objected, and the court sustained such objection. The defendant contended, and still does contend, that this proof would have conclusively shown that the Standard Oil Company had no possible motive in shipping over the Alton, and thereby violating the law, when it might just as readily and conveniently have shipped all of its oil over the Eastern Illinois, and not have violated any law.

"Under such circumstances, and in view of the fact that petroleum had been openly carried over the three roads from Whiting to East St. Louis for from 10 to 14 years for 6 cents, it is a severe draft on human credulity for the prosecution to assert that 18 cents was the only possible lawful rate. The uncontradicted evidence also showed the Standard Oil Company was advised by the rate clerk of the Chicago & Alton that this 6-cent rate was filed with the Interstate Commerce Commission.

"The court, however, instructed the jury that the shipper must know not only what the rate was, but also that such rate was actually filed with the Interstate Commerce Commission. That is to say, the view of the court was that a shipper must know absolutely what was the legal rate, at the risk of suffering enormous penalties, in the event either that he was misinformed by the railroad company, or in the event that he did not exercise as much diligence as, in the judgment of the court, he should have exercised in ascertaining what the rate really was.

"Knowing that the rate on the Eastern Illinois was but 6 cents, having no reason for shipping over the Alton in preference to the Eastern Illinois, and able to ship all of its oil over the latter road, we insist that the facts, many of which the court did not permit us to show, not alone demonstrate innocence, but inherently forbid the idea of guilt."

The Railroads of Mexico.*

BY ERDIS G. ROBINSON, C.E.
Formerly of the Engineering Department of the Mexican Central.

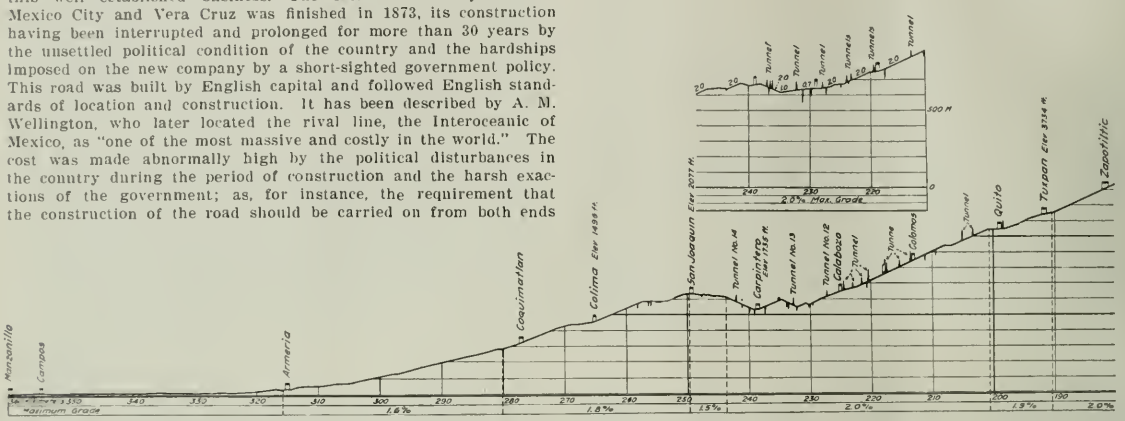
II.

THE PRINCIPAL RAILROADS.

Vera Cruz had early become the main Atlantic seaport of Mexico; even before the advent of the railroad a considerable business was handled at that port. The town was connected with the City of Mexico by an excellent road which became established as a regular traffic route. Therefore it was to be expected that the first line of railroad to be built in the country should be one to handle this well established business. The Mexican Railway between Mexico City and Vera Cruz was finished in 1873, its construction having been interrupted and prolonged for more than 30 years by the unsettled political condition of the country and the hardships imposed on the new company by a short-sighted government policy. This road was built by English capital and followed English standards of location and construction. It has been described by A. M. Wellington, who later located the rival line, the Interoceanic of Mexico, as "one of the most massive and costly in the world." The cost was made abnormally high by the political disturbances in the country during the period of construction and the harsh exactions of the government; as, for instance, the requirement that the construction of the road should be carried on from both ends simultaneously, which entailed extremely heavy transportation expenses on construction materials. Mr. Wellington has estimated that the cost of construction was doubled by such hindrances. Therefore, dividing the actual cost by two, he estimated that the 223 miles of comparatively light work cost about $40,000 a mile, while the 60 miles of heavy work cost about $185,000 a mile, thus making an average for the whole road of $70,670 a mile. Notwithstanding this heavy cost of construction, the grades and curves are more severe than those of any other line in Mexico. On the mountain section there are uncompensated grades of 4 per cent., with curves of 325 ft. radius (about 18 deg.), often with no tangent between reverse curves. Although the volume of business is large, operating expenses are high. The high cost of construction also makes interest charges large.

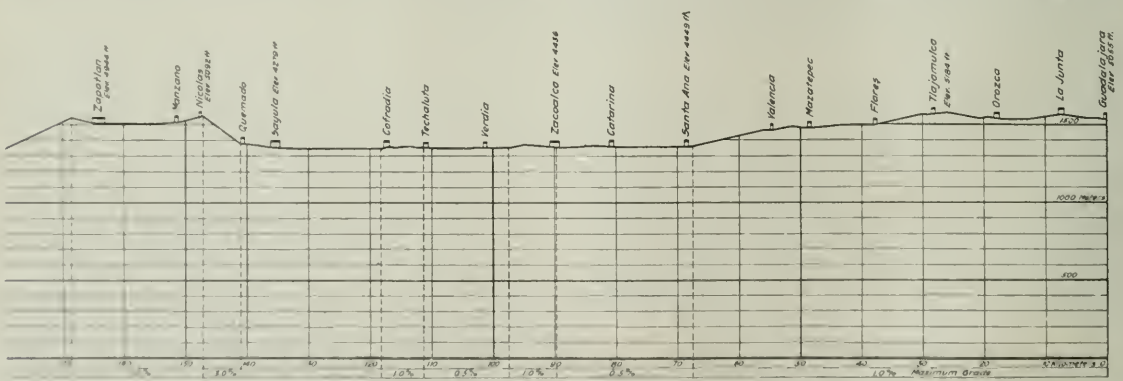
The volume of business at Vera Cruz later tempted other English capitalists to undertake construction of a second line from that port to Mexico City. The preliminary survey of this line was in charge of Mr. Wellington. His description of the work in a paper presented to the American Society of Civil Engineers is of unusual interest. The new line, the Interoceanic, parallels the older road in that it connects the same terminal cities, but otherwise departs widely from it. Although built to handle the business between Vera Cruz and Mexico City, its length was materially increased in order to reach two important cities, Jalapa and Puebla, which were not on the line of the Mexican Railway, this location being entirely consistent with the principles so ably advocated by Mr. Wellington in his "Economic Theory of Railroad Location." The Mexican Railway was projected to handle the through business and neglected local possibilities; the other road was lengthened so as to include certain intermediate cities at the cost of longer haul on its through traffic. It is interesting to note that it has been found advisable to alter both locations. The Mexican Railway has built a branch line to reach the city of Puebla, while the Interoceanic has built a cut-off which reduces the length of through haul by which that same city is left at one side.

The Interoceanic Railway was built with narrow gage, the grade kept down to 2 per cent. (uncompensated) and curvature to 289 ft. radius (20 deg.). The 2 per cent. grade extends unbroken for nearly 75 miles. The estimated cost of this road was $40,000 a mile, about one-half of that of the earlier road. The gross earnings are about the same for both roads, not far from $3,000,000 a year.



Profile of the Mexican Central's Line from Guadalajara to Manzanillo (1).

Extending to the south from Vera Cruz is one of the newer roads, the Vera Cruz & Pacific, built to exploit the rich tropical lands and to connect with the Tehuantepec National Railway, which crosses the isthmus of that name. The Tehuantepec road is interesting in that its construction was undertaken directly by the Mexican Government and marked the entrance of the government into the railroad field. The road follows the route of the line proposed by Captain Eads for a ship railroad and crosses a summit of only 850 ft. elevation.



Profile of the Mexican Central's Line from Guadalajara to Manzanillo (2).

The second company to enter Mexico was the Mexican Central. The organization of this road in 1880 was followed vigorously by surveys and construction, and in 1884 the line was completed from El Paso to the City of Mexico, 1,225 miles. This was the first road to be built under a law passed in 1880 to encourage railroad building. It received a government subsidy of $15,000 a mile, free importation of construction material and exemption from all taxation for 50 years.

The general location of this road has met with considerable

*The first article was published in the *Railroad Gazette* of July 12, 1907.

criticism. The line follows the entire length of the high plateau in the western part of Mexico and therefore its through route for international business is unnecessarily long. It was projected by men who had been building in the western part of the United States roads like the Atchison, Topeka & Santa Fe whose prosperity was dependent on the future development of the tributary country. The Mexican Central was located on the same theory. That to depend largely on local business was the correct view is indicated by the fact that the international freight and passenger business of the road is only 30 per cent of its total traffic, and that much of the local traffic comes from the northern part of the road. The growth of this company has been constant. The branch to Tampico, the second most important port in Mexico, was finished in 1890. During 1908 a line to the Pacific coast at Manzanillo will be put in operation. The Tampico branch makes the sharp descent from the plateau over a country similar to that crossed by the Mexico City-Vera Cruz lines, while the Pacific extension crosses the great Sierra Madre range. Though penetrating a more difficult country than is encountered by any other Mexican road, this extension is to have the easiest grades and lightest curvature of any line to either coast, a result which will be obtained only after most careful location and costly work. A Fellow of the Royal Geographical Society has said in regard to this extension:

"I have seen some of the most apparently hopeless problems of circumvention overcome, such as the magnificent bit of line from Wellington in Cape Colony; the 5,000-ft. climb of the La Guira & Caracas Ry. in Venezuela; the stupendous passage over the Sierras of the Sao Paulo Ry. in Brazil, and the clever piece of construction work on the Mexican Railway. In my opinion the new line from Tuxpan to Colima [the Mexican Central's Pacific extension] is incomparably more imposing than any of these and infinitely more difficult."

A topographic map and profile of this new extension are shown. The following table shows the rates of grade and costs of construction of certain mountain divisions of various Mexican railroads.

Table 1. *Rates of Grade and Cost of Construction on Mountain Divisions of Mexican Railroads.*

Name of railroad.	Location of grade.	Length of grade, miles.	Average cost per mile (U. S. currency).	Rate, grade, per cent.	Radius of curvature (ft.).	Deg. curve (100 ft. chord).	Gage.
Mexican Central	Tampico division	27	....	3	262	22	S.
" "	Cuernevaca division	25	....	3½	..	..	S.
" "	Colima extension	100	$50,000	2	627	9	S.

" "	Tuxpan-Colima	4	200,000	2	627	9	S.
Mexican Railway	Vera Cruz, main line	60	185,000	5	320	18	S.
" "	Vera Cruz, main line	283	70,670	5	320	18	S.
Interoceanic	Vera Cruz, main line	73	40,000	3	262	22	N.

S = Standard gage.; N = Narrow gage.

The Mexican National Railway, now the National Railway of Mexico, was projected to form a short line from Mexico City. It was promoted by men interested in the Denver & Rio Grande and other narrow gage roads in this country, and was intended to form part of a large system of affiliated narrow gage lines. The Mexican National operated for many years at a great disadvantage in handling its through business. A few years ago it was changed to standard gage. This change made, the fact that it is much shorter than any [illegible] gives it an [illegible].

The Mexican International Railway [illegible] interests crossing the [illegible] from the international boundary at Eagle Pass to the rich mining city of Durango. This was built standard gage and through a country which required only light grades. It crosses the Mexican Central at Torreon. For many years it was virtually a feeder of that system and by means of a traffic agreement served as a short outlet for the through business of that road. Mineral products form a larger percentage of this company's traffic than of any other of the larger roads of Mexico, being something like 75 per cent.

Is it not possible that the promoters of these roads have builded better than they knew, in view of recent developments in the railroad situation in Mexico? The proposed absorption of all these railroads except the Mexican Railway in the government merger by which competition will be done away with, makes it appear fortunate that the different lines were laid out on different principles—some to promote local business, some to handle through traffic, and some to care largely for mineral traffic. The business coming to the railroads in Mexico has not generally been of sufficient magnitude to encourage the construction of many competing parallel lines so that the way was made easy for the formation of government's merger.

(To be continued.)

Topography of the Mexican Central's Pacific Coast Extension.

Standard Specifications for Structural Timber.

Committee Q of the American Society for Testing Materials at the annual meeting of the society last month presented the following proposed specifications for grading structural timber:

STANDARD DEFECTS.

The definitions of standard defects are as follows:

Measurements which refer to the diameter of knots or holes should be considered as referring to the mean or average diameter.

1. *Sound Knot.*—A sound knot is one which is solid across its face and which is as hard as the wood surrounding it; it may be either red or black, and is so fixed by growth or position that it will retain its place in the piece.

2. *Loose Knot.*—A loose knot is one not firmly held in place by growth or position.

3. *Pith Knot.*—A pith knot is a sound knot with a pith hole not more than ¼ in. in diameter in the center.

4. *Encased Knot.*—An encased knot is one which is surrounded wholly or in part by bark or pitch. Where the encasement is less than ⅛ in. in width on both sides, not exceeding one-half the circumference of the knot, it shall be considered a sound knot.

5. *Rotten Knot.*—A rotten knot is one not as hard as the wood it is in.

6. *Pin Knot.*—A pin knot is a sound knot not over ½ in. in diameter.

7. *Standard Knot.*—A standard knot is a sound knot not over 1½ in. in diameter.

8. *Large Knot.*—A large knot is a sound knot, more than 1½ in. in diameter.

9. *Round Knot.*—A round knot is one which is oval or circular in form.

10. *Spike Knot.*—A spike knot is one sawn in a lengthwise direction; the mean or average width shall be considered in measuring these knots.

11. *Pitch Pockets.*—Pitch pockets are openings between the grain of the wood containing more or less pitch or bark. These shall be classified as *small, standard* and *large* pitch pockets.

(*a*) *Small Pitch Pocket.*—A small pitch pocket is one not over ⅛ in. wide.

(*b*) *Standard Pitch Pocket.*—A standard pitch pocket is one not over ⅜ in. wide, or 3 in. in length.

(*c*) *Large Pitch Pocket.*—A large pitch pocket is one over ⅜ in. wide, or over 3 in. in length.

12. *Pitch Streak.*—A pitch streak is a well-defined accumulation of pitch at one point in the piece. When not sufficient to develop a well-defined streak, or where the fiber between grains, that is, the coarse-grained fiber, usually termed "Spring wood," is not saturated with pitch, it shall not be considered a defect.

13. *Wane.*—Wane is bark, or the lack of wood from any cause, on edges of timbers.

14. *Shakes.*—Shakes are splits or checks in timbers which usually cause a separation of the wood between annual rings.

15. *Rot, Dote and Red Heart.*—Any form of decay which may be evident either as a dark red discoloration not found in the sound wood, or the presence of white or red rotten spots, shall be considered as a defect.

16. *Ring Shake.*—An opening between the annual rings.

17. *Through Shake.*—A shake which extends between two faces of a timber.

STANDARD NAMES FOR STRUCTURAL TIMBERS.

The following trade names are recommended:

1. *Southern Yellow Pine.*—Under this heading two classes of timber are used, (*a*) longleaf pine, (*b*) shortleaf pine.

It is understood that these two terms are descriptive of quality, rather than of botanical species. Thus, shortleaf pine would cover such species as are now known as North Carolina pine, loblolly pine and shortleaf pine. "Longleaf pine" is descriptive of quality, and if Cuban, shortleaf or loblolly pine is grown under such conditions that it produces a large percentage of hard summer wood, so as to be equivalent to the wood produced by the true longleaf, it would be covered by the term "longleaf pine."

2. *Douglas Fir.*—The term "Douglas fir" to cover the timber known likewise as yellow fir, red fir, western fir, Washington fir, Oregon or Puget Sound fir or pine, norwest and west coast fir.

3. *Norway Pine*, to cover what is known also as "red pine."

4. *Hemlock*, to cover southern or eastern hemlock; that is, hemlock from all states east of and including Minnesota.

5. *Western Hemlock*, to cover hemlock from the Pacific coast.

6. *Spruce*, to cover eastern spruce; that is, the spruce timber coming from points east of Minnesota.

7. *Western Spruce*, to cover the spruce timber from the Pacific coast.

8. *White Pine*, to cover the timber which has hitherto been known as white pine, from Maine, Michigan, Wisconsin and Minnesota.

9. *Idaho White Pine*, the variety of white pine from western Montana, northern Idaho and eastern Washington.

10. *Western Pine*, to cover the timber sold as white pine coming from Arizona, California, New Mexico, Colorado, Oregon and Washington. This is the timber sometimes known as "Western yellow pine," or "Ponderosa pine," or "California white pine," or "Western white pine."

11. *Western Larch*, to cover the species of larch or tamarack from the Rocky Mountain and Pacific coast regions.

12. *Tamarack*, to cover the timber known as "Tamarack," or "Eastern Tamarack," from states east of and including Minnesota.

13. *Redwood*, to include the California wood usually known by that name.

STANDARD SPECIFICATIONS FOR BRIDGE AND TRESTLE TIMBERS.

(To be applied to solid members and not to composite members.)

General Requirements.

Except as noted all timber shall be cut from sound trees and sawed standard size; close grained and solid; free from defects such as injurious ring shakes and crooked grain; unsound knots; knots in groups; decay; large pitch pockets, or other defects that will materially impair its strength.

Standard Size of Sawed Timber.—Rough timbers when sawed to standard size, shall mean that they shall not be over ¼ in. scant from actual size specified. For instance, a 12-in. x 12-in. shall measure not less than 11¾ in. x 11¾ in.

Standard Dressing of Sawed Timbers.—Standard dressing means that not more than ¼ in. shall be allowed for dressing each surface. For instance, a 12-in. x 12-in. shall after dressing four sides, not measure less than 11½ in. x 11½ in.

Stringers

1. *Longleaf Yellow Pine and Douglas Fir.*—Shall show not less than 80 per cent. of heart on each of the four sides, measured across the sides anywhere in the length of the piece; loose knots, or knots greater than 1½ in. in diameter, will not be permitted at points within 4 in. of the edges of the piece.

2. *Longleaf Yellow Pine, Shortleaf Pine, Douglas Fir and Western Hemlock.*—Shall be square edged, except it may have 1 in. wane on one corner. Knots must not exceed in their largest diameter one-quarter the width of the face of the stick in which they occur. Ring shakes extending not over one-eighth of the length of the piece are admissible.

Caps and Sills.

1. *Longleaf Yellow Pine and Douglas Fir.*—Shall show 85 per cent. heart on each of the four sides, measured across the sides anywhere in the length of the piece; to be free from knots over 2½ in. in diameter; knots must not be in groups.

2. *Longleaf and Shortleaf Yellow Pine, Douglas Fir and Western Hemlock.*—Shall be square edged, except it may have 1 in. wane on one corner, or ½ in. wane on two corners. Knots must not exceed in their largest diameter one-quarter the width of the face of the stick in which they occur. Ring shakes extending not over one-eighth the length of the piece are admissible.

Posts.

1. *Longleaf Yellow Pine and Douglas Fir.*—Shall show not less than 75 per cent. heart, measured across the face anywhere on the length of the piece; to be free from knots over 2½ in. in diameter, and must not be in groups.

2. *Longleaf and Shortleaf Yellow Pine, Douglas Fir and Western Hemlock.*—Shall be square edged, except it may have 1 in. wane on one corner, or ½ in. wane on two corners. Knots must not exceed, in their largest diameter, one-quarter the width of the face of the stick in which they occur. Ring shakes shall not extend over one-eighth of the length of the piece.

Longitudinal Struts or Girts.

1. *Longleaf Yellow Pine and Douglas Fir.*—Shall show one face all heart; the other face and two sides shall show not less than 85 per cent. heart, measured across the face or side anywhere in the piece; to be free from knots 1½ in. in diameter and over.

2. *Longleaf and Shortleaf Yellow Pine, Douglas Fir and Western Hemlock.*—Shall be square edged and sound; to be free from knots 1½ in. in diameter and over.

Longitudinal X-Braces, Sash Braces and Sway Braces.

1. *Longleaf Yellow Pine and Douglas Fir.*—Shall show not less than 80 per cent. heart on two faces and four square edges; to be free from knots over 1½ in. in diameter.

2. *Longleaf and Shortleaf Yellow Pine, Douglas Fir and Western Hemlock.*—Shall be square edged and sound; to be free from knots 2½ in. in diameter and over.

SPECIFICATIONS FOR CAR SILLS AND CAR FRAMING FOR FREIGHT CARS.

The following specifications are submitted as a preliminary report, it being the intention of the committee to give these further consideration during the coming year:

General Rules.

All timber shall be sound, sawed standard size, square edged, unless otherwise specified, free from unsound or loose knots, knot holes and ring shakes.

Standard Size of Sawed Timbers.—Rough timbers when sawed to standard size, shall mean that they shall not be over ¼ in. scant from actual size specified. For instance, a 12-in. x 12-in. shall measure not less than 11¾ in. x 11¾ in.

Standard Dressing of Sawed Timbers.—Standard dressing means that not more than ¼ in. shall be allowed for dressing each surface. For instance, a 12-in. x 12-in. shall after dressing four sides, not measure less than 11½ in. x 11½ in.

Sills.

1. *Longleaf Pine or Douglas Fir.*—Shall be square edged and show not less than 85 per cent. heart on wide faces, measured anywhere in the length of the piece; sound, tight knots less than 2 in. in diameter and standard pitch pockets permitted when not clustered; grain must be close and straight.

2. *Longleaf Pine, Shortleaf Pine, Norway Pine, Western Pine, Douglas Fir, Western Hemlock.*—Same specifications as for (1), except that sound, tight knots less than 2½ in. in diameter, if well scattered, will be permitted in longleaf pine and Douglas fir; wane not to exceed 10 per cent. of the width of adjacent faces will be permitted on opposite corners not to exceed one-half the length of the piece.

End Sills, End Plates, Posts, Braces and Carlines.

1. *White or Red Oaks.*—Shall show not less than 85 per cent. heart on each face, measured anywhere in the length of the piece; well-scattered, standard knots permitted.

2. *Longleaf Pine or Douglas Fir.*—Shall show not less than 85 per cent. heart on each face, measured anywhere in the length of the piece; must be close, straight-grained and free from all defects, except well-scattered, sound, tight knots, not over 1 in. in diameter.

Side Plates.

1. *Longleaf Pine, Douglas Fir.*—Shall show not less than 85

per cent. heart on wide faces, must be close straight grained, well scattered standard knots and standard pitch pockets permitted.

2. *Longleaf Pine, Douglas Fir, Western Pine, Western Hemlock, Shortleaf Pine.*—Same as for (1) except that a few well scattered, large knots will be permitted in longleaf pine and Douglas fir.

FRAMING FOR BUILDINGS.

The following specifications for framing for buildings are submitted as a preliminary report, it being the intention of the committee to give further consideration to these during the coming year.

General Requirements.

All timber shall be cut from sound timber and sawed standard size, close grained, free from ring shakes, decay and unsound knots, or knots and other defects that will materially impair its strength and durability.

Standard Size of Sawed Timber.—Rough timbers when sawed to standard size, shall mean that they shall not be over ¼ in. scant from actual size specified. For instance, a 12-in. x 12-in. shall measure not less than 11¾ in. x 11¾ in.

Standard Dressing of Sawed Timbers.—Standard dressing means that not more than ¼ in. shall be allowed for dressing each surface. For instance, a 12-in. x 12-in. shall after dressing four sides, not measure less than 11½ in. x 11½ in.

Posts—Longleaf Yellow Pine.

Will admit 1 in. wane on corners as measured on faces of timber. Must be free from knots 3 in. in diameter or over, and knots must not be in groups.

Beams and Girders—Longleaf Yellow Pine.

Will admit 1 in. wane on one corner as measured on faces of timber. Sound knots less than 3 in. in diameter will be permitted on the vertical faces at points not less than one-quarter the depth from the edge of the piece; sound, tight knots not exceeding 1½ in. in diameter at other points, provided they are not in clusters.

Joists—Longleaf Yellow Pine, Shortleaf Yellow Pine.

All joists over 2 in. in thickness to comply with the requirements for beams and girders.

Joists 2 in. in thickness will admit sound knots, none of which in 2 x 4's should be larger than 2 in. in diameter on one or both sides of the piece, and on wider stock which do not occupy more than one-third of the cross-section at any point throughout its length if located at the edge of the piece; or more than one-half of the cross-section if located away from the edge; pith knots, or smaller or more defective knots which do not weaken the piece more than the knot aforesaid; will admit of seasoning checks, firm red heart, heart shakes that do not go through, wane three-quarters deep on edge, one-quarter the width and one-third the length of the piece, pitch, sap stains, pitch pockets, splits in ends not exceeding in length the width of the piece, a limited number of small worm holes well scattered, and such other defects as do not prevent its use as substantial structural material.

Railroad Legislation in Connecticut.

BY CLARENCE DEMING.

In a railroad sense the seven months' session of the Connecticut legislature just ended, the longest in the history of the state, has been, if not important, at least most incongruous and fantastic. The session opened last January under peculiar and exceptional conditions. The anti-corporation wave sweeping over the country had struck Connecticut also, though with one of its minor surges. There was sharp criticism of railroad influence over-exercised in the lobby, albeit it had been modified in the legislature of 1905 in which the persuasive tongue of President Mellen in his so-called "open air" lobby had been more effective than the usual agencies. Meanwhile the Mellen policy of absorbing street railway lines had practically combined interests formerly at war, which new condition the legislature now faced for the first time. But the climax of that policy in the state by which, under the lease of the Connecticut Railway & Lighting Company's property some $18,000,000 of watered stock had become a dividend paying security, had, just before the meeting of the legislature, been sharply assailed in the press and apparently provoked public resentment. It had been carried through under the lax legislation of former years and the added laxity of a flabby and "political" railroad commission; and on the face of the disclosures, it seemed pretty certain that the legislature would seek the back track and pass severe statutes to secure honest street railway capitalization.

This natural forecast fell far short of fulfillment and, indeed, was reversed. Unexpectedly at the opening of the legislature trolley schemes came in like a flood. The state is small, its populous centers laced with trolleys and practically all of its really profitable street railway territory long ago occupied; yet, if it had been virgin street railway soil, the onset of trolley enterprises could hardly have been greater. They were some 24 in number besides those of minor importance. Most of them were of the "cross country" type and not a few of them called for layout through regions well [illegible] of patronage. In the case of a [illegible] the travels were parallel to the steam lines. Others appeared to involve pocket charters pure and simple—charters held merely for ulterior sale with no intention to build. In one particular region there was also a suspicious grouping of charters suggesting future consolidation and long distance paralleling, especially when coupled with power companies securing [illegible] privileges. What had actually come to pass was that trolley promoters instead of being deterred by the public clamor against the Railway & Lighting "deal" had been stirred by its success to try to repeat it by securing charter rights, building the new trolleys on bonds placed at a high broker's commission with the investing public and bonusing the stock among the projectors.

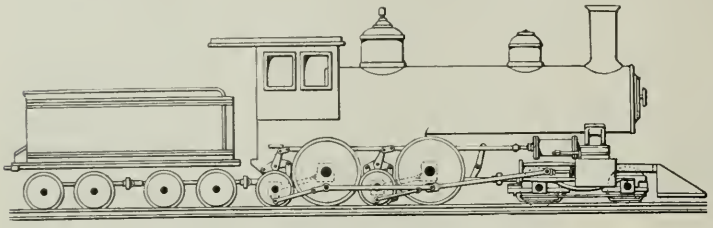
The promoters combined and went to work cleverly, drawing the "farm interest" into their net. In a Connecticut legislature this farm interest is very potential and, when united, dominant in the lower house, which at the last session contained 91 representatives who were farmers by vocation—in a house containing 255 members altogether—besides other members not farmers themselves but representing farm towns. This farm interest is to some extent consolidated in the granges of the state and much more effectively by the so-called "Farmers' Association" made up of members of the sitting legislature and holding a caucus at the opening of each legislative week to pass upon pending measures bearing on rural interests. Almost none of these farm members had seen previous legislative service and their ignorance of railroad and street railway questions was dense. On this soft timber, the more workable because green, the specious reasonings of the promoters were struck hard and cut deep. The benefits of the cities and larger towns from the trolleys as compared with the rural regions were contrasted. If the cities had parallel lines why couldn't the country have them too? The New Haven Railroad Company having now acquired the trolley roads, future extension must be left mainly to private enterprise; and such private enterprise would never try—in times like these with solid investments paying 5 per cent.—to link the farms with the cities unless "baited" by free gifts of street railway stocks as a bonus. These reasonings addressed to class selfishness prevailed in the lower house and, in most cases, in the Senate also. They were in brief: "Give us the trolleys and let the financing take care of itself." And the state of Connecticut, a *quasi* conservative and certainly a moneyed commonwealth, has been thus placed in the humiliating and discreditable position of approving dishonest street railway finance.

The trolley projects—except one or two which were a direct menace to the New Haven railroad—did not go through without stout resistance by Governor Woodruff who redeemed his pre-election pledge that his administration would be businesslike and not for party or persons. He sent in veto after veto of trolley charter bills, some 20 in number altogether. In almost all of these he urged in vain the undue opportunity for stock watering. But in all but two or three cases the bills were passed over his veto and so often that the certainty of an overruling vote became a theme of legislative laughter and jest. The temper of the Connecticut lawmakers was further indexed by the defeat of a bill for more careful and responsible engineering estimates of the value of new street railways as a basis for the amount of bonded debt. So far as it bears on street railways the substantial outcome of the session is the authorization of a new crop of watered trolley projects and pocket charters; and, in a larger civic sense, a most discouraging exhibit of blended ignorance, selfishness and fiscal laxity in the legislature of a New England state.

Steam railroad legislation of the session while not voluminous was stormy and the anti-corporation feeling much more in evidence than usual. The railroad interest secured control of the railroad and judiciary committees but in the latter case not without a contest which left behind bad blood, led to recrimination in the Senate and, incidentally, the passing of the lie between two Senators as to the nature and purpose of a joint interview with President Mellen. Sharp criticism of the New Haven company and personal attack upon its regular legislative counsel led to his withdrawal and the substitution of a new railroad attorney. Once again a bill was drawn modifying the four days car detention statute of the state; and, again, for the third successive legislative session it was withdrawn owing to resistance of the farm element and certainty of defeat in the lower house. Soon after the session opened the bill providing for issue of the New Haven company's convertible debentures was introduced with a pendant relating to mergers which, seemingly, added nothing to the corporation's existing charter powers. After a brief reverse in the lower house the measure went through and in the sequel, it appeared that the annex cleared definitely the way, under Connecticut law, for the absorption of the Boston & Maine. Under new laws records of mergers by a railroad company must be filed with the Secretary of State; towns and cities can appeal for proper facilities in street railway service; hours of labor of railroad telegraphers and train despatchers are regulated and reduced; towns and cities can appeal to the railroad commission for orders to stop trains and street railway employees are

subjected to the same penalty as those of a railroad in case of injury to passengers. Except at minor points the appeal of the Governor for larger powers of the railroad commission was disregarded, the legislature possibly thinking that a body that has not exercised powers already possessed would not use larger ones if granted. Bitter criticism of the work of state commissioners and other state officers in the lobby led to the suppression during the session of their usual pernicious activity.

In the way of indirect legislation that may include railroads should be noted the outcome of an acute telephone contest which still leaves with the state courts the question of the public necessity and convenience in authorizing rival lines. The result hints somewhat strongly at the theory of "natural monopoly" in public utilities though it is doubtful whether many members of the legislature recognized the fact. Just at the close of the session the Governor's insistent demand for a temporary commission to investigate the subject of public utilities legislation came to a head forced by his threat to summon an extra session if the legislature failed to act. A brief and loose law, naming the commissioners and thus taking their appointment out of the Governor's hands, was passed—in the lower house by a party vote. The commission of five is a weak one, deeply infused with politics, four of the five state officers present or past and, presumptively, representing corporation interests by which they were named. It is a body whose opportunity is likely to be larger than its courage or its works.



Bothwell Principle Applied to 8-Wheel Locomotive.

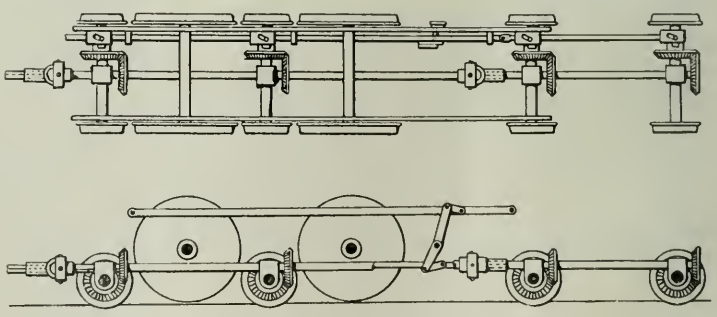
The Bothwell Locomotive.

A novel and interesting scheme for increasing locomotive tractive power and securing the additional adhesion to utilize this power, has been devised by George A. Bothwell, of Owen Sound, Ontario. Briefly, Mr. Bothwell's scheme consists in providing a second set of driving wheels of much smaller diameter than the regular drivers, to give the requisite greater tractive effort, and a system of gearing for utilizing the adhesion of the engine truck, and also of the tender, if desired. When the small drivers are on the rail the large ones are lifted clear of it and *vice versa*. The purpose of the scheme is a locomotive of maximum hauling capacity with minimum weight; that is, to provide within locomotives of the usual types means for taking over ruling grades trains which they would otherwise be unable to haul, or for which helper service would be needed.

The photograph and sketches herewith show the application of the idea to an eight-wheel locomotive. The change from one system to the other is effected by a cylinder controlled from the cab and worked either by steam or air. The working of the mechanism is such that by means of suitable clutches the gearing for driving the trucks is thrown into and out of service simultaneously with the changes between drivers. The mechanical details of the scheme are very ingeniously worked out.

The locomotive shown in the illustration was rebuilt at the Hicks Locomotive & Car Works, Chicago Heights, Ill. The auxiliary drivers are 32 in., the large ones 60 in., and the engine truck only is utilized to give the extra adhesion. This engine was equipped to demonstrate the feasibility of the idea. In a test made at the works, the engine running on the large drivers stalled with 25 empty cars on the grade on which the test was made, after taking 23 cars over. With the Bothwell mechanism it took 47 cars over and stalled with 50, showing a hauling capacity of about double the ordinary.

The scheme would appear to be limited to types of locomotives having not more than three pairs of drivers, on account of the necessary lengthening of the wheel-base. However, it is the inventor's idea that with such a mogul or 10-wheeler he would be able to take over the road trains for which much more powerful locomotives are now used and which may require helper service in addition on the critical grades. He would thus have the lower first cost and operating economies and advantages of the lighter locomotive, which it is considered would more than warrant the cost and maintenance, as well as the complication, of the additional mechanism for increasing its hauling capacity when desired. The Bothwell Locomotive Co. has been formed with headquarters at Owen Sound, Ont.



Sketch of Gear Mechanism; Bothwell Locomotive.

The Bothwell Locomotive.

GENERAL NEWS SECTION

NOTES.

In Cole County, Mo., the Missouri Pacific has been indicted on 14 counts for violating the law forbidding the employment of telegraph operators more than eight hours a day.

At a "family talk" of the Traveling and District Passenger and Freight Agents of the Wisconsin Central which was held in Milwaukee last week 52 traffic men employed by the company in various distant cities were present.

The Louisiana state railroad commissioners have ordered the Pontchartrain Railroad within 60 days to provide better cars for its passenger trains, and to run its trains to and from the Louisville & Nashville Central street station in New Orleans.

The principal railroads of Nevada have secured temporary injunctions against the new railroad commission of that state forbidding it to disturb freight rates. A hearing on the question of making the injunction permanent will be given on September 16.

The Central of New Jersey has begun suit at Easton, Pa., to test the validity of the Pennsylvania law passed this year, to go into effect October 1, reducing all passenger fares to 2 cents a mile. The Central avers that the proposed reduction would reduce its receipts $100,000 a year.

In Cole County, Missouri, the Missouri Pacific Railway has been indicted by the Grand Jury for failing to run at least one train each day over the Bagnell branch, and also, on 14 counts, for violating the law forbidding the employment of telegraph operators more than eight hours a day.

The New York, New Haven & Hartford now uses electric motors on all main line passenger trains which begin or end their trips at Portchester and New Rochelle, about 15 each way. All are suburban trains, most of them running to New York in the morning and from New York in the afternoon.

Complaint has been made to the Interstate Commerce Commission that the fare over the Michigan Central from Michigan City, Ind., to New Buffalo, Mich., 10 miles, which is 30 cents, is extortionate, to the extent of 50 per cent., 2 cents a mile being the intrastate rate both in Indiana and in Michigan.

According to a press despatch from Omaha, an order has been issued by the Union Pacific that between all stations where there is another railroad competing for passenger traffic, the rates on the Union Pacific shall be as low as those of the competitor; which will result in fares less than 2 cents a mile in many cases.

On the Mexican Central and the Mexican National Railroads second class fares and third class cars have been abolished. Henceforth there will be two classes, first and third, and the third class passengers will be carried in the cars hitherto used for second class. For third class passengers only 33 lbs. of baggage will be carried free.

The Adams Express Co. no longer does business on the Boston & Albany, and it has closed its offices at those stations between Boston and Worcester, where it has hitherto done local business, except those places which are reached also by the New York, New Haven & Hartford. The American Express now has exclusive rights on the B. & A.

The Isthmian Canal Commission announces that the excavation on the canal during July was as follows: Culebra division, 770,570 cu. yds.; Gatun, 74,765 cu. yds.; dredging in canal prism, 212,710 cu. yds.; total, 1,058,776 cu. yds., against 780,957 cu. yds. in June. This is the largest month's work yet done. The rainfall for the month is reported at 9.5 in., against 14 in. in June.

The arrests made on the Pennsylvania Railroad lines last month by the company's police numbered 638. Of these arrests, 237 were for illegal train riding. Of this number 31 paid the fare, while 107 were sent to jail and 66 were fined. The report shows that 147 arrests were made for trespassing, 63 for larceny and burglary and 13 for breaking into cars; and for stoning trains 13.

The Grand Trunk Railway has appealed to the Supreme Court against the recent order of the Canadian Railway Commission to run third-class cars on one passenger train each way daily, with tickets at 2 cents a mile. It appears that the Commission's order requires only what was required by a provision in the company's charter which, though never lawfully abrogated, has remained a dead letter.

In the Federal Court at Chicago, August 3, indictments were returned against the New York, Chicago & St. Louis and the Lehigh Valley railroads for granting illegal rebates on shipments of freight made in cars of the Overland Refrigerator Express Co. It is charged that commissions paid to the refrigerator company were used to reduce the [illegible] The [illegible] of the [illegible] erator [illegible]

The Chicago, Milwaukee & St. Paul, the Chicago & North-Western and the Wisconsin Central have given notice that on [illegible] they will reduce fares in Wisconsin to 2 cents a mile. [illegible] the Wisconsin Central say [illegible] the [illegible] of competition. The [illegible] & [illegible] bring it within [illegible]

At Jamaica, N. Y., last week Ralph Peters, President of the Long Island Railroad, and James A. McCrea, General Superintendent, were arrested on a criminal charge in connection with a railway crossing accident, and held in $1,000 bail each to await the action of the Grand Jury. The arrests were made on order of a coroner who declared these officers criminally negligent in failing to safeguard a crossing where two persons in an automobile were killed about two weeks ago.

At Palestine, Tex., one night last week, according to a press despatch, George Brush, a citizen of the state of Kentucky, presumably traveling in Texas, was arrested and fined $10 for taking a drink of whiskey while on a train of the International & Great Northern Railroad. According to the statement Mr. Brush had the whiskey in a flask, which he carried in his pocket, and he was only "sampling" it. In the eyes of the law, however—a law lately passed—drinking is drinking, and the drinker had to surrender to the sheriff.

The state of Arkansas, like Alabama, has a law designed to prevent railroads from transferring law suits from the state to the federal courts, the penalty being the forfeiture of the property of the company to the state. The Chicago, Rock Island & Pacific offended in this respect recently, and the Secretary of State started to apply the law, but, on application to the United States Circuit Court at St. Paul, August 5, the road secured an injunction against the Secretary of State, hearing on the injunction to be held at Little Rock, October 2.

The recent order of the state railroad commissioners of Missouri limiting the speed of trains on certain parts of the Missouri Pacific appears to have been due in considerable degree to political considerations, and parts of the order have been rescinded or suspended. Press despatches give contradictory information, so that the real facts are not made clear. It appears that there is dissension in the board, and two of the members have announced that the sections of railroad condemned are safe. The order limiting speed was made after the hearing of a complaint which was presented by an attorney for a trackmen's union.

The Wisconsin railroad commission has ordered sweeping reductions in freight rates on coal from Superior and Ashland to Eau Claire and intervening points over the Chicago, St. Paul, Minneapolis & Omaha. The reduction is about 40 cents a ton. The commission has also decided that at common points all railroads must switch each other's cars to their respective sidetracks for reasonable switching charges. They cannot charge distance tariff rates. It is also decided that a railroad acquiring a spur must so operate it as to serve the public reasonably and impartially; and again, that a certain minimum of passenger service must be maintained on a railroad regardless of the question of whether it is profitable.

The Southern Railway and other roads in Virginia have had to compromise with the Governor of that state concerning passenger fares in about the same way that they yielded to the Governor of North Carolina. In Virginia the Corporation Commission last April issued an order reducing fares to 2 cents and the railroads secured an injunction suspending the operation of the law, but on Saturday last the Governor told the railroads in substance that Virginia intended to fight for low fares on about the same plan that North Carolina has followed, and that an extra session of the legislature would be called if necessary to carry out what the Governor believes to be the wishes of the people. After a long conference the railroads agreed to reduce their fares on October 1 to 2 cents a mile, it being assumed that the United States Court would readily suspend its injunction forbidding such reduction. The railroads agreed to keep the low rate in force until the pending cases are settled by the Supreme Court of the United States, and both parties agree to secure such decision as speedily as possible. The Seaboard Air Line adopted the $2\frac{1}{2}$-cent rate for passengers in both Virginia and North Carolina on July 1. In Virginia, although the Jamestown Exposition is now stimulating travel, the receipts for passengers since the reduction have been less than in the corresponding period last year. In North Carolina the local passenger travel in July has been about 2 per cent. more than the last month while the passenger receipts have decreased 22 per cent.

A Phase of "Rapid" Transit in New York City.

Unless the Metropolitan Street Railway Company, which is now the owner of the old horse car line running from the Bartow station to City Island, on the Sound, gets some new horses to draw its cars before to-morrow, its line will be tied up. This was the order issued by the Society for the Prevention of Cruelty to Animals to-day. Of the 24 horses used on the line, one-half are about played out from old age, while others are suffering from sore shoulders. The horses have been worked on the line every day for nine years. It is bad enough to drive them over hill and dale at breakneck speed, with their rattletrap cars behind them, but in addition the horses suffer terribly from mosquito bites, as the entire country from Bartow to City Island is notorious for these pests. The company declares that it has been expecting for some time past to install electric cars but has been prevented from making this improvement because the city of New York is slow in widening and improving the street.—*New York Times.*

Blocking the Wheels of Civilization.

The Missouri, Kansas & Texas refuses to haul the Parker carnival train from Kansas City to Sedalia in the first week in October. The Missouri Pacific also refused to accept the train at Cole Camp and haul it to Sedalia. The railroads claim that they have entered into an agreement not to haul circus trains and will make no rate to haul them as circus trains, and can only accept them at the classified rates per 100 lbs., which would make the charges prohibitive. Operating officials contend that they must take special precautions with such trains and that they interfere with the movement of regular freight and cause congestion at the smaller terminals.—*Press Despatch.*

Another One.

A locomotive cab signal made by H. J. Jefcoate, of Crewe, England, was recently exhibited on the Wirral Railway, and the exhibition is described in a Consular Report as follows:

"A locomotive running 60 miles an hour, with its cab enveloped in tarpaulin, so that the engineer was entirely shut off from the outer world, was confronted by the distant signal set against it. The engine at once began to slacken and stopped dead at the home signal until the semaphore arm dropped, when it moved ahead again. The state of the signals was communicated to the engineer by an indicator in the cab, which announced them by bell, semaphore, and light. Two long bars parallel to the rails, one beginning where the other ended, were placed at both the distant and home signals, and as the engine passed over them, according as the semaphore was 'on' or 'off,' one or other of these bars rose on its pivots and pushed up one or other of two little plunger wheels which projected from the locomotive, and as it did so a bell was rung in the cab."

Railroad Course at New York University.

The New York University School of Commerce, Accounts and Finance will begin on September 26 a special one-year course in railroad traffic and accounts. The classes will be held on Monday and Thursday evenings. The following subjects will be included: Railroad accounts, corporation securities and reports, railroad transportation in the United States, and railroad traffic problems. Under the advice of railroad men of experience every effort has been made to make the course thoroughly practical.

Individual Car Owners' Association.

This is the name of an organization formed at Cleveland August 1 by 50 representatives of corporations, firms and individuals (other than railroad companies) owning freight cars, the meeting having been called by leading Pittsburg car owners. It is said that the men present at the organizing meeting represented 125,000 cars. All belong in states east of the Mississippi river. W. L. Andrews, of Baltimore, was chosen Chairman, and R. J. Bailey, of Pittsburg, Secretary. Other men prominent in the organization are: C. McIlvaine and C. O. Johnson, Pittsburg; T. J. Richman and Max Epstein, Chicago; C. D. Chamberlain, Cleveland.

Forty Passengers Killed in France.

In a derailment near Angers, France, on Sunday last, the engine, baggage car and the first passenger car of a passenger train fell off the side of a stone bridge crossing the Loire river, the parapet giving way, and all of the occupants of this part of the train, except the conductor and the fireman, were drowned. The passenger car, a third class, carried 40 passengers, and not one of them was able to get out of the car, although a part of the roof was forced off when the car sank in the water. The engineman was drowned, making 41 victims in all. The river at this place is 50 ft. below the track. The remainder of the train remained on the roadbed. Angers is at the junction of several railroads. The name of the road on which the accident occurred is not given in the press despatches.

Summer in the Suburbs.

W. Hardy Eshbaugh, living in Montclair avenue, Montclair, drives in his automobile to the Lackawanna station every morning. Yesterday he had just reached the station, when the 8 o'clock express pulled out. Mr. Eshbaugh had an important engagement at his office, and he told his chauffeur to "beat the train" to Bloomfield, nearly two miles away. The machine was thrown wide open, and only a streak of dust could be seen along Bloomfield avenue. Passing through Glen Ridge at a pace that surprised the natives, the automobile drew up at the Bloomfield station four minutes ahead of the train. When the chauffeur returned to Montclair Recorder Yost fined him $5 for excessive driving.—*New York Tribune.*

The old story about the Georgia ox team that beat a mixed train in a 10-mile run will now be retired.

The "Thor" Hose Coupling.

The "Thor" hose coupling for shop use is shown in the accompanying illustration. It is made of tough bronze to stand hard usage, and it will not rust. It has three hook-shaped lugs, which are made to engage by a third of a turn and produce a tight coupling. The couplings are made for ⅜ in., ½ in., ¾ in. and 1 in. hose or pipe with the same sized head, so that large and small hose or pipe can be coupled together without using reducers. Another advantage of this feature is that should a ¾-in. hose, for instance, burst and nothing be immediately available but a 1-in. piece, say, it can be used and delay thus avoided. There are no rights and lefts, every coupling joining to any other. There are only two patterns, one being to screw on to iron pipe, and the other being for hose. The "Thor" coupling is made by the Independent Pneumatic Tool Co., Chicago.

"Thor" Hose Coupling.

New Jersey Tax Law.

The New Jersey Court of Errors and Appeals has sustained the constitutionality of the Duffield act of 1905, under which second-class railroad and canal property is assessed at local tax rates instead of 1 per cent. as formerly. Under the Duffield act the entire revenue from this class of property goes to the municipality and none of it to the state, which now derives its revenues from a part of the tax levied against "main stem" property. The main stem consists of the right of way not exceeding 100 ft. in width, and second-class property is the real estate used for railroad purposes but not included in the main stem.

The test case was instituted by the Bergen & Dundee Railroad. Its second-class property in Passaic was taxed at $2.92 per $100. This rate varies in the different municipalities of the state, but in practically every instance is a substantial increase over the 1 per cent. rate formerly paid by the railroads.

INTERSTATE COMMERCE COMMISSION RULINGS.

In an opinion by Commissioner Clements the Commission has announced its decision in the case of Quimby and others against the Clyde Steamship Company and others. It appeared that class rates from North Atlantic ports were the same to a group of suburban mills as to Augusta, Ga., for 10 or 12 years before the absorption of the South Carolina & Georgia Railroad by the Southern Railway; that subsequent to such absorption the long-existing rates to these suburban points were increased by the concerted action of the defendant carriers, though the mill group is still recognized on shipments in the opposite direction, and that this grouping system is still effective to the extent of classing together some of these suburban points which are as far apart as Augusta is from the nearest of them. It also appeared that water lines by way of the Savannah river secure most of the freight of the heavy and bulky classes for these mills, and that a restoration of the Augusta rates to these suburban points would divert much of this traffic to the

defendant lines and thus increase their revenues. The Commission held that the rates to these suburban mill points in excess of those to Augusta are, under the circumstances, unjust and unreasonable. The places ordered to be put in the Augusta group are Aiken, Langley and Graniteville, S. C., but Blackville, S. C., 46 miles east of Augusta, was not ordered to be included in the Augusta group.

In an opinion rendered by Commissioner Clark, the Commission has announced its decision in the matter of the distribution of coal cars. The cases were brought by the Railroad Commission of Ohio against the Hocking Valley and the Wheeling & Lake Erie. Defendants are engaged principally in transportation of coal. Certain other railroads send their own cars to the coal companies with which railroads so sending their cars have contracts for fuel supply. Certain other coal operators have so-called "private" cars, devoted exclusively to their use. During a part of the year defendants are unable to furnish all of the cars desired by coal operators along their lines, and at such times the available cars not specially consigned or restricted as to use are divided among the several coal companies according to the capacities of their several mines. But in such distribution the foreign railroad fuel cars and the leased or private cars are excluded from consideration and are given to the coal companies to which they are consigned or assigned in addition to the full share of cars allotted to such mines in the proportionate distribution. Complaint alleges unjust discrimination against other coal operators along the lines of defendants, in that such distribution of cars and such failure to count the foreign railroad fuel cars and the private cars gives the coal operators to whom such cars are consigned and assigned unwarranted advantages over other operators in the mining and marketing of coal.

Upon the foregoing facts the Commission held that a carrier should give to the owner or lessee of private cars the use of such cars; and should also give to a coal company the foreign railroad fuel cars consigned to it; but that such private and foreign railroad fuel cars should, in the distribution of cars, be counted solely against the company to which delivered; and such company should not be given, in addition to such delivery, a share of the system cars (H. V. or W. & L. E.) except when the number of private and foreign railroad fuel cars so delivered to it is less than its distributive share of the available cars, including system cars, foreign railroad fuel cars, and so-called private cars, in which event it should be given only so many of the system cars as are necessary, when added to the number of private and foreign railroad fuel cars assigned to it, to make up its distributive share of the total available cars, including system cars, foreign railroad fuel cars, and so-called private cars. Defendants were ordered to distribute coal cars after Sept. 15 next on the basis here laid down.

TRADE CATALOGUES.

Storage Batteries.—The Gould Storage Battery Co., New York, is introducing a new design storage battery for small installations of closed circuit duty such as fire alarm and railroad telegraph systems, private telephone exchanges, etc., which is described in a recent catalogue. It is known as the "Tandem" couple type cell and it differs from other types in that the plates are placed end to end instead of side by side. Two plates only are used to each cell. The positive plate of one cell is lead burned to the negative plate of the next cell and no bolted connections are used. This method of grouping does away with separators and distributes the discharge and hence the wear and tear uniformly over all parts of both sides of the plates in each cell. The removal of plates for cleaning, inspection or renewal is also facilitated.

Storage Batteries.—Catalogue S-2 of the Westinghouse Machine Co., East Pittsburg, Pa., illustrates and describes the Westinghouse Type "S" storage battery for stationary service. This battery is of the pure lead sulphuric acid type with the active material formed from the lead itself after the Planté process. The advantages claimed for it are long life, high efficiency and freedom from injurious sulphation.

Mining Hoists.—Bulletin No. 56 of the Sullivan Machinery Co., Chicago, shows a number of views of typical installations of the large and powerful types of mining hoists developed in response to the demands of the Lake Superior iron and copper mines and now generally used in the West. There is also a brief description and a list of the advantages of the Sullivan machines.

MANUFACTURING AND BUSINESS.

The Falls Hollow Staybolt Co., Cuyahoga Falls, Ohio, is building a new mill of three times the capacity of the present mill.

Wilbur J. Watson, C. E., hitherto in charge of the bridge department of [illegible] Engineering Co., Cleveland, Ohio, [illegible]

The Northern Engineering Works, [illegible] Detroit, Mich., have installed a [illegible] Toledo Gas & Electric Co. [illegible] phy power plant at Detroit, Mich.

G. N. Sw[illegible], [illegible] Superintendent of Motive Power of the Rock Island system, was appointed Manager of Sales in the railroad department of the [illegible] Co., 174-176 E. Lake street, Chicago, on August 1.

On July 31, 1907, in the Circuit Court of the United States, District of New Jersey, a [illegible] was rendered in favor of the [illegible] Metal Company of Philadelphia, Pa., and [illegible], relative to infringement made upon their [illegible]

The Central Inspection Bureau, New York City, has [illegible] inspectors at the works of the Cincinnati Car Co., Cincinnati, Ohio; the Southern Car Co., High Point, N. C.; the Jewett Car Co., Newark, Ohio, the Niles Car & Manufacturing Co., Niles, Ohio, and at the J. G. Brill Company's plant.

E. H. Keating, M. Inst. C. E., M. Can. Soc. C. E., M. Am. Soc. C. E., and W. H. Breithaupt, C. E., M. Can. Soc. C. E., M. Am. Soc. C. E., have formed a partnership, with offices at Toronto, Ont., as Consulting Engineers, taking up railroad and municipal work, power development, bridges, foundations, buildings, etc., in Canada and other countries.

The mid-summer meeting of local managers and representatives from the Chicago house of The Sherwin-Williams Co. was held at the South Shore Country Club, Chicago, August 2. There were about 50 persons present, including Alex. Sclater, District General Manager of the company; Geo. A. Martin, Manager of the Cleveland district; J. P. Coleman, Manager of the Minneapolis district, and R. W. Sample, Manager of the Chicago district. There were talks by these managers and remarks from others among the representatives, following a dinner, after which the time was given up to social enjoyment.

In July the railroad department of the Westinghouse Electric Company, East Pittsburg, Pa., booked orders for about $2,500,000 worth of equipment. The Brooklyn Rapid Transit ordered 400 motors, 200 of which, of 200-h.p. each, are for 100 elevated railroad cars, while the rest, of 60 h.p. each, are for 100 surface cars. The cars were ordered last March. In connection with the elevated car equipment, the company will also furnish the Westinghouse multiple unit control. The Schoepf interests, of Cincinnati, Ohio, ordered a complete equipment of electrical apparatus for 24 substations, consisting of rotary transformers and switchboard appliances as well as four Westinghouse turbo-generators, aggregating 26,000 h.p.

Iron and Steel.

The Interborough Rapid Transit Company is in the market for 4,000 tons of rails.

The Southern has ordered 16,000 tons of bridge material from the Phoenix Bridge Co.

The Northern Pacific has ordered nearly 15,000 tons of steel for bridges from the American Bridge Co.

The Terminal Railroad Association of St. Louis has ordered 2,500 tons of bridge material from a St. Louis firm.

The New York, New Haven & Hartford has ordered 1,400 tons of steel for a Scherzer lift bridge at Providence from the Phoenix Iron Works.

The Atlanta, Birmingham & Atlantic has ordered steel for a number of bridges on its new line near Birmingham, from the American Bridge Co.

The Pennsylvania has ordered 750 tons of steel for bridges across streets in connection with the New York terminal, and 627 tons for the Duquesne Way elevated viaduct in Pittsburg.

It is reported from Chicago that an Illinois electric railroad has ordered 25,000 tons of rails for this year's delivery, and that other traction companies are in the market for from 5,000 to 10,000 tons.

The Detroit & Adrian Traction Co., a new company which is projecting a 61-mile interurban line in Michigan, is reported to be in the market for about 6,500 tons of 71-lb. rails. Address care of Security Trust Co., Detroit.

The Atchison, Topeka & Santa Fe has ordered 10,000 tons of rails from the Pennsylvania Steel Co. for 1908 delivery. This makes 40,000 tons that this company has bought for next year's delivery, the other 30,000 tons having been ordered from the Bethlehem Steel Co.

ELECTIONS AND APPOINTMENTS.

Executive, Financial and Legal Officers.

Alabama Great Southern.—See Cincinnati, New Orleans & Texas Pacific.

Central New England.—The authority of the following officials of the New York, New Haven & Hartford has been extended over the Central New England: H. M. Kochersperger, Vice-President; H. A. Fabian, Assistant to the President, and Thomas F. Paradise, Assistant to the Treasurer.

Cincinnati, New Orleans & Texas Pacific.—T. C. Powell, Vice-President of the Southern, has been elected also Vice-President of the C., N. O. & T. P., and of the Alabama Great Southern, with office at Cincinnati, Ohio, in charge of the operating department and purchasing department. W. J. Murphy, Vice-President, will be the resident executive officer at Cincinnati.

Escanaba & Lake Superior.—Edward Wicking has been appointed Auditor, with office at Wells, Mich., succeeding C. W. Kates, transferred. See this company under Operating Officers.

New Orleans, Ft. Jackson & Grand Isle.—F. T. Howard has been elected President, succeeding H. C. Warmoth, resigned.

New York, New Haven & Hartford.—See Central New England.

Susquehanna, Bloomsburg & Berwick.—H. R. Slifer has been appointed Auditor, with office at Watsontown, Pa.

Wisconsin State Railroad Commission.—John H. Roemer, of Milwaukee, has been appointed Chairman, succeeding John Barnes, resigned.

Operating Officers.

Atlantic Coast Line.—W. B. Darrow, Superintendent of the Southern at Jacksonville, Fla., has been appointed Superintendent of Transportation of the First division of the Atlantic Coast Line, with office at Rocky Mount, N. C. F. T. Bowles has been appointed Superintendent of Terminals, with office at South Rocky Mount, N. C. R. C. Westcott has been appointed Trainmaster of the Richmond district, with office at Richmond, Va., succeeding E. C. Lucas, resigned.

Canadian Pacific.—J. T. Arundel, Superintendent at Winnipeg, Man., has been appointed Superintendent at Vancouver, B. C. A. L. Clements has been appointed Superintendent of Terminals at Vancouver.

Chicago & Illinois Midland.—W. S. Cook has been appointed Superintendent, with office at Pawnee, Ill., succeeding M. A. Zook.

Chicago, Rock Island & Gulf.—D. Van Hecke has been appointed Assistant Trainmaster of that part of the Mexican division from Dalhart, Tex., east. G. W. Keene has been appointed Assistant Trainmaster in charge of the line from Dalhart west.

Erie.—A. J. Stone, Assistant General Manager, has been appointed General Superintendent, with office at Jersey City, N. J., succeeding R. H. Bowron, resigned, and the office of Assistant General Manager has been abolished.

Escanaba & Lake Superior.—Charles W. Kates, Auditor, has been appointed Superintendent, with office at Wells, Mich., succeeding Wesley E. Wells, resigned to become Manager of the John O'Brien Lumber Co., Somers, Mont.

Interoceanic of Mexico.—E. W. Thompson has been appointed Trainmaster at Puebla, succeeding E. W. Bowans, resigned to go to the National of Mexico.

Lehigh Valley.—G. B. Minshull has been appointed Inspector of Transportation, succeeding W. D. Vincent, transferred.

Louisville, Henderson & St. Louis.—W. R. Hensley has been appointed Car Accountant, with office at Louisville, Ky., succeeding Ridgely Case, assigned to other duties.

McCloud River.—J. C. Wilder has been appointed Superintendent, with office at McCloud, Cal., succeeding M. H. Burkhalter, deceased.

Minneapolis & International.—The office of the General Manager has been moved from St. Paul, Minn., to Brainerd, Minn.

New York Central & Hudson River.—F. E. Williamson, Assistant Superintendent of the Harlem division, has been appointed to the new office of Superintendent of Freight Terminals at Albany, N. Y.

Oklahoma Central.—F. C. Hand, Chief Engineer, has been appointed also General Superintendent.

Southern.—J. A. Baumgardner has been appointed Superintendent at Jacksonville, Fla., succeeding W. H. Darrow, resigned to go to the Atlantic Coast Line. See Atlantic Coast Line.

Traffic Officers.

Baltimore & Ohio.—Edward M. Davis, division freight agent at Baltimore, Md., has been appointed General Eastern Freight Agent, with office at New York, succeeding F. M. Johnson, resigned.

Birmingham & Atlantic.—H. J. Meade has been appointed General Freight and Passenger Agent, succeeding W. M. Tarpley, resigned.

Cumberland & Pennsylvania.—J. T. Robertson has been appointed General Passenger and Freight Agent.

Litchfield & Madison.—F. M. Campbell has been appointed General Freight Agent, with office at Edwardsville, Ill.

Mexican International.—Fritz Niggli, General Agent at Torreon, has resigned to go into other business.

Engineering and Rolling Stock Officers.

Atlantic Coast Line.—L. L. Sparrow has been appointed Engineer of Roadway of the First division, with office at Rocky Mount, N. C.

Chicago, Indiana & Southern.—L. Slattery has been appointed Signal Engineer, with office at Gibson, Ind., succeeding Byron Layton.

Kalamazoo, Lake Shore & Chicago.—W. K. Christie has been appointed Master Mechanic, with office at South Haven, Mich.

Kingston & Pembroke.—G. G. Hare has been appointed Chief Engineer, succeeding T. W. Nash.

New York, Chicago & St. Louis.—W. J. Bergen, Chief Supervisor of Track, has been appointed Assistant to the Chief Engineer, with office at Cleveland, Ohio. C. B. Hoyt succeeds to the duties of Mr. Bergen with the title Superintendent of Track Maintenance and Construction, reporting to the General Manager.

New York, New Haven & Hartford.—W. L. Larry, Master Mechanic at Taunton, Mass., has resigned to become an inspector for the Massachusetts State Railroad Commissioners.

Northern Central.—See Philadelphia, Baltimore & Washington.

Pennsylvania.—George D. Fowle, Signal Engineer of this company and of the Philadelphia, Baltimore & Washington, the Northern Central and the West Jersey & Seashore, has been appointed Consulting Signal Engineer of the three companies. A. H. Rudd, Assistant Signal Engineer, succeeds Mr. Fowle. C. C. Anthony, inspector of signals, succeeds Mr. Rudd.

Philadelphia, Baltimore & Washington.—See Pennsylvania.

West Jersey & Seashore.—See Philadelphia, Baltimore & Washington.

Purchasing Agents.

Seaboard Air Line.—W. M. Portlock has been appointed General Storekeeper, with office at Portsmouth, Va., succeeding R. E. Dickinson, resigned to go to another company.

Special Officers.

St. Louis & San Francisco.—Dr. Herman Von Schrenk has been appointed Supervisor of Timber Preservation, with office at St. Louis, Mo.

LOCOMOTIVE BUILDING.

The Las Vegas & Tonopah has ordered four locomotives.

The Northern Pacific is said to be in the market for five switch engines.

The Galveston, Houston & Henderson is said to be in the market for two switching locomotives.

The Sandy Run Lumber Company, Norfolk, Va., is said to be in the market for one locomotive.

The Great Northern has ordered two rotary snow plows from the American Locomotive Company.

Jones & Laughlin have ordered one 4-wheel tank locomotive from the American Locomotive Company.

Swift & Co., Chicago, it is said, are having one locomotive built by the Baldwin Locomotive Works.

The Tombigbee Valley, it is said, has ordered two locomotives from the Baldwin Locomotive Works.

The Nevada, California & Oregon, it is said, has ordered one locomotive from the Baldwin Locomotive Works.

The Escanaba & Lake Superior, it is said, is having one locomotive built by the Baldwin Locomotive Works.

The Detroit & Toledo Shore Line, it is said, has ordered four locomotives from the Baldwin Locomotive Works.

The Wichita Falls & Northwestern has ordered two mogul locomotives from the American Locomotive Company.

The Chilian Government is said to have bought 25 heavy locomotives from the American Locomotive Company.

The Chicago & North-Western, it is said, is having 20 additional locomotives built by the Baldwin Locomotive Works.

The American Steel & Wire Company is said to have ordered one locomotive from the Baldwin Locomotive Works.

The Wickwire Steel Company, Cortland, N. Y., has ordered one 4-wheel tank locomotive from the American Locomotive Company.

The Kiangsu Railway, Japan, has ordered through Mitsui & Co., New York, three mogul locomotives from the American Locomotive Company.

The San Antonio Madruga Plantation, Cuba, has ordered through the Czarnikow, MacDougall Company, New York, one mogul locomotive from the American Locomotive Company.

The San Pedro, Los Angeles & Salt Lake recently ordered 23 simple consolidation locomotives from the American Locomotive Company for November and December, 1907, delivery. These locomotives will weigh 208,000 lbs., with 187,000 lbs. on drivers; cylinders, 22 in. x 30 in.

CAR BUILDING.

The Las Vegas & Tonopah has ordered 10 tank cars.

The San Pedro, Los Angeles & Salt Lake has ordered 110 tank cars.

The Northwestern Elevated, Chicago, will buy 50 additional cars in the near future.

The Northwestern Pacific recently asked prices on 200 steel underframe flat cars.

Charles Clarke & Co., Galveston, Tex., are in the market for narrow gage side dump cars.

The Cold Blast Transportation Company, Chicago, has ordered 200 stock cars from Haskell & Barker.

The Texas Central is said to have ordered three sleepers from the American Car & Foundry Company.

The Erie denies being in the market for freight equipment, as reported in the *Railroad Gazette* of August 2.

The San Antonio & Aransas Pass, as reported in the *Railroad Gazette* of July 26, is asking prices on 500 box cars.

The Connecticut Electric Company has ordered seven double-truck derrick cars from the McGuire, Cummings Manufacturing Company.

The Chicago, Burlington & Quincy, as reported in the *Railroad Gazette* of July 26, recently ordered 1,000 steel gondola cars of 100,000 lbs. capacity from the Bettendorf Axle Company.

The Union Pacific has ordered 25 all steel box cars similar to the experimental car built at its Omaha shops. The company is building 22 gasolene cars and will shortly start building more.

The Interborough Rapid Transit has ordered two steel underframe snow sweepers mounted on McGuire, Cummings heavy pedestal trucks from the McGuire, Cummings Manufacturing Company.

The New York & Long Island Traction, Long Island City, N. Y., has ordered three steel underframe snow sweepers, mounted on McGuire, Cummings heavy pedestal trucks, from the McGuire, Cummings Manufacturing Company.

The Delaware, Lackawanna & Western is reported to be in the market for freight equipment. The company has not ordered one chair car, as reported in the *Railroad Gazette* of August 2, and the order for one baggage and mail car, also reported on that date, is an old order.

The Louisville & Nashville, as reported in the *Railroad Gazette* of August 2, will build at its own shops the following equipment during the present year: Six hundred 36-ft. box cars of 65,000 lbs. capacity; 700 36-ft. drop bottom gondolas of 80,000 lbs. capacity; 350 40-ft. flat cars of 80,000 lbs. capacity; 250 30-ft. double hopper ore cars of 100,000 lbs. capacity, and 100 40-ft. refrigerator cars of 50,000 lbs. capacity. During the first half of next year it will build: Four hundred 36-ft. box cars of 65,000 lbs. capacity; 350 36-ft. drop bottom gondolas of 80,000 lbs. capacity; 100 40-ft. flat cars of 80,000 lbs. capacity; 50 30-ft. double hopper ore cars of 100,000 lbs. capacity, and 100 40-ft. refrigerator cars of 50,000 lbs. capacity.

The Intercolonial has ordered 400 box cars of 60,000 lbs. capacity from the Crossen Manufacturing Company. These cars will weigh 34,800 lbs. and will measure 36 ft. long, 8 ft. 6 in. wide and 8 ft. high, inside measurements, and 36 ft. 9⅝ in. long, 9 ft. ⅝ in. wide and 13 ft. 5 in. high, over all. Bodies and underframes will be of wood. The special equipment includes:

Roofing	Semi-x
Brake beams	Simplex
Brake-shoes	Carlton
Brakes	Westinghouse
Brasses	Canadian Ironsides Co.
Door fastenings	National Malleable Castings Co. "Security"
Doors	Independent sandard
Draft rigging	Miner tandem
Dust guards	Pennsylvania
Journal boxes	M. C. B.
Paint	Red oxide
Roofs	Chicago
Trucks	Interchangeable standard

The Isthmian Canal Commission, as reported in the *Railroad Gazette* of August 2, has received bids on 500 dump cars of 12 cu. yds. capacity and 115 dump cars of 4 cu. yds. capacity. The bids on the larger cars were as follows: American Car & Foundry Company, $524,000; Kilbourne & Jacobs Manufacturing Co. of Columbus, Ohio, $215,000 for 100 cars; Arthur Koppel, Pittsburg, Pa., $665,000. William J. Oliver Manufacturing Co., Knoxville, Tenn., $562,000; Russell Wheel & Foundry Co., Detroit, Mich., $697,500. Standard Steel Car Company, $622,500; Western Wheel & Scraper Co., Aurora, Ill., $645,000. On the smaller cars the bids were as follows: Continental Car & Equipment Co., New York, $19,500; Kilbourne & Jacobs Manufacturing Co., $25,875; Kilgore Peteler Co., Minneapolis, Minn., $28,635; Arthur Koppel, $34,500; William J. Oliver Manufacturing Co., $24,725; Western Wheel & Scraper Co., $25,415.

RAILROAD STRUCTURES.

ARMOURDALE, KAN.—The Chicago, Rock Island & Pacific has begun work on shops that will cost $585,000, including a 27-stall roundhouse to cost $58,000. The plant will give employment to 1,500 men.

CLINTON, IOWA.—The Chicago & North-Western is reported to have let the contract for its new double-track steel bridge two miles long across the Mississippi.

DAUPHIN, MAN.—The Canadian Northern is to build a new roundhouse and make other improvements.

FORT WILLIAM, ONT.—The Canadian Pacific is said to be planning a coal handling plant here to cost $1,250,000.

KAMLOOPS, B. C.—The Canadian Pacific is getting bids on a station, freight house and oil house.

MACON, GA.—The Central of Georgia has let the contracts for shops to cost $1,400,000 to the McKenzie DeLeon Construction Co., Savannah.

PORT ARTHUR, ONT.—The Grand Trunk Pacific is said to have bought a block of land as a site for a passenger station and freight houses.

SAN ANTONIO, TEX.—The International & Great Northern is reported to have let the contract for its new passenger station to the Stewart Construction Company of St. Louis, Mo.

SASKATOON, SASK.—The Canadian Pacific is getting bids on a station and freight shed.

SPRINGFIELD, MO.—Bids were opened in St. Louis, on July 27, for a freight depot to be built here for the Missouri Pacific. Plans are being prepared for a passenger station to cost $65,000.

SUPERIOR, WIS.—The Great Northern is to build shops here for making steel, ore and freight cars. The cost of the plant is estimated at $200,000.

The Great Northern is reported to have let the contract for new shops for building ore cars to Schmidt Brothers & Hill.

RAILROAD CONSTRUCTION.

New Incorporations, Surveys, Etc.

ATLANTA, BIRMINGHAM & ATLANTIC.—The Third division has been extended from La Grange, Ga., west to Roanoke, Ala., 25 miles.

ATLANTIC & GULF TRANSPORTATION CO.—Chartered in Texas to build in Orange, Chambers, Harris, Galveston, Brazoria, Matagorda, Jackson, Victoria, Calhoun, Refugio, San Patricio, Neuces and Cameron counties. Alfred A. Glazier, Boston, J. P. Underwood, Chicago, and J. S. Macnamara, C. M. Teagle and J. M. Conley, of Beaumont, Tex., incorporators.

COLORADO & SOUTHERN.—A new branch from Marshall, Colo., to Eldorado Springs, three miles, has been opened for business.

DETROIT & ADRIAN TRACTION.—This company has been organized with $2,000,000 capital to build an electric road on a private right-of-way from Detroit to Adrian, 61 miles.

RAILROAD GAZETTE

ESTABLISHED IN APRIL, 1856.

PUBLISHED EVERY FRIDAY BY THE RAILROAD GAZETTE AT 83 FULTON STREET, NEW YORK
BRANCH OFFICES AT 375 OLD COLONY BUILDING, CHICAGO, AND QUEEN ANNE'S CHAMBERS, WESTMINSTER, LONDON.

EDITORIAL ANNOUNCEMENTS.

THE BRITISH AND EASTERN CONTINENTS edition of the Railroad Gazette is published each Friday at Queen Anne's Chambers, Westminster, London. It contains selected reading pages from the Railroad Gazette, together with additional British and foreign matter, and is issued under the name Railway Gazette.

CONTRIBUTIONS.—Subscribers and others will materially assist in making our news accurate and complete if they will send early information of events which take place under their observation. Discussions of subjects pertaining to all departments of railroad business by men practically acquainted with them are especially desired.

ADVERTISEMENTS.—We wish it distinctly understood that we will entertain no proposition to publish anything in this journal for pay, EXCEPT IN THE ADVERTISING COLUMNS. We give in our editorial columns OUR OWN opinions, and these only, and in our news columns present only such matter as we consider interesting and important to our readers. Those who wish to recommend their inventions, machinery, supplies, financial schemes, etc., to our readers, can do so fully in our advertising columns, but it is useless to ask us to recommend them editorially, either for money or in consideration of advertising patronage.

CONTENTS

VOL. XLIII., No. 7. FRIDAY, AUGUST 16, 1907.

THE ELECTRIFICATION OF THE NEW HAVEN.

On July 24 the New York, New Haven & Hartford began running a few suburban trains out of New York with electric locomotives. This was the beginning of operation of the first system of single-phase alternating current electric traction for heavy steam railroad service in America. It is an experiment in the sense that it is new and untried in actual service of this kind, but it has been carried out on such a tremendous scale that it must succeed, because the railroad and the builders of the apparatus simply will not let it fail. There is published elsewhere in this issue of the *Railroad Gazette* an article by the Vice-President of the road in charge of engineering, who has had the supervision of the plans and work of electrification, which is illustrated with many photographs, and describes important features of the system. This article is of particular interest because it is the first authoritative statement of its kind, we believe, of the position of the New Haven on the much-discussed subject of electric traction for heavy railroad service.

The New Haven started its electrification plans with two narrow limitations. On the one side, whatever system was adopted must permit operating trains over the New York Central tracks from Woodlawn to Grand Central Station, and the Central had already begun to install 600-volt direct current, third-rail. This limited the consideration of systems to low-tension direct current identical with the New York Central apparatus and single-phase alternating current. Multi-phase alternating current and high-tension direct current systems, now well beyond the experimental stage in Europe, were out of the question. On the other side, the railroad company had to consider that whatever system of electric traction was to be adopted would sooner or later be extended over most, if not all, of the New Haven's present steam railroad system. There are a number of good reasons for this expectation. The mileage of the road is grouped closely together in a comparatively small territory; nearly half of its earnings come from passenger business and a large proportion of its freight is carried in small trains at a rate approximating the average passenger speed on many of the branch lines. Thus, as Mr. McHenry points out, it should be possible when electric traction is extended to operate various diverging lines each from central electric-producing stations serving a definite surrounding territory. There is a further reason, not far in the future, for the extension of electric operation. The consolidation of the New York, New Haven & Hartford and the Boston & Maine, now delayed, but in all probability delayed only by the restraining action of the Massachusetts legislature, will have particularly important results in its effect on terminal and suburban facilities at Boston. The thickly clustering lines owned either by the New Haven or the Boston & Maine leading into that city make this a peculiarly desirable field for electrification. President Mellen, indeed, has already promised to electrify along with the rearrangement and reconstruction of the present Boston terminals, once the consolidation is completed.

Mr. McHenry discusses the relative advantages and disadvantages of the two systems of electrical distribution in a fair-minded spirit, and shows how, all things considered, a single-phase alternating current system more nearly meets all the requirements of the present and further development of electric traction on the New Haven. It permits joint operation over the New York Central tracks out of New York, has a high efficiency of distribution over wide areas from power house to contact conductor and a high efficiency of consumption in the motors. The cost of installing and maintaining the apparatus and structures is little different from that required for a direct current installation, and the capacity of the locomotives and feeder lines is ample for the work to be done.

Another interesting point which is brought out is the standardization of power supply. The decision to use 25-cycle current instead of the more economical 15-cycle current was based entirely on commercial grounds. The standard frequency in nearly all street railway and electric lighting plants is 25 cycles, and in the event of breakdowns or other emergencies it was essential to be able to draw on outside sources for current. Furthermore, there was the advantage of future centralization of power supply for all the varied uses of such a railroad system as the New Haven. Now or later one central power house in each district can supply power not only for the electric service on the present lines of steam railroad and the street railways and interurban lines, of which the New Haven already controls some 1,500 miles as well, but for station lighting, station heating, small power plants for other uses and, provided the railroad company permanently retains the various lighting and power companies of which it became possessed as part of its Connecticut Railway & Lighting and other trolley purchases, the furnishing of power for these plants for local consumption in various towns and cities. Such centralization of the power supply of a given

district in one compact central station will result in great economies as soon as the scheme can be completely carried out—economies which should make up for a considerable part of the greater expense of heavy electric traction when first installed.

RULES AT THE END OF THE TONGUE.

In the Lackawanna coal mines each foreman henceforth must have the rules for safety at his tongue's end. Passing an examination when taking a job will no longer be sufficient; there will be a test every six months. The rules which these men have to memorize are not exactly parallel to railroad rules, and the catechising alone, even if it were more frequent than half yearly, would not in the railroad service insure safety; but this announcement of the coal mine manager* should be suggestive to railroad superintendents, nevertheless. The railroads of this country have made great progress since 1886, when they examined their men on rules very little, but most of them have great progress yet to make, if they are going to put their train service on a satisfactory basis. What conductor or engineman has even the more important rules of the standard code at his tongue's end? It may be said that such minute knowledge is not always necessary for safety. Granted; but it would greatly assist the examiner in gaining a knowledge of the employee's competency and reliability, and the teaching process would aid him in weeding out inefficient men. Compulsory half yearly study of rules would have a beneficial general effect, regardless of any improvement that could be specified in regard to any particular rule.

We advocate increased attention to rules—which already receive proportionately too much attention—because improvement in that feature could be expected to lead up to improvement in the other and more important one of increased attention to practice. Take, for example, the rule that conductor and engineman shall co-operate in checking train-registers, interpreting orders, and at other important junctures; after this rule has been revolved times enough in the minds of examiner and examinee they will begin to see more clearly the connection between the collision record and careless acts which could have been prevented by the correction of loose habits which are very common. Even the best conductors and enginemen, with rare exceptions, obey many of the rules loosely. We are not here asserting that the best men do dangerous things; the more competent they are, the more latitude can they take, in many situations, without danger; but they do omit precautions. Granting for the moment that such a course by a high-grade man usually is not an impairment of safety, the fact remains that the only safe course for the superintendent is to require exact compliance by all grades of trainmen. Only by being rigid with the good men can he enforce reasonable obedience among those who are not so good.

The requirement that conductors and enginemen shall jointly perform the most important acts incident to the movement of their train will be of less consequence as the block system comes more generally into use (unless the conductor rides in the cab); for the safety of the train, as regards its right of way, will depend more exclusively on the keeping of a good lookout at the forward end; but the joint-responsibility rule will not become a dead letter, for the block system has to be virtually suspended now and then, making it necessary that men in charge of trains shall know perfectly how to get them over the road promptly and safely without rules. The block system is not yet in use on all important lines—not to mention the less important—and in many cases where it is used some of its features are neglected or ignored. Apparently, American railroad officers and employees are to go through a long process of slow acquisition of knowledge by experience before they will come to depend as constantly and exclusively on the space-interval as they now depend (for the control of passenger trains) on the automatic air-brake; though it is certain that such complete dependence will be recognized eventually as the only safe and satisfactory plan.

Not the least attractive feature of this coal mine order is the promise of a reward for proficiency. In the enforcement of train rules the granting of a "trophy" would be looked upon probably as a measure too mild to be useful, but the principle is important. Every railroad superintendent who has paid premiums or prizes has apparently continued to have a favorable opinion of the practice; and yet it does not make headway. Why is such a simple means of arousing men's interest in their work so persistently neglected? Outside of the roadway department, where prizes, rewards and "honorable mention" have been used acceptably on a number of roads for many years, the employment of any kind of bonus is so rare that one has to search his memory to find any instances at all. Where it does not seem to cost anything, commendation of excellent service is favored; but why not make the matter a little more tangible? The recording of "merits" by the Atchison, Topeka & Santa Fe is highly commendable, but it is really only a beginning—a sample. Surely this is not the only way to show good will to employees. If tedious discussions with overbearing labor leaders abont wages have come to take up so much of our railroad superintendents' time and energy that they have no time to cultivate and increase their good will for their employees, it is time that a few presidents stepped in and corrected the wrong tendency. The American railroad superintendent, in the management of his men, has to deal with some of the hardest problems known, and yet he everywhere neglects one of the simplest means of mitigating hard problems—the granting of special compensation for voluntary improvement or unusual effort by individual employees. To give a prize for having rules on the tongue's end would be a very simple thing. It might not produce real improvement in the service for some months or years. An improvement, when effected, might not be demonstrable, mathematically. Yet such a prize might be a useful stepping stone to something more detailed and definite, and could be made to lead to marked betterment of service. It will be highly discreditable to the railroads if coal mines are made safer than passenger trains!

*School of Safety for Coal Mine Foremen. Realizing that rules are readily forgotten unless constantly discussed, the Delaware, Lackawanna & Western has decided to hold competitive examinations every six months concerning the details of its coal mine regulations. State mining laws and company's rules must be on the "tongue's end" of every mine foreman, fire boss, barn boss or driver boss. An examining board, consisting of the General Manager, his assistant, and the Chief Engineer, are to examine the men in a hall specially engaged for the purpose. To each man will be given practical questions to answer. The answers, recorded by a stenographer, will be carefully gone over and receive marks of relative merit. To the district showing the highest average for all men examined, will be awarded a handsome trophy which can be retained until the next competitive examination. If any district wins the trophy three times in succession, it is then to own it. Mine foremen and assistant foremen are examined by boards appointed by the State before receiving certificates which permit them to hold their position, but these examinations conducted by the company are intended to be supplementary to those prescribed by the State.

TRANSATLANTIC STEAMSHIP DEVELOPMENT.

We show this week, on another page, a very striking photograph of the new Cunarder, Lusitania, taken on her trial trip on the Clyde last month. To all persons who are interested in transatlantic navigation, the Lusitania is, and is likely for some time to remain, a peculiarly interesting vessel. She enjoys the transitory distinction of being the fastest and much the largest transatlantic steamship ever built. She is also the first transatlantic steamship to be fitted with four sets of engines driving four propellers (also two sets to go astern with), and these engines are turbines, developing 68,000 h.p., 26,000 more than that of any other vessel in the merchant service.

Besides these physical details, the most interesting thing about the Lusitania is the fact that she is a theoretic ship. The builders have had only moderate opportunity to study the workings of large turbine marine engines, and the work demanded of the Lusitania is so much heavier than that of any of the other three turbine steamers now in transatlantic service that the builders have been obliged to place entire reliance upon the calculations intended to meet a set of conditions largely new. The first turbine steamer to cross the Atlantic was the Victorian, of the Allan line, built in 1904 for the service between Liverpool and Montreal. She has been followed by a sister ship, the Virginian, and by the Carmania of the Cunard line, built in 1905. The Lusitania will, therefore, be the fourth turbine steamship in transatlantic service, although a considerable fleet of these vessels is now doing coastwise work in Great Britain and there are four upon our American coast—the Creole, of the Morgan line, between New York and New Orleans, and the Yale, Harvard and Governor Cobb, owned by Mr. Morse and his associates.

The gross tonnage of the Lusitania is 32,500, and the next largest steamer afloat, the Adriatic, of the White Star line, is approximately 7,500 tons smaller. The increases in gross tonnage, accompanied by changes in type, during the last 20 years have been so great and so significant that the topic is worthy of special notice. The Cunard line began its operations in 1840 as the pioneer among companies furnishing a regular steam service across the Atlantic, but during the next 48 years only one ocean steamship was built with a gross tonnage exceeding 10,000, and that was the famous Great Eastern (1858), which was 680 ft. long and of 18,918 tons, propelled by both paddle and screw, but with a maximum speed, seldom attained in actual service, of 14 knots, and with horse-power and design of engines totally inadequate to the task at

hand. As a result, the Great Eastern, as everybody knows, was a monumental failure.

In 1888 the Inman & International Company built the City of New York and City of Paris, of approximately 10,500 tons each, and these vessels remained the largest afloat until the Cunard line built the Campania and Lucania, in 1893. The latter were of 12,950 gross tons, and remained the largest on the ocean until 1897, when the North German Lloyd built the Kaiser Wilhelm der Grosse, of 14,349 gross tons. The first vessel of over 15,000 gross tons was the Oceanic, built for the White Star line in 1899 and having a gross tonnage of 17,274. The first vessel to exceed 18,000 tons was the Celtic, of the White Star line, built in 1901, and having a gross tonnage of 20,904. Since that time, approximately 16 vessels with a gross tonnage in excess of 18,000 have been built and a number of others are building.

Along with these increases in dimensions certain changes in type have also been developed. It may be said in general that the best transatlantic lines of steamers, from the earliest beginnings of steam navigation up to about 1896, were composed of vessels which were built for speed, the slower vessels on the line as a characteristic being older ships which were frequently record holders in their day. An instance of this may be found in the Cunard fleet at the time the Campania and Lucania were built, the next best vessels being the Etruria and Umbria, each of which at one time held the transatlantic record, while the older Auranla, Gallia and Bothnia were once famous as fast ships. Similarly, the best and most popular steamers of the North German Lloyd line in the north Atlantic service were small but fast vessels, each one of which had achieved a reputation for speed at the zenith of its career. Of course, the defect in a fleet of this kind from an economical standpoint was that each one of the older vessels burned altogether too much coal in proportion to the results gained. Beginning about 1896, therefore, a number of lines began building vessels of large carrying capacity and equipped with excellent passenger accommodations but capable of only a moderate speed. The Barbarossa, of the North German Lloyd line, with a gross tonnage of 10,915 and a speed of about 15 knots, was one of the first of these vessels, and they became so profitable that they became the characteristic carriers of the last decade. The four Red Star steamers, built between 1900 and 1902, had gross tonnages of about 12,000 and a speed of about 15 knots. The Holland-America fleet and the Atlantic Transport fleet were about the same size and the same speed. These boats were great carners, and their owners were quite content to allow the palm for speed to other lines willing to pay the very high price necessitated. As an example of the economy of this type of construction it may be noted that La Bretagne, built as a fast steamer by the French line in 1886, and having a gross tonnage of 7,010, burns slightly more coal per day than the Baltic, built as an economical ship of moderate speed, with a gross tonnage of 23,876, while the old Fürst Bismarck (Hamburg-American, built 1890; 8,430 tons) burned 300 tons a day, as against 110 tons burned by the President Lincoln (1907; 17,540 tons).

It is a striking fact, therefore, that in the 15 years of astonishing size development since the building of the Campania and the Lucania, no British steamer has been built to exceed them in speed in the transatlantic service. The two great German companies, the North German Lloyd and the Hamburg-American Packet, have found it profitable to maintain express steamers, perhaps in part for their advertising advantage, the North German Lloyd having four of these fast vessels now in operation and the Hamburg-American line, one. The Lusitania and her sister ship, the Mauretania, represent what is virtually a protest by the British government at having the ocean speed record held by Germans. To enable these new steamers to be built an arrangement was made by which the government virtually furnished funds to the steamship company at a cost of about 2½ per cent. to the company.

On her recent trial trip the Lusitania made a speed of approximately 25½ knots, and it is confidently expected that she will succeed in crossing the ocean in less than five days. It may be noted briefly that the first ship to cross in less than six days was the City of Paris, then of the Inman & International line, in 1889. The first ship to cross in less than seven days was the Alaska, of the Guion line, in 1882; the first to cross under eight days was the City of Brussels, of the Inman line, in 1869; and the first ship to cross under nine days was the Scotia, of the Cunard line, in 1862. The gross tonnage of the Scotia (paddle wheel) was 3,871; the gross tonnage of the Lusitania, as mentioned, is 32,500, and she has to burn about 1,000 tons of coal per day to make her contract speed. It has apparently not been proved that turbine steamers are more economical of coal than [illegible] although the space saved gives [illegible] are almost wholly free from vibration, a feature much appreciated by passengers. But a turbine engine of the present type (Parsons turbines are used on the Lusitania) cannot be driven astern, [illegible] auxiliary turbines have to be used for manoeuvering. This has been a defect in existing ships; we have seen the Virginian require an hour to turn around in Lough Foyle, when space was limited and the tide was running. The manoeuvering problem, however, should resolve itself into a question of the power of the auxiliary turbines, and it is to be presumed that the Lusitania has profited by the experience of earlier builders.

NEW PUBLICATIONS.

American Railways as Investments. By Carl Snyder. 762 pages, 6½ x 9 in. Published by the Moody Corporation, 35 Nassau Street, New York, 1907. $3.20; by mail, $3.40.

Mr. Snyder, in his voluminous and in many ways comprehensive work, has the very laudable idea that the private investor in American railroad securities ought to have some other standard of comparison and basis of judgment than that furnished by *ex parte* statements from bankers and brokers desirous of selling certain stocks and bonds. In the introduction to his book he very properly points out the folly of buying from tips supplied by persons who are not disinterested in the course of the market, and he emphasizes the importance of forming independent conclusions of values, based upon the relation of capitalization and charges to earnings, after the management of a road and its general history and prospects are taken into account. Mr. Snyder shows the important difference between nominal and actual capitalization and gives a fairly good rule of thumb for determining true capital. To do this, he takes stocks and bonds outstanding, adds to them rentals, capitalized on a 4 per cent. basis, and subtracts from the result the value, as well as it can be obtained, of securities held as assets. He also calls attention to the importance of a careful consideration of a road's equities in the earnings of other properties and very properly cites the New York Central as an example of a road whose securities sell for a much higher price than is indicated by the actual excess of earnings over expenses, for the reason that it controls a group of highly prosperous subsidiary companies earning far more than they are dispersing in dividends, so that these dividends can be raised when the parent company needs a greater income, as was done this year.

The author calls attention also to the investigation of concealed earnings, that is, earnings which have been "plowed back" into the property, but we cannot agree with his comment, given as a note on page 66, to the effect that costs of material, etc., have so increased in the last year or so that there are, except in rare instances, no concealed earnings in the maintenance accounts of 1906 and 1907. This is obviously incorrect. It would be possible to cite an extremely large group of roads which have spent from 25 per cent. to 100 per cent. more than their strict requirements in maintenance of way and maintenance of equipment during the past year. We are also disposed to criticise the tabular statements of costs of maintenance of way per mile and of maintenance of equipment per mile, as given for each road discussed. The author makes it clear in his introduction that it is miles of single track and not route mileage which determines the cost of maintenance on the mile basis, and yet, in contradiction to his own rule of conduct, he uses the route mile throughout his work. The fallacy of estimating equipment maintenance on a mileage basis is too well known to need comment. Averages are queer cattle at best, and the only kind of an average that is of any use in a hasty comparison of equipment maintenance is an average based upon the numbers of each kind of equipment in use or upon the miles of service obtained from each engine and car. The author, so far as we have observed, does not even point out the most common pitfall of all to which the investigator of equipment and maintenance is subjected, that is to say, the fact that a very large number of roads charge renewals in the repair account without saying anything about it, while an equally large number carefully separate the two.

The general plan of the work is to take each of the principal railroads in the country and most of the smaller lines as well and give a rough outline of the principal facts in their respective developments, followed by a discussion of present ownership, of capitalization, of equities owned, character of traffic, stability of earnings, maintenance improvements from earnings, dividend record, balance sheet, and investment value, so called. A tremendous amount of material has been gathered together in this way and, even though the critical reviewer may find instances of loose work, such as have been cited, and methods of analysis which seem to him superficial, it is nevertheless true that the book is prolific in suggestions and is capable of material usefulness to the investor, provided he takes the author's own advice and forms independent conclusions, based upon the facts presented.

CONTRIBUTIONS

The Collision at Salem, Mich.

Bristol, Va.-Tenn., Aug. 7, 1907.

To the Editor of the Railroad Gazette:

I have read with interest your editorial in the August 2 issue of the *Railroad Gazette* in regard to the collision at Salem, Mich. Let me suggest that a ruled train order blank, similar to that used by a great many railroad companies, would probably have prevented this accident. If the train order had been put upon a blank of this kind and had been properly taken by the receiving operator the leaving time of the special would have been shown on a level with the word Salem, and in that event it is not likely that the engineer and conductor would have misread the order. J. H. M'CUE.

Superintendent, Virginia & Southwestern.

Difficulties With Track Circuits.

Jamaica, N. Y., Aug. 5, 1907.

To the Editor of the Railroad Gazette:

I was much interested in your timely editorial entitled "Track Circuits in Railroad Signaling," in your issue of July 26th. There is one phenomenon, however, on which you did not touch; the effects of metallic structures, such as bridges, acting as condeusers to retard the pick-up of a track relay. In one especially noteworthy case of this that once came to my notice the retardation was so great that a fast passenger train would pass through two blocks before the first home signal would clear. I know of no remedy for this except cutting the circuits.

I have long been in favor of two track relays to a track circuit under certain conditions, but the battery should be placed in the middle of the section, with a relay at each end, the relays to be of equal resistance. No combination of two relays, however, will guard against dangers from foreign current. With one relay, one unbonded joint is liable to cause a clear failure; with two relays, it requires only two unbonded joints, or two broken rails a train length apart, to produce the same condition.

Likewise should we consider putting three or more relays in the circuit, the additional relay would only protect against one additional break in the circuit. Probably where A. C. track circuits cannot be used a great measure of protection could be secured by using stick relays, each relay to be restored by the one in advance.

W. H. ARKENBURGH.

Railroad Legislation of the Year.

As most conveniently summarizing the numerous and important statutes affecting railroads that have been adopted by state legislatures in the United States within the past 12 months we have made the following brief abstract of these laws, arranged by subjects. Important changes in railroad rates or practices which have been made in obedience to orders of state railroad commissions are also included, these in most cases having the force of direct legislative action. The compromises in North Carolina, Virginia and Alabama by which the principal railroads have complied with reduced-rate laws under protest are fresh in the mind of the reader. The new railroad law of the state of New York, in some respects more important than that of any other state, was printed in full in the *Railroad Gazette* of May 31, 1907. The other states which have passed general, comprehensive and radical railroad laws within the past year are Michigan, Oregon and Vermont.

PASSENGER FARES.

Alabama.—Roads 100 miles long or over 2½ cents a mile. For shorter roads the State Railroad Commission may prescribe rates. The commission is also to see to the introduction of interchangeable mileage tickets. The railroads secured an injunction against the enforcement of this law, but, following the compromise in North Carolina, the Southern Railway and at least one other have agreed to put the 2½-cent rate in effect pending litigation to settle the validity of the law.

Arkansas.—Two cents a mile; went into effect April 9.

Georgia.—The commission ordered the larger roads to reduce rates to 2 cents; other roads to 2¼ cents and still smaller roads to 2½ cents. This order was to go into effect September 2 next. One prominent road advises that no decision has yet been reached as to whether the law shall be complied with or be challenged in the courts.

Illinois.—Two cents a mile, all roads; went into effect July 1. Passengers paying fare in the cars may be charged 3 cents a mile.

Indiana.—Two cents a mile.

Iowa.—Two cents a mile on roads earning more than $4,000 per mile per annum; 2½ cents a mile on roads earning $3,000 per mile per annum; 3 cents a mile on smaller roads. Went into effect July 1.

Kansas.—No legislation concerning ordinary fares. Five-hundred mile tickets at 2 cents a mile required on all roads, and interchangeable 2,000-mile tickets at the same rate (net); went into effect May 1.

Michigan.—Two cents a mile on roads having passenger-train receipts of $1,200 per mile per year; 3 cents a mile on smaller roads; higher rates allowed on journeys of 10 miles or less. The rate on the main line of the Michigan Central has been 2 cents a mile for over four years past. The new law goes into effect September 27 next. The Detroit & Mackinac in one place will have to carry passengers 197 miles for $3.34, this being the rate by the shorter competing line.

Minnesota.—Two cents a mile; went into effect May 1.

Missouri.—Two cents a mile on all roads over 45 miles long; 4 cents a mile on shorter roads; went into effect June 19.

Montana.—New railroad commission required to "adopt" rates. Mileage tickets (3,000 miles) sold by large roads at 2½ cents.

Nebraska.—Two cents a mile; went into effect March 6.

New York.—New commission has power to prescribe rates.

North Carolina.—Two and one-quarter cents a mile on roads over 60 miles long; higher rates on smaller roads. The principal railroads secured an injunction against the enforcement of these rates, but they have this month agreed, under protest, to put the low rates in effect pending litigation to test the validity of the law.

Pennsylvania.—Two cents a mile; to go into effect October 1 next. The Pennsylvania Railroad has this year reduced to 2½ cents a mile all local passenger rates higher than that, making substantial reductions throughout its lines; and has introduced 1,000-mile tickets at 2 cents a mile, good for bearer.

South Dakota.—Railroad commission ordered to make valuation of railroads and then proceed to establish fares not over 2½ cents a mile.

Vermont.—New railroad commission has power to prescribe rates.

Virginia.—Two cents a mile on the principal roads; on other roads and on certain divisions of large roads higher rates are allowed, namely, 2½ cents, 3 cents, 3½ cents. The railroads secured an injunction against the enforcement of this law, but have agreed, under protest, to put the low rates in effect.

West Virginia.—Two cents a mile on roads over 50 miles long; on other roads 3 cents; went into effect May 21.

Wisconsin.—Two cents a mile on roads having over $3,500 receipts per mile per year. This goes into effect August 15.

The constitution of the new state of Oklahoma, not yet in effect, names a passenger rate of 2 cents a mile, but the railroad commission will have power to order increases if the low rate is found to be unjust.

RESTRICTION OF FREE TRANSPORTATION.

Alabama, Indiana, Iowa, Kansas, Michigan, Minnesota, Nebraska, Nevada, New York, Oregon, South Dakota, Texas and Vermont have passed prohibitory laws similar to that passed by Congress. In Nebraska monthly reports must be made to the state, and in Michigan yearly. In Nevada the classes excepted from the prohibition include teachers and students. The Texas law is more radical than any of the others. New Hampshire passed a law forbidding state officers to ride on passes and providing for an appropriation to pay their fares. In Oregon the persons excepted include judges and state officers; and a certain law passed to facilitate the appropriation of land by railroads, had a proviso that any road that desired to secure the benefit of the law must agree with the state to carry free the Governor, the members of the legislature and all the principal state officers.

FREIGHT RATES.

Alabama.—Rates in effect were made the legal maximum. Reductions were prescribed on over 100 commodities with a proviso for changes by the commission. The railroads have secured an injunction against the enforcement of this law, but the compromise which has been made concerning passenger rates probably will include some arrangement concerning freight rates.

Georgia.—Reductions ordered by commission some months since; order suspended by the courts; suits now pending.

Iowa.—The commission has this year ordered a reduction in rates on live stock, and a reduction of 20 per cent. in all joint through freight rates.

Kansas.—All grain rates reduced 15 per cent. This superseded certain changes made by the commission last year. Coal rates reduced by the commission (1906).

Michigan.—New commission (not yet in office) will have power to change freight rates. A law passed this year prescribing the procedure to be followed in securing rights of way has a proviso limiting certain carload freight rates.

Minnesota.—Many commodities were reduced 10 per cent.; but injunctions have been secured restraining the enforcement of the law.

Missouri.—Rates prescribed on apples, bricks, stone and certain other commodities. Commodity rates made in 1905 further reduced.

Nebraska.—Commission must make classification and fix rates. Legislature ordered a reduction of 15 per cent. on many commodities.

Nevada.—Legislature prescribed maximum rates much lower than those in effect, but new commission has power to change. Railroads have secured injunctions against enforcement of the law. Legislature prescribed rates on eight grades of ores. The Western classification was made the state classification.

New York.—New commission has power to prescribe rates.

North Carolina.—Reduction of 15 and 25 per cent made in joint through rates, suspended by injunction.

Oregon.—Commission must see that a uniform classification is adopted.

Texas.—No recent legislation, but the commission, which has prescribed rates for several years has, within the past 12 months, made heavy reductions on the rates for many commodities. For example, Fuller's earth, formerly charged 34 cents for 250 miles, must now be carried that distance for 9 cents. The commission about a year ago ordered the adoption of the Western classification in Texas. On carpets and rugs rates have been reduced 40 per cent. On certain iron articles heavy reductions were ordered in rates to Galveston and certain other centers, but this was not a general reduction. Low rates were established on refined oils and heavy reductions were made in rates on green hides. The commission has ruled that freight wrongly described by shippers for the purpose of securing lower rates may be subjected to 10 per cent increase on the proper rate as a penalty.

DEMURRAGE.

Alabama.—Reciprocal. Free time, 48 hours, but on many commodities 72 hours.

Colorado.—Reciprocal. Free time, 48 hours.

Indiana.—Reciprocal. Penalty, $5 a day.

Kansas.—Reciprocal. Penalty, $5 a day; free time on cars holding 30 tons, 48 hours; on larger cars, 72 hours.

Michigan.—New commission has power to prescribe rates.

Minnesota.—Reciprocal. Free time, 48 hours, except coal, lumber, etc., which are allowed 72 hours.

Missouri.—Reciprocal. Free time for cars holding 30 tons, 48 hours; larger cars, 72 hours.

New York.—New commission has power.

Oregon.—Reciprocal; commission may suspend.

South Dakota.—Reciprocal. *Texas.*—Reciprocal.

Vermont.—Reciprocal; severe conditions; free time four days.

Washington.—Reciprocal.

TARIFFS.

New tariffs must be posted in advance of the day they are to go into effect as follows:

Alabama	10 days.	New York	30 days.
Colorado	30 "	Oregon	10 "
Indiana	10 "	Vermont	30 "
Michigan	10 "		

SECRET RATES PROHIBITED.

Provisions like those of the Federal law have been enacted in Alabama, Colorado, Michigan, Nevada, New York, Oregon and Vermont. In Montana the new commission must prevent discrimination and extortion. Nebraska has prescribed heavy fines.

DISTRIBUTION OF CARS.

Fair distribution of freight cars is required under heavy penalties in Alabama, Indiana, Kansas, Michigan and Nevada. In New York the new commission has large powers in this matter. In Indiana and New York track connections must be built to private sidings wherever the commission may require.

JOINT PASSENGER STATIONS.

Railroads are required to provide suitable joint passenger stations at intersections in Alabama (where practicable), Michigan, Missouri and Oregon.

NEW RAILROAD COMMISSIONS.

New railroad commissions have been established as follows:

Alabama.—Three members, four-year terms, elected by popular vote.

Colorado.—New commission of three members. The railroads have begun a suit to enjoin the commissioners from exercising their functions. Law was to have gone into effect June 10.

Michigan.—In place of present single commissioner there is to be a new commission of three members; one a railroad lawyer and one familiar with transportation and traffic. For the third member no restriction is mentioned.

Montana.—New commission of three members, six-year terms.

Nebraska.—A new commission; appointees must be 30 years old.

Nevada.—New commission of three members, three-year terms.

New Jersey.—New commission of three members.

New York.—Old commission has been abolished. The state is divided into two districts, and for each district there is a Public Service Commission of five members having control not only over railroads, including street railroads, but also electricity and gas. The first district comprises New York City and the second all the rest of the state.

Oregon.—New commission of three members. These are to be elected, one at large and one from each of the two congressional districts.

Pennsylvania.—New commission, three members; to take office January 1, 1908.

Vermont.—In place of the old commission of three members a new one was established consisting of the same number. The Governor designates the chairman.

The commissions of Indiana, Washington and Wisconsin were established in 1905.

In Arkansas and Iowa the powers of the existing commissions have this year been materially enlarged.

WORKING HOURS.

Laws limiting the working hours of men having to do with the operation of trains and of telegraph operators have been passed in 12 states. We give a brief statement for each state, omitting the qualifying clauses for which the reader will have to refer to the fuller reports heretofore published.

Connecticut.—Telegraphers, eight hours; small offices, 12 hours.

Indiana.—Trainmen, 16 hours. *Kansas.*—Trainmen and telegraphers, 16 hours. *Maryland.* (1906).—Telegraphers, eight hours. *Minnesota.*—Trainmen, 16 hours.

Missouri.—Telegraphers, eight hours; small offices, 12 hours.

Montana.—Trainmen and telegraphers, 16 hours.

New York.—Trainmen, 16 hours (March 4, 1908); telegraphers, eight hours (October 1, 1907); small roads excepted.

North Carolina.—Trainmen, 16 hours; telegraphers, 12 hours. Penalties for violation, fine and imprisonment.

South Dakota.—Trainmen, 16 hours. *Texas.*—Trainmen, 14 hours; telegraphers, 8 hours, small offices excepted. *West Virginia.*—(1906). Telegraphers, eight hours.

TRAIN CREWS.

The minimum number of men to be assigned to the management of trains has been prescribed by law in Arkansas, Indiana, Kansas, Texas and South Dakota.

EXPRESS COMPANIES AND PRIVATE CARS.

Express companies are brought under the regulative power of the state railroad commissions in Colorado, Iowa, Kansas, Michigan, Montana, Nebraska, Nevada, New Hampshire, New York, Oregon and Vermont. Private cars are brought under the regulative power of the commission in Colorado, Michigan, Montana, Nebraska, New York, Oregon and Vermont. The Colorado law specifies pipe lines and the Kansas and New York laws specify sleeping cars.

ACCIDENTS.

Railroad accidents are mentioned in recent laws as follows:

Colorado.—Commission to investigate.

Indiana.—Serious cases to be reported in five days; commission to investigate.

Minnesota.—Serious cases to be reported by telegraph. Commission to investigate if found necessary.

Montana.—Commission to investigate important accidents.

Nevada.—Accidents to be reported at once. Commission may investigate.

Vermont.—Serious cases to be reported by telegraph.

Washington.—Commission to investigate if any person killed. Monthly reports required same as those made to Interstate Commerce Commission.

EMPLOYER'S LIABILITY.

Laws extending liability of employers for accidents to employees, due to negligence of fellow employees, or accidents due in part to the victim's contributory negligence, have been passed in Iowa, Kansas, Nebraska and South Dakota.

MISCELLANEOUS.

The foregoing list embraces those subjects which have been most generally discussed and in which interest is felt throughout the country. In addition to these, there are numerous other matters of local importance which have been made the subject of legislation in one state or another within the past year. We note some of these.

Cabooses.—In Montana only eight-wheel cabooses may be run.

Confiscation of Coal.—Kansas, Montana and North Carolina have passed laws regulating the confiscation of coal by railroads. In Kansas and Montana the owner must be paid double the value of the coal. In North Carolina he must pay 125 per cent. of its value.

Express Rates.—Nebraska has passed a law reducing the rates for transportation of merchandise by express companies 25 per cent. The express companies have taken action in the courts to restrain the enforcement of this law.

Fences.—Iowa and Montana have passed laws requiring railroads to be fenced on both sides.

Frogs.—Missouri has adopted a law similar to that long in effect in many states requiring frogs and switches to be suitably blocked so that workmen shall not catch their feet in them.

General Powers.—Arkansas has passed a number of laws affecting the powers of railroad corporations, including one requiring that a general office shall be maintained in that state. In California a new law defines the rights of railroad corporations in regard to buying land, etc.

Headlights.—In Texas all train engines must have electric headlights.

Intoxication.—In Vermont a railroad company is now subject

to $3,000 fine for employing on trains men known to be dangerous on account of their drinking habits, and any person working in the train service and being intoxicated is liable to imprisonment for one year.

Lobbyists.—Nebraska has a law requiring legislative agents to be registered and to report their expenses.

Mercantile Business.—The new constitution of Oklahoma, not yet in effect, has a clause, like that in the Federal statute, forbidding railroads to transport their own products or manufactures except for their own use.

Penalties for Appealing.—Three states, Alabama, Arkansas and Missouri, have enacted laws designed to punish any railroad company which by appeal, or by any process, transfers to a Federal court any suit begun in a state court to enforce the laws of the state against the railroad.

Taxation.—In Nebraska a new law affecting local taxes increases the burden on the railroads of the state $500,000 yearly. In New Mexico there is a new law taxing sleeping cars. In Utah taxation is regulated by a new law, chapter 9.

Telephones.—In Montana railroads are required to allow all telephone companies to put up instruments in stations.

Train Rules.—An Indiana law requires the State Railroad Commission to see that the rules of the operating department of railroads shall be adequate and satisfactory. There is a provision for holding a convention of railroad men annually to consider this subject.

Safety Appliances.—We have made no mention of laws regulating safety devices—air-brakes, automatic couplers, grab irons, etc. Several states have passed laws of this kind, but as all are substantially similar to the Federal law on this subject, and as the practice of nearly or quite all of the railroads in every state now conforms to the Federal law, at least as well as it would conform to a state law, these new state statutes may be treated merely as confirmatory supplements to the Federal law. It is to be noted, however, that there are now three states in which the use of the block system is compulsory, on the order of the State Railroad Commission, namely, Indiana, Massachusetts and Minnesota. In Massachusetts this law has been in effect about a year but we have as yet heard of no mandatory order being issued. The state of Washington has provided for a safety appliance inspector at a salary of $2,000 a year. He must look after railroad safety generally. He may order dangerous cars out of service. The appointee must have had seven years' experience in railroad operation and must give a bond of $5,000 for the faithful performance of his duties.

In Nebraska night telegraph operators and towermen must be at least 21 years of age. In Minnesota the state commission must inspect and approve new railroads before they are put in use. The commission may require interlocking signals not only at crossings of one road with another, but also at junctions and drawbridges. In Illinois the law regulating the establishment of crossings has been revised.

Mallet Compound Locomotive for the Erie Railroad.

The Mallet compound locomotive, introduced to American railroads three years ago in the monster that was built for the Baltimore & Ohio by the American Locomotive Company, has been so efficient from the start, both in economy of operation and maintenance, that its construction was followed closely in the engines of the same general type for the Great Northern illustrated in the *Railroad Gazette* of October 12, 1906; and then came the placing of an order for three of the original general type but of greater capacity for the Erie, to be used in pusher service on the 1.3 per cent. grade between Susquehanna and Gulf Summit, where, with a consolidation locomotive ahead, they will be capable of handling 2,660 tons. Although these Erie engines are much heavier and more powerful than the Baltimore & Ohio engine, the essential features of the two designs—such as flexible joints to high and low-pressure cylinders, receiver and exhaust pipes, articulated connection between frames, boiler, bearings, power reversing gear, etc., are practically the same, none of these features having failed to give perfect satisfaction during the two years this engine has been in continuous service.

The accompanying tabular comparison will show the principle differences in the two designs:

	Baltimore & Ohio.	Erie.
Wheels	0-6-6-0	0-8-8-0
Total weight	334,500 lbs.	"
Size of cylinders	20 & 32 x 32 in.	25 & 39 x 28 in.
Diameter of drivers	56 in.	51 in.
Tractive effort (working simple)	71,500 lbs.	91,800 lbs.
Steam pressure	225 "	215 "
Total wheel base	30 ft. 8 in.	39 ft. 2 in.
Driving wheel base, rigid	10 ft.	"
Total heating surface	5,600 sq. ft.	5,313.7 sq. ft.
Grate area	72.2 "	100.0 "
Weight on drivers, tractive effort	4.78	"
Total weight, total heating surface	59.9	"
Trac. eff. x diam. drivrs., total htg. surf.	700	910
Htg. surf., vol. equiv. simple cylinders	295	217
Grate area, vol. equiv. simple cylinders	385	108

It must be noticed in comparing the above ratios that the engine illustrated is provided with a 4 ft. combustion chamber which decreases the total amount of heating surface, a point that will

be discussed later. The weight of the Baltimore & Ohio engine was 334,500 lbs., which was carried by three pairs of driving wheels. This has been increased to 410,000 lbs. in this case; which necessitated the introduction of one more pair of wheels in each unit, thus increasing the total number to 16, by which means the load per wheel has been reduced to about 25,600 lbs., which is well below the limit set by a number of other road engines in service. The fact that this has been done is regarded by the builders as an argument showing the advantage of this type for obtaining a maximum adhesion for tractive power with a minimum rail pressure per wheel.

Of course in an engine of this size the point vital to its successful operation is the boiler. In this case the largest locomotive boiler ever built is used. It is of the radial stayed type with conical connection, the inside diameter of the first or smallest course being 82 in., while the inside diameter of the largest course is 96 in. The heaviest ring of the shell is 1 1/16 in. thick. This is also the thickest plate that has been used, and is needed for carrying the pressure of 215 lbs., which is also well up to the upper limit of what has been used in locomotive practice. The water alone in the boiler weighs 42,700 lbs., and the tubes, of which there are 404, 2¼ in. outside diameter and 21 ft. long, weigh 23,700 lbs. The total weight of the boiler with water is 139,900 lbs. The firebox is of the Wooten type, 120⅛ in. long and 114¼ in. wide, and has a grate area of 100 sq. ft. The water space at the mud ring is 5 in. on all sides. Aside from these dimensions the boiler has little about it of striking novelty, beyond the use of a cast steel dome; which, while not entirely new, is still sufficiently uncommon to attract attention. It was placed where it is, at the center of the length of the boiler, in order to avoid the possible disadvantages that might arise, due to the working of the engine in both directions, if it were near one end. It is on the conical course. It will be noticed that the conical course is lighter than the front, and is 1⅛ in. thick; still with the dome base and the stiffening ring for the opening there is an impressive mass of metal 3⅜ in. thick at the top. This is not far from the width of many foundation rings, and serves to account for the great weights noted above.

The cutting down of the actual amount of heating surface as compared with the smaller engine of the Baltimore & Ohio is another tribute to the demonstrated efficiency of the combustion chamber. By equating the heating surface of the two engines, it will be found that the Baltimore & Ohio engine had a total equated firebox heating surface of 1,369 sq. ft., while the Erie has 1,428.7 sq. ft., showing that, on the basis of the Vaughan formula, an allowance has, in reality, been made for the increased size and capacity of the engine. Attention is again called to the location of the injector check, which, on this boiler, is set only 8 in. back

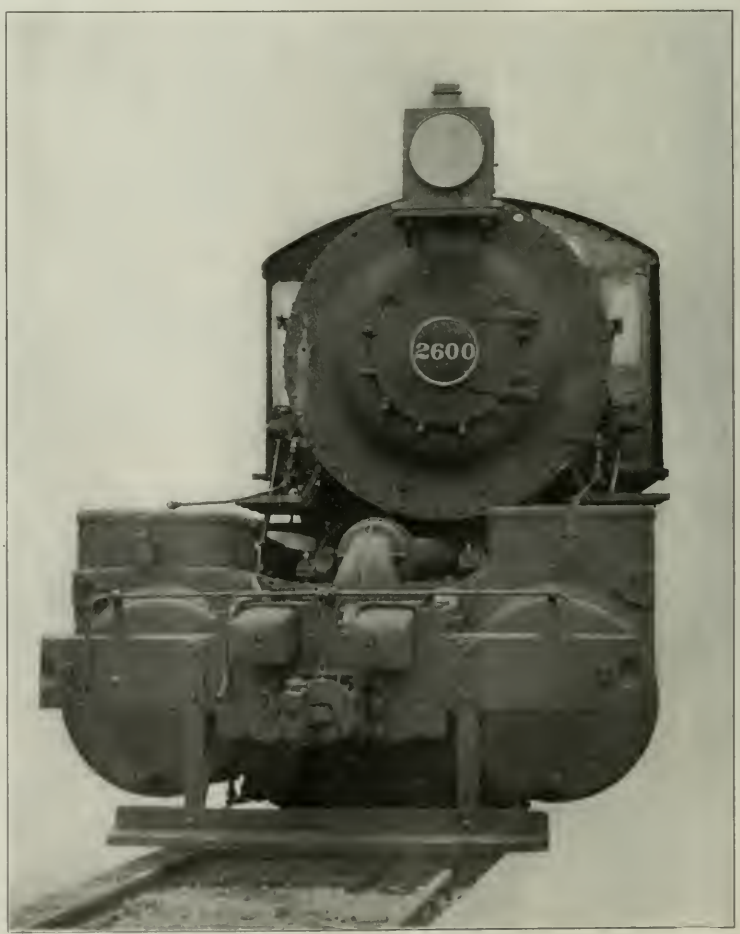
Boiler for Erie Mallet Compound.

of the front tube sheet and is nearer than in any other boiler yet shown in the *Railroad Gazette*. In the construction of the firebox and combustion chamber, sheets $\frac{1}{2}$ in. thick are used for the latter, and the ordinary thickness, $\frac{5}{16}$ in., for the crown and side sheets. The crown sheet drops $5\frac{1}{2}$ in. in its slope from front to back.

The throttle valve is of a peculiar and somewhat novel construction. The great height of the top of the boiler above the rail (14 ft. $7\frac{1}{2}$ in.) necessitates the use of a very low dome, and this in turn makes it advisable to take steam from the top of the same. The throttle valve has therefore been designed with this end in view; and, while it is balanced in the usual manner, steam is taken from the highest and dryest part of the dome only. To accomplish this the throttle casing A is surmounted by a crown piece B that curves in and beneath the overhang of the hood C that is fastened to the top of the valve and moves with it. The valve is hollow and is closed at the bottom by a piston $8^{31}/_{16}$ in. in diameter. This piston is furnished with water packing grooves and moves in a cylinder bored in the casing. Steam is admitted at all times to the top and interior of the valve through the space between the crown B and the hood C, a space which is never less than $\frac{1}{4}$ in. This arrangement serves not only to take the steam from near the top of the dome but also acts as a separator. This last feature is due to the fact that it is a tendency of steam under pressure and flowing rapidly over a concave surface, to deposit its contained water under the influence of centrifugal action on that surface. The water so deposited follows along past the upper lip D of the opening to the valve interior and thence down through the central space around the stem to the water in the boiler. Steam is led from the throttle pipe through a short dry pipe to a point directly in line with the high-pressure cylinders, from whence it passes through the top of the shell and is divided in a tee-pipe and passes down through wrought iron steam pipes on either side of the boiler to each of the high-pressure valve chambers. The design of the high-pressure cylinders which is shown in the accompanying illustration is similar to that used on the Baltimore & Ohio engine, the cylinders being cast in pairs with saddles, and the separation between the two cylinders being $8\frac{1}{2}$ in. to the right of the center line of the saddle, to make room for the receiver pipe. The engines are compounded on the Mellin or Richmond system, the intercepting valve being located in the upper part of the left cylinder casting. Exhaust steam from the right high-pressure cylinder passes through a cored passage to the back of the cylinder casting, from whence it passes through an outside U shaped pipe connecting to a passage in the left cylinder casting leading up into the intercepting valve chamber into which the exhaust steam from the left high-pressure cylinder also passes. The emergency exhaust valve is located in the side or the left cylinder casting and has a $4\frac{1}{2}$-in. jointed pipe connection with an opening in the back of the exhaust pipe in the smokebox. A three-way cock within easy reach of the engineer operates the emergency exhaust valve.

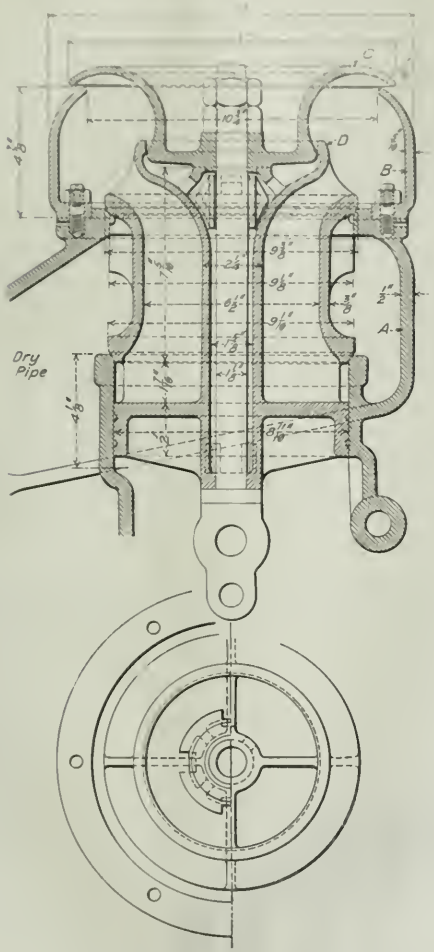
Steam from the high-pressure cylinder passes into a 9-in. receiver pipe extending forward from the center of the cylinder saddle to which it is connected by means of a ball joint. In order to facilitate putting in place or removing, this pipe is made up of three sections and is connected at the front end by means of a slip joint to cover variations in length due to curving to a Y pipe through which steam reaches each of the low-pressure steam chests. The receiver pipe is laid out for 16-deg. curves. The flexible connections are the same as those used in the Baltimore & Ohio design, which have proved so satisfactory—no trouble from leaky joints having been experienced throughout the entire two years this engine has been in service. Steam from the low-pressure cylinders, which are located considerably ahead of the front end of the boiler, exhausts back through a flexible pipe connection to the exhaust pipe in the smokebox. The high-pressure cylinders are equipped with piston valves, and the low-pressure cylinders with Richardson slide valves. The valve gear is, of course, of the Walschaert type. By an ingenious arrangement of the reversing gear the weights of the valve motion of the front and rear engines counterbalance each



Front View of Erie Mallet Compound Rounding a Curve.

other. The side elevation clearly shows the arrangement. As the high pressure valves have an internal admission and the low pressure an external admission it was possible with this arrangement of reversing gear to obtain a most satisfactory valve motion with both eccentric cranks leading the pin, the rear engines taking the forward motion from the top of the link and the front engines from the bottom of the link. The operation of the engine is rendered easier than that of an ordinary rigid engine by the application of pneumatic reversing cylinders to the ordinary gear with positive automatic locking in any desired position. The frames of both the front and rear engines are of cast steel, 5 in. wide. The articulated connection between the front and rear frames is shown in the illustration of the side elevation.

The part of the weight of the boiler which is carried on the forward engines is supported by a self-adjusting sliding bearing located between the third and fourth driving-wheels. This bearing consists briefly of a built-up saddle casting which extends down and bears on a cast steel cross-tie directly below it, through a wrought iron case hardened sliding plate. A brass wearing plate is introduced between the boiler bearing casting and the wrought iron plate. The sliding plate is radially planed on the bottom so that it adjusts itself to the alinement of the engine and the load on the sliding plate is at all times perfectly distributed and there is no cutting of the wearing surfaces. Movement in a vertical direction is prevented by a safety connection between the boiler bearing casting and the cross-tie, which prevents the frames from dropping away from the boiler in case of any derailment. There is also a similar safety connection provided at the front end of the boiler between the guide yoke casting and the exhaust pipe elbow.



Throttle Valve; Erie Mallet Compound.

Another sliding support is located between the second and third pair of driving wheels. This support is so adjusted that it does not take any of the load except under unusual conditions when [illegible] it necessary. It is provided with a floating [illegible] which serves to take some of the load off the main boiler bearing. This device consists of a pair of [illegible] one on either side of the center of the engine from [illegible] as the engine turns through curves. These columns have a ball joint connection at the upper ends with saddle castings bolted to the boiler and a ball joint connection at the lower ends with flap castings hinged to the bottom of a cross tie across the lower rails of the frame. Around the outer ends of these hinged castings are U bolts, the bars of which extend up through the bottom of the cross tie and through coil springs seated on the cross tie. These springs thus exert an upward force on the columns equal to the total compression of the springs. The initial total compression is 30,000 lbs., which can be increased by screwing down the spring caps by means of nuts on the ends of the U bolts. This boiler support is also provided with a spring centering device of the same design as that used on the Baltimore & Ohio engine.

Another sliding support is formed between the exhaust pipe elbow and the guide yoke casting. As mentioned above this support also forms a connection between the boiler and the frames.

The four pairs of front driving wheels are equalized together on each side and cross equalized in front of the forward drivers, making this system equivalent to a single supporting point. The rear engine on the other hand is equalized throughout on each side only without cross equalization. This forms a complete three point suspended engine, or the best obtainable condition for flexibility and ease on the track.

The following are some of the principal dimensions of the engine:

Cylinder diameter, H. P.	25 in.

Picked Up on the Road.

BY GULF.

I am not what is ordinarily known as a traveling man, though I do move about somewhat, and I am not disposed to draw final conclusions from the experience of one man; still I cannot help wondering whether my experience is exceptional or whether I am a railroad hoodoo. During the past eight or nine months I have moved across a considerable territory in the south, east and north, on many different roads, and I have not yet reached my destination on time. This is a broad statement, but it is rigidly true. The

trains have been from 15 minutes to six hours late, and in not a single instance was it due to accident or track obstruction, but to carelessness and inefficiency in getting started or the inability of the locomotive to haul the train on schedule time. Yet when I speak to a railroad man on the subject he invariably claims that a late train is the exception. My experience tells me that that is not the truth, and I would like very much to see a show-down of the despatcher's sheets. I remember once, a number of years ago, I had such a controversy with a superintendent of one of the roads running out of New York, and he claimed that his trains were always on time. So I kept a record of about 275 trains on that road during the next nine months, and found only one that fell within the five-minute limit, and that was two minutes late. When I called the superintendent's attention to the subject I received no reply.

As a matter of fact there is no reasonable excuse that can be offered for a train regularly off schedule. Oh, yes; I know all about bad coal, head winds, slippery rail, loading baggage, and the other causes that are given as excuses *ad nauseam*, but they are not excuses. These causes of delay will occur and should be provided for in the schedule. It looks very nice to make up a schedule on a 50-mile pace for an express or a 30 for a local, but what is a paper schedule good for if the locomotive cannot do the work? The general manager and superintendent work it out that a certain type of engine ought to haul a given train between terminals in a definite time. The superintendent of motive power is coerced into saying "yes, under favorable conditions." So the schedule goes into force on the assumption that the conditions will always be favorable on our line, and the train may make one or two trips on time. Then an extra car is added, or there is a little more slate than usual in the coal, or a theatrical company with a lot of baggage sees fit to go that way, and then the capacity of the hauling power is exceeded and "train late" is the result. "Train late" then becomes the rule, but the beautiful fast schedule remains on paper, a mockery to the trustful traveler who innocently confides in its untruthfulness.

It seems that the definition of the time-table should be changed from "a statement of the time at which trains are expected to arrive and depart from the several stations," to "a statement of the time at which some people hope they will."

Now, what is the result of this state of affairs? In the first place there is a feeling of unmitigated disgust aroused in the mind of the traveler. He feels that he has been imposed upon; that the railroad company has been derelict in the execution of its part of the contract; and there comes a determination to get even at the first opportunity. There is not one man in a thousand who would not prefer, by far, to travel on a very slow schedule and be sure of reaching destination on time than to take these fancy fast trains that lose time every inch of the way. This is not the expression of an individual opinion, but is the consensus of statements made to me by hundreds of men with whom I have talked on the subject. At present it is well-nigh impossible to schedule a trip with any certainty that the itinerary can be followed because of that *bete noir* of all travelers, the late train. So, if I have any advice to give to managers on the subject, it is, "Do not bite off more than you can chew; don't make a paper schedule that your wheels can only follow on rare occasions, if you wish to secure the favor of your patrons."

The effect of a late train on the employees is demoralizing, to say the least. Ask any yardmaster what it means to him to have a train late. His movements are all disturbed and the orderly execution of his work made an impossibility. His crews will try to steal a few more seconds on the main line or be late in breaking up the train, and so more time is lost and a bad matter becomes worse, and when this is scattered throughout the line, the despatchers become overworked, crews and agents become confused by the multiplicity of orders, and the climax is reached by somebody forgetting. Then there are damages galore, that ought to put a damper on the complacency of the general manager. But instead of that he puts the blame on the poor devil who forgot, instead of realizing that the fast schedule that the engine could not make was the primary cause of the trouble, and that "Thou art the man" should be sent home to him.

I know of the troubles with labor and the difficulty of securing reliable men, and so does every superintendent in the land. And knowing this, the blame comes home so much the more, in that there is put upon this unreliable material a task that it is impossible for it to perform. If state legislatures and railroad commissioners and general executive reformers would pay less attention to rates and rebates and see to it that the railroads do not make time-table bargains that they cannot execute, and when an accident occurs to a belated train, besides hauling up the forgetful one, would go deeper and see what may have been the record of that train in the past as to punctuality, and what is the common practice of the road, they would get closer to the true cause of the difficulty than they usually do. Then, if they must act or legislate, let it be along the lines of cutting down impossible schedules and seeing to it that those made are lived up to, and thus earn the commendation of all concerned—the traveler and the employee—with the possible exception of the manager who is so smugly complacent over the 50-mile schedule for a 40-mile gait, and whose complacency may well be ruptured for the general good of the public.

The Lusitania, of the Cunard Line, on Her Trial Trip. (See Editorial Page).

Electrification of the New York, New Haven & Hartford.

BY E. H. MCHENRY,
Vice-President, N. Y. N. H. & H.

The New Haven company was one of the pioneers in the field of heavy electric traction, and has operated six of its shorter branch lines by electricity for a number of years past beginning as early as 1895. Three of these lines, aggregating 35 miles, were equipped for overhead contact, and the remaining lines, aggregating 39½ miles, for third rail operation. All lines were operated with 500 volt continuous current, supplied from main stations and substations. The third rail was primitive in form and without protective devices of any sort. So many accidents followed the use of this method of supplying current to the motors that the railroad was compelled to abandon all third rail operation in Connecticut, and revert to steam service, by a decree of the Superior Court dated June 13, 1906, and it now has no third rail in service except a junction overlap with the New York Central at Woodlawn. The unsatisfactory experience with this type of construction influenced the company's decision in favor of the single phase system for the New York terminal electrification, which was finally adopted after a careful investigation of the relative merits and disadvantages of the two methods of construction.

Had the study of the question been limited to the equipment of the terminal section in New York, considerations of uniformity and expediency would doubtless have influenced the decision in favor of continuous current motors, taking current from a third rail. The New Haven, however, recognized the importance of its decision in its effect on future extensions of electric service to other parts of its system, and the final decision was based upon a study of the subject as a whole rather than upon the solution of the terminal problem only. The selection of a system of transmission which combines efficiency, flexibility, simplicity and lowest first cost, was important. The New Haven system comprises a network of lines and its transmission problems must be worked out for areas rather than for linear distances, thus reversing ordinary conditions. As the area served increases as the *square* of the radius of transmission from the generating center, the commercial and practical value of high potential transmission is much increased.

While both methods under consideration included high tension transmission by alternating current, it was believed that the combination method requiring transforming devices and continuous current motors was less well adapted to the conditions than single phase for many reasons. The electric efficiency of the combination system between power house bus bars and engine shoes is 75 per cent. only, as compared with 95 per cent. for the single phase system. The flexibility of the combination system is impaired by the limited radius of the secondary low tension distribution, requiring substations at frequent intervals, and still further by the limitations imposed by the use of a third rail. The position and height of this rail must be rigidly maintained, and the practical margin of permissible variation is small. Its continuity is broken at switches and crossings by frequent transferrence of the conductor rail to the opposite side of the track or to an overhead position. In contrast, the single phase system requires no substations or secondary circuits; the continuity of the overhead conductor is complete, and its position and height may vary within vertical and horizontal limits of 8 ft. and 4 ft., respectively, without losing contact with the collecting shoes on the pantagraph frames.

It is yet too early to furnish definite and positive comparisons of cost of the two methods under consideration, but the calculations and experience of the company's engineers indicate that the total cost of a single phase installation will be much less than that of the continuous current system, and that the higher electrical efficiency, lower fixed charges, maintenance and operating expenses of the single phase system all tend to reduce the relative cost of current delivered to the engine shoes in about the same proportion.

The determination of the most economical and desirable frequency and voltage of the transmission system involved the consideration of many factors. The choice of frequency was limited to 15 cycles or 25 cycles. The lower frequency afforded a material reduction in weight, size and cost of motors, a reduction in conductor losses and induction disturbances, together with an increase in the power factor of the motors, but its adoption would have materially impaired the commercial value of the system as a whole, in restricting or preventing its extension for many other uses incidental to railroad operation. The standard frequency in general use is 25 cycles, and as the New Haven already owned a number of power houses generating current at this frequency for trolley operation, and, in addition, had equipped many of its shops with 25-cycle motors, the adoption of 15 cycles would have required the abandonment of a large amount of standard apparatus, or the interposition of costly and inefficient means of transiation. It was also considered desirable to provide for operation in parallel with the 25-cycle generators already adopted by the New York Central. The practical effect of a change from 25 to 15-cycle apparatus was thus substantially equivalent to a "break in gage," and it was decided that the practical commercial value of the higher frequency outweighed the theoretical merits of the lower one.

Various alternatives were considered before fixing the best trolley and transmission *e. m. f.* of the system. It was at first proposed to increase the economical radius of transmission to the utmost by generating current at the highest initial voltage for which generators could be safely designed (about 22,000 volts) and to provide substations at suitable intervals, equipped with static transformers, for supplying current at 3,000-6,000 volts to secondary contact circuits. As the two motors in each electric locomotive truck are permanently connected in series, current must be supplied at 550 volts through the transformer which forms part of the locomotive's equipment. It became evident, however, that a great gain in simplicity would result if the intermediate substations and line transformers could be cut out altogether by reducing the initial *e. m. f.* to 11,000 volts and raising the ratio of the locomotive transformer to correspond. This was done with a resulting reduction in capital and operating cost, coupled with an increase of electrical efficiency. Incidentally, the difficulties in designing satisfactory collecting devices were greatly diminished.

Before giving a detail description of the apparatus used in the electrified district it may be interesting to give a few comments on the commercial aspects of electric traction, as the natural prejudice of the stockholder in favor of the continued maintenance of dividends must be respected, and the technical expert too frequently neglects this in his scientific ardor.

Numerous analyses and comparisons of the comparative costs of electric and steam operation have been published from time to time, which tend to prove that a considerable saving in fuel, engine repairs and other operating expenses may be expected. Under favorable conditions this saving may be large enough to pay interest and other fixed charges on the additional construction investment and still leave a satisfactory margin to be applied to dividends. Under general conditions, however, it is altogether improbable that the direct saving resulting from the simple substitution of electric for steam power will be sufficient to justify the additional investment and financial risk.

In changing the method of motive power on existing railroads, the conditions are by no means so simple as in the construction of new lines, since a great amount of capital already invested must be sacrificed, and the problems of adaptation to existing conditions are peculiarly severe. The transition stage in bridging over the gap between steam and electric operation is both expensive and difficult, as the change affects train lighting and heating, telegraph and telephone service, signaling and track maintenance, for which both temporary and permanent provision must be made. The simultaneous maintenance of facilities and working forces for both steam and electric service within the same limits will rarely be profitable, for the reason that a large proportion of expenses incident to both kinds of service is retained, without realizing the full economy of either.

To secure the fullest economy it is necessary to at least extend the new service over the whole length of the existing engine district, and to include both passenger and freight trains.

The application of electric traction to heavy railroad service will probably be governed by other and more important considerations than its mere relative cost as a motive power under similar conditions, as illustrated in the development of the ordinary trolley service. In this development the commercial value of higher speeds and of increased car capacity is so large that the relative cost of electric versus animal tractive power becomes almost negligible by comparison. Analogous results may be hoped for in the corresponding development of electric traction in heavy railroad service, as the new conditions will afford opportunities for at least two radical modifications of existing conditions, quite apart from minor economies.

In steam service the weight and speed of trains are limited by the horse-power capacity of the locomotive, which generates its own power, and there are but few locomotives which can generate sufficient steam to utilize their full cylinder tractive power at speeds in excess of 12 miles an hour. Consequently, any increase of speed beyond certain limits can only be attained by sacrificing train tonnage in a corresponding degree. The division of the train-mile cost by the lesser number of tons increases the ton-mile cost proportionately.

The high cost of fast freight service is principally due to this effect of a diminishing divisor, while it would seem that electric traction should permit high speeds without sacrificing commercial tonnage, as, with a relatively unlimited source of power at command, the maximum drawbar pull permitted by the motor design, may be maintained at all speeds.

Hardly less important is the opportunity afforded for the economical operation of trains of *minimum* capacity. The train capacity cannot be reduced, without loss, below the point where the earnings equal the train-mile cost, and if this cost cannot be reduced proportionately with reduced capacity, the inferior limit of capacity may be uneconomically large. In steam service the irre-

ducible elements entering into the train-mile cost are so large that it is rarely profitable to operate trains earning less than 40 to 50 cents per mile. In contrast, electric service permits an extreme reduction of the train length to single car units, costing to operate but 10 to 15 cents per car-mile. Hence, the frequency of service may be increased and rates reduced, which in turn will react on the volume of traffic, with the final result of increasing both gross and net earnings. It may, therefore, be claimed for electric traction that it will extend the limits of profitable operation of high-speed heavy trains, and also of light trains of low capacity.

Other but relatively minor advantages are possible in the effect on earnings, due to the elimination of smoke, gases, dust, cinders and heat, the better ventilation of cars, the extension of electric train lighting and heating; and of the effect on expenses due to the concentration of power production in large and economical power houses, a reduction of engine repairs, an increase of effective engine and train mileage, a more or less complete elimination of engine houses, turntables, fuel stations, water tanks, cinder pits and other operating facilities, the consolidation of power requirements for traction, pumping, operating shops, elevators and general uses, and the use of current for lighting switch lamps, stations and other buildings.

Finally, the availability and value of real estate and structures at large terminals will be greatly augmented by the possibilities of using two or more superimposed track levels, as in the new terminals in New York for the New York Central and the Pennsylvania.

A general change from steam to electricity will render unproductive a very large amount of invested capital, and create the necessity for the expenditure of additional amounts still greater, but there is no reason to doubt that the transition already in progress will be rapidly extended and applied at all points where congested terminals, high frequency of train service and low cost of power create favorable conditions.

Overhead Catenary Construction over Four Tracks; New York, New Haven & Hartford.

OVERHEAD LINE CONSTRUCTION.

The overhead line construction is of the catenary type and consists of two steel cables of high strength, supported at intervals by steel bridge structures. A copper conductor or trolley wire is suspended below the two supporting cables by means of hangers placed at frequent intervals. Wherever the cables pass over the steel supporting bridges they rest on porcelain insulators, and at intervals heavy bridges are provided against which the cables are anchored by means of specially constructed strain insulators.

The steel supporting bridges are of varying lengths so as to accommodate four, five, six or as many as 12 tracks, as the local conditions require, without placing posts between tracks. These bridges are of a uniform design and consist of angle iron and lattice bar construction. The anchor bridges are provided with automatic circuit-breakers by means of which the different sections may be isolated, and also the several parallel tracks separated from one another in case of accident to any one track. The anchor bridges also carry lightning arresters, shunt transformers for operating the circuit-breakers, together with foot walks, hand railings, lighting circuits and the wires and conduit for the auxiliary control circuits.

The main conductors over the running tracks are paralleled throughout their entire length from Stamford to Woodlawn by two feeder wires. These feeders constitute auxiliaries to the main track conductors and are connected with the latter at each anchor bridge through circuit-breakers. The auxiliary feeders provide means for feeding around any one section in case it is cut out of service on account of some accident in that particular section.

In laying out the bridges for the section from Woodlawn to Stamford, it was found that the sharpest curvature was 3 deg. As this curvature will permit of stringing trolley wire in straight lines between points of support 150 ft. apart without deviating from the center of the track more than 8½ in. on each side, it was decided to place all bridges a fixed distance of 300 ft. apart, and on curves to provide guide poles from which pull-over wires are attached and secured to the catenary spans. By this means a minimum amount of overhead wiring was obtained, and the deviation from the center of the track was maintained within safe limits.

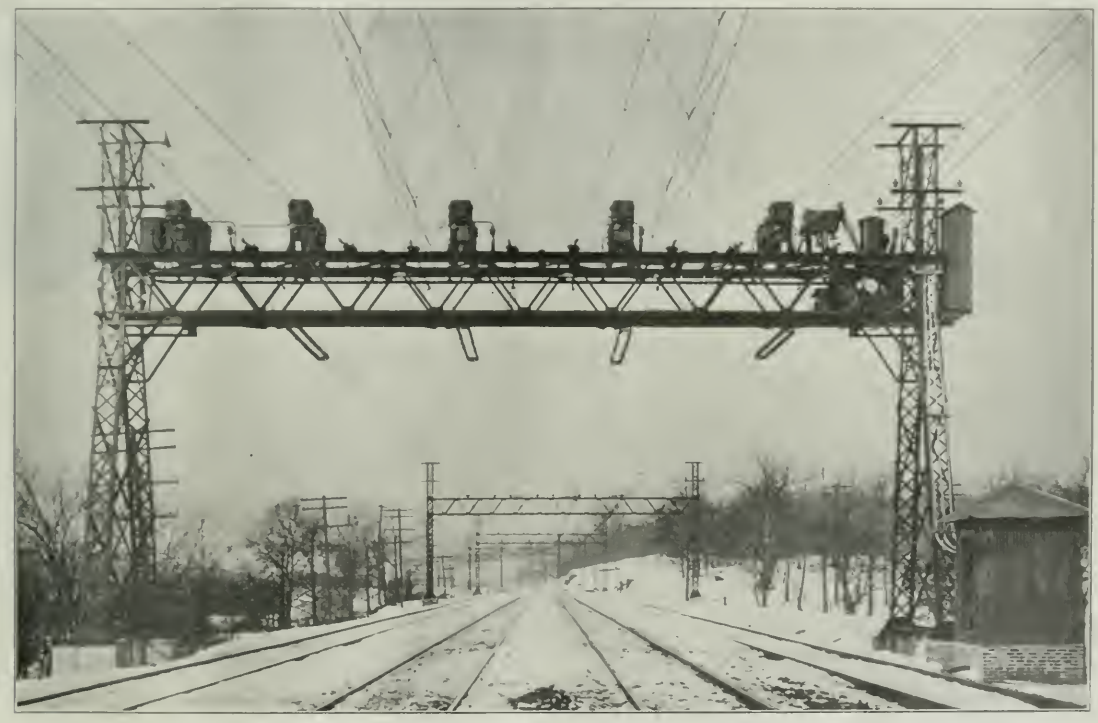
The standard four-track intermediate bridge consists of two supporting side posts and a horizontal truss. Each supporting post is approximately 38 ft. long by 1 ft. 10 in. square. Each is composed of four 4-in. x 4-in. x $^{7}/_{16}$-in. angles, secured together by 2¼-in. x ⅝-in. lacing bars. Each post rests on a concrete foundation. The cross truss is bolted to the vertical posts, allowing a distance of 23 ft. 4 in. from the lower side of the truss to the top of the rails. The truss is 4 ft. 6 in. deep from back to back of the upper and lower chord angles, which are placed 1 ft. 10 in. from back to back. The upper chord angles are 3½ in. x 6 in. x ⅜ in. and the lower are 4 in. x 3½ in. x $^{9}/_{16}$ in.

The extensions of the side posts above the trusses are utilized for supporting the feeder wires which are carried on angle iron cross arms bolted to the posts. The lower cross arm carries the auxiliary feeder. The upper cross arm is located 5 ft. above the lower one and carries two wires of three-phase circuit. The third wire of the three-phase circuit is carried on a light vertical channel iron support which is not shown in the illustration.

Anchor bridges of heavy construction are placed every two miles, and against these bridges the catenary cables are anchored. The auxiliary apparatus and signals are mounted on the bridge, the semaphore blades being located below the truss so as to afford an unobstructed view to the engineer. The four-track anchor bridge consists of two A-shaped posts having a spread at the base of 15 ft. and a width at right angles to the track of about 2 ft. The main members of the posts consist of 6-in. x 4-in. x ⅝-in. angles. These posts are also extended above the truss for carrying the feeder

wires. The truss is bolted to the side posts allowing a clearance above the rails to the lower side of the truss of 24 ft. 3 in., and is 4 ft. 6 in. deep by 5 ft. wide between the backs of the chord angles. The upper chords consist of 8 in. x 8 in. x $^{7}/_{16}$-in. angles, and the lower chords consist of 4 in. x 3½ in. x $^{5}/_{16}$-in. angles.

A ladder is provided on one of the posts leading to a small platform at the end of the truss. This platform is provided with a hand rail and carries upon it a box containing an 11,000-volt, low-equivalent lightning arrester. A portal is provided in the end of the truss by means of which the attendant may step to the platform supported upon the lower chord of the truss. From this platform access is provided to the short ladders leading to the signal lanterns and a second short ladder extending up to another platform supported upon the upper chord of the truss. This platform is surrounded by a hand rail which is also attached to the iron supporting frames of the circuit-breakers in such a manner that the attendant can in no way come in contact with the live parts of the circuit. At each end of the truss a 5-k.w., 11,000-volt, shunt transformer is provided, one of these being connected directly into a bus-bar which runs around the outside of the circuit-breakers and which is supported on porcelain insulators and bus-bar brackets



Four-Track Anchor Bridge with Circuit Breakers and Section Breaks.

secured to the upper chords of the truss. The other transformer is connected directly to one of the "power" feeders. As the "power" feeder is connected to the third phase of the generating system, this provides means for operating the switches in case of accident to the trolley section. The four-track anchor bridge is secured to concrete foundations by long anchor bolts and nuts.

Each of the two catenary cables which support the copper trolley conductor consists of an extra high strength steel cable, $^{9}/_{16}$ in. in diameter, consisting of heavy strands. This steel has an ultimate strength of about 200,000 lbs. per square inch, and each strand is heavily galvanized. The completed cable has an ultimate strength of 33,800 lbs. These cables are strung between the bridges, with a sag at mean temperature of 6 ft. in a standard span of 300 ft.

The trolley wire, which is No. 0000 grooved copper, is supported every 10 ft. from the catenary cables by triangular trolley hangers of varying lengths. These hangers are so adjusted in length that the trolley wire is maintained in a horizontal position, 6 in. below the catenary cables at the middle point of the span. They consist of a pair of small drop forged steel jaws, which engage with the grooves of the trolley wire and are clamped by means of a malleable iron Y which is screwed down upon the threaded portions of the jaws. The sides of the triangle are then screwed into the Y and are bolted to the messenger cable above. As all of the threads

to the bridge above the insulating structure to prevent accumulations of dirt and water on the insulators.

At a number of points where there are numerous side-tracks, it is necessary to provide extra long bridge supports. An illustration shows one of these long bridges, which is designed to cover 12 tracks. The catenary cable insulators are attached to the lower member of the truss. Both rails of all tracks are bonded with No. 0000 compressed terminal flexible bonds placed round the fish plates.

Wherever one track diverges from another a section insulator is inserted in the trolley wire. Insulators are inserted in the catenary cables supporting the diverging wire between parallel tracks.

The diverging trolley wire is connected to the main wire by a frog of standard design, and in order to prevent the contact shoes on the locomotive from catching, deflector wires are placed in the angles between the two trolley wires. These deflectors are carried by yokes screwed to the trolley wires and to yokes at the ends fastened to the catenary hangers. These deflectors are raised at each end so that the collector shoe cannot catch over them.

ELECTRIC LOCOMOTIVES.

The specifications under which the locomotives were built require that they shall be able to handle a 200-ton train on the most severe schedule in the present time-table, corresponding to the local express which stops about every 2.2 miles and operates on a schedule

speed of over 26 miles an hour. This requires a maximum speed of about 45 miles per hour. The locomotive is also to haul this weight of train at 65 to 70 miles per hour and a 250-ton train at 60 miles per hour in the long runs. Three 100-ton, or even heavier, trains may also be handled on the long runs at reduced speeds. Heavy trains may be operated at high speeds by coupling two or more of the locomotives together and operating them on the multiple-unit system.

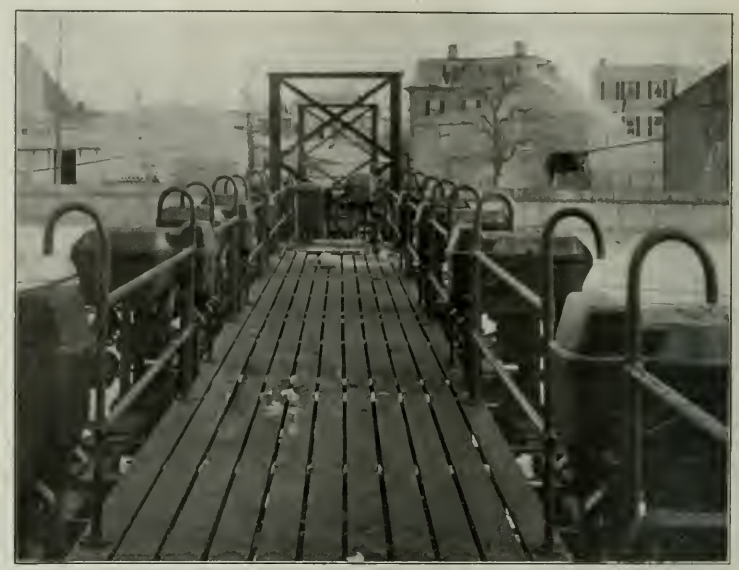
The design of the locomotives was largely dictated by certain requirements: (a) Gearless motors having a flexible drive and with all the weight carried on springs were desired and finally adopted as the most desirable form, and (b) operation on 600 volts direct-current necessitated the use of four motors in order that they might be operated in the usual series-parallel relation.

The bogie truck type was adopted after careful consideration as the one best adapted to meet the conditions imposed. Its riding qualities are the best and it offers the least resistance in taking the curves in the line. The locomotives are 36 ft. 4 in. over bumpers and weigh approximately 90 tons.

The mechanical parts of the locomotive were built by the Baldwin Locomotive Works from designs developed with the co-operation of the Westinghouse Electric & Manufacturing Company and the New Haven engineers.

The longitudinal members of the frame consist of deep plate girders reinforced at the top by channels and at the bottom by heavy angles and plates. To these frames are riveted plate cross members, one over each truck, forming the transoms. These transoms are further braced by gusset plates riveted to the bottom flanges of both sets of channels, which transmit the tractive power from the center-pin to the side frames. The side girders are placed outside the wheels as low down as the wheels and drawhead will permit and are braced and squared by substantial steel flooring plates which are riveted to the top flanges. The drawbar effort is transmitted to the side frame through deep box girders joining the frames at the ends of the locomotive. The cab is built up on a framework of Z-bars which are riveted to the side girders. This forms a light but strong construction, able not only to transmit large drawbar pulls but to resist heavy shocks in bumping.

The running gear consists of two trucks, each mounted on four 62-in. driving wheels. The trucks have side frames of cast steel



Deck of Anchor Bridge, Showing Circuit Breakers and Other Auxiliary Apparatus.

Method of Erecting Bridge Columns with Locomotive Crane.

to which are bolted and riveted pressed steel bolsters which carry the center plates. A strong construction is secured without excessive weight by the use of bolsters 30 in. wide at the center plate and extended to nearly double that width at the ends where they are bolted to the side frames. Center bearings 18 in. in diameter transmit the tractive effort to the frame. They are well lubricated to permit free motion on curves. The weight on the journal boxes is carried by semi-elliptic springs. Under the ends of the equalizer bars are small spiral springs to assist in restoring equilibrium. The distance between truck centers is 14 ft. 6 in.

The motors are of the gearless type. The hollow shaft of the armature is made in two halves. These two halves are alike and each is provided with an end disk from which project seven hollow pins. Each half is forced by hydraulic pressure into the ends of the hollow armature spider and is securely keyed in place. The armature and quills are mounted on the locomotive axle. The split housings at each end of the armature carry the armature bearings and are rigidly clamped to the outer field frame of the motor. On each end of the locomotive axle is mounted a 62-in. driving wheel in the hub of which are formed seven circular pockets which contain helical springs for assisting in carrying the weight of the motor and for transmitting the torque from the armature. Into each of these pockets there projects one of the hollow pins on the end of the armature shaft. Each pin is surrounded by a spring placed between the outer circumference of the pin and the inner circumference of the pocket. This spring is arranged so as to tend to hold the pin concentric with the pocket, and it resists yieldingly to any gravitational or torsional force for a total movement of ¾ in. The spring is of unusual form; its turns are progressively eccentric. Thus an end view of the spring would show an inner radius and an outer radius differing from each other by ¾ in. greater than the thickness of the stock from which the spring is built. Between the outer circumference of the spring and the inner circumference of the pocket is fitted a sheet iron tube, and a similar tube is placed between the spring and the pin. These tubes and the spring form a unit which may be taken intact from the pocket when the outer end cap is removed. On account of their mechanical form and their position in the pockets these springs cannot be stretched beyond their elastic limit, and, since each pocket is provided with adequate lubrication it is expected that they will withstand the most severe wear and last indefinitely. They are capable of sustaining the whole weight of the motor, but they will normally be used solely for transmitting the torque to the drivers. Each pin contains a hollow space in which is placed an additional spring which serves for receiving the end thrust of the motor against the drivers.

The method of carrying the weight of the motor from the truck and of resisting the backward torque of the field structure is by providing a steel frame entirely distinct from the truck and pivoted from the journal boxes of each locomotive axle. From this frame

the weight of the motor is carried by springs on which rest lugs of the field structure. The adjustment of the tension on these springs determines what portion of the weight of the motor is carried by them and just how much weight is carried through the pinion on the armature quill. Since the frame from which the motor is suspended is distinct from the truck the swinging of the locomotive can have no effect on the motor and the motor delivers a cushioned blow to the rails. The backward torque of the field is transmitted to the truck through rods which permit a certain amount of vertical motion

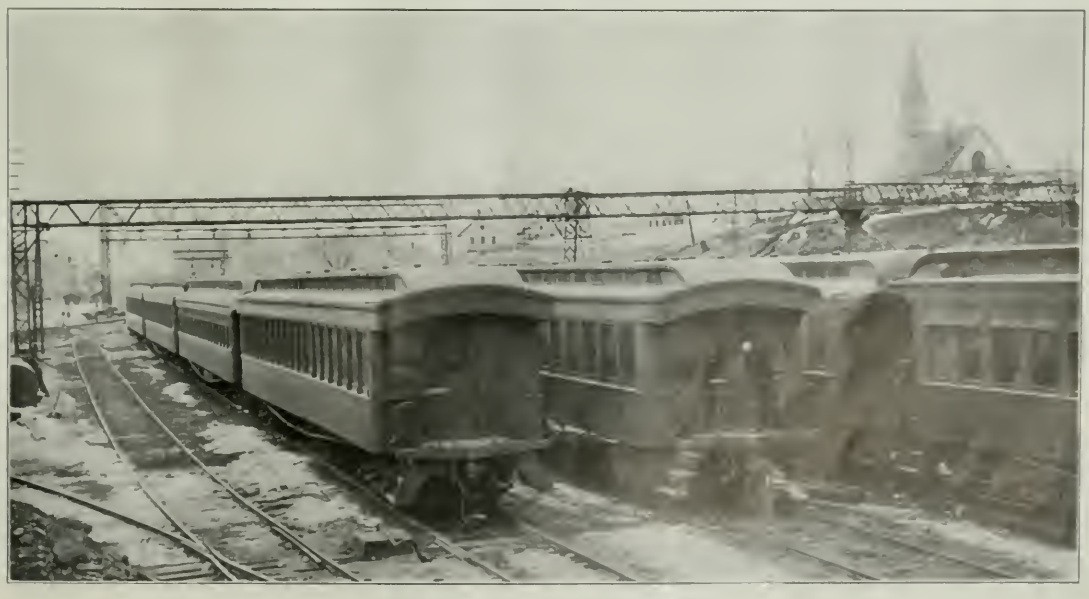
Erecting a Long Trolley Bridge Truss in the Yards.

in the motor. The armature and field windings are of the usual form employed in Westinghouse single-phase series motors. The armature winding is closed in itself and is indirectly connected to the commutator through preventive leads which reduce the short circuit current produced when the brushes pass from one commutator segment to the next. The field winding is of the compensated type with the compensating field evils wound in slots in the projecting pole pieces. These compensating coils are always in series with the armature circuit and serve to neutralize the reactance of the armature.

There are several brushes per holder and both the brushes and holders resemble closely those used for direct-current work. The brushes are ⅝ in. thick and are pressed against the commutator by a coiled spring. The total locomotive mileage is not yet sufficient to determine the life of the armature except by approximation from the present rate of wear and this has been so small that an accurate estimate cannot yet be made. A flexible copper jumper or shunt is used for carrying the current to the brush.

The two armatures on each truck with their corresponding compensating field coils are joined permanently in series and are operated at all times as a unit. For direct-current work the two-motor units of each locomotive are connected in series at starting and in parallel at full speed, while for alternating-current work the two units are joined in parallel at all times. Although during direct-current operation the familiar series-parallel method of control is employed, several unusual features have been introduced so that the losses during acceleration are equally as small as would be the case if there were complete series paralleling of the four motors by the method used ordinarily with four-motor equipment. The motors being of the compensated type will run sparklessly with the fields weakened to any desired extent, and this condition is taken advantage of during the acceleration period before passing from the series to the parallel position. Thus there is eliminated a large portion of the loss which would take place in the resistance if the motors were changed directly from the normal series position without resistance to the parallel position with the full resistance in circuit. Much of the lower part of the normal speed range in the parallel position is covered by the motors connected in series with shunted field coils.

The acceleration is extremely smooth, which is to be attributed partly to the facts just stated and partly to the fact that in passing from the series to the parallel connection the circuit to neither motor is opened nor is either motor short-circuited. In the initial series position at starting, one motor unit is connected to the ground side and the other to the trolley side, with the resistance in series between them. In the final series position the resistance is out of circuit and two units are in series across the line. If now there be connected in parallel with each motor unit a resistance of a value such that one-half of the line voltage will cause to flow through it a current equal in value to that passing through each motor, the two motor units will in effect be connected in parallel across the line, each unit having in series with it a resistance which absorbs one-half of the line voltage. Under this condition no current will flow directly through the middle-voltage connection between the two motor units, and this connection may be broken without changing the performance of the motors, after which the resistance in series with each motor may be decreased until the two units are directly in parallel across the line.



Special Trolley Bridge over Yard Tracks.

During alternating-current operation each motor unit is fed at variable voltage from the secondary of a step-down transformer, there being two separate transformers on each locomotive. The same master controllers are used for alternating-current as for direct-current.

Each switch used in the motor circuits is of the Westinghouse "unit" type, operated by air under 80 lbs. pressure and controlled by an electromagnet which receives current from a 20-volt storage battery. There are, therefore, on the locomotive three systems of wiring: the 11,000-volt primary circuits to the step-down transformers; the lower-voltage motor circuits (corresponding to the secondary circuits from the transformers and the equivalent 600-volt direct-current circuits), and the battery electromagnet circuits. The high-potential circuits pass directly from the trolleys through the manually-operated oil switch to one terminal of the primary of each of the step-down transformers, the other terminals of which are grounded to the locomotive frame. The lead from the trolleys to the oil switch is protected by a grounded covering, and only the 20-volt battery runs to the master controller. The motor circuits pass either from direct-current trolley, third-rail shoe or the taps on the secondaries of the transformers to the unit switches and through the motors to the ground.

The unit switches are arranged in groups for convenience, and the switches of each group have their magnetic blow-out coils placed mechanically in the same line so that they assist one another in producing the blow-out flux.

The locomotive may be controlled from either end by means of a master controller which is of the usual type except that its handle is somewhat different from those heretofore used. The handle resembles somewhat the throttle lever of a steam locomotive. No gears are used, the handle being connected directly to the drum shaft. The reverse lever is mounted immediately below the operating lever of the controller. The circuits which run to one master controller are in multiple with those to the other controller. A continuation of these circuits through flexible leads from one locomotive to another allows any number of locomotives to be operated simultaneously from one master controller. When the master controller is in the off position, connections are so established that all circuit-breaker trips which may be open may be closed by pressing a small push button on top of the controller. Current is supplied to the control circuits by two sets of 10-cell storage batteries, each of which has a capacity of 40 ampere-hours and weighs 150 lbs. In connection with the switch groups, cut-out switches are provided so that either pair of motors may be cut out by simply rendering certain switches inoperative. It is thus possible to cut out the motors without manipulating the main circuit.

There are two pantagraph bow trolleys for collecting the current from the 11,000-volt overhead conductor system. The upward pressure against the wire is supplied by springs. Compressed air is admitted to a cylinder when it is desired to lower the collector. When the collector is in its lowest position a catch engages the mechanism and holds it in place. This can be released by means of an electro-pneumatically operated lever when compressed air is on hand, or it can be released manually if desired. The framework of the pantagraph mechanism is built up of steel tubing and the collector bow is a broad strip of soft copper. The collector mechanism is mounted on moulded insulators bolted to the roof of the locomotive.

For use over the New York Central tracks there have been provided both a second and lower overhead direct-current pantagraph trolley and third-rail contact shoes. The direct-current trolley is

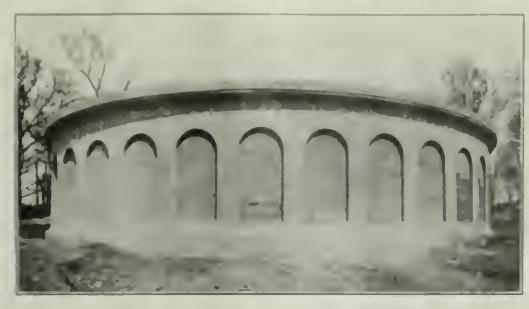
New Haven Electric Locomotive with A. C. Trolleys Raised.

of the same general type as that used of the high-potential collectors and it is mounted over the center of the locomotive. There are two mechanically separate but electrically interconnected contact shoes on each side of each truck, making a total of eight shoes per locomotive. These shoes are designed for use with either an over-running or an under-running rail, and the mechanical pressure in each case is supplied by springs. On account of the fact that no third-rail will be used over the high potential portion of the route, and the projecting shoes in their normal position would be liable to strike any small obstruction along the side-paths, a device is used for lifting the contact shoes out of the way when the locomotive is using alternating-current. This device will be operated electro-pneumatically and will be automatic so that when the alternating-current circuit is completed the shoes will be lifted from the rails.

All of the controlling mechanism of the locomotive is placed in the cab. In addition to the various switch groups and the two main transformers referred to above, the cab contains two air compressors driven by compensated motors of the same general type as the main driving motors. The circuits to these motors are con-

Cos Cob Power House and Coal Dock; New York, New Haven & Hartford.

trolled automatically by the pressure of the air in the main reservoirs which are located underneath the locomotive. The four main traction motors, the high-potential transformers and the main circuit rheostats are cooled by air furnished at low pressure by means of two motor-driven centrifugal blowers which draw air through openings in the cab. The low-pressure air has two paths. One path passes first through the transformer and then to the rheostat. The other path goes directly to the motors. It enters the armature near the shaft, passes around and between the armature laminations, flows outward through the ventilating ducts in the field cores and reaches the outer air through perforated caps on the frame of the motor.



Concrete Water Reservoir at Cos Cob Power House.

Since a considerable volume of air is required for each motor and it is undesirable to cause the air to assume a high velocity, it was necessary to provide a large flexible conduit between the air passages on the cab and those on the motors proper. The flexible conduit is made of heavy canvas tubing which is reinforced with wire and given an accordion pleating. By the use of the air blast the temperature of the motors under load has been so decreased that the continuous rating is almost equal to the one-hour rating.

COS COB POWER HOUSE.

The initial single phase electrification comprises that portion of the New York division of the New York, New Haven & Hartford from Stamford, Conn., to the junction with the New York Central at Woodlawn, N. Y., 21 miles. From Woodlawn to the Grand Central Station the New Haven trains are operated over the tracks of the Harlem division of the New York Central by the New Haven electric locomotives, using direct current from the New York Central's third rail electric equipment. The power house at Cos Cob furnishes single-phase current for the operation of electric trains over the New Haven road and is also designed to deliver three-phase current to the Port Morris power house of the New York Central to compensate for the energy required to operate the New Haven trains over the lines of the New York Central.

The power house is adjacent to the main line of the railroad and on the bank of the Mianus river about one mile from Long Island sound. Coal can be delivered either by water or rail, and an unlimited amount of salt water for condensing purposes is available. By the erection of a dam in the river about a mile up-stream from the power house an abundant supply of pure boiler feed-water is obtained.

The general style of architecture of the power house building is Spanish Mission; the walls are built of plain-faced concrete blocks. The site selected was on solid rock, and this required blasting the excavation for the basement and the condenser intake and discharge flumes. The building walls, below the water-table, and the machinery foundations are monolithic concrete. The interior columns in the boiler room are of structural steel, but all other columns required in the building are of concrete blocks. The steel roof trusses over the turbine room are supported on concrete block pilasters formed in the building walls, while over the boiler room they are carried by the pilastered building walls and by the interior steel columns, which also support the boilers, the mechanical draft equipment and the stack. The front of the switchboard gallery, at the south end of the turbine room, is carried on concrete block columns which also support a reinforced concrete girder forming one of the crane runways. The other crane runway is formed on another reinforced concrete girder built into the partition wall between the engine room and boiler room, and is supported on pilasters formed in this wall. The basement floor is concrete laid on the rock. All other floors in the building are of reinforced concrete and the roof is of reinforced cinder concrete finished with Ludowici tile.

A self-supporting steel stack 14 ft. 6 in. in diameter extending to a height of 100 ft. from the engine room floor is carried by the steel columns which support the fan room floor, leaving the space below, on the boiler room floor, entirely clear.

The turbine room is 60 ft. wide by 112 ft. long and the switchboard occupies a space next the turbine room which is 25 ft. wide by 110 ft. long. The boiler room is 160 ft. long and 110 ft. wide.

The initial generating equipment of the power house consists of three multiple expansion parallel flow Parsons steam turbines direct-connected to single-phase Westinghouse generators. Provision has been made for the installation of a fourth unit of corresponding size. The turbines are rated at 4,500 brake horse-power each and the generators at 3,000 k.w. each, at 80 per cent. power factor.

As the requirements necessitated the generation of three-phase current for delivery to the New York Central system as well as single-phase current for the operation of the electric locomotives over the New Haven railroad, the generators are wound for three-phase current but are arranged for the delivery of both three-phase and single-phase current. The turbines are operated at 1,500 revolutions per minute by steam at 200 lbs. pressure and 100 deg. superheat. The continuous overload capacity of the units is 50 per cent., and momentary overloads of 100 per cent. can be taken care of when operating condensing.

The generators are entirely enclosed by a casing into which air is drawn through suitable ducts from a fresh air chamber under the switchboard gallery, and from which the air is discharged through other ducts into the basement. This renders the operation of the generators practically noiseless.

The excitation of the generator fields is provided for by two 125-k.w. direct-current generators, direct-connected to Westinghouse engines; and one motor-driven exciter.

To prevent rapid deterioration of the brass condenser tubes by galvanic action a motor generator set has been installed and provided with suitable controlling apparatus for maintaining in each condenser a counter electro-motive force slightly in excess of the electromotive force due to galvanic action and the stray currents.

Interior of Turbine Room at Cos Cob Power House.

The initial installation of boilers consists of twelve 525-h.p. Babcock & Wilcox water-tube boilers set in batteries of two boilers each, and arranged with eight boilers on one side and four boilers on the other side of the boiler room separated by a 21-ft. firing floor. Provision is made for four additional boilers to take care of the fourth turbo-generator unit when installed. These boilers are equipped with Roney mechanical stokers and Babcock & Wilcox

superheaters and deliver steam at 200 lbs. gage pressure and 125 deg. superheat.

Under ordinary conditions the boiler feed water is delivered from the pump house at Mianus through a 10-in. main to a concrete reservoir of 600,000 gallons capacity just outside the power house. From this reservoir the water flows by gravity to two 13,000 gallon feed water tanks in the boiler room basement. These tanks also receive the discharge from the hot well pumps. The water is then drawn from these tanks by the feed pumps and delivered through the feed water heaters and the economizers into the boilers.

An auxiliary source of feed water supply is provided for by a connection to the mains of the Greenwich Water Company.

Four 14-ft. fans, direct-connected to horizontal high-speed engines, deliver the flue gases from the economizers to the stack, which is only of sufficient height to carry the gases away from the building.

All coal received by water is unloaded from barges by a steel derrick operating a clam shell bucket and delivering to a hopper of 15 tons capacity at a height of 55 ft. above the dock. From this hopper the coal is fed by gravity into a coal crusher and from the crusher it drops into steel cars where it is weighed. The cars are then drawn by cable up an inclined railroad into the boiler room through an opening near the roof. Two cars can be operated on this track, passing each other through an automatic turnout at the center. The cars discharge the coal into a hopper, from which it is delivered into two flight conveyors, extending the length of the boiler room. Openings in the bottom of the flight conveyors discharge the coal into spouts leading to the stoker hoppers of the boilers. The capacity of the flight conveyors is in excess of the amount of coal required to operate the boilers, and the surplus coal is discharged at the further end of the boiler room into a concrete storage bin below the boiler room floor. Coal received by rail is dumped from the car directly into a chute leading to this storage bin. When the boilers are to be supplied from this source the coal is discharged from the bin by gravity into a coal crusher, thence into a bucket conveyor located in a tunnel underneath the bin, by which it is delivered to the flight conveyors above the boilers, and thence through the chutes to the stoker hoppers. The cable railway and the conveyors are operated by three-phase induction motors, taking current from the station service line.

The ashes are disposed of by gravity from the dumping grates of the stokers into chutes leading to narrow-gage cars in the basement, by which they are at present carried to the low ground in the neighborhood of the power house and used for filling.

The Westinghouse Electric & Manufacturing Company were the contractors for the electric locomotives, catenary track equipment and turbo-generator units. Westinghouse, Church, Kerr & Company were the contractors for the Cos Cob power house and equipment. The task of determining and analyzing operating conditions and requirements was assigned to Calvert Townley, Consulting Engineer, and William S. Murray, Electrical Engineer, of the New Haven company, to whom credit is due for the design, supervision and execution of the details.

Cultivating Public Opinion.*

The drastic and to some extent revolutionary amendments to the Interstate Commerce law made last year, whatever their beneficial effect, must be much changed to meet even the quasi-approval of the general shipping public, which they were designed mostly to benefit. Shippers are beginning to point out the hardships of the law, and the decisions of the Commission threaten to paralyze their business and to bring greater destruction than under the worst of the old conditions. The Merchants' Association of Illinois, a representative body, has submitted a list of grievances against the new law. There has recently been held in New York a meeting of representatives of shippers of eastern states to formulate a protest against the practical working of the rate law.

Prosecutions with convictions have been secured under the Elkins law with beneficial results, yet that law has been in effect several years, and the government with its great resources could as easily have secured its evidence long ago as now for such convictions. An increase of power was desired, and if to gain this and the government allowed conditions which are now known to have prevailed, the responsibility should rest in the public mind where it belongs.

In the cases of recent convictions for payment of rebates, I believe the public reached the conclusion that all lines were equally guilty, and that they disobeyed the law by choice for their own special aggrandizement. Their attention was not directed to the fact that in most cases the railroads simply met conditions which they did not create and which they were powerless to control. This is not intended as a justification, but to call attention to the fact which the public had no way of hearing, that the lines which were perhaps really at fault were not those which were so severely punished. There is no justification for breaking the law, but there is justification for meeting conditions which are forced by the lax enforcements of such laws.

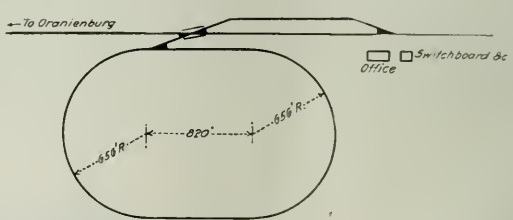
The railroads must take the public more closely into their confidence. There must be a bending backward of every official and every employee to satisfy as nearly as possible an exacting patronage, and to argue on sound premises in working for the rights conferred by constitution or charter. As public opinion has been outraged by the methods of high finance, care must be taken that the reasons for new capital should be given not only to the stockholders but to the public. If reorganizations are necessary, such necessity and expected results must be explained in detail. If this is an invasion of private rights, or tending to thwart the best results, it must, nevertheless, be done, or else there will be the same public distrust in the necessity and suspicion of private benefit at the expense of the public welfare. The fact must be brought home to the public mind that if the railroads are to be under government control, they have the right to expect the government to protect their interests as scrupulously as it looks after the interests of the public.

*From an address by C. A. Swope, Eastern Freight Agent, Louisville & Nashville.

Test Track of the Prussian State Railways.

Last December the Prussian State Railways put into operation near Oranienburg, 20 miles from Berlin, a special curved test track, a plan of which is shown in the accompanying drawing. It was built to carry out an exhaustive series of tests to determine: (1) The influence of different kinds of ballast and of different designs of ties on the vertical and horizontal alinement of track on curves; (2) efficiency of various forms of rail joints on curved and straight track, and (3) wear of rails on curved and straight track.

The track is oval, with two semi-circular curves of 656 ft. radius, joined by tangents 820 ft. long, giving a total circumference of about 5,762 ft., or nearly 1.1 miles. On the curves the superelevation is



Curved Test Track of the Prussian State Railways.

4.92 in. and the gage is widened 0.095 in. The elevation is tapered off 1:300, 1:500, 1:1000 and 1:1500 at the four points of tangency to determine the effect of the different tapers on the running of the cars.

Power is furnished by a single phase alternating current of 6,000 volts. The conductor is overhead, connection with the car being by means of a sliding contact.

Two motor cars of 58 tons each are provided. Each car has two 6-wheel trucks and is equipped with 4 motors. The motors develop 45 h.p. in ordinary steady running, with a maximum hourly capacity of 110 h.p., and they can develop for a short time 125 h.p. It is proposed to increase the capacity for steady running to 60 h.p., then by coupling on some freight cars it will be possible to run a train weighing 190 tons at a speed of 31 miles an hour for any length of time.

The train is run without a crew, the current being switched on and off from a small building provided with switchboards, meters, etc. With the exception of Sundays and holidays the train is to run 20 hours daily, the number of laps being automatically registered. At a speed of 31 miles the train would make 570 circuits of the track daily. With a train weighing 190 tons and running for 300 working days, upward of 32,000,000 tons will pass over every part of the track annually.

In these experiments the fundamental principle to be observed is that different constructions are to be compared only under identical conditions. Thus, if rail joints are to be tested, then ties and ballast must be the same; if ties are to be compared, rail joints and ballast must be the same; if different materials for ballast are under examination, rail joints and ties are to be the same.

The locomotive works of J. A. Maffei in Munich have built for the Bavarian State Railroads a locomotive capable of hauling a train weighing 165 tons at a speed of 93 miles an hour. This engine was tested July 1 and 2, and maintained for a prolonged time a speed of 96 miles an hour, which is declared to be the greatest speed ever made in Europe by a steam locomotive. It is a four-cylinder compound with 6-ft. drivers, Schmidt superheaters, and Westinghouse high-speed brakes.

GENERAL NEWS SECTION

NOTES.

The general storehouse of the Erie at Susquehanna, Pa., was destroyed by fire on the morning of August 14

The State Railroad Commission of Wisconsin has ordered a reduction of 20 to 25 per cent. in freight rates on live stock from all parts of the state to Milwaukee

Mrs. Russell Sage has given the sum of $50,000 for a building for the railroad Young Men's Christian Association at Long Island City, N. Y. The railroad company will give the ground for the building.

The railroads and the Minnesota state railroad commission have agreed that Duluth, St. Paul and Minneapolis shall be the only "terminal" points in the state at which, under the law, cars must be supplied within 48 hours after being ordered.

The State Railroad Commissioners of South Dakota, at their regular meeting, on August 29, will consider the question of reducing passenger fares in the state to 2½ cents a mile, in accordance with the recent act of the legislature.

On August 9 the Grand Jury in the Federal Court at Jamestown, N. Y., reported indictments against the Standard Oil Company, the New York Central & Hudson River Railroad and the Pennsylvania Railroad for making illegal rates on oil from Olean, N. Y., to points in Vermont.

In the United States Court at Minneapolis, Aug. 10, the Wisconsin Central Railway was fined $17,000 for paying rebates. This was in the suit in which the company was convicted last April. Burton Johnson and G. T. Huey, freight officers of the road, were fined $2,000 and $1,000 respectively.

A strike of the Brotherhood of Railway Trainmen members employed by the Colorado & Southern, which had disturbed freight traffic for a week, was settled August 13 by the granting of one cent an hour increase to yardmen and switchmen. It was agreed to arbitrate the demand for another cent.

Against the protest of initial lines in California, Eastern roads have decided to make a charge of $5 a car on shipments of citrus and deciduous fruits, after two diversions in transit. Heretofore there has been no restriction, and at times cars have been diverted five or six times before the fruit was finally disposed of.

In Alabama the Southern Railway and the St. Louis & San Francisco have agreed with the officers of the state to put in effect the laws passed this year reducing passenger fares to 2½ cents a mile, and reducing freight rates on 110 commodities. The agreement provides for the early reference of these laws to the courts of last resort to settle their constitutionality.

The National Industrial League claims now to have a membership of 20,000 firms, although only one month old. This is a combination of shippers which, it is declared, will contest the recent ruling of the Interstate Commerce Commission that railroads have the right to publish notice in their through tariffs that the initial road reserves the right to route the freight beyond its own lines.

The railroad commissioners of Indiana, who are seeing to the enforcement of the law recently passed in that state requiring a certain minimum number of men in the crew of each train, find that some of the railroads propose to class the porter of a passenger train as a member of the crew and thus avoid the expense of employing a higher grade man to comply with the law. The Brakemen's Brotherhood is vigorously opposing this interpretation of the statute.

Judge Grosscup, in the United States Circuit Court at Chicago, Aug. 12, issued the final order turning over to the Chicago Railways Company all the street railways on the north and west sides of the city, which heretofore have been operated under the name of the Chicago Union Traction Company. An application has been made for an appeal from the order in behalf of the holders of the first mortgage bonds of the North Chicago Street Railway. The hearing of the appeal is set for next Monday.

The Long Island Railroad has prepared statistics to show that in the matter of protecting grade crossings that company has done better than any other prominent road in the state of New York. On all the steam railroads in the state there are 6,793 unprotected crossings, 1,940 protected crossings, 714 overhead and 930 undergrade crossings. The percentages of crossings protected by gates, flagmen or bells are as follows: Long Island road, 52 per cent.; D., L. & W., 43; New York Central, 41; Erie, 36; Delaware & Hudson, 30; N. Y., O. & W., 30. On the Long Island 22 per cent. of all crossings are either above or below grade as against 10 per cent. on the D. & H., 13 per cent. on the D., L. & W., 13 per cent. on the Erie, 12 per cent. on the Lehigh Valley, 19 per cent. on the N. Y. C. and 16 per cent. on the N. Y., O. & W. On all the roads of the state there are 8,734 crossings at grade. Estimating the average cost of changing each one at $50,000 each, the cost of abolishing all grade crossings in the state would be in the neighborhood of 300 million dollars.

The Nebraska State Railroad Commission has filed with the Interstate Commerce Commission a complaint of exorbitant rates on coal over the Union Pacific from the mines of Wyoming to points in Nebraska. The complaint recommends and asks that a reduction of $1.50 a ton be ordered from the mines to Omaha, a reduction of 25 per cent. Further west reductions of from 50 to 65 per cent are asked. In the past the Union Pacific has charged a blanket rate to all Nebraska points from Wyoming, points only 300 miles distant being made to pay the same as those 800 miles from the mines.

Judge Lacombe, in the United States Circuit Court at New York Aug. 10 denied the motion of the Delaware, Lackawanna & Western Railroad for a preliminary injunction restraining the Interstate Commerce Commission from carrying out its order directing the railroad to transfer tank cars containing petroleum to the dock of Preston & Davis, independent dealers in Brooklyn. The road claimed that the danger of fire on the Brooklyn dock prevented it from doing this business for Preston & Davis, but the judge holds that the danger can be overcome by sufficient watchfulness and care, and leaves all questions to be decided at the final hearing.

Prof. Benjamin Succeeds Prof. Goss at Purdue.

Prof. Charles Henry Benjamin has been appointed Dean of the Schools of Engineering of Purdue University, to succeed Dean W. F. M. Goss, who resigned to accept a similar appointment at the University of Illinois. Professor Benjamin has been professor of mechanical engineering at Case School of Applied Science, Cleveland, Ohio, since 1889, prior to which time he was for three years engaged in engineering practice and for six years as instructor and professor of mechanical engineering in the University of Maine, of which institution he is a graduate. He is well known as a teacher, investigator, author and engineer. Prof. Benjamin is a member of the American Society of Mechanical Engineers and has contributed a number of papers on power transmission and flywheels to that society.

Explosions.

At Essex, Ont., Aug. 10, half a carload of nitroglycerine exploded and did damage estimated at $200,000. Two men were killed, three were fatally hurt and 50 were slightly injured. The explosion wrecked every building in the town and was felt for 20 miles around. The car containing the explosive was side-tracked near the Michigan Central station. When a train was being made up a brakeman discovered that the explosive was leaking in the car. He was trying to stop the leak when the explosion came. The new stone station, the freight sheds, Green's elevator and Fagin & Ritchie's mill were wrecked.

At Boulder, Colo., on the same day a fire in the Colorado & Southern station destroyed the building and a lot of freight and spread to a powder house containing 1,000 lbs. of dynamite. This exploded, injuring about 100 persons. Two of the injured will die. The property loss is estimated at $250,000.

Exhibit of the American Locomotive Company at Jamestown.

The American Locomotive Company has an exhibit at the Jamestown Exposition, which includes two locomotives for Southern railroads built at the Richmond, Va., works. Both of these are consolidation locomotives, one for the Chesapeake & Ohio, with a total weight of 208,600 lbs., and the other for the Southern Railway, weighing 202,800 lbs. Both locomotives have Walschaert valve gear. There is also on exhibition a four-wheel-connected saddle-tank locomotive weighing 36,000 lbs., for use by contractors, on logging roads, in industrial plants, and anywhere on sharp curves and light rails. The Atlantic Equipment Company is exhibiting the latest design of the Atlantic steam shovel. The hoisting machinery of this shovel is mounted directly on the boom, so that no guide sheaves are necessary, and the power can be applied with the least possible loss. The hoisting is done by direct wire rope with one sheave instead of by chain with from five to seven sheaves. In the construction of the dipper the bail and sheave have been discarded and the double hoisting rope attached directly to the back of the dipper in such a way that the lines of force meet in line with the strain applied to the teeth. This shovel is being exhibited with a patent

dump car made by the Oliver Manufacturing Company. The car is elevated on a trestle representing a bank, so that the shovel has a lift of over 16 feet.

Compulsory Block Signals in Indiana.

The State Railroad Commission of Indiana has ordered all railroads whose earnings are in excess of $7,500 a mile, to proceed to equip their lines with block signals and to have them completed by July, 1909. The Commission asks for an immediate reply. The Commission's expert will confer with the general managers as to the kind of systems that must be put in.

Erie Canal Contract.

The contract for enlarging the Erie Canal from Oneida Lake, N. Y., westerly to Mosquite Point bridge on the Seneca river, has been awarded to the Stewart, Kerbaugh & Chanley Company, of New York City, whose bid was $3,395,766. This was on the second call for bids. The first time bids were called for none were received. The accepted bid was in excess of the engineers' estimate but under these circumstances was accepted by the state of New York.

Twenty Passengers Killed in Germany.

According to a press despatch of August 6, a passenger train, drawn by two engines, was derailed near Posen, Prussia, on the evening of that day and 20 or more persons were killed; while a large number were injured.

University of Iowa Engineering Prize.

An annual prize of $100 has been established in the College of Applied Science of the State University of Iowa for the best thesis submitted for the first degree in engineering. The prize is to be known as the "Thomas J. Cox Prize in Engineering," in memory of the father of the donor, who is Arthur J. Cox, of Iowa City, a graduate of the engineering department.

Railroad Taxes in New Jersey.

The Supreme Court of New Jersey has sustained the constitutionality of the Perkins act of 1906, providing for the taxing of so-called main stem railroad property, including franchise and tangible personal property. Under the present act main stem property is taxed for state purposes at the average rate of the state tax, or [this year] $1.80 per $100 valuation. Prior to its passage, this class of railroad property was taxed at an arbitrary rate of 50 cents per $100 of valuation. In 1905 the main stem tax amounted to $950,991. In 1906, under the Perkins act, it was $3,503,529. Under the decision rendered a few days earlier on the "second class" property tax, combined with the present decision, the taxes on railroad property in the state will be increased between $4,000,000 and $5,000,000 a year.

British to Build Railroad in Africa.

Speaking in the British House of Commons, Winston Churchill, Under Secretary of the Colonial Office, announced last week that the government had decided to build 400 miles of railroad in northern Nigeria, from Baro by way of Bida, Zungeru and Zaria to Kano, with the object of developing the colony, and especially the cotton growing industry. The work of construction will be entrusted to Lieut.-Col. Sir Edouard P. C. Girouard and will take four years.

Japanese Railroad Visitors.

Seven engineers sent out by the Japanese government have recently arrived at San Francisco to study American railroads, with particular regard to methods of construction. This is because the Japanese government is to undertake the building of several thousand miles of new steam railroads. The party includes three railroad engineers, two railroad managers, one harbor engineer and one steamship engineer.

INTERSTATE COMMERCE COMMISSION RULINGS.

Higher Rates for Fast Service.

Commissioner Clark has announced the decision of the Commission in the case of the American Fruit Union, of Cincinnati, Ohio, v. Cincinnati, New Orleans & Texas Pacific. It appeared in this case that in conference between officials of the carrier and representatives of certain of its patrons, it was agreed that higher rates would be charged and paid for the transportation of strawberries in consideration of special expedited trains on which they would be hauled and by which they would be delivered for the early morning market; but on account of reconstruction and improvement work along the line of the carrier it was unable to furnish the expedited service agreed upon and which it had furnished for several years. The shipper contended that if the expedited service was not provided the higher rate should not obtain, and the Commission held that where an unusually high rate is charged because and in consideration of a special and expedited service it is the duty of the carrier to provide such service or to cease and desist from charging the higher rate. "This principle is recognized in contracts between the Federal Government and the railroads for fast mail service and by the railroads in connection with their excess-fare limited passenger trains. In both instances carriers forfeit a part of the compensation if they fail to make the time agreed upon." The defendant's rate on strawberries in carloads, under refrigeration, from Chattanooga and Oakdale, Tenn., to Cincinnati, Ohio, was found unreasonable and reduction was ordered. Reparation was also awarded to injured shippers because of such unreasonable rate on strawberries during the season of 1907. The rate of 27 cents per crate of 24 qts. was ordered to be reduced to 22 cents per crate.

Published Rates Are Laws.

The Commission, in an opinion rendered by Commissioner Harlan, has announced the decision of the Commission in the case of the A. J. Poor Grain Co. v. Chicago, Burlington & Quincy et al. In this case the Commission decided that a rate on wheat of 75 cents per 100 lbs. from Nebraska common points to California terminals via. the C., B. & Q. through Denver and thence via the Union Pacific and Southern Pacific to destination, is unreasonable and excessive. It is manifestly so, as compared with the through rate of 55 cents on corn over that route, and a through rate of 55 cents on both corn and wheat from Nebraska points via the Union Pacific and Southern Pacific to those destinations. Any rate on wheat over the route in question from these points of origin to California terminals in excess of 65 cents per 100 is held to be unreasonable. Complainant was awarded reparation on his shipments on that basis, but was not given an order of reparation on his shipment to Reno, Nev.

The published rate governing transportation between two given points, so long as it remains uncanceled, is as fixed and unalterable either by the shipper or by the carrier as if that particular rate had been established by a special Act of Congress. When regularly published, it is no longer the rate imposed by the carrier, but the rate imposed by law. Regardless of the rate quoted or inserted in a bill of lading, the published rate must be paid by the shipper and actually collected by the carrier. Failure on the part of the shipper to pay or of the carrier to collect the full freight charges, based on the lawfully published rate for the particular movement between two given points, constitutes a breach of the law and will subject either one or the other, and sometimes both, to its penalties. Not even a court may interfere with a published rate or authorize a departure from it when it has voluntarily been established by the carrier. If a carrier, contrary to shipper's instructions, forwards cars by a more expensive instead of a cheaper route, or, without any instructions, sends the cars by a more expensive route, such action is *prima facie* without justification and constitutes a fair basis for reparation; but if the shipper gives definite instructions to move the cars by the more expensive route, the carrier is relieved of the obligation to forward by the cheaper route. Shippers along the line of an interstate carrier are entitled to have their products moved in either direction at reasonable rates, and the Commission cannot agree that a carrier may establish prohibitive rates on any commodity on the ground that it is not desirable traffic for that carrier.

TRADE CATALOGUES.

Rock Island Employees' Magazine.—The second number of this monthly periodical of the employees of the Rock Island system is much larger than the initial number, and has an appropriate cover design. There are articles on "Growth of the Rock Island Lines," by Geo. H. Crosby, Treasurer; "Get the Business," by E. F. Strain, Division Freight Agent; "Chicago Terminal District Telephone System," by J. G. Jennings, Superintendent of Telegraph. There is also a plan of the organization of the Rock Island lines; a description of some new consolidation locomotives recently received; a roll of honor "for doing more than duty"; plans and a description of a moderate priced cottage, it being the intention to show one of these a month; miscellaneous items of interest, and notes from important points on the system.

Dominion Atlantic Railway.—"Nova Scotia, the Land of Summer Rest," and "Vacation Days in Nova Scotia" were recently issued by the passenger department. The first is the 1907 edition of a former publication. It is charmingly written and has excellent photographs. It describes the seacoast passed by the steamers on the trip from New York to Yarmouth, N. S., then the west coast of

Nova Scotia and across the Island to Halifax. The second booklet describes similar country from the standpoint indicated in the title, being rather a guide to those who spend some time in the region than for casual tourists.

Locomotive Cranes, Grab Buckets, Etc.—The McMyler Manufacturing Co., Cleveland, Ohio, has a new catalogue of locomotive cranes, bridge conveyors, grab buckets and car dumpers. This company designs and build locomotive stationary or revolving cranes; car dumping machines; clam-shell buckets, including special styles for ore, orange-peel buckets, railroad coaling and ash-handling stations, coal and ore unloaders, slag handling machinery and bridge conveyors. The catalogue illustrates and describes this product.

Reinforced Concrete.—Part IV. of "Trussed Concrete Illustrated," being published serially by the Trussed Concrete Steel Co., Detroit, Mich., shows the Kahn system of reinforced concrete construction as applied to hotels, residences and apartment houses. The illustrations include the Marlborough-Blenheim and Traymore hotels at Atlantic City, N. J.; the Murphy hotel and apartments, Richmond, Va.; Perry apartments, Seattle, Wash., and several large residences in different cities.

Ideal Power.—The July number of the Chicago Pneumatic Tool Co.'s magazine has for leading articles, "Rock Drills in Quarry and Tunnel Work" and "Locomotives for France Built in the United States on the Metric System." There are also pictures of the two new Cunard Line steamships "Lusitania" and "Mauretania," on which Duntley electric drills were used. Other matter includes notes of interest and reprints of articles from other journals.

MANUFACTURING AND BUSINESS.

The receivers of Milliken Brothers, Inc., are continuing in full operation the structural and ornamental departments of the company. The main office is at 11 Broadway, New York, and the works are at Milliken, Staten Island, New York.

F. D. Laughlin, formerly Vice-President of the Atlantic Brass Co., Richmond, Va., has been appointed eastern sales manager of the Pittsburg Pneumatic Co., Canton, Ohio, with office at 90 West street, New York City, succeeding Glenn B. Harris.

Isham Randolph, Consulting Engineer, and until recently Chief Engineer, of the Sanitary District of Chicago, and builder of the Chicago drainage canal, has opened an office as Consulting Engineer in the American Trust & Savings Bank Building, Chicago.

The Terry Railway Equipment Co., Monadnock Block, Chicago, has been organized by George N. Terry, formerly with the Safety Car Heating & Lighting Co., and recently with the Ryan Car Co., Chicago, to deal in second-hand cars and locomotives and in railroad supplies. George N. Terry is Manager and E. B. Terry, Secretary.

The American Locomotive Company has recently received an order for 101 4-wheel motor trucks for the Brooklyn Rapid Transit Company. They will follow closely M. C. B. standards, and embody as far as possible the practices of locomotive construction, thereby insuring strength combined with easy riding qualities, the two essential characteristics of the motor truck of the present day.

The Italian government has made a contract with the owners of the patent of the Rueping process for treating timber to have the ties used in future on the government railroad system of Italy, which includes almost all of the railroad mileage of the country, treated by that process. During the first year that the contract is in operation about 1,500,000 Rueping treated ties will be laid. C. Lembcke & Co., 78 Wall street, New York, are the American agents for this process.

Iron and Steel.

The Atchison, Topeka & Santa Fe is reported to have ordered 15,000 tons of rails from the Colorado Fuel & Iron Co., and 8,000 tons from the Maryland Steel Co., both for immediate delivery.

Orders are pending for about 25,000 tons of steel for railroad, bridge and track elevation work. The Chicago, Milwaukee & St. Paul recently gave an additional order for 1,700 tons for a viaduct to the McClintic-Marshall Construction Co.

The Northern Pacific has given a supplementary order for 5,000 tons of rails for early shipment. The Idaho & Northern has ordered 6,000 tons for 1908 delivery, and Chicago reports state that 10,000 tons for delivery next year have been ordered by a new road. Miscellaneous small orders from 1,000 to 3,000 tons have been given aggregating 10,000 tons for this year's shipment.

OBITUARY NOTICES.

Israel Munson Spencer, who was President of the Boston & Maine for 10 years from 1899 to 1909, died on August 9 at Marblehead, Mass., at the age of 61.

Dr William Thomson, the distinguished Philadelphia physician, ophthalmologist and pioneer in the field of automobile surgery, who died recently at the age of 71, was a pioneer in the testing of railroad men's eyes, having prepared the first regulations for this work on the Pennsylvania Railroad. He wrote important monographs on the subject, and devised the "Thomson stick" for use in testing for color blindness by means of yarns. Dr Thomson was a brother of the late Frank Thomson, President of the Pennsylvania Railroad.

ELECTIONS AND APPOINTMENTS.

Executive, Financial and Legal Officers.

Alabama & Vicksburg.—See New Orleans & North-eastern.

Cape Girardeau.—See Chester, Perryville & Ste. Genevieve.

Chester & Saline Valley.—See Chester, Perryville & Ste. Genevieve.

Chester, Perryville & Ste. Genevieve.—Ralph H. Schultz has been appointed Auditor and Assistant General Freight and Passenger Agent, with office at Cape Girardeau, Mo.

Cincinnati, New Orleans & Texas Pacific.—Thomas Carr Powell, Vice-President of the Southern Railway, in charge of the St. Louis-Louisville lines, who was recently elected Vice-President of the Cincinnati, New Orleans & Texas Pacific and of the Alabama Great Southern, returns to his native city and first railroad in taking up his headquarters at Cincinnati. There he was born on September 5, 1865, and at the age of 19 began railroad service as a mail clerk on the Cincinnati, New Orleans & Texas Pacific. He next became chief rate clerk and chief clerk to the Traffic Manager and, on June 1, 1893, was appointed Assistant General Freight Agent. In 1895 he went to the Southern Railway as chief clerk to the General Freight Agent in charge of the rate and tariff department. He was appointed General Freight Agent of the Southern Railway and of the Northern Alabama in 1898 and, in 1899, Assistant Freight Traffic Manager of those railroads. In 1902 he became Freight Traffic Manager and, in 1905, Fifth Vice-President of the Southern Railway in charge of traffic in the West and of the operating department of the St. Louis-Louisville lines. With the rearrangement of the executive officers of the Southern after the death of Mr. Spencer he became Vice-President at St. Louis in direct charge of the St. Louis-Louisville lines. He goes to the Queen & Crescent as Vice-President in charge of the operating, purchasing and traffic departments.

Thomas C. Powell.

Great Northern.—F. H. McGuigan, First Vice-President, has resigned.

New Orleans & North-eastern.—Larz A. Jones, Vice President, is also Comptroller of the New Orleans & North-eastern, the Alabama & Vicksburg, and the Vicksburg, Shreveport & Pacific. H. H. Leltoy, Assistant Auditor, has been appointed Assistant Comptroller.

St. Joseph & Grand Island.—Frederick C. Uhlman, Auditor, has resigned. See Virginian Railway.

Vicksburg, Shreveport & Pacific.—See New Orleans & North-eastern.

Virginian.—Frederick C. Uhlman, Auditor of the St. Joseph & Grand Island, has been appointed Auditor, with office at Norfolk, Va.

Virginia & Southwestern.—H. W. Oliver, assistant to the engineer of construction of the Louisville & Nashville, has been appointed Secretary and Treasurer of the Virginia & Southwestern and the Virginia Iron, Coal & Coke Co.

Operating Officers.

Alabama & Vicksburg.—See New Orleans & North-eastern.

Atlantic Coast Line.—G. B. McClellan, Superintendent at Rocky Mount, N. C., has been appointed Superintendent at Fayetteville, N. C. F. M Doar, Superintendent at Savannah, has been appointed Superintendent of Transportation of the new Second division. J. C. Murchison, Superintendent at Wilmington, N. C., has been appointed Superintendent at Charleston, S. C. G. D. Pugh, Superintendent at Charleston, S. C., has been appointed Superintendent at Savannah, Ga. R. A. McCranie has been appointed Superintendent at Waycross, Ga. S. B. Hennett has been appointed Superintendent at Montgomery, Ala. T. E. Hansell, Acting Superintendent at Waycross, Ga., has been appointed Superintendent at Newberry, Fla.

Birmingham Southern.—F. Kestler, Assistant Superintendent of the Louisville & Nashville at Birmingham, Ala., has been appointed General Superintendent.

Boston & Maine.—See St. Johnsbury & Lake Champlain.

Chicago & North-Western.—C. T. Dike, Resident Engineer at Pierre, S. Dak., who has had charge of the construction of the new Pierre-Rapid City line, has been appointed Superintendent of a new division, which consists of this new line, with headquarters at Pierre.

Chicago, Cincinnati & Louisville.—W. B. Allen, Superintendent of Telegraph and Chief Train Despatcher, has been appointed Trainmaster at Peru, Ind., succeeding G. S. Cooke, resigned. E. C. Murphy succeeds Mr. Allen, with office at Peru.

Houston & Texas Central.—W. E. Langley has been appointed Trainmaster, with office at Houston, Tex.

Illinois Central.—J. D. Brennan, Trainmaster at Carbondale, Ill., has been transferred to Champaign, Ill. George W. Berry succeeds Mr. Brennan, with office at Carbondale, Ill.

Louisville & Nashville.—James A. Morrison, Trainmaster at Birmingham, Ala., has been appointed Assistant Superintendent of the Birmingham Mineral division, the Alabama Mineral division and the South and North Alabama Railroad, with headquarters at Birmingham, Ala., succeeding F. Kestler, resigned. See Birmingham Southern.

New Orleans & North-eastern.—Edward Ford, Superintendent of the Alabama & Vicksburg and the Vicksburg, Shreveport & Pacific, has been appointed General Manager of the New Orleans & North-eastern, Alabama & Vicksburg and Vicksburg, Shreveport & Pacific, succeeding D. E. Curran, now President of these companies. Walter E. Harvey, Assistant Superintendent of the Alabama & Vicksburg and Vicksburg, Shreveport & Pacific, succeeds Mr. Ford as Superintendent of the Alabama & Vicksburg. H. B. Hearn, Assistant General Freight Agent of the three roads at Shreveport, La., succeeds Mr. Ford as Superintendent of the Vicksburg, Shreveport & Pacific. A. J. Chapman, Commercial Agent at Dallas, succeeds Mr. Hearn as Assistant General Freight Agent, with headquarters at Shreveport.

New York, New Haven & Hartford.—The office of Joseph H. Dunn, Assistant Superintendent of the Berkshire and Naugatuck divisions, has been moved from New Haven, Conn., to Waterbury.

Northern Pacific.—T. E. Coyle, Assistant Trainmaster at Tacoma, Wash., has been appointed Trainmaster, with office at Tacoma, succeeding F. E. Willard, promoted.

Oregon Short Line.—John McCarty has been appointed Trainmaster of the sixth, seventh and eighth districts of the Salt Lake division, with headquarters at Mina, Nev., succeeding F. C. Smith, resigned.

St. Johnsbury & Lake Champlain.—F. C. Mayo has been appointed Assistant Superintendent, succeeding George W. Cree, now Assistant Superintendent of the Boston & Maine at Lyndonville, Vt.

Seaboard Air Line.—S. B. Zartman, Trainmaster at Jacksonville, Fla., has been appointed Superintendent of Terminals at Jacksonville. E. R. Teague succeeds Mr. Zartman.

Vicksburg, Shreveport & Pacific.—See New Orleans & North-eastern.

Virginia & Southwestern.—Joseph W. Bailey has been appointed Car Accountant, with office at Bristol, Va.-Tenn.

Traffic Officers.

Alabama & Vicksburg.—See New Orleans & North-eastern under Operating Officers.

Atchison, Topeka & Santa Fe.—D. L. Meyer, Traffic Manager of the Southern Kansas Railway of Texas and the Pecos Valley & Northeastern, has been appointed General Freight and Passenger Agent of the Southern Kansas of Texas and of the Eastern Railway of New Mexico which recently bought the Pecos Valley & Northeastern. His office is at Amarillo, Tex.

Great Northern.—D. J. Black, General Agent of the Freight Department at Minneapolis, has been appointed General Agent at Spokane, Wash., succeeding A. H. Campbell, who went to the Spokane International. T. J. McGaughey, Commercial Agent at Cleveland, succeeds Mr. Black.

Gulf, Colorado & Santa Fe.—W. L. Alexander has been appointed General Claim Agent, with headquarters at Galveston, Tex., succeeding T. J. Lee, resigned on account of ill health.

Missouri Pacific.—Henry C. Townsend, General Passenger and Ticket Agent, has resigned on account of ill health.

C. E. Wager, Commercial Agent at Atchison, Kan., has been appointed General Agent at Pueblo, Colo., succeeding J. B. Trimble, now General Agent at Pittsburg, Pa.

New Orleans & North-eastern.—See New Orleans & North-eastern under Operating Officers.

Vicksburg, Shreveport & Pacific.—See New Orleans & North-eastern under Operating Officers.

Engineering and Rolling Stock Officers.

Chicago & Alton.—C. G. Delo, Engineer of Maintenance of Way at Kansas City, Mo., has been transferred to Bloomington, Ill., succeeding W. C. Causey, now Superintendent at Bloomington.

Chicago, Burlington & Quincy.—E. D. Andrews has been appointed Master Mechanic of the Sterling division, Lines West of the Missouri river, with headquarters at Sterling, Colo., succeeding F. Newton, resigned.

Hocking Valley.—M. A. Kinney, roundhouse foreman of the Baltimore & Ohio at Newark, Ohio, has been appointed Master Mechanic of the Hocking Valley, with headquarters at Columbus, Ohio, succeeding E. J. Powell, resigned.

Louisville & Nashville.—E. L. Trowbridge has been appointed assistant to the engineer of construction at Louisville, Ky., succeeding H. W. Oliver, resigned. See Virginia & Southwestern under Executive, Financial and Legal Officers.

Mexican Central.—B. F. Elliott has been appointed Assistant Master Car Builder, with headquarters at Aguascalientes.

Missouri Pacific.—M. M. Meyers, formerly on the Denver & Rio Grande, has been appointed Master Mechanic, with office at De Soto, Mo., succeeding A. S. Grant.

Santa Fe Central.—G. A. Baker has been appointed Superintendent of Motive Power, with office at Estania, N. Mex., succeeding T. J. Tonge.

Special Officers.

Chicago, Rock Island & Pacific.—Dr. Hermann von Schrenk has been appointed Supervisor of Timber Preservation, with headquarters at Tower Grove and Flad avenues, St. Louis, Mo. The Supervisor of Timber Preservation will have direct charge of the inspection of the preservative treatment given ties and timber, and will act in an advisory capacity in any and all matters pertaining to increasing their durability.

LOCOMOTIVE BUILDING.

The Northwestern Pacific has been figuring on buying new locomotives.

Edward Haynes, 18 Broadway, New York, is in the market for small locomotives for canal and plantation work.

The Temiskaming & Northern Ontario has ordered six six wheel switching locomotives from the Canadian Locomotive Co., Kingston, Ont., for February, 1908, delivery.

The Atchison, Topeka & Santa Fe is said to have ordered a number of 16-wheel Mallet compound locomotives to be used on the mountain grades of the La Junta division.

The Intercolonial Railway, as reported in our issue of July 19, has ordered 10 passenger locomotives from the Locomotive & Machine Co., of Montreal, and 22 consolidation and three switching locomotives from the Canadian Locomotive Co., Kingston, Ont.

CAR BUILDING.

The Canadian Pacific recently ordered 500 box cars from Barney & Smith

Edward Haynes, 18 Broadway, New York, is in the market for small cars for canal and plantation work.

The Toledo, Fostoria & Findlay (Electric) has ordered four interurban motor cars from the Niles Car & Manufacturing Co.

The New York City Railway has ordered 100 double-truck street cars of the "pay-as-you-enter" type from the J. G. Brill Co.

The Virginian is reported to have ordered 10 steel dump cars of 60 tons capacity from the Atlas Car Manufacturing Co., Pittsburg.

The Wisconsin Steel Company has ordered 15 steel underframe gondola cars of 100,000 lbs. capacity from the Western Steel Car & Foundry Co.

The Detroit & Toledo Shore Line denies having ordered 400 coal cars from the American Car & Foundry Co., as reported in the *Railroad Gazette* July 26.

The San Pedro, Los Angeles & Salt Lake, as reported in the *Railroad Gazette* of August 9, has ordered 100 tank cars of 100,000 lbs. capacity from the Pressed Steel Car Co.

The Erie is reported to have re-entered an order for 3,000 box cars placed last February with the American Car & Foundry Co., as reported in our issue of Feb. 15, and which was canceled in June.

The Chicago, Milwaukee & St. Paul is turning out 24 steel underframe box cars a day at its West Milwaukee shops, these cars being a part of an order for 3,000 cars placed last spring, as reported in our issue of March 15.

RAILROAD STRUCTURES.

Austin, Tex.—Local reports state that the Missouri, Kansas & Texas has plans made for extensive terminal improvements in a number of cities in Texas, including Fort Worth and Dallas, where about $600,000 is to be spent enlarging the present terminals. Two-thirds of this will be used for repair shops and a roundhouse, and for laying yard tracks at Fort Worth.

Chicago, Ill.—Preliminary work on the Chicago & North-Western's new passenger station has been begun. One-half of the property for the site has been bought, and the rest will be bought this year. Actual construction work will be begun early next year. The buildings are being removed between Canal and Clinton streets and north of Madison street, where the station will be built.

Globe, Ariz.—The Southern Pacific has plans ready for putting up a new passenger station, for which a site has been bought. The station is to be used by the Gila Valley, Globe & Northern. The cost of the improvement will be about $100,000.

Trinidad, Colo.—Final arrangements have been made by the Atchison, Topeka & Santa Fe to make improvements here at a cost of $60,000. The work includes a new freight house, a roundhouse and a coal chute. A new side track will also be laid.

RAILROAD CONSTRUCTION.

New Incorporations, Surveys, Etc.

Atlanta, Birmingham & Atlantic.—This company is to build from Bone's Gap, Ala., to Adamsville, penetrating a coal district. This line is a companion to the line from Bessemer to the new coal town of Mulga, and the proposed line from Birmingham to Gate City, where a rolling mill district is entered. The Birmingham district branches of the A., B. & A. will cover about 25 miles, and will give an entrance into many important industrial centers.

Central Kentucky Traction.—This company has issued $300,000 bonds and executed a mortgage for $250,000 to secure funds to finish the construction of its lines from Lexington, Ky., east to Winchester, 20 miles, and south to Nicholasville, 15 miles.

Chicago, Burlington & Quincy.—According to reports, this company has filed plans for its proposed extension in Wyoming. The route is from Guernsey northwest along the North Platte river to Douglas, thence west to the Shoshone Indian Reservation, about 200 miles. Surveys reported under way.

Chicago, Milwaukee & St. Paul.—President Earling is quoted as saying that work on the Pacific extension will be pushed to completion as fast as men and machinery can accomplish the task. Several thousand additional men are to be put on work to have the line finished to Butte next May. He does not say when work will begin on the Seattle division. The company is soon to begin work on the 8,000-ft. Bitter Root tunnel and on the 10,000-ft. tunnel in Snoqualmie Pass.

Chicago, Rock Island & Pacific.—The Carrollton-Irving cut-off, it is expected, will be finished and ready for operation in a few weeks. The new line will be 11 miles long and will connect Irving, Tex., which is on the Fort Worth-Dallas line of the Rock Island, with Carrollton, on the St. Louis & San Francisco. (July 26, p. 111.)

Corvallis & Alsea River.—Incorporated in Oregon with a capital of $150,000 to build a line from Corvallis southwest via Alsea, thence south to Bicony in the Lake creek district, about 45 miles. Stephen Carver, B. W. Johnson, V. E. Watters, A. Fischer, E. R. Bryson and F. L. Miller, of Corvallis, are directors.

Fort Worth & Rio Grande.—See St. Louis & San Francisco.

Gulf, Colorado & Santa Fe.—Plans reported made for extensive improvements at Port Bolivar, Tex., which is to be an important lumber exporting point. A pier 300 ft. wide and 1,200 ft. long is to be constructed and barges are to be used to transport passenger trains across the bay to Galveston. The Gulf & Interstate division, which runs from Bolivar to Beaumont, connecting at this point with the line north to Center, is building a connecting line from Center to Timpson, which will give a connection with the Texas & Gulf. Plans are ready for extending the T. & G. north from Longview to a connection with the Santa Fe's Kansas City line at a point in the Indian Territory. When these connecting links are finished the Santa Fe will have a shorter route from Kansas City to Galveston.

Gulf, Plainville & Northern.—This company, chartered to build 60 miles of line from Plainville, Kan., north to the Nebraska state line, and which has an office at Plainville, is reported recently to have given a contract to the W. C. Ross Company, of Chicago, to build the line. It is said that sub-contracts for grading will shortly be let. (March 15, p. 384.)

Louisville & Nashville.—The work carried out by this company since January 1 of this year is as follows: Revision of line, Knoxville division, Corbin, Ky., to Saxton, Ky., 1.60 miles; revision of line, Henderson division, Greenbrier, Tenn., to Guthrie, Ky., 1.80 miles; Meadow Spur, Knoxville division, 1.30 miles; Chenoa branch extension, 1.82 miles; Skelton Creek extension, 6.25 miles, mine spurs, 3.33 miles. Extensions under way: Savoy, Ky., to coal mines, 19 miles; Mount Pleasant, Tenn., to Mayfield, Tenn., 17 miles; completion of work of revision of line, Greenbrier, Tenn., to Guthrie, Ky., 25.70 miles; revision of line, Kentucky division, Corbin, Ky., to Livingston, Ky., 31.70 miles.

Mexican Roads.—The concession granted to W. C. Palmer to build railroads in the state of Zacatecas, Mex., has been modified to include a line from a point between Gutierrez and Canitas, on the Mexican Central, west to Sombrerete, 60 miles. Surveys must be started within two months and the work finished for 30 miles within 18 months. Permisson has also been granted to build a line from Sombrerete, or a point on the above line, south to Chalchihuites, 35 miles, on which surveys must be started within six months, and the line finished within four years. The other stipulations of the concession as originally granted remain in force. (March 15, p. 396.)

Mississippi Roads (Electric).—A company is being organized with a capital of $90,000 in Mississippi to build an electric line from Scranton northeast via Orange Grove and St. Elmo, Miss., and Grand Bay, Ala., to Mobile, about 40 miles. The proposed line will parallel the Louisville & Nashville for most of the way. M. J. McDermott, S. Lowenstein, of the Bank of Mobile; J. D. Willoughby and R. C. Harris, of Scranton, are interested.

Pennsylvania.—An additional section of the Kensington branch of this road in northeast Philadelphia, which now extends from Frankford Junction to Front and Narrow streets, 2.9 miles, is to be elevated, contract for the work having recently been let to the James McGraw Co. The work includes raising three tracks over six streets. It is expected to have it finished next spring, when additional contracts will be let. The track elevation, which will cost when completed about $2,500,000, was begun in 1900 and continued to a point south of Venango street and then discontinued for about four years pending negotiations with the city. The city is to pay $900,000 towards the cost of the work.

This company, it is said, will spend $1,500,000 in the construction of a new yard at Williamsport, Pa. The new yards will be adjacent to the large yards of the Philadelphia & Reading and the New York Central, and also the new yards of the Susquehanna & New York.

Pensacola, Alabama & Western.—Bids are wanted by the Interstate Contract Co., 224 Brent building, Pensacola, Fla., for grading, masonry and bridges on 105 miles of railroad as mentioned on advertising page 22. At a meeting of the promoters of this company and the Pensacola & Northeastern the bids recently submitted by contractors to grade 20 miles of roadbed of each of these proposed roads were rejected. The work for which bids are now asked includes grading all of the Pensacola & Northeastern from Pensacola, Fla., to Andalusia, Ala., 85 miles, and also for 20 miles on the Atmore division of the Pensacola, Alabama & Western. (June 28, p. 949.)

Pensacola & Northeastern.—See Pensacola, Alabama & Western.

St. Louis & San Francisco.—Announcement is made that the Fort Worth & Rio Grande is to be extended from Brady, Tex., south-

east to San Antonio, about 150 miles; and that a west branch is also to be built from Brady to San Angelo, about 60 miles. Surveys reported made.

Southwestern Railway.—Application is to be made in Texas for a charter by a company being organized by Uriah Lott, with office at San Antonio. The promoters propose to build a line from Kingsville, Tex., on the St. Louis, Brownsville & Mexico, north to San Antonio, about 150 miles.

Sugarland Railway.—This company, which now operates 15 miles of road from Arcola, Tex., to Sugarland, will, it is said, build an extension north to Hempstead, about 45 miles. The road is ultimately to be extended north to Fort Worth or Dallas, 200 miles.

Texas Roads.—The Stone & Webster Syndicate, of Boston, Mass., according to local reports, has under consideration the question of building an interurban electric line from Austin, Tex., south to Lockhart, about 30 miles. Surveys have been made and most of the rights of way secured. Power is to be supplied from the works at the Colorado river of the Consolidated Construction Co., of New York.

Union Pacific.—Work has been resumed on the Athol Hill cut-off south of Cheyenne, Wyo. Starting on the main line of the Union Pacific between Denver and Cheyenne, near Carr, Colo., the cut-off is to run northeast to Borie, Wyo., connecting with the main line through Wyoming, 9½ miles west of Cheyenne. A branch leaves the main line between Carr and Borie three miles south of Corlett, connecting with the Wyoming division 4½ miles west of Cheyenne. The total length of the new lines under construction is 17 miles, and the saving in distance between Denver and Borie and points west by the cut-off is over 13 miles. Maximum grade on the present line between Carr and Cheyenne is 1.8 per cent. in both directions. This grade by the new line is cut down to 1.2 per cent. north or westbound, with no adverse grades south or east. The troublesome curves of the present line are also avoided. It is expected to have the cut-off completed and in operation this year. There will be 220,000 cu. yds. of roadbed excavation, about 30,000 yds. of which is solid rock, and 900,000 cu. yds. of embankment. The largest fill is 2,700 ft. long and 45 ft. high. Bridging on the new line consists of concrete arches, cast iron pipe culverts and pile trestles of 5, 8 and 10 spans. The longest arch is 135 ft. There will be three new stations on the line.

Wisconsin Central.—The suit between the Wisconsin Central and the Milwaukee Southern over the right of way in the Menominee valley has been withdrawn by the Milwaukee Southern, and the Wisconsin Central can now build into Milwaukee. The Milwaukee Southern had a franchise from the city council for entrance into Milwaukee, but it was unable to raise sufficient capital to carry out the project. Condemnation proceedings started and won by the Milwaukee Southern have been dismissed.

Wolfe, Megantic & Lotbiniere.—This company, which was chartered to build a line from Lime Ridge, Wolfe county, Quebec, north about 100 miles, has surveys made from Lime Ridge to Lyster, 60 miles. An officer informs us that nothing has been done towards constructing the line. W. H. Lamby, Inverness, Que., Secretary. (March 15, p. 396.)

RAILROAD CORPORATION NEWS.

Alabama Terminal Company.—See Atlanta, Birmingham & Atlantic.

Atlanta, Birmingham & Atlantic.—The Alabama Terminal Company, which represents the Atlanta, Birmingham & Atlantic in the Birmingham district, has increased its capital stock from $2,000,000 to $3,000,000 and is to issue $4,000,000 bonds.

Central of Georgia.—Since the sale of this road in June to Oakleigh Thorne and Marsden J. Perry there has been considerable agitation by holders of the first, second and third preference income bonds who fear that interest payments on these bonds will be sacrificed to the further building up of the road. A bill has even been introduced into the legislature of Georgia, now in session, providing that the income bond holders shall have the same voting rights as stockholders. It is said that the income bondholders may be given the chance to exchange their securities for fixed interest bonds.

Erie.—A plan is said to have been discussed by the directors for paying the dividend on Erie preferred stocks in scrip. At present prices Erie second preferred returns nearly 12 per cent to the investor.

Georgia & Florida.—The capital stock of this company, a consolidation of a number of small roads in Georgia and Florida, controlled by John Skelton Williams, has been increased from $1,000,000 to $8,750,000, of which $3,500,000 is preferred stock and $5,250,000 common stock.

Grand Trunk.—The dividend on the third preference stock has been passed. Three per cent. was paid from the 1906 earnings.

Houston Belt & Terminal.—The Houston Belt & Terminal Railway has filed a mortgage securing $5,000,000 first mortgage 5 per cent. bonds. The mortgage covers property in Houston to be used for passenger and freight terminals. This company is controlled by the Gulf, Colorado & Santa Fe, Trinity & Brazos Valley (Colorado & Southern-Rock Island Company), St. Louis, Brownsville & Mexico, and Beaumont, Sour Lake & Western (Colorado Southern, New Orleans & Pacific).

Interborough Rapid Transit.—Both tubes of the so-called Belmont tunnel from East 42d street to Long Island City have been joined. It was announced during the course of the investigation of the New York city transit lines now under way by the Public Service Commission of the First district that the Interborough Rapid Transit Company owns this tunnel.

Nashville, Chattanooga & St. Louis.—Gross earnings for the year ended June 30, 1907, were $12,238,472 against $11,120,982 in 1906. Operating expenses increased more than gross earnings, leaving net earnings $2,508,311 in 1907 and $2,766,069 in 1906. Surplus, after interest, taxes and rentals, was $713,980 against $971,537 in 1906.

New York Central & Hudson River.—The operating ratio in the quarter ended June 30, 1907, was 76 per cent., which compares with 83 per cent. in the preceding quarter. Gross earnings for the quarter and six months ended June 30, 1907, were as follows:

For the Quarter.			
Earnings	$25,142,126	Inc.	$3,555,155
Expenses	19,197,643	"	3,869,492
Net earnings	$5,944,483	Dec.	$314,337
Other income	2,551,561	Inc.	898,008
Gross income	$8,496,044	Inc.	$583,671
First charges and taxes	5,768,170	"	235,416
Available for dividend	$2,727,874	Inc.	$348,255
Quarterly dividend, 1½ per cent	2,679,480	"	814,507
Profit	$48,394	Dec.	$460,252
For Six Months.			
Earnings	$46,930,896	Inc.	$4,051,671
Expenses	37,400,514	"	6,624,601
Net earnings	$9,530,382	Dec.	$2,572,930
Other income	4,911,076	Inc.	1,665,842
Gross income	$14,441,458	Dec.	$907,088
First charges and taxes	11,494,091	Inc.	438,512
Available for dividend	$2,947,367	Dec.	$1,345,600
Semi-annual dividend, 3 per cent	5,358,960	Inc.	1,629,015
Deficit	$2,411,593	Inc.	$2,974,615

New York Central Lines.—Gross earnings for the month of July, 1907, were as follows:

New York Central & Hudson River	$8,769,318	Inc.	$1,040,096
Lake Shore & Michigan Southern	3,804,876	"	220,445
Lake Erie & Western	398,485	Dec.	34,754
Chicago, Indiana & Southern	235,225	Inc.	69,147
New York, Chicago & St. Louis	809,256	"	534
Michigan Central	2,386,844	"	267,872
Cleve., Cin., Chic. & St. Louis	2,312,464	"	109,099
Peoria & Eastern	234,676	Dec.	9,960
Cincinnati Northern	84,136	Dec.	4,216
Pittsburg & Lake Erie	1,433,695	Inc.	117,923
Rutland	286,276	Inc.	36,352
Total	$20,755,251	Inc.	$1,872,538

New York, Ontario & Western.—Gross earnings for the year ended June 30, 1907, were $8,202,361 against $7,265,058 in 1906, an increase of $937,303. Operating expenses increased $411,059, leaving net earnings of $2,558,015, an increase of $526,244. The surplus after charges was $1,654,782, larger by $467,281 than in 1906.

Northern Pacific.—For the month of July the estimated freight earnings were $4,816,901, an increase of 19 per cent. over the same month in 1906; passenger earnings, $1,885,006, an increase of 36½ per cent., and gross earnings, $6,955,407, an increase of $1,266,481, or 22 per cent.

Pere Marquette.—Subscriptions to the $5,000,000 five-year 6 per cent. notes, issued as part of the reorganization plan, have been received from over 90 per cent. of the preferred stockholders.

Southern Pacific.—The gross earnings of the Southern Pacific Company for the year ended June 30, 1907, were $124,942,527 against $105,632,550 in 1906. There were 9,350 miles operated last year, against 9,192 in 1906. Net earnings over expenses and taxes were $41,825,598 against $35,047,361 in 1906. Thus the increasea for the year were as follows: Gross earnings, $19,300,000; expenses and taxes, $12,500,000; net earnings, $6,800,000. Gross earnings for June, 1907 (9,432 miles operated), were $11,082,899, an increase of $1,852,252. The increase in expenses and taxes was almost as large, leaving net earnings over taxes of $2,641,391 against $2,530,469 in 1906.

RAILROAD GAZETTE

ESTABLISHED IN APRIL, 1856.

PUBLISHED EVERY FRIDAY BY THE RAILROAD GAZETTE AT 83 FULTON STREET, NEW YORK.
BRANCH OFFICES AT 870 OLD COLONY BUILDING, CHICAGO, AND QUEEN ANNE'S CHAMBERS, WESTMINSTER, LONDON.

EDITORIAL ANNOUNCEMENTS.

THE BRITISH AND EASTERN CONTINENTS edition of the Railroad Gazette is published each Friday at Queen Anne's Chambers, Westminster, London. It contains selected reading pages from the Railroad Gazette, together with additional British and foreign matter, and is issued under the name Railway Gazette.

CONTRIBUTIONS.—Subscribers and others will materially assist in making our news accurate and complete if they will send early information of events which take place under their observation. Discussions of subjects pertaining to all departments of railroad business by men practically acquainted with them are especially desired.

ADVERTISEMENTS.—We wish it distinctly understood that we will entertain no proposition to publish anything in this journal for pay, EXCEPT IN THE ADVERTISING COLUMNS. We give in our editorial columns OUR OWN opinions, and these only, and in our news columns present only such matter as we consider interesting and important to our readers. Those who wish to recommend their inventions, machinery, supplies, financial schemes, etc., to our readers, can do so fully in our advertising columns, but it is useless to ask us to recommend them editorially, either for money or in consideration of advertising patronage.

OFFICERS.—In accordance with the law of the state of New York, the following statement is made of the office of publication, at 83 Fulton St., New York N. Y., and the names of the officers and editors of The Railroad Gazette.

CONTENTS

VOL. XLIII., No. 8. FRIDAY, AUGUST 23, 1907.

Exports of domestic products from this country during the fiscal year ended June 30, 1907, were valued at $952,000,000; $62,000,000 more than in the previous year. The value of the cotton exported was $481,000,000, an increase of $81,000,000, while that of breadstuffs and provisions was $391,000,000, a decrease of $18,000,000. In the last classification are found the most striking figures of the report. The value of the exports of canned beef dropped from $6,400,000 in 1906, to $1,600,000 in 1907, a reduction of 75 per cent., meaning a loss in wages paid to working people of perhaps $2,000,000. In Secretary Taft's eulogy of the President, a few days ago, he omitted mention of this instance of "his amazing quality for doing things on their (the people's) behalf." The President made the lurid charge that packing processes were disgusting and the product poisonous. The investigation and analyses failed to substantiate this, and independent investigators (see Hoff & Schwahach) expressed their opinion that American packing houses were the best in the world. Congress passed a law on the subject, however, and the President, having nearly annihilated one export industry, turned his attention to another subject with untiring versatility.

SECRETARY TAFT ON RAILROAD REGULATION

We print in another column a liberal extract from that part of Secretary Taft's Columbus speech which concerns railroads. Mr. Taft has a much clearer idea of the possibilities and desirabilities of corporation regulation by the government than a certain other redoubtable maker of speeches has, and his comments are worth reading. Mr. Taft believes, with the editor of the *Railroad Gazette*, that the chief benefit of the rate law is likely to be its influence in discouraging attempts to renew old abuses. He does not mention the secondary advantage, that the presence of a strong law and an intelligent commission will some day tend to lessen legislative action against railroads, on the same principle that mob rule decreases when efficient police power increases. He believes, further, that far too much pother was made about the court review provisions of the rate law, since the courts would in any case have had it in their jurisdiction to determine whether the administrative tribunal had followed correctly the limitations upon its course of action imposed by the act of Congress creating it, and also whether its order, taken as an authorized expression of the legislative power, deprived the railroad company of its right, under the Fourteenth Amendment, to derive a fair profit from the use of its property. Mr. Taft recommends an amendment which will enable the Interstate Commerce Commission to prescribe a uniform freight classification, and one which will make it impossible for a railroad company engaged in interstate commerce to issue stocks and bonds without the approval of the commission. He also favors legislation which will make it impossible for a railroad to own shares in a competing line, or for a single officer or director to serve on two competing lines. He is opposed to government ownership, for reasons which he clearly sets forth, and he believes that the supervision which he outlines as proper will work against it, and will not materially reduce individualism in railroad operation. He believes in legally sanctioned rate agreements; thinks the importance of fixing rates is much overestimated, and deprecates the assumption that a physical valuation can be a chief means for a great reform in rates. Finally, he believes in additional legislation to promote public safety, and may perhaps approve of the abolition of the fellow-servant rule, though he does not say so, in his guarded discussion of it.

It is both interesting and important that we should have Mr. Taft's creed thus set forth. He is likely to be our next chief executive, and, whether he is or not, he represents the sober thought of the present administration, as opposed to its wild words. The general impression obtained from a careful reading of his speech is that he believes in a simple, matter-of-fact application of government police power to check abuses. We do not concur in all that the Secretary says. We think that he has much exaggerated the existing over-capitalization of certain railroads. In one paragraph he says in effect that if securities had not been used for fraudulent purposes, and if the proceeds from the sale of them had been applied direct to the properties we should have had much less car shortage and other difficulties occasioned by physical defects in the railroad systems than we have had. We believe the impression conveyed by this statement is not quite correct. The manipulation of the Alton securities has frequently been cited as an example of the state of affairs to which the Secretary alludes, yet we know that the Alton securities were issued to cover improvements made to the property out of earnings during a series of past years, and if these improvements had been charged direct to capital at the time they were made, the Secretary's requirements would apparently have been fulfilled while the situation would have been unchanged, as regards the physical condition of the property.

But the speech as a whole is an uncommonly sound document. The comment on valuation of railroads to the effect that it is not necessarily objectionable if thought relevant to any issue, but that it cannot be used alone to reform rates, is thoroughly sane, and directly in line with what has often been said in the *Railroad Ga-*

zette; and the statement that tariff wars do not help either the public or the railroads by the violent fluctuations in rates which they occasion, and that rate agreements should be allowed, subject to the approval of the Interstate Commerce Commission, is good doctrine. We note, however, that the Secretary has apparently some fear that consolidation of railroad properties will go far beyond anything we have now seen, and he urges that a railroad should not be allowed to hold the stock of a competitor. We are not prepared to subscribe to this, principally for the reason that it is extremely hard to define the word "competitor," and also because a train of argument not unlike that used by the Secretary in referring to rate agreements can be applied equally well to the general competition between railroads. It is easy to overdo government by commission, and we think most thoughtful persons will agee that this country has been greatly over-governed in the last two years.

THE NEW HAVEN-BOSTON & MAINE SYSTEM.

The action of the Massachusetts Legislature against the merger of the New York, New Haven & Hartford and the Boston & Maine is suspensive and in no sense final. As the case stands, with the New Haven holding, through its agents, about two-fifths of the outstanding shares of the Boston & Maine, with many other of the Boston & Maine stockholding interests friendly to the merger, and President Tuttle and a number of the Boston & Maine directors also favoring the plan, the New Haven control is practically assured and waits only for details until the next meeting of the Massachusetts law-making body. The legislature may harass and delay but it cannot in the end check the union of the two systems. For purposes of analysis and description, the merger may therefore be treated as a completed fact and sanctioning, as a condition and not a hypothesis, the map of the combined systems, shown on another page, including the electric system of the New Haven in three states, never heretofore published, and a second map taken from the larger one, showing in larger scale these electric lines alone.

The double combination of electric and steam roads has no parallel or even analogy in the railroad systems of the world. Other systems have greater mileage, larger equipment, and penetrate more unique or more picturesque regions. New England has no counterparts of the snow-clad mountain ranges of the Canadian Pacific, nor, on the other hand, the features of the railroad lines of tropical Africa or sub-tropical Mexico. But nowhere will be found a region where industrial energy, dense population, great factory product, extensive coast line and sea traffic, and freight and passenger business in about equal proportions, and both large, absolutely, are controlled under equal conditions of territorial monopoly. Then, again, there is the great electric annex of the steam system. This alone, representing a field into which President Mellen has pushed as a venturesome pioneer, gives the new combinations an abiding meaning in the science of transportation. A very few years more, especially if they include a recession of prosperity, will not only try out in New England on a great scale the policy of joint operation of formerly competing steam and street railroads, but very likely also solve, positively or negatively, the problem of exchanged traffic with steam power, much more generally than roads superseded by electricity. On shorter lines and more restricted areas the test is being made elsewhere. But in southern New England its size and variations dwarf all others.

This electric ownership of the New York, New Haven & Hartford calls for special attention. Its location and wide sweep in Connecticut will first be noticed. That state contains 18 cities. Of these, New Haven, Hartford, Bridgeport, Waterbury, New Britain, New London, Norwich, Norwalk and South Norwalk, Stamford, Meriden, Willimantic, Ansonia, Derby, Middletown, Putnam and Rockville—17 in all—besides townships like Winchester, Greenwich and Torrington, that are more populous than some of the cities—are covered exclusively by the New Haven's street railway lines. Its reach along the populous western coast of the state and even more populous central region, with almost every cross-country line paralleling the steam road, as well as focussing at the cities, suggests those possibilities of "bunching" cars and retrainment which President Mellen has repeatedly forecast.

Turning next to Massachusetts, the striking feature is the electric paralleling of the Boston & Albany by the New Haven's electric lines. They already span the gap between Springfield and Worcester with a number of laterals; stretch nearly half-way between Springfield and Pittsfield, with power to build between the latter city and Albany; and complete parallelism of the Boston & Albany goes on apace, tending more and more to cut off its local passenger traffic and reduce it to a through line—a kind of long bridge between Boston and Albany. In Rhode Island the grouping of the acquired trolley system is evidently defensive rather than aggressive, protecting the populous Providence and Fall River region and Blackstone Valley against long-distance electric rivalry.

The great parallel electric mileage which the New Haven has acquired in the narrow valleys like the Naugatuck, upper Housatonic and Blackstone, suggests another feature of the Mellen policy likely to be realized ere long—reduction of local trains, the use of the valley steam roads chiefly for express service, and the transfer of purely local business to the trolleys. Joined with this are comprehensive plans for expansion of trolley, express and freight service already begun, and combinations of steam-trolley excursion service. The high potential for such purposes of a vast trolley system that represents some 1,300 miles of single trackage, market value of $100,000,000 or more, and gross earnings of some $18,000,000 a year, most of it in a densely populated region and touching seaside resorts at many points, goes with the statement.

Coming next to the import of the new merger itself, its magnitude in figures cannot be expounded accurately owing to recent changes in capitalization of the New Haven and unreported earnings of its now somewhat complex marine properties. But, as a rough statement, the steam mileage of the combination may be given as 5,700 miles, to which some 3,700 more would have to be added in terms of mileage for single track. Gross earnings of the system, counting in the New York, Ontario & Western, the Central New England, the Sound lines, the electric roads—which, by the way, show a constant increase—and the newly acquired coastwise properties, will hardly fall during the first year of joint operation below $150,000,000 a year, putting the system in absolute earning power in the front line of the great railroad systems of the country, and with exceptional earning power per mile of steam road operated. After the proposed issue of some $30,000,000 of new stock of the New Haven, the total steam road capitalization may be roughly estimated at about $150,000,000, calling for dividend requirement at the 8 per cent. rate of $12,000,000 a year. Since the last official annual statement charges of the New Haven system as a whole, ahead of dividends, have so shifted, and the charges themselves are so intricate, that no satisfactory estimate of debt—including in that term capitalized leases—can be made. Out of the whole steam mileage in New England, when the merger is completed, the New Haven will control about three-quarters, and of really profitable local traffic practically the whole, nearly all of the outside roads, except the Bangor & Aroostook, being of the through traffic or "bridge" type, like the Boston & Albany and the Canadian extensions into Maine.

The possibilities of the merger are many and some of them intricate. They are so numerous that they can here be stated only in condensed shape. They include:

(1) The unifying, acceleration and enlargement of service through central New England from New York city to Canada and coastal points in Maine.

(2) Closer connection for through business with the Canadian roads, which, incidentally, may deepen the New England cry for Canadian reciprocity and father ultimately an acute political issue in New England politics.

(3) Terminal improvements on a large scale at Boston, including subways to stations.

(4) Development of the coastwise business in connection with through rail lines to the southward, this possibly including ownership of southern coal mines as feeders of fuel to the amount of between 5,000,000 and 6,000,000 tons a year which the new system will consume.

(5) The application to the Boston & Maine system (a) of the steady and persistent policy of fiscal and physical consolidation which has already advanced so far in the New Haven system proper, and (b) a co-operative street railway policy applied to Boston & Maine territory.

(6) Possible transatlantic service.

(7) Last and largest, great outlays on the too dormant Boston & Maine group of roads, to improve roadbed, bridges and equipment, and increase train load after the Northern Pacific precedent.

Between these greater plans many sub-problems lie. Some of them are within the process of merger, some of them afterdate it. There are the legislative conditions to attend the consent of Massachusetts to a merger general and legal, as well as based on stock control. There is the attitude of that state, as well as others, to the system after the merger has been consummated. There is the question of the exercise or non-exercise of the New York Central option—now extended for six months—on the Ontario & Western,

and, along with it, the outcome of the new trackage rights acquired by the New Haven on the Boston & Albany, and the policy of the newly-merged corporation toward the Boston & Albany itself. How far will the greater New Haven avail itself of its territorial monopoly to "trade" business with the through trunk lines and exchange high-class freight for low class on long haul? What will be its policy on the question of car detention and per diem? Will it change its prolix and localized name for a briefer and more descriptive one like "The New England Railroad?" and will it shift its administrative center from New Haven to Boston, and cease to be a Connecticut corporation?

The bold and highly condensed statement of the policies and plans ahead of the merger thus fills considerable space. Collectively, they vest the new railroad combination with absorbing interest and a value that reaches far beyond the bounds of New England.

CLASHES BETWEEN FEDERAL AND STATE AUTHORITY.

Whatever may be thought of the merits or demerits of the legislation and of the action of the southern governors which has threatened to bring about clashes between federal and state authorities in three southern states, there is reason for congratulation in the fact that the ultimate result will be to send to the Supreme Court of the United States a series of cases, the decision of which ought to settle, once for all, the question whether a state can close the doors of the United States courts in the face of any citizen, or obstruct in any way the orders of those courts issued for the preservation of rights guaranteed by the constitution. It is to be hoped that the decision of these cases will also make clearer the dividing line between federal and state authority over railroads doing both interstate and intra-state business, and that they will afford some guide for future legislators as to how far they can go in the direction of arbitrary reductions of railroad charges without their acts becoming confiscatory.

The railroads have applied to the federal courts in several states for protection against reductions in charges alleged to be confiscatory, but, thus far, the proceedings have followed the usual course, except in the three southern states of North Carolina, Virginia and Alabama.

In North Carolina the legislature prescribed a maximum passenger rate of two and one-quarter cents a mile for all roads over sixty miles long, without any attempt to differentiate between roads on account of relative density of traffic, and similarly arbitrary reductiona of about fifteen per cent. were prescribed on joint freight rates on routes wholly within the state.

In Alabama, the legislature prescribed a maximum passenger rate of two and one-half cents a mile, without taking into account differences in density of traffic, and prescribed reduced maximum rates on 110 commodities.

In Virginia, freight rates were not affected, and the Corporation Commission, by which the reduced passenger rates were prescribed, went about the matter more intelligently, prescribing a two-cent maximum for the principal lines, but prescribing two and one-half, three and three and one-half cents on certain minor roads and branch lines.

Although this legislation was resisted by all the principal lines the brunt of the fight in each state was borne by the Southern Railway Company. In North Carolina, the legislation was attacked on the ground that it was confiscatory, in that the rates prescribed would not yield fair compensation for the service performed. It was also contended that the penalties proposed to be imposed for failure to put the prescribed rates and charges in effect were excessive and would operate to deny to the railroads the equal protection of the laws and due process of law. It was further contended that the arbitrary exception of roads not over sixty miles long was a denial of the equal protection of the laws.

In Virginia, the action of the Corporation Commission was alleged to be unconstitutional on three grounds. It was contended that the provision of the state constitution creating the Corporation Commission was in violation of the constitution of the United States in that, by proposing to give to the Corporation Commission legislative, executive and judicial authority over transportation and transmission companies, it sought to deny to those companies due process of law and the equal protection of the laws. It was contended that the order of the commission, so far as it applied to the Southern Railway Company, was unconstitutional on the ground that it was an impairment of the obligation of the contract entered into by the state of Virginia in granting the charter of the Southern Railway Company, there being in effect at that time, and forming a part of the charter, a legislative provision whereby the state was precluded from changing the rate of the company without its assent. It was further contended that the rates prescribed were confiscatory.

In Alabama it was alleged that the rates prescribed were confiscatory and that a separate act, providing that if any railroad company should contest these rate laws in the federal courts or attempt to move from the state courts to the federal courts, any act relating to rates, its license to do business in the state should be revoked, was unconstitutional.

At the instance of the Southern Railway Company and other companies, sweeping injunctions against the enforcement of the acts of the North Carolina and Alabama legislatures were granted by United States Circuit Judges Pritchard and Jones, and Judge Pritchard also enjoined the enforcement of the order of the Virginia Corporation Commission. In both Virginia and North Carolina, the orders of Judge Pritchard, at the request of the railroads, required the giving to each purchaser of transportation evidence of his payment in excess of the prescribed rates and the deposit in the registry of the court of sums sufficient to repay these amounts if the rates should be finally sustained.

The orderly procedure in all of these cases would have been to allow them to take the usual course to the Supreme Court of the United States, and this would have been done but for a violent outbreak of states' rights sentiment in North Carolina, led by Governor Glenn and some of the radical newspapers. The railroads and Judge Pritchard were denounced for their alleged defiance of the laws and authority of the state of North Carolina, and the governor sent a circular letter to each of the superior court judges of the state, asking them to instruct the grand juries to indict the agents and employees or the higher officers of the railroads for "openly acting in defiance of law." The Southern Railway Company was singled out by the governor as the object of attack. Its agents were arrested—two of them being sentenced to thirty days' imprisonment—and President Finley, who was at Asheville, was taken into custody on a police court warrant. Justice Pritchard promptly ordered the release of all prisoners, as soon as they could be brought before him on writs of habeas corpus. In the meantime, all efforts made by the railroad officials, supplemented by a special representative of the department of justice, to reach an agreemnt whereby the rights of the railroads could be protected, pending proceedings in the courts, were rejected. The governor would agree to nothing that did not involve putting the reduced passenger rates into effect, and he threatened to call an extra session of the legislature to enact laws, including new railroad tax laws, that would still further harass the railroads, and to continue the policy of indicting and arresting the agents and employes of the Southern Railway.

The contest had been carried to a point where it ceased to be a question of rates, and was a question of whether the United States would enforce the process of its courts against the opposition of a state government. Judge Pritchard showed no sign of yielding, but the Southern Railway Company was unwilling to be the cause of a conflict of authority between the state and the United States, and, with the consent of Judge Pritchard, yielded the protection of his interlocutory injunction so far as to put the passenger rates into effect, the other still standing as to the freight rates and the pending litigation being left so as to carry the constitutional questions at issue to the Supreme Court of the United States. The other resisting roads followed the lead of the Southern in putting in the passenger rates.

Governor Glenn having achieved his "victory," the states' rights fever broke out in Virginia. The publication of the order of the Corporation Commission had been enjoined by Judge Pritchard, but Governor Swanson threatened to call an extra session of the legislature to enact a law prescribing the rates ordered by the commission. This would have meant a repetition of the same fight that had been made in North Carolina, and, having yielded in that state, there was nothing to do but yield in Virginia.

Up to this time, the only action that had been taken in Alabama had been the appropriation of $50,000 for the expense of the contest in the United States courts, but an accidental occurrence gave Governor Comer his opportunity to get into the lime light. Judge Jones had held the act attempting to prevent the railroads from instituting suits under the rate laws in the federal courts, or removing such suits to those courts, to be unconstitutional, and had enjoined the secretary of state from cancelling the license of a railroad for disregarding this act. Another act had been passed, however, applying to corporations generally and providing for the cancellation of the license of any corporation of any other state which should attempt to remove any suit to a federal court. A subordinate at-

torney of the Southern Railway Company, without the knowledge of the general officers, and as a routine matter of business, filed a petition to remove to the federal courts a suit for damages for personal injury, had no relation to the rate laws, and which was filed several months before their passage. The secretary of state at once cancelled the license of the Southern Railway Company to do intra-state business in Alabama, acting under the law forbidding corporations generally from removing suits to the federal courts. This law, though clearly unconstitutional, if Judge Jones was right in holding the act applying specifically to railroads to be so, was not directly passed upon in his decision. The Southern Railway Company, notwithstanding the cancellation of its license, continued to do business in the state, pending an effort to arrange a settlement with Governor Comer. This governor was even more uncompromising than Governor Glenn had been. He insisted upon the railroads putting in the reduced freight rates as well as the passenger rates, and to force the railroads to his terms, he threatened wholesale arrests and a special session of the legislature. For the sake of the object lesson that would have been given, it is unfortunate that the officials of the Southern Railway did not stand firm and force the governor to compel them to stop their intra-state business, thus giving the people along their lines a practical demonstration of the wrongheadedness of the policies of their governor and their legislators. However, pursuing that policy of conciliation that has marked the administration of President Finley, and preferring to suffer injustice rather than antagonize its patrons, the company yielded, and applied to Judge Jones for such a modification of his order as would permit it to put the rates into effect pending the determination of their reasonableness and justice. Judge Jones, with much reluctance, consented to this modification, but, in so doing, took occasion to leave no room for doubt as to his opinion that the course of Governor Comer tended to anarchy and declared that he would be unfaithful to the high trust confided in him if he did not utter "words of warning against the extraordinary course which has been pursued to drive a suitor from the courts."

The net results of these proceedings will be that the railroads will be subjected to loss of revenue pending the final determination of the pending litigation, and the question as to whether the rates prescribed in each instance are confiscatory or not will be settled. It is to be hoped that a still more important result will be a clear and unmistakable decision as to the power of a state government, directly or indirectly, to place limitations on the right of any individual or corporation to seek in the courts the protection of every legal and constitutional right, for, in the words of President Finley, "if an appeal to a court of justice is a violation of law, then all our courts should come to an end."

Train Accidents in July.[1]

Our record of train accidents occurring on the railroads of the United States in July includes 26 collisions and 14 derailments and one other accident, 41 accidents in all. This record is not published in full as was formerly done, except in the cases of the few accidents which are especially prominent—in the present instance eight collisions and one derailment. The record of "ordinary" accidents —which term includes, for our present purpose, only those which result in fatal injury to a passenger or an employee or which are of special interest to operating officers—is given in the shape of a one-line item for each accident, showing date, location, class and number of deaths and injuries. This record is based on accounts published in local daily newspapers, except in the cases of accidents of such magnitude that it seems proper to send a letter of inquiry to the railroad manager. The official accident record published quarterly by the Interstate Commerce Commission is regularly reprinted in the *Railroad Gazette*.

The most disastrous accident in the present list, the collision at Salem, Mich., on the 20th, was reported in the *Railroad Gazette* of July 26 and August 2. It was due to misreading of a despatcher's order.

The collision at Johnson City, Tenn., on the 14th, occurred at 7.30 p.m., and was due to the carelessness of a hostler in charge of a locomotive in the yard, who occupied the main track on the time of eastbound passenger train No. 42. He had accepted incorrect information from a telegraph operator when he should have had a written despatcher's order. He was running toward the passenger train. He saw the passenger engine in season to reverse and jump off. The engine and first three cars of the passenger train were knocked off the track and overturned, but the switching engine was not derailed and it immediately ran back to Carnegie, where it was stopped, without damage, by the opening of a switch. Six passengers were killed in the collision and eight passengers and three trainmen were injured, two of the passengers fatally. All of the passengers killed were riding in the second class car.

In the rear collision on the Chicago Great Western at Bethel, Kan., on the 16th, one passenger in the sleeping car of the leading train was killed. Only two other persons were injured, both of these being also on the leading train. This train was No. 22 of the Burlington road, its presence on the Chicago Great Western track being due to a blockade on the Burlington line. The train which ran into it was C. G. W. passenger train No. 4.

The passengers killed in the rear collision on the Chicago & North-Western near Belle Plaine, Iowa, on the 22d, were two drovers, riding in the caboose of a freight train. This train was run into at the rear by an express passenger train which had run past distant and home automatic signals set against it. One drover and the engineman and fireman of the passenger train were injured.

The butting collision just north of Greenville, Pa., on the 23d, was between a northbound special passenger train and a southbound empty engine, both of them running as second sections of regular passenger trains. The empty engine was overturned and its conductor was killed. The empty engine had absolute right of way and a clear block under the telegraph block system, to Greenville. It had just left its train, consisting of seven cars of excursionists, at Osgood, a non-block telegraph station, for delivery to the Lake Shore road. The switch of the siding into which the train was backed is a considerable distance south of the telegraph office. Being delayed in switching the excursion cars, this train was delaying the northbound train and the despatcher attempted to meet the two trains at this place (Osgood), placing the restricting order with the Osgood operator. But without waiting to receive the signatures of the conductor and engineman he completed the order to the inferior northbound train. Momentarily forgetting the importance of treating directly with the conductor and engineman at this non-block station, he accepted the erroneous assurance of the operator that he could hold the train for the delivery of the order. But the southbound engine was within its rights, being in a clear block, and, there being no semaphore facilities at Osgood to govern movements of trains, it got away. When too late, the operator found that the cars had been left at the south end of the siding, and that the engine, instead of coming to the station as is customary, had departed.

The butting collision of passenger trains at Stony Creek, Va., on the 27th, about 9 p.m., was caused by the mistake of the engineman of the southbound train, who mistook a freight, standing on the side track, for the northbound passenger which he was to meet.

The collisions at Campello and Middleboro, Mass., on the 28th and 29th are notable from the fact that in both collisions the foremost train, a freight, was the same. Two different empty trains (passenger crews) ran into it.

In the boiler explosion at Milan, Tenn., on the 30th, the length of the casualty list is explained by the fact that the explosion occurred just as the train—a northbound fast fruit train—was passing another freight train standing on a side track. Two of the killed were trespassers.

[1] Abbreviations used in Accident List:

re . . . Rear collision.
bc. . . Butting collision.
xc. . . Other collisions, as at crossings or in yards. Where only one train is mentioned, it is usually a case of a train running into a standing car or cars, or a collision due to a train breaking in two on a descending grade.
b. . . . Broken.
d. . . . Defective.
dr. . . . Defect of roadway
eq. . . . Defect in car or engine.
n. . . . Negligence.
unf. . . Unforeseen obstruction.
unx . . Unexplained.
derail. . Open derailing switch (negligence of engineman or signalman).
ms. . . . Misplaced switch
acc obst . Accidental obstruction
ma . . . Malicious obstruction of track or misplacement of switch.
boiler . . Explosion of boiler of locomotive on road.
fire. . . . Cars burned while standing
Pass . . Passenger train.
Ft. . . . Freight train (including empty engines, work trains, etc.).
*Wreck wholly or partly destroyed by fire.
†One or more passengers killed.

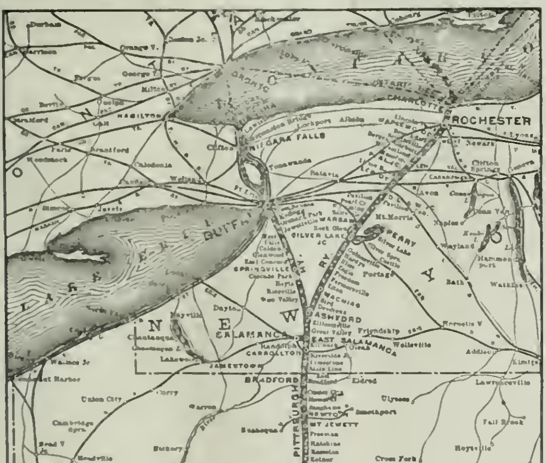
Of the 15 serious electric car accidents reported in the newspapers in July eight resulted in one or more fatalities each. These occurred at Alexandria, Va.; Bellingham, Wash.; East Providence, R. I.; North Tonawanda, N. Y.; Clarksburg, W. Va.; Schenectady, N. Y.;* New York, N. Y. (Third Avenue Elevated line), and Watson, Ind.

Buffalo, Rochester & Pittsburgh.

The Buffalo, Rochester & Pittsburgh is the first of the coal mining railroads to separate itself from its coal properties since the Federal law which requires such segregation by August, 1908, went into effect. Previous to the passage of the law the Baltimore & Ohio had sold control of the Consolidation Coal Company, the most important shipper of bituminous coal on its lines. The Buffalo, Rochester & Pittsburgh controlled the Rochester & Pittsburgh Coal & Iron Company, which has large coal and iron mining interests. Last fall the Mahoning Investment Company was incorporated in the state of Maine, and to it was sold the stock of the Coal & Iron



Buffalo, Rochester & Pittsburgh.

Company owned by the railroad. In return for this giving up of the railroad's investment, the stockholders of the Buffalo, Rochester & Pittsburgh received all but a small fraction of the stock of the Mahoning Investment Company. Meantime the railroad's profit and loss account was debited with a little more than $1,000,000 of extra dividend payments, on this account.

Under this arrangement the railroad's common stockholders receive the same income returns that they formerly did on their holdings, but part on their railroad stock and part on their Mahoning Investment stock. The [illegible] has been [illegible] [illegible] Mahoning Investment Company [illegible] to the B., R. & P. [illegible] Preferred stockholders [illegible] their railroad stock, and in addition [illegible] which [illegible] railroad earnings, from 6 to [illegible] are maintained, while the company [illegible] as the same [illegible] the railroad stock and the [illegible] company's stock [illegible]. Yet there is always the possibility [illegible] of the investment company may pass to different [illegible] those who hold the railroad stock. In the case of [illegible] by the Iselin family, this is not likely to happen, but the possibility is interesting particularly in case a similar arrangement should be adopted by some of the other coal roads. The action of the Buffalo, Rochester & Pittsburgh, however, cannot be taken as a precedent for the anthracite carriers, which are the railroads most vitally affected by this provision of the rate law. The road is organized not under a special charter specifically permitting it to operate coal mines, but under the general railroad law of Pennsylvania. Most of the anthracite roads, on the other hand, have charters antedating the Pennsylvania railroad law empowering them to operate coal mines. At least one of them, the Lackawanna, has announced that its rights to mine coal cannot be impaired by the Interstate Commerce Law, and it is probable that all the other companies which possess charters specifically granting the rights to mine coal will take the same ground.

The financial record of the Buffalo, Rochester & Pittsburgh during the year brings out clearly the present difficulty of securing capital for railroad use. On August 1, 1906, the company issued three-year construction and improvement notes to the amount of $1,500,000, bearing $4\frac{1}{2}$ per cent. interest. Six months later more funds were needed and on March 17, 1907, a new issue of $1,000,000 one-year notes was made; these bore 6 per cent. interest, a rapid jump in interest rate. On May 1 a new consolidated mortgage was created, covering $35,000,000 50-year bonds, of which $3,000,000 are to be turned over to the company for immediate use, $18,145,000 to be retained for retiring underlying obligations and $13,855,000 to be issued after July 1, 1908, at a rate not exceeding $1,500,000 a year, for the future needs of the company. The $3,000,000 immediately available will, no doubt, be sold as soon as they can be at a reasonable price in order to provide funds for the $1,000,000 notes payable next March and the additional $1,500,000 payable in two years. These note issues are carried in the balance sheet as current liabilities. As a result current liabilities stand at $4,603,052, against current assets of $4,573,286, of which only $3,419,513 is cash. The showing therefore is better than it appears, but it is obvious that the road could well have a larger supply of working capital.

In increase in tax payments the company came off worse than did the Lehigh Valley with its tax increase of 25 per cent. The B., R. & P.'s taxes for the year, with no change in the amount of mileage owned and leased, were 35 per cent. larger than in 1906. The increase in the tax burden of the company during recent years may be even better shown by the fact that in the last three years, with an increase of only 43 miles of road owned and leased, a gain of 11 per cent., taxes have increased from $115,200 to $212,858, a rise of 85 per cent.

The road is a small low-grade bituminous coal carrier which brings coal from the Pennsylvania fields east and northeast of Pittsburgh, north to Buffalo and Rochester and by a car-ferry owned jointly with the Grand Trunk, to be opened in October, to Cobourg, Ont. It also competes with the Buffalo & Allegheny Valley division of the Pennsylvania for traffic between Pittsburgh, which the B., R. & P. reaches by trackage over the Baltimore & Ohio, and the two New York State cities. Coal furnishes nearly two-thirds of the tonnage moved, and coal, coke, iron ore and iron over three-quarters. The revenue train load last year was 543 tons and the revenue locomotive load 435 tons. The locomotive department has lately been strengthened by the addition of six decapod engines for pushing service over the maximum northbound gradient. These were described in the *Railroad Gazette* of August 9, 1907.

Gross and net earnings for 1907 both stand at record figures. Gross earnings were $8,666,[illegible] and net earnings $3,524,237, the former an increase of $837,129, and the latter of $253,809, over 1906. There was $103,965 spent on extraordinary expenses and improvements against $92,2[illegible] in the previous year.

The freight tonnage increased 14 per cent. and the freight earnings 10 per cent. The number of passengers carried increased 11 per cent., but owing to a reduction in passenger fares over the whole road on November 1, 1906, to a rate similar to that of the Pennsylvania, earnings from passengers show a small decrease.

No detailed figures under the different groups of operating expenses are given. Maintenance of way works out at $1,7[illegible]5 per mile owned and leased against $1,547 in 1906, figures which are probably much too high as they take no account of the 127 miles of trackage. Without facts as to the arrangements for maintenance

of the lines used under such contracts it is impossible to show the unit maintenance of way expense with any accuracy. The figures given bring out little more than the increased amount spent on this account over the previous year. Operating expenses as a whole increased 12 per cent. over 1906.

The following table summarizes the principal operating results of the last two years:

	1907.	1906.
Mileage owned	442	442
Mileage worked	569	568
Passenger earnings	$1,143,444	$1,154,089
Freight earnings	7,382,345	6,603,112
Gross earnings	8,666,580	7,829,452
Maint. way and structures	775,929	688,158
Maint. of equipment	1,279,986	1,099,368
Conducting transportation	2,882,251	2,606,693
Operating expenses	5,142,343	4,559,113
Net earnings	3,524,238	3,270,339
Net income	1,435,239	1,417,391

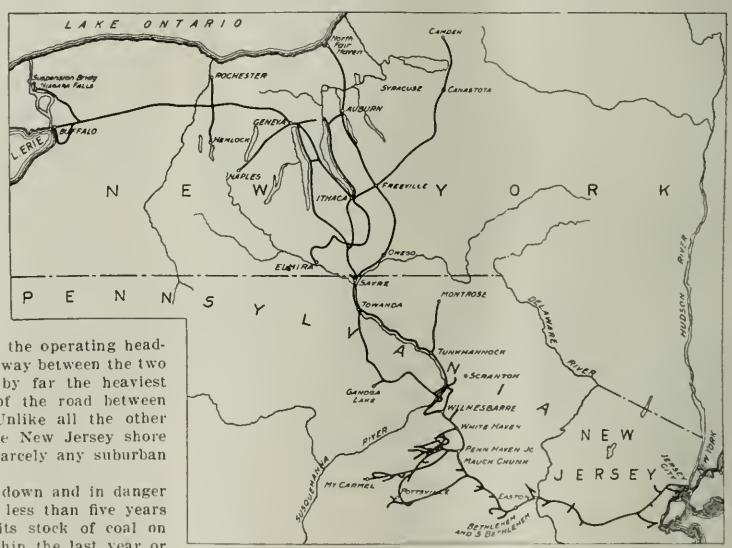
Lehigh Valley.

The annual report of the Lehigh Valley for the year ended June 30, 1907, the first to be received of the large number of railroad reports covering that same period, is likely to be typical of many of the others. It shows the largest gross earnings in the company's history, a large increase in operating expenses, particularly in conducting transportation, and a tremendous increase in tax payments—in other words, more business and smaller profits.

The Lehigh Valley is a combination anthracite coal road and New York-Buffalo trunk line. As shown by the map, it has a large mileage of branches tapping the anthracite coal fields about Pottsville, Shenandoah, Hazleton, Tomhicken and Mauch Chunk, most of which have their principal connection with the main line at Penn Haven Junction. In the region about Cayuga and Seneca lakes and south of them as far as the Pennsylvania state line the road has a number of branch lines serving this farming and manufacturing territory. The through line of the road is double tracked and equipped with automatic block signals all the way between Jersey City and Buffalo. There are over 100 miles of double track besides this. Included in the main line are 56 miles of three tracks and 20 miles of four tracks. Bethlehem and South Bethlehem, Pa., the junction point with the Philadelphia & Reading, which gives the Lehigh Valley a Philadelphia connection, is the operating headquarters rather than some point like Sayre, half way between the two terminals or Jersey City or Buffalo, because by far the heaviest business of the road is on the eastern end of the road between the coal workings and Atlantic tidewater. Unlike all the other trunk lines which have their terminals on the New Jersey shore of the Hudson river, the Lehigh Valley has scarcely any suburban traffic to New York.

Ten years ago the Lehigh Valley was run down and in danger of bankruptcy. As recently as January, 1903, less than five years ago, the company's credit was so poor that its stock of coal on hand was pledged as collateral for loans. Within the last year or two there have been numerous predictions that the Lehigh Valley would shortly come to be a second Lackawanna, paying dividends of 10 to 20 per cent. on its common stock. At the last annual meeting of the road in January, a strong effort was made by a large minority interest to secure larger dividend payments on the common stock. The first dividend on the stock was 1 per cent., paid in 1901. At the beginning of 1905, 4 per cent. was established as the regular rate; it has remained so since that time, but the last two semi-annual dividends have each included an extra 1 per cent., which raises the rate last paid to 6 per cent. The preferred stock amounts to only $106,300 par value. It receives 10 per cent. annually. In 1904, when dividends on this issue were begun, a suit was brought to secure payment of back dividends from 1893 to 1901 inclusive, on the ground that dividends during that period were cumulative. The Supreme Court of Pennsylvania sustained this contention, and back dividends with interest amounting to $10,000 more than the par value of the preferred stock were paid from net income during the last fiscal year. After this unusual deduction, the net income for the year 1907 was 15 per cent. on the common stock, against 15½ per cent. in 1906. In spite of this showing, President Thomas last January, answering the malcontents, referred to the uncertainty as to the future cost of operation, the effect of recent laws and the heavy demands for shorter hours and increased wages as well as the shortage of freight cars, and declared that a conservative policy in dividend payments was to the best interest of the stockholders. He further pointed out that the two branches of the company's business represented respectively by the Lehigh Valley Railroad and the Lehigh Valley Coal Company together had gross earnings of $65,000,000 annually and that for current improvements, whether they were ultimately to be charged to capital account or to income, and for ample working capital, it was imperative to have large cash balances constantly on hand. The attempt to secure a larger dividend was defeated.

The results of the year just passed bear out these contentions. Gross earnings have increased $3,278,575, or 10 per cent., but operating expenses have also increased 10 per cent., or $1,962,042. Among the operating expenses, the non-productive expense of conducting transportation increased $1,208,728, or 11 per cent., "due to an increased volume of traffic, increased rates of wages paid employees and greater cost of all materials and supplies." Taxes increased 25 per cent. over the previous year. At the same time, the item of cash on hand as of June 30 has decreased from $11,676,966 in 1906 to $6,612,849 in 1907. Furthermore, the net results of the coal department were seriously affected by several unfortunate events, such as a cave-in at one of the mines resulting in a gas explosion that set it on fire and made it necessary to flood the whole operation; the destruction of a breaker by tornado; the loss of seven months' time at another breaker due to necessary repairs long postponed during the recent series of prosperous years for the anthracite industry, and the destruction of the coal-handling plant and storage yard at South Chicago with 40,000 tons of coal, by fire. Car shortage also made it necessary to close down collieries at a time when coal could have been sold at the greatest profit. All these facts, added to the present strain and doubtful condition of the money market, commend the stand taken by the directors in paying a smaller dividend than could be justified by the earnings.



Lehigh Valley.

It is by no means to be assumed, however, that the year has been on the whole an unsatisfactory one for the Lehigh Valley. The gross and net earnings were each the largest in the company's history. In spite of the increase in cost of conducting transportation and maintenance expenditures even slightly more liberal than in 1906, the operating ratio shows a slight decrease. It was, of course, natural to expect a gain in coal freight earnings in comparison with a year when anthracite mining was suspended for two months, as in April and May of 1906. Earnings from coal increased $1,862,334, or 14 per cent. The loss that the suspension of mining brought on the railroad may be judged from the fact that in April, 1906, gross earnings decreased 45 per cent., and net earnings 70 per cent., while in April, 1907, gross earnings increased 69 per cent. and net earnings 288 per cent. over the low figures of the same month in the previous year. The decrease in production of anthracite fell more heavily on the Lehigh Valley than on any other of the large railroads. The Lehigh Valley's normal proportion of the anthracite traffic is about 16 per cent.; it suffered 27 per cent. of the loss in anthracite shipments during 1906.

Merchandise freight earnings, which increased 12 per cent. in 1906, gained 8 per cent more last year. Passenger earnings, following an increase of 13 per cent. in 1906, were 10 per cent. larger last year. Maintenance of way cost $2,215 a mile, against $2,207 in 1906. Maintenance of equipment was charged $3,266 per locomotive in 1907, against $3,020 in 1906, $744 per passenger car, against $685 in 1906, and $62 per freight car, against $61 in 1906. This account, as a whole, increased 13 per cent. There were bought from this account 15 new locomotives.

Large quantities of equipment were bought and charged to other accounts. Forty locomotives and 500 steel underframe box cars of 80,000 lbs. capacity were charged to capital account. Five hundred more cars of the same class, 1 dining car and 20 express cars were charged to additions and improvements. Five hundred steel gondola cars of 80,000 lbs. capacity, 102 steel underframe produce cars of 60,000 lbs. capacity, 25 steel underframe automobile cars of 60,000 lbs. capacity, and 10 steel underframe box cars of 80,000 lbs. capacity were charged to expenses and equipment renewal reserve. Two thousand steel underframe box cars of 80,000 lbs. capacity and 2,000 steel coal cars of 100,000 lbs. capacity were bought under a new equipment trust. Included in the company's equipment are many small wooden box and coal cars with capacities of from 20 to 30 tons. While perfectly serviceable for use under ordinary conditions of railroad operation 10 or 15 years ago, they are constantly damaged and frequently cause wrecks when placed between modern heavy steel cars. In order to retire such cars, a special appropriation of $1,250,000 out of the net earnings of the year has been made under which as many cars as this appropriation will provide for are to be condemned. In addition to all the equipment already bought, contracts have been placed for 5,000 modern box and coal cars to be delivered shortly. The tonnage of these new cars will exceed the total tonnage of the equipment to be condemned.

A number of considerable improvements have been made during the year. The Lehigh & Lake Erie Railroad, a new terminal line shown on the map around the city of Buffalo to the south, which was consolidated during the year with the Lehigh Valley Rail Way Company, the company which owns the lines in New York state, has one track laid and will be ready for operation as a double track line by the end of next month. In connection with this new line, $250,000 is to be spent for additional yard and terminal facilities.

A new double track steel girder bridge 1,800 ft. long has been built over the Susquehanna river during the year, a work which included reduction of curves and change of line for 6½ miles. The total cost of this improvement was $810,818. The work was described in the *Railroad Gazette* of February 8, 1907. The third and fourth tracks have been extended for short distances at various points between Mauch Chunk and Easton. As soon as some of this work now under way is finished, the company will have a continuous four-track line for 12.7 miles in the neighborhood of South Bethlehem and Easton. Three new transfer bridges and a freight yard of 1,000 cars capacity are to be built at the Jersey City terminal at a cost of $350,000. Work costing $140,000 is already under way at that point in extension of bridges and tracks.

The Lehigh & Lake Erie Railroad has already been mentioned as a subsidiary company through which the Lehigh Valley is extending its terminal facilities at Buffalo. This subsidiary company originally issued a first mortgage to secure $3,000,000 4 per cent. 50-year bonds. On March 1, 1907, a new mortgage was made, similar to the old one but with the rate of interest 4½ per cent. These first mortgage bonds on a modern terminal railroad, and presumably bearing the guarantee of the Lehigh Valley, appear to have been unsalable at the 4 per cent. rate, an event exceedingly typical of the financial developments of the year.

The following are the principal statistics of operation:

	1907.	1906.
Mileage worked	1,443	1,429
Passenger earnings	$4,363,452	$3,971,392
Coal freight earnings	15,110,899	13,248,565
Misc. freight earnings	14,996,673	13,934,127
Gross earnings	36,068,432	32,789,854
Maint. way and structures	3,196,854	3,153,245
Maint. of equipment	6,186,642	5,485,794
Conducting transportation	12,100,681	10,891,954
Operating expenses	22,114,253	20,152,213
Net earnings	13,954,179	12,637,646
Net income	6,136,204	5,770,073

Why We Have Late Trains.

New York, Aug. 19, 1907

To the Editor of the Railroad Gazette:

I have read with amusement mingled with pity the recent lucubration of Gulf in his Picked Up on the Road about the subject of late trains. To me it seems that Gulf utterly fails to grasp the real sense and humor of the situation. Of course there are a few hard-headed old thinkers like your contributor who want to know what they can do before they do it and never bet except on a "dead sure thing." They have no sporting blood in their veins, and are utterly devoid of that faith that would move mountains or make a tree of a mustard grain. Most people are of a different brand. They take as gospel truth what the time-table says, just as they take what the yellow journals have to say about the motives of railroad managers. They like the sensation of planning a railroad journey and getting there in no time. And the managers count on this faith. Besides, what difference does it make, any way? Trains on our lines always wait for a late connection and a man has no business wanting to make connections so as to travel on any other road. Why, [illegible] year [illegible] good policy to make him miss his foreign connections? It will teach him a wholesome lesson not to wander off on [illegible] gets.

I have heard it suggested that managers do not expect to run on fast schedules. When they are making out the time-table they draw the string up pretty close to the vertical and ask: "Do you think she can make it?" Well, she may if everything goes our way, including the wind. If she can make it once that's enough, and so the string remains on the steep slant.

Here is where Gulf fails to appreciate the humor of the situation. He would know at a glance, if he had the size of the engine, weight of train, number of passengers and tonnage of express and baggage, that that particular schedule is one grand joke and laugh. Instead of that, he, too, accepts the time-table on faith and then gets mad because his faith is misplaced. If he were a philosopher and had any sporting blood he would drop in the smoker and form a little pool on the run, as on a transatlantic liner, and knowing the general probabilities, would guess high, rake in the pool, and be happy. Having done this once or twice, he would stop his howling about late trains and would be writing to you in glorification of the magnificent service he always gets. He simply doesn't know how to take advantage of the situation.

P. D. Q.

The Settlement of Freight Claims

New York, Aug. 20, 1907

To the Editor of the Railroad Gazette:

Your interesting editorial, August 9, on this subject, is deserving of thoughtful consideration by all who are directly interested in the investigation and adjustment of these numerous and often troublesome differences between shippers and carriers. Several features of the article, however, invite comment, and since my recent paper on the subject is referred to, you will perhaps allow me space for a few remarks.

If there are any freight claim agents who would intentionally delay or endeavor to evade the payment of a just claim, be the amount large or small, they are as great an injury to the carrier they serve as is the "surly agent who curtly tells the consignee that the other road is to blame for the delay," for neither practice represents the true policy of the management of the average transportation company. Every act of discourteous or unfair treatment of shippers or consignees by carriers' employees tends to engender resentment against the entire management, as do the injudicious or arbitrary decisions of claim investigators reflect upon the claim agent. In part, Colonel Prout's remarks upon the incivility of certain railroad employees are undoubtedly justifiable, and too much cannot be said on this subject, for in the saying others than railroad employees may profit thereby. Only those who represent corporations employing large forces can fully appreciate the unreasonable and selfish demands made upon them by many who only have regard for their personal interests, and are unwilling to apply the "square deal" principle in their business dealings.

As to Colonel Prout's protest against "being considered a swindler until, at great pains, he proves himself an honest man," there doubtless are many claim offices which are over-zealous for the carriers' interests, in consequence of which unnecessary investigations are pursued and unreasonable demands or inquiries made upon claimants. If all claimants conducted their affairs upon the methods employed by the Colonel's firm, the claim office would perhaps enjoy a better reputation for expeditious settlements instead of being at all times congested with claims possessing every character and condition demanding consideration.

Delays in the settlement of freight claims most frequently occur through efforts to determine their merits, and in ascertaining how and where the irregularity occurred, and since this can only be accomplished through the medium of correspondence with agents located at more or less distant points, under the best of circumstances, much more time must necessarily be consumed than the average claimant, with limited understanding of transportation methods, is willing to accord. Then, too, a large percentage of the freight claims made against carriers are not accompanied by documents or data to enable the claim office to locate the particular shipment in question or verify the account, consequently additional papers or information must be requested. Claimants not infrequently send in their bill without such necessary documents as the bill of lading or freight receipt, and when these are requested they often either object to furnishing them in support of their claim or say they have been returned to shipper or destroyed; in fact, few claims except those made by large concerns are reasonably substantiated when first received. Thus it will be seen that the subject of prompt settlements has another phase which has not been developed in your article or my paper.

In the general criticism of freight claim methods and tardiness in claim settlements, the above conditions, being unknown to the critic, are not usually considered, nor is the fact that the majority of claims are promptly adjusted to the entire satisfaction of claimants. It is the few claims, particularly those on account of interline traffic, which are so often subject to unreasonable delay, and

which create annoyance and criticism on the part of claimants, and to this class of claims it is the duty of every freight claim office to give serious thought, and employ every possible measure to minimize the time necessary for their adjustment.

Referring to the four features of my paper which you classify:

(1) By "thorough system, devoid of circumlocution," is implied the practice of deciding, in the most direct manner possible, the question of liability, and without further considerations effect settlement of the claim, taking up for investigation questions of cause, location of fault and remedies thereafter. It likewise implies the careful examination of all claim papers by investigators; also prompt, intelligent and courteous replies to letters, qualities which can only be secured by constant supervision and insistence upon by those in charge.

(2) Prompt investigations may be conducted by one claim office, but good results therefrom can easily be defeated by dilatory tactics or actual neglect by others, and especially is this fault experienced in connection with the adjustment of claims in which distant roads are involved, the only effective remedy being for the claim representatives of every carrier to give the same consideration and prompt treatment to foreign claims that they apply to those in which they are alone involved.

(3) Claimants have the right to expect from claim offices uniformly business-like communications, although they should perhaps make some allowance for the difference between the dictation of a claim investigator and the composition of officials of the company. However, according to my experience, there never is any excuse for curt, random or evasive letters, and the investigators who appreciate this are the kind always in demand for more responsible positions.

(4) Your comment upon this seems to be based upon the assumption that all small claims are valid, and should be paid without the carrier "standing on its rights," i. e., investigating to determine liability. If this were attempted, even with claims from people of known repute, would there not be great danger of violation of commerce laws, and would not claimants of less repute demand similar treatment of their claims? Even if insurance companies have practiced the payment of certain claims in advance of confirmation, is it a good business principle, or one which can be safely adopted by corporations whose every act is closely scrutinized by the public?

Your suggestion that an experienced claim clerk be located at every large freight station is a most excellent one, and should receive the consideration of all freight claim and other officials, for here is a plan which has had but limited trial, and, if generally adopted, has excellent possibilities in the direction of accurate information and proper papers for the claim office, intelligent explanations to claimants, and all with a promptness that is otherwise difficult to obtain.

Freight claim methods are steadily improving, and with the assistance of our friend the claimant, the claim office may yet be regarded with favor and even with acclaim.

R. L. CALKINS,
Freight Claim Agent, New York Central & Hudson River R. R.

Cross-Rolled Steel Ties.

New York, Aug. 17, 1907.

To the Editor of the Railroad Gazette:

I read with much interest your editorial in your issue of Aug. 9, in which you give a suggestion from the chief engineer of a leading railroad that the 60 per cent. discard of 25 per cent. from top of ingot, in the recently proposed rail specifications, could be profitably utilized by rolling into steel ties and other sections by the York transverse rolling. I endorse what you say in reference to the improvement of the physical qualities by cross rolling, also the possibility of being able to roll any form of steel tie that will meet the necessary requirements in modern railroad practice. I have submitted my steel ties of various designs, with fastenings, to the chief engineers of the leading railroads of the United States and England, and invariably they have said they seemed to cover every requirement. Because they are strong, cheap, elastic and have perfect fastenings, and because the system of rolling permits any modification desired by the railroad engineers to suit any special condition they received their thorough endorsement. The ties presented to the engineers referred to were my designs, rolled from old scrap rails, but I can roll, from new steel, any design desired, either beam or trough sections, with flanges 24 in. wide, if called for.

I respectfully disagree with your statement that no steel tie has been devised that will give the resiliency of a wooden tie. I claim to roll a tie that will give the necessary resiliency, under light or heavy axle loads. I refer you to the editorial in your issue of Nov. 24, 1905. The question of lateral movement in the ballast is entirely overcome, in the opinion of railroad engineers, by my corrugating the lower flange of the tie.

I can best answer the question of ties rusting by quoting from the experience of engineers, who have had the supervision of railroads on which metal ties were used. In your issue of August 30, 1901, under the caption of "Steel Railroad Ties in Europe" by Foster Crowell, C.E., I find the following quotations from the report of Mr. J. W. Post, Chief Engineer of the Netherlands State Railroads, referring to iron ties of beam sections that had been in gravel and sand ballast for 35 years. The original weight of the tie was 125 lbs. They decreased in weight from rust and wear one-quarter of a pound per year, or 8¾ lbs. in 35 years. Mr. H. L. Porter, Chief Engineer of the Bessemer & Erie Railroad, states that the breaking of a steel tie of the trough type after six years service does not indicate that rusting under ordinary conditions should cause any anxiety.

The question of insulation can be successfully met by the adoption of the York steel tie.

JAS. E. YORK,
President York Rolling Process Co.

Curve Mechanics and the Woodlawn Wreck.

London, July 27, 1907.

To the Editor of the Railroad Gazette:

The Woodlawn wreck on the New York Central last February can only be explained as being due to a violation of the fundamental principles of mechanics: (1) in the design of the New York Central electric locomotives and (2) in the application of the brakes when

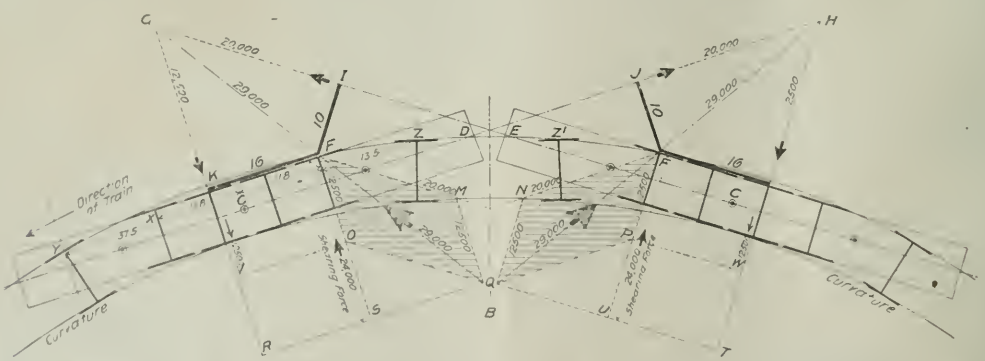

Fig. 1.—Diagram of Forces Acting to Derail Electric Locomotives When Rounding a Curve with Brakes Applied.

rounding a curve. When running around a curve at high speed with brakes applied, large buckling forces are set up throughout the train, acting obliquely to each other at every coupling, but the direct cause of the derailment was the forces set up in the first engine. Centrifugal force played only a small part—so small as almost to be ignored when compared with the powerful leverage exerted by the first engine tending to force the rails apart and to shear the spikes, due to the short, rigid wheelbase and the long, projecting rear and fore parts which were actually made all the more dangerous by the use of spring-centered pony trucks. In rounding the curve these pony trucks are always tending to derail each other and to break the locomotive in two. A similar accident can happen at any time if the same mistake is made on the part of the driver.

Referring to the diagram, Fig. 1 represents an exaggerated curve with two locomotives shown thereon. When rounding the curve the driver applied the brakes on the train, with the result that an enormous buckling force was set up at the coupling between the first and second locomotive acting in the direction I. G. This

oblique force tended to revolve the first locomotive about the center of moments, F. The rigid wheelbase became cramped and binding hard against the inside and outside rails greatly increased the retarding force on the first locomotive and simultaneously increased the effect of the momentum of the following locomotive and cars acting in an oblique line. When this force, I G, became sufficiently great it caused the rear trailing truck of the first locomotive, the second locomotive and the first coach to be derailed to the outside and at the instant of the derailment increased the binding on the rigid wheelbase enormously, due to the velocity with which the rear driving wheel of the first locomotive was thrown against the outer rail. At this instant the spikes holding the rails were sheared by the enormous wedging force exerted on them by the rigid wheelbase. The action of these forces and their result was of course, almost instantaneous, but it seems to be pretty well established that the driver partially released his brakes when he felt the train riding roughly behind him and again applied power. The effect of this was to straighten out the two locomotives and pull the second or derailed one to the inside, leaving its front pony truck on the track. No forces other than these could have produced the effects, which are a matter of record.

The direction of the forces acting are shown on the diagram, the magnitude of the forces being assumed for purposes of demonstration. It is necessary first to determine the mechanical lever I F K constituted by the first engine. This is found by projecting the tangent, C. E., indefinitely and as F (the rear driving wheel of the first locomotive) is being pressed against the outer rail, that point becomes the fulcrum. Therefore, draw F. I. to and at right angles with the projected line, C. E. Then F. I. will represent one arm of the lever. The other arm is determined by drawing F. K. parallel with the tangent, extending it to the second driving axle, the inner wheel of which is bearing hard against the inside rail. The line F. K. represents the second arm. This enables us to resolve the forces exerted outwardly at both the inside and outside rails. Assume that 20,000 lbs. (it may be 60,000 or 100,000 lbs.) is exerted through C. E. at I. The ratio of the two arms, K. F. and F. I. is as 16 10, therefore the inward thrust at the second inside driving wheel, represented by K. V., is 16:10::20,000—12,500 lbs. To find the resultant outward thrust at F., which becomes the center of moments, draw F. O. equal to and parallel with K. V., then draw F. M. parallel with C. E. I., lay off on this line at any convenient scale 20,000 lbs. and complete the parallelogram F. M. Q. O. The diagonal F. Q. (29,000 lbs.) represents the magnitude and direction of the force exerted at F. on the outside rail. To find the square thrust of the rear wheel at F., draw Q. S. parallel with the tangent C. D. Completing the triangle, F. S. (24,000 lbs.) represents the square outward thrust against the rail at F.

To make the explanation still clearer, suppose the rigid wheelbase had been much shorter. The lever arm, F. K., would be shorter and more powerful. If, for example, the wheelbase was only 6 ft., no track construction yet proposed would be strong enough to resist the enormous shearing forces exerted.

The action of the second locomotive under the forces exerted was entirely different from that of the first locomotive. The tendency of the second locomotive was to be forced bodily outward without turning about its center of gravity so long as the retarding force of the first locomotive remained equal to the momentum of the following cars. The destruction of the train would have been even more complete had not the driver acted as he did in applying the power at the moment the train [illegible]. Whether he knew or did not know what the effect of this would be, [illegible].

In the foregoing no consideration was [illegible] to the [illegible] effect of centrifugal force. It [illegible] that if we consider the centrifugal force as acting through the center of gravity the resultant shear on the spikes of the [illegible] rail is much less than the centrifugal force set up by the locomotive, because the resultant of the centrifugal force and the weight of the locomotive even at high speed [illegible] without the angle of repose of the rail on the tie plate. The force exerted by the short wheelbase of the locomotive acting as a [illegible], however, acts as a direct shearing force on the spikes.

The lesson to be derived from the accident is obviously the danger of building a locomotive with a short rigid wheelbase and long overlap from the wheelbase to the couplings. Also the danger of applying the brakes when rounding a curve. The fact that two locomotives were placed at the head of the train was primarily responsible for the derailment because their long overlapping parts gave the buckling forces a much more powerful leverage than would have been the case with a coupling between the locomotive and a passenger car of the ordinary dimensions and construction. In rounding the curve the mechanical levers are constituted in every engine with the greatest effect at that point which becomes the center of moments—on the inside rail when the engine is pulling and the outside rail when the engine is retarding.

Before concluding allow me to correct Mr. G. R. Henderson, who in his article on "Moment of Inertia and Curvature" in your issue of June 7, says, in referring to the effect of a locomotive or car entering the curve: "Our attention was called to this by Mr. T. H. Brigg, but, as far as known, the writer is the first to work out the actual calculation of the amount of this force." It seems scarcely fair that opinions which I submitted to him, more or less in confidence, should have been published without my consent. If I did not present figures in his way I did in my own way, and these figures, together with diagrams illustrating my ideas, were compiled and copyrighted as far back as May. Furthermore, my views are not correctly implied by Mr. Henderson. I disagree with him that the rear driving wheel becomes the center of rotation, and also with his statement that the same forces are exerted in the opposite direction when an engine is leaving the curve and entering a tangent. The locomotive, when running around a curve, tends at all times to leave the curve at the tangent. The instant the curve ceases to affect its diverting force centrifugal force ceases and the locomotive continues on the tangent. If Mr. Henderson means by angular acceleration that the locomotive, once diverted to a curve, will in the slightest degree follow that curve of its own accord, he is mistaken.

T. H. BRIGG, C. E.

Union Pacific Gasolene Motor Cars.

The Union Pacific Railroad is operating at the present time four regular motor car services. A motor service has been in operation between Kearney and Callaway, Neb., a distance of 65 miles, since October, 1905. This car makes a round trip of 130 miles daily except Sunday. On the Leavenworth, Kan., branch a regular motor car service has been maintained since February, 1906. This car hauls a trailer for baggage, mail and express, and makes one round trip daily between Lawrence and Leavenworth, 34 miles. The services on the Beatrice branch, 40 miles, between Beatrice and Lin-

Union Pacific Gasolene Motor Car No. 10 Hauling Ten Empty Freight Cars.

coln, Neb., and on the Loup City branch, 39 miles, between Loup City and St. Paul, Neb., have been in operation since September, 1906.

There have been scarcely any interruptions in the services on these branches; in fact, the motor cars have performed so successfully that the Union Pacific is now arranging to increase considerably the use of these motor cars on branch lines. Twenty-two cars are now being built at the Omaha shops. They are a l-steel cars, of the latest design, having the round windows and side-door entrance, and equipped with the Union Pacific 200-h.p. engine.

Motor car No. 10, the first of this new order, has recently been tested out by Mr. McKeen, Superintendent of Motive Power of the Union Pacific and designer of the cars, who personally supervises their breaking-in as they are turned out of the shop. In one of the photographs this car is shown hauling 10 empty freight cars on a 0.5 per cent. grade, on July 29. The motor car demonstrated its efficiency by switching these cars back and forth. The car is not recommended for this sort of service, but this test showed the ability of the gasolene engine to start heavy loads. The driving wheels of the motor cars slip very readily, and it was only by the constant use of sand that the car with this load could be got in motion. The other photograph shows the car pushing a 40-ton coal car up a coal chute incline of 7.6 per cent.

Motor Car No. 10 Pushing a Loaded 40-Ton Coal Car Up a 7.6 Per Cent. Incline.

Secretary Taft's Columbus Speech.

In opening his own campaign as a presidential candidate at Columbus, Ohio, August 19, Secretary of War William H. Taft reviewed the present situation and spoke with great clearness about some of the new problems involved in corporation regulation. We quote the following paragraphs, believing that they add a much needed tone of conservatism to the discussions which are rife:

The opponents of the measure (the rate law) continue to denounce it, but now, instead of pointing out its disastrous effect, they say it is a failure and that in the year since its passage it has not helped a single shipper. They insist that the only effective and an all-sufficient law to regulate railroads is the Elkins act, passed in 1903, and that this is shown by the fact that all the prosecutions in which convictions have been had against railroad companies and favored shippers in the last two years have been under the Elkins act and not under the rate bill. Let us look into the facts in regard to this allegation. The chief prosecutions which have been instituted have been criminal indictments against the sugar trust and the Standard Oil Company and certain railroads and their agents and officers for taking and giving secret money rebates. They could not have been brought under the rate bill, because the acts prosecuted were committed before the passage of the rate bill.

It is true that these prosecutions were instituted under the Elkins act, but it is also true that had the Elkins bill never been passed the same acts could and doubtless would have been prosecuted as giving and receiving unjust discriminations against the persons committing them under the amendment to the interstate commerce act of 1889, which the Elkins law supplanted. The Elkins law was really an amendment to the interstate commerce act, enlarging and making more effective the procedure for prosecuting violations of the prohibitions of that law and describing them in more comprehensive form. It gave greater latitude in respect of the district where the offence would be prosecuted and it made the company necessarily responsible in a fine for the act of its agents, without other proof of direct complicity than the agency. Under the 1889 amendment, however, the individuals convicted could have been sent to the penitentiary, whereas under the Elkins act the punishment by imprisonment was taken away, while the fine was increased. The chief effect the Elkins law had on these particular prosecutions which have been given so much prominence was to make it easier to convict the corporation and to increase its fine but to save the guilty individual perpetrators from imprisonment.

In the rate bill Congress amended the Elkins bill and restored imprisonment as part of the punishment for secret rebates. Had the rebating and dishonest practices of the railroad companies and the trusts, been as clearly known to Congress and the public, when the Elkins bill was considered as they were when the rate bill was passed the Elkins bill would not have passed so smoothly.

Scope of Elkins Bill as Compared with Rate Bill.

I do not wish to decry the merits of the Elkins bill because, aside from its elimination of imprisonment as punishment, it is a most useful measure, but its scope is so narrow in respect of the regulation of railroads that it cannot be compared in importance of operation and effect to the rate bill. The increase by the rate bill in the powers of the commission in supervision, investigation, rate fixing and effective order making to prevent discrimination is great. Elaborate machinery for making it difficult to violate the law without discovery and for discovering violations when they exist and for affording affirmative and mandatory relief in requiring railroads to furnish equal facilities to all is found in the provisions of the new rate bill. Criminal prosecutions will continue to be under the Elkins law, but as amended by the new rate bill. This is because the Elkins law, as amended, contains the part of the interstate commerce legislation which prescribes the punishment for violations of the law and so, in ordinary practice, comes into operation after the violations have been discovered under the other provisions of the rate bill.

The rate law has not been in operation a year, and the beneficial results from its operations, though clear, are not ready to be presented in statistical array. Moreover, the chief benefit of the act is likely to be its influence in discouraging attempts to renew the old abuses and such benefits do not appear in statistics. The immediate effect of the act has certainly been to compel railroads to regard the commission now as the important tribunal whose views they must follow. They are manifesting every outward disposition strictly to comply with the law and to avoid prosecution or complaint. The time has gone by in which the action of the commission can be ignored or laughed at. The commission itself has taken up its duties with renewed energy, has proceeded, without awaiting the intervention of the railroads or the filing of complaints, to construe the act by administrative rulings in order to assist the railroads in complying with the law. With the large powers for correcting evils which the commission now has we may reasonably expect a marked improvement in the conduct of the railroads of the country.

Court Review.

Mr. Bryan contends that the law was greatly weakened in authorizing, or recognizing, judicial intervention to restrain the orders of the commission. This criticism has not the slightest foundation. There can be no judicial appeal in the nature of a complete review on the merits from the commission to the Supreme Court or to the Circuit Court of the United States, for the commission is not a court of first instance, but only a mere administrative tribunal. The only power a federal court could validly exercise would be to decide first, whether the administrative tribunal had followed correctly the limitations upon its course of action imposed by the act of Congress creating it; and, secondly, whether its order taken as an authorized expression of the legislative power deprived the railroad company of its right, under the Fourteenth Amendment, to derive a fair profit from the use of its property. Whether the federal courts were expressly given this power in the law or not, they would have had it under their general jurisdiction. If their power had not been recognized and a purpose of Congress had been expressed to prevent an appeal to the courts, the law would have been invalid. The extent of the judicial remedy could not be either diminished or enlarged by Congressional action, with due regard to the validity of the act. Congress was wise, therefore, in not attempting to define what the court should or should not do, and in merely recognizing the right of the companies to appeal to

the federal courts to test the validity of the action of the commission. No victory was gained by either the conservative or the radical party in this regard.

AMENDMENTS TO THE RATE BILL NEEDED.

The rate law does not go far enough. The practice under it has already disclosed the necessity for new amendments, and will doubtless suggest more. Such is the true method—the empirical and tentative method—of securing proper remedies for a new evil. The classification of merchandise for transportation is a most important matter in rate fixing; for by a transfer from one class to another the rate is changed and may work injustice. With the power of rate fixing it would seem should go the power in the commission to classify and to prescribe rules for uniform classification by all railroads.

Recent revelations have emphasized the pernicious effect of the so-called over-capitalization of railroads which aids unscrupulous stock manipulators in disposing of railroad securities at unreasonably high prices to innocent buyers. This evil would not of itself justify federal restraint or control, because such stock and bonds are usually issued under state charters. The practice, however, has a tendency to divert the money paid by the public for the stock and bonds which ought to be expended in improving the roadbed, track and equipment of railroads into the pockets of the dishonest manipulators and thus to pile such an unprofitable debt upon a railroad as to make bankruptcy and a receivership probable in the first business stringency. This result in an interstate railroad necessarily interferes with and burdens interstate commerce and justifies the exercise of the regulative power of Congress to stop the practice. A railroad company engaged in interstate commerce should not be permitted, therefore, to issue stock or bonds and put them on sale in the market except after a certificate by the Interstate Commerce Commission that the securities are issued with the approval of the commission for a legitimate railroad purpose. The railroads that are honestly conducted would accept the certificate of the commission as a valuable one in the markets of the world, and only railroad stock manipulators who look to the floating of watered securities as their best source of profit would have reason to complain.

A much used means of eliminating competition among interstate lines serving the same territory is the acquisition by one company of the stock in another and the election of directors to represent that stock. This process is facilitated by the uncontrolled power to issue securities beyond the needs of the company for its legitimate business and would be curbed by the restriction proposed. The evil ought further to be directly restrained by making it unlawful for an interstate railroad to acquire stock in a competing line. This is a simpler remedy of meeting the evil than by recourse to the anti-trust law under the Northern Securities case. In addition to this, competing lines should be prohibited from having common directors or officers.

These suggestions of additional legislation in respect to the supervision and control of interstate railroads have been made by the Interstate Commerce Commission, and I heartily concur in them. They are plainly within the federal jurisdiction under the interstate commerce clause. I do not think that in order to accomplish a good which the federal government with its greater resources and wider geographical reach can bring about more quickly and efficiently the constitutional limits upon federal action should be blurred out or an undoubted federal power should be expanded by doubtful construction into a field which really belongs to the state. But the right of Congress to take any action, not confiscatory, in the most rigid control of interstate commerce cannot be denied.

The measures taken and proposed are radical perhaps, viewed from the standpoint of the *laissez faire* doctrinaire whose ideas have been allowed to prevail in respect of railroad management down to the present; but no one can read the report of the commission on the history of the union of the Southern Pacific and Union Pacific systems with the Illinois Central system without trembling at the enormous power that one man, by the uncontrolled use of the stock and bond issuing power of interstate railroads under state charters, has acquired in respect of a vital power of the country's business and without looking for some means of remedying such a dangerous tendency which, if not stopped, will lead to the absorption of all the railroads of the country into one hand.

RATE BILL NOT SOCIALISTIC.

The contention on behalf of the railroads, already noticed, that such supervision as the rate bill and these suggested amendments afford is socialistic and tends to government ownership is utterly without basis. Efficient regulation is the very antidote and preventive of socialism and government ownership. The railroads until now have been permitted to wield without any real control the enormously important franchise of furnishing transportation to the entire country. They have constructed 230,000 miles of road. In certain respects they have done a marvellous work and have afforded transportation at a cheaper rate per ton, per mile and per passenger than in any country in the world. They have, however, many of them, shamelessly violated the trust obligation they have been under to the public of furnishing equal facilities at the same cost to all shippers. The watering of stock and bonds and the over-capitalization of some of them for the profit of their managers have prevented the needed improvement of their railroads in construction and equipment. The tremendous demand for increased facilities due to the enormous growth of business shows the inadequacy of their equipment and construction. While they might not have been expected to meet in full such an extraordinary demand the obligations some of them have assumed in the form of stocks and bonds leave no doubt that had the money they represented been put into the roads in good faith the shortage of cars and equipment and inadequacy of roadbed and track would not be so great. They discharge a public function. They have been weighed in the balance and found wanting. The remedy for the evils must be radical to be effective. If it is not so then we may certainly expect that the movement toward government ownership will become a formidable one that cannot be stayed.

OPPOSED TO GOVERNMENT OWNERSHIP.

I am opposed to government ownership.

First, because existing government railroads are not managed with either the efficiency or economy of privately managed roads and the rates charged are not as low and therefore not as beneficial to the public.

Second, because it would involve an expenditure of certainly twelve billions of dollars to acquire the interstate railroads and the creation of an enormous national debt.

Third, because it would place in the hands of a reckless executive a power of control over business and politics that the imagination can hardly conceive and would expose our popular institutions to danger.

The supervision proposed need not materially reduce the legitimate operation of individualism in railroad enterprise. It will indeed limit the opportunity to accumulate enormous fortunes through overcapitalization or secret rebates, but the legitimate profit which comes from close attention to operation, to efficiency of service and economy in details and from broad conceptions of new methods of reducing cost without impairing the service will not be disturbed in the slightest. There is no attempt to take away the property of the railroad companies; there is no furnishing of public money to the enterprise and no public officers are required to administer the property. There is no more attempt in this law to make transportation a government business than there is in the national banking act to making banking a government business.

SANCTION OF RATE AGREEMENTS.

The movement of competing railroad companies to consolidate arose originally from fear that the anti-trust act forbade them to make agreements as to uniform tariffs. If they were now permitted to make such agreements subject to the approval of the Interstate Commerce Commission such a tendency would lose much of its force. It is impossible to prevent competing railroads from seeking to make their tariffs uniform in order to prevent an unending and disastrous tariff war, and though such agreements are against the law it is perfectly apparent that tacit arrangements for uniformity exist. These arrangements do not prevent the operation of competition from time to time, as one company finds that it may acquire new business without loss by a reduction of rate and insists on it, but they do prevent a tariff war which helps neither the public nor the railroad by violent fluctuations in rates. As the public now asserts the right to fix maximum rates and thus to eliminate one phase of competition, it is logical to permit an agreement on rates, if approved by the Interstate Commerce Commission, tribunal appointed to fix rates. The President and the commission both recommend a provision permitting such agreements. In this way there would be restored that respect for law which many railroad men in the last decade seem to have lost. Moreover, every company under such a system would be a policeman to see to it that every other company obeyed the agreement and the law and strictest obedience would be secured.

PHYSICAL VALUATION.

Mr. Bryan is most insistent in discussing rate regulation that the present physical value of all roads in the country should be ascertained for the purpose of fixing rates by allowing to the railroad companies only a fair profit on such valuation. Whenever the Interstate Commerce Commission deems it important as an aid in fixing rates to determine what it would cost now to rebuild any railroad it has complete power to do so, but it would doubtless be found in respect to most of them that in spite of overcapitalization and lack of economy in construction, land for terminals and right of way and the cost of construction have increased so enormously that the total of their securities upon which they pay dividends and interest is not much if any in excess of present physical value. More than this, physical valuation, as the President pointed out in his Indianapolis speech, and as the Supreme Court had in effect said before him, is only one of a number of data to be considered in reaching what is a fair profit upon the investment; and in determining a particular rate, the proper relation between that rate and the total net profit of operation is so complicated with an infinite variety of other circumstances that it is most difficult

in rate fixing to use the latter to affect the former. The importance of fixing rates, complained of as too great in and of themselves, is much exaggerated; for the overwhelming evidence is that on the whole, rates in this country, especially as compared with those of all European railroads, many of which are owned and operated by the government, are low. The chief evil consists in unjust discrimination in rates between individuals and localities. I do not object to valuation, if thought relevant to any issue, but I merely deprecate the assumption that it is to be the chief means of a great reform in rates.

SAFETY REGULATIONS.

The frightful loss of life and limb among the railroad employees of this country, reaching more than 4,000 killed and 65,000 injured in one year, has properly attracted the attention of Congress and the legislatures. It makes apparent that service in connection with trains of a railroad is an extra hazardous business and may well call for government supervision and exceptional rules to secure the safety of the passengers and reduce the danger to employees. Congress, years ago, passed stringent laws for the adoption of safety devices to protect both employee and passenger on interstate railroads. With the same purpose it has recently limited the hours of continuous service for which employees on such railroads may be engaged.

Finally, it has regulated the rules for the liability of an interstate railroad company to an employee injured in its service. This is an important measure, for an unfortunate lack of uniformity has existed heretofore in respect to the rules of liability in such cases, dependent on the court in which the case has been tried. The new statute makes everything uniform as to interstate railroads. It has introduced into federal law what is called the comparative negligence theory by which if an employee is injured proof of negligence on his part does not forfeit his claim for damages entirely unless the accident was due solely to his negligence. If there was negligence by the company, the jury is authorized to apportion the negligence and award compensation for the proper part of the damage to the employee, and the question of negligence is always for the jury.

ABOLITION OF FELLOW SERVANT RULE.

The most important provision of this law, however, is that abolishing what is known as the fellow servant rule, by which an employee injured cannot recover from his employer for injury sustained through the negligence of a co-employee. This rule was incorporated into the law by Chief Justice Shaw, of Massachusetts, on the ground of public policy. It was acquiesced in by the courts of England and of this country. Whatever may have been the wisdom of the rule originally, a change of conditions justifies its abrogation. Public policy can be changed by statute, so that this exemption from liability is not secured by the Constitution to the railroad companies. The abolition of the exemption certainly furnishes a strong motive to the railroad companies for the exercise of greater care in the selection, supervision and control of all of their employees, which tends not only to the safety of their employees but also to the safety of their passengers.

With these changes all claim by employees against railroad companies except in a few extreme cases will doubtless be settled by the railroad companies without litigation, just as they now settle without suit substantially all claims for injuries to passengers. The validity of this law is under consideration by the Supreme Court. The only serious doubt in regard to its constitutionality grows out of some carelessness of language in limiting its application to interstate railroads, and therefore even if the present law should fall, there will be no difficulty in re-enacting it in proper form.

South Boston Coaling Station of the New York, New Haven & Hartford.

A construction view and description of the large coaling station being built for the New York, New Haven & Hartford at Northern avenue and B street, South Boston, Mass., was given in our issue of March 15. The station has been finished and a view of it is shown herewith. It is 1,071 ft. long, divided as follows: Main storage pocket, 379 ft.; wharf, 480 ft. long, carrying trestle 20 ft. wide and 30 ft. high containing shipping bins, and between main pocket and wharf a steel bridge of 175 ft. span and 40 ft. of trestle. An endless cable railway extends from end to end of the structure. The two Mead Morrison, Boston type unloading towers, which traverse the entire length of the wharf, are unloading a vessel in the view. They discharge into the cars of the cable railway, and these empty into the shipping bins or carry the coal to the main storage pocket, as desired. The shipping bins occupy 250 ft. of the central part of the trestle and have capacity for 500 tons. They discharge directly into trains of gondola cars. The main storage pocket has capacity for 13,000 tons. The capacity of the unloading towers is 150 tons per hour each, and of the cable railway 300 tons per hour.

There is a power house containing 250 h.p. of boilers, a cable road engine, pump etc., and in the main pocket the necessary power equipment for driving the elevators and conveyors it contains. The plant was designed and built by Roberts & Schaefer Co., Consulting Engineers and Contractors, Chicago.

Panoramic View of South Boston Coaling Station; New York, New Haven & Hartford.

The Tidewater and the Deepwater Railways.

II

VIADUCTS AND BRIDGES

In the first article of this series attention was called to the heavy viaduct work that is required all along the line, especially on the Deepwater section. Viaducts are used, not on account of the large streams that have to be crossed, but because they are cheaper than the excessively high fills that would otherwise have to be built, though the latter are sometimes used, as in the case of the one at Micajah's Gap, illustrated in the first article on page 345 of the *Railroad Gazette* of March 15.

Three-Story Wooden Trestle; Deepwater Railway.

As in the case of the smaller openings of drains and culverts, the general type of the viaduct structure has been standardized so that the work of designing individual pieces has been greatly simplified. Ordinarily the viaduct is formed of 30-ft. towers with 60-ft. spans, with the legs of the former carried on concrete piers. The same care has also been taken in the standardization of the wooden trestles that are used at the northern end of the Deepwater section, and which were put in before it was decided to use steel at all such points. In the review of the line, that has already been published, the places where high trestles are used were mentioned, and two of these on the section of the line already in operation are shown in the accompanying illustrations. Both of these are upon curves, one a three- and the other a five-story structure; the latter was located about $1\frac{1}{4}$ miles north of Harper, and was 112 ft. high, but has recently been filled in.

The standardization of these trestles consists in the establishment of designs for the bracing and the heights of the bents. The standard in itself applies only to bents of 32 ft. or less, and the characteristics are the same for all above 18 ft. in height. One uniform batter of one in five is used for all bents, and, where they are less than 18 ft. in height, single bracing may be used as in the illustration of the 17-ft. bent. Where the height is greater than 18 ft. intermediate horizontal braces are used as shown in the illustration of the 21 ft. bent. The greater heights differ only in the length of the posts and sills, both increasing with the height. Where the bents rest upon a rock foundation they are carried on subsills; in all other places they are supported on piles or piers. The dimensions of posts and sills are 12 in. x 12 in., the bracing is of 3 in. x 10 in., and the caps of 12 in. x 14 in. x 14 ft. long for all bents. The superelevation of the outer rail on all curves up to 2 deg., is taken care of by dapping the ties. Above 2 deg. it is taken care of in the [illegible] and [illegible] [illegible] in the square timber trestles and in the piles in pile trestles. The amount of superelevation is fixed at [illegible] in. per degree of curvature up to 8 deg., beyond which it is constant.

The longitudinal bracing of trestles is cared for by erecting the bents of single-deck trestles in 14-ft. towers measured between centers of posts, with a 14-ft. span between the bents. The towers are braced with diagonal braces only up to a height of 18 ft., beyond which horizontal braces are inserted as shown in the picture. Where more than one deck is used a [illegible] bracing is put in between the towers, as shown in the reproductions of the photographs.

There are no timber trestles south of the first 40 miles at the north end of the Deepwater section. Beyond this steel only is used. The general type of the steel viaducts and bridges has also been reduced to a standard to assist not only in the duplication of parts for different structures, but also for the sake of maintaining uniformity in the work.

The regular system is to erect the bents in towers and connect them by plate girders whose span is twice the width of the towers. Usually the tower width is 30 ft. and the span between 60 ft., though, in some of the larger structures, the dimensions are raised to 40 ft. and 80 ft. respectively.

A typical example of this viaduct construction is given in the details of the one over Black Lick creek at milepost 453. It is formed of two 30-ft. towers at each end, connected by 60-ft. spans, and four 40-ft. center towers with 80-ft. spans, to which must be added two 45-ft. spans carried by a single bent, making a total length of 910 ft. between abutments. The height of the base of the rail is 179.17 ft. This viaduct is on a tangent and grade of 0.4 per cent., and is shown in outline in the engraving. A general outline of the towers is also given in the engraving of the highest one. The posts have a uniform batter of 1 in $5\frac{3}{4}$ regardless of the height. These posts are formed of four 4-in. angles and three plates. For the lower ends of the columns the thickness of the web plate is ⅝ in., while it is but ⅜ in. at the top. In the same manner the thickness of the metal of the angles decreases toward the top, from ⅝ in. to ⅜ in. For the diagonal bracing the same weight of angle is used for each bent, and measures 5 in. x $3\frac{1}{2}$ in. x ⅜ in.

Five-Story Wooden Trestle; Deepwater Railway.

All structures of this class that are erected are proportioned to carry, in addition to the weight of the structure, which is estimated at 450 lbs. per lineal foot of each track, a live load on each track, consisting of two (Cooper Class E 50) engines, coupled and followed by a uniform train load of 5,000 lbs. per lineal foot, as

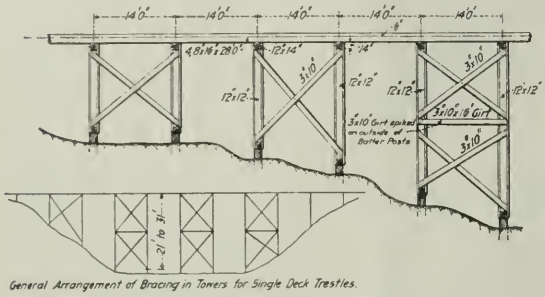
shown on the diagram. Then, in proportioning the members of the structure, the minimum strains from this live load are increased for the effect of impact, vibrations, etc., by the amount given by the formula:

$$I = S\left(\frac{300}{L + 300}\right)$$

in which

I = effect of impact.
S = maximum live load strain.
L = loaded length of single track in feet, producing live load strain.

Liberal allowances are also made for the wind pressures. These are taken at 30 lbs. per sq. ft. on the exposed surface of the entire



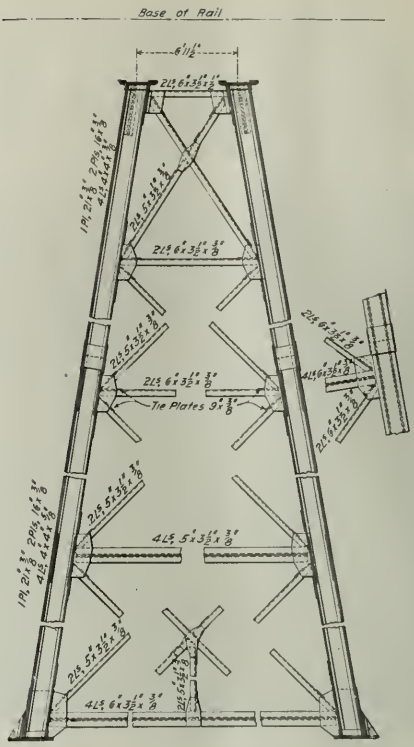
General Arrangement of Bracing in Towers for Single Deck Trestles.

Longitudinal Bracing, Single Track Trestle.

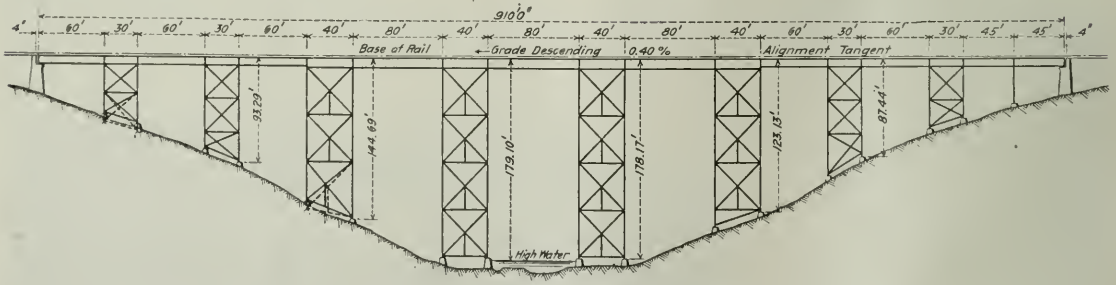
structure, as seen in elevation, in addition to a train of 10 ft. average height, beginning 2 ft. 6 in. above the base of the rail and moving over the bridge; and also at 50 lbs. per sq. ft. on the exposed surface of the entire loaded structure, as seen in elevation.

In the determination of the requisite anchorage for the loaded structure, the trains are assumed to weigh 8,000 lbs. per lineal foot.

As many of the viaducts and bridges along the line are located on curves, provision for the additional effect of centrifugal force was also incorporated in the specifications. This is based on the effect of as many trains as there are tracks, and is calculated by



Details of Black Lick Creek Viaduct.



Viaduct over Black Lick Creek; Deepwater Railway.

a simple formula and added to the live load strains. This formula is:

C = .02 W D for curvature up to 5 degrees,

in which

C = centrifugal force in pounds.
W = weight of train in pounds.
D = degree of curvature.

Where the curvature is sharper than 5 deg., the coefficient .02 is reduced by 0.001 for each degree above five.

Variation in temperature to the extent of 150 deg. Fahrenheit is also provided for.

Finally, all parts of these standard structures have been so proportioned that the sum of the maximum live and dead loads, together with the impact, shall not cause the tensile stress to exceed 17,000 lbs. per sq. in; while, in compression members, the permissible stress of 17,000 lbs. per sq. in. is reduced in proportion to the ratio of the length to the least radius of gyration of the section by the formula:

$$p = \frac{17{,}000}{1 + \frac{l^2}{10{,}000\ r^2}}$$

in which

p = permissible working strain per sq. in. in compression.
l = length of member in inches between centers of connections.
r = least radius of gyration in inches.

To this is added the proviso that no compression member shall have a length exceeding 100 times its least radius of gyration, except lateral struts, which may have a length not exceeding 120 times the least radius of gyration.

The specifications under which the bridges and viaducts are

Standard Diagram of Train Loads; Deepwater and Tidewater Railways.

built also include not only the physical but the chemical properties of the metal to be used. These requirements are as follows:

	Bridge steel.	Rivet steel.
Maximum phos. basic, per cent	0.04	0.04
" phos. acid, per cent.	0.08	0.04
" sulphur, per cent.	0.05	0.04
Desired ultimate strength in lbs., per sq. in.	60,000	50,000
Minimum elongation in 2 in.	22 per cent.	

In this there is no specification as to carbon, that being left to the manufacturer.

These are the main features of the specifications under which the bridge work has been done, and apply to all of the work on the line as well as that of the Black Lick viaduct with which they are especially associated here.

In the plate girders there are two lengths used in the standard structures of 60 ft. and 80 ft. respectively. The 60-ft. girder has a depth of 72½ in. at the ends and is built up with a ⅜ in. web. At the top two extra cover plates are used, 29 ft. and 40 ft. long respectively, and at the bottom in addition to two of [illegible] length, there is one of 48 ft. The 80-ft. girders have a depth of 96½ in., have a ⅜ in. web and cover plates of the same arrangement as the 60-ft. girders, except that they are 36 ft., 52 ft. and 64 ft. long respectively.

Bridge 68; Deepwater Railway.

The piers for the viaduct towers are of a rich concrete (1-3-6) in which the broken stone varies from 1½ in. to 6 in. in diameter. Great care has been exercised in the construction of all of these piers to see to it that the foundation is of a proper character to carry the load, and the specifications for the Portland cement that is used are very rigid.

What has been said of the viaducts applies with equal force to all other bridge construction, and the matter has been taken up in this detail in order to show that the thoroughness that characterized the surveys and other work, as set forth in the first article, has been carried in the details of the execution. This again means the execution of work with the courage of one's convictions, for a great portion of this fine viaduct work is hidden away among the mountains of West Virginia on the Deepwater section of the line. What the character of this country is, is shown in part by the reproductions of the photographs. The concrete work and the construction of the pedestals was done on the steep slopes of the mountain hollows of which those for the bridge at Herndon, known as No. 70, may be taken as typical examples. Naturally, too, in such a rough country, where the grade is so strictly limited, it frequently happens that the viaduct must be on a curve of greater or less radius. This occurs with some frequency north of the passage of Micajah's gap, as shown by the pictures of bridges Nos. 65 and 66. It will be noticed, too, that in all of these heavy viaducts, provision has been made at the tops of the towers for double tracking, though only the single track has yet been laid. This is done in the expectation that as soon as the road is opened, the coal traffic will develop so rapidly that it will only be a matter of a short time before the second track will be required; hence provision has been made, regardless of present cost, to meet that requirement when it comes.

It is needless to show the profile and outline of more than one of these viaducts, as they are all of the same character, differing only according to the profile of the valleys which they cross and in height and number of spans.

The construction is carried on from the north. The road is opened for traffic to Mullens, and beyond this the grading has been completed on to Matoaka, and the viaducts are following rapidly

Pedestals of Bridge 70; Deepwater Railway.

Bridge 65; Deepwater Railway.

As soon as one is erected, the rails are laid on to the next opening and construction begun immediately, sometimes with an interval of not more than from 24 to 48 hours.

After the passage of Clark's gap the road enters a more open country, though this can only be said of it in comparison with that lying to the north, and finally it reaches a branch of the Norfolk & Western north of Matoaka. It follows this road as far as Rock, at which point there is a high viaduct, and in the meantime crosses it. The character of the foundations for the crossings at Widemouth creek and Matoaka are well shown by the engravings.

The same features are characteristic of the bridge as well as the viaduct work. There are some notable examples of bridge work along the line, of which the most remarkable is that of the New river bridge at Glen Alen. Reference has already been made to the spectacular features of the location of this bridge in the previous article, where, abandoning the first location that followed the bend of the East river, crossed the New river at right angles to the flow of that stream, about 45 ft. above the water, it strikes through a bluff on the south shore and runs in an air line diagonally across the river at a height of 122 ft. above the low water line to a bluff on the other side that marks a bend in the stream. The character of this leap is but faintly shown by the photograph of the location in which the camera was located near the site of one abutment, and the location on the opposite shore is marked by the black line which shows the path trodden by the engineers in running through a cornfield and up the slope to the bluff that road is to round and follow.

The outline of the bridge is shown in the engraving, and will there be seen to consist of two approach spans at the east end of 57 ft. 8 in. and 60 ft. respectively, carried by a single bent, followed by eleven 60-ft. tower spans; then five river spans of 136 ft. each, a span of 125 ft over the Norfolk & Western Railway, ending in two spans of 60 ft. and 51 ft. 8 in. respectively. The 60-ft. spans are of the plate girder type and identical with the standard viaduct construction and are carried by 30-ft. towers as already described. The river spans are trussed and designed especially for this work, and are carried on concrete piers. Owing to the diagonal location of the bridge above the stream these piers stand at an angle of 55½ deg. to the center line of the tracks, and No. 1, or that nearest the west bank of the river, is illustrated as typical of the whole. It rises to a height of nearly 62 ft. above the extreme high water, and is carried down to rock beneath the bed. As the total rise of water in the river at this point amounts to 25½ ft., with a very swift current, there must be an ample provision for starkwater protection. From the high-water level to the rock is about 33½ ft., so that the latter is but 8 ft. below extreme low water and 6 ft. below the bed of the stream. The starkwater protection rises 2 ft. above extreme high water and is provided throughout its whole height with a steel fender made of an 8 in. x 8 in. x ¾ in. angle anchored to the concrete by ¾-in. bolts 14 in. long. The whole pier is formed of what is known as the standard class B concrete of the road set in a batter of ¾ to 12 on all sides except on the broad sides of the upper part where it is ½ to 12. This class B concrete is 1-3-6 Portland cement mixture and is used for retaining walls and bench walls of arches, abutments and other similar places. The specifications for this class of concrete also permit the use of irreg-

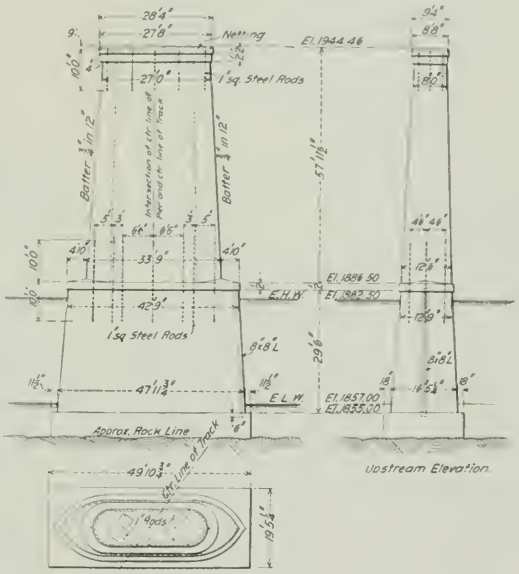
ular shaped rubble stones of sizes not exceeding 1¼ cu. ft. to be laid in each course of concrete, provided they are so arranged that spaces of at least 12 in. are left between adjacent stones, which spaces must be thoroughly filled with concrete. An exception to this is made in the case of concrete that is deposited under water, where the use of rubble stones is not permitted.

While the class B concrete is used for the main body of the

Matoaka, W. Va., Showing N. & W. and Deepwater Railways.

pier, one that is much richer and known as the class C is used for the coping. This is a Portland cement (1-1-2) mixture and is used for copings, pedestals and bridge seats. In laying this the top surface is floated and rubbed smooth and hard and true to grade and line, and is tied together by wire netting. In case it is to be called upon to sustain an extra heavy concentrated load it is reinforced by I beams or rails so embedded as to distribute the stresses. In



Piers of New River Bridge; Tidewater Railway.

Site of Bridge over New River; Tidewater Railway.

This reinforcement consists of 1 in. straight square steel rods 20 ft. long and 20 in number. Reinforcement is also used between the coping and the pier, in addition to the netting used near the top of the coping itself.

The abutment of the bridge, of which the drawings of the one at the west end are reproduced are built of the same materials and in essentially the same manner as the piers. The slope of the natural surface of the rock at these points renders stepping necessary, and this is done in order to secure a horizontal footing for the concrete. The reinforcing is also somewhat different, and it will be seen that the lower courses are anchored to the rock and that each succeeding course is anchored to the one below it. The anchors to the rock are of steel 1 in. square, and extend 18 in. into the same and are leaded and rise 24 in. into the concrete. The horizontal reinforcing is placed in each course up to the highest step in the rock and runs in two directions at right angles to each other the longitudinal rods being placed near the top and bottom of each course on 4-ft. centers with those at right angles to them between with a

vertical distance between the several rows of 12 in. Weep holes are also carried from the back to the front on an incline to provide drainage, as shown.

The roadbed immediately back of the abutment is made 16 ft. wide with a gradual increase to 18 ft.

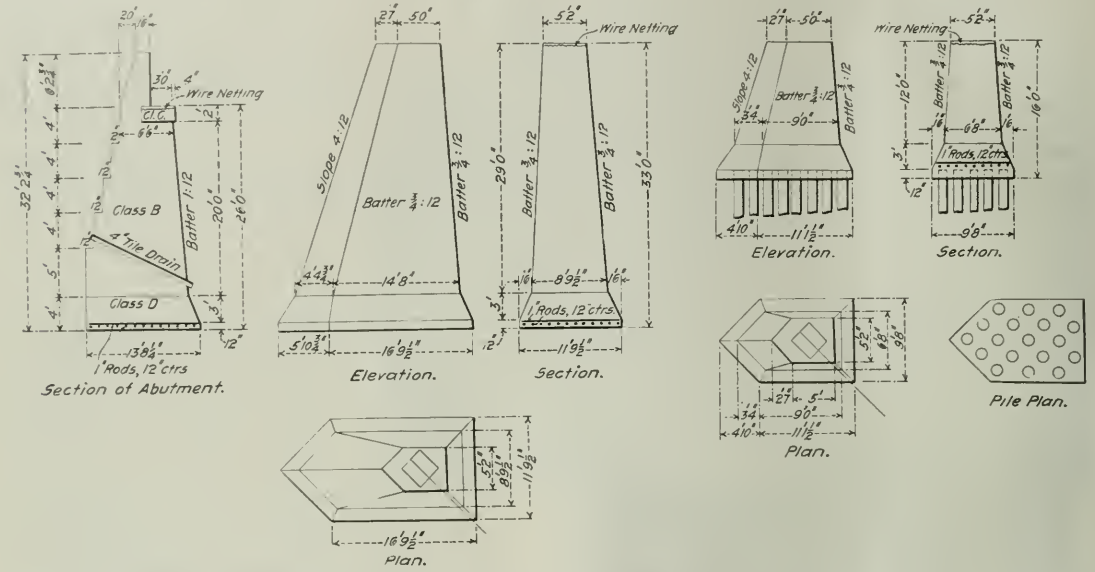
While the New river bridge is, perhaps, the most interesting on the line owing to the boldness of its location, there are a number of others that are possessed of interesting engineering features.

One of these is that over Falling river and the Norfolk & Western Railway at Brookneal, about 174 miles from Sewall's Point. This is a tangent structure with an approach over a 5 deg. curve from the east. It has a total length between back walls of 1,650 ft. 8 in. and consists of two 45-ft. spans at the eastern end followed by fourteen 60-ft. spans, then one of 90 ft.; one of 50 ft. and two of 45 ft., or 20 spans in all. These are supported by the usual 30-ft. towers of the standard type already described, with the exception of the short spans at the ends, where single bents are used. The usual plate girder is used for all spans, and the grade has a rise of 0.16 per cent. from west to east. The structure comes more probably perhaps under the classification of a viaduct in that it crosses, for the greater portion of its length, over the flats at the east of Falling river, though one small stream is crossed. These flats are, however, subject to overflow, so that the pedestals are carried well up above the ground and high water mark. The tops of these pedestals are set about 61 ft. below the base of the rail, and the latter is about 80 ft. above extreme low water in Falling river. Borings were made along the center of the structure, and the rock was found to average from 8 ft. to 13 ft. below the surface, though at the edge of the river borings were run down 21 ft. without finding rock. In places where the depth of the rock was excessive the pedestals were set on piles. Where this was done they were driven in nests of 16 on 2-ft. 6-in. centers, and their tops extended up into the pedestals for 12 in., as shown, and the first layer of reinforcement was 6 in. above that. This rule applies to the ordinary pedestals away from the river, but in the case of the bent at the water's edge, where the pedestals stand at an angle with the center line of the bridge, they are given a starkwater protection and the pile plan is that shown.

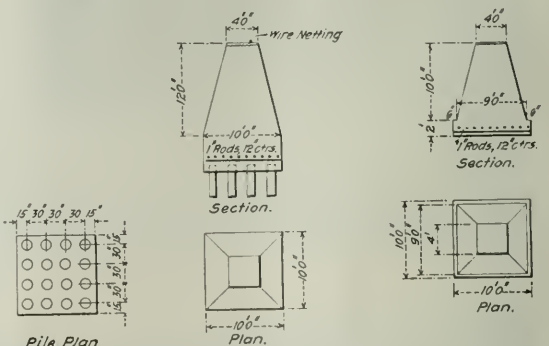
As in the case of the New river bridge piers, the class B (1:3:6) concrete is used for the pedestals, with a wire netting reinforcement near the top and bottom. The batter used is ¼ to 1, and the sizes of the pedestals vary with the height to which they are carried in order to raise the foot of the tower above high water.

The abutments for this bridge may be taken as example of the standard type of this structure used all along the line. In it the class B concrete is used for all of the wall and upper portion, with the exception of the seat, which is class C. It rests on a foundation of a somewhat poorer mixture. This is 1-4-7½ Portland cement concrete and is used for foundations only. As in the case of the class B, the use of rubble stones not more than 1¼ cu. ft. in volume is permitted, provided a spacing of 12 in. well filled with concrete is allowed, and none used in that deposited under water. Such foundations are usually reinforced with 1-in. square steel rods set near the bottom on 12-in. centers.

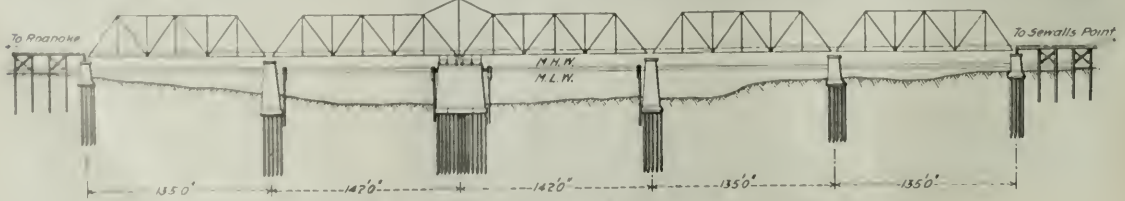
These abutments are provided with drains formed by 4-in. tiles set in the body of the concrete and dropping sharply down from



Masonry Details of Bridge over Falling River and Norfolk & Western; Tidewater Railway.



Masonry Details of Bridge Over Falling River and Norfolk & Western; Tidewater Railway.



Elevation of Drawbridge over South Branch of Elizabeth River; Tidewater Railway.

the back to the front. On the front face there is a batter of 1 in to the foot, and the back of the wall is stepped as shown.

The back filling at all abutments is of cinders or other porous material, and the back face of each wall is waterproofed. This consists of five-ply No. 28 tar roofing felt, mopped together with straight run coal tar pitch.

At the front the slopes are well rip-rapped, and this is also done at any pedestals where it is considered that there is any liability to washing.

Finally, on reaching tidewater, the road crosses two navigable streams as it swings around the outskirts of Norfolk in its approach to Sewall's Point. These are the southern and eastern branches of the Elizabeth river. Here at the edge of the Great Dismal swamp the soil is a soft alluvial deposit where dredging can best be done by pumping, and where the bearing capacity is below that which would be required for carrying the foundations and piers of a heavy railroad bridge. These are, therefore, carried on piles cut off well below the bottom line of the river, and on them a cribwork is built and above it the concrete piers for span and drawbridge supports. They do not differ in the general features of construction from those of the New river bridge already described except in the details of the dimensions.

The superstructure of the bridge over the western branch is shown in outline. It is a double track, through, riveted girder construction, and has the same general appearance as the other work along the line. The skyline of the trusses is straight except for a rise at the center of the draw, represented by the location of the operating cabin. The draw opening is 110 ft. in the clear on each side. The elevation of the rail is but 16½ ft. above mean low water, a condition resulting from the low character of the ground on each side of the river over which the approach is made.

The New Haven-Boston & Maine System.

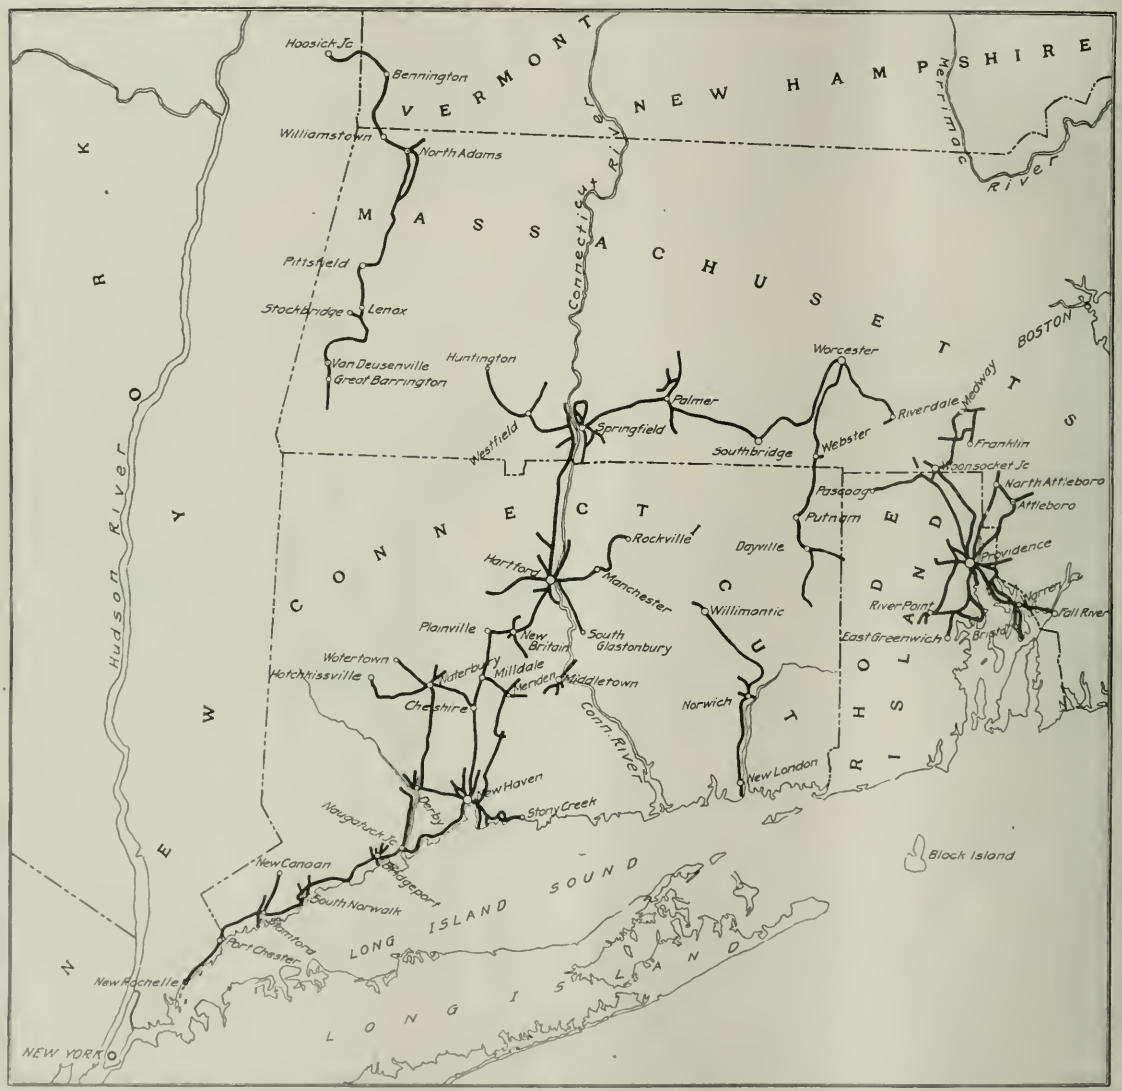
Of the two maps published herewith, the first shows the steam railroad mileage owned by the New York, New Haven & Hartford, not including the New York, Ontario & Western, which it controls but which it is likely sooner or later to relinquish, and the mileage of the Boston & Maine and its controlled roads in Maine, the Maine Central, the Somerset Railway and the Washington County Railway. The electric lines owned by or associated with the New York, New Haven & Hartford are shown on this map by light lines. The trackage rights obtained not long ago by the New Haven over the

The New York, New Haven & Hartford and the Boston & Maine.

Boston & Albany and the northern end of the Harlem division of the New York Central as well as the running rights which the Boston & Maine has long exercised on its Connecticut River Line over two short stretches of the Central Vermont, are also indicated. The steamboat lines of the New England Navigation Company are shown but not the Merchants & Miners lines which the New Haven controls, from Boston, Fall River and Providence to Philadelphia, Baltimore, Norfolk, Newport News and Savannah. In a word, the map represents the New England system of the combined New Haven and Boston & Maine companies and gives an accurate idea of the property involved in the pending consolidation.

The other map, which is official and published for the first time, is a reproduction separately and on a larger scale of the New Haven's electric railways shown on the first map but there obscured at many points by the thickly clustering steam railroad lines. All the electric lines except those in Massachusetts are controlled through the Consolidated Railway Company. The New England Investment & Security Company holds all the Massachusetts lines. It will be noticed that the electrified steam line from New York to Stamford is not included among the electric lines; on the other hand, the Stamford-New Canaan line and the road from Providence to Warren and Bristol, both usually shown on maps of the steam lines of the road, are included. The extent of the New Haven's electric railway interests may be judged from the fact that with one or two unimportant exceptions the electric system represents all of the street railways in the cities of Providence, Worcester, Springfield, Hartford, Waterbury, Bridgeport and New Haven, as well as numbers of smaller cities, besides all of the interurban mileage shown. The total mileage represented is about 1,300 miles.

Further comment on the consolidated New Haven-Boston & Maine system will be found in the editorial columns.



The Electric Railway Interests of the New York, New Haven & Hartford.

Foreign Railroad Notes.

In Barcelona and in northwest Spain, the chief industrial regions of the country, a movement has begun in favor of reducing the Spanish broad gage to the standard. This would have been done long ago, doubtless, but that the interchange of freight between Spain and the rest of Europe is effected mostly by sea, near which are all the productive parts of Spain.

The Wurtemberg State Railroads are about to reconstruct the Stuttgart terminal, with a great deal of heavy earthwork, masonry, etc. When the matter came up in the Parliament, a socialist member moved that the contractors be required to employ only citizens of the German Empire. The Minister of Railroads and the General Manager both declared this to be not only inadvisable but impossible, if the work is to be completed within a reasonable time. The latter said "You all know that great earthworks can't be made without Italians. For tunnel work there are no more skillful workmen."

GENERAL NEWS SECTION

NOTES.

The Seaboard Air Line has decided to comply with the Virginia law reducing passenger fares to two cents a mile

The Railroad Commission of Nebraska has ordered reductions in freight rates on corn and wheat, but will, in September, hear railroad companies which have objections to offer.

At Montgomery, Ala., August 14, the Federal Court, acting on the application of the Louisville & Nashville, enjoined all state officers from enforcing the 2½ cent passenger-fare law against the L. & N.

The Chicago, Burlington & Quincy has been found guilty, at Chillicothe, Mo., of violating the eight-hour law as applied to telegraphers, and fined $200. An appeal was taken. This is the first conviction under the law passed at the last Missouri legislature.

Local newspapers report that block signal operators on the New York Central, in central New York, now receiving from $52 to $65 a month, have received notice of a reduction of wages on October 1, when, under the new state law, their working time will be reduced to eight hours a day.

The Pittsburg & Lake Erie, according to a local paper, has placed its telegraph operators on an eight-hour basis. While the company is not required by the Federal law to make this change until March 4 next, the officers thought it best to provide the road with a full force of competent telegraphers.

In the month of July the Bessemer & Lake Erie carried 781,000 tons of ore, or 74,000 tons more than in any one previous month. During the season, to the first of this month, the total weight of ore carried by the road was 2,978,780 tons, which is 16.5 per cent. more than the total for the same period last year.

The New York State Public Service Commission, Second district, has called upon all railroads and street railroads to send in by September a statement showing all mileage books or mileage tickets of any description on sale, with prices, and all rules or regulations governing the sale, use and redemption of such tickets.

In a fire at Kingston, N. Y., on Sunday evening last, the freight house of the New York Central, 800 ft. long, together with 40 freight cars, both house and cars being filled with merchandise, was completely destroyed. Some of the cars contained black powder and others many barrels of oil, so that the fire was uncontrollable almost from the start. Loss about $300,000.

Complaint is being made in Wisconsin that since the two cent fare law went into effect the railroads have abolished certain low commutation rates from cities to manufacturing establishments a few miles out of the city; an advance in rates which imposes a hardship on workmen engaged in these factories and living in the city. The low commutation rates were originally established to encourage the building of the factories.

The Railroad Commission of Wisconsin on an application of the Rib River Land Company, holds that the road of the Wisconsin Central from Goodrich to Athens, formerly a logging road, must be put in first class shape and opened to the public for the transportation of freight. The Wisconsin Central claimed that the line in question was only a logging road and that the company, therefore, was not bound to operate it as a common carrier.

The State Railroad Commission of Oregon has issued an order requiring the maintenance of bulletins at all passenger stations showing the probable arrival of trains, including, apparently, those on time as well as trains which are delayed; another requiring applications for cars to be recorded at each station, in a book open to shippers, with a view to enforcing impartiality. A third order requires clean and otherwise satisfactory waiting rooms at all stations. This last order is the result of a formal finding that on all of the principal roads of the state the service in this respect is unsatisfactory.

The Novelty Souvenir Company, of Marinette, asked the Wisconsin State Railroad Commission to order the American Express Company to accept packages addressed to the American District Telegraph Company at its different offices. The packages contain a number of different parcels to be delivered by the messenger boys of the telegraph company. The express company answered that it was engaged in local delivery as well as train delivery business, and that it could not be compelled to carry the packages on its train routes and turn them over to a rival delivery company at the terminal. The Commission dismissed the petition, holding that it is entirely within the province of a common carrier to require that all goods shipped in a single package shall be for a single consignee.

The New York State Public Service Commission, First district, has issued rules to prevent overcapitalization of corporations and designed to prevent not only stock watering transactions but merging of railroad companies except where such amalgamations would be in the public interest. Another rule adopted relates to the procedure companies must follow in seeking to increase their capital. Three applications have already been made to this commission for permission to increase bonded indebtedness. The Brooklyn Union Railroad Company wants to borrow $20,000,000, the Nassau Electric Railroad $5,000,000 and the Queens Electric Light & Power Company $1,000,000.

The Public Service Commission of the Second district of the state of New York has issued a circular of questions concerning demurrage on freight cars, and all roads are required to send answers by September 9. The Commission will go very thoroughly into the whole matter. For example:

"Give names and titles of all officers or agents who are authorized to control and direct the distribution of cars. Are consignees permitted to select and load cars for shipment, from those delivered to them with freight, irrespective of strict application of rules for car distribution? State the practice in the past.

"Submit a statement showing the aggregates for each operating division, separately, of the following items of demurrage account during the year ending June 30, 1907: Number of stations reporting; number of cars reported; average detention; percentage released in limit; earnings; collections; total uncollected; agents' relief; refunds; . . ."

Trade Catalogues Wanted.

The Technology Department of the Carnegie Library of Pittsburg announces that it is endeavoring to make an extensive collection of trade catalogues and will be glad to receive catalogues from any of the advertisers in the *Railroad Gazette*. These catalogues will be given a prominent place on the shelves, carefully catalogued under both firm name and subject, and made accessible to the public. They should be addressed care of H. W. Craver, Technology Department, Carnegie Library of Pittsburg.

United States Express Company Statement.

The minority stockholders of the United States Express Company have been trying to have the dividend rate made larger than the 4 per cent. now paid on the $10,000,000 capital stock. The income account for the six months ended June 30, 1907, which has just been sent to the stockholders, shows, however, that the company is earning less than the present dividend rate. The company has not been issuing regular reports. Gross earnings increased 7 per cent. over the corresponding period of 1906, but net decreased 63 per cent.; the net income was $137,097, or 1⅜ per cent. on the capital stock, an annual rate of only 2¾ per cent., while during the same period last year the net income was at the rate of 7½ per cent. yearly on the capital stock. The balance sheet as of July 1, 1907, shows total assets of $13,700,000, over half of which consist of investments in other companies. Current liabilities were $569,000 larger than current assets. The profit and loss surplus was $639,000.

The South and the Railroads.

It might be well enough for Alabama to drive the Southern Railway out of the transportation business within the limits of that state, so that the people may realize what a grand and glorious thing it is to have no railroads to grind them to the earth. It seems to be the determination of Alabama to test the thing and make a serpentless Eden by turning the state into a railroadless Alabama. The law of Alabama requires a foreign corporation to abdicate its rights under the constitution before it can be licensed to operate a railroad in that state.

If the railroad mileage of Alabama were double what it is, the transportation facilities of that state would not be equal to those enjoyed by the people of Indiana. No state is more abundantly endowed by nature than Alabama. Soil and climate are all that could be desired. Her mountains and hills are full of iron, coal and stone. Birmingham is one of the marvels of American energy and the product of railroads. The northern part of the state should abound in manufacturing cities, aggregating millions of inhabitants, busy in the hives of industry. All that is lacking is for the corporations and the people to practice justice in their mutual intercourse and be friends.

And friends they would be if it were as odious for politicians to practice demagogy in Alabama as it now is for corporations to operate railroads in that state. No other section is so sorely in need

of more and better roads as the South. It is a blind, fatuous folly for the South to discourage the railroad business, but that is what the South is doing, and at a time when that region was never so prosperous and its destiny never so promising.—*The Washington Post.*

Rogers Journal Box with Wick Oiling Device.

The Rogers journal box with wick oiling device is shown in the accompanying illustrations. The construction is best shown by the longitudinal section, Fig. 1. The lower part of the box is in two parts, the forward one of which is the oil tray of Fig. 2. Within the latter is a wick holder, which fits over four pins in the tray and contains a central longitudinal opening in which the wicking is placed and held by six transverse pins in the holes shown. The

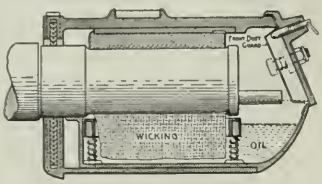


Fig. 1—Rogers Journal Box; Lateral Section.

oil springs over the oil-tray pins keep the wicking pressed against the journal. The oil tray, or cellar, with the contained wick holder and wicking may be removed readily for examination and necessary attention. The wicking is the ordinary cotton variety, such as used in lamps, woven in widths to suit, several layers being used for a box.

The journal box has front and rear dust guards. The front guard is made of sheet metal and formed to fit into the lid opening. It is secured to the lid. This guard is not only for the exclusion of dust and other foreign matter, but to prevent oil being thrown out around the lid by the rotating journal. The rear guard is made in two sections, which slip into openings cast in the sides of the box. The inner edges are rabbeted to overlap each other, and on the outer edge of each is a flat spring which presses against the vertical strip inserted in suitable slots to close the opening and retain the guard.

The claims made for the device are, a substantial saving in oil, elimination of the use of waste, prevention of hot boxes and reduced wear on journals and brasses. It has been tested in service for some time on equipment of different kinds, including freight cars

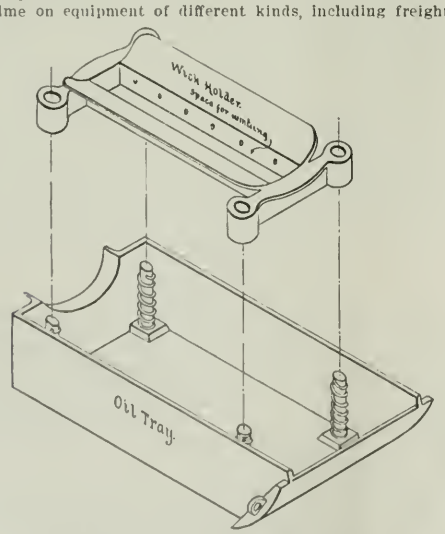

Fig. 2—Oil Cellar and Wickholder.

on the Stock Island, suburban passenger cars on the Illinois Central and switching engines of the St. Louis National Stock Yards, with good results, the superintendent of terminals of the last-named company stating, for example, that on two switch engines on which the boxes have been in service for over a year, there were no hot journals, no perceptible wear on brasses, no driving-box cellars to pack, and no trouble of any kind. Two more engines are being equipped. The Kansas City Railway Foundry Co., Kansas City, Mo., is the maker, and Hotchkiss, Blue & Co., Chicago, are sole agents.

Lines in Italy to be Electrified.

The following is a list of the various electrification projects for which the Italian government has obtained sanction:

		Length, miles.
1.	Pontedecimo to Busalla	6
2.	Savona to San Giuseppe	13
3.	Bardonecchia to Modane	4
4.	Milan to Monza and Lecco	31
5.	Usmate to Bergamo	16
6.	Caloizlo to Ponte San Pietro	11
7.	Gallarate to Arona	31
8.	Gallarate to Laveno	20
9.	Domodossola to Iselle	11
10.	Pistoia to Porretta	25
11.	Naples to Torre Annunziata and Salerno	33
12.	Torre Annunziata to Castellammare	4
	Total	205

Of these, the Italian Westinghouse Company is equipping No. 1 with three-phase current, while Nos. 4, 5, 6 and 9 will probably be direct-current. The first project, which is to give additional facilities to Genoa, is intended to take full advantage of the regenerative possibilities of the three-phase system. There are to be three short up-trains at intervals of 10 minutes, for each one coming down at intervals of 30 minutes, the latter weighing five times that of the former. Two engines, one pushing and the other pulling, will be used on the up grade. A power station of 7,500-k.w. capacity, generating current at 13,000 volts and a frequency of 15 cycles, is being erected at Genoa. Current will be transformed in static sub-stations to the line pressure of 3,000 volts.

TRADE CATALOGUES.

Boiler Compound.—The H. W. Johns-Manville Co., New York, distributors of the "Magic" boiler compound made by John Callahan & Co., Chicago, are sending out a small folder with the title "How to Clean a Boiler," in which are set forth the things which the "Magic" compound will do and will not do in a boiler. The compound is put in the boiler with the feed water and it is claimed that it will remove scale and prevent its formation without causing foaming or attacking the boiler plates or steam packing.

Road Treatment.—The Barrett Manufacturing Co., New York, describes in a handsomely illustrated pamphlet a system of macadam road treatment with a coal tar compound for the prevention of dust. The compound is known as "tarvia," and it is poured and swept over the surface of the road while hot. It forms an efficient binder for the stones and preserves the surface, making it smooth and dustless. One treatment is said to last for at least a year.

Structural Steel.—The Bethlehem Steel Co., South Bethlehem, Pa., has had prepared for the use of architects, structural engineers and others a small handbook of tables of properties of the special structural shapes which will be rolled in the new universal mill at South Bethlehem. These shapes include wide flange I-beams, special girder beams and H-columns.

Belt Conveyors.—A 4-page pamphlet, issued by the Robins Conveying Belt Co., New York, illustrates and describes a package conveyor system in a new large department store. The installation includes three 30-in. conveyors varying in length from 71 to 190 ft., and one 36-in. belt 75 ft. long. They are driven by electric motors.

Drills.—A 20-page booklet, issued by the Ingersoll-Rand Co., New York, describes the Temple-Ingersoll electric-air rock drill. The air compressor is portable, being mounted on a small steel truck and geared to a direct or alternating current electric motor. Armored cables connect the motor to the feed wires.

Roofing Slates.—A pamphlet entitled "The True Cost of Things," issued by the Genuine Bangor Slate Co., Easton, Pa., argues in favor of the company's product on the grounds of its durability, looks, fire protection and other features, as compared with metal, wooden and other roofings.

Variable Speed Motors.—A pamphlet issued by the Electro Dynamic Co., Bayonne, N. J., consists of half-tone illustrations of inter-coil variable speed motors as applied to different machine tools. These motors are made in sizes from ½ h.p. to 150 h.p.

Coal Handling and Storage Machinery.—Catalogue No. 70 of the Dodge Coal Storage Co., Philadelphia, Pa., describes more than 100 different types of coal handling and storage machinery which have been built by this company.

Pneumatic Tools.—Catalogue No. 8, of the Independent Pneumatic Tool Co., which supersedes all former issues, illustrates and describes all types and sizes of Thor pneumatic tools, including

hammers, drills, boring and grinding machines, hose couplings, rivet forges, flue rollers and other tools. Numerous illustrations reproduced from photographs show the various kinds of work to which these tools are adapted.

Asbestos Roofing.—A folder distributed by the H. W. Johns-Manville Co., New York, describes some of its asbestos products, including "J-M" asbestos roofing, "Asbestoside" for wall siding and Keystone hair insulator.

MANUFACTURING AND BUSINESS.

C. M. Mileham has been appointed Master Car Builder of the Doud Stock Car Company, Chicago.

The Stone & Webster Engineering Corporation, Constructing Engineers, Boston, Mass., now occupies its own building at 147 Milk street, Boston.

Carl R. Green, Consulting Mechanical Engineer, Dayton, Ohio, has designed a line of pneumatic hammers for the Columbus Pneumatic Tool Co., Columbus, Ohio. These hammers have been on the market for several months.

The Electric Storage Battery Co., Philadelphia, Pa., has removed its San Francisco sales offices from the temporary location, at 11 Hawthorne street, to the Crocker building, where they will be permanently located.

The Power Specialty Co., 111 Broadway, New York, has secured the exclusive selling rights of Duval metallic packing in this country, Canada and Mexico. It will carry a complete stock of this packing in standard sizes.

The Dayton Pneumatic Tool Co., Dayton, Ohio, has established an agency with Root, Neal & Company, 178-180 Main street, Buffalo, N. Y., who will carry in stock a complete line of "Dayton" and "Green" pneumatic hammers, repair parts and accessories.

John Reid, who for several years has been connected with the Consolidated Railway Electric Lighting & Equipment Co., New York, has resigned to become Assistant to the Vice-President in charge of sales of the Bliss Electric Car Lighting Co., Milwaukee, Wis., with office at New York.

The Wallace-Coates Engineering Co., Chicago and Portland, Ore., has been retained by the Portland & Seattle to design and supervise the construction of two large reinforced concrete structures to be built on the line of that road. One is a long viaduct in Vancouver, B. C., and the other is a 160-ft. arch over the Klickitat river. This will be the longest concrete bridge in the far west.

The Central Inspection Bureau, New York, recently inspected a large number of flat cars for the Parral & Durango Railway, at the Middletown Car Works; also a number of box, flat and stock cars at the Terre Haute plant of the American Car & Foundry Co.; a large number of interurban cars for the American Railways Company at the Jewett Car Works, and a number of interurban cars for the Eastern Pennsylvania Railway at the works of the Cincinnati Car Co.

Hiram J. Slifer has opened an office as Consulting Civil Engineer at 49 Exchange place, New York City. Mr. Slifer will specialize in steam railroad work and is prepared to make physical appraisements, examinations, surveys, analyses of transportation costs and maintenance of way economics and supervise construction. His long and varied experience makes him well qualified for this work. He is a graduate of the Polytechnic College of Pennsylvania, and for 20 years was engaged in location, construction and maintenance with the Mexican National Construction Co., the Pennsylvania and the Chicago & North-Western. From 1898 to 1905 he was Superintendent and General Superintendent on the Chicago & North-Western and the Chicago, Rock Island & Pacific. Since 1905 he has been construction manager on steam railroad properties for J. G. White & Co., New York. He is a member of the American Society of Civil Engineers, the American Railway Engineering and Maintenance of Way Association and the Western Society of Engineers.

Iron and Steel.

The New York, New Haven & Hartford is asking bids for about 200 tons of bridge steel.

The Panama Railroad, it is said, is in the market for 3,000 tons of Bessemer rails for immediate delivery.

The Erie has bids in for bridge material to be used on the structure over the Hackensack river and approaches.

The sale of 1,000 tons of rails is reported for a plantation line in Cuba and the same quantity for a line in Newfoundland.

ELECTIONS AND APPOINTMENTS.

Executive, Financial and Legal Officers.

Toledo, Angola & Western.—J. M. Kutner has been appointed Auditor and Traffic Manager, with office at Toledo, Ohio.

Operating Officers.

Baltimore & Ohio.—A. W. Thompson, Superintendent of the Wheeling division, has been appointed Chief Engineer of Maintenance of Way, with office at Baltimore, Md., succeeding J. B. Dickson, resigned to become Assistant to the General Manager of the Erie. O. Rickert, Division Engineer of the Monongah division, succeeds Mr. Thompson, with office at Wheeling, W. Va. W. C. Barrett, Division Engineer of the Wheeling division, succeeds Mr. Rickert, with office at Grafton, W. Va. F. J. Bachelder, Division Engineer of the Shenandoah division, succeeds Mr. Barrett, with office at Wheeling. J. B. Myers, Assistant Engineer of the Cumberland division, succeeds Mr. Bachelder. Mr. Thompson was born at Erie, Pa., in 1875. He was educated at Allegheny College, Meadville, Pa., and began railroad work in 1898 as a rodman on the Pittsburg & Lake Erie. From August, 1899, to September, 1900, he was a transitman on the Pittsburg division of the Baltimore & Ohio, he was then made Assistant Engineer. He was appointed Division Engineer of the Cumberland division in the fall of 1901, and in November, 1902, was promoted to be Division Engineer of the Pittsburg division in charge of maintenance and construction. The next month he was made Superintendent of the Cumberland division, and in February, 1904, was transferred to the Wheeling division, where he remained until his present promotion.

Thomas Jamison, yardmaster at Connellsville, Pa., has been appointed to the new office of Trainmaster of the Somerset & Cambria branch of the Connellsville division.

Buffalo & Susquehanna.—F. W. Allen has been appointed Superintendent at Galeton, Pa., succeeding S. P. Henderson, resigned.

Chicago, Rock Island & Pacific.—The authority of H. E. Allen, Assistant Superintendent of the Oklahoma division, has been extended over the Fort Worth division.

Erie.—J. B. Dickson, Chief Engineer of Maintenance of Way of the Baltimore & Ohio, has been appointed Assistant to the General Manager of the Erie.

New York Central & Hudson River.—M. E. Welch has been appointed Trainmaster at Batavia, N. Y.

Pacific & Idaho Northern.—W. M. Hauser, chief clerk to the Vice-President and General Manager of the Wheeling & Lake Erie, has been appointed Assistant General Manager of the Pacific & Idaho Northern, with office at Weiser, Idaho.

Southern Pacific.—T. R. Jones, Superintendent at Sacramento, Cal., has resigned. D. Burkhalter, Superintendent at Bakersfield, Cal., is Acting Superintendent, succeeding to the duties of Mr. Jones.

Traffic Officers.

Chicago & North-Western.—Samuel F. Miller, Assistant General Freight and Passenger Agent, has been appointed General Freight and Passenger Agent of the Nebraska and Wyoming divisions, with office at Omaha, Neb.

Intercolonial.—J. J. Wallace, General Freight Agent of this road and of the Prince Edward Island Railway, has retired.

Prince Edward Island.—See Intercolonial.

Trinity & Brazos Valley.—Harry Bronson, chief clerk to the General Passenger Agent of the Chicago, Rock Island & Pacific, has been appointed General Passenger Agent of the Trinity & Brazos Valley, effective September 1.

Engineering and Rolling Stock Officers.

Baltimore & Ohio.—See this company under Operating Officers.

Chicago, Burlington & Quincy.—J. Dietrich, Assistant Superintendent of Motive Power of the Lines West of the Missouri river, has been appointed Master Mechanic of the Lincoln division of the Lines West, with office at Lincoln, Neb., succeeding J. J. Buttery, assigned to other duties.

Chicago, Milwaukee & St. Paul.—M. J. La Court, foreman of the car department at La Crosse, Wis., has been appointed General Traveling Inspector of Cars.

Nashville Terminal Company.—E. G. Holladay, Engineer, has resigned to go into other business. H. R. Manby, Assistant Engineer, succeeds Mr. Holladay.

Seaboard Air Line.—R. P. C. Sanderson, Superintendent of Motive Power, has resigned. See Virginian Railway.

Virginian Railway.—R. P. C. Sanderson, Superintendent of Motive Power of the Seaboard Air Line, has been appointed Superintendent of Motive Power of the Virginian Railway, with office at Norfolk, Va.

LOCOMOTIVE BUILDING.

The Augusta Southern has been figuring on buying two locomotives.

The Mobile, Jackson & Kansas City is said to be in the market for 20 locomotives.

The Guantanamo Plantation, Cuba, has ordered one mogul locomotive from the American Locomotive Company.

The Tonopah & Goldfield, it is said, has ordered eight freight locomotives from the Baldwin Locomotive Works.

The Newburgh & South Shore has ordered two six-wheel switching locomotives from the Baldwin Locomotive Works.

The Hokkaido Railroad, Japan, has ordered 26 consolidation locomotives from the American Locomotive Company.

The Sabina Coal Company, Mexico, has ordered one four-wheel tank locomotive from the American Locomotive Company.

The Isthmian Canal Commission is receiving bids until August 30 on 12 four-wheel saddle tank 3-ft. gage switching locomotives.

The Hang Yang Iron & Steel Works has ordered one additional four-wheel tank locomotive from the American Locomotive Company.

The Illinois, Iowa & Minnesota has ordered two consolidation locomotives and one switching locomotive from the Baldwin Locomotive Works.

The Belgian Government is in the market for 300 locomotives and 200 tenders. Address Minister of Railways, Posts and Telegraphs, Brussels.

The Atchison, Topeka & Santa Fe has ordered 25 six-wheel switching locomotives and 10 additional simple consolidation locomotives from the Baldwin Locomotive Works.

The Russian Government has appropriated $47,000,000 to be spent for cars and locomotives during the next four years. Address Minister of Ways and Communications, St. Petersburg.

The Chilian Government Railroads have ordered 20 consolidation locomotives from the American Locomotive Company instead of 25 locomotives, as reported in the *Railroad Gazette* of August 9.

The Antioquia Railroad, a Colombian government railroad operated by a commission with headquarters at Medellin, Colombia, S. A., has ordered three consolidation locomotives from the American Locomotive Company.

The Las Vegas & Tonopah, as reported in the *Railroad Gazette* of August 9, has ordered one 10-wheel passenger (4-6-0) locomotive and three consolidation (2-8-0) locomotives similar to the San Pedro, Los Angeles & Salt Lake standard from the American Locomotive Company.

The Temiskaming & Northern Ontario, as reported in the *Railroad Gazette* of August 16, has ordered from the Canadian Locomotive Company six simple 10-wheel locomotives for February, 1908, delivery. The specifications for these locomotives are the same as those published in the *Railroad Gazette* of March 29 for the locomotives ordered from the Locomotive & Machine Company of Montreal.

The Wichita Falls & Northwestern, as reported in the *Railroad Gazette* of August 9, has ordered two simple mogul locomotives from the American Locomotive Company for December delivery.

General Dimensions.

Type of locomotive	Mogul
Weight, total	114,000 lbs.
Weight on drivers	97,000 lbs.
Diameter of drivers	56 in.
Cylinders	18 in. x 24 in.
Boiler, type	Straight top
" working steam pressure	180 lbs.
" number of tubes	240
" material of tubes	Charcoal iron
" diameter of tubes	2 in.
" length of tubes	11 ft. 2 in.
Firebox, length	96 "
" width	34¼ "
" grate area	23 sq. ft.
Heating surface, total	1,530 "
Tank capacity	4,000 gals.
Coal capacity	8 tons

Special Equipment.

Air-brakes	Westinghouse
Injectors	Nathan
Safety valves	Coale
Sight-feed lubricators	Nathan
Steam gages	Crosby

CAR BUILDING.

The Ann Arbor has asked prices on 100 freight cars.

The Pere Marquette has made an appropriation for 3,000 freight cars.

The Italian Government is said to be in the market for 200 baggage cars.

Wells-Fargo & Co. are said to be in the market for 10 refrigerator express cars.

The Northwestern Pacific has ordered 10 passenger cars from the St. Louis Car Co.

The Atchison, Topeka & Santa Fe is figuring on 10 combination automobile and horse cars.

The Mobile, Jackson & Kansas City is said to be figuring on buying some passenger equipment.

The Washington, Idaho & Montana has ordered one combination passenger and baggage car from the Pullman Co.

The City of Chicago is about to ask for an appropriation for 40 or 50 standard gondola cars of 100,000 lbs. capacity.

The Chilian Government, it is said, has ordered 42 motor cars and 175 other cars from the St. Louis Car Company.

The Middletown Car Works is said to be asking prices on specialties for 500 hopper cars of 100,000 lbs. capacity.

The Ontario Portland Cement Co., Blue Lake, Ont., is said to have ordered 12 flat cars, two of which are motor cars.

The United States Steel Corporation, it is said, is about to order 50 all-steel box cars similar to the Union Pacific design.

The Virginia & Southwestern is said to have ordered 500 freight cars of 80,000 lbs. capacity from the Western Steel Car & Foundry Company.

The Harriman Lines, as reported in the *Railroad Gazette* of May 17, having again revised plans for 30 steel postal cars, are now asking prices.

The Santa Fe, Raton & Des Moines has ordered 30 self-clearing flat bottom wood gondola cars of 100,000 lbs. capacity from the National Dump Car Co.

The Russian Government has appropriated $47,000,000 to be spent for cars and locomotives during the next four years. Address Minister of Ways and Communications, St. Petersburg.

The Isthmian Canal Commission, as reported in the *Railroad Gazette* of August 9, has ordered 115 dump cars from the Continental Car & Equipment Co., and 500 dump cars from the American Car & Foundry Co.

The Buffalo & Susquehanna is reported to have ordered 200 steel hopper cars, 200 steel underframe box cars, 500 gondolas of 100,000 lbs. capacity, and 100 cars for general service, all from the Pressed Steel Car Co.

The Pennsylvania is building at Altoona 35 all-steel passenger cars as follows: Seventeen 70-ft. postal cars, ten 70-ft. dining cars, two 60-ft. baggage cars and six passenger coaches, five of which are 70 ft. long.

The Canadian Pacific, as reported in the *Railroad Gazette* of July 26 and August 2, has ordered 1,000 box cars of 60,000 lbs. capacity; 500 from the American Car & Foundry Co., and 500 from Barney & Smith. These cars will measure 36 ft. long, 8 ft. 6 in. wide and 8 ft. high, inside measurements, and 36 ft. 8 in. long, and 9 ft. 5⅜ in. wide, over all. Bodies and underframes will be wood. The special equipment includes:

Bolsters	Simplex
Brake-beams	Simplex
Brake-shoes	Steel back diamond S.
Brakes	Westinghouse
Center bearings	One malleable iron; one steel
Couplers	Tower
Door fastenings	"Positive"
Doors	"Security"
Draft rigging	Miner tandem
Dust guards	Harrison
Journal boxes	McCord
Paint	Mineral brown
Roofs	Chicago Winslow Improved
Side bearings	Susemihl roller
Springs	Canadian Pacific standard
Trucks	Barber roller Simplex
Wheels	Cast Iron

RAILROAD STRUCTURES.

Lethbridge, Alb.—John Gunn & Sons, Winnipeg, have been given the contract at $200,000 for the abutments and concrete superstructure for the Canadian Pacific bridge here. The steel work will cost approximately $900,000.

London, Ont.—The barns and five cars of the Southwestern Traction Co. have been destroyed by fire; loss $150,000.

Macon, Ga.—The Central of Georgia has let the contract for

car shops and power house only to the McKenzie De Leon Construction Co., Savannah, and not for the entire shops, as reported in our issue of Aug. 9. These buildings are part of the company's new shop scheme which will ultimately cost $1,400,000. Work has begun on the car shop, which will be a brick building 195 ft. wide and 300 ft. long. The power house will be of brick with steel framing 104 ft. by 92 ft.

MT. UNION, PA.—A contract for work on the bridge over the Juniata river, which is to be 618 ft. long and 16 ft. wide, has been let to Andrew Buchanan, of Chambersburg, at $17,000. Work has been under way for some time by L. A. Green, of Huntingdon, who has the contract for the piers and abutments. The Pennsylvania Railroad will pay $25,000 as its share of the work.

OTTAWA, ONT.—The plans for the new central station at Ottawa, to be built by the Grand Trunk, described in the *Railroad Gazette* of May 31, 1907, have been approved by the Federal cabinet. They include an office building 10 stories high, to be equipped with all labor saving conveniences. Work will be begun at once. The cost of the structure is estimated at $1,500,000 or possibly $2,000,000. The Grand Trunk is also prepared to build a hotel near the station, to cost $1,000,000. Plans have been submitted to the government for a hotel building in Major Hill Park.

PHOENIXVILLE, PA.—The Montgomery & Chester Electric Railway Company is to build a $14,000 bridge at Ironsides.

PRINCE ALBERT, SASK.—Arrangements have been made between the Canadian Northern and the Provincial Government of Saskatchewan whereby the former will build a bridge over the Saskatchewan river here.

SPRINGFIELD, MO.—The St. Louis & San Francisco, it is said, has begun work on shops here which are to be finished by March, 1908. There are to be six buildings, to include a machinery and erecting shop, 173 ft. x 566 ft.; forge shop, 102 ft. x 245 ft.; boiler and tank shop, 117 ft. x 344 ft.; coach shop, 207 ft. x 303 ft.; paint shop, 182 ft. x 183 ft., and a powerhouse, 117 ft. x 160 ft.

TWO HARBORS, MINN.—The Duluth & Iron Range, it is said, has begun work on a new steel ore dock here. The pile foundation is to be filled with rock, on which is to be laid concrete to a height of 5 ft. above water line.

VANCOUVER, B. C.—The authorities have presented a petition to the Premier for the erection of a combined highway and railroad bridge to connect the North Vancouver district with the city and districts south. Estimated cost $700,000 to $1,000,000.

WEST ALBANY, N. Y.—Contracts for the new shops for the New York Central are reported let to R. Richard & Son, of Utica, for the general work, and to F. Schoemaker & Co., of New York, for the steel frame work. It is proposed to have the work finished within four months.

WINNIPEG, MAN.—The plans for the new station at this place, to be used jointly by the Canadian Northern and the Grand Trunk Pacific, are being changed. The Canadian Northern will begin the work as soon as plans are accepted. Besides a union station, the plans include bridges over both the Red and Assiniboine rivers, each to carry two tracks.

Kelly Bros. & Mitchell have been given a contract by the Canadian Northern for building an erecting shop 600 ft. x 160 ft. with annexes, to cost $200,000.

RAILROAD CONSTRUCTION.

New Incorporations, Surveys, Etc.

ATLANTA & ST. ANDREWS BAY.—This company now has 36 miles of road in operation from Dothan, Ala., south to Domer, Fla. The projected route is from Atlanta, Ga., via Opelika and Dothan, Ala., to Panama City, Fla., 290 miles. Work on the southern end, from Dothan to the gulf, 85 miles, it is said, is being pushed vigorously. The road has been built to Compass Bond, within 20 miles of Panama City, the southern terminus. This road is being built by the Enterprise Lumber Company, of Columbus, Ga. (March 15, p. 379.)

ATLANTIC, QUEBEC & WESTERN.—The first two sections of this road will shortly be opened for traffic. The road is now completed from New Carlisle, Que., north to Port Daniel, 23 miles. Active operations are under way from Port Daniel north to Gaspe Basin, 80 miles. At L'Anse au Gascon 100 men and teams are at work. Operations are shortly to be started at Grand River, Cape Cove and Gaspe Basin. Bids will soon be asked for ties, rails and the construction of bridges. Contracts will be let this fall and the whole line is to be under construction by spring. At Port Daniel the company will begin at once tunneling through Hell's Cape, 400 ft. (June 28, p. 948.)

CANADIAN PACIFIC.—Contract is reported let to J. G. McArthur for grading 73 miles from Moose Jaw, Sask., northwest. The contract is said to amount to about $300,000.

CANANEA, YAQUI RIVER & PACIFIC.—See Southern Pacific.

CHICAGO & NORTH WESTERN.—Surveyors who have been in the field since early spring are said to have found a grade which does not exceed 1½ per cent. through the mountains at the headwaters of the Salmon river, Idaho. The route as surveyed runs westerly to the Pacific coast. It runs northwest down the Lemhi and Salmon rivers to Lewiston, thence to Puget Sound or Portland.

CHICAGO & OAK PARK ELEVATED (ELECTRIC).—This company proposes to build a line to Elgin, Ill. At present it has a double track elevated line from Fifth avenue and Lake street, Chicago, to Oak and Lake streets, with a branch down Market street to Madison street, with a connection to the Chicago & Harlem, a total of 22 miles of track.

CHICAGO, ROCK ISLAND & PACIFIC.—Preliminary work is reported under way for double-tracking this road from Topeka, Kan., west to McFarland, 32 miles.

EAST ST. LOUIS & EASTERN.—Incorporated in Illinois with office at East St. Louis. The company is to build a line from a point near Belleville, St. Clair county, to the county line. The incorporators and first board of directors include L. C. Hayns, T. W. Gregory, G. C. Pierce, F. H. Thomas and F. H. Kruger.

EVANSVILLE & PRINCETON TRACTION.—An extension will be built from Princeton, Ind., north to Patoka, about five miles, and after this extension is completed a survey will be made for an extension from Patoka to Vincennes, 30 miles. It is the intention of the company to eventually have a through line from Evansville to Indianapolis.

GRAND TRUNK PACIFIC.—This company seems to be preparing to rush the construction of the western end of the line. In addition to building the branch from Kitamat Arm, B. C., north to Hazelton, 180 miles, the contract for which has been let to Foley Bros. & Larson, the main line work on the section from Prince Rupert, B. C., east up the Skeena river as far as Kitselas canyon, 100 miles, will be undertaken this fall. This includes a large amount of rock work and it is expected will take two years to build. Arrangements also have been made to start work this fall on 200 miles of the section west from Edmonton, Alb., to a point 60 miles east of the summit of the Rockies.

MINNEAPOLIS & ST. LOUIS.—The Minnesota, Dakota & Pacific, under construction from Conde, S. Dak., west to Le Beau, on the Missouri river, 115 miles, which was put in operation as far as Cresbard, 42 miles, last July, has recently been opened for freight service an additional 42 miles to Hoven. This leaves about 31 miles to finish the line to Le Beau. (July 5, p. 27.)

MINNEAPOLIS, KANSAS CITY & GULF (ELECTRIC).—Under this name a company is reported incorporated in Oklahoma with a capital of $50,000,000 to build an electric line from Minneapolis, Minn., south to Galveston, Tex. The names of the incorporators are not given.

MINNESOTA, DAKOTA & PACIFIC.—See Minneapolis & St. Louis.

NEW YORK SUBWAYS.—The Public Service Commission of the First district has taken action toward beginning work shortly on the proposed improvements in the subway of the Interborough Rapid Transit Company, which includes the laying of three additional tracks under Broadway between 96th and 102d streets. This work was approved by the Rapid Transit Commissioners before they went out of office, and now requires the approval of the Board of Estimate and Apportionment of New York city before it can be carried out.

RUSSELLVILLE & OZARK MOUNTAIN TRACTION, LIGHT & POWER COMPANY.—Incorporated in Arkansas with $200,000 capital by residents of Pine Bluff, Russellville, Ozark and Atkins. It is proposed to build an electric line between Russellville and nearby towns. The incorporators include Adam J. Robinson, President; J. C. Wilson, Assistant President; J. Gould, Secretary; W. N. Langford, Treasurer; T. D. Brooks, A. S. Hayes, A. B. Plaston, E. Stoneker, M. M. Bruce and J. C. Wilson.

SOMERSET & NASHVILLE.—Incorporated in Kentucky with $10,000 to build a line from Somerset to a point on the Cumberland river near Burnside, seven miles. The Commercial Club of Somerset, and local capitalists are interested.

SOUTH CAROLINA ROADS (ELECTRIC).—Application will shortly be made by a company in Georgia to build an electric line from Greenville, east to Spartanburg, about 31 miles. A. A. Gates, C. C. Good, H. H. Prince and O. K. Maulden are incorporators.

SOUTHERN PACIFIC.—Grading work on the Cananea, Yaqui River & Pacific has progressed as far as the right of way of the Kansas City, Mexico & Orient in the state of Sinaloa, which is to be crossed at a point east of the port of Topolobampo. Construction forces are working south towards this point. A large force of men are now at work on the Yaqui Valley, in Sonora, and on the Alamos branch. Grading work out of Orendain on the Guadalajara branch

is progressing rapidly, and a large force of men are at work. The Mexican Contracting Company, of Mexico City, is building this branch.

South Shore Traction.—This company recently obtained a franchise from the town board and highway commissioners of Hempstead, L. I., and now has an uninterrupted chain of franchises from Patchogue, L. I., to the New York city line. Among those interested in the company are: Arthur P. Heinze, J. T. Wood, W. P. Youngs, F. D. Kilburne and P. T. Brady.

Temiskamino & Northern Ontario.—The preliminary surveys for the proposed branch from Cobalt, Ont., to Sudbury have been made by the government engineers. The route is from the main line between Gillies and Cassidy west to Sudbury, 90 miles. From the junction point the road is to run west along the north shore of Portage bay, crossing the Montreal river at Park Rapids, thence southwest into the Temagami reserve district via Eagle lake, the west shore of Whitefish lake, and thence the north end of Oharika lake and along its west shore for 10 miles into the Sturgeon valley and down the valley to Sudbury. The proposed line will not only save 60 to 70 miles for ore shipments to the Copper Cliff smelters, but also will furnish another direct means of transportation between Toronto and Cobalt. (May 17, p. 695.)

Valley Railroad of West Virginia.—Under this name a company has been organized to build a line from Piedmont, W. Va., southwest into Pocahontas county, about 100 miles. The Tyrone Paper Company and a number of Tyrone and Huntingdon (Pa.) capitalists are interested.

Valley Transit Light & Power Co.—Incorporated in Ohio with $100,000 capital to build an electric line from Canton southwest via Dover, New Philadelphia, New Comerstown, Coshocton and Newark to Columbus, about 150 miles. The office of the company is at New Philadelphia, and the incorporators include C. J. Kneisely, M. Siebold, W. W. Snyder, T. F. Hynes, W. J. Wise, E. S. Rhoades, F. G. Knonzli and F. O. Richards.

White Deer & Loganton.—Passenger service was recently started on this narrow-gage road from White Deer, in Union county, Pa., west to Loganton, 24 miles.

RAILROAD CORPORATION NEWS.

Baltimore & Ohio.—See Chicago Terminal Transfer.

Birmingham Railway, Light & Power.—This company has made a mortgage to the Old Colony Trust Company, of Boston, for $25,000,000. The company operates 127 miles of electric road in and near Birmingham, Ala. Over a year ago it was reported that it would be consolidated with the street railways of Little Rock, Ark.; Memphis, Tenn.; Nashville, Tenn.; Houston, Tex., and Knoxville, Tenn. Extensions, including a new power house in Birmingham, are proposed.

Chicago & Illinois Western.—This company has increased its capital stock from $500,000 to $1,000,000. The road runs from Chicago 17 miles toward Joliet, Ill., and the remaining 34 miles into Joliet are under construction.

Chicago, Burlington & Quincy.—See Chicago Terminal Transfer.

Chicago Terminal Transfer.—An offer of $25 a share has been made for the preferred stock held by minority stockholders. It is understood that 70 per cent. of the $17,000,000 preferred stock is held by the Chicago, Burlington & Quincy, and that the present offer is made by Baltimore & Ohio interests. It is believed that the Chicago, Burlington & Quincy and the Baltimore & Ohio have reached an agreement for the joint control of the Chicago Terminal; the Baltimore & Ohio some time ago assumed the $15,000,000 first mortgage bonds of the terminal company.

Erie.—This company has applied to the New York Public Service Commission for the Second district for permission to issue $6,216,345 5 per cent. car trust notes. Of these notes, $156,345 run for five years and are secured on 60 passenger coaches; the remainder run for 10 years and are secured on 3,000 box cars, 3,000 steel hopper coal cars and 38 freight locomotives.

Cleveland, Cincinnati, Chicago & St. Louis.—Gross earnings for the quarter and six months ended June 30, 1907, were as follows:

	For Quarter.		
Earnings	$6,775,198	Inc.	$929,218
Expenses	5,022,615	"	192,062

*At the annual rates of 5 per cent. on preferred and 4 per cent. on common.

Florida East Coast.—Work on the extension along the Florida Keys to Key West has been temporarily stopped because of the scarcity of labor.

Interborough-Metropolitan.—It is reported that the quarterly dividend of 1¼ per cent., payable in October, on the preferred stock of this company, which controls all of the traction lines in New York city, will be passed. The highest price of the stock for 1907 was 75, reached early in January; this week, influenced by the investigation of the company by the Public Service Commission of the First district, it sold down to 20. Metropolitan Street Railway stock, on which the New York City Railway in 1902 guaranteed 7 per cent. dividends for 999 years, is also to have its dividend passed, according to the same report. On Wednesday it sold at 39 from a high record of 107 on January 23.

Lake Shore & Michigan Southern.—Gross earnings for the six months ended June 30, 1907, were as follows:

Earnings	$21,589,538	Inc.	$982,442
Expenses	16,313,272	Dec.	97,842
Net earnings	$5,276,266	Inc.	$1,080,284

Dividend (3 per cent.)	562,140	"	187,380
Surplus.	$75,537	Dec.	$74,906

Pere Marquette.—A special meeting of the stockholders has been called for October 28 to act on the reorganization plan proposed last June. The plan includes the termination of the present receivership, the exchange of the present preferred stock for new preferred stock, the subscription by present preferred stockholders to an issue of $5,000,000 notes (90 per cent. of which have been subscribed to) and the abrogation of the Cincinnati, Hamilton & Dayton's lease of the Pere Marquette. (June 28, p. 949.)

Public Service Corporation.—A new company is to be formed under the name Public Service Street Railway Company, as a consolidation of the North Jersey Street Railway, the Jersey City, Hoboken & Paterson Street Railway and the United Street Railway Co. of Central Jersey. The new company is to have $38,000,000 capital stock. The capital stocks of the three companies to be merged are held almost entirely by the Public Service Corporation.

Southern Pacific.—In making application to the New York Stock Exchange for the listing of additional preferred stock, the company announces that the common and preferred stockholders subscribed to all but $64,588 of the $35,677,388 offered to them last June. The new issue is a capitalization of expenditures made by the company in retiring $38,500,000 securities as follows: $22,747,000 Southern Pacific Company two-five-year, 4½ per cent. bonds; $6,961,000 Southern Pacific Railroad Company 6 per cent. bonds, and $8,822,000 Central Pacific Railway Company 3 per cent. notes to the United States Government.

Winnipeg Electric.—This company is to offer at par to holders of the $1,500,000 capital stock, of record on August 31, $1,500,000 additional stock at the rate of one share of new stock for every three shares already held. The company operates 32 miles of road, consisting of all the street railways in Winnipeg, Man., and St. Boniface. It also does all the gas and electric business in both places.

LEHIGH VALLEY RAILROAD COMPANY—FIFTY-THIRD ANNUAL REPORT.

Philadelphia, August 14, 1907

To the Stockholders of the Lehigh Valley Railroad Company.

The Board of Directors herewith submit the fifty-third annual report of the business of your Company and its allied interests for the fiscal year ended June 30, 1907.

MILEAGE.

The mileage of railroads owned and operated by the Lehigh Valley Railroad Company, the main line of which extends from Jersey City, N. J., to Buffalo, N. Y., is as follows:

Owned or controlled by ownership of entire capital stock	1,295.48
Controlled by ownership of majority of capital stock	157.39
Controlled by leases	27.88
Total mileage operated (owned and controlled)	1,390.75
Trackage rights over railroads owned by other companies	49.47
Total mileage	1,440.22

—of which 579.14 miles, or 40.21 per cent., have second track, 56.18 miles have third track and 20.47 miles have fourth track. There are also 1,067.29 miles of yard tracks and sidings on the system.

The decrease of 4.74 miles of first track is due principally to the removal of various colliery branches and to the change of a portion of the old main line at Allentown to third and fourth tracks.

The decrease shown in miles of yard tracks and sidings is occasioned by withdrawing therefrom the fourth track mileage which, in view of additional construction, is now shown as a separate item. The more important increases are referred to elsewhere in the report.

EARNINGS AND EXPENSES.

The following statement shows the gross earnings, expenses and net earnings from the operation of the entire system for the fiscal year, not including other income.

For comparative purposes, similar figures are also given for the fiscal year of 1906.

GROSS EARNINGS.

FROM	1907	1906	Increase	Decrease
Coal freight	$15,110,899.38	$13,248,565.42	$1,862,333.96	.....
Other freight	14,996,672.62	13,934,127.10	1,062,545.52	.....
Passenger	4,363,452.12	3,971,392.05	392,060.07	.....
Express	373,953.30	367,706.36	6,246.94	.....
Mail	217,792.69	217,745.88	46.81	.....
Miscellaneous	1,005,661.40	1,050,319.82	.....	$44,658.42
Total earnings	$36,068,431.51	$32,789,856.63	$3,278,574.88	.....

OPERATING EXPENSES.

For	1907	1906	Increase	Decrease
Maint. of way and structures	$3,196,854.34	$3,153,245.22	$43,609.12	.....
Maint. of equipment	6,186,641.83	5,485,794.06	700,847.77	.....
Conducting expenses	12,100,681.44	10,891,953.73	1,208,727.71	.....
General expenses	630,075.28	621,217.71	8,857.57	.....
Total expenses	$22,114,252.89	$20,152,210.72	$1,962,042.17	.....
Net earnings from operations	$13,954,178.62	$12,637,645.91	$1,316,532.71	.....
Percentage of operating exp. to gross earnings	61.31	61.46	.....	.15

The gross earnings of the Company for the year amounted to $36,068,431.51, an increase as compared with the previous fiscal year of $3,278,574.88, or 10 per cent. The total operating expenses amounted to $22,114,252.89, an increase of $1,962,042.17, or 9.47 per cent. The ratio of expenses to earnings was 61.31 per cent., a decrease as compared with the previous year of .15 per cent.

EARNINGS.

COAL FREIGHT.

The transportation of coal, including coke, yielded a revenue of $15,110,899.38, an increase of $1,862,333.96, or 14.06 per cent., as compared with the previous year.

The percentage of coal earnings to gross earnings was 41.89 per cent., an increase of 1.49 per cent.

The coal and coke tonnage transported, not including supply coal, amounted to 14,374,216 tons, an increase of 1,621,163 tons, or 12.71 per cent., over the year previous.

The number of tons moved one mile amounted to 2,022,206,603, an increase of 209,028,261, or 11.53 per cent.

The average haul decreased from 142.18 miles to 140.68 miles, a decrease of 1.50 miles, or 1.06 per cent.

The coal tonnage was 51.06 per cent. of the total tonnage hauled during the year, as against 49.88 per cent. for the previous year, being an increase of 1.18 per cent.

MERCHANDISE FREIGHT.

The earnings derived from the transportation of merchandise freight amounted to $14,996,672.62, an increase of $1,062,545.52, or 7.63 per cent., as compared with the previous year.

The percentage of earnings derived from the transportation of merchandise freight to gross earnings was 41.58 per cent., a decrease of .92 per cent.

The tonnage moved, exclusive of Company material, was 13,779,764 tons, an increase of 964,506 tons, or 7.53 per cent.

The number of tons carried one mile amounted to 2,747,893,327, an increase of 218,194,304 tons, or 8.63 per cent.

The average haul increased from 197.40 to 199.42 miles, an increase of 2.02 miles, or 1.02 per cent.

Company's material amounting to 431,139 tons was transported during the year, being an increase of 23,923 tons, or 5.87 per cent.

GENERAL FREIGHT TRAFFIC.

The total earnings from both coal and merchandise freight amounted to $30,107,572.00, an increase of $2,924,879.48, or 10.76 per cent., as compared with the previous year.

The entire freight traffic amounted to 28,153,980 tons, being an increase of 2,585,729 tons, or 10.11 per cent.

The number of tons carried one mile was 4,770,099,930, an increase of 427,222,565, or 9.84 per cent.

The average distance carried was 169.43 miles, a decrease of .42 mile, or .25 per cent.

The average revenue per ton was 106.94 cents, as against 106.71 cents last year, being an increase of .63 cent, or .59 per cent.

Company's freight, not included in the above, amounted to 2,481,863 tons, an increase of 270,926 tons, or 12.25 per cent.

The total freight train mileage was 9,062,037 miles, an increase of 440,174 miles, or 5.11 per cent., while the volume of tonnage increased, as shown above, 10.11 per cent.

Revenue received per freight train mile was $3.32 as compared with $3.15, being an increase of 17 cents, or 5.40 per cent.

The average train load of revenue freight was 526.38 tons, an increase of 22.08 tons, or 4.50 per cent. Including Company's freight, the average train load was 546.28 tons, as against 523.34 last year, an increase of 22.94 tons, or 4.38 per cent.

The average number of tons of revenue freight in each loaded car was 21.83 tons, an increase of 1.37 tons, or 6.70 per cent. Including Company's freight, the average carload on the system was 22.66 tons, an increase of 1.40 tons, or 6.59 per cent.

PASSENGER TRAFFIC.

The revenue from this class of traffic amounted to $4,363,452.12, an increase of $392,060.07, or 9.87 per cent., as compared with the previous year.

Total number of passengers carried was 5,181,533, an increase of 191,544, or 3.84 per cent.

The number of passengers carried one mile increased 23,102,299, or 10.16 per cent.

The average revenue paid by each passenger was 84.21 cents, an increase of 4.62 cents, or 5.80 per cent.

The average revenue per passenger per mile was 1.742 cents, a decrease of .005 cent, or .29 per cent.

The average distance traveled by each passenger was 48.34 miles, an increase of 2.78 miles, or 6.10 per cent.

Passenger train mileage was 4,084,695, an increase of 175,385, or 4.49 per cent.

The earnings from passengers per passenger train mile were 106.82 cents, an increase of 5.23 cents, or 5.15 per cent.; the average number of passengers per train was 61.32, an increase of 3.16, or 5.43 per cent., and the average number of passengers per car was 17.88, a decrease of .03, or .17 per cent.

EXPRESS.

The earnings from this source amounted to $373,953.30, an increase of $6,246.94.

MAIL.

The revenue derived from the transportation of United States mails amounted to $217,792.69, an increase of $46.81.

MISCELLANEOUS.

Miscellaneous earnings amounted to $1,005,661.40, a decrease of $44,658.42. The details of these earnings appear in Table No. 8.

EXPENSES.

MAINTENANCE OF WAY.

Expenditures amounting to the sum of $3,196,854.34 were made for the maintenance of way and structures, being an increase of $43,609.12, or 1.38 per cent., as compared with the previous 12 months.

During the year 11 steel bridges, replacing lighter metal structures, and 17 steel bridges, replacing wooden bridges and trestles, were erected. Eight metal bridges and four wooden bridges and trestles were filled in.

97.55 miles of single track were fully ballasted and 29.70 miles partially ballasted with stone, for which purpose 307,637 cu. yds. of crushed stone and 46,379 cu. yds. of screenings were used. In addition, 36 miles were fully ballasted with gravel, and 41 miles raised and ballasted with cinders.

235,752 ft., or 44.65 miles, of Company's sidings, and 30,835 ft., or 5.84 miles, of private sidings were constructed.

19,743 tons of new 90-lb. rail, together with necessary frogs, switches, etc., were placed in the track.

373,985 tie plates were used.

569,272 cross ties, 1,606,213 ft. B. M. switch ties, 377,127 ft. B. M. bridge ties and lumber amounting to 3,906,278 ft. B. M., were used during the year.

Drain tile to the extent of 10,800 ft., or 2.05 miles, was used.

1.26 miles of portable snow fences were erected at various points.

A new 62-lever electrically operated interlocking plant was put in operation at Wyandotte street, South Bethlehem, replacing manual plants at North Penn Junction and Brodhead avenue. At Van Etten, a 25-lever electrically operated plant was installed, replacing a manual plant of 11 levers. Interlocking plants were installed at Cortland with 31 levers, Silver Brook 16 levers, Laurel Junction, 18 levers, Malone's Siding 2 levers, and additions made at Sayre of 4 levers, Pittston Junction 5 levers, Pine Junction 5 levers, and Coxton 6 levers.

Increased commissary and laundry accommodations for the dining car department were provided at South Easton.

At Scott street, Buffalo, additional team tracks and driveways were put in and the canal bridge removed. Two local delivery sidings were constructed

at Constable Hook. The local freight facilities at Allentown were increased by the construction of two sidings and a driveway.

Track scales of 100 tons capacity each were installed at South Plainfield, Delano and North Fair Haven.

2.25 miles of new telegraph and telephone pole line were constructed, 17.44 miles rebuilt and 81 miles reset. Telegraph wires were extended from Silver Brook Junction to New Boston Junction, a distance of 6.2 miles.

Copper metallic telephone circuits were extended from Roun to Lumber Yard, a distance of 6.75 miles; from Coxton to Ransom, 3.5 miles; and at the Tifft Farm Terminal, 2.3 miles. Iron metallic telephone circuits were erected between Rockport and Penn Haven Junction, a distance of 6.1 miles.

Grounded telephone circuits were installed between Treichler and Rockdale, a distance of 6.2 miles, and between Swartwood and Park Station, a distance of 3.8 miles.

115.6 miles of new copper, 1 mile of new iron and 37.45 miles of second-hand iron wire were used in extending telephone, telegraph and signal wires. 105.5 miles of copper wire were used in replacing worn out wires in the same service.

MAINTENANCE OF EQUIPMENT.

The sum of $6,186,641.83 was expended during the year for the maintenance of equipment, being an increase of $700,847.77, or 12.78 per cent., as compared with the preceding year. This increase is due to the necessarily greater expense of maintaining the larger number of locomotives and cars now comprising the Company's equipment, to the additional cost of labor and material and to the increased charges to this account for equipment condemned and taken out of the service.

Forty freight, 10 switching and 5 passenger locomotives were purchased, 40 of which were charged to Capital Account. Two 8-wheel locomotive cranes and 15 8,000 gallon capacity tenders were also purchased.

Ten locomotives, unfit for further service and too light to warrant rebuilding, were sold and Operating Expenses charged with their value.

The total number of locomotives at the end of the year was 857, having a tractive power of 22,777,258 lbs., an increase of 45 locomotives and 1,828,909 tractive power pounds.

The average tractive power per locomotive at the close of the year was 26,578 lbs., an increase of 780 lbs., or 3.02 per cent.

Nine locomotives were rebuilt. 63 new fireboxes, two new tender frames and two new cisterns were applied. Three 4,500-gal. capacity tenders were constructed.

There were purchased and placed in service during the year under Equipment Trust, Series I, two thousand 80,000-lbs. capacity steel underframe box and two thousand 100,000-lbs. capacity steel coal cars. Five hundred 80,000-lbs. capacity steel underframe box cars were purchased and charged to Capital Account. Five hundred 80,000-lbs. capacity steel underframe box, one dining and 20 express cars were purchased and charged to Additions and Improvements. Five hundred 80,000-lbs. capacity steel gondola, one hundred and two 60,000-lbs. capacity steel underframe produce, twenty-five 60,000-lbs. capacity steel underframe automobile and ten 80,000lbs. capacity steel underframe box cars were purchased and charged to Expense and Equipment Renewal Reserve.

Thirteen 4-wheel steel underframe caboose cars and one set of 285,000-lbs. capacity gun and armor trucks were built.

One combination passenger and baggage car, one express car, 998 freight equipment cars and 26 road service cars were condemned and destroyed during the year and the value thereof charged to Operating Expenses.

The total number of freight equipment cars in service at the end of the year was 41,810, having a capacity of 1,357,740 tons, an increase of 4,649 cars and 221,784 tons.

One café car was converted into a dining car, one chair car into a passenger coach and three coaches assigned to road service.

394 passenger equipment cars were painted and varnished and 15 equipped with wide vestibules and standard steel platforms.

Air brakes were applied to 397 freight equipment cars at a cost of $21,940.

CONDUCTING TRANSPORTATION.

The total expense of conducting transportation was $12,100,681.44, being an increase of $1,208,727.71, or 11.10 per cent., as compared with the previous fiscal year. Freight train mileage increased 5.11 per cent., and ton miles increased 9.81 per cent. Passenger train mileage increased 4.11 per cent., and passenger miles increased 10.16 per cent.

The ratio of conducting transportation to gross earnings was 33.55 per cent., as against 33.22 per cent. last year, an increase of .33 per cent.

The increase in this class of expenses is due to an increased volume of traffic, increased rates of wages paid employees and the greater cost of all materials and supplies.

GENERAL EXPENSES.

The total expenditures under this head amounted to $630,075.28, an increase of $8,857.57.

TAXES.

The taxes paid amounted to $885,008.95, or 2.46 per cent. of the Company's gross earnings, an increase of $178,869.05, or 25.30 per cent.

THE LEHIGH VALLEY COAL COMPANY

The financial condition of The Lehigh Valley Coal Company is indicated by its General Balance Sheet published herewith. [See tables on page 220.] The following statement shows the funded debt of the Company and the yearly interest charges thereon.

Name.	Principal.	Date of maturity	Rate, per ct.	Yearly interest When due.	Amount.
The Lehigh Valley Coal Co.					
First mortgage bonds, issue of 1892	$10,114,000	Jan. 1, 1933.	5, gold.	Jan. Jul.	$505,700
First mortgage bonds, issue of 1892	1,400,000	Jan. 1, 1933.	4, gold.	"	56,000
Snow Shoe mortgage	359,500	Jan. 1, 1910.	5.	"	17,975
Delano Land Co.:					
First mortgage bonds	1,084,000	Jan. 1, 1932.	5, gold.	"	54,200
Total, Jan. 30, 1907	$12,957,500				$633,875

The total production of anthracite coal from the lands owned and controlled by The Lehigh Valley Coal Company and other companies in which it and the Lehigh Valley Railroad Company are interested, through ownership of stock, was 8,867,254.18 tons for the fiscal year ended June 30, 1907, as against 7,667,665.14 tons for the preceding year, an increase of 1,199,589.04 tons, or 15.64 per cent.

During the year The Lehigh Valley Coal Company and affiliated companies produced and purchased 87.11 per cent. of the anthracite coal transported by the Lehigh Valley Railroad Company.

From the operations of the Snow Shoe property there were mined 187,390.03 tons of bituminous coal, as compared with 210,728.17 tons for the previous twelve months.

The net results for the fiscal year have been seriously affected by many adverse circumstances. At the beginning of the year a cave-in occurred at Warrior Run, resulting in an explosion of gas that fired the mine, making it necessary to flood the entire operation. In October Exeter Breaker was demolished by a tornado. Centralia Breaker was idle for a period of seven months due to the breakage of machinery and the need of extensive repairs that could no longer be deferred without endangering the entire plant. Not only was the tonnage from these operations lost to the Company at a time when most needed and productive of the greatest profit, but the expense of reopening the Warrior Run mine and repairing the damaged breakers was so heavy, combined with other conditions, as to reduce the earnings to a minimum for several months. The anthracite coal handling plant and storage yard at South Chicago, with a stock of coal exceeding forty thousand tons, was entirely destroyed by fire in November and, although partially covered by insurance, the loss of these facilities was an additional burden upon the Company. Further, the shortage of cars was so severe during the winter and early spring as to require many of your collieries, spread over the extended region in which the Company's operations are conducted, to close down frequently during that period with less than a day's output, and this, with the inability of connecting roads to promptly move to destination such tonnage as had been sold, resulted not only in an excessive cost of operation, but prevented the sale of coal during a time when it could have been marketed at the greatest profit.

The Warrior Run Colliery and also Exeter and Centralia Breakers, which were rebuilt and enlarged to permit of handling a greater tonnage, are now in full operation. The new Sayre Colliery at Mt. Carmel, referred to in the last annual report, is also in successful operation. The work of rebuilding the coal handling plant and yard at South Chicago, with an increased capacity, on a basis permitting of more economical operation than the old plant, was begun immediately after the fire and the same will be in operation before the winter.

The construction of an additional coal storage building and dock, with a capacity of 75,000 tons, together with necessary machinery for handling anthracite coal, at Milwaukee, has been authorized and the work is under way. New retail coal yards and trestles have been established at 59th street, Chicago, and Syracuse, and a new trestle is in process of construction at Geneva. The coal handling plant and storage yard at West Superior, and the yards at 31st street, Chicago, and Walden avenue, Buffalo, are being enlarged. The total cost of this work to June 30th was $167,855.20.

In addition to the foregoing, improvements and betterments amounting to $708,169.09 were made to the various collieries during the year, of which amount $250,000 has been charged to the special appropriation made by the Board from the income of the previous fiscal year.

With the rebuilding of the operations mentioned, together with the improvements under way, and the property in a better physical condition than formerly, the future is encouraging.

The Advance Royalty Account has been decreased by $25,918.69.

The sinking funds of the several mortgages have been fully maintained.

FINANCIAL.

There were issued during the year, under authority of your Board, $5,539,000 General Consolidated Mortgage Bonds, bearing interest at the rate of four per cent. per annum, of which $539,000 were sold for various sinking fund purposes and to provide for the acquirement of additional capital stock of certain subsidiary companies the majority of whose capital stock is owned by your Company. The remaining $5,000,000 bonds, together with $2,000,000 previously issued, are in the treasury, making $7,000,000 of these bonds available for future needs.

The Montrose Railroad Company, successor to the property and franchises of the Montrose Railway Company, as referred to in the last annual report, created during the year a first mortgage securing an issue of $100,000 four per cent. fifty-year bonds. The same have been issued to your Company and are now in its treasury in exchange for a like amount of bonds, issued by the old company, which were cancelled.

An equipment trust known as Series I, amounting to $4,000,000, was created under date of August 1, 1906, covering two thousand coal cars of 100,000 pounds capacity each and two thousand box cars of 80,000 pounds capacity each. The certificates issued under the trust agreement bear interest at the rate of four per cent. per annum and are payable in ten annual instalments of $400,000 each, the last instalment being due September 1, 1916. All of the certificates are in your treasury.

The $300,000 Canastota Northern Railroad Company First Mortgage six per cent. Bonds were paid off at maturity, July 1, 1906, and the mortgage satisfied of record.

The mortgage of The Lehigh & Lake Erie Railroad Company, which provided for the issue of $3,000,000 four per cent. First Mortgage Bonds to cover the cost of constructing that road, together with the bonds issued thereunder, was cancelled and a new mortgage, dated March 1, 1907, securing a similar amount of bonds, maturing in fifty years and bearing interest at the rate of four and one-half per cent. per annum, was executed. $2,000,000 of these bonds were received and sold by your Company, the proceeds being applied in partial settlement of the advances made to date for construction, leaving a balance of $353,574.96 not reimbursed at the close of the year. This amount and the further advances necessary to

complete the road will be reimbursed by the remaining $1,000,000 bonds.

Under date of June 27, 1907, The Lehigh & Lake Erie Railroad Company was consolidated with The Lehigh Valley Rail Way Company, your New York State railroad. The authorized capital stock of the latter company was increased by $2,343,000, of which $343,000 was issued to your Company, $25,000 to absorb the stock of the former and $318,000 in reimbursement of the amount advanced, with interest thereon, to The Lehigh Valley Rail Way Company to retire the Canastota Northern Railroad Company First Mortgage six per cent. Bonds, an obligation of the Rail Way Company that matured July 1, 1906, as previously mentioned. The stock so received was pledged with the Trustee of the General Consolidated Mortgage, as provided therein. The remaining $2,000,000 stock will be issued to the Lehigh Valley Railroad Company as future advances are made for improvements and betterments to the property of The Lehigh Valley Rail Way Company.

To reimburse your Company for advances made for the construction and enlargement of their plants, the Hazleton Water Company and the [illegible] Mountain Water Company, the entire capital stock of which companies is owned by the Lehigh Valley Railroad Company, have issued, in the case of the former, $50,000 additional capital stock and $300,000 First Mortgage fifty-year five per cent. Bonds and, in the case of the latter, $75,000 additional capital stock and $125,000 First Mortgage fifty-year five per cent. Bonds. All of these securities have been received by your Company and are in the treasury, with the exception of $50,000 Hazleton Water Company Bonds held in reserve by that company for future use.

The construction account of the Bay Shore Connecting Railroad Company has been closed and capital stock of the company received by the Central Railroad Company of New Jersey and your Company in settlement of advances made, as referred to in the previous annual report.

There were sold for sinking fund purposes $41,000 bonds of the Mutual Terminal Company of Buffalo.

Payments amounting to $1,002,000 were made on account of matured principal of Equipment Trusts Series B, C, D, E, F, G and H and the Maritime Mortgage of the Lehigh Valley Transportation Company. Car Trust Series B and the Maritime Mortgage, both of which matured during the year, were paid off and satisfied of record. The title to the equipment pledged under the former, consisting of one thousand 60,000-pounds capacity coal, fifty stock and six combination cars, was vested in the Lehigh Valley Railroad Company, and the title to the floating equipment pledged under the latter mortgage, being the two lake steamers, "Wilkes-Barre" and "Mauch Chunk," and thirty-two barges, was vested in the Lehigh Valley Transportation Company, the entire capital stock of which is owned by your Company. At the close of the year the total outstanding equipment trust obligations of the Company in the hands of the public were $2,024,000. Equipment Trust Certificates Series H and I, amounting to a total of $4,540,000, are in your treasury and may be sold as occasion arises.

A suit was brought in the year 1904 by the holders of the preferred capital stock of the Company to secure the payment of dividends from the year 1893 to 1904 inclusive, which such holders claimed were cumulative. The Supreme Court of Pennsylvania sustained their contention and the dividends with interest, amounting to the sum of $116,673.96, were paid.

Your Board, on December 19, 1906, declared a semi-annual dividend of five per cent. on the preferred capital stock and a semi-annual dividend of two per cent., with an extra dividend of one per cent., on the common capital stock of the Company payable January 12, 1907. Similar dividends were declared on June 19, 1907, payable July 13, 1907.

The increase of $5,955,552.55 in Capital Amount represents the purchase of new equipment during the year, as previously mentioned.

Current Assets are $8,413,967.54 in excess of Current Liabilities.

The value of material and supplies on hand at the close of the fiscal year amounted to $2,099,145.22, an increase of $283,218.32, which is due to the greater cost as well as the additional quantity required for the increased equipment and business of the Company.

The increase in Securities Owned is explained by the additional securities issued to your Company for advances made to various subsidiary companies, and by the purchase of outstanding stock of companies the majority of whose capital stock is owned by the Lehigh Valley Railroad Company.

Bills Receivable Account has been increased by $182,500 notes of the Buffalo, Thousand Islands & Portland Railroad Company, a road projected by the New York Central & Hudson River Railroad Company and this Company to give additional connection with the Niagara Frontier, for sums advanced from time to time for surveys and right-of-way of that line, a portion of which has heretofore been carried in the account Advances to Other Companies.

The amount of capital stock issued remains unchanged.

The Company's cash on hand shows a decrease as compared with the previous year, which is due principally to the large purchases of equipment that were paid for out of current cash.

The accounts of the Company for the fiscal year, in accordance with the usual practice, have been examined by certified public accountants and the result of such examination is set forth in the accounts' certificate published herewith.

The General Balance Sheet and various statements appended show the financial condition of the Company at the end of the fiscal year.

GENERAL REMARKS.

The general improvement of your property has continued throughout the year and it has been fully maintained.

Included in the Company's equipment are many small wooden coal and box cars, ranging from twenty to thirty tons capacity, that are expensive to maintain by reason of their age as well as productive of but little revenue owing to their limited capacity. While these cars have been fully maintained and would, under previous conditions, be serviceable for additional use, yet placed as they necessarily are at various times between the modern heavy steel cars of this Company or foreign roads, they are being constantly damaged and are a frequent cause of wreck and disaster. Considering this and the fact that the Company's equipment has been more than maintained upon a tonnage basis and exceeds in value the total amount of the Equipment Account, your Board, [illegible] operation of the property, [illegible] a special appropriation of $[illegible] out of the net results of the fiscal year and [illegible] equipment as the appropriation will provide for. The same has been placed in a special reserve and will be credited to Capital Account as the cars are taken out of service.

Contracts have been [illegible] for the [illegible] and delivery during the early part of the next fiscal year of five thousand [illegible] capacity box and coal cars, the tonnage of which will more than exceed the tonnage of the equipment to be condemned.

Substantial progress has been made in the construction of the terminal railroad at Buffalo, referred to in the previous annual report as the Lehigh & Lake Erie Railroad, and it is expected that the line will be [illegible] with double track and be in operation by September 30. In connection with this improvement, and in order to properly handle the lake and [illegible] traffic, an expenditure of $250,000 has been authorized for additional yard and terminal facilities at Tifft Farm, which work is now under way.

The new double track 1,800 ft. steel girder bridge over the Susquehanna River, including the reduction of grades and change of alinement from Wysox to west of Towanda, has been completed and placed in service at a total cost of $810,818. The credit balance remaining in the special reserve fund charged with the cost of this and other similar work has been credited to General Reserve Fund.

The construction of third and fourth tracks from East Penn Junction to a point west of Freemansburg, a distance of 6.5 miles, is completed and a further extension of these tracks to east of Redington, a distance of 4.2 miles, has been authorized and is now in progress. This work, when completed, will give a continuous four-track line from Gap Junction to east of Redington, a distance of 12.7 miles, and will greatly facilitate the movement of traffic. The expenditure to date for this improvement amounts to $300,018.

The extension of the fourth track from Mauch Chunk to Glen Onoko, mentioned in the last annual report, was completed during the year to Coalport Bridge, a distance of 1.25 miles.

The third and fourth tracks at Bridge 28 were extended to New Market, a distance of 1.2 miles.

To relieve Coxton Yard and to eliminate main track shifting, the third and fourth tracks were extended from Falling Spring to Weldon, a distance of 1.73 miles, at a cost of $21,842.

Double track was extended from Morris Ridge to Mt. Carmel, a distance of 1.5 miles, making a continuous double track line from Hazleton to Mt. Carmel Yard.

The change in alinement on the Ithaca Branch between Ithaca and Willow Creek, a distance of five miles, has been completed, reducing the maximum curvature on that section of the line from 6 degrees to 1 degree and 30 minutes.

The car repair yard at Packerton has been remodeled and enlarged to accommodate 250 additional cars.

In order to overcome the present delay to traffic at the Jersey City Terminal and provide for increased business, the sum of $350,000 was authorized for the construction of three new transfer bridges and a freight yard of one thousand cars capacity at the National Docks, Communipaw. This work is now in progress and when completed will relieve the congestion at Jersey City and reduce the cost of operation. The plan under which the improvement is being made will permit of economical enlargements from time to time as necessity may require. Further relief at that point will also be afforded when two of the present float bridges are replaced with new bridges, made necessary by the use of heavier equipment of larger capacity, and Oak Island Yard has been enlarged by the construction of thirteen additional tracks. The aggregate cost of this work, which is now well under way, is $140,000.

New double track gravity ash pits of concrete construction, with depressed track for cinder cars, were constructed at Coxton, the expense being $24,049. A combination coal and ash-handling plant was installed at Hazleton at a cost of $16,496.

To increase the safety of train movements over the single track between Laurel Junction and Silver Brook Junction, a distance of 6.2 miles, a staff signal system was installed at a cost of $9,854.

Automatic signals were installed throughout Ithaca Yard and between Jersey City and Park View.

New stone and brick passenger stations were constructed at Catasauqua and Towanda, and a new frame station at Mt. Carmel, the latter replacing one destroyed by fire. A new freight house was constructed at Canastota, and a new brick freight house and transfer shed are in course of construction at Sayre.

A transfer station was established at Depew Junction, for handling passenger business via Suspension Bridge, at a cost of $12,546.

The locomotive coaling trestle at East Buffalo, which was partially destroyed by fire in January, 1906, was rebuilt during the year at an expense of $27,325.

Extensive renewals were made to Pier 3, New York, and Wharf No. 2 at Perth Amboy, aggregating a cost of $37,114.

A water tank of 100,000 gallons capacity, together with the necessary piping and pumps, was installed at Coxton, and a 34,000-gallon capacity tank at Niagara Docks. Two ten-inch standpipes were installed at Manchester and one ten-inch standpipe at National Stores.

During the year 71 new industries were located on your Company's line, track connections being made with 28 of these plants.

65.17 per cent. of the total operating expenses of the Railroad Company, or $14,412,015.11, was paid direct to labor, being distributed among 23,003 employees.

The principal purchases of real estate have been at Bayonne, Lehighton, Wilkesbarre and Buffalo, where additional land was required for the extension or enlargement of present facilities.

The Board takes pleasure in hereby tendering its thanks to the officers and employees of the Company for the efficient and loyal services rendered by them during the year.

By order of the Board of Directors,

E. B. Thomas, *President.*

COMPARATIVE INCOME ACCOUNT FOR THE YEARS ENDED JUNE 30, 1907 AND 1906.

Lehigh Valley Railroad Company.

RAILROAD GAZETTE

ESTABLISHED IN APRIL, 1856.

PUBLISHED EVERY FRIDAY BY THE RAILROAD GAZETTE AT 83 FULTON STREET, NEW YORK.
BRANCH OFFICES AT 376 OLD COLONY BUILDING, CHICAGO, AND QUEEN ANNE'S CHAMBERS, WESTMINSTER, LONDON.

EDITORIAL ANNOUNCEMENTS.

THE BRITISH AND EASTERN CONTINENTS edition of the Railroad Gazette is published each Friday at Queen Anne's Chambers, Westminster, London. It contains selected reading pages from the Railroad Gazette, together with additional British and foreign matter, and is issued under the name Railway Gazette.

CONTRIBUTIONS.—Subscribers and others will materially assist in making our news accurate and complete if they will send early information of events which take place under their observation. Discussions of subjects pertaining to all departments of railroad business by men practically acquainted with them are especially desired.

ADVERTISEMENTS.—We wish it distinctly understood that we will entertain no proposition to publish anything in this journal for pay, EXCEPT IN THE ADVERTISING COLUMNS. We give in our editorial columns OUR OWN opinions, and these only, and in our news columns present only such matter as we consider interesting and important to our readers. Those who wish to recommend their inventions, machinery, supplies, financial schemes, etc., to our readers, can do so fully in our advertising columns, but it is useless to ask us to recommend them editorially, either for money or in consideration of advertising patronage.

OFFICERS.—In accordance with the law of the state of New York, the following announcement is made of the office of publication, at 83 Fulton St., New York, N.Y., and the names of the officers and editors of The Railroad Gazette:

CONTENTS

VOL. XLIII., No. 9. FRIDAY, AUGUST 30, 1907.

In our issue of Aug. 2 we called attention to the first of the bulletins issued by the committee on car efficiency of the American Railway Association, showing surpluses and shortages of revenue freight cars on July 10 on all the principal roads. Statistical bulletin No. 2 has now appeared, continuing the previous study in the effort to show the causes which affect the efficiency of a freight car Mr. Hale, chairman of the committee, has done a remarkable piece of work in collecting the figures thus presented. His report covers 163 roads, and gives for each one, except in rare cases where the information was partially not available, a complete history of its car balance and performance for the six months ended Dec. 31, 1906. Four measures are used to determine car efficiency: per cent. of cars in shop, average miles per car per day, per cent. of loaded mileage and average loading of cars. Thus, the average per cent. of cars in shop for all roads reporting is 5.48. Mr. Hale points out that it is customary on many roads to make reductions from time to time in shop expenses, and though this may not occur often when there is a local shortage, it is frequent practice when there is a general shortage. His statistical findings show very clearly the actual cost of this, since a decrease of but one-half of 1 per cent. in the number of cars in shop would be equivalent to an increase of 9,490 cars in service, with an approximate value of $9,500,000. One of the roads listed showed a percentage of cars in shop as high as 30.69. The average number of cars on line per freight engine owned is given as 82, but individual averages run as high as 231, excluding one company not fairly comparable. The average daily earnings of all cars on the line is $2.51, and the average per car owned is $2.59. In one instance the individual average of all cars on the line was $11.42, and it is reported as low as 88 cents in ordinary service, but it does not fall below $1.07 on any railroad of importance. Earnings of from four to six dollars a day occur frequently in the compilation. The common assumption, therefore, that freight cars on a busy line earn five dollars a day is a conservative one. The average mileage per car per day is 24.2, including, as in the previous figures, 11 Canadian and Mexican lines, and 71 per cent. of the mileage is loaded. The average ton mileage per car mile is 13.6, and the average ton mileage per loaded car mile, 19.4 per car per day, the average ton mileage is 329. The average daily car journey is lowest in the southern states (18.3 miles), not in the New England states (18.5 miles) as might have been expected. The Union Pacific reports a daily car journey of 48.8 miles in Montana, Wyoming, Nebraska and the Dakotas, while one of the largest lines in the South can only get 14.6 miles.

THE PRESENT COST OF MONEY.

In accounting for the present depreciation in the quoted values of railroad and industrial shares and securities it is often mentioned and it is apparent that a general cause is the world-wide demand for money, aggravated in the United States by a hostile governmental and legislative attitude. It is interesting and perhaps worth while to look a little farther and see if this unprecedented demand for capital among all the great nations is comparatively permanent or passing.

In the period of from two to five years ago the transportation and other industries in this country were at high tide, as they still are. They needed and easily got, at reasonable interest rates, all the money needed for rapidly increased facilities, and this money came from England, Germany, Holland, and for the first time in large amounts from France, as well as from our own people. In that period the industrial situation on the Continent was none too good. In spots it was bad. German manufacturing was only beginning to show signs of improvement under the artificial stimulus of cash subsidies and a rebate of freight rates on exported products. The government contribution to the German maker of exported locomotives is about ten per cent., not far from $1,500 per locomotive. Generally speaking, the capital requirements in Germany and the other European manufacturing nations was less than normal, because business was not very good. In England business was distinctly bad. "Armies of the unemployed" were organizing and marching to an extent that was mildly threatening. Old schemes, many of them fantastic, for making work for working people without enough to live on, were revived, discussed and sometimes tried. Money earning small return in Europe flowed in billions to investment in American railroads and, less generally, in industrials.

Looking back for thirty-five years there is further and quite uniform evidence for an inference. During our periods of most acute depression following the years 1873 and 1893, as well as during our other severe but less keenly felt reaction, the conditions in Europe were quite different, and sometimes were reversed. For a generation our seasons of highest prosperity have not been coincident with foreign prosperity. For the first time in recent history we meet long continuing prosperity in the four great manufacturing nations. They are in opposition. More and more capital expenditures in all these countries have at the same time become highly profitable, both as a means of earning more and in order to produce cheaper. When it pays to borrow capital money for great under-

takings at from six to seven per cent., and when Fortune, perforce, smiles alike in three languages, the resulting effect on the interest rate is inevitable.

And the awakening; the certain effect on the prices of shares, notes and first-class bonds? The price of bonds is affected the least. The holdings of restricted institutions, trustees and estates are the last to be changed, but the market is narrowed and almost choked. The device of two- and three-year notes of great corporations, to tide over the times of too widespread prosperity, has been useful, until the coming of the 7 per cent. rate; then the conservative officer halts.

As we look back at it now, the prices of dividend paying stocks have been too slow to yield to the pressure. Up to about a year ago, strong stocks may be said to have sold at a price to yield from 4 to 4½ per cent. Speaking generally, good stocks are now quoted on a 6½ to 7 per cent. basis. With a prevailing interest rate increased from 4 to 5½ per cent.; from 4½ to 6, and from 5 to 7 per cent., varying with the time and the security, there comes quite late a depreciation in the prices of good stocks of from 17 to 33 per cent.

The object of this reference is not at all to consider the investment or speculative value of corporate securities at present prices; it is simply to point out to officers of railroad and manufacturing companies that this present depreciation in security prices, this increased interest rate, means to them not only added difficulty in getting new capital, but also an increased operating cost, or, rather, more deduction from net earnings. They buy materials and hire labor and money. The cost of material has increased less than is ordinarily counted. For example, the cost of locomotives per unit of horse-power developed is less now than it was ten years ago. The cost of labor has increased quite 20 per cent., rated in cost per hour, but its efficiency has decreased largely—by a percentage which no one is competent to estimate. The added cost of money comes last, and it is evidently as much as 25 per cent.

THE SALE OF THE CHICAGO & ALTON.

Even while Wall Street is in the depths, there comes news of a new railroad merger. The Toledo, St. Louis & Western, a small road with one single line connecting Detroit and Toledo on the east with St. Louis on the west, adds to its 450 miles of line and $4,200,000 of gross earnings the 970 miles and $11,600,000 gross earnings of the Chicago & Alton, a far stronger and better equipped property. This has been brought about through its acquisition of $20,800,000 of the total of about $40,000,000 capital stock of the Chicago & Alton. This controlling block of Alton stock was sold by the Rock Island Company and interests identified with it. The Rock Island made its investment in Chicago & Alton in 1903 after the Union Pacific has acquired over $10,000,000 Chicago & Alton preferred stock. The Rock Island's object was to prevent the road from falling under entire control of the Union Pacific. In this the Rock Island interests were successful, for they secured more than enough stock to give them actual control of the property. Despite this fact, an agreement was made with the Union Pacific by which the Alton was to be held under a system of alternating control, the Union Pacific managing the property one year and the Rock Island the next. This agreement, however, was abrogated last June. The Rock Island Company controls the Chicago & Eastern Illinois, which parallels the Alton between Chicago and St. Louis, and the St. Louis, Kansas City & Colorado, which parallels the Alton between St. Louis and Kansas City. The Rock Island's control of the Alton therefore drew unfavorable criticism from the Interstate Commerce Commission. The Rock Island interests realized that they would not be allowed by the United States Government to keep possession of the Chicago & Alton, and therefore were glad to sell the property to the Toledo, St. Louis & Western at a loss said to be about $1,500,000 on the original investment.

The Chicago & Alton stock purchased by the Toledo, St. Louis & Western is to be paid for by that company by issuing its collateral trust bonds secured by the Alton stock. Four per cent. bonds are to be issued against the preferred stock at par and 2 per cent. bonds against the common stock at 35. The rate on these latter bonds is to be raised to 4 per cent. at the end of five years. Figuring the preferred stock at par and the common stock at 35, the par value of these collateral securities which the Toledo, St. Louis & Western is to issue will be $11,227,000, of which $6,380,000, issued against the preferred stock, will be paying 4 per cent. and $4,847,000, issued against the common stock, will be paying 2 per cent. This makes an average rate of 3.1 per cent. which the Clover Leaf will be paying on the par value of its Alton-collateral bonds during the first five years of their existence. It is obvious that in the present state of the market collateral trust bonds of a road like the Toledo, St. Louis & Western, which until five months ago had never declared a dividend and which occupies by no means a commanding position among the railroads of the country, secured by stock of the Chicago & Alton, a railroad at a moment peculiarly under the ban of alleged over-capitalization, could not be sold on a basis to yield anything like 3.1 per cent. In fact they almost certainly could not be sold on twice as favorable an income basis; for short term notes and equipment trusts of the strongest railroads in the country are selling at better than 6.2 per cent. Yet since the Clover Leaf has five years before its rate of payment on the total amount of these bonds rises from 3.1 per cent. to 4 per cent., it is hardly fair to figure the investment at the extremely low prices now prevailing, which would probably give an income return on these bonds of 7 per cent. or more. Taking 6.2 per cent., twice the rate paid on the par value of the bonds, as a fair rate for the five years, we may consider the actual cash price paid for the Rock Island's Alton holdings as $5,613,500, half the par value of the collateral trust 4 per cent. and 2 per cent. bonds. The Rock Island's original investment in Chicago & Alton stock is said to have been about $10,000,000; on this basis the loss was about $4,400,000. If there is to be a decided change for the better in stock market conditions, and continued prosperity, the rising value of the collateral trust bonds would lower the amount of this loss.

As for the physical aspects of the merger, there is one obvious advantage to both roads. By building seven miles of line from Panama, Ill., on the Toledo, St. Louis & Western 50 miles northeast of St. Louis, west to Litchfield, the eastern terminus of a Chicago & Alton branch line, the consolidated system will have a short through line from Kansas City east to Toledo and Detroit, giving a long haul on traffic between Kansas City and the East. Aside from this, there are no strikingly obvious physical advantages from the merger. A map on another page shows the relation of the two roads and also the Iowa Central and the Minneapolis & St. Louis, two roads controlled by the same interests as those at the head of the Toledo, St. Louis & Western. With the building of the short connection already mentioned, it will be possible to haul grain from points as far west as the Missouri river in northern South Dakota, east as far as Lake Erie over the system's own rails; but, as can be seen from the map, this would be a rather roundabout route. It would also be possible with the same limitation to form a through route from Chicago to Minneapolis and St. Paul and to South Dakota over the Chicago & Alton to Peoria, the Iowa Central to Albert Lea, Minn., and the Minneapolis & St. Louis to St. Paul and South Dakota. It is possible that the four roads will be more closely united in a single system with centralized management. They all serve rich traffic territory, but highly competitive. On all through business they must meet severe competition by better situated carriers; yet such a system is not without its possibilities.

"STRIKE" CHARTERS AND THEIR WARNINGS.

A phase of prospective street railway overcapitalization which made its appearance not long ago in Connecticut serves at once as a text and a warning to conservative capital in these hustling days when that kind of capital—along with more blameworthy sorts—is so commonly the object of public and legislative attack. We have heretofore had occasion to point out the symptoms and seriousness of the dropsy disease in street railway finance in both Rhode Island and Connecticut and how in the latter state there had come too late a public awakening and reaction, caused immediately by what was, in effect, the guaranteeing of a 4 per cent. annual dividend on some $18,000,000 of watered stock of the Connecticut Railway and Lighting Company by the New York, New Haven & Hartford. This aroused public sentiment naturally gave the street railway promoters a pause; but it was only a temporary pause, evolving into a new and rather original form of subtlety.

At the opening of the last Connecticut legislature, and during the first few weeks allowed for the introduction of new measures, it was noticed that there were bills relating to street railway charters remarkable in number for a period of tight money and public suspicion about trolley enterprise, and in a state where, as it seemed to the expert eye, profitable trolley territory had been exhausted. At first these projects did not attract attention. They seemed independent of each other, isolated, and with no coherent and ulterior purpose. But presently it was observed that they seemed to focus

in a definite region along the shore and in rough parallelism to the New Haven company's steam line of about 50 miles between New Haven and New London, and reaching up toward Middletown, besides some other proposed parallels in other parts of the state. About the same time two other schemes came to the surface. They involved charters like that of the Connecticut Railway & Lighting Company, which gave large power of purchase, absorption and merger and unlimited privilege in the issue of stock. The "promoting" scheme in its full magnitude was finally brought to light, namely, the bunching of the street railway projects in one or two power companies, next either a "sell out" of the whole watered outfit to the menaced steam corporation or the building of the parallels and the enlargement of the club to pound the steam company into final surrender. Later in the session the scheme was substantially defeated.

This Connecticut case is cited here only as one of numberless instances elsewhere of the workings of "high finance" in its relations to legislation. The devices have been many: First there is the new charter, seemingly harmless in shape and formal in outward character but, hidden away in some obscure clause, containing the desired and dangerous powers. Next there is the "charter amendment," sometimes prolix and masking the same evil. Again, most subtle and dangerous of all, is the "merger" trick worked through the minor charter of a small railway enterprise. The small charter—so small as to the project that it quite escapes notice—is asked for and obtained readily. Next comes along, a year or two later, the true parent, the larger corporation, which, having acknowledged ownership of the small enterprise, asks for merger with acquisition also of its charter powers. Nobody in the legislature remembers what the small charter granted, and the merger bill that may invest the great corporation with immense and undreamed of powers, goes through with a snap on some day of high legislative pressure of business. Added to such examples are the multiplied cases of "hawk" charters obtained simply to be sold and, too often, charters with such a reach that they apply legally to enterprises far different than those indicated by any cursory reading of the text.

The average legislator, though he may be absolutely honest, is apt to be too ignorant or inexpert to detect such charter stratagems. Railroad committees of state lawmaking bodies are too often "set up" to let just such projects through; and state railroad commissions are apt to deem prevention as beyond their own jurisdiction and refer them to the law-making responsibility. The public is protected from them in most cases only when it happens that some strong corporate interest is opposed. In the Connecticut case, for instance, it is doubtful whether the seeming "strike" on a large scale would have been exposed except for the antagonized interest of the New Haven company. But the public find the stratagems out at last, usually too late to be rectified by law, but not too late to excite public wrath. It would be interesting if we could measure how far that discovery, repeated year after year and driven into the public mind by repetition, now enters into the anti-corporation feeling of the country, that involves the railroads. It certainly is a component in that feeling not to be ignored. And its lesson to the corporations is that legislation, and particularly, charter legislation, when sought hereafter should be sought along straightforward and not devious lines.

To corporation interests that are unscrupulous, such an appeal, of course, is made in vain. But there are other corporation interests broad-minded and far-sighted enough, we trust, to see that trick legislation harvests in the end as its share of a general penalty greater loss than can be made good by transitory gain. In other words, as to such matters as stock watering, honest finance and the public are as one in partnership and should be equally aggressive in resistance. Had honest finance, expressed in the corporation form, realized that fact sooner, and with its keener and quicker intelligence set itself against the evil, we might now be hearing less of public prejudice and legislative inequity.

The Railway Employment Safety Appliances Committee.

"The Railway Employment Safety Appliances Committee" of the British Board of Trade is the name of a board of three gentlemen—H. A. Yorke, Richard Bell and Robert Turnbull—which has during the past 12 months been considering the question whether or not the hand brakes on freight cars can be arranged so that the brakeman can apply them or let them off from either side of the car; and the committee gives it up as an impracticable task. This committee was appointed by the Board of Trade a year ago last April, and although it was instructed to examine, so far as new fit, any kind of appliance designed to diminish danger to railroad employees, it has thus far considered only this one subject. The reader will recall that seven years ago the English Parliament after two years' investigation, passed a law dealing with a number of questions concerning safety appliances, chiefly questions connected with freight yard work, and that the Board of Trade two years later issued rules on the subject. The rules, however, did not cover the brake question and the appointment of this committee appears to have been in pursuance of the policy, begun in connection with the legislation of 1900, to do everything possible to meet the demands, some of them rather unpractical, of the labor unions. Mr. Bell, the second member of this committee, is head of the Amalgamated Association of Railway Servants; Mr. Turnbull is Chief Passenger Manager of the London & North-Western Railroad, and Colonel Yorke, Chairman of the Committee, is the well known Chief Inspector of the Board of Trade.

The "Either-Side Brake" question has been agitated because when a shunter, in the hurry of his work, finds that a car which he wishes to move has the brake held on by the lever on the opposite side of the car, he is liable to risk his life by crossing to the other side of the car or train under dangerous conditions. The brakes of the English freight car ("waggon") are controlled by a long horizontal lever on the side of the car, and the men are most of the time on the ground. The weight of this lever, when the handle end is not fastened up, is alone sufficient to apply the brakes with considerable force. To apply it more forcibly the brakeman can press it down, while running along on the ground at the side of the car, or he may jump up and stand on the lever, utilizing the whole weight of his body. Still further, he may use a stick, somewhat larger than the "pick-handle" used by American brakemen, and by utilizing the sill of the car as a fulcrum he can secure the advantage of double leverage.

It is easy enough to arrange the two levers on the opposite sides of the car so that either one can be used to apply the brakes, but the difficulty is to interconnect these two levers so that when releasing one of them the other one shall also be unfastened.

The committee met 14 times during the year. Thirty or 40 brakes or models of brakes were examined and criticised or rejected, and then after a few weeks the same and other devices would be taken up again; but finally, after giving every opportunity to inventors and railroad companies, the committee decided that none of the appliances had sufficient merit to warrant its general adoption. Moreover, if a simultaneous movement of the two levers could be satisfactorily accomplished, there would always be danger that with men on opposite sides of a wagon, one of them, unknown to the other, would move the lever so as to cause bodily danger to the other man.

There are in the United Kingdom 1,400,000 vehicles to which the ordinary hand brake is applicable; of these 33,000 are already fitted with brakes which can be applied and released from either side; 172,000 have brakes which can be applied on both sides but not released. Included in the total mentioned are 650,000 private cars. The committee finds that where there are two levers they are often fixed so that both extend in the same direction from the middle of the car, whereas they ought to extend in opposite directions, so that the arrangement would be "cross-cornered."

In looking over the records of men killed and injured because of the lack of a lever on one side of a wagon, it was found that more men were killed when applying brakes than when releasing; so, finally, the committee recommended that the Board of Trade require after a certain date, that all new wagons have cross-cornered brake levers; that within seven years wagons having a lever on one side shall have a lever on the other side, and those having none shall have two; that within 10 years those having the levers single-ended be changed to cross-cornered; and that no either-side brake be put on hereafter unless it has been approved by the Board of Trade, on the advice of this committee.

The New York Central on Sunday last restored its New York City electrified terminal lines to "right-hand running," at the same time putting 13 miles of its elaborate new all-electric signaling in service. This was a great undertaking and it appears to have been carried out with a good degree of success. A brief account of it is given on another page. Trains were delayed on Monday forenoon and Monday evening, many of them for over an hour each, but Tuesday morning showed an improvement and Tuesday evening was almost normal.

These delays were due to instructions to lose a little time, to extreme caution on the part of enginemen, to one switch failure, and to a few mistakes of signalmen. The task of the men on Monday morning was made harder by a heavy extra passenger movement. There were further delays on Wednesday, due apparently to failures in automatic signal working; but as a whole the work appears to have been highly creditable. Comparing the delays with the magnitude of the work the results appear to have been far more

satisfactory than on the occasion of former radical changes at the New York terminal. In changing the interlocking at 56th street, where the four tracks in Park avenue diverge to the station layouts, an exceptional record was made. Here a new interlocking plant had to be installed. An 88-lever all-electric machine replaced an 84 all-electric machine. The entire change was made from the old to the new machine and the new put in operation for traffic (at 4 a.m.) in just seven minutes. To make this change, 38 men were assigned. The last previous change made at this point was in April, 1906, at which time a low pressure pneumatic machine was replaced by the 84-lever all-electric machine. The change at that time consumed 25 minutes.

A description of the way in which the change was made is published on page 227.

CONTRIBUTIONS

The "Brother Jonathan" and the "Robert Fulton."

Binghamton, N. Y., Aug. 10, 1907.

To the Editor of the Railroad Gazette:

At the end of the year 1833 Stephenson & Co. built two engines named "Brother Jonathan" and "Robert Fulton" for the Mohawk & Hudson Railroad, which was chartered in 1826 and opened September 12, 1831. This railroad is now a part of the New York Central system. The builder's numbers of these locomotives were 60 and 61.

I do not know who designed these engines, but probably one of the two Stephensons, who founded their locomotive works at Newcastle-upon-Tyne in 1821, the business being still carried on under the name of Robert Stephenson & Co., but they have lately moved their shops to Darlington.

Herewith I send you a copy of the working drawing of the above named engines, which, although it is very imperfect, is the only one in Messrs. Stephensons possession, as they recently informed me.

The cylinders were inside the smokebox. Under the barrel of the boiler there were a pair of vibrating shafts, each having an inner and an outer arm. The inside arms received motion from the pistons and usual rods, and transmitted it by the outside arms and connecting rods to the driving wheels. This was probably done to retain the advantage of inside cylinders with the driving wheel position afterwards adopted by Baldwin. It also got rid of the long connecting rod, which was an objectionable feature of the early Baldwin engines.

The cylinders were 10 in. diameter by 15 in. stroke; driving wheels, 48 in. diameter. The eccentric blades ran back from the driving axle and were connected by rocking arms and drop hooks to the reversing levers, and from thence forward to the rocking shafts behind the smokebox. The valve chests must have been at the top of the cylinders.

In reference to the Baldwin engines it may be noted that the idea of placing the driving wheels behind the firebox did not originate with him as is generally supposed, for his first engine of this design was not completed until February 18, 1834, but the first locomotive with a leading truck, designed by John B. Jervis, Chief Engineer of the Mohawk & Hudson Railroad, and placed in service at the beginning of 1832, was an inside connected engine with the driving wheels behind the firebox, and its history will be found in the *Railroad Gazette*, Vols. III. and IV.

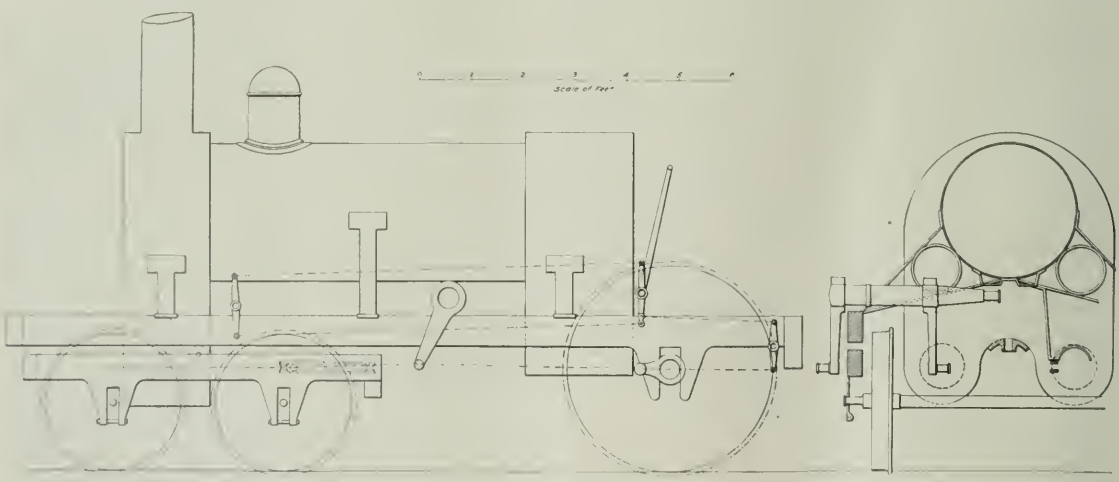
In the early days of the locomotive, many curious designs were brought out which quickly fell into disuse, although some of them were revived from time to time, and a few of them quite recently. A study of locomotive history reveals the fact that nearly every modern improvement in the locomotive, including the four-crank balanced engine, can be traced back to the early thirties, when George Stephenson was in the height of his power, and his "Rocket" was doing regular every day work. An illustration of the fact that history repeats itself may be made by taking the designs of locomotives having intermediate gear between the cylinders and driving wheels to balance the reciprocating parts without the use of four cranks. This was done as far back as 1833, but strong patent claims for these designs have been granted to more than one modern inventor, and I have reason to believe that the time is not far distant when we shall have a revival of this class of locomotive.

In the engines illustrated herewith there was no attempt to balance the reciprocating parts, since both inner and outer side levers rocked in the same direction. Had the inside arms been oppositely disposed to the outside arms, we should have had an example of the side lever locomotive which was introduced about the same time as these Stephenson engines, and drawings of which I may send you at some future time.

Herbert T. Walker.

Railroad Legislation in Pennsylvania.

The laws passed this year in Pennsylvania to establish a Railroad Commission and to reduce passenger fares have already been noticed in the *Railroad Gazette*. Besides these the Legislature also passed a number of less important acts, a summary of which is given herewith, together with some of the details of the Railroad Commission Law.



Working Drawings of Stephenson's Engines Numbers 60 and 61 for the Mohawk & Hudson Railroad, 1833-34.

An Act prohibiting the placing of lights at places where they may interfere with the view of railroad signals.

One requiring railroads to report Aug. 31, and every third year thereafter, the exact number of statute miles of line operated; penalty for violation $5,000.

One forbidding a demurrage charge of more than $1 per car per day; free time 48 hours.

One prohibiting common carriers from engaging in mining or manufacturing. Mining or manufacturing companies are permitted to haul their own product for a distance of 50 miles.

Forbidding railroad officers and employees to have any interest in any coal or mining or manufacturing property along the line of the railroad after Jan. 1, 1908; penalty $250 to $1,000 fine or three months to one year's imprisonment.

Prohibiting railroad companies from acquiring control of competing parallel street passenger railway lines.

Requiring railroad companies whose lines pass through forest land containing oil or gas wells to remove all inflammable material from the right of way at least once annually, also to provide suf-

ficient trackmen to extinguish fires; also to provide engines with spark arresters.

A number of laws were passed prescribing penalties for violation of provisions of the constitution, and all of the laws above mentioned have severe penalty clauses.

A law was passed permitting street railways to carry express and light freight, and granting to them power to acquire a contemplated route by condemnation proceedings where 51 per cent. of the property owners consent.

The Railroad Commission law provides that one of the three members shall be learned in the law. One of the three is to be appointed for five years and ultimately five years will be the term of all the members. The Governor is to designate the Chairman. The Commission is to have a Secretary, an Attorney and a Marshal. The Attorney is to conduct the examination of witnesses at hearings, when requested to do so by the Commission, and is to assist the Attorney General of the state in all actions brought by him incidental to the recommendations and rulings of the Commission. The Commission may appoint other officers including an inspector, who must be a civil engineer skilled in railroad affairs and another inspector expert in electrical affairs. The office of the Commission will be in Harrisburg. Its proceedings shall be public upon the request of either party interested. The act appears to be intended to give the Commission authority over all common carriers, though we do not find a clear statement to this effect; but section six, defining the term "common carrier" includes persons and corporations transporting freight or passengers by water as well as by railroad or electric railway; it also includes pipe lines "engaged in the transportation of oil" and sleeping car companies "engaged in transporting passengers" and express companies "engaged in transporting property upon any railroad, electric railway, street railway or by water"; also telegraph and telephone companies.

The Commission after full hearing may declare rates unjust and recommend what will be the just rate to be thereafter observed as the maximum. (Section 8.)

Section 9. If a shipper or consignee renders any service in connection with transportation, the allowance therefor shall not be more than is just and reasonable.

Section 10. The Commission or its agent may enter and remain during business hours in cars, offices and depots, and may examine books, etc. It may order the production of testimony or of papers, and in case of disobedience may call on the Court of Common Pleas to enforce such an order. Where the Court finds that neglect or refusal of a witness is occasioned by the advice or consent of a carrier, the fine against the witness may be collected from the carrier.

On request of the Secretary of Internal Affairs or the Legislature, or the Governor, the Commission may have a hearing on any proposed change of law relating to common carriers.

Section 12. The Commission may require every common carrier to file with it a copy of its annual report which is sent to the Interstate Commerce Commission.

Section 13. The Commission is to investigate accidents when deemed advisable. Accidents must be reported immediately after their occurrence.

Section 14. The Commission is to regulate the establishment of crossings of one railroad with another, including electric railways, and shall recommend what safety appliances are necessary both at new crossings and at existing grade crossings.

Section 15. If a common carrier violates the law or neglects its duty or usurps authority not granted by law, the Commission is to notify the carrier; and, if the offence is continued, certify the matter to the Attorney General.

Common carriers must within 30 days notify the Commission whether or not they intend to comply with an order.

Section 17. In case of excessive rates or insufficient or unsafe fixtures or works, or inaufficient trains or cars or faulty modes of operating, the Commission shall notify the carrier what to do, and if after full hearing the carrier refuses or neglects, or fails to satisfy the Commission that nothing should be done, the Commission must certify to the Secretary of Internal Affairs and the Attorney General the facts for their action according to law.

In case of a proposed increase in stock or bonds, the Commission may employ experts to investigate the necessity for the proposed increase, and report to the Secretary of Internal Affairs.

Section 18. No examination, request or advice of the Commission nor any investigation or report made by it shall impair in any manner or degree the legal rights, duties or obligations of any common carrier or its legal liabilities for the consequences of its acts or of the negligence or mismanagement of any of its agents or employees.

Section 19. Common carriers must furnish the Commission any necessary information concerning rates, contracts, etc. The Commissioners shall not make this information public unless the public interest requires publicity, nor if publicity would injure the common carriers of the state.

Section 21. An annual report is to be made to the Governor by the second Monday of January, and a duplicate filed with the Secretary of Internal Affairs. Nothing in this act shall impair the authority of the Secretary of Internal Affairs in the exercise of supervision of railroads and canals.

Section 23. Salary of Commissioners, $8,000 each; Secretary $4,000; attorney, $4,000, and marshal, $2,500.

Section 24. The total annual expenses of the Commission shall not exceed $100,000.

This Act goes into effect January 1, 1908.

Newark Warehouse of the Central Railroad of New Jersey.

The Newark Warehouse Company, a subsidiary company of the Central Railroad of New Jersey, on August 1 formally opened for service its building at Mechanic, Lawrence and Ward streets, Newark, N. J. The accompanying photographs and drawings show the size and general arrangement of this modern freight handling depot. Freight cars are switched into the building on the second floor level, from which their contents are unloaded either to be lowered to the floor below and loaded directly on trucks, for which there are driveways on this floor, or to the platforms and then by a complete elevator system lifted to the floors above, there to be stored awaiting consignee's orders.

The building is 357 ft. by an average depth of 145 ft.; it is 102 ft. high and has a ground area of 52,000 sq. ft. and a floor area

Newark Warehouse, Showing Wagon Entrance.

of 370,000 sq. ft. It occupies the whole of a rectangular city block just between the point at which the Central Railroad of New Jersey tracks into Newark cross over the main line of the Pennsylvania and the Broad street terminal station in Newark. The warehouse has six floors and a basement. The first floor is the team floor, the second, the track floor; the third, fourth, fifth and sixth, the storage floors. The total storage capacity is about 1,200 carloads of freight.

The whole building is made of reinforced concrete and fireproof. The construction is steel frame and concrete wall, with a foundation of steel beam grillage and concrete. The floors are of metal plate and reinforced concrete, designed to support 300 lbs. per sq. ft. throughout and 500 lbs. per sq. ft. in certain areas. The partitions are steel frames and hollow fireproof tile. Windows and sky-lights have metal frames and wire glass and close automatically. All partition openings are protected by automatically closing fireproof doors.

There are nine platform elevators, two 8 ft. x 12 ft. and seven

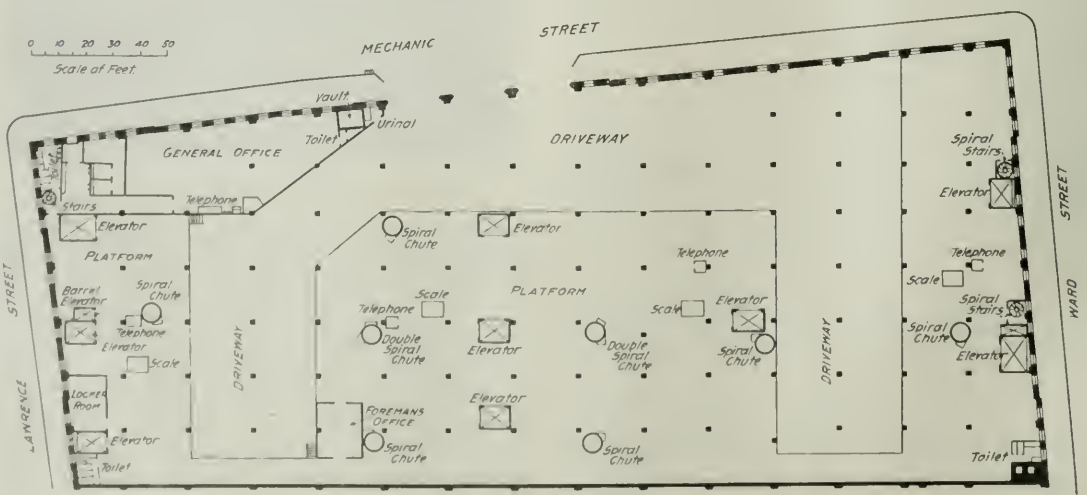
Plan of Second Floor Showing Railroad Tracks and Platforms.



Plan of Street Level Floor Showing Driveways and Elevators.

7 ft. x 10 ft., all of 6,000 lbs. capacity; also five barrel elevators with capacity of eight flour barrels per minute each, and eight spiral chutes, pneumatic chutes for carrying invoices, etc. The building is lighted by electricity throughout, and has complete telephone connections. The fire protection for merchandise on storage consists of automatic Springer equipment with two 750 gal. electric-driven fire pumps.

The location is convenient to the wholesale business district of Newark. The building is approached by well paved streets, and the teamways on the first floor are large enough to furnish access to platform space of 25,800 sq. ft., on which goods can be handled for team delivery; this floor is to be used only for this purpose. On the track floor there is standing room for 43 cars alongside freight platforms.

View of Newark Warehouse from Central Railroad of New Jersey Tracks.

This warehouse is worthy of note because it represents the latest and most improved designs and methods for such a building, and also because it is an example of a railroad entering indirectly in the warehouse business. The warehouse company suggests that merchants can abandon local storage or relieve crowded storage space by sending their goods to the warehouse, where storage charges will be less than the cost would be to the merchant himself, with the great additional advantage that goods can be received or shipped without any cartage expense. The warehouse company is prepared to act as the representative of merchants and handle goods as directed. The manufacturer may at certain seasons, when it is necessary to hold goods to accommodate trade conditions, store them with the warehouse company, who will insure them and act as shipper, distributing the goods as ordered and furnishing the manufacturer with negotiable warehouse receipts that may be realized on at once if desired. The broker or commission merchant, who sells and buys, can get along with only an office or deskroom by having the warehouse company take care of his goods, fill the orders that he issues and forward his consignments, all for less expense than can be secured elsewhere. He can also in this way buy large quantities of goods and hold them for change in market and have the warehouse company care for them and issue negotiable warehouse receipts. The connection of the railroad with such a project lies in the fact that if the warehouse company furnishes satisfactory service to these different classes of business men, the business of these men will, as long as they are using these warehouse facilities, naturally travel over the Central Railroad of New Jersey. For the information, photographs and drawings published herewith, we are indebted to Joseph O. Osgood, Chief Engineer of the Central Railroad of New Jersey, and Engineer of the Newark Warehouse Company.

Track Floor of Warehouse, Showing Tracks and Platforms.

Reversal of Track Running on the New York Central.

On Sunday last, August 25, the trains of the Harlem division of the New York Central between New York and Croton Falls, 41 miles, began running on the right-hand track, reversing the left-hand practice that has been in vogue for the past 12 or 13 years, and at the same time the section of 13 miles nearest New York, all four tracks, called the Electric division, was the scene of a sweeping change in signaling, the new all-electric block and interlocking signals being put in service, and green adopted for the night all-clear indication. These signals have been in course of construction for the past year and a description of them was published in the *Railroad Gazette* of June 28, 1906.

The line may be briefly described as follows: The southern terminus consists of the old (Grand Central) and the new (Lexington avenue) yards side by side. These converge at 56th street where the four-track line and tunnel begin. The outside tracks are numbered 1 and 4. The tunnel extends north from 56th street to 98th street, two miles. The first station is 125th street. One-half mile farther is the Harlem river draw (135th street). At 149th street is Mott Haven Junction, 5¼ miles from the terminal, where the Hudson division diverges to the left. The Electric division extends to Wakefield, 7¼ miles from this junction and 12½ miles from the terminals. Just south of Wakefield the New York, New Haven & Hartford diverges to the right. Following is an account of the work done on the Electric division. Between Wakefield and Croton Falls a similar change was made, involving chiefly automatic block signals which had to be changed but not renewed. Here as on the Electric division the night fixed signal indications were changed from white to green for proceed and green to yellow for caution. On part of the territory a number of new style "D" Union electric motors were put in service.

CHANGES ON ELECTRIC DIVISION.

Tracks 2 and 3 between 56th street and Wakefield were put out of service at 7 p.m. Saturday and were restored to service under right-hand traffic at 4 a.m. Sunday; also tracks 2 and 3 between Wakefield and Mount Vernon.

At 4 a.m. Sunday tracks 1 and 4 between 56th street and Wakefield were put out of service and at 8.30 a.m. were restored to service under right-hand running between Wakefield and Mott Haven Junction. Between Mott Haven Junction and 56th street these

tracks were put in service under right-hand running at 7.30 p.m. Sunday.

All of the new automatic signals were set up (minus the blades) and worked for a number of days before they were put in service; so that at the final moment the principal part of the work on these was to attach the blades to the new signals and take the blades and lamps off from the old ones. Between 98th street and Mount Vernon the old signals were controlled manual. The work at interlockings was of course more complicated.

The total mileage affected by this reversal was approximately 13.37 miles of four track and one-half mile of double track. On this territory there was a drawbridge equipped with mitre end lift rails. The position of these lift rails was reversed to accommodate the new conditions. The drawbridge was interlocked with an interlocking plant which was kept in service on two tracks during the transition period and a new all-electric machine was put in use in place of it. In other words, while work was progressing on tracks 2 and 3 the mechanical machine controlled the draw and protected movements over the two tracks then in service (1 and 4) and the new electric machine was installed on 2 and 3 so that when the traffic was reversed and these tracks put in service protection was afforded by the new machine. At the same time all of the lock and block apparatus, including torpedo machines, gongs, mechanical and electrical indicators in the Park avenue tunnel, were rearranged in all their details to accommodate right-hand movement on tracks 2 and 3 prior to the reversal of traffic, and the same thing was done to tracks 1 and 4 while they were out of service.

At 56th street trains are diverted to the two separate terminal stations. Here an all-electric machine has been in service for several months. This was abandoned and a new machine substituted, adding a number of new switches and signals. Also the electro-pneumatic interlocking at Mott Haven Junction was entirely rebuilt under traffic, as well as a second electro-pneumatic at the junction on the west side of Mott Haven yard, where it connects with the Hudson division.

The change in the tunnel not only affected the lock and block apparatus but also five mechanical machines and two low-pressure pneumatics as well. The revolving signals which have been in use in this tunnel for a number of years had to be connected to the towers for right-hand running and their indications were changed from white to green for proceed and from green to yellow for caution.

At the same time that these changes were being made, the two low-pressure pneumatic interlocking machines in the old terminal and one all-electric in the Lexington avenue terminal were rearranged for right-hand routes. The mechanical interlocking plants at 106th street and at Mount Vernon were also changed under traffic.

Altogether the change brought about the abandonment of five mechanical, one low-pressure pneumatic and four electro-pneumatic interlocking plants, while seven electric interlockings were put in service. To accomplish this work 575 men were employed in the various signal, track and bridge departments, and the entire reversal was accomplished by 4 p.m. on Sunday, and all tracks were restored to service at 7.30 p.m.

At the time that this reversal was taking place it was also necessary to change from white to green for proceed and from green to yellow for caution on the night signal indications throughout all of the territory named, and also the old and new terminals; also between High Bridge and Spuyten Duyvil cut on the Hudson division.

The following is a list of the plants affected:

	Levers.	
MECHANICAL PLANTS ABANDONED.

The signals placed in service supplied 344 high indications (homes and distants) and 201 dwarfs.

In order that this work should be efficiently handled a separate system of despatching for work trains was established. Work trains were assigned to the tracks which were put out of service, and these were used for the handling of material and men from one point to another. North of Mott Haven Junction electric work trains were used and south of Mott Haven Junction steam engines, it being found advisable to do so on account of the added convenience of cutting off the current from the rails on which work was in progress.

All of the forces employed on this work were handled through this despatching system under the direct charge of H. S. Balliet as installation director, who worked by telegraph from his office at No. 5 Vanderbilt avenue, west of the Grand Central Station. All the men assigned to the work reported to that office and were not permitted to move from one locality to another without first receiving its authority. In this way the work was concentrated very effectively.

The details of the work were handled through the Electric Zone Signal Department under the charge of Azel Ames, Jr., Signal Engineer; the General Railway Signal Company, W. G. Hovey, Construction Manager; C. E. Lindsay, Engineer Maintenance of Way on the Electric division, and H. S. Balliet, Engineer of Maintenance of Way of the Grand Central Station and Signal Engineer of the Electric division.

At the Harlem river draw the interlockings have been so designed that under the new arrangement considerable time is saved in opening and closing the draw. The new interlocking (all-electric) is so arranged that the draw and lever controlling the engine part of the draw as well as each individual lift-rail are bolt locked, with a facing point lock. Derails of the Hayes type are fixed on each track at each end of the draw.

The signals for the normal direction are standard semaphores. For reverse movements, standard electric dwarfs are used, of two types; one the standard shape of arm, of small size, and the other a disk. The disk is used on but one track, and this is on account of scant clearances.

On the north fixed span there are automatic home and distant block signals. These were put in for the purpose of better spacing the trains. The full block over-lap is used with all of the signals north of the tunnel. Through the tunnel, the controlled manual system continues in service, the levers being controlled by track circuits throughout the block, and with 800 ft. over-laps.

Under the present arrangement—that is, as long as steam engines are used in the tunnel—there will be no change in block sections, but after automatic signaling is introduced in the tunnel there will be one more inbound and two more outbound blocks on each track. Between 98th street and Mott Haven Junction the aggregate number of blocks on the four tracks has been increased from 13 to 26; and between Mott Haven and Woodlawn from 25 to 46.

A New Transcontinental Cut-Off for the Southern Pacific and the Santa Fe.

With the taking over last April of the Phoenix & Eastern, a Santa Fe branch line running from Phoenix, Ariz., east 100 miles to Winkleman on the Gila river, by the Southern Pacific, and the election of Epes Randolph, President of various Southern Pacific lines in Arizona, as its President, a definite step was taken in the development of what will in all probability ultimately become a new transcontinental cut-off for both the Southern Pacific and the Atchison, Topeka & Santa Fe.

Plans by both companies for the development of a new and better transcontinental line through Arizona have been in the making for at least two or three years. The accompanying map shows the present location of the through lines of the two roads and indicates, as nearly as it is possible to do at present, the extent of the new cut-off line. The recently completed Belen-Texico cut-off of the Santa Fe is included in the map as well as its eastern connection from Texico northward toward Kansas City, and the proposed connection southeast to Brownwood, Tex., and thence to Galveston.

The heavy lines on the map west of Belen mark the known or the probable location of the new transcontinental cut-off of the two roads. The Phoenix & Eastern, as shown, runs from Phoenix,

Ariz., southeast to Florence, where it meets the Gila river and then follows up the river eastward to Winkleman, the present terminus. At San Carlos, about 34 miles up the Gila river beyond Winkleman, the Gila Valley, Globe & Northern line of the Southern Pacific crosses the river. To the north it runs to Globe; to the south, it follows up the river as far as Solomon (formerly Solomonville), and then turns south to connect with the Southern Pacific main line at Bowie.

The route between Winkleman and San Carlos was for years disputed by the Southern Pacific and the Santa Fe. As nearly as can be ascertained, the Santa Fe surveyed the first route northeast up the Gila canyon from Winkleman. This was an invasion of Southern Pacific territory, as such a line not only cut across the Gila Valley, Globe & Northern, but if extended less than 100 miles further would reach the Clifton mining district, now served only by the Arizona & New Mexico, which is the line owned by the Arizona Copper Company connecting the Clifton mines with the Southern Pacific main line at Lordsburg, N. Mex. The Southern Pacific at once hurried a surveying party to the Gila canyon and located almost exactly the same line that the Santa Fe had adopted from Kelvin, 15½ miles west of Winkleman, east to San Carlos. The Southern Pacific map of this route was filed a few hours before the Santa Fe map. The rights under these surveys were then carried into the local courts, where there were decisions and counter-decisions almost without number. Meanwhile the Santa Fe built and put in operation its line from Florence east to Winkleman. After Santa Fe trains were already running over the track on regular schedules a decision was handed down by one of the local courts awarding 17½ miles of the right-of-way from a point two miles west of Kelvin east to Dudleyville, which is two miles east of Winkleman, to the Southern Pacific, but forbidding either company to use this track for commercial purposes until the case was finally decided. On appeal, the Supreme Court of Arizona returned the track to the Santa Fe, pending a further appeal to the United States Supreme Court, on condition that the Santa Fe give a bond to indemnify the Southern Pacific in case the Santa Fe lost the final appeal. In order to strengthen its demands for the contested right-of-way the Southern Pacific in the fall of 1904 put a considerable force of men at work grading the proposed route east of Dudleyville. In November of that year there were about 500 men employed. Before work was stopped, early in 1905, grading was nearly finished from Winkleman through the lower Gila Box canyon, that is, for about 10 miles up the river. Meanwhile the Santa Fe awaited the final decision of the case.

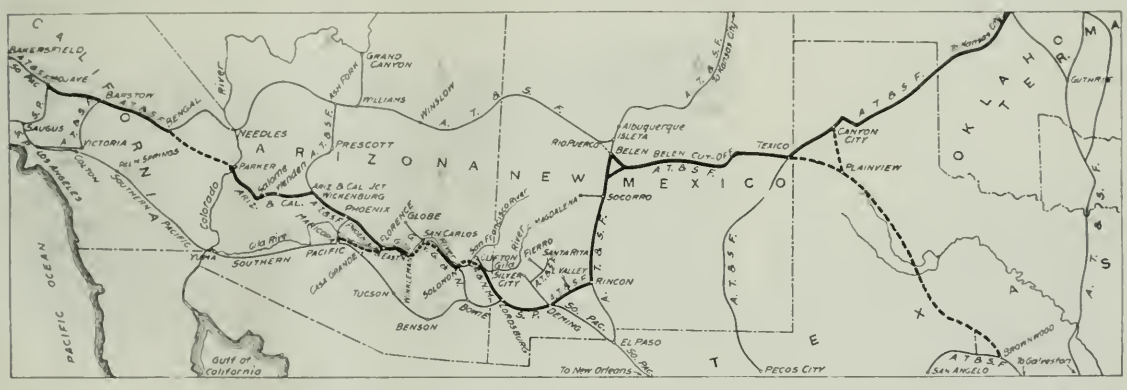
The Southern Pacific's grade through the Box canyon is on the north side of the Gila river. The contest between the two companies was not for a route where there was only one possible location, for from an engineering point of view there is little difference in the difficulties of construction on the two sides of the river through the canyon; but it was for ownership of an important feeder line over a route where it would not pay to build two competing lines. The decision of the United States Supreme Court was in favor of the Santa Fe, but by the sale of the Phoenix & Eastern to the Southern Pacific interests, ownership of the proposed route through the Gila canyon finally falls, as it should naturally from its territorial location and connections, to the Southern Pacific.

It is probable that this line was turned over by the Santa Fe to the Southern Pacific in course of arrangements for a new through line through Southern Arizona for both railroads. For the past three years construction work has been under way on a Santa Fe branch line, the Arizona & California, from Wickenburg, on the Ash Fork-Phoenix line, westward to the Colorado river. This is at present an undeveloped territory, though mining development is under way. The Arizona & California a new [illegible] the Colorado river, and its ultimate destination has been announced as Bengal, Cal., on the present Santa Fe main line, 80 miles west of the Colorado river. Bengal is to be the western end of the new transcontinental cut-off.

On the east, the Santa Fe plans have not been made public. The map shows how the Gila Canyon line could be reached over existing Santa Fe lines and a short stretch of the present Southern Pacific main line. This is a roundabout route but is marked out here in the absence of any official or semi-official information as to where a more direct connection with the new cut-off line is likely to eventually be built. A connection from Socorro, N. Mex., to the headwaters of the San Francisco river, thence down that river to its junction with the Gila near Clifton looks feasible on paper, but this route we are informed is more or less impracticable from an engineering standpoint and therefore is not ever likely to be built. Some such through connection, however, would seem to be a necessary part of the eventual plans of the Santa Fe if it is to share most efficiently in the new cut-off line through Arizona.

The connection on the east as shown on the map is as follows: A short connection will probably be built from the Belen cut-off to the present El Paso line, which will be followed as far south as Rincon, N. Mex., from which a Santa Fe branch now runs to Deming on the Southern Pacific. From here the route is over the Southern Pacific to Lordsburg, near the New Mexico-Arizona boundary, 60 miles. From Lordsburg the route would be the same for both Santa Fe and Southern Pacific.

Leaving the main line at Lordsburg, it would be either over the Arizona & New Mexico road nearly as far as Clifton, thence down the Gila river to Solomon, or by a new line built direct from Lordsburg to Solomon. From Solomon the route is over the Gila Valley, Globe & Northern (part of whose line is to be changed as shown) to San Carlos, where it would meet the extension of the Phoenix & Eastern line through the Gila canyon at its eastern terminus. Over the Phoenix & Eastern the route would run to Phoenix, over the Santa Fe to Wickenburg, and the Arizona & California to Bengal.



A Proposed Transcontinental Cut-Off Through Southern Arizona.

Adoption of these plans will result in changing the present transcontinental routes of both roads for many hundred miles. On the Santa Fe, from Rio Puerco, N. Mex., to Bengal, Cal., is 621 miles. Adding the approximate length of the connection from the new Belen cut-off to the present main line at Rio Puerco, the distance from Belen to Bengal by existing lines is about 640 miles. Of the projected route west of Belen already described there are three sections not yet built, so that it is impossible to get an exact estimate of the distance, but from Belen to Bengal the through route outlined on the map, which is undoubtedly, as already explained, considerably longer than any which is likely to be eventually

adopted, would probably be about 800 miles, made up as follows:

		Miles.
Belen, N. Mex. to Rincon	A., T. & S. F.	146
Rincon to Deming	A., T. & S. F.	53
Deming to Lordsburg	So. Pacific.	60
Lordsburg, N. Mex., to nr. Clifton, Ariz.	A. & N. M.	65
Point near Clifton to Solomon	Estimated.	42
Solomon to San Carlos	G. V., G. & N.	59
San Carlos to Winkleman	Estimated.	25
Winkleman to Phoenix	P. & E.	96
Phoenix to Wickenburg	A., T. & S. F.	54
Wickenburg to Colorado river	Ariz. & Cal.	113
Colorado river to Bengal, Cal.	Located.	92
Total		805

If the new through line of the Santa Fe east of Belen is counted in, the amount of new through line eventually to be used by that road is more than double this figure. From Newton, Kan., to Rio Puerco by the present through line via the Hutchinson cut-off is 737 miles. By the line from Newton southeast to Texico and Belen, the southern part of which is shown on the map by a heavy line, it is 716 miles; adding 19 miles as before for the distance from Belen to Rio Puerco, the total is 735 miles, the saving by the new line being in grades rather than in distance.

For the Southern Pacific the distance is less. From Lordsburg to Casa Grande over the present line is 230 miles. The new short cut-off would probably approximate the same length. From Lordsburg, N. Mex., to Mojave, Cal., by the present line is 765 miles. The new cut-off between these points would probably be just about 700 miles long, made up as follows:

		Miles.
Lordsburg, N. Mex., to Bengal, Cal.	As above.	546
Bengal to Mojave	A., T. & S. F.	163
Total		709

But saving in distance is not the object of the new cut-off line for either road. It is being built to get better grades and curvature. There are steep grades on the existing lines of both roads to be avoided. On the Southern Pacific in the neighborhood of Benson, Ariz., there is a ruling grade both east and westbound of 74 ft. to the mile, or 1.4 per cent. On this 164 miles between Lordsburg and Tucson there are total ascents of 2,148 ft. westbound and 4,003 ft. eastbound. These would be avoided by even the short Lordsburg-Casa Grande cut-off. Further west there are heavy grades which would be avoided by using the longer cut-off all the way to Mojave, Cal. Between Palm Springs, Cal., and Colton, 49 miles, the limiting gradients are 103 ft. to the mile, or 1.9 per cent. westbound, and 104 ft. eastbound, with total ascents of 1,898 ft. west- and 1,612 ft. eastbound. Between Colton and Los Angeles, 57 miles, the maximum grade exceeds 1 per cent. both ways, being 66 ft. to the mile, or 1.2 per cent. westbound, and 64 ft. to the mile eastbound, with total ascents of 395 ft. west- and 1,066 ft. eastbound. Thus such a new cut-off line would avoid three grades of over 1 per cent. both east- and westbound with total ascents of 4,441 ft. west- and 6,681 ft. eastbound.

On the Santa Fe between Winslow, Ariz., and Needles, Cal., 292 miles, there are 5,307 ft. of westbound and 9,678 ft. of eastbound ascents with ruling grades of 75 ft. to the mile (1.4 per cent.) westbound, and 137 ft. to the mile (2.5 per cent.) eastbound. From Needles west to Goffs, 31 miles, there is a rise of 2,104 ft. to the top of the Piute summit, and from Goffs west, a fall of 1,876 ft. in the 46 miles to Bengal. The Piute summit has an elevation of 2,580 ft. against a maximum elevation of 1,053 ft. over the Old Woman Mountain summit which the Arizona & California is to cross between the Colorado river and Bengal.

As the new line is not yet built it is impossible to say how much saving it will show in gradients and curvature over the existing lines, but as it follows water courses for much of its distance and has been laid out with the idea of improving on the existing roads, it is fair to assume that it will be a much more efficient line to operate than the present through line of either road.

Progress on the Florida East Coast's Key West Extension.

Rapid progress is being made on the Key West extension of the Florida East Coast Railroad, and unless some unforeseen difficulties arise or a violent tropical storm destroys some of the water work trains will be running over the "ocean route" within two years. The first locomotive crossed from the mainland, south of Homestead, over the drawbridge at Jew Fish creek to Key Largo, six months ago, and construction trains are now running over half the distance from Miami to Key West. Most of the water construction, however, lies west of the Matacombe keys, so work over the balance of the line may prove relatively slower. All told there will be a little more than 5¾ miles of concrete arches, which will require 206,100 cu. yds. of sand, 286,800 barrels of cement, 176,900 cu. yds. of stone and 4,810 tons of steel. One of the accompanying photographs shows a section of the Long key viaduct under construction.

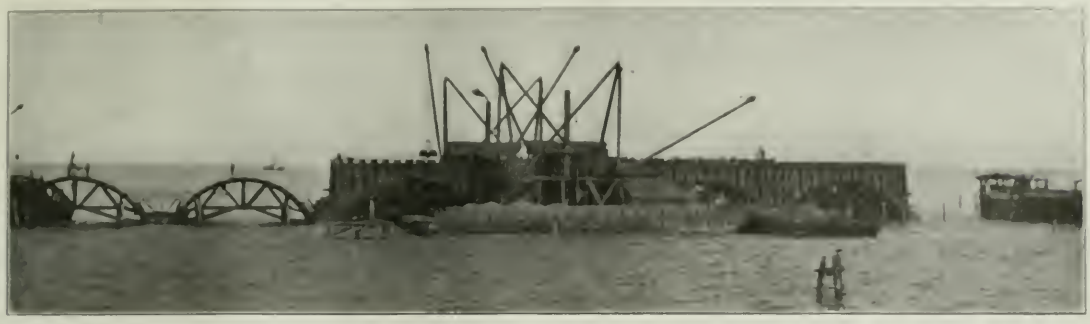
Embankment Thrown Up by Dredging.

Nearly 50 of the 184 concrete arches required at this point to connect with Conch key have been finished. They rise 31 ft. above the tide and have a span of from 50 ft. to 60 ft. There will be several drawbridges in this section.

The distance from Homestead, the old terminus of the Florida

Hydraulic Dredge Throwing Up Embankment in Shallow Water.

East Coast to Key West is 126 miles. Of this distance about 65 miles of the extension is built on solid ground on the keys. Of the remaining 60 miles nearly six miles will be concrete arches over deep water. The longest stretch is from Long key to Conch key 10,500 ft. Knight's key channel is 7,300 ft. Moser key channel 7,800 ft., and Ithala Honda channel 4,950 ft. The openings between



Long Key Viaduct under Construction; 184 Concrete Arches.

the keys will be closed by embankments where the water is shallow. These are thrown up by dredging and then rip rapped. Great difficulty has been experienced in reaching several of the small islands west of Big Pine key. The water between them is a series of rocky lagoons through which a channel had to be blasted to allow dredges and boats to get near the land.

A base of material supplies has been established at Knight's key, where a dock 600 ft. long by 175 ft. wide has been built with 19 ft. of water alongside. Sand, rock, cement and steel are stored there in enormous quantities. On Big Pine key a large tank has been built for storing water that was formerly carried on tank barges from Miami to the different camps. This reservoir holds over 1,000,000 gallons, being 90 ft. long, 40 ft. wide and 15 ft. deep.

The destructive tidal wave of last October which engulfed

End of Grade on Grassy Key; Florida East Coast's Key West Extension.

Elliott's key and other islands and drowned scores of workmen did little damage to the railroad construction work.

Symmetrical Masonry Arches—Coefficients for Reactions and Moments at the Supports.

BY MALVERD A. HOWE.

The elastic theory in designing masonry arches is coming into use with the introduction of concrete reinforced with steel. A thorough analysis of the stresses, however, is rarely made. This is probably due to a lack of familiarity with the methods or a lack of time, and, furthermore, because practical considerations do not make it feasible to design the arch ring to correspond to the maximum stresses at each section.

The application of the formulae based upon the elastic theory is very much more flexible than is generally supposed. The results obtained from a thorough analysis of a given arch ring can be used in designing a great number of other rings having quite different dimensions. The formulae in their integration form can rarely be employed owing to the shape of the arch axis and the variation in the moments of inertia. Summation formulæ have been devised, while approximate, which are quite accurate for all practical purposes. The summation formulae assume that the arch ring is divided into a number of finite lengths ds, sometimes equal but more often of unequal lengths, for which the moment of inertia is constant from one section to the next. This moment of inertia is usually that at the center of ds.

Assume that a certain arch ring has been designed upon and that its dimensions are known including the span and rise of the arch axis. Divide the span into 20 equal parts and measure or compute the lengths of the axis having these equal divisions as horizontal projections. These lengths are designated ds_1, ds_2, ds_3, etc. Bisect each of the 20 equal divisions of the span and through these points draw verticals until they intersect the axis of the arch. Beginning at the left number these points 1, 2, 3,....10, and from the right 1′ 2′ 3′....10′. Determine the co-ordinates x and y of each point referred to the left end of the span. Also compute the moment of inertia of the arch section at each point 1—1′ inclusive. Then for vertical loading, neglecting the axial stress, the horizontal thrust is given by the formula

$$2\,H_1 = \frac{\Sigma\, m_v\, \Delta \left(y - \frac{\Sigma\, y\, \Delta}{\Sigma\, \Delta} \right)}{\Sigma\, y\, \Delta \left(y - \frac{\Sigma\, y\, \Delta}{\Sigma\, \Delta} \right)}.$$

Where H_1 = the horizontal thrust

$\Delta = ds \div$ moment of inertia of section

y = ordinate of points 1, 2, 3, etc.

Σ = sum of factors for points 1—1′ inclusive

m_v = the common moment for the given loading on a beam supported at the ends *plus* the moment of an equal and symmetrical loading.

All quantities in the above expression with the exception of m_v are independent of the loading and consequently are constant for the given arch ring. Let $y = fy'$ and $\Delta = \Delta' \Delta_{10}$ where f = the rise of the arch axis and Δ_{10} = the value of Δ at point 10, then,

$$2\,H_1 = \frac{\Sigma\, m_v\, \Delta' \left(y' - \frac{\Sigma\, y'\, \Delta'}{\Sigma\, \Delta'} \right)}{f\, \Sigma\, y'\, \Delta' \left(y' - \frac{\Sigma\, y'\, \Delta'}{\Sigma\, \Delta'} \right)}$$

In which y' and Δ' have fixed values relative to the rise of the arch axis which has been taken as unity and the value of Δ at point 10 which has also been taken as unity, respectively. As long as the actual values of Δ vary in the same manner as the values of Δ' the value of H_1 will remain unchanged. Consequently an infinite number of arch rings can be designed fulfilling this condition without changing the value of H_1. If the actual values of y vary as the values of y' then the value of H varies inversely as the actual rise of the arch axis. The two statements made above assume that the

values of m_x remain the same under all conditions.

For a single vertical load

$$m_x = Px - \Sigma^x P\ (x - a)$$

where P = the magnitude of the load

and a = the abscissæ of the point of application of the load.

$$\text{Let } x = \frac{\delta_x}{2} z \text{ and } a = \frac{\delta_x}{2} k$$

then

$$m_x = P\frac{\delta_x}{2}\left(z - \Sigma^x (z - k)\right)$$

and when P = unity

$$m_x = \frac{\delta_x}{2}\left(z - \Sigma^x (z - k)\right) = \frac{\delta_x}{2} m_x'$$

For a single vertical load then, since $\frac{\delta_x}{2} = \frac{l}{40}$

$$2 H_1 = \frac{P\,l}{40 f} \frac{\Sigma m_x' \Delta' \left(y' - \frac{\Sigma y' \Delta'}{\Sigma \Delta'}\right)}{\Sigma y' \Delta' \left(y' - \frac{\Sigma y' \Delta'}{\Sigma \Delta'}\right)} = \frac{2\,l}{40 f} H' (P)$$

or

$$H_1 = \frac{l}{40 f} H' \text{ for unit load.}$$

Since m_x' is independent of the span and rise and also of any dimension of the arch ring, as long as the actual values of y and the actual values of Δ vary as y' and Δ' respectively, the value of H_1 varies directly as the span and inversely as the rise of the arch axis. The factor H' ÷ 40 is a constant and can be computed independently. It is more convenient to simply compute H'.

In table A are given the values of y', Δ' and H' obtained from the actual values for an arch ring having a span of 100 ft. and a rise of 8½ ft. The values of H_1 found from the coefficients in table A do not include the effect of the axial thrust. For very flat arches this should not be neglected. The horizontal thrust produced by the axial thrust is

$$H_a = H_1 \frac{\Sigma \frac{\delta_x}{F} \cos \Phi}{D' f^2 \Delta_{10} + \Sigma \frac{\delta_x}{F} \cos \Phi}$$

where H_a = the horizontal thrust due to the axial thrust

H_1 = the horizontal thrust neglecting the axial stress

δ_x = 1 ÷ 20 = length of one division of the span

F = area of arch ring at points 1, 2, 3, etc., respectively

f = rise of the arch axis

Δ_{10} = value of Δ at point 10

D' = coefficient given in table A.

The thrust H_a acts in a direction opposed to H_1 and consequently the true horizontal thrust is H_1—H_a. The effect of the axial stress may be considered independently as it is equivalent to a fall in temperature producing a horizontal thrust equal to H_a. The moment at each support is

$$M_1 = H_a \frac{\Sigma y \Delta}{\Sigma \Delta} = H_a f \frac{\Sigma y' \Delta'}{\Sigma \Delta'} = M_2$$

For changes in temperature

$$H_t = \frac{c\ t^0\ E}{D' f^2 \Delta_{10}} l = \frac{c\ t^0\ E\ l}{D}$$

where H_t = the horizontal thrust due to temperature changes

c = coefficient of expansion for 1°

t° = number of degrees change in temperature

E = Young's modulus of elasticity of the material composing the arch ring

l = length of span of arch axis:

The other factors have the significance given above.

The moment at each support is

$$M_t = H_t f \frac{\Sigma y' \Delta'}{\Sigma \Delta'} = M_2.$$

The moments at the supports produced by vertical loading can be found from the formula

$$M_1 = H_1 \frac{\Sigma y \Delta}{\Sigma \Delta} - m_1$$

Substituting the values of H_1, y and Δ used above

$$M_1 = \frac{l}{40 f} H' \frac{f \Delta_{10}}{\Delta_{10}} \frac{\Sigma y' \Delta'}{\Sigma \Delta'} - m_1 = \frac{\delta_x}{2}\left(H' \frac{\Sigma y' \Delta'}{\Sigma \Delta'}\right) - m_1$$

The value of m_1 is

$$m_1 = \frac{\Sigma m_x \Delta \left(x - \frac{\Sigma_x^2 \Delta}{\Sigma_x \Delta}\right)}{\Sigma \Delta \left(\frac{1}{2} l - \frac{\Sigma_x^2 \Delta}{\Sigma_x \Delta}\right)}$$

substituting $m_x = \frac{\delta_x}{2} m_x'$, $\Delta = \Delta' \Delta_{10}$ $x = \frac{\delta_x}{2} z$ and $l = 40 \frac{\delta_x}{2}$

$$m_1 = \frac{\Sigma m_x' \Delta' \left(z - \frac{\Sigma z^2 \Delta'}{\Sigma z \Delta'}\right)}{\Sigma \Delta' \left(40 - \frac{\Sigma z^2 \Delta'}{\Sigma \Delta'}\right)} \frac{\delta_x}{2} = \frac{\delta_x}{2} m_1'$$

Therefore for a unit load

$$M_1 = \frac{\delta_x}{2}\left(H' \frac{\Sigma y' \Delta'}{\Sigma \Delta'} - m_1'\right) = \frac{\delta_x}{2} M_1'$$

The expression within the brackets is independent of the span length and is constant as long as y and Δ change in the same manner as y' and Δ'.

In table A, columns 6-9 inclusive, give the values of $H'. \frac{\Sigma y' \Delta'}{\Sigma \Delta'}$ = K', m_1', m_2', M_1' and M_2'. The last two are all which are necessary as far as the arch analysis is concerned. The others are given as in some cases they were used for checks. Col. 8 should equal Col. 5 minus Col. 6 and Col. 9 should equal Col. 5 minus Col. 7. The last figure may not check as each column was computed independently and reduced by slide rule for the table.

The reactions V_1 and V_2 at the left and right supports are easily found

$$V_1 = \frac{M_2 - M_1}{l} + R_1$$

where R_1 is the left reaction for the loading if on a simple beam supported at the ends. The expression may be written, for unit load.

$$V_1 = \frac{\frac{\delta_x}{2}(M_2' - M_1')}{l \div \frac{\delta_x}{2}} + R_1$$

R_1 is constant for any span. The first term of the second member is also constant as both terms of the fraction have been divided by the same quantity giving quotients which are constant. Therefore the reactions remain constant for all spans as long as the actual values of y and Δ vary the same as y' and Δ'.

Knowing the values of H_1 M_1 and V_1 for unit loads the equilibrium polygon for each load may be constructed and then the points selected which must be loaded to produce the maximum moment at any given point of the arch rib. This was done for the values given in table A and the points determined which should be loaded to produce maximum moments at the support, the crown and point 6'. Then the corresponding values of H', M_1', M_2' and V_1 were computed. These quantities are given in table A, columns 16—19 inclusive.

These loadings are not absolutely correct in some cases but are not much in error. The effect of the axial stress has been neglected but can be included as shown above. Columns 16—19 are to be used for uniform moving loads only. The coefficients assume a unit load at the points designated in column 15.

For the dead or fixed loading the coefficients in columns 5, 8, 9, 11 and 12 are to be used and each coefficient multiplied by the fixed load corresponding to its number. If a slide rule is employed it means setting the rule but 10 times and obtaining 50 products composed of five sets of values which when added give everything necessary for the construction of the true equilibrium polygon.

Of course the above method of coefficients cannot be employed in the examination of a given arch ring. Its principal use is in designing new rings or modifying rings which do not fulfill certain conditions.

Table A.

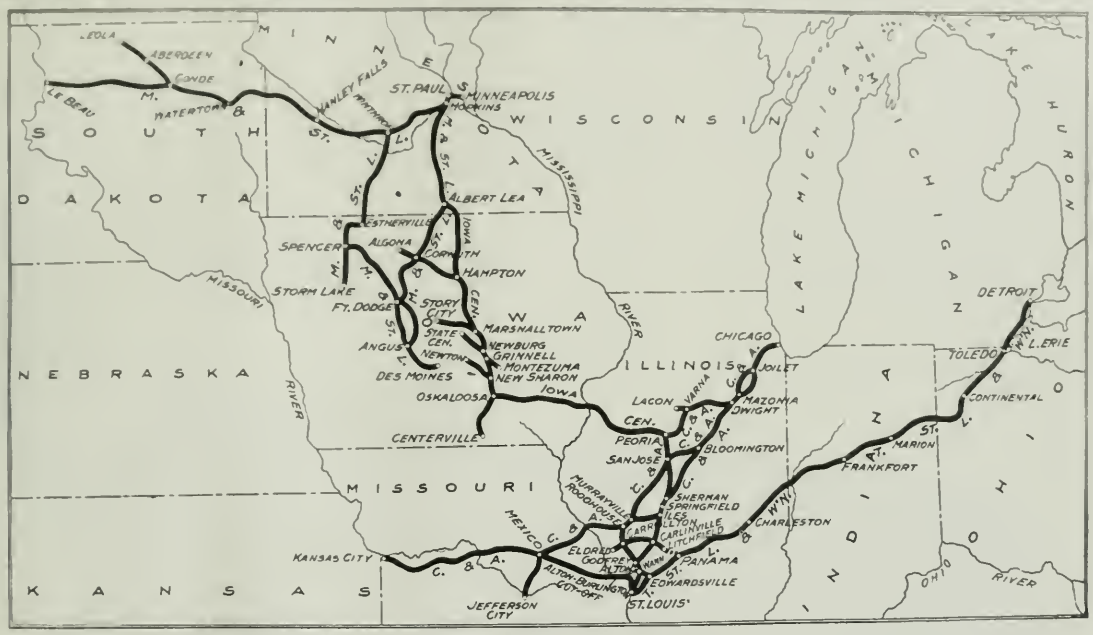
The Sale of the Chicago & Alton to the Toledo, St. Louis & Western.

On August 23 it was announced that the Toledo, St. Louis & Western had acquired control of more than a majority of the capital stock of the Chicago & Alton. The controlling interests in the Toledo, St. Louis & Western also control the Iowa Central and the Minneapolis & St. Louis. The accompanying map, therefore, shows these four railroads and their relation to each other. The Colorado & Southern, which runs from Orin Junction, Wyo., south through Denver, Colo., to Fort Worth, Houston and Galveston, Tex., in which the same men are largely interested, is not included in the map. The Toledo, St. Louis & Western has 451 miles of line and gross earnings of $4,200,000, the Chicago & Alton has 970 miles of line and gross earnings of $11,600,000. The Minneapolis & St. Louis has 800 miles of line and gross earnings of $3,700,000, and the Iowa Central, 558 miles of line and gross earnings of $3,000,000.



The Toledo, St. Louis & Western; Chicago & Alton; Iowa Central, and Minneapolis & St. Louis.

On May 11 1889 a new railroad law was passed. This contained all the good qualities of the earlier law, with certain improvements suggested by later experience both at home and abroad. Railroad building was encouraged as in the previous law by liberal land exemptions from taxes and duties for certain periods of years while the operation of the roads was facilitated by permission to form pools, divide shipments and apportion business by preventing the building of unnecessary parallel lines and by forbidding ticket scalping and all forms of rebates. At the same time the interests of the state were well cared for in the law by provisions whereby the actions of pools should be subject to approval of the government which also has the power to regulate and adjust freight and passenger rates at intervals of three years and to approve rates before they become operative. Further, the law lays down the rates to be charged for government business and provides for free mail service; this last provision being very different from the custom of some countries of paying higher rates than other shippers. One of the most interesting features is that which provides that the railroad property, except rolling stock and similar appliances, shall pass to the possession of the government at the expiration of the life of each concession, which is limited to 99 years.

The modern tendency toward consolidation appeared in Mexico in due course of time, among the railroad companies. The Mexican Central, originally 1,224 miles long, had been increased from time to time by construction of branch lines and finally by purchase of smaller roads, to about 3,000 miles of line in 1903. At this time rumors were in the air to the effect that certain interests, allied with the Standard Oil Company, were acquiring control of the system and that there were to be further combinations. Certain facts, as for instance the fact that H. Clay Pierce was Chairman of the Board, tended to confirm this rumor. Now it happened that the company was making surveys and plans for construction of a short line to the United States with terminus at San Antonio, Tex. This line would not only tap the valuable coal lands of northeastern Mexico, but also would remove the handicap under which the road had carried on its through business of the long haul by way of El Paso, which it could avoid only by making traffic arrangements with the Mexican International. About this time the government stepped into the breach. By acquiring stock in the open market, it obtained control of the National of Mexico, the Mexican International and the Interoceanic, which were combined in one system, though still retaining in a way their separate organizations. The combined mileage of these roads very nearly equalled that of the Mexican Central. It then appeared that the Mexican Central would not be given a concession for a line to the United States as had been planned, crossing the Rio Grande between the lines of the National and International roads, as this privilege had been granted to these latter roads exclusively. This put a stop to the Central's aspirations for a short line connection, and, in the light of subsequent events, made more desirable the merger now under way of all these roads under government control.

The Railroads of Mexico.*

BY ERDIS O. ROBINSON, C.E.
Formerly of the Engineering Department of the Mexican Central.

III.

RELATIONS BETWEEN GOVERNMENT AND RAILROADS.

Railroad development in Mexico as influenced by the laws of that country may be considered as having passed through several distinct periods. During the first there were no special inducements offered by the government to aid railroad construction and to attract capital. Nevertheless there were several roads planned and companies organized. There was ample confidence in the country and its industrial advancement. But, commercially, Mexico was new, business growth slow, distances great, and railroad construction difficult and costly; and with one exception these plans were not carried out. The only road built during this period was the Mexican Railway, from Vera Cruz to Mexico City, which was built to handle a well established business and therefore did not have to depend on future development.

In 1880 the government, realizing the necessity of railroad development to advance the prosperity of the whole country and being itself firmly established and at peace, enacted a law which provided for liberal subsidies, tariff and customs exemptions and governmental regulation of rates, life of concessions, charges for government business, etc. Thus early was inaugurated a policy which has since been followed consistently, whereby on the one hand railroad construction has been made easy for the companies, while on the other the rights and interests of the state have been carefully guarded. This law remained in force till 1900 and consequently most of the railroads have been built under it.

*The first article was published in the *Railroad Gazette* of July 12, 1907; the second, in the issue of Aug. 9, 1907.

It is not to be supposed that the government entered the railroad business merely to make money on its investment. Its object rather was to secure the prosperity of the country and guarantee its future against the arbitrary control of railroad corporations. It was not content to stop with what had been done. The difficulty encountered by the United States in its attempts to regulate the great railroad mergers did not pass unnoticed, nor did the fact that these efforts of the United States, though at times seeming to prevail, still in the end apparently put little hindrance in the way of railroad consolidations. The Mexican government felt that it was necessary to act before the railroads had become so powerful as to be invincible.

Hardly had the country become accustomed to the new order of things when, following later rumors as to the purchase of the Mexican Central by certain interests in the United States, it was announced in December, 1906, that the Mexican government had acquired a controlling interest in the securities of that road. By that act it became virtually supreme in the railroad field of the country, since it was the controlling influence in the three principal lines reaching the United States border, all the lines reaching the port of Tampico, the interoceanic line from Mexico City to Vera Cruz, the road under construction to the Pacific port of Manzanillo, the railroad crossing the Isthmus of Tehuantepec and the road connecting this with the Vera Cruz lines. Thus has Mexico become innoculated with the germ of modern life that produces an irresistible desire for consolidating like industries, and is fighting the trust tendency with the trust style of warfare. There is this difference, however, that the motives of the government are unselfish, since its desire is to protect the interests of the nation, which means of the people of the country, and also to advance the value of the railroad properties.

This action of Mexico merits the careful attention of the rest of the world, and will call for the exercise of rare tact and wisdom on the part of the government's representatives. Probably the fact that Mexico is in reality a paternal or autocratic government will render more simple the working out of the problem. Following the first merger, the National Lines of Mexico, under governmental control, the railroads combined were still, in the details of their management, operated as separate companies, while their larger policies were influenced by the government control. Probably some policy of this kind will be followed now, with the government in control but advised by practical railroad managers.

A question that has entered vitally into the operation of the railroads of Mexico, and on which the government has shown a friendly attitude toward the roads, has been the fluctuating value of the silver peso as compared with the standard gold coins of other nations. It will be seen that this fluctuation works to the advantage or disadvantage of the railroads according as to whether they are spending money at home or abroad. The income of a road doing business in Mexico is received in the peso of that country. Certain items of operating expenses such as wages and taxes, are paid in the same coin. If these were all that entered into the problem the matter of money fluctuation would affect the prosperity of the railroad company in only an indirect way. But the railroads have other payments to make. They are financed on a gold bond basis the interest payments of which must be met in gold, and many supplies must be purchased in foreign countries where gold payments are required. It will be seen that for every 1,000,000 pesos of net earnings there will be a shrinkage of $10,000 for every decline of one cent in the price of silver. In the early '90s there were declines in the peso of nearly 10 cents in a single year. This decline with a road earning 5,000,000 pesos would mean a shrinkage of $500,000 in the fund to be applied to bond payments or foreign purchases.

There is, of course, another side to this question. In borrowing money abroad to be expended on works in Mexico, it is evident that money borrowed while silver is at a low price will buy a greater number of silver pesos and consequently cover more work, since wages and domestic supplies do not fluctuate with the value of silver.

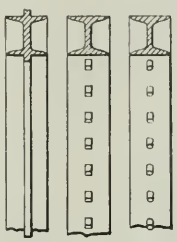
Expressed in figures the Mexican peso declined steadily in value from 83 cents in 1891 to 37 cents in 1902, and then rose again to a value of 50 cents in 1905. In this year the government, after a most careful and extended study of the whole matter, inaugurated a monetary reform. It was the object of this measure to place the Mexican currency on a stable gold basis with the value of the peso fixed at 50 cents. Up to the present time the attempt has succeeded, as the value of the peso has fluctuated little from that fixed figure. This stability of exchange warrants confidence in values, encourages the investment of capital, and by making money transactions more dependable greatly increases the convenience of doing business.

(To be continued.)

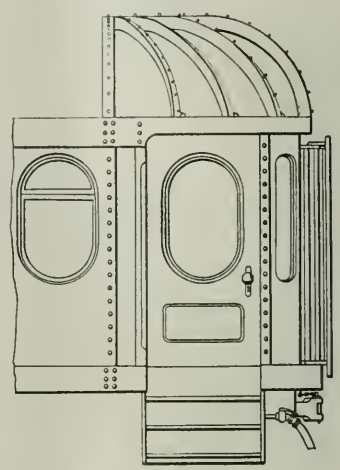
A New Pressed Steel Passenger Car.

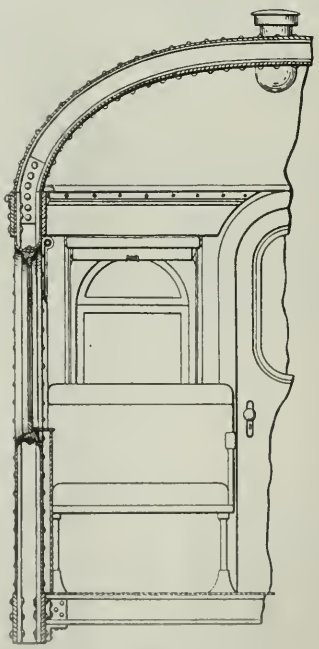
A patent has recently been issued to William G. Wagenhals, St. Louis, Mo., covering a design of steel passenger car built largely of pressed steel shapes. One of the accompanying photographs has been "doctored" to show the general appearance of a car built in this way. The drawings show the principal details of construction on which the patent was allowed. Steel plates about ⅛ in. thick, of a length equal to the height of the side of the car and of sufficient width to give the window opening desired, are placed in a special press and the oval openings for the windows are punched in them. The plates are then placed in another flanging press and the edges of the openings are bent down to form a continuous flange. All the rivet holes in the flanges and along the vertical edges of the plate are punched at one time. These plates are then made up in pairs, one forming the outside wall and the other the inside wall of the car. The oval flange on the inside plate is made smaller than the flange on the outside plate so that the two flanges overlap and can be riveted together.

The framing of the car is made up of two side sill plates between which the vertical I-beam posts are riveted. These I-beam

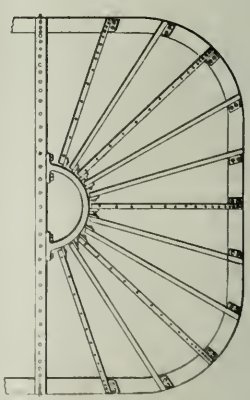


Method of Forming Rivets on I-Beam Posts.





Half Cross Section Through Wagenhals's Pressed Steel Car.

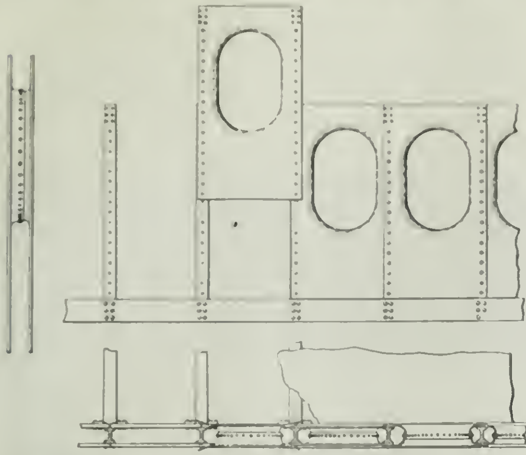


Plan and Side Elevation of Vestibule Hood Framing.

posts are rolled preferably from soft Norway iron suitable for riveting and are made with a projecting rib in the middle of each flange. By means of a special machine sections are cut out of these projecting ribs leaving square lugs which are afterwards rounded up into [illegible] plates. The frame having [illegible] plates are lowered into position over [illegible] out to clear the projecting rivets on the posts. [illegible] to overlap each other and when assembled [illegible] back over the rivets and the rivets headed up, securing both plates at one time.

After the sides are constructed, the roof beams are riveted in place. These roof beams are of the same construction as the side beams, except that they are curved to form an oval or turtle back roof, and are somewhat lighter in weight and size than the side beams as they are not required to carry any strain except holding the roof and sparing the sides. The rivets on these roof beams are formed in the same way as in the side beams. The roof and ceiling plates are riveted to these roof beams, in the same way as the sides, the plates running entirely across the roof and being in width about equal to the distance of four or five side sections. The outside plates are first riveted on and then the ceiling plates. Before riveting the roof plates in place, the letter board plates and transom plates are riveted in place at the top of the side plates. The roof plates overlap the upper edge of the letter board plate and the edges are secured by a finish molding running longitudinally and screwed in place. The ceiling plates are riveted in place last of all, and the joint between the ceiling plates and this inside plate is concealed by a metal molding.

For the window frames, a framework of aluminum or brass to fit the opening formed as a window opening in the side plates is used. This frame will cover the rivet heads in the window section, and in it is mounted the stationary window and a movable window, which can be lowered to open by drawing in the lower end of the window sash and dropping it into the pocket between the seats.



Method of Assembling Side Plates and Riveting to Posts.

Steel Passenger Car for the New York Central, Built by the St. Louis Car Company.

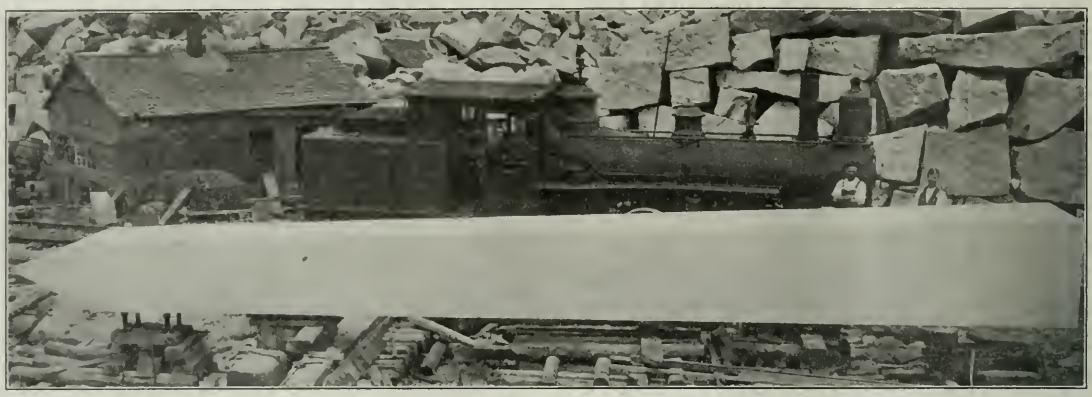
Wagenhals's Proposed Modification of Steel Passenger Car with Pressed Steel Side Plates and Curved Roof.

The sash for the windows are aluminum castings. The shade roller is mounted above the window on the inside of the car, in a metallic case, which case has extensions that reach to the bottom of the windows, and cover the rivet heads of the plate joints inside the car. They also have grooves on the inner sides to guide the curtain to the bottom of the window and to retain it in position.

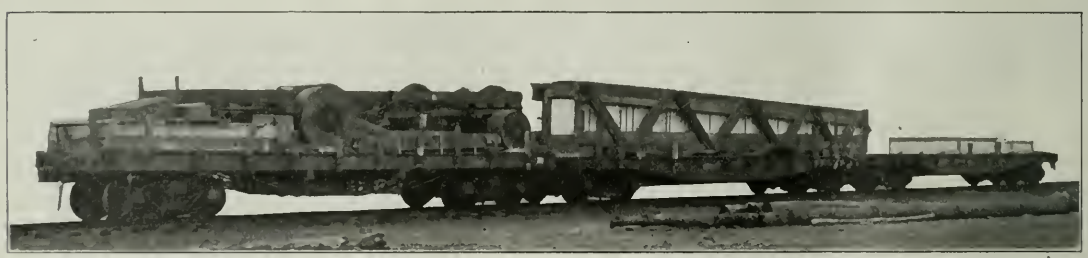
The construction of the ends of the car, the side walls of the vestibules, the door frames and the doors is the same as the construction for the sides of the car, but for the hoods over the vestibules a novel construction is provided. The last carline at each end of the car runs straight across from one side to the other, and to the middle of this carline is bolted a semi-circular casting of brass, steel or malleable iron, with lugs cast thereon extending out radially.

An Obelisk for Sault Ste Marie.

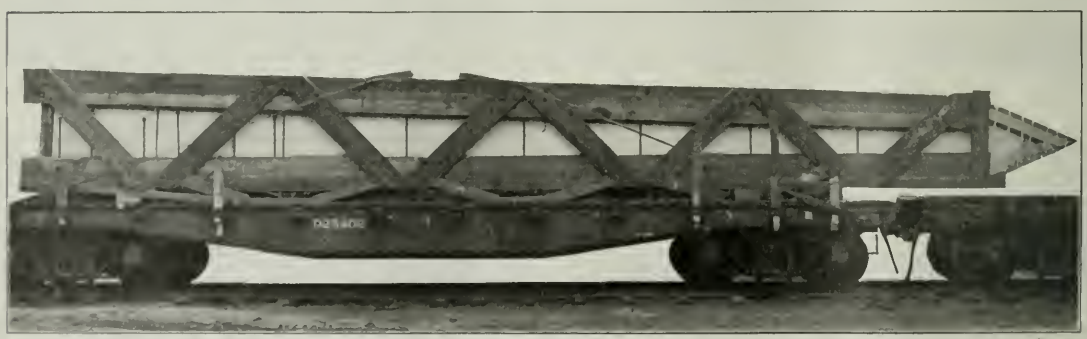
There was recently shipped from a quarry at Stony Creek, Conn., by The Norcross Brothers Company, general contractors, an obelisk which is to be erected in Locks Park, Sault Ste. Marie. The shaft is of hammered Stony Creek red granite, 5 ft. 5 in. square at the foot, tapering to 1 ft. square near the top and then finished to a point. It is 45 ft. long and is believed to be the longest shaft ever transported by rail in this country. The stone weighs about 60 tons. It was loaded on Pittsburg, Fort Wayne & Chicago car 931,701 and the bases on Pennsylvania Company car 92,540, the former of these cars being one generally used to transport heavy ordnance. As this car, which is 36 ft. long, was the longest car available, the



Obelisk for Sault Ste. Marie in the Quarry.



Whole Shipment, Including Obelisk, Bases and Machine.



Obelisk Loaded on Car.

Holes are cored in these wings or lugs and hood carlines bent to the shape of the roof required are bolted or riveted to the lugs of the casting and radiate therefrom to the edge beam of the roof to which they are secured by angle plates. The hood carlines are constructed in the same way as the side posts and main roof carlines with the rivets formed integrally on the top of the beams.

Instead of punching oval openings in the side plates for window openings, rectangular window spaces can be formed, and the flanges riveted together as in the case of the oval openings, but in such construction the corners of the flanges would have to be cut or severed, and the openings can then be covered by an ornamental molding forming part of the window frame. The oval construction, however, obviates the necessity of severing the flanges.

shaft was rested on a bed mounted on swivels to allow for the sway around curves. In loading the stone, it was jacked up to the level of the car; greased timbers similar to launching timbers for a ship put under it, and it was then smoothly and easily slid on the car without the use of any derrick. The accompanying photographs show the obelisk in the quarry before being loaded on the car; the obelisk boxed for shipment and loaded on the car and the three cars which made up the shipment; one containing the machine which was used to carry it at Sault Ste. Marie; the second the obelisk; and the third, the bases on which it is to rest. The shipment was made from Stony Creek, which is on the Shore Line division of the New York, New Haven & Hartford, west to Harlem river, and thence via the Star Union Line to its destination at Sault

Ste. Marie. The shipment left Stony Creek on July 16 and arrived at Sault Ste. Marie in good order on August 7.

The obelisk is being erected by the semi-centennial commission appointed two years ago to celebrate the opening of the first canal at Sault Ste. Marie.

Poor's Manual for 1907.

The advance sheets of the statistical tables from the 1907 edition of Poor's Manual, covering the year ended June 30, 1906, are at hand this year some two months earlier than usual.

The total length of railroads completed on Dec. 31, 1906, is given as 222,635 miles, as compared with 217,341 miles on Dec. 31, 1905, an increase for the year of 5,294 miles, while the increase of 1905 over 1904 was 4,947 miles. These figures, it will be observed, are for the calendar year, the balance of the statistics deal with the June 30 year. In the 12 months ended June 30, 1906, the southwestern group of states, embracing Missouri, Arkansas, Texas, Kansas, Colorado, New Mexico, Indian Territory and Oklahoma, built the most mileage, as in 1902, 1904 and 1905, the total for this group being 1,433 miles of new construction, as compared with 1,140 miles in 1905, 1,716 miles in 1904 and 1,892 miles in 1903. The northwestern group stands next with 1,099 miles, then the Pacific group, with 919. Texas has a long lead among the individual states, with the surprising record of 667 miles, as compared with 337 in 1905. Louisiana, with 323 miles, is second, and South Dakota, 309 miles, third. The new mileage in Texas is little short of the sum of new construction in the 11 states making up the middle and central northern group. New Hampshire, Vermont, Rhode Island, Connecticut, Delaware and Iowa built no new mileage.

Foreign Railroad Notes.

The Russian Minister of Railways has, according to press despatches, submitted to the Council of Ministers a scheme for improvements in the state railroads, which it is proposed to carry out during 1908-1912. The total estimated expenditure is $458,000,000, divided among five annual budgets. The principal items are: Double tracking, $46,000,000; bridges and embankments, $30,000,000; stations, $59,500,000; work-shops, $52,000,000; new rails, $30,000,000; cars and engines, $151,000,000.

The Austrian authorities are having a survey made of the streams available for water power in the mountainous parts of the country, with a view to their utilization for railroad motive power. The Railroad Minister declares that electricity should be used for large parts of the Arlberg Railroad, on the new Alpine railroads, and in all the long tunnels.

The Finance Minister of Argentina, in his budget for the year 1908, says that the government will henceforth leave the construc

tion of new railroads to private parties, and he proposes the annulment of several laws looking to the construction of railroads by the state. This recommendation, if carried out, will make a difference of $50,000,000 in the future national expenditures. The state owns about 1,700 miles of railroad, but there has been much waste of money in the construction of these lines and only one of them returns any interest on its cost. The Central Northern Railway, a state owned railroad extending toward Bolivia, will be completed to the frontier of that country by the end of this year, and the Argentine government, under a contract with Bolivia, will extend the railroad to Potosi.

The Chinese Eastern Railroad runs from the junction with the Vladivostok main line at Harbin southwesterly to Port Arthur, with connections to Pekin. It seems that since the war a gap of eight miles has been left between the northern section, controlled by the Russians, and the southern, which the Japanese manage. The through passenger from Europe to China must make this part of the journey on a Chinese cart or a Russian vehicle, either much less comfortable than a sleeping car. The passage is not made after dark, for fear of brigands. It takes from 80 to 96 hours to go from Harbin to Pekin, with several changes of cars.

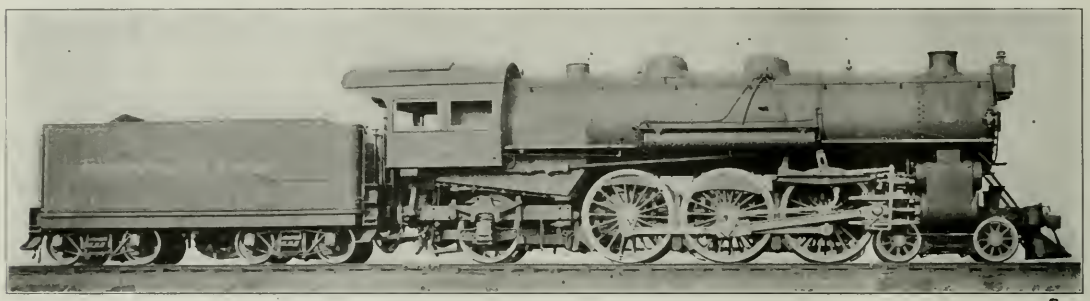
The Shantung Railroad (German) has made its report for the year 1906. It was opened for through business on June 1, 1904. The gross earnings of the 271 miles of railroad were $4,002 per mile in 1906, which is 13½ per cent. more than in 1905. The working expenses increased but a trifle, and were but 36 per cent. of gross earnings; so that the net earnings per mile were $2,561 in 1906, against $1,836 in 1905. A dividend of 4½ per cent. was paid. The traffic increased, but was by no means large, 816,810 passengers and 420,814 tons of freight having been carried, 228,663 tons of which were coal.

A plan has been worked out for the operation by electricity of the state railroads of Sweden. Power is to be generated at five water falls, the Karse, the Trollhätta, the Motala, the Hammarby and the Elfkarleby. Based on the requirements for 1905, the installation of the central power stations and the transmission lines would cost $16,400,000. The yearly operating expenses, including administration, are estimated at $1,578,000, as against $1,700,000 at present, a saving of $122,000. Single-phase current is to be used. The scheme will affect the operation of 1,240 miles of road and is the most extensive that has yet been proposed in Sweden.

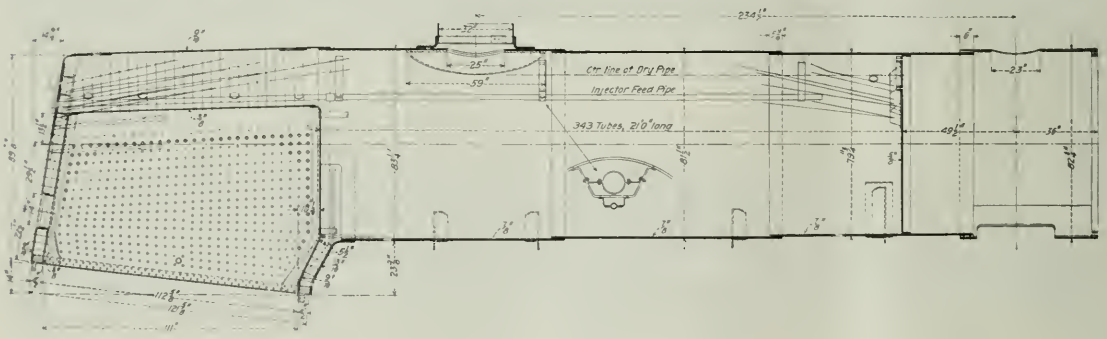
The British Government is to build 400 miles of railroad in Nigeria, Northern Africa.

Pacific Locomotive for the Pennsylvania Lines West.

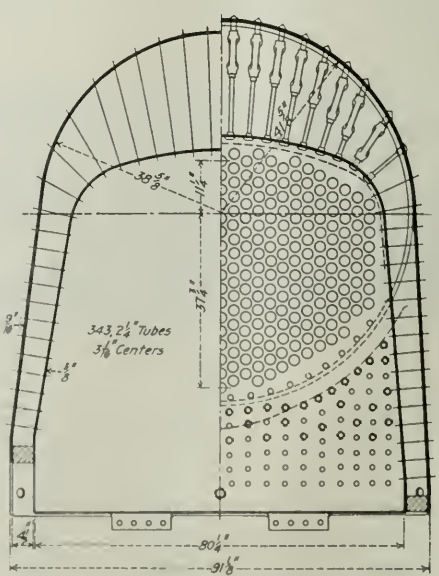
The American Locomotive Company has recently built a Pacific (4-6-2) locomotive for the Pennsylvania Lines West which is the heaviest passenger engine that has been built up to the present time for any road. The cylinders have a diameter of 24 in. and a piston stroke of 26 in. and can develop a tractive power of 31,000 lbs. This is about 22 per cent. more than that developed by the E-3d Atlantic engines of the same road. The introduction of the type was due to the demands of the traffic department for the movement of trains of greater weight, and because these demands could not be met without raising the weight on drivers on Atlantic engines above that which was considered safe. The Pacific type was therefore a necessity, if the weights on the driving wheels were



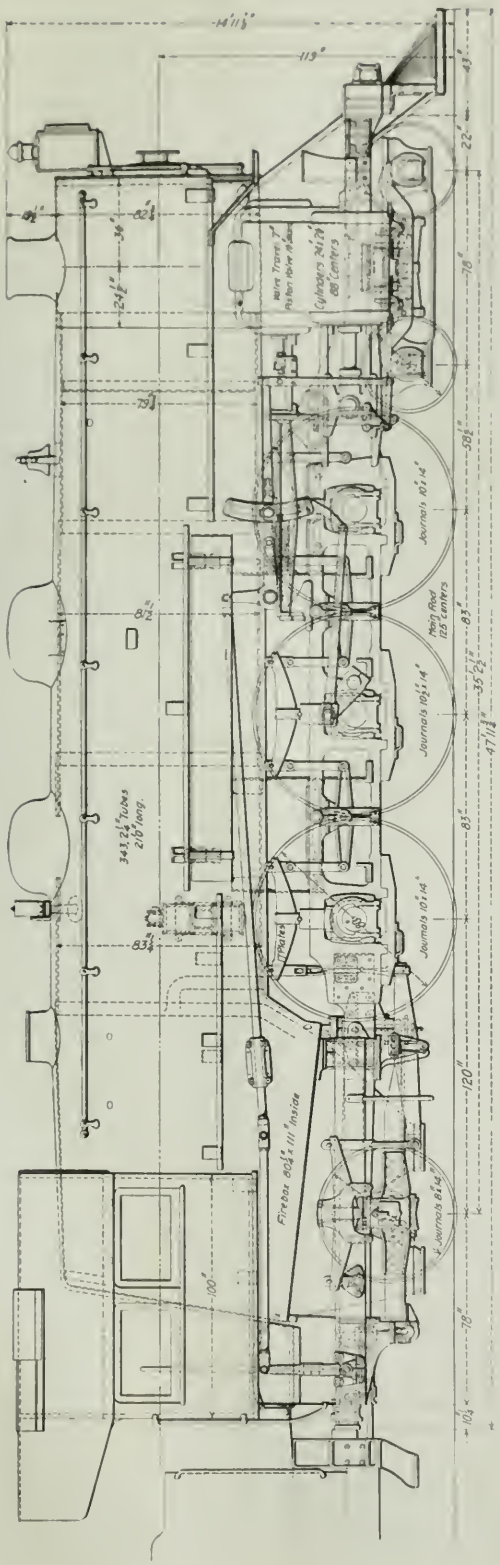
The Heaviest Passenger Locomotive; Pennsylvania Lines West.



Boiler of Pacific Locomotive; Pennsylvania Lines West.



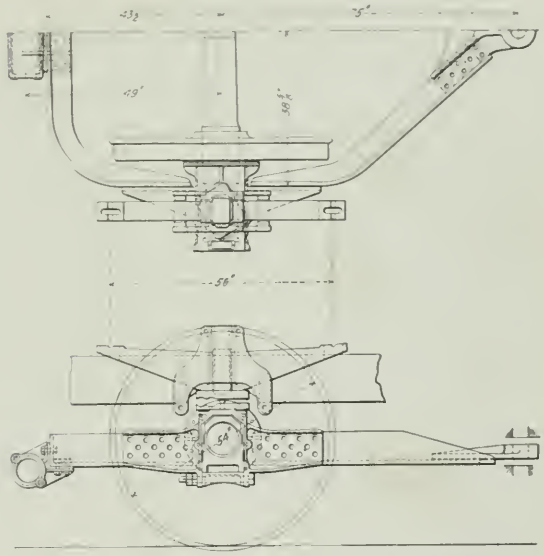
Section of Boiler at Firebox.



General Elevation; Pacific Locomotive for Pennsylvania Lines West.

to be kept below 60,000 lbs. per axle. As it is, this maximum is closely approached for, on the main drivers, it is [illegible] lbs., which is close to the upper limit.

Comparing this locomotive with the Atlantic E3d type which is used for heavy high-speed service it has cylinders 22 in. in diameter and 26 in. stroke, or an excess of 35 per cent. in cylinder capacity. Cylinder capacity however avails but little unless there is a corresponding steaming capacity to supply it. In this case the total heating surface is 4,427 sq. ft. for the Pacific as compared with 2,640 sq. ft. for the Atlantic. This marked increase is obtained by lengthening the tubes from 15 ft. to 21 ft., increasing their number from 315 to 343, and for this extra length a diameter of 2¼ in. was used instead of 2 in. This required a larger shell, which has accordingly been made 79¾ in. in diameter instead of 65 in. on the smaller engines. The boiler presents no striking features of construction aside from its size and the fact that it is a departure from the standard Belpaire firebox that has been in use on the Pennsylvania for all classes of equipment. The steam pressure is 210 lbs. This combination of large diameters and high pressure involves somewhat heavier sheets than are ordinarily used, and the thickness has accordingly been increased to ⅞ in. for the whole shell, or 1/16 in. more than the sheets ordinarily used on boilers of smaller diameter. The roof sheet and the back tubesheet are each 7/16 in. thick, and the front tubesheet is ⅝ in. The staybolt spacing is 3¾ in. and bolts 1 in. in diameter are used. The flexible stays are carried down on the front and back rows to within four



Trailing Truck; Pacific Locomotive for the Pennsylvania Lines West.

and six bolts from the foundation ring respectively, and then across the top row with a cluster in the upper corners. Sling stays are not used for the crown, but in their place are bolts whose length and tension is adjusted by a turn buckle.

For this great amount of heating surface a large grate is essential, and the one used has an area of 61.8 sq. ft. Its length is 9 ft. 4 in., with a width of 6 ft. 8¼ in. between the plates. This is undoubtedly ample for the heating surface, but the question of firing so large a grate with the engine hauling a heavy passenger train at high speed will probably prove a tax on physical endurance, for at a rate of combustion of only 100 lbs. of fuel per square foot of grate per hour, it will involve the handling of more than three tons of coal in that time.

Owing to the large diameter of the shell and the height of its center (9 ft. 7 in.) above the rail, the dome must be low. It is 32 in. inside diameter and the opening is strengthened by a stiffening plate ¾ in. thick to which is added a 1-in. dome base. In the shell the circumferential seams are double riveted, and the horizontal seams are of the usual sextuple riveted type with inside and outside welts. At the front the forward course is extended to form the rear end of the smokebox, and reaches out 29 in. beyond the front tubesheet. This is not common practice, as it is usually unnecessary to use as heavy a sheet for the smokebox as for the shell; but the length and weight of this boiler has rendered such a construction advisable.

The tubes are placed in vertical rows and are spaced on 3[illegible] in.

centers. It is only a few years ago that the advisability of using tubes of greater length than 16 ft. was under discussion at the New York Railroad Club, and the most progressive speaker on the floor stated that while he did not think that any difficulty would be experienced, so far as keeping tubes tight was concerned up to 20 ft. in length, he did not know that he could recommend such tubes because of the decrease of efficiency per foot of length as the length was increased. In accordance with Vaughan's formula this efficiency decreases inversely as the square root of the length, so that, taking the efficiency of the 16-ft. tube per foot of length as one, that of those of greater length would be as given in the following table:

Length of tube in ft.	16	17	18	19	20	21
Efficiency per ft. of length	1.000	0.969	0.943	0.917	0.895	0.873

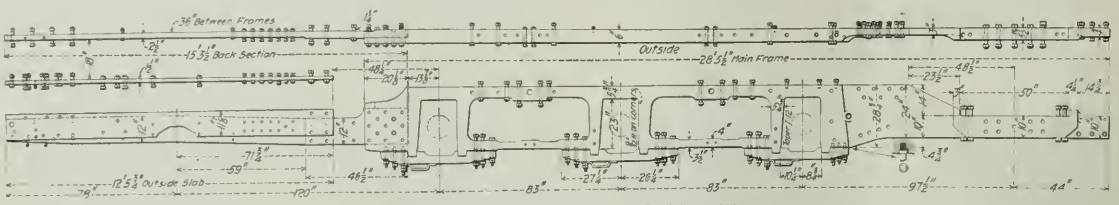
From which it appears that the difference in efficiency per foot of length is not great as between tubes of 16 ft. and 21 ft., and is more than made up by the length. Thus a 21-ft. tube has a total efficiency of 14.5 per cent. more than a 16-ft. tube of the same diameter, while in this case the increased diameter adds to the total efficiency per tube which will thus probably be raised to from 25 to 28 per cent. in excess of the smaller and shorter one, a percentage of no small moment where the demand for steam will be as great as in this engine.

The feeding of the boiler is in accordance with the standard practice of the Pennsylvania Lines West, and is accomplished through the long internal pipe reaching from the back head to a point within 34 in. of the front tubesheet; a 2½-in. iron pipe 17 ft. 9 in. long being used for the purpose.

The total length of the boiler from the bottom of the back head to the edge of the flanging of the front tubesheet is 31 ft. 10 in., to which 2 ft. 3½ in. must be added for the front course and then 4 ft. 6½ in. to reach the end of the smokebox, making a total length of 38 ft. 10 in.

The cylinders are cast in the usual shape with half saddle attached. The valve chests are above and slightly outside the cylinder centers and are bored out to 19 in. to take the bushing for the 16-in. piston valve. The port opening in the cylinder has a chord length of 21 in. The steam passages are worked out on easy curves so that the movement may be as unobstructed as possible. The valves are driven by the Walschaert gear and are inside admission. They are built up about a wrought iron tube of 10 in. outside diameter. The heads are of malleable iron of the form shown, riveted to the tube, and are fitted with cast-iron spring rings.

The frames are of wrought iron forged in one piece from the front end to a point just back of the rear driver pedestal, where there is a seat for bolting the plate forming the rear section. The double bar type is used with an upper rail 5 in. deep and 6 in. wide between the pedestals and 5¾ in. deep above the opening. The pedestal binders are correspondingly heavy and are not only fitted to take the direct outward thrust, but are held by three bolts upon each side as well. The cylinders are held by nine 1½-in. bolts. At the rear, the frame is formed of two plates. The inner one is set in line with the main frames and is 2½ in. thick. The outer plate is separated from it 18 in. and is 1½ in. thick. The trailing truck wheel is between the two with the journal box outside of both, and



Frame of Pacific Locomotive; Pennsylvania Lines West.

with the weights so equalized upon it that the load carried by the back end of the frame is only 12,340 lbs.

The truck is of the radial type with a radius bar of 75 in. virtual length, and formed of a heavy box and yoke casting to which the cross piece and the diagonal radius bar are rivetted.

The frames are crossbraced by a heavy casting at the front at the point of guide yoke attachment, and at three intermediate points between that and the front end of the firebox.

The principal weights and dimensions of the engine are as follows:

Cylinders	24 in. diameter; 26 in. stroke.
Piston valve	16 in. diameter; 7 in. stroke.

GENERAL NEWS SECTION

NOTES.

The enginehouse of the Buffalo, Rochester & Pittsburgh, at Rochester, N. Y., was destroyed by fire on August 24, and 14 locomotives were badly damaged. The fire started from the explosion of a crude-oil apparatus used in firing up engines.

A press despatch from Atlanta dated August 21, says that the Governor of Georgia has suspended from office Railroad Commissioner Joseph M. Brown and appointed in his place A. G. McLendon. The order cites the law authorizing the Governor to take such action but gives no reason for the suspension.

In the United States District Court at Minneapolis, August 23, the Chicago, St. Paul, Minneapolis & Omaha was fined $20,000 and its former General Freight Agent, H. M. Pearce, $2,000 for granting rebates to the Spencer Grain Company. The jury in this case returned a verdict of guilty on April 11.

A press despatch from Omaha says that on account of the scarcity of help, the Union Pacific has had to greatly curtail work in its coal mines and is buying coal in Illinois for which it pays $1 a ton. The estimated cost of this coal after carrying it to Utah is $8 a ton. The Southern Pacific has ordered coal from Australia. Japanese miners in Wyoming are drawing as high as $170 a month.

The railroads of Missouri have notified the Attorney General of that state that henceforth they will carry 150 lbs. of baggage free for each first-class passenger. It appears that under the new law recently passed, the railroads were allowed to charge for the transportation of all baggage over 100 lbs. for each passenger, but the Attorney General has induced the roads to restore the old arrangement.

The Board of Conciliation appointed to adjust the controversy between the Grand Trunk Railway and its locomotive engineers, reports that a settlement has been reached and an agreement signed for three years from Aug. 1, 1907, giving a substantial increase of wages. This is the second important dispute between the Grand Trunk and its employees which has been settled under the Canadian industrial disputes act.

The Chicago, Burlington & Quincy has issued a circular announcing that all lands and buildings owned by the company and occupied by others must be paid for at a reasonable rental. It appears that the Burlington, like some other roads, has granted the use of its property at many places to shippers and others at nominal rentals. Henceforth applications for leases must be referred to an executive officer of the company.

Complaint has been made to the New York State Public Service Commission at Albany of the Pullman parlor car fare between Buffalo and New York, which is $2, having been advanced from $1.50. The complainant says that between Chicago and Minneapolis, about the same distance, the charge is only $1. He also calls attention to the fact that in Wisconsin the Legislature has passed a law requiring upper berths in sleeping cars to be kept closed when not actually occupied.

The New York State Shippers' Protective Association, consisting of about 100 shippers in the central part of the state, has asked the Public Service Commission to require the railroads to give them adequate service and proper treatment. They want suitable cars to carry perishable products in the winter; want a full supply of cars at all times; want all agents to give through rates; want damage claims settled promptly, and want the railroad to be as fair to them as to itself in fixing demurrage charges.

The Wisconsin State Railroad Commission, deciding a complaint made by Nicholas Streveler, holds that the Marathon County Railroad, known as a "logging road," is a common carrier. In some cases passengers were carried free, as were many less-than-carload lots of lumber. The company published no tariff. The road is owned by the Connor Lumber Co., of Marshfield, and W. D. Connor, Lieutenant-Governor and chairman of the Republican State Central Committee, is its chief owner. The Commission held that the rates on lumber were extortionate and ordered them reduced from $5 and $7 a car to $3.50 and $4.50 a car; and, finally, "The carload business is charged with the additional expense of conducting the less-than-car load and passenger business, which is unlawful, inequitable and socially and economically parasitic."

The Chicago, Milwaukee & St. Paul has appealed to the Circuit Court of Dane county from the Wisconsin Railroad Commission's order directing the company to place its terminal facilities at the disposal of a competing road. The state Institute for the blind, a mile and a half south of Janesville on the Milwaukee road, wanted the St. Paul to switch to the sidetracks at the Institution cars from the North-Western road; and the Commission, despite vigorous protest by the company, held that one road must switch the cars of another at a reasonable switching charge.

The Grave Danger from Tramps.

The startling explosion of nitroglycerine by a tramp ejected from a freight train at Ridgway, Pa., will alarm every traveler and every train hand. There is grave neglect in this matter by the state. The tramp is always a trespasser. He is most of the time a criminal. Every ride he steals is theft. There is not a county in the state along the main line of any leading railroad where the country roads are safe to women. Yet the state does nothing to suppress this chronic piracy. It shifts on railroad corporations the public duty of keeping the peace. There is no more justice in this than for a city to make a householder police his front door and back yard. Train hands go in peril of life. Every state should meet this by a state police and make every mile of track secure. Men at their honest work ought not to have to put up a fight for life, as train hands daily do. The mere increase of property value due to safety would pay for such a state police.—*Philadelphia Press.*

On the Baltimore & Ohio last year there were 2,617 arrests for "ride stealing," most of which were followed by no punishment. The 900 vagrants arrested for trespassing on the Pennsylvania Railroad last year constituted but a small proportion of the total number constantly traveling over the road. In a single recent month 300 tramps were arrested by Pennsylvania Railroad police. A representative of that road says: What is going to be done about it? The railroads are willing to do their part in the way of furnishing police if they can have some assurance that offenders will be properly punished after they are arrested. Strict vagrancy laws strictly enforced will provide a remedy. Small localities can ill afford to bear the expense of keeping in prison a tramp that happens to drop off a passing railroad train. It is largely this matter of expense that prevents vagrants from being punished. If the state would undertake the punishment of vagrants, town and county officers would much more readily co-operate with railroads in putting an end to the really serious state of affairs.

Railroad Building in the Lewiston, Idaho, District.

An era of competition for the immense grain traffic of the Pacific Northwest has begun in the Lewiston, Idaho, country, the result of which may make Lewiston one of the most important inland railroad centers west of the Rockies. The Union Pacific, it is said, has the route for a line through the Rocky mountains from Butte, Mont., via Lewiston to the Pacific coast located. From Lewiston east to Kooskia the line has been surveyed for a year and is ready for construction. It has been decided to run the line up the Selway fork, through the Nez Perces pass and thence to Butte.

The Oregon, Washington & Idaho, building from Lewiston to Riparia, Wash., is to be finished in a few months; the officials say the line is to be opened January 1. This line, being built jointly by the Northern Pacific and the Oregon Railroad & Navigation Co., will connect with the latter's road at Riparia, giving a direct, all-rail route from Lewiston to Portland. Work is under way on a line for the Oregon Railroad & Navigation Co. along the upper Snake river, and work on the Lewiston end is to begin this fall. The line is projected from Huntington to Lewiston, connecting at that place with the new Riparia line and thus on to Portland. The probable intention of the company is to route both freight and passenger traffic over the new line, thus avoiding the heavy grades and sharp curves over the Blue mountains, beside getting a water grade to the coast.

The Chicago & North-Western is reported to be planning to reach

Puget Sound via the Lewiston country waterways by building an extension via St. Anthony, Idaho. Though permanent surveys have not been made, it is understood that the line will pass down the Salmon, Snake and Columbia rivers to the sound.

Another railroad, the Chicago, Burlington & Quincy, has for several years planned to take advantage of the easy water grade via the Lewiston district to reach coast terminals. The road now reaches Billings, Mont., and the proposed extension will probably be down the Middle Fork and Clearwater rivers to Lewiston.

The proposed electric lines to be built include the Lewiston & Southeastern, which will open up the country from Lewiston southeast to Grangeville. Work is to be begun within 90 days and will be rushed to completion.

The Spokane & Inland Empire is building an electric line from Spokane south to Lewiston, 115 miles, with a parallel line on the west leaving the first line at Spring Valley Junction, Wash., to a connection with the same line at Moscow, 65 miles. The east line has been finished to Moscow, 50 miles south of Spring Valley Junction, and the west line to Colfax, 36 miles south of the junction. Early next year the remaining link is to be built. The line will carry large quantities of grain through Lewiston that now pass through Spokane, and through a traffic arrangement furnish an entrance for the Canadian Pacific into Lewiston.

A third interurban line is to enter Lewiston from the southwest, being projected from Walla Walla, Wash., by way of Pomeroy. Construction may begin next year.

The project of the government to open the Columbia river to navigation by building a canal around Celilo rapids, the only portion of the entire distance between Lewiston and the coast that is not navigable, for which large sums of money have been appropriated, is likely to come within the next decade.

Union Pacific Gasolene Motor Test.

As an endurance test, on August 22, Union Pacific motor car No. 12 was run from Omaha to Denver in 16 hrs. 34 min., running as the second section of No. 1, the Overland Limited, Omaha to Julesburg. The running time of the regular Denver fast train is 17 hrs. 15 min. The distance run was 570 miles, making the speed of the motor about 34½ miles an hour, a very satisfactory long distance test. The motor cars now in service at Denver have been making 172 miles a day, and have been on time constantly. The company is building 18 additional cars.

A Railroad Journey from Peking to Hankow.

The Peking-Hankow Railroad from Peking to Hankow, opened at the beginning of this year, is 800 miles long and passes through continuous plains of rice fields, stretching as far as the eye can reach on either side of the railroad. Generally the water is pumped up by hand from the river to the highest level and then led down in bamboo pipes to the various terraces on which the rice is growing.

About half way on the journey the train crosses the Yellow river on a bridge a mile and a quarter long. The train proceeds at a very slow speed, as the oscillation is considerable and the Chinese engineers do not like accidents, for the road is owned and operated by the government, and heads would be likely to fly off if anything happened through carelessness. The oscillation when the first passenger train went over was so great that some of its occupants became uneasy. Herbert Brewster, a New Yorker who made the initial trip, said that he went out on the platform of the rear car and found the chief engineer of the road standing by with a life belt in his hand, but no accident occurred. This was fortunate, as there were no more life belts on the train.

There is a daily express train from Hankow to Peking, and vice versa, which makes the journey in three days. Passengers have to eat their meals and sleep each night in Chinese inns, with primitive accommodations. In addition to the express service there is a train de luxe composed of sleeping and dining cars, which performs the journey in 36 hours, for which there is a supplementary charge of $13 gold beyond the $20 ordinary fare. It leaves Hankow at 11 p.m. on Saturdays, arrives in Peking at 11 a.m. Mondays, and returns at 11 p.m. Wednesdays, arriving at Hankow at 11 a.m. on Friday. Already this train has paid so well that a bi-weekly service will be run next season.

There are no arrangements for checking baggage in China, and the scene at Hankow on the open platform, dimly lighted with Chinese lanterns, just before the departure of the Peking train on Saturday night, puts an ordinary bridge crush in the shade. The Chinese have taken kindly to railroad travel and crowd every train, their enthusiasm being due in large measure to the number of free passes issued. As it is a government road, all officials of high and low degree are entitled to passes. Only foreigners and poor Chinese coolies appear to pay their fares. At stations three or four Chinese bands, composed chiefly of horns, cymbals and drums, mingle ear-soothing strains with the voices of hundreds of Chinamen all talking at once. When a Mandarin travels on the train this performance is gone through at each stop made during the night as well as the day. Baggage is placed in a closed car and guarded by an armed Chinese watchman. As people are allowed to board the car at each station, and haul out any package they may want, it is just as well to give the watchman a quarter and indicate one's own baggage. The government warns all travelers that it takes no risk.

The sleeping cars on the train de luxe are similar to those in use in Europe, and are divided into two and four berth compartments. Chinese boys make up the berths, and an Italian conductor has charge of the train. Chinamen fill the diner all day long, eat and drink everything in sight, then smoke their long pipes filled with some soul destroying weed while the American passengers eat their meals. Frantic demands that the Chinamen should be made to smoke in the baggage car fall unheeded on the ears of the conductor of the diner. He is a guileless heathen Chinee. The strong odor of garlic and decayed seaweed mingled with the smoke of the quaint Chinese tobacco makes a subtle perfume, and puts one next to the people at once, as a Boston man described it.—*New York Times.*

The "American" Tender Hose Coupling.

The "American" tender hose coupling shown herewith is a gravity coupling, based on the wedge principle, a single straight movement only being required in coupling and uncoupling, without the

The "American" Tender Hose Coupling.

aid of any tool. It is claimed that it is perfectly tight at all times, automatically adjusts itself to changes in temperature, and vibrations tend to tighten it; that it does not leak under the most severe conditions. It is guaranteed to carry water or oil between engine and tender without waste. It is durable and there is little or no wear, except on the gaskets. The couplings are made to fit 2½-in., 3-in. and 3½-in. hose. They are in use on a number of roads. The American Coupling Co., St. Louis, Mo., is the maker.

Roadbed of Salt for the Western Pacific.

At a point about 120 miles west of Salt Lake City on the new line of the Western Pacific is a great area of salt beds eight miles wide and 40 miles long. Immediately west of Salt Lake City, the line of the road skirts the southern end of the Great Salt lake, crossing it at one point for a distance of six miles. At milepost 80 it enters the Great American Desert and for the next stretch of nearly 40 miles crosses a vast sea of alkali, gleaming in dazzling whiteness in all directions. Near the western end of the desert lie the salt beds where the previous whiteness of the landscape changes to a glaring sparkle of the salt crystals. So closely are these crystals packed together that they form a strong roadbed for the railroad. In building the line this hard level surface required no ballasting and no blasting: track-laying was a simple and rapid operation. In placing telegraph poles, however, it was necessary to blast out the salt, whose rock-like hardness made it impossible to dig down the required eight feet. This distance of eight feet for the telegraph poles is the deepest bore which has so far been made in the deposit, so that its true depth is not yet known. With no greater depth than this the commercial value of this salt deposit, which is said to be 95 per cent. pure, is very large. There is a theory that this deposit drains underground to the Great Salt lake. This is borne out by the fact that salt beds are 27 ft. higher than the lake, with the slope toward the lake. More than this, the salt deposit contains moisture, for ties and telegraph poles imbedded in it become moist to a point four or five inches above the surface. This also argues

an underground stream since the air is too dry to furnish enough moisture for this. Placer claims are already staked out on the salt beds.

New Scale of Wages on Bavarian Railroads.

In Baden also new scales of wages have been introduced. Those men who are paid for 365 days in the year are divided in four groups, according to the locality where they work, and in the year when they begin work are to receive 3 marks, 2.90, 2.80 and 2.70 marks a day, with an extra allowance of 10 per cent. for those employed in Mannheim. Three marks is 71.4 cents. Heretofore there were five classes, beginning to work at 2.20, 2.30, 2.40, 2.50, 2.60 and 2.70 marks, respectively. Those who are paid only for the days they work receive 10 pfennig a day more. An addition of 10 pfennigs a day is made after the first, the second, the fourth, the sixth, the ninth and the twelfth year. Thus the man who begins to work at 3 marks a day after 12 years' service will receive 3.60 marks (85.7 cents) a day. This is interesting to us, chiefly as an example of gradation of wages according to the varying living expenses in different parts of a small country.

The Atchison's Recreation Houses.

My work is to assume in every man on our road such qualities of honor and cultivation that no one of them ventures to fall below par. I work on the theory that a man has a strong tendency to become what he is assumed to be. Accordingly, I assume that every man is a gentleman, a man of honor, a man of reading and education. And I have had the gratifying experience of seeing thousands of men palpably bettered.

The Santa Fe has established a system of reading rooms, circulating libraries and club houses from end to end of the road, and I receive daily reports from each of the 25 reading rooms, each of the seven club houses, and from the circulating libraries. We charge a nominal fee for the privileges of the clubs. One of the finest features of the system is the fact that it is established for the whole families of the employees. That is a great factor in promoting domestic happiness. There are few divorces among our employees. We have the women as well as the men enjoying the benefits of the billiard table and the bowling alleys. We have the women reading in the reading rooms. We have the men and their wives at their own firesides reading the good books from the circulating libraries. The system, while not as yet absolutely self-supporting, can be made so very soon without any hardship to the men.—*S. E. Busser, Superintendent of Department.*

Disastrous Collision in France.

In a collision between a passenger train and a freight train at Contras, France, August 24, 12 persons were killed and 31 injured.

Empire Bridge Company's Improvements.

The improvements to the Elmira, N. Y., plant of the Empire Bridge Company, Pittsburgh, Pa., have been under way since early in 1907, and it is expected that the enlarged plant will be in full operation before the end of the year. The completed plant will cover about 15 acres. It is served by the Erie, the Delaware, Lackawanna & Western and the Pennsylvania. Heretofore there has been but one building, 90 ft. x 100 ft.; the improvements consist of an extension to the original building, which will be the main bridge shop, making it 215 ft. x 528 ft.; a boiler and power house, a machine shop, a templet shop and a forge shop. All buildings are of steel construction, column bearing, with brick curtain walls, concrete foundations, and slate or slag roofs.

The present plant employs about 250 men and has an annual output of about 15,000 tons of steel bridge and building work. The enlarged establishment will require more than twice as many and the output will be quadrupled. Electric power, 220 volts, direct current, will be used throughout for individual motor drive and lighting. About two miles of standard gage railroad is being laid in yards and side tracks; cars are handled by a 40-ton switching locomotive owned by the company. About two miles of narrow gage track is being laid throughout the plant for conveying material. Two 100-ton track scales, one at the receiving end of the shop and the other at the finishing end, will record the weight of all carloads of raw material received and of finished product shipped out. The water supply comes from wells, and a water purifying system has been installed. Fire protection is afforded by a complete and independent system of piping with a high capacity pump kept under steam and ready for immediate use at all times. An emergency hospital will be maintained on the premises.

The boiler house is 42 ft. x 90 ft. There are four 250 h.p. water tube boilers, equipped with mechanical stokers, damper regulators and feed water regulators, and fed by two compound duplex pumps, each of which can supply all boilers. The power house is part of the same building, it is 80 ft. x 60 ft., and contains two 300 k.w. generators, driven by horizontal tandem compound condensing engines, and one 100 k.w. generator of the same type driven by a vertical cross compound condensing engine. There are two air compressors whose total capacity is 3,600 cu. ft. per minute, and other minor engines. The power house is spanned by a 20-ton electric crane. The machine shop building is 60 ft. x 240 ft. Planers, shapers, boring mills, heavy lathes and other machines for heavy work will be in the main aisle, which is 30 ft. wide and is served by a 15-ton crane running the length of the shop, while machine tools for lighter work will occupy the 15-ft. wings on either side, served by traveling jib cranes of special design. The forge shop, 60 ft. x 240 ft., will be used in part for making bolts, nuts and rivets, and the rest for bending, forging, tempering and making loop rods and light eye-bars. The templet shop will be 50 ft. x 224 ft. The main bridge shop is 215 ft. x 528 ft. In this building will be the tools for making main members of bridges and buildings of the heaviest type. There will be a system of 10-ton and 20-ton cranes overhead for general service, while all small machines will be served by special jib cranes. An extension 55 ft. x 80 ft. at the west end of the main shop will give space for detail material. The receiving yard and the shipping yard are each served by two electric traveling cranes on separate runways 600 ft. long. The combined storage area of these two yards is about 225,000 sq. ft., all of which is covered by skids to protect the material from rust by contact with the ground.

The Empire Bridge Company is a subsidiary of the American Bridge Company, New York.

Long Runs on English Passenger Trains.

The number of regular passenger trains now running on British railroads every week day which make trips of 100 miles or more without stopping is 156. This is shown by a list which has just been made up from the July time-tables. The total is slightly less than last year. Moreover, some of the trains have been made a trifle slower than formerly. Between London and Sheffield there are now only two such trains as compared with five a year or two since. Of the 156 trains in this year's list, 49 are on the London & North-Western, 32 on the Great Western, 25 on the Great Northern, 14 on the Midland, 10 on the North Eastern, seven on the Great Eastern, five on the Great Central, four on the London & South Western and 10 on the Caledonian. The last named is the only one of these roads outside of England. As regards speeds, the Great Western still stands at the head, six of the seven runs scheduled at 57 miles an hour or faster being on that road. The best speed of all is that made by the Great Western between London and Bristol by way of Bath, 118⅜ miles in two hours, 59.2 miles an hour.

Chicago Pneumatic Tool Company.

The income account of the Chicago Pneumatic Tool Company for the half year ended June 30, 1907, is as follows:

Profits for the half year		$507,528
Depreciation of buildings, plant and machinery including repairs and renewals of buildings and plant	$97,834	
For developing and perfecting new tools	10,800	
		108,634
Net profit		$398,894
Reserve for bond interest	$87,500	
Sinking fund reserve	25,000	
		82,500
Available for dividends		$316,394
Quarterly dividends, Nos. 17 and 18		125,576
Surplus for half year		$190,818
Surplus brought from 1906		878,410
Surplus carried forward		$1,069,228

Chicago Subway.

Samuel McRoberts, the new President of the Illinois Tunnel Company, announces that by November 1 the subway will probably be carrying daily to and from railroad freighthouses of the city 10,000 carloads of freight of two or three tons each. The tunnel railroads—18 east and west and 12 north and south—connect with the freighthouses of the 23 railroads centering in the city. Mr. McRoberts has lately made freight contracts with all of these roads. The tunnel lines already have connections with a number of important stores and the expected new business will, no doubt, be from these stores to the freighthouses and vice versa, as well as from one freighthouse to another. The tunnel motors already make 1,000 trips a day with United States mails between the post office and railroad stations, and in the last three months has carried 2,516,-

430 pouches, of which 99.97 per cent. were delivered on time. The tunnel company has, on its 2-ft. gage tracks, 1,200 cars and 80 electric motors; and 50 more motors will soon be received.

Hours of Labor on English Railroads.

The British Board of Trade has issued another report showing for a single month (April, 1907) the number of railroad employees in the United Kingdom who were on duty more than 12 hours at a time or who, after being on duty more than 12 hours, were allowed to resume work with less than nine hours' rest. The total number of trainmen and signalmen on the roads reporting is 109,257. These men worked, during the month of April, 2,639,851 days; and 46,201 persons were, on one or more occasions, on duty more than 12 hours at a time. The total number of instances of overwork was 87,431, or only about 3.3 per cent. of the total days' work. Most of the roads send supplementary statements showing that after deducting the hours in which the men do no work, although they are nominally on duty, a more favorable showing is made. The railroad companies have been notified that hereafter the Board of Trade will ask for a statement of this kind for one month in every quarter.

TRADE CATALOGUES.

The San Luis Valley of Colorado.—The Denver & Rio Grande has issued a folder describing the live stock and agricultural resources of the great San Luis valley in the southern central part of the state of Colorado, which embraces an area of over 3,000,000 acres of arable lands, as great an area as the state of Connecticut. The most profitable industry is hog raising, which has been given a great boom by the discovery of the value of the field pea as a feeding crop. The great advantage of this plant is that it is rich in nitrogen, which is valuable both as food for stock and as an enrichment of the soil. Grain fields worn out by continual recropping in wheat are being rejuvenated by planting them with field peas, whose roots store nitrogen from the air. Pea-fed mutton and pork sells for more than the same grain-fed products. The San Luis valley is also famous for its grain. Furthermore, the greatest yield of potatoes on a measured acre of ground ever recorded, 794 bushels, was raised in the valley in 1902, in competition for a prize offered by the *American Farmer*. The soil is well suited for sugar beets, but as yet no sugar factories have been established. The valley extends north and south 100 miles and east and west at the widest part 10 miles, and is surrounded on every side except the south by high mountain ranges. Its elevation is from 7,500 to 8,000 ft. above the level of the sea, yet it is the most level stretch of land of its size in the state of Colorado. The mountain ranges cut off severe storms, so that the climate is exceptionally good.

Virginia Hot Springs.—The passenger department of the Chesapeake & Ohio has issued an exceedingly attractive small booklet of convenient size (5 in. by 3½ in.) describing the attractions and advantages of Virginia Hot Springs as an all the year round pleasure and health resort. The booklet is an unusual example of taste in advertising. Both front and back covers are decorated in colors, the front cover bearing simply the words Virginia Hot Springs and the back cover Dr. Johnson's familiar quotation, "There is nothing by which so much happiness is produced as by a good tavern or inn." The full page illustrations are 3½ in. by 2 in. and there are many smaller photographs, yet these are so successful and well chosen that the book is more intelligently illustrated than many a larger volume. There are views of the "Homestead," the Virginia Hot Springs hotel, and of its surrounding buildings and attractions. The various baths and springs and their effects on various physical troubles are described. There are also a number of photographs of interesting scenery on the Chesapeake & Ohio.

Metal Specialties.—The William Powell Company, Cincinnati, Ohio, has issued a complete catalogue of its brass and iron specialties for engines and boilers. The catalogue gives all the necessary dimensions of each article and explains in detail its merits. The company's products include: Valves, lubricators, oil cups, injectors, gages, whistles and similar fittings. The catalogue includes a series of tables and rules which are useful to engineers and shop managers.

MANUFACTURING AND BUSINESS.

J. I. Boggs has resigned from the Virginia Bridge & Iron Co., Roanoke, Va., to become Contracting Engineer of the Southwestern Bridge Co., Joplin, Mo. Mr. Boggs' headquarters will be at Dallas, Tex.

The American Railways Company, Philadelphia, Pa., has secured property in Dayton, Ohio, on which to build new car barns and repair shops for the Peoples Railway, a subsidiary. Dodge & Day, Philadelphia, have been commissioned to draw up plans for the buildings.

The Buffalo, Rochester & Pittsburgh is to extend its Clarion Junction shops this fall and also put some new machinery in the Dubois and Rochester shops.

The Central of Georgia has ordered from the Savannah Blow Pipe Co., Savannah, Ga., a blow pipe and heating and ventilating system for the new shops being built at Macon. The Savannah Blow Pipe Co. also has a contract for equipping the new shop being built for the Atlantic Coast Line at Waycross.

A. P. Eckert, heretofore with the Safety Insulated Wire & Cable Company, is now General Sales Manager of the Duplex Metals Company, 208 Fifth avenue, New York City. The Duplex Metals Company makes the Monnot "copper-clad" wire, samples of which were recently exhibited and described at a meeting of the Railway Signal Association.

E. H. Symington, Manager of Western Sales of the T. H. Symington Co., Baltimore, Md., who was thrown from his horse and seriously injured a few months ago, suffering from a fractured skull, is steadily improving and leaves this week on an extended trip around the world, including Japan, China, India and other Oriental countries. Mr. Symington hopes to be able to get back to work at his office in Chicago by the first of the year.

The London County Council recently received bids for two 7,500 h.p., three-phase steam turbo-generating sets to be installed in the new Greenwich power plant for the electric lines under construction in and near London. The lowest bid, £37,872 ($189,360) was made by the British Westinghouse Electric & Manufacturing Co. The Parsons Steam Turbine Co. bid £40,502 ($202,510), while the highest figure was £49,090 ($245,450). The whole plant will cost over £1,000,000 ($5,000,000).

The A. Gilbert & Sons Brass Foundry Co., St. Louis, Mo., makers of Velox bronze and other bearing metals, is building a new plant on Forrest Park boulevard between Vandeventer and Sarah streets, on a plot 75 ft. x 180 ft. The building will be a one-story structure, with a two-story front, the second floor to be used for offices. The roof will be of the saw-tooth pattern, with 18,000 sq. ft. of skylight. It will be supported on iron beams, leaving the ground floor clear of pillars. The new plant will cost in all about $25,000, and is expected to be in operation by October 1.

The United States Consul General at Marseilles, France, has made a report on the conditions under which American manufacturers can hope to sell their products to French railroads. He says there is much red tape in the purchasing departments of French railroads and advises that manufacturers study the French market in person. He suggests that non-competing firms should form combined sales agencies and he has sent a list, which is now on file at the Bureau of Manufactures at Washington, of people and firms in France who might be willing to handle railroad equipment.

Compressed Air is no longer published by the Kobbe Company, New York, but by the Compressed Air Magazine Company, Bowling Green building, New York. W. L. Saunders, M. Am. Soc. C. E., remains editor, and Frank Richards has succeeded W. R. Hulbert, M.E., Assoc. Am. Soc. M. E., as managing editor. Mr. Richards, who is author of the book, "Compressed Air," was for ten years one of the editors of the *American Machinist;* before that he was for some time Superintendent of Shops of the Ingersoll-Sergeant Drill Company. Lucius I. Wightman is Manager of the new publishing company.

The resignation of Mansfield Merriman as Professor of Civil Engineering in Lehigh University takes effect on September 1. Hereafter his time will be largely devoted to practice as a consulting engineer, his office being at 45 Broadway, New York. The vacancy caused by his resignation has been filled by the appointment of Frank P. McKibben, as Professor of Civil Engineering, and of Winter L. Wilson as Professor of Railroad Engineering, the former having been for several years an assistant professor at the Massachusetts Institute of Technology and the latter an assistant professor at Lehigh University.

F. B. Maltby, who has been Principal Assistant Engineer on the Panama Canal, has resigned to become Chief Engineer of Dodge & Day, Philadelphia, Pa. Mr. Maltby is a graduate of the University of Illinois, class of 1882, and in 1907 received an honorary degree from the same institution. He has had long experience in railroad construction work, municipal engineering and irrigation work, and been at various times on the Wisconsin Central, the Missouri Pacific, the Chicago Great Western and the Illinois Central. He has had charge, for the United States Government, of all the dredging in the lower Mississippi river, and he designed and built the lock and movable dam on the Osage river in Missouri for the Government. He has been on the Panama canal for the last two and a half years, having had charge of railroad construction, docks and wharves,

chief, dredging and some buildings in Panama. He was in charge of the preliminary plans and construction of the Gatun lock and dam.

Iron and Steel.

The Northern Central has ordered 2,000 tons of bridge steel.

The Panama Railroad is in the market for 3,000 tons of 90-lb. rails.

The Baltimore & Ohio is reported to have made reservations for rails for 1908 delivery.

The Norfolk & Western is reported to have made reservations for rails for 1908 delivery.

Orders for rails for 1908 delivery are said to aggregate less than for several years past at this season.

The Atchison, Topeka & Santa Fe is reported to have ordered 15,000 tons of 85-lb. rails for delivery as soon as possible from the Minnequa works of the Colorado Fuel & Iron Co., at Pueblo, Col.

The new open hearth rail mill of the Bethlehem Steel Company, South Bethlehem, Pa., was to be in operation by the end of this month. The structural steel plant, it is expected, will be ready toward the end of the year.

The Pittsburg Steel Company has ordered a 42-in. blooming mill from the Macintosh-Hemphill Company to be installed at the new Monessen plant. Additional ground has been bought, and it is said that other mills will be built.

According to press despatches, the Braddock and Homestead plants of the Carnegie Steel Company, Pittsburg, Pa., have put on extra crews of men to rush orders for rails and structural material for Japan, aggregating about $2,000,000.

The Isthmian Canal Commission has ordered from the Maryland Steel Company 3,000 tons of 75-lb. rails, with accessories, to be used in Panama in connection with the canal construction work. The company, it is said, agrees to furnish the rails for $95,250, shipment to be made in September; as compared with the bid of the United States Steel Corporation of $97,350 for November shipment.

OBITUARY NOTICES.

In speaking of the death of Israel Munson Spellman in the *Railroad Gazette* of August 16th, it was said that he was President of the Boston & Maine for 30 years, from 1839 to 1869. This was a mistake. Mr. Spellman was President of that company for only two years, from 1863 to 1865.

MEETINGS AND ANNOUNCEMENTS.

(For dates of conventions and regular meetings of railroad conventions and engineering societies, see advertising page 24.)

Association of Railway Superintendents of Bridges and Buildings.

At the seventeenth annual convention of this association to be held at the Republican House, Milwaukee, Wis., October 15-17, committee reports will be presented on the following subjects:

Concrete Bridges, Arches and Subways, W. H. Finley (C. & N.-W.), Chairman.

Concrete Building Construction, A. O. Cunningham (Wabash), Chairman.

Expansion and Contraction of Concrete Walls, A. S. Markley (C. & E. I.), Chairman.

Action of Sea Water on Concrete, Grosvenor Aldrich (N. Y., N. H. & H.), Chairman.

Use of Wooden and Asbestos Smoke Jacks for Engine Houses, J. H. Cummin (Long Island), Chairman.

Lock for Rolling and Sliding Doors on Freight Houses, C. A. Lichty (C. & N.-W.), Chairman.

Towers and Guides for Lights on Drawbridges, John N. Penwell (L. E. & W.), Chairman.

Protecting Steel Bridges Against Action of Salt Brine from Refrigerator Cars, R. P. Mills (N. Y. C. & H. R.), Chairman.

Pile and Frame Trestle Bridges, W. E. Smith (C., M. & St. P.), Chairman.

Water Supply, C. E. Thomas (Illinois Central), Chairman.

Fire Protection, Wm. C. Carmichael (C., R. I. & P.), Chairman.

Fences, Road Crossings and Cattle Guards, W. M. Noon (D. S. S. & A.), Chairman.

Preservative for Wood and Metal, J. F. Barker (Southern Pacific Railway), Chairman.

ELECTIONS AND APPOINTMENTS.

Executive, Financial and Legal Officers.

Georgia State Railroad Commission.—Gayton McLendon has been appointed a member of the Commission to serve the remainder of the term of Joseph M. Brown.

Wisconsin State Railroad Commission.—Professor B. H. Meyer has been elected Chairman, succeeding John Barnes, resigned. J. H. Roemer succeeds Mr. Barnes as a Member of the Commission.

Operating Officers.

Baltimore & Ohio.—C. F. Tompkins, general yardmaster at Chicago Junction, has been appointed Inspector of Yards, succeeding J. H. Rosenstock, resigned to go to another railroad company.

Buffalo & Susquehanna.—F. W. Allen, who was recently appointed Superintendent of the Buffalo division, began railroad work in April, 1897, as a rodman on the Erie. On July 1 he was transferred to the maintenance of way department on the Buffalo division. In October, 1901, he was appointed clerk in the general manager's office at New York in the maintenance of way and construction department. In 1902 he was appointed Division Engineer of the Wyoming and Jefferson divisions, and the next year was made Division Engineer of the Allegheny division. This position he resigned on August 1, 1904, to become roadmaster of the Cascade division of the Great Northern. In 1905 he was appointed Assistant Superintendent of the Minot division of that road, where he remained until going to the Buffalo & Susquehanna to take his present position.

Hidalgo & Northeastern.—See Mexican International.

Mexican International.—F. A. Latting, Superintendent of the Hidalgo & Northeastern, has been appointed Superintendent of the Northern division of the Mexican International, with office at Monclova, Coahuila, succeeding R. J. Schmalhausen, resigned to become General Manager of the Bolivian Central.

St. Louis & San Francisco.—J. E. Hutchison, Superintendent at Fort Scott, Kan., has been appointed General Superintendent of the First district, with office at Springfield, Mo., succeeding J. H. Young, resigned to go to the Southern Pacific.

Southern Pacific.—Oscar Giffen has been appointed Car Accountant of the Pacific system, with office at San Francisco, Cal., succeeding R. A. Barker, resigned.

Traffic Officers.

Duluth, South Shore & Atlantic.—S. R. Lewis, chief clerk in the General Freight department, has been appointed Assistant General Freight Agent of this road and of the Mineral Range, effective September 1.

Mexican Central.—Charles F. Berna, commercial agent at El Paso, Tex., has been appointed to the new office of General Agent at that place, and his former office has been abolished.

Mineral Range.—See Duluth, South Shore & Atlantic.

New York, Chicago & St. Louis.—James Webster, General Freight Agent, has been appointed to the new office of Traffic Manager, effective September 1.

Engineering and Rolling Stock Officers.

Chicago & North-Western.—The headquarters of F. W. Peterson, Master Mechanic at Fond du Lac, Wis., have been moved to Green Bay, effective September 1.

Chicago, Rock Island & Pacific.—See Denver & Rio Grande.

Denver & Rio Grande.—F. E. Fox, Master Mechanic of the Chicago, Rock Island & Pacific at Goodland, Kan., has been appointed Master Mechanic of the First division of the Denver & Rio Grande, with office at Burnham, Denver, Colo., effective September 1.

Hocking Valley.—Mendell A. Kinney, who was recently appointed Master Mechanic, with office at Columbus, Ohio, was born in 1871 at Conneaut, Ohio. After a high school education he began railroad work in 1889 as an apprentice in the New York, Chicago & St. Louis shops at that place. He was made air-brake inspector in 1893 and later went to the Chicago shops as pit foreman and machine foreman. He was made general foreman at Fort Wayne, Ind., in 1903 and the next year went to the Baltimore & Ohio as general roundhouse foreman at Newark, Ohio. Last April he went to the Hocking Valley as general foreman of the South shops at Columbus, Ohio, where he remained until his recent promotion.

Mexican Central.—J. M. Fulton, Master Mechanic at Chihuahua, has been appointed Master Mechanic of the Aguascalientes division, succeeding W. O. Morton, resigned. R. A. Johnson succeeds Mr. Fulton.

LOCOMOTIVE BUILDING.

The Ragley Lumber Company has ordered one locomotive from the Hicks Locomotive & Car Works.

The Parkersburg Mill Company, Parkersburg, W. Va., is understood to be in the market for one 36-ft. gage locomotive to weigh 10 or 12 tons.

The Northwestern Pacific, as reported in the *Railroad Gazette* of August 16, is about to order two eight-wheel locomotives and four 10-wheel locomotives.

The Lehigh Valley, it is said, has ordered 10 locomotives from the American Locomotive Company, and 15 locomotives from the Baldwin Locomotive Works.

The Chicago-New York Electric Air Line, Chicago, is in the market for one locomotive for construction work, and is figuring on buying an additional locomotive.

The New South Wales Government Railways, as reported in the *Railroad Gazette* of May 24, have ordered 15 ten-wheel passenger locomotives, 10 tank locomotives and 30 consolidation locomotives from Beyer, Peacock & Co., Gorton Foundry, Manchester, England. Bids on this equipment were asked from builders in Great Britain, America, Europe and Australia.

The Atchison, Topeka & Santa Fe, as reported in the *Railroad Gazette* of August 23, has ordered from the Baldwin Locomotive Works 10 consolidation locomotives, weighing about 180,000 lbs. on drivers; two Pacific locomotives, with about 150,000 lbs. on drivers, and 23 switch engines, with about 144,000 lbs. on drivers. The consolidation engines will be equipped with Baldwin superheaters. All engines are duplicates of previous orders.

The Newburgh & South Shore, as reported in the *Railroad Gazette* of August 23, has ordered two simple six-wheel switching locomotives from the Baldwin Locomotive Works, for March, 1908, delivery.

General Dimensions.

Type	Switching
Weight, total	137,000 lbs.
Diameter of drivers	52 in.
Cylinders	20 in. x 26 in.
Boiler, type	Straight top
" working steam pressure	170 lbs.
Tubes, number	290
" maker	National Tube Co.
" length	10 ft. 11 in.
Firebox, length	108 in.
Firebox, width	33 "
Grate area	25 sq. ft.
Heating surface, total	About 1,803 "
Tank capacity	4,500 gals.
Coal capacity	9 tons

Special Equipment.

Air brakes	Westinghouse
Bell-ringer	Gollmar
Couplers	Climax
Injector	Sellers
Piston and valve-rod packings	Twentieth Century Metallic
Sanding devices	Leach
Sight feed lubricators	Detroit
Tires, driving wheel	Latrobe

CAR BUILDING.

The Southern Pacific is understood to be asking prices on 50 caboosea.

The Lehigh & New England is said to be in the market for 700 freight cars.

The New Orleans Great Northern is in the market for 700 freight cars.

The Maine Central has ordered two postal cars from the Pullman Company.

The Pacific Coast Company is said to be in the market for passenger equipment.

The American Steel & Wire Company, Chicago, is reported in the market for 300 freight cars.

The Chicago & Illinois Midland has ordered six flat cars from the Hicks Locomotive & Car Works.

The Dayton & Troy Union has ordered eight side-dump cars from the Hicks Locomotive & Car Works.

The Boston & Maine has ordered 1,008 steel underframe box cars from the Western Steel Car & Foundry Company.

Wells Fargo & Co. have not yet decided to buy 10 refrigerator cars, as reported in the *Railroad Gazette* of August 23.

The North Georgia Marble Co., Ellijay, Ga., is said to be in the market for three or four side-dump cars for hauling ore.

The Western Maryland is said to be in the market for 1,000 cars, including 500 coal cars. A similar report last month was denied.

The Crossett Lumber Company has ordered two coaches, four box cars and three flat cars from the Hicks Locomotive & Car Works.

The Cold Blast Transportation Company, Chicago, has been receiving quotations on some tank cars, but nothing definite has been decided.

Eyre-Shoemaker, Incorporated, contractors, Philadelphia, Pa., has ordered eight second-hand furniture cars from the Hicks Locomotive & Car Works.

The Antrim Iron Co., Mancelona, Mich., is in the market for from 15 to 20 standard gage second-hand flat cars of from 80,000 lbs. to 100,000 lbs. capacity.

The Erie did not at any time cancel the order for 3,000 box cars placed last February, as reported in the *Railroad Gazette* of August 16. Delivery of these cars is expected to begin in October.

The Northwestern Elevated, Chicago, as reported in the *Railroad Gazette* of August 2, has ordered 40 semi-convertible cars from the American Car & Foundry Co. The body of each car, with fixtures, will weigh 23,700 lbs., and the cars will measure 44 ft. 1¾ in. long, 7 ft. 9 in. wide and 8 ft. 7 in. high, inside measurements. The special equipment includes:

Brake-shoes	Love Brake-Shoe Co.
Brakes	Westinghouse
Brasses	Northwestern Elevated standard
Curtain fixtures	Curtain Supply Co.
Curtain material	Pantasote
Journal boxes	Northwestern Elevated standard
Paint	Northwestern Elevated standard
Wheels	Standard Steel Works

RAILROAD STRUCTURES.

Burlington, Iowa.—The Chicago, Rock Island & Pacific, it is said, is back of a project to build a bridge over the Mississippi river to be used by the railroad and by electric car lines, and also as a highway. Application is to be made to Congress.

Flushing, N. Y.—The New York & Queens County announces that it has plans ready for putting up car barns and repair shops on land recently bought, fronting Jackson avenue. The cost of the proposed improvements will be about $250,000.

Greenville, Pa.—Additions and improvements, it is said, are to be made by the Bessemer & Lake Erie to its shops here at a cost of about $350,000.

Homestead, Pa.—Preliminary plans are reported made by the Pittsburgh & Lake Erie for putting up a new passenger station here to cost about $25,000.

Nisbet, Pa.—The Pennsylvania has bids in for building a seven-span steel truss bridge to be 1,128 ft. long and 30 ft. above the water over the Susquehanna river to replace the present structure. The piers are to be built to carry two tracks, but the steel superstructure for the present will be single track. The contract is to be let as soon as permission to build the structure from the Water Commissioner of Pennsylvania has been granted. An order for 2,000 tons of bridge material was recently let by the Pennsylvania to the American Bridge Company.

Philadelphia, Pa.—Bids are wanted, September 11, by the Philadelphia Department of Public Works for the construction of bridges over the Pennsylvania Railroad at Belmont and Girard avenues and 31st street and Columbia avenue, and for two bridges along the line of the Torresdale boulevard. The bridge at Belmont avenue will cost about $85,000, of which the railroad will pay $20,000. The estimate for the 31st street bridge is $52,500, the expense to be divided equally between the railroad, the Rapid Transit Company and the city. The Boulevard bridge over Little Tacony creek will cost about $100,000, while the cost of the other bridge to span the Reading tracks is estimated at $45,000. Bids are also asked for a number of main and branch sewers, the estimated cost of which will be $220,000.

Pittsburg, Pa.—Announcement is made that the Wabash will soon ask for a franchise to build a bridge over West Carson street, in the west end, for the West Side Belt Line.

Portsmouth, Ohio.—The Norfolk & Western, it is said, has bought 75 acres of ground for extensions to its shops at this place. In the enlarged shops 4,000 men will be employed.

Pottsville, Pa.—The borough officers of Mt. Carbon are considering the question of building a bridge from Cape Horn west over the electric car tracks, the old canal, the river and the Philadelphia & Reading tracks and abandoning the road near the Pennsylvania Railroad yards at Mt. Carbon. It is said that the Pennsylvania Railroad will pay for the improvements in return for the land granted.

RAILROAD CONSTRUCTION.

New Incorporations, Surveys, Etc.

ATCHISON, TOPEKA & SANTA FE.—Work is under way putting in 85-lb. rails on this road, between Pueblo, Colo., and Atchison, Kan.

BEAUMONT & GREAT NORTHERN.—This road, in operation from Trinity, Tex., on the International & Great Northern southeast to Onalaska, 20 miles, is being extended southeast to Beaumont, 95 miles from Trinity. The extension is expected to be finished to Livingston, 15 miles, next November, when contracts for a 50-mile section are to be let. It is said that the line when built is to be turned over to the International & Great Northern.

BRITISH COLUMBIA (ELECTRIC).—This company has plans under way for building a branch from New Westminster, B. C., southeast to Cloverdale, 30 miles. R. H. Sperling, General Manager, Vancouver, B. C.

BROOKVILLE & MAHONING.—See Pittsburg, Shawmut & Northern.

CALIENTE & PIOCHE.—See San Pedro, Los Angeles & Salt Lake.

CANADIAN PACIFIC.—General Superintendent Robert Marpole, of the Pacific division, is reported as saying that surveys for the extension of the Esquimalt & Nanaimo from Nanaimo, B. C., west to Alberni, 50 miles, are sufficiently advanced to permit construction work to be begun.

CENTRAL OF GEORGIA.—The work of installing passing tracks at all of the stations between Atlanta and Macon is about finished. Over 30 miles of new side tracks have been laid and counting the double track of eight miles from Atlanta to Hapeville the road has 38 miles of double track. It is understood that as soon as the new shops at Macon are finished, work will be begun on double-tracking the entire line between Macon and Atlanta. All of the recent work has been done by the company's men instead of by contractors.

CHICAGO & ALTON.—See Toledo, St. Louis & Western.

CHICAGO, ST. PAUL, MINNEAPOLIS & OMAHA.—This company is buying right of way at Eau Claire, Wis., preparatory to building another section of double track.

CLEVELAND, ALLIANCE & MAHONING (ELECTRIC).—Contracts, it is said, are shortly to be let for building a section of this proposed line from Ravenna, Ohio, east to Newton Falls, 18 miles. (Mar. 15, p. 382.)

COLORADO SOUTHERN, NEW ORLEANS & PACIFIC.—See St. Louis & San Francisco.

DANVILLE & SCOTTSVILLE.—This company was incorporated about two years ago in Kentucky. It is now said to have about $2,000,000 subscribed and to have begun actual construction at Scottsville. The proposed route is from Danville, Ky., southwest via Moreland, Hustonville and Liberty to Scottsville, 100 miles. At a recent meeting of the directors, J. S. Allen, of New York, was elected President, and E. P. Combast, of New York, Vice-President. M. J. Farris, President of the Citizens Bank, is Treasurer, and A. E. Hundley, Secretary, both of Danville. (March 15, p. 382.)

DULUTH, RAINY LAKE & WINNIPEG.—The bridge over Rainy lake is to be finished and through service begun September 1, on the extension of the Duluth, Virginia & Rainy Lake to the Canadian boundary at Rainier, where connection is to be made with the Canadian Northern. The road now extends from Virginia, Minn., north 93 miles. It is said that the company now proposes to build the line from Virginia south to Duluth, about 65 miles. (March 15, p. 383.)

DULUTH, VIRGINIA & RAINY LAKE.—See Duluth, Rainy Lake & Winnipeg.

ESQUIMALT & NANAIMO.—See Canadian Pacific.

INDIAN CREEK VALLEY.—Announcement is made that regular passenger trains have begun running on this road, recently finished from Indian Creek, Pa., northeast five miles to Normalville. It is also said that an extension is to be built from Normalville northeast to Ligonier, 25 miles. The road was built chiefly for the business of the McFarland Lumber Company, which has options on coal land north of Normalville and the proposed extension is to be built to develop this property.

INTERURBAN CONSTRUCTION COMPANY.—A franchise has been granted to this company to build a line from Denver, Colo., north to Greeley, 50 miles. The route of the proposed road is parallel to the Union Pacific for most of the way. Work must be started within six months, and be finished within two years. E. N. Reaser, President, Denver.

KANSAS TRACTION COMPANY.—Surveys are being made and rights of way secured for this proposed electric line to be built from Coffeyville, Kan., northeast via Lawrence and Topeka to Kansas City, Mo., 200 miles. Contracts are to be let for the work in November. It will be low grade, mostly heavy, with 5½ miles of [illegible] construction. F. B. Shirley, President, Coffeyville.

LAKE ERIE, ALLIANCE & WHEELING.—See Lake Shore & Michigan Southern.

LAKE ERIE & YOUNGSTOWN (ELECTRIC).—This company, incorporated to build an electric line from Conneaut, Ohio, south to Youngstown, about 60 miles, has all the rights of way secured and will shortly begin the work. Plans have been made for the extension of the line into Youngstown, where connection is to be made with the Youngstown & Southern, which has been built to Columbiana, and is to be extended to East Liverpool, on the Ohio river, 100 miles from Conneaut. (April 12, p. 531.)

LAKE SHORE & MICHIGAN SOUTHERN.—Surveys, it is said, are under way for an extension of the Lake Erie, Alliance & Wheeling from its southern terminus at Piney Fork, in Jefferson county, Ohio, southeast to Martin's Ferry, 21 miles.

MEXICAN MILLING & TRANSPORTATION COMPANY.—This company has been authorized to build railroads in the municipalities of Guanajuato and La Paz, connecting with the Mexican Central near Santa Rosa, and a number of branches, a total of about 50 miles. The line must be located within three months, six miles built within 15 months and a similar amount finished each year, the entire work not to take over five years. An agreement has been entered into by the Department of Communications and Public Works and George W. Bryant to build the line.

MEXICAN PACIFIC.—A concession was recently granted to this company to build a branch in the state of Guerrero from Acapulco northwest via Pie de la Cuesta to a point on the Coyuca river, about 30 miles. According to the terms of the concession, location surveys must be begun within six months, three miles of the road must be built the first year, and the entire line finished within four years. The office of the company will be at Acapulco.

MICHIGAN ROADS.—A new logging road, it is reported, will be built by the Sawyer-Goodman Company in Mastodon township, Iron county, about 15 miles long. The proposed line is to penetrate a large tract of timber owned by the Sawyer-Goodman Company.

MIDCONTINENTAL TRACTION.—This company, recently organized by eastern capitalists to build an electric line from Tulsa, Ind. T., via Red Fork and Sapulpa, to the Glen Pool oil fields, about 21 miles, has completed financial arrangements and will shortly begin work. F. L. Smart, Kansas City, Mo., President; J. R. Burnham, Chief Engineer, Tulsa.

MIDLAND VALLEY.—The branch from Jenks, Ind. T., to Glen Pool, 6½ miles, has been opened for passenger service. (July 26, p. 111.)

MINNEAPOLIS, ST. PAUL & SAULT STE. MARIE.—An amendment to its charter has been filed by this company in Wisconsin, permitting it to build a branch from Brooton, Minn., northwest, 180 miles, to Superior.

MISSISSIPPI VALLEY (ELECTRIC).—Contract is reported let by this company to the Federal Construction Company of New York, to build its proposed electric line from Fort Madison, Iowa, south, via Keokuk, and thence east via Hamilton, Ill., to Carthage, Ill., 45 miles. Rights of way have been secured and capital, it is said, necessary to build the line has been obtained.

OCEAN SHORE (ELECTRIC).—The San Joaquin Valley Western, incorporated to build an extension of this road from Santa Cruz, Cal., east via Holester, is said to have located the line and secured the right of way for about 100 miles. Work will shortly be begun. The line when finished, including branches, is to be 220 miles long and to cost about $6,000,000. (March 15, p. 388.)

PENNSYLVANIA.—This company, it is said, has opened its Pittsburg, Brownsville & Monongahela Railroad, a new branch from Brownsville, Pa., to Rice's Landing, 15 miles.

PENNSYLVANIA ROADS (ELECTRIC).—The Mercer Construction Co. has been granted a charter in West Virginia with $25,000 capital to build an electric line from Mercer, Pa., northwest to Greenville, 15 miles. It is also proposed to build an extension from Greenville southwest to Sharpsville, 11 miles, where connection is to be made with the Sharon & Sharpsville. The proposed extension is to form part of a line to connect Erie with Pittsburg. The incorporators include J. M. Campbell, L. W. Orr and T. P. Filer, of Mercer; W. Hilderbrand, of Pittsburg, and S. D. Downs, of Greenville.

PITTSBURG, SHAWMUT & NORTHERN.—The Brookville & Mahoning, building from Hydes, Pa., southwest towards Pittsburg, to Freeport, 101 miles, for which contracts were let to the Miller Construction Company, of Lockhaven, has filed with the State Department of Pennsylvania a report of an increase of $500,000 in capital stock. The company was authorized some time ago to increase its capitalization from $1,350,000 to $10,000,000. (March 15, p. 390.)

ST. LOUIS & SAN FRANCISCO.—The Colorado Southern, New Orleans & Pacific has been formally leased to this company. The division from Houston east, it is said, is to be opened for traffic

September 15 to De Quincy, and possibly as far east as Opelousas. The remainder of the line east to New Orleans is to be ready for operation about January 1. (July 26, p. 111.)

San Francisco, Idaho & Montana.—This company, which was incorporated to build a line from Butte, Mont., southwest to San Francisco, according to a reported statement of E. R. Place, General Manager, has bought all the necessary right of way, with the exception of 12 miles near Winnemucca, Nev., for the branch from Caldwell, Idaho, to Winnemucca, Nev., 196 miles. As yet we have not heard of any contracts being let except for 16 miles from Caldwell to Homedale. Donald Grant, President, Faribault, Minn.; I. H. Richardson, Chief Engineer, Caldwell, Idaho. (March 15, p. 391.)

San Joaquin Valley Western.—See Ocean Shore.

San Pedro, Los Angeles & Salt Lake.—Freight and passenger service on the Caliente & Pioche, it is reported, has been established for 15 miles north of Caliente about half way to Pioche. (March 15, p. 380.)

South Dakota Central.—This company, building an extension from Rutland, S. Dak., north 75 miles to Watertown, has been finished to Nunda, six miles; the work has been delayed on account of lack of laborers. A large grading outfit has recently been put at work and the grading will be finished to Watertown by December. Work is now under way near Arlington, where the Chicago & North-Western tracks will be crossed. (May 10, p. 663.)

South Dakota Roads.—The promoters of the proposed line from Mitchell, S. Dak., northeast to Marshall, Minn., about 130 miles, recently held a meeting at Mitchell and appointed a committee to exploit the project. L. L. Ness, D. B. Miller, O. E. Cassem, of Mitchell; J. Wadden, J. Larkin, C. B. Kenned, of Madison; L. P. Johnson, R. F. Schulz, of Ivanhoe; G. West, E. Olson, F. Sherwin, of Brookings; C. L. Johnson, L. A. Larson, G. P. Skortum, of Hendricks; I. J. Todd, of Salem; W. S. Dotym, of Epiphany; C. W. Shirley, of Clarno, and A. Swanson, of Winnifred, are on the committee. The proposed line is intended eventually to be extended from Mitchell, southwest to the Missouri river at Wheeler, giving the south central part of South Dakota a more direct connection with Minneapolis and St. Paul.

Southern Wisconsin (Electric).—This company, formerly the Madison Street Railway Company, has petitioned the Wisconsin State Railroad Commission for a certificate of authority to build an interurban line from Madison southeast via MacFarland to Janesville, 40 miles. The Madison council about a year ago refused to grant the company a 40-year franchise for this purpose.

Stephensville North & South Texas.—This company was organized to build a line from Stephensville, in Erath county, Tex., south to Hamilton, 35 miles. It has been finished to Alexander, about 13 miles, and this section is said to be now open for traffic. The company expects to have the entire line to Hamilton finished about the middle of October. Read & Montgomery, Stephensville, contractors; McK. Johnstone, Chief Engineer. (Mar. 15, p. 388.)

Toledo, St. Louis & Western.—This road having acquired control of the Chicago & Alton, a connection is to be built from Panama, Ill., west to Litchfield, the eastern terminus of a Chicago & Alton branch, seven miles. By construction of this seven-mile link the two roads will together have a through route from Detroit and Toledo on the east to Kansas City on the west.

Wagner, Lake Shore & Aamoua Traction.—An officer writes that this company, which expects to let contracts in July for building its proposed electric line from Wagner, S. Dak., north via Lake Shore, Armour and Hillslide to Mitchell, 65 miles, has been unable to carry out its plans by reason of its failure to secure satisfactory franchises in the city of Mitchell. Work has been under way for some time on the power plants at Armour and Platte, and these are now being rapidly finished. (May 31, p. 760.)

Wisconsin Midland.—A franchise has been granted this company, which has a capital of $30,000, to build a line from the Chicago & North-Western at Chester, Wis., northwest, five miles, to Waupun. The line is eventually to be extended south from Waupun to a point beyond Beaver Dam. Thomas Mercein, of Milwaukee, is the principal promoter.

RAILROAD CORPORATION NEWS.

Belmont, Sour Lake & Western.—See St. Louis & San Francisco.

Central of Georgia.—The directors have passed the dividend on the $4,000,000 third preference income bonds. The usual dividend of 5 per cent. was declared on the first income bonds, but only 3.729 per cent. on the second incomes. For the last four years 5 per cent. has been paid on the first income bonds, the rate was 3 per cent. in 1902, 5 per cent. in 1901, 3¼ per cent. in 1900 and 2 per cent. in 1899 and 1898. On the second incomes 5 per cent. has been paid for the last two years, 2 per cent. in 1904 and nothing previously; on the third incomes 5 per cent. has been paid for the last two years and nothing previously.

Chicago & Alton.—See Toledo, St. Louis & Western.

Chicago, Milwaukee & St. Paul.—This company is about to begin the electrification of its line from Wilson avenue, Chicago, to Evanston, Ill., according to an ordinance of the city of Chicago. The Northwestern Elevated is to operate its cars over this line. The cost, estimated at $1,000,000, as well as the revenue from the service, will be divided between the two companies. It is expected that operation will begin in three months.

Colorado Southern, New Orleans & Pacific.—See St. Louis & San Francisco.

Erie.—The Directors have decided to pay the regular semi-annual dividend of 2 per cent. on the $47,892,400 first preferred and the annual dividend of 4 per cent. on the $16,000,000 second preferred stock in warrants which will run for 10 years and bear 4 per cent. interest.

Great Northern.—The first distribution of profits by the trustees of the Great Northern's iron ore property, leased to the United States Steel Corporation last fall, has been declared. It is $1 a share, payable September 16. The interest in the property was divided into 1,500,000 shares, with no fixed par value, which were distributed, share for share, to holders of Great Northern stock. It was announced last fall that a distribution of profits would be made at least once a year. In making this first distribution, however, the trustees did not say whether the present rate would be maintained or changed.

Interborough-Metropolitan.—See Metropolitan Street Railway.

Metropolitan Street Railway.—Movements have been started to form a protective committee of the stockholders of this company because it is feared that the 7 per cent. guaranteed dividend on the $52,000,000 stock may be reduced or passed entirely. The property is leased to the New York City Railway, the rental being the dividend referred to, the payment of which is guaranteed by the Metropolitan Securities Company, which owns all the stock of the New York City Railway. The Metropolitan Securities Company is controlled by the Interborough-Metropolitan Company. It is understood that the Metropolitan Street Railway has not been earning enough to cover the dividend and that the Metropolitan Securities Company has been making up the deficit. The last named company, however, has no apparent source of income other than what it gets from the stock of the New York City Railway. The Interborough-Metropolitan, it is said, has decided not to pay unearned dividends on the Metropolitan Street Railway stock if the Metropolitan Securities Company is not able to do so.

Northwestern Elevated.—See Chicago, Milwaukee & St. Paul.

Rock Island Company.—See Toledo, St. Louis & Western.

St. Louis & San Francisco.—The Colorado Southern, New Orleans & Pacific's property has been leased to the St. Louis & San Francisco. The road is under construction from Baton Rouge, La., to De Quincy, 138 miles; from De Quincy to Beaumont, Tex., 47 miles, the tracks of the Kansas City Southern are to be used and the Beaumont, Sour Lake & Western, which ran from Beaumont to Sour Lake, 22 miles, and was acquired some time ago by the St. Louis & San Francisco, has been rebuilt and extended to Houston. Connection is ultimately to be made between Baton Rouge and New Orleans.

Southern.—A semi-annual dividend of 1¼ per cent. has been declared on the $60,000,000 non-cumulative 5 per cent. preferred stock, payable October 17. The annual rate has been 5 per cent. since 1901, when it was 4 per cent. It was 3 per cent. in 1900, 2 per cent. in 1899, and 1 per cent. in 1898 and 1897. After reducing the dividend, the Directors announced that, though feeling that the unusual results of last year were not liable to be repeated, they believed it best to limit the distribution of profits until the permanent effects of high prices, increasing taxes and legislative reduction of earnings could be fairly measured.

Toledo, St. Louis & Western.—This company is to buy control of the Chicago & Alton from the Rock Island Company and interests associated with it. In return for $6,380,000 preferred and $14,420,000 common stock of the Chicago & Alton out of $19,544,000 preferred and $19,542,800 common outstanding, the Toledo, St. Louis & Western is to issue collateral trust bonds to be turned over to the Rock Island Company. For the preferred stock bought, 4 per cent. collateral trust bonds are to be issued at par and for the common stock collateral trust bonds are to be issued at 35, which are to bear interest at 2 per cent for five years and then 4 per cent. For further comment on this purchase, see editorial column and also a short article with map published in this issue.

RAILROAD GAZETTE

ESTABLISHED IN APRIL, 1856.

PUBLISHED EVERY FRIDAY BY THE RAILROAD GAZETTE AT 83 FULTON STREET, NEW YORK.
BRANCH OFFICES AT 376 OLD COLONY BUILDING, CHICAGO, AND QUEEN ANNE'S CHAMBERS, WESTMINSTER, LONDON.

EDITORIAL ANNOUNCEMENTS.

THE BRITISH AND EASTERN CONTINENTS edition of the Railroad Gazette is published each Friday at Queen Anne's Chambers, Westminster, London. It contains selected reading pages from the Railroad Gazette, together with additional British and foreign matter, and is issued under the name Railway Gazette.

CONTRIBUTIONS.—Subscribers and others will materially assist in making our news accurate and complete if they will send early information of events which take place under their observation. Discussions of subjects pertaining to all departments of railroad business by men practically acquainted with them are especially desired.

ADVERTISEMENTS.—We wish it distinctly understood that we will entertain no proposition to publish anything in this journal for pay, EXCEPT IN THE ADVERTISING COLUMNS. We give in our editorial columns OUR OWN opinions, and these only, and in our news columns present only such matter as we consider interesting and important to our readers. Those who wish to recommend their inventions, machinery, supplies, financial schemes, etc., to our readers, can do so fully in our advertising columns, but it is useless to ask us to recommend them editorially, either for money or in consideration of advertising patronage.

OFFICERS.—In accordance with the law of the state of New York, the following announcement is made of the office of publication, at 83 Fulton St., New York, N.Y., and the names of the officers and editors of The Railroad Gazette:

CONTENTS

VOL. XLIII., No. 10. FRIDAY, SEPTEMBER 6, 1907.

ELECTRIFICATION ON THE SOUTHERN PACIFIC.

The Southern Pacific has directed its electrical engineer, Allen H. Babcock, and Frank J. Sprague, who has been retained as consulting engineer, to study the possibilities of increasing the capacity of the Sacramento division of the old Central Pacific by electrifying between Rocklin, Cal., and Sparks, Nev., 134 miles over the Sierra Nevada mountains. These gentlemen constitute a sub-committee within a committee of five, consisting of themselves and three engineers of the Harriman lines, not yet named. This committee will consider the relative advantages of a number of proposed plans for relieving the present congestion of traffic over this important connecting link between the Union Pacific and the Southern Pacific coast lines, and will make final recommendations to Mr. Kruttschnitt, Director of Maintenance and Operation of the Harriman lines.

This electrification is perhaps the most difficult and important installation which has so far been seriously considered. The New York Central and the New Haven electrifications are simple problems compared to it. The New York Central was compelled by law to abandon steam locomotives in the Park avenue tunnel, and it planned its electric equipment, not so much with the idea of immediate economy in operation, as with the belief in great expansion of business in the future in a thickly populated territory which could be handled more profitably and with greater comfort to passengers by electric trains than with steam trains. The New Haven went even farther and designed its installation with the idea of immediate economy of operation and the ultimate extension of electricity over the greater part of its network of lines in Connecticut.

The economy of electric operation is still open to some discussion. The possibility of increasing the carrying capacity of a given piece of track by substituting electricity for steam as motive power is perhaps more easily proved, yet heretofore this has been a consideration of secondary importance. In the Southern Pacific's problem it is the first important consideration; reasonable economy must, of course, be attained, but it would be worth while to increase the cost of operation slightly if it was found possible to increase the capacity of the line one-half or more. Any of the plans proposed will cost enormous sums to carry out, and the committee will have to decide which method will best meet present and future needs for the least ultimate cost.

The Sacramento division crosses the Sierra Nevada mountains at an elevation of 7,018 ft. It is the most direct route to San Francisco, and all the through traffic of the Union Pacific which is not diverted north over the Oregon Short Line to Portland or south over the San Pedro, Los Angeles & Salt Lake to Los Angeles must be carried up the steep slopes on one side and down the equally steep slopes on the other side. The traffic is heavy, but quite irregular and blockades are frequent in the yards at both ends of the division. The road is single track with few sidings, and because of the difficult location it is practically impossible to double-track it throughout or to greatly increase the length of the sidings. The road is full of sharp curves, and between Rocklin and Sparks there are more than 31 miles of tunnels and snow sheds. Rocklin, at the foot of the eastbound grade, has an elevation of 250 ft. and from that point to the summit, 83 miles, there is a total rise of 6,768 ft., an average of 81½ ft. per mile, with a maximum of 116 ft. per mile. Westbound the maximum grade begins at Truckee, and the rise to the summit, 14 miles, is 1,198 ft., an average of 85½ ft., with a maximum of 105 ft. per mile. In the winter the snow often accumulates to a depth of from 15 to 20 ft. in the exposed places.

Various methods have been proposed and carefully looked into for relieving in part the congestion of this very much overworked line. An entirely new single-track line has been located some distance away which has slightly more favorable grades, and if built would be equivalent to providing a second track on the present location. Tunneling the Sierras at a lower elevation and thus reducing the length, as well as the steepness of the grades on each side, has also been proposed.

Mr. Babcock has been studying the possibilities of a change in motive power from steam to electricity for nearly three years and has collected much of the necessary data on which a report can be based. It is by no means assured, however, that the company will decide to adopt electricity instead of the difficult construction work for a new line or the daring scheme of a long tunnel under the mountains, for the difficulties of installing and maintaining the necessary electrical equipment may be found to be too great. The principal advantage of electricity as a motive power would be that it could be installed in much less time than a new line could be built, and the results would be noticeable from the beginning of operation of the first section. In case a tunnel was built it would be necessary in any event to use electricity as a motive power.

Some of the difficulties to be overcome if electric operation of the entire division is finally decided upon are: Installation and maintenance of transmission lines to withstand heavy snows and violent storms without interruption. Provision for wide variations in load

with heavy but very intermittent traffic. Danger from fire in snow sheds during the summer and from short circuits due to melting snow in the spring. Extreme cost of substantial and permanent overhead line construction and danger to trainmen in tunnels and snow sheds if this method should be employed. Interference by snow in the open if third rail construction is used.

The two engineers who will report on this problem have not as yet decided on any of the details of the apparatus which might be employed. They are approaching the subject with open minds, and it is possible that after a thorough consideration of the problem they may report to the committee that the scheme is not practical. In any event, their report, when made, will be an interesting study of the possibilities of electric operation along lines which are beginning to attract serious attention.

RAIL SECTIONS AND SPECIFICATIONS

The Progress Report of the Special Committee on Rail Sections of the American Society of Civil Engineers, embodying the "Recommended Specifications for Bessemer Steel Rails" is given in full herewith. As stated by the committee "in the designing of heavier sections, particular attention is being given to the advisability of increasing the percentage of metal in the webs and flanges, as compared with the existing sections recommended by your society." This proposed change would probably prove a decided step in the right direction, in that it would not only increase the strength and stiffness of the rail, but would allow of a much lower finishing temperature in rolling than is possible with the present thin flanges.

For convenience of comparison and discussion these recommended specifications are printed below in parallel columns with those adopted by the American Railway Engineering and Maintenance of Way Association and those passed to letter ballot by the American Society for Testing Materials at its recent annual meeting. A discussion of the report made to the American Society of Civil Engineers by the special committee has been made an order of business for the annual meeting to be held in January next, and a committee of the American Railway Association is also engaged in the study of the problem of rail sections and rail specifications. The time seems opportune, therefore, to call attention to some of the differences in the above specifications.

It is believed that a specification embodying the best features of the three specifications here cited with adequate provision for tests would insure a safe rail of good wearing properties. It may be safely asserted that the unsatisfactory experience within recent years with rails under modern service conditions have been due mainly to the fact that the specifications under which such rails have been furnished were not sufficiently rigid, and that the mills have been disinclined to accept orders under specifications designed to insure a better and more uniform material. It is certain, however, that no matter how exacting the specifications may be made in the letter, the standard of excellence that they are designed to secure cannot be insured without more rigid inspection than has been customary in the past.

The three specifications referred to are as follows: (For convenience of comparison the sequence of the paragraphs has been slightly modified to adapt them to the specifications recommended by the special committee of the American Society of Civil Engineers.)

AMERICAN SOCIETY OF CIVIL ENGINEERS.

"Recommended Specifications for Bessemer Steel Rails.*

"*Process of Manufacture.*—The entire process of manufacture and testing shall be in accordance with the best state of the art, and the following instructions shall be faithfully executed:

"Ingots shall be kept in a vertical position in the pit heating furnaces until ready to be rolled, or until the metal in the interior has had time to solidify.

"No bled ingots shall be used.

"There shall be sheared from the end of the blooms formed from the top of the ingots not less than twenty-five per cent., and if, from any cause, the steel does not then appear to be solid, the shearing shall continue until it does. If, by the use of any improvements in the process of making ingots, the defect known as piping shall be prevented, the above shearing requirements may be modified.

"The number of passes and speed of train shall be so regulated that on leaving the rolls at the final pass, the temperature of the rail will not exceed that which requires a shrinkage allowance at the hot saws, for a 33-ft. rail of 100-lb. section, of 6 7-16 in., and 1-16 in. less for each 5-lb. decrease of section. These allowances to be decreased at the rate of 1-90 in. for each second of time elapsed between the rail leaving the finishing rolls and being sawn. No artificial means of cooling the steel shall be used after the rails leave the rolls, nor shall they be held before sawing for the purpose of reducing their temperature."

"*Chemical Composition.*—Rails of the various weights per yard specified below shall conform to the following limits in chemical composition:

	70-79lb. Percentage.	80-89lb. Percentage.	90-100lb. Percentage.
Carbon	0.50-0.60	0.53-0.63	0.55-0.65
Phosphorus shall not exceed	0.085	0.085	0.085
Silicon shall not exceed	0.20	0.20	0.20
Sulphur shall not exceed	0.075	0.075	0.075
Manganese	0.75-1.00	0.80-1.05	0.80-1.05

*Chemical composition may be varied to suit local conditions.

AMERICAN RAILWAY ENGINEERING AND MAINTENANCE OF WAY ASSOCIATION.

SPECIFICATIONS FOR BESSEMER STEEL RAILS.

STANDARD SPECIFICATIONS.

(1) (a) The entire process of manufacture and testing shall be in accordance with the best current practice, and special care shall be taken to conform to the following instructions:

(b) Ingots shall be kept in a vertical position in the pit heating furnaces until ready to be rolled, or until the metal in the interior has time to solidify.

(c) No bled ingots shall be used.

(d) There shall be sheared from the end of the blooms formed from the top of the ingots not less than twenty-five (25) per cent., and if, from any cause, the steel does not then appear to be solid, the shearing shall continue until it does. If, by the use of any improvements in the process of making ingots, the defect known as piping shall be prevented, the above shearing requirements may be modified.

(2) Rails of the various weights per yard specified below shall conform to the following limits in chemical composition:

(5) The number of passes and speed of train shall be so regulated that on leaving the rolls at the final pass, the temperature of the rail will not exceed that which requires a shrinkage allowance at the hot saws for a 33-ft. rail of 100-lb. section of 6 7-16 in., and 1-16-in. less for each 5-lb. decrease of section, these allowances to be decreased at the rate of 1-90-in. for each second of time elapsed between the rail leaving the finishing rolls and being sawn. No artificial means of cooling the steel shall be used after the rails leave the rolls, nor shall they be held before sawing for the purpose of reducing their temperature.

	Percentage 70-79 lbs.	80-89 lbs.	90-100 lbs.
*Carbon	0.50-0.60	0.53-0.63	0.55-0.65
Phosphorus shall not exceed	0.085	0.085	0.085
Silicon shall not exceed	0.20	0.20	0.20
Sulphur shall not exceed	0.075	0.075	0.075
Manganese	0.75-1.00	0.80-1.05	0.80-1.05

*Carbon may be reduced to suit local conditions.

AMERICAN SOCIETY FOR TESTING MATERIALS.

PROPOSED STANDARD SPECIFICATIONS.

1. (a) The entire process of manufacture and testing shall be in accordance with the best current practice, and special care shall be taken to conform to the following instructions: (b) Ingots shall be kept in a vertical position in the pit heating furnaces until ready to be rolled or until the metal in the interior has time to solidify. (c) No bled ingots shall be used. (d) There shall be sheared from the end of the blooms formed from the top of the ingots not less than x %,† and if, from any cause, the steel does not then appear to be solid, the shearing shall continue until it does.

†The percentage of minimum discard in any case to be subject to agreement and it should be recognized that the higher this percentage the greater will be the cost.

4. The number of passes and speed of train shall be so regulated that on leaving the rolls at the final pass the temperature of the rail will not exceed that which requires a shrinkage allowance at the hot saws, for a 30-foot rail of 100-pound section of 6 11-16 inches, and 1-16 inch less for each 5-pound decrease of section. These allowances to be decreased at the rate of 0.01 inch for each second of time elapsed between the rail leaving the finishing rolls and being sawed. No artificial means of cooling the rails shall be used between the finishing pass and the hot saws.

2. Rails of the various weights per yard specified below shall conform to the following limits in chemical composition:

	Carbon.	Phosphorus, shall not exceed.	Silicon, shall not exceed.	Manganese.
50-59 lbs., per cent.	0.35-0.45	0.10	0.20	0.70-1.00
60-69 lbs., per cent.	0.38-0.48	0.10	0.20	0.70-1.00
70-79 lbs., per cent.	0.40-0.50	0.10	0.20	0.75-1.05
80-89 lbs., per cent.	0.43-0.53	0.10	0.20	0.80-1.10
90-100 lbs., per cent.	0.45-0.55	0.10	0.20	0.80-1.10

*Progress report of the Special Committee on Rail Sections, A. S. C. E.:

Gentlemen:—Your committee respectfully report that they have given the report, which they submitted under date of Jan. 17, 1906, and which was referred back to them, careful consideration, and would now report that they are in consultation with committees representing other societies and organizations, as well as other interested parties, on the subject of modified rail sections, with the purpose of preparing and submitting to your society a new series of such sections. In this designing of heavier sections, particular attention is being given to the advisability of increasing the percentage of metal in the webs and flanges as compared with the existing sections recommended by your Society. This they hope to accomplish in due time, and in the meantime respectfully submit to the society for its consideration the following specifications for the manufacture of Bessemer and open-hearth rails:

A. S. C. E.

Drop Test.—One drop test shall be made on a piece of rail, not less than 4 ft. and not more than 6 ft. long, selected from each blow of steel. The test piece shall be taken from the top of the ingot. The rails shall be placed head upward on the supports and the various sections shall be subjected to the following impact tests under a free falling weight:

70 to 79 lb. rails	18 ft.
80 to 89 lb. rails	20 ft.
90 to 100 lb. rails	22 ft.

"If any rail breaks, when subjected to the drop test, two additional tests may be made of other rails from the same blow of steel, also taken from the top of the ingots, and if either of these latter rails fail, all the rails of the blow which they represent will be rejected, but if both of these additional test pieces meet the requirements, all the rails of the blow which they represent will be accepted.

"The drop-testing machine shall have a top of 2,000 lb. weight, the striking face of which shall have a radius of not more than 5 in., and the test rail shall be placed head upward on solid supports 3 ft. apart. The anvil block shall weigh at least 20,000 lb., and the supports shall be part of, or firmly secured to, the anvil. The report of the drop test shall state the atmospheric temperature at the time the test was made."

"*Section.*—The section of rail shall conform, as accurately as possible, to the templet furnished by the railroad company, consistent with the paragraph relative to specified weight. A variation in height of 1-64 in. less, or 1-32 in. greater than the specified height, and 1-16 in. in width will be permitted. The section of rail shall conform to the finishing dimensions.

"*Weight.*—The weight of the rails will be maintained as nearly as possible, after complying with the preceding paragraph, to that specified in contract. A variation of one-half of 1 per cent. for an entire order will be allowed. Rails will be accepted and paid for according to actual weights.

"*Length.*—The standard length of rails shall be 33 ft. Ten per cent. of the entire order will be accepted in shorter lengths varying by even feet to 27 ft., and all No. 1 rails less than 33 ft. long shall be painted green on the ends. A variation of ⅛ in. in length from that specified will be allowed.

"*Drilling.*—Circular holes for splice bars shall be drilled in accordance with the specifications of the purchaser. The holes shall conform accurately to the drawing and dimensions furnished, in every respect, and must be free from burrs.

"*Straightening.*—Care must be taken in hot-straightening the rails, and it must result in their being left in such condition that they shall not vary throughout their entire length more than 5 in. from a straight line in any direction, when delivered to the cold-straightening presses. Those which vary beyond that amount, or have short kinks, shall be classed as second-quality rails and be so stamped.

"Rails shall be straight in line and surface when finished—the straightening being done while cold—smooth on head, sawed square at ends, variation to be not more than $\frac{1}{32}$ in., and, prior to shipment shall have the burr occasioned by the saw cutting removed, and the ends made clean. No. 1 rails shall be free from injurious defects and flaws of all kinds.

"No. 2 rails shall be accepted up to 5 per cent. of the whole order. They shall not have flaws in their heads of more than ¼ in., or in the flange of more than ½ in. in depth, and, in the judgment of the inspector, these shall not be so numerous or of such a character as to render them unfit for recognized second-quality rail uses. The ends of No. 2 rails shall be painted white, and shall have two prick-punch marks on the side of the web near the heat number brand, and placed so as not to be covered by the splice bars. Rails from heats which failed under the drop test shall not be accepted as No. 2 rails.

M. of W.

(3) One drop test shall be made on a piece of rail not less than 4 ft. and not more than 6 ft. long, selected from each blow of steel. The test piece shall be taken from the top of the ingot. The rails shall be placed head upward on the supports, and the various sections shall be subjected to the following impact tests under a free falling weight:

70 to 79 lb. rails	18 ft.
80 to 89 lb. rails	20 ft.
90 to 100 lb. rails	22 ft.

If any rail breaks when subjected to the drop test, two additional tests may be made of other rails from the same blow of steel, also taken from the top of the ingots, and if either of these latter rails fail, all the rails of the blow which they represent will be rejected, but if both of these additional test pieces meet the requirements, all the rails of the blow which they represent will be accepted.

(4) The drop-testing machine shall have a top of 2,000 lbs. weight, the striking face of which shall have a radius of not more than 5 in., and the test rail shall be placed head upward on solid supports 3 ft. apart. The anvil block shall weigh at least 20,000 lbs., and the supports shall be part of, or firmly secured to, the anvil. The report of the drop test shall state the atmospheric temperature at the time the test was made.

(7) Unless otherwise specified, the section of rail shall be the American Standard, recommended by the American Society of Civil Engineers, and shall conform, as accurately as possible, to the templet furnished by the railroad company, consistent with paragraph No. 8, relative to specified weight. A variation in height of one sixty-fourth (1-64) inch less, or one thirty-second (1-32) inch greater than the specified height, and one-sixteenth (1-16) inch in width, will be permitted. The section of rail shall conform perfectly to the finishing dimension.

(8) The weight of the rails will be maintained as nearly as possible, after complying with paragraph No. 7, to that specified in contract. A variation of one-half (½) of one per cent. for an entire order will be allowed. Rails shall be accepted and paid for according to actual weights.

(9) The standard length of rails shall be 33 ft. Ten per cent. of the entire order will be accepted in shorter lengths, varying by even feet to 27 ft., and all No. 1 rails less than 33 ft. shall be painted green on the end. A variation of one-fourth of an inch in length from that specified will be allowed.

(10) Circular holes for splice bars shall be drilled in accordance with the specifications of the purchaser. The holes shall accurately conform to the drawings and dimensions furnished in every respect, and must be free from burrs.

(11) Rails shall be straight in line and surface when finished—the straightening being done while cold—smooth on head, sawed square at ends, variation to be not more than $\frac{1}{32}$ in., and, prior to shipment shall have the burr occasioned by the saw cutting removed and the ends made clean. No. 1 rails shall be free from injurious defects and flaws of all kinds.

(12) Care must be taken in hot-straightening the rails, and it must result in their being left in such a condition that they shall not vary throughout their entire length of 33 ft. more than 3 in. from a straight line in any direction, when delivered to the cold straightening presses. Those which vary beyond that amount, or have short kinks, shall be classed as second quality rails and be so stamped. The distance between supports of rails in the gagging press shall not be less than 42 in.

(15) No. 2 rails will be accepted up to five (5) per cent. of the whole order. Rails that possess any injurious defects, or which for any other cause are not suitable for first quality, or No. 1 rails, shall be considered as No. 2 rails; provided, however, that rails which contain any physical defects which impair their strength shall be rejected. The ends of all No. 2 rails shall be painted white in order to distinguish them. Rails rejected under the drop test will not be accepted as No. 2 rails.

A. S. T. M.

3. One drop test shall be made on a piece of rail not less than four feet and not more than six feet long, selected from each blow of steel. The test shall be taken from the top of the ingot. The rail shall be placed head upward on the supports, and the various sections shall be subjected to the following impact tests under a free falling weight:

Weight of rail pounds per yard	Height of drop feet
45 to and including 55	15
More than 55 to and including 65	16
More than 65 to and including 75	17
More than 75 to and including 85	18
More than 85 to and including 100	19

If any rail breaks when subjected to the drop test, two additional tests taken from the top of the ingot, will be made of other rails from the same blow of steel, and if either of these latter tests fails, all the rails of the blow which they represent will be rejected, but if both of these additional test pieces meet the requirements, all the rails of the blow which they represent will be accepted.

5. The drop testing machine shall have a top of 2,000 pounds weight, the striking face of which shall have a radius of not more than five inches, and the test rail shall be placed head upwards on solid supports three feet apart. The anvil block shall weigh at least 20,000 pounds, and the supports shall be part of, or firmly secured to, the anvil. The report of the drop test shall state the atmospheric temperature at the time the test was made.

7. Unless otherwise specified, the section of rail shall be the American standard, recommended by the American Society of Civil Engineers, and shall conform, as accurately as possible, to the templet furnished by the railroad company, consistent with Paragraph No. 8, relative to specified weight. A variation in height of 1-64 of an inch less, or 1-32 of an inch greater than the specified height, and 1-16 in. in width will be permitted.

8. The weight of the rails will be maintained as nearly as possible, after complying with Paragraph No. 7, to that specified in contract. A variation of one-half of 1 per cent. for an entire order will be allowed. Rails shall be accepted and paid for according to actual weights.

9. The standard length of rails shall be 30 ft. Ten per cent. of the entire order will be accepted in shorter lengths, varying by even feet to 24 ft., and all No. 1 rails less than 30 ft. shall be painted green on the end. A variation of one-fourth of an inch in length from that specified will be allowed.

10. Circular holes for splice bars shall be drilled in accordance with the specifications of the purchaser. The holes shall accurately conform to the drawing and dimensions furnished in every respect, and must be free from burrs.

11. Care must be taken in hot-straightening the rails, and it must result in their being left in such a condition that they shall not vary throughout their entire length more than 5 in. from a straight line in any direction when delivered to the cold-straightening presses. Those which vary beyond that amount, or have short kinks, shall be classed as second quality rails and be so stamped. The distance between supports of rails in the gagging press shall be not less than 42 in. Rails shall be straight in line and surface when finished—the straightening being done while cold—smooth on head, sawed square at ends, variations to be not more than $\frac{1}{32}$ in., and, prior to shipment, shall have the burr occasioned by the saw cutting removed, and the ends made clean. No. 1 rails shall be free from injurious defects and flaws of all kinds.

14. No. 2 rails will be accepted up to 10 per cent. of the whole order. Rails which possess any injurious defects, or which for any other cause are not suitable for first quality, or No. 1 rails, shall be considered as No. 2 rails; provided, however, that rails which contain any physical defects which impair their strength shall be rejected. The ends of all No. 2 rails shall be painted white in order to distinguish them.

A. S. C. E.

"*Branding.*—The name of the maker, the weight of the rail, and the month and year of manufacture, shall be rolled in raised letters on the side of the web; and the number of the blow shall be plainly stamped on each rail where it will not subsequently be covered by the splice bars.

"*Inspection.* The inspector representing the purchaser shall have free entry to the works of the manufacturer at all times when the contract is being filled, and shall have all reasonable facilities afforded him by the manufacturer to satisfy him that the finished material is furnished in accordance with the terms of these specifications. All tests and inspection shall be made at the place of manufacture prior to shipment.

"The manufacturer shall furnish the inspector, daily, with carbon determinations for each blow and a complete chemical analysis every 24 hours, representing the average of the other elements contained in the steel, for each day and night turn. These analyses shall be made on drillings taken from small test ingots. On the request of the inspector, the manufacturer shall furnish drillings for check analyses.

"*For Basic Open-Hearth Rails.*—The specifications for rails made by the Basic Open-Hearth process shall be the same as for Bessemer rails, excepting that a full chemical determination shall be furnished for each heat and two drop-tests from each. Their chemical composition shall be:

	Per cent.		
	70 to 79 lbs.	80 to 89 lbs.	90 to 100 lbs.
Carbon	0.53 to 0.63	0.58 to 0.68	0.65 to 0.75
Phosphorus*	0.05	0.05	0.05
Silicon*	0.20	0.20	0.20
Sulphur*	0.06	0.06	0.06
Manganese	0.75 to 1.00	0.80 to 1.05	0.80 to 1.05

*Shall not exceed.

M. of W.

(13) The name of the maker, the weight of rail and the month and year of manufacture shall be rolled in raised letters on the side of the web, and the number of blow shall be plainly stamped on each rail where it will not subsequently be covered by the splice bars.

(14.) The inspector representing the purchaser shall have free entry to the works of the manufacturer at all times when the contract is being filled and shall have all reasonable facilities afforded him by the manufacturer to satisfy him that the finished material is furnished in accordance with the terms of these specifications. All tests and inspection shall be made at the place of manufacture prior to shipment.

(6) The manufacturer shall furnish the inspector daily with carbon determinations for each blow, and a complete chemical analysis every 24 hours, representing the average of the other elements contained in the steel, for each day and night turn. These analyses shall be made on drillings taken from small test ingots.

"For Basic Open-Hearth Rails.—The specifications for rails made by the basic open-hearth process shall be the same as for Bessemer rails, excepting that their chemical composition shall be:

	Per cent.		
	70 to 79 lbs.	80 to 89 lbs.	90 to 100 lbs.
Carbon	0.63 to 0.73	0.68 to 0.78	0.75 to 0.85
Phosphorus*	0.03	0.03	0.03
Silicon	.075 to 0.20	.075 to 0.20	.075 to 0.20
Sulphur*	0.06	0.06	0.06
Manganese*	0.90	0.90	0.90

*Shall not exceed.

A. S. T. M.

12. The name of the maker, the weight of rail and the month and year of manufacture shall be rolled in raised letters on the side of the web, and the number of blow shall be plainly stamped on each rail where it will not subsequently be covered by the splice bars.

13. The inspector representing the purchaser shall have free entry to the works of the manufacturer at all times when the contract is being filled and shall have all reasonable facilities afforded him by the manufacturer to satisfy him that the finished material is furnished in accordance with the terms of these specifications. All tests and inspections shall be made at the place of manufacture prior to shipment.

6. The manufacturer shall furnish the inspector, daily, with carbon determinations for each blow, and a complete chemical analysis every 24 hours, representing the average of the other elements contained in the steel, for each day and night turn. These analyses shall be made on drillings taken from a small test ingot.

The more important points of difference between the above specifications will now be briefly considered:

Process of Manufacture.—The American Society of Civil Engineers and Maintenance of Way specifications provide for a discard of 25 per cent. from the end of the blooms formed from the top of the ingots, and it is added that "if, by the use of any improvements in the process of making ingots, the defect known as piping shall be prevented, the above shearing requirements may be modified," whereas the American Society for Testing Materials specifications leave the percentage of minimum discard blank with the provision that "the percentage of minimum discard in any case is to be subject to agreement, and it should be recognized that the higher this percentage the greater will be the cost."

It is frequently claimed by the manufacturers that a minimum discard of 25 per cent. is excessive, and that many of the failures of rails in service which are ascribed to piping are really due to other causes. Nevertheless, it can hardly be denied that piped steel is responsible for many cases of rail failure which might have been avoided by a more liberal discard. This important problem of piping would seem to be one deserving of the most careful investigation through the co-operation of all parties in interest with a view of determining by what means and to what extent it may be controlled. If, for example, it should appear that by the use of steel of certain chemical composition, cast at a lower temperature than is now customary, the piping can be reduced the specific percentage of minimum discard may then be modified accordingly. There can be no question that the safety of the rail should be the first consideration, irrespective of incidental increased cost, and that until the amount of piping can be more definitely controlled it is preferable that the discard be somewhat excessive rather than too low.

The claim that with large discard the accumulation of bloom ends cannot be advantageously utilized should not be regarded as valid so long as such heavy discards are really necessary to insure solid metal. Moreover, the bloom ends may frequently be used, at least in part, for rolling light rails, as has been done in the past at certain mills. Such materials under proper restrictions might also be utilized for heavy rails of second grade to be put in sidings.

In each of these specifications the importance of securing a sufficiently low finishing temperature in rolling is recognized, and it is aimed to secure the same by specifying the maximum allowable amount of shrinkage for rails of different weights. This provision is undoubtedly in the right direction, but the conditions are complicated by the fact that the present rail sections do not lend themselves readily to low finishing temperatures by reason of insufficient metal in the web and flange, as compared with the head. With the proposed increased thickness of metal in web and flange the requirements in this particular can be much more satisfactorily met.

In this connection attention may be called also to the trouble caused by too heavy reductions in the early passes in the blooming mill, tending to tear the metal. Such defects, although they may apparently disappear during subsequent rolling to the extent of escaping surface inspection, may become sources of weakness in service and direct causes of failure.

The tendency on the part of the mills to use an insufficient number of passes in rolling in the rail mill is also calculated to have a detrimental effect on the product, and it is believed that mill practice in this respect might be modified to good advantage.

The percentage of second quality rails to be accepted, which is fixed at 5 per cent. by the American Society of Civil Engineers and Maintenance of Way specifications and at 10 per cent. by the American Society for Testing Materials specifications, also influences the quality of the product indirectly to an important degree. The lower this percentage the greater becomes the incentive to the manufacturer to exercise care at every stage of manufacture to avoid the accumulation of rejected rails, which under a larger percentage would be accepted as second quality.

In each of these specifications the importance of allowing sufficient time for the ingots to properly solidify is provided for in a general way, but in practice it is difficult to insure strict compliance with this provision.

Referring to the above features collectively, it is believed that an earnest effort on the part of the mills to secure improved conditions of manufacture in the directions indicated, together with the adoption of a heavier and better balanced rail section, would obviate the present difficulties to a large extent.

Chemical Composition.—The American Society of Civil Engineers and Maintenance of Way specifications prescribe that the phosphorus shall not exceed 0.085, with a range in carbon of 0.55 to 0.65 for the heaviest sections, whereas the American Society for Testing Materials specifications fix the phosphorus limit at 0.10 and the carbon limits at 0.45 to 0.55. The maintenance of way specifications provide, however, that the carbon limits "may be reduced to suit local conditions."

It is generally admitted that a higher percentage of phosphorus tends to increase brittleness, especially with higher carbon content. The supply of low phosphorus ores is, however, said to be insufficient to permit of the general adoption of the 0.085 percentage of phosphorus. If the validity of this claim be admitted there is apparently no good reason for not rolling such rails to the extent

to which low phosphorus ores are available for use in situations in which quality is of first importance. It is likely that the conditions in this respect will also be improved by the use of rails made of open hearth steel.

While it is conceded that good rails have been made in the past with a phosphorus content not exceeding 0.10, this limit is believed to be too high for rails of the present weight and section under the conditions of manufacture usually prevalent and for the present heavy service conditions. If the section be suitably increased with the added metal distributed between the web and flange it is possible that with proper care at every stage of manufacture a percentage of phosphorus not exceeding 0.10 for Bessemer steel rails will be found admissible.

Drop Tests.—The American Society of Civil Engineers and Maintenance of Way specifications call for one drop test from each blow of steel with 22 ft. height of fall on 90 to 100 lb. rails, whereas the American Society for Testing Materials specifications require one drop test from every fifth blow and a 19-ft. fall on a 85 to 100 lb. rail. It is important to note that each specification requires the test piece to be taken from that portion of the rail representing the top of the ingot.

The provision in the American Society of Civil Engineers and Maintenance of Way specifications, by which one test is required from every heat of steel and higher drop tests are called for than in the American Society for Testing Materials specifications, seem reasonable and preferable, especially since the present average quality of rails has proven unsatisfactory, and it is therefore desirable that the requirements should be raised rather than lowered.

Length of Rail.—The American Society for Testing Materials specifications require a standard length of 30 ft., as against 33 ft. adopted in the other two specifications. The only justification for adherence to a 30-ft. length is believed to be the shortage in cars of suitable length for hauling the longer rails, but since this difficulty is rapidly disappearing it may doubtless be assumed that the 33-ft. length will soon be adopted as a general standard.

Straightening.—All of the specifications recognize the importance of having the rails as straight as possible when they come from the cooling beds and two of the specifications limit the distance apart between the supports of the rails in the gagging press to not less than 42 in. This is one of the most important clauses in the specifications, as serious injury may be done to the rail in gagging, and any improvement that can be made either in section of rail or in rolling to avoid this severe treatment would be an important gain. The omission of any reference to the distance between supports of rails in the gagging press in the American Society of Civil Engineers specifications is believed to be undesirable. On the other hand the restriction of the camber to 3 in. in these, as well as the maintenance of way specifications, is doubtless preferable to the 5-in. limit prescribed by the American Society for Testing Materials specifications, and it is believed that the lower limit does not impose undue hardship on the mills.

No. 2 Rails.—The bearing of the allowable percentage of second quality rails to be accepted on the question of manufacture has already been referred to above under "process of manufacture." Aside from this it is believed, however, that the provisions governing the classification of No. 2 rails in all of these specifications are too lenient, and that rails embodying certain of the defects stated should be rejected absolutely as unfit for use.

Basic Open Hearth Steel Rails.—The American Society for Testing Materials specifications contain no reference to basic open hearth rails. The American Society of Civil Engineers specifications prescribe a limit of 0.05 for phosphorus and a carbon range of 0.65 to 0.75 for 90-100-lb. rails, as against a limit of 0.03 for phosphorus and 0.75 to 0.85 for carbon in the Maintenance of Way specifications, the aim of the latter being doubtless to secure a rail of equal wearing properties and decreased brittleness. The latter specifications are believed to be preferable, and it is to be hoped that the small range of ten points in carbon can be met by the manufacturers of basic open hearth steel, since it is a well-established fact that the carbon content cannot be controlled in this process as readily as in the case of the high carbon steels manufactured by either the acid open hearth or Bessemer processes.

It will be noted that the maintenance of way specifications contain the same provisions for drop tests for basic open hearth steel as for Bessemer steel, whereas the American Society of Civil Engineers specifications call for two drop tests from each heat of open hearth steel and a full chemical determination for the same. Both of these provisions are believed to be desirable to insure uniformity of product in the case of open hearth steel.

In conclusion it may be said that in the use of the [illegible] process the desirability of a change of section, as well as the exercise of due precaution at every stage of manufacture [illegible] the important question of finishing temperature is just as great as in the case of the Bessemer process, although possibly experience will show that an increased weight of section will be necessary for open hearth rails. The *Railroad Gazette* will welcome discussion of this subject in its columns, not only from the committee [illegible] whom the subject has been entrusted, but also from railroad officers who may differ from any of the conclusions expressed above.

The *Electric Traction Weekly*, quoting what we said concerning the recent disastrous collision at Salem, Michigan, and particularly that "the only way to cure the faults in the despatching system is to abolish the system and use in its place the block system," says:

"This would be most encouraging if, unfortunately, roads equipped with block systems did not have as many collisions as roads where the block has not been installed. How can the uncertain human factor be eliminated from train movements? How, for instance, after the most perfect system that human genius can devise has been put in force, can you make sure that the operator will make his dots large enough between the station name and the schedule figures?"

The implication that collisions are as frequent under the block system as on roads not thus worked, must be based on data from trolley roads which use various electrical arrangements that are not block signals in the true sense of the term. Where has our contemporary found any statistics really comparable, to justify the statement made? The best way to "eliminate the uncertain human factor" is to adopt the electrical and mechanical safeguards of the true block system. With that, the question how to make sure of an operator's dots no longer troubles.

The action of the Master Car Builders' Association, in providing a virtual penalty for putting paper and cloth advertisements on freight cars, is now taking effect. The Pennsylvania Railroad has given instructions to agents to see that shippers do not violate the rule and, in any event, to see that cars do not go forward with advertisements posted on them. Other roads have taken similar action. If any one misses the mental stimulus of these varied advertisements, he still can gaze, any day, at any station, on some big, yellow refrigerator car, bearing on its side in vivid and artistic (?) lettering the advertisement of the firm owning the car.

The increase in the express business which has been so widespread in the territory east of the Missouri river during the past few years, leading to the establishment, both for through and way business, of separate trains for the carriage of parcels, appears to be confined to no particular section of the country. The Southern Pacific has decided to run one train each way daily throughout its principal lines for the accommodation of the express company's business, namely, from San Francisco to Ogden, Utah; to Portland, Ore., and to El Paso, Tex. Some of these trains will incidentally carry a limited number of local passengers, but their main business will be to carry the express company's traffic. The through passenger trains will of course by this relief be enabled to shorten their stops and thus more surely maintain their schedule time. The aggregate length of these three routes is 2,844 miles.

Central of Georgia.

The 1907 year of the Central of Georgia is especially interesting for two primary reasons; first, because the $5,000,000 capital stock of the company which has been held by the reorganization committee of the Richmond Terminal Company since 1896 was sold during the year to Oakleigh Thorne and Marsden J. Perry, and, second, because of the company's inability on the face of published earnings to pay the full dividend on the second series of income bonds or any dividend at all on the third series, and the contest instituted by a committee representing income bond holders, who maintained that the equity of the earnings of the Ocean Steamship Company of Savannah should be used to provide for the return on the income bonds of the railroad company.

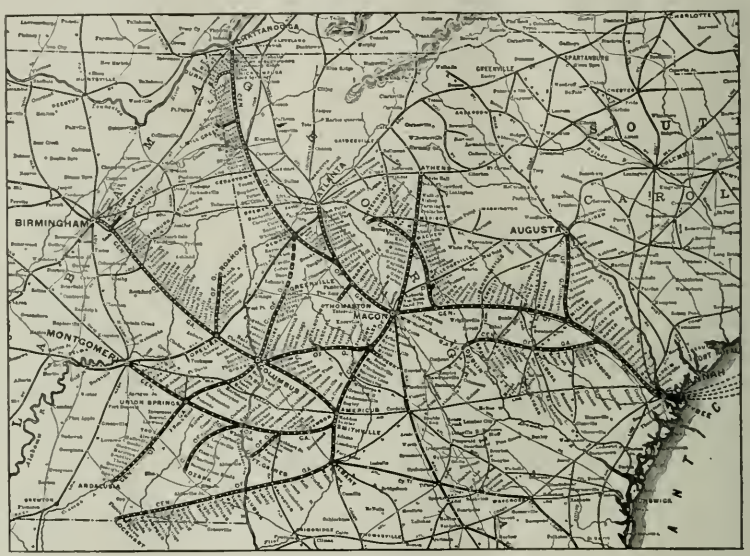
It will be recalled that in 1895 the company succeeded to the foreclosed property of the Central Railroad & Banking Company of Georgia. The capital stock of the company has remained unchanged at $5,000,000, which is at the rate of only about $3,348 a mile, and ownership of this stock has never been advertised, except that President Spencer, of the Southern Railway Company, stated in his testimony in 1899 that the Southern was entitled to the financial benefit of any sale of the stock, though it did not assume to control the railroad. The operation of the property may, therefore, be described as having been on a semi-independent basis, friendly to the Southern Railway.

Last June, Adrian H. Joline, Chairman of the Richmond Terminal reorganization committee, announced that the committee had sold to Mr. Thorne and Mr. Perry all the stock of the Central of Georgia, the net proceeds of which were to be paid to the Southern

Railway, while the new owners declared their purpose to operate and develop the system independently for the benefit of the shareholders, and announced that they would hold at least 60 per cent. of the stock for at least two years.

On August 14 a meeting took place in New York of the owners of the property and of representatives of the larger bond holders to formulate a plan for the retirement of the income bonds, the face value of which is $15,000,000, about one-fifth of which is held in Savannah, Ga., and perhaps one-third in New York. It is understood that the plan proposed was that the 5 per cent. income bonds should be exchanged for an equal amount of 4 per cent. bonds with interest as a part of the fixed charges, but there was a disagreement, as has been mentioned above, as to the payment of the interest on these bonds through the medium of a dividend which the Central of Georgia presumably could receive if it chose to do so from its subsidiary company, the Ocean Steamship Company of Savannah, which operates a fleet of 10 excellent steamships (including a new one not quite completed) between New York and Savannah and Boston and Savannah.

Details of the capitalization of the Ocean Steamship Company are not to be found in the railroad company's report, but the rail company guarantees $1,579,000 bonds for the water company and owns its entire capital stock of $2,000,000, of which $1,995,000 is pledged as security for the collateral trust bonds, and also owns the entire capital stock of the New England & Savannah Steamship Company, practically the entire issue of which is pledged as security for the consolidated mortgage bonds. These two companies may to all intents and purposes be considered as a single going concern, operated with the same ships and financed with the same capital. No dividends are paid on the marine stock, but the value of the 10 sea-going vessels could not be appraised at less than $3,000,000, and their earnings should certainly be large in view of the fact that they are continuously fed with traffic by a railroad company and perform an active and doubtless a profitable service, the six newer vessels being particularly well designed to carry a maximum amount of freight on a minimum coal consumption. The attitude taken by the railroad company is that the equity in the earning of the marine properties belongs not to the income bonds but to the stock of the company. It is not our province to pass judgment upon this contention, but merely to indicate the interesting and unusual facts, which furnish an exceedingly clear illustration of the principle of a subsidiary concern with concealed earnings, since it must be assumed that a considerable portion of the cost of the marine fleet has been paid for out of its own earnings, as was done in years past with such marked success and profit by the White Star Line of transatlantic steamships.



Central of Georgia.

Gross earnings of the railroad company in 1907 were $12,082,777, as compared with $11,396,123 in 1906; an increase of $686,655, but operating expenses and taxes increased $1,371,004 in the same period and charges increased $155,514, with the net result that the balance available for interest on the income bonds was $448,126, as against $1,250,671 in 1906. Out of this sum, $12,937 was credited direct to profit and loss; 5 per cent. interest was reserved for the $4,000,000 first preference income bonds; 3.729 per cent. was reserved for the second incomes, and $32.95 was carried forward. In 1905 and 1906 all three classes of income bonds received their full 5 per cent.; in 1904 the second preference received their first payment, 2 per cent.

The increase in operating costs was caused by increased costs of labor and materials, in addition to a condition both of local and of general congestion. Presumably on account of this congestion, the average train load of revenue freight decreased from 218 to 212 tons, although the average car loading increased from 13.52 to 14.60 tons. According to Mr. Hale's figures, the Georgia Central, for the first six months of the current fiscal year, made a good showing in percentage of cars in service, but a rather poor one in ton miles per car per day, as compared with the other railroads in its territory. The ton-mile earnings for the year also fell off from 1.655 to 1.569, and the passenger mile earnings from 2.455 to 2.419, and there is the unmistakable inference that, as the result of recent legislation in the southern states, these unit earnings are likely to show even a further decrease in the 1908 year. There is also a strong indication that taxes have been materially increased and are likely to figure still more largely next year, but they are lumped with general expenses, so the figures cannot be given.

In spite of this disadvantageous feature, the expenditures on maintenance account were consistently liberal, as they have been for several years past. The company has 40 more locomotives in service than it had a year ago, and spent an average of $2,460 for the maintenance of each of the 292 in use, including renewals, doubtless, but not the undistributed charge for superintendence, etc. The maintenance charge for cars in passenger service was on the basis of $914 per car, which is, of course, a very high average, and freight cars were charged at $102, which means that the amount spent for renewals under this head was greater than the amount spent for ordinary maintenance. Way and structures were charged at $824 per mile of main track operated, and at the rate of $727 per mile of single track, estimating, roughly, that two miles of spur tracks and sidings are equivalent in maintenance cost to one mile of main track. This is a good figure for the southern states, although much remains to be done, as indicated by the fact that the company had 531 miles of 56-lb. rail in service on June 30.

The following table of increased unit costs tells an important story, although it must be borne in mind that the congested conditions of traffic referred to above affected economical working unfavorably.

Cost Per Mile Run; Cents.

	1907.	1906.
Wages of engineers and firemen	7.042	6.326
Wages of roundhousemen	1.471	1.209
Repairs	6.206	4.452
Fuel	9.996	8.214
Water supply	.490	.472
Oil, tallow and waste	.228	.186
Other supplies	.093	.073
Total, per locomotive-mile	25.526	20.932

The traffic returns show an increase of 33.41 per cent. in manufactures and miscellaneous freight carried; of 24.83 per cent. in forest products; of 19.86 per cent. in product of mines, and of 20.19 per cent. in products of agriculture; an excellent showing. Bituminous coal and manufactured articles have shown particularly noteworthy gains in the last few years; the total freight tonnage has doubled since 1900, and the bituminous coal tonnage has increased in seven years from 251,508 tons to 854,303 tons.

The total impression gained from a careful reading of the report is that the company is in excellent shape as regards its traffic, and is making up deficiencies in physical condition from earnings as well as from new capital expenditures, as fast as can be done, but that, in common with every railroad in the south, it is genuinely suffering from high costs forced upon it from the inside and from low rates decreed by legislative bodies, at the very time that it is of the most urgent importance, from the standpoint of railroad and commonwealth alike, that rates should be increased, to strengthen the company's credit and make much needed improvement work possible.

The following are the principal statistics of the year's operation:

	1907.	1906.
Average mileage operated	1,899	1,878
Gross earnings	$12,082,777	$11,396,123
Maint. way and structures	1,579,010	1,845,793
Maint. of equipment	2,249,318	1,712,132
Conducting transportation	4,887,176	3,892,830
General expenses and taxes	890,712	784,457
Operating expenses and taxes	9,606,216	8,235,213
Net earnings	2,476,561	3,160,910
Other income	311,939	274,621
Total income	2,778,500	3,435,531
Interest and rentals	2,330,374	2,184,860
Balance	448,126	1,250,671

NEW PUBLICATIONS.

Hendricks' Commercial Register of the United States. For Buyers and Sellers. Sixteenth annual edition. Cloth. 1,224 pages. 7x10 in. Published by Samuel E. Hendricks Co., 74 Lafayette Street, New York. Price, $10, express charges prepaid.

Hendricks' Commercial Register is designed to be a complete and reliable index of the architectural, mechanical, engineering, contracting, electrical, railroad, iron, steel, mining, mill, quarrying, exporting and kindred industries. The present volume contains over 350,000 names and addresses of manufacturers and over 15,000 business classifications with full lists of the manufacturers and of the dealers in everything employed in the manufacture of material, machinery and apparatus used in these industries. The publication is well indexed by the class of goods manufactured with sub-classifications by states. Thus, for example, a list of makers of gas engines, sub-divided into 29 states, is given. Eight manufacturers are named for so highly specialized a product as a screw pitch gage. The book is well planned and has apparently been carried out in a thorough manner. It is an extremely useful publication.

Curve Mechanics and the Woodlawn Wreck.

Waltham, Mass., Aug. 29, 1907.

TO THE EDITOR OF THE RAILROAD GAZETTE:

The communication on "Curve Mechanics and the Woodlawn Wreck," in your issue of August 23, suggests the following notes:

If the leading locomotive exerts a retarding force on the rest of the train, the direction of that force will be tangential and not in the direction I. G. (See figure on page 198.)

The reactions of the rails, through friction, are additional forces acting on the lever I F K, which have been ignored.

Under the worst conditions, with no brakes on any other vehicle of the train and with the driving wheels of the leading locomotive at the point of sliding, on a 3½ deg. curve, this retarding force will fall far inside the rear driver, its transverse component will be less than 1,000 lbs.; and, according to the transverse location of the resultant rail reaction, this 1,000 lbs. would be distributed among several or all of the wheels.

With brakes applied to all of the vehicles, the force acting between the locomotives is so small that it is uncertain whether it is one of tension or compression, depending on the percentage of braking power of the loaded vehicle and the coefficients of friction involved.

If such a force as that described by your correspondent had existed, it would have derailed the rear driver instead of the trailing wheel on such a curve as that at Woodlawn.

The difference between the forces required to guide the center of gravity of a body in a given path and those required to change the rotative velocity of the body about its center of gravity, has been lost sight of. The former is the centrifugal force, and the latter is the subject of Mr. Henderson's investigation.

All of the mechanical points in dispute in connection with the Woodlawn wreck have been of an elementary nature, and there is evident a need of much more attention to the subject of mathematical mechanics.

O. E.

Complimentary Tickets.

New York, Aug. 28, 1907.

TO THE EDITOR OF THE RAILROAD GAZETTE:

In the *Wall Street Journal* I find the following:

It is difficult to persuade some people that there is a law against passes. Many still believe that they are entitled to free transportation, and some of these men are so important that railroad presidents find it impolitic to refuse their requests. One prominent railroad man [presumably a president] pays from $500 to $600 a month out of his own pocket to buy railroad tickets over his own road, to give to such applicants for passes as he feels unable to turn away.

This is as it should be. I assume that, of course, this $6,000 to $7,200 yearly expense is covered by the president's salary. (We ordinary officers, receiving from $3,000 to $6,000 yearly, are almost unanimous in the opinion that salaries of $35,000 to $60,000 can "cover" a contingent expense of $7,000 without damage to the social fabric.) If my assumption is correct, this president's policy puts the free-ride item on the same basis as "legal expenses" and other railroad expenditures which for years it has been deemed necessary to charge to some account where they will not be too conspicuous. In giving free passes and making no account of the mileage traveled on them, an injustice is done to the "conducting transportation" department. Unless the prohibition of gratuitous railroad service is going to be made to cover everything from 5-cent cigars to complimentary tickets allowing a non-passenger to walk up and down the train platform, the railroad company should have some place in which to charge complimentary rides; and the president's salary is just the place. If a railroad cannot give away anything whatever, why, it is time that President Roosevelt began paying fare for his wife and children on the "Mayflower."

But what if Professor Adams should decree that railroad presidents' salary vouchers be apportioned among the 258 different accounts into which he has classified railroad expenses?

A. M. P.

The Brick Arch.

Cuyahoga Falls, Ohio, Aug. 26, 1907.

TO THE EDITOR OF THE RAILROAD GAZETTE:

Permit me to have space in your valued paper to direct thought to this subject. It was referred to recently in a technical paper in the words in quotation marks, which prompt my comments in the words thereafter following:

"It is of interest to note that in the recent convention of the Master Boiler Makers' Association, the remarks of the speakers indicated a general abandonment of the brick arch in locomotive practice, chiefly because of the unreliability of arch tubes as generally applied, together with some vague impression that its use was detrimental to the back firebox sheets, and possibly the side sheets. To one unacquainted with the process by which devices rise and fall and railroads, in general, those conditions might appear somewhat absurd. But to those familiar with the idiosyncrasies developed on railroads, the conclusions are not surprising. The factor of fuel economy is given so little regard in this country that a very little trouble with any device tending to such an end is sufficient to condemn it."

It may be admitted as true that the "factor of fuel economy is given so little regard" on railroads, that they take very little trouble." But the boilermakers, having had daily opportunities for close observation, were able to speak at their convention from their own experience, and that experience, which would be legal evidence in a court of justice, should not be lightly discredited. Without commenting on their reasons, I would suggest thought on two other reasons why the brick arch should be abandoned:

First.—Carbon dioxide is one of the products of combustion. It is the resultant of the perfect union (combustion) of carbon and oxygen. It is not combustible. It is 50 per cent. heavier than air. In its own heat it has energy aided by the draught to rise and pass out of the firebox to the smoke stack, but if it has not sufficient heat to energize it, or if there be not sufficient draught to draw it out of the furnace, or if its exit from the furnace be hindered by a brick arch, it spreads over the firebox as a diluent, and the temperature of the furnace is reduced by its failure to fully move out with the draught.

Second.—The gases which rise from the firebed gain nothing by contact with a brick arch. Their tendency is to lose heat in touching a solid.

JOHN LIVINGSTONE.

Reducing Black Smoke on Soft Coal Burning Engines.

The committee of the Traveling Engineers' Association, reporting on this subject, sent out to members a circular letter with questions, some of which were:

How do you prepare your coal before putting on tender?

How do you prepare your fire when starting train?

What grades of coal do you use?

Have you noticed any difference in the smoke with the different grades of coal.

Answers to the first question showed that only a few roads prepare their coal. Those that do get good results, the general method being to break the large pieces into lumps from 4 to 6 in. in diameter. One method which appears practical and inexpensive is to provide coal sheds with breakers made by placing ¾ in. x 3 in. iron bars set on edge about 5 in. apart. On these breakers the coal is dumped and must be broken into pieces less than 5 in. in diameter before it will fall through. The value of such practice should not be overlooked by railroad companies.

In answer to the next question, almost without exception the same plan is advocated for preparing the fire. It is built up gradually until a good level bed of coals is secured of sufficient thickness to hold without tearing under heavy exhaust, and thereafter the use of the single scoop system in replenishing the fire. When stops are made the fire should be in such prime condition that it will not be necessary to put on much green coal when starting train, and the engineer should use every effort to assist the fireman in holding his fire by pulling out carefully, and when the stop is to be a short one the fireman should endeavor to have his fire in such condition that no green coal need be added until the train has left the station. The blower should be used to pull just enough air through the fire to combine with gases, and grates and ash-pan should be kept clean and in good condition. The condition of grates has much to do with the suppression of black smoke.

The replies to the third question show that probably the great-

est stumbling block in the way of eliminating black smoke is the grade of coal used by the roads and the use of a great many different grades on a single system. The poorest grades of coal seem to be received by most of the roads, and as many as 17 or 18 different grades on a single road. Since this is the case, the problem of reducing black smoke is even more troublesome than it should be. A fireman who gets one grade of coal trip after trip so that he can get accustomed to using it to the best advantage, even if it is of the poorest quality, can get better results than the fireman of equal ability who gets a good grade of coal on one trip and a poor grade on the next.

Only one report indicated satisfactory coal conditions. In this instance 50 per cent. of bituminous and 50 per cent. of anthracite coal was used, and little trouble was experienced from smoke, as it could be regulated by increasing the percentage of anthracite at times when excessive smoke was objectionable.

The last question is supplementary to the one preceding and the replies further prove the disadvantage of having several grades of coal to contend with. Fine coal is found to produce more smoke than lump, as it ignites more rapidly and the smoke and gases formed have less chance of being burned off. This is also true of the lighter grades as compared with the heavier. Also, it is more difficult to prevent smoke with coking coal than with no coking, and still more difficult with slack coal.

On roads where several grades are in use there is no benefit derived from the use of the best grades except in that they produce steam more satisfactorily, and the better the grade of coal the more carbon it contains and the more smoke it will discharge. This is only true, of course, because the fireman does not get the good coal frequently enough to become accustomed to firing it properly. If the better grades were used exclusively and the firemen became acquainted with the right method of handling it, much less smoke would result and lighter firing would be possible.

In summarizing the report, the committee advocated the serious consideration of two things:

First, a campaign to bring about the standardizing of grades of coal furnished for locomotives. That, both in the line of economy and convenience, better grades of coal would be desirable is unquestionable, but if managements cannot be brought to realize the economy of good coal or if it is impossible to obtain it at all times, efforts should be made to insure the furnishing of one particular grade at all times in place of from half a dozen to twenty different varieties. No mechanic on earth could turn out satisfactory work if the style and pattern of his tools were changed daily, and it is just as impossible for the fireman to do himself justice or work for the best interests of his employers if a continual change is being made in the kind of fuel he must use.

Second, a realization of the fact that the present tendency toward still heavier power must necessitate a change in the old methods of handling a locomotive. Mechanical devices to assist the fireman in the duties that now overtax his strength must sooner or later be put in use, both in the interest of economy to the company and in fairness to the engineer. What devices will best accomplish the desired results is still a question, for the reason that the managements of railroads are backward in taking up anything that looks like an additional expense in maintaining power, while the mechanical departments dread the trouble and nuisance of experimenting with new devices. The enginemen themselves are probably as much to blame as any one for blocking changes that are bound to come at no distant date. New conditions to-day are making necessary new devices, and the really progressive railroad man will meet the conditions and do all that he can to discover which are the best means of making it possible for the fireman to fire his engine as it should be fired to prevent black smoke, to hold his steam and to waste as little coal as possible.

The report is signed by Jno. Lynch, chairman; W. H. Bradley, C. L. Brown, Martin Whelan and W. J. Toy.

Disastrous Collision Near Charleston, Ill.

In a butting collision between a passenger car, with a trailer, and an express car, on the Charleston & Mattoon Interurban Electric Railroad, near Charleston, Ill., on Friday last, 11 passengers were killed and 65 were injured. The collision occurred on a sharp curve, and the passengers had neither warning nor chance to escape. So high was the speed with which the cars approached each other that the crowded motor car and trailer were both completely wrecked. A misunderstanding of telephone orders is said to have caused the disaster. The line on which the collision occurred is but twelve miles long. Telephones are placed every few miles, by which orders are transmitted to conductors and motormen passing over the road. Who is to blame for the confusion of orders is not stated. This is said to be the third disastrous wreck on this line in the last two years, all caused by cars meeting on curves. As a result of the last one, John A. Backus, who was in charge of the despatching system, committed suicide.

Two Strike Documents.

During the present strike of commercial telegraphers, the wires have been kept open through the good services of loyal employees, junior officers of the company and volunteer telegraphers of experience. The men handling the keys at the central office in New York are well known to the strikers, who watch their movements closely. One of these men has handed us a copy of the following "Summons," which he believes was sent to every one at work last week.

SUMMONS

FROM THE REAL FRIENDS OF THE NON-STRIKERS:
READ IT CAREFULLY—PONDER IT WELL.

Do you realize that you have been charged in the Court of Human Nature with the highest form of crime known to mankind—Treason—a crime against humanity?

If you are pronounced guilty do you know what the penalty will be?

It is because the history of the world, in all days had among all races of people, barbarian and civilized, says with a unanimous voice of thunder:

> Ye who are ostracised, shunned and hated by every man, woman and child, your relatives, brother, sister, father and YOUR MOTHER. Ye, indeed, shall suffer the tortures of the severest punishment known this side of hell.

It is because we do not want TO PASS this terrible SENTENCE upon you WITHOUT A TRIAL that we hand you this notice.

You are hereby summoned to appear at Room 317 . 56 Pine St. on or before 12 o'clock noon Tuesday Aug 29. 1907 TO ANSWER THE CHARGE MADE AGAINST YOU. If you appear we shall listen with care and sympathetic consideration to your defense.

If you do not appear, you shall be adjudged guilty by default.

What is your answer?

God Almighty made Hell for Traitors. Pray to God to give you light and strength.

We know that seductive influences have been at work on your feelings; that you have been coaxed or bulldozed; that every form of lie within the scope of the imagination of a soulless corporation has been told you, but we can not believe that you have been bought with a box of candy or a cigar. Perhaps money, the curse of an imperfect civilization, has played its part with a few of you, but we are charitable, as to the majority, and honestly believe that the horrors of THE COMPANY'S BLACKLIST, pictured to you, no doubt, with corporation ingenuity and inhumanity, has had its effect.

Still frightful as the Company's Blacklist may be, it is as day to night when compared with THE BLACKLIST OF MANKIND—LIVING DAMNATION!!

Why not come and be one of us? ALL WILL BE FORGIVEN

With anxiety for your future welfare, we are

Yours,

THE COMMERCIAL TELEGRAPHERS' UNION OF AMERICA.

To this fervid appeal to avoid living damnation and to come and be forgiven, the following reply was made:

New York, N. Y., Aug. 29, 1907.

THE COMMERCIAL TELEGRAPHERS UNION OF AMERICA,
56 Pine Street, New York City.

Referring to the "summons" to appear in room 317, No. 56 Pine street, on or before 12 o'clock noon of a certain day to answer the charge of treason, etc.

Treason is a crime committed against a state or government, to whom the party accused owes allegiance. Do you have the supreme impudence to assert that we owe allegiance to you? Have we ever authorized *you* to act as sponsors, to dictate what we shall, or shall not do? Who gave you the authority to direct the affairs of your fellowmen?

The constitution of this land guarantees to all life, liberty and the pursuit of happiness, and we are controlled and regulated only by the laws made by the duly accredited representatives of the people. Your body does not represent government, nor order, and you have no authority to "hereby summon" any one, by any right whatsoever, unless it be by the red flag of anarchy, and by that treason of which you yourselves are guilty, in thus arrogating to yourselves the laws of God, and of your country, in a criminal attempt, by threats and high sounding phrases, to deprive a few men of the right to mind their own business. You say "God Almighty made Hell for traitors." This is correct, and while you are warning others to be careful of yourselves, for if ever a crude composition bore the imprint of his satanic majesty's press, your circular does.

"Treason"; just why you attempt to apply this word to those who are faithful to their trusts, while your small clique are the ones who have actually undertaken a rebellion, is a mystery, except that perhaps in your "lost cause," it is a last desperate attempt to intimidate those who are endeavoring to be loyal to their employers.

Then there is that other word which you use, "Deserter." The definition of which is "one who leaves his position, his party, or his friends, particularly a soldier or seaman, who quits service without permission and in viola-

tion of his agreement. This is exactly your position. You have forsaken your position and quit the service without permission and in violation of your obligations. If we operators now at work were in a similar position and had received a summons from the company to answer such a charge, we would without doubt appear before the proper officers with an appeal for forgiveness. Our position, however, is reversed. You are the so-called soldier or "scab." Is the case

You ask why not come and be one of us, to which we reply,—because yours is a *lost cause*, and you are unable to control or retain those who have previously united themselves with the union.

We ask why be so foolish as to prolong this controversy, depriving a few honest men from earning a living to support their families, who are made victims, when there are daily those being employed by the telegraph companies who are assigned to the good positions which you have deserted? In a word, who pays your salary when you are not working?

A LOYAL EMPLOYEE.

P. S.—I request that this letter be published in your publication entitled "Fair Play."

Wire Testing.

BY L. M. JONES,
Assistant Superintendent Telegraph, A. T. & S. F.

In the successful operation of a telegraph system, carrying, as most systems do, a volume of business almost equal to the capacity of the facilities under favorable conditions, it is of the utmost importance that all the wires available be kept in use as nearly all of the time as possible.

To do this, some one must be made responsible for all delays in locating and removing trouble, which can best be done by the division of the territory into wire testing districts.

The proper location of the wire testing offices is very important, as there are usually many things to be taken into consideration. Almost invariably there exists on every wire testing district a necessity for repeaters or quadruplex apparatus, and in order to have these located under the direct supervision of the wire chiefs, the office is located where the repeaters and multiplex apparatus are required.

In order to secure the best results, the hours of duty should not be such as to overtax the physical ability of the wire chief. The 24 hours may best be divided into three tricks of eight hours each, corresponding with those worked by train despatchers. The first trick, 8 a.m. to 4 p.m., can be taken care of by the manager of the office, with the dual title of wire chief and manager; the second trick, 4 p.m. to midnight, and the third trick from midnight to 8 a.m.

The wire chief and his assistants, to be successful, must, in addition to having had experience in wire testing, be fully posted in the handling of multiplex apparatus.

One thing very essential to the successful wire chief is patience. Few operators at way offices understand thoroughly their switchboards and circuits even when regular, consequently when asked to make a patch, they lack confidence in their own ability, and should the wire chief lose patience, the result will probably be a wrong connection, and the loss of much valuable time. Each wire testing office should be supplied with, in addition to a spring jack switchboard and spare sets at the board for testing purposes, a milammeter and voltmeter of suitable scale ranges.

In the location and clearing of trouble, the methods in use are much the same everywhere; however, I will enumerate separately those which are usually followed, and from which satisfactory results are obtained.

FOR A GROUND.

The margin or pull of the relay magnet will give you a good idea as to whether the wire is grounded near you; then proceed by having offices open the wire until the ground is located between two offices.

FOR AN OPEN CIRCUIT.

If the circuit is a comparatively long one, and paralleled by other working circuits, place your voltmeter in the circuit for a moment. If near you, the needle will remain almost stationary; if very unsteady, the open place is probably some distance from you. Or place the open wire on a battery of preferably more than 100 cells, then cut in a test set and let the relay spring down low, opening and closing your key. If the break is comparatively close, a very short dot will follow the opening and closing of the key; if further away, the dot will become perceptibly plainer, increasing with the distance from the test office to the open. A large number of relays in the circuit, however, will detract from the sensitiveness of this latter test. This will save time in tracing for the location. Have different offices ground the wire until located in an office, or between two offices. If the wire is broken between offices, one end will usually touch the ground and remain grounded, while the other will remain open. This, if known, will give you a good idea as to the location outside of an office. However, the usual office tests should be made.

FOR A CROSS.

When two or more wires are crossed, have the proper terminal open all wires affected except the most important, were affected. Then locate by having different offices open one or more of the wires which are cut. When located between offices, have the usual office tests made to be sure it is outside.

FOR AN ESCAPE.

An escape may be either an escape to a ground, or to another wire. An escape to a ground is located in the same manner as a ground. An escape to a cross is located the same as a cross. If only slight, it may only be felt with a voltmeter and resemble closely poor insulation.

OFFICE TESTS.

In testing for trouble in an office, first have the wire cut out at the bottom of the board, removing the instrument plugs. This will clear the wire if trouble is not in the board. If this does not clear it, have the wires removed from the top of the board and the ends twisted together. This will clear if in an office. The same test at the other of the two offices between which the trouble was located will definitely locate it outside of an office.

To clear a switchboard of a burned lightning arrester, remove the grounded wire temporarily until the plate can be removed and filed or scraped, and insulated with mica. If an office has hinge or gate cutouts instead of a switchboard, the wire should first be cut out, then if the trouble does not disappear, the removal of the ground wire from the cutout will have the same effect as taking the wires out of the top of the switchboard. A plug cutout or one-wire board should be handled in the same manner as a switchboard.

Wire chiefs often complain of failure of operators to follow instructions, especially when requested to remove wires from the top of switchboards and cutouts. This is sometimes due to the fact that linemen have used pliers to tighten nuts, and the operator not having a pair, is unable to take the wires out, and rather than tell the wire chief he cannot do so, makes a bluff by waiting a sufficient length of time and probably saying, "Now," leading the wire chief to believe the wires have been removed.

In order that a lineman may not be given a wrong location, for example, the day chief locates trouble on his district, which, the lineman being at some distant point, and train service such as to make it impossible to reach the trouble before dark, instead of notifying him at once, transfers the trouble to the second trick chief; he re-tests and transfers to the third trick chief, who re-tests and notifies the lineman. In this way, no time is lost in clearing the trouble, and the lineman is not disturbed in case the wire comes clear in the meantime. If an interruption is reported to a lineman by the first or second trick chief, and he fails to clear the trouble before dark, he reports this to the wire chief on duty. The wire should then be re-tested and the lineman advised if still in, or of any new developments.

All wires should be tested by the third trick chief before daylight. Linemen understand if no trouble is reported to them none exists, leaving them free to carry out any projected work on hand.

The train wire is of first importance, and must be made good, if need be at the expense of everything else. The through quadruplex wires are of next importance. After locating and patching trouble out of a circuit, the patched circuit should not be again disturbed until it is known that the trouble has been removed. However, the section where trouble exists must be watched closely and tested frequently without waiting for the lineman to call for a test. In testing, the through circuit should be left intact, and the section where the trouble existed tested by using a local circuit.

When cleared and circuits are regular again, if a quad wire, the offices having the quad sets should be notified at once in order that a new balance may be taken, if necessary. The taking out of 50 or 75 miles of iron wire from a copper circuit often working on a very narrow margin may so affect the balance as to make the wire almost unworkable.

In order that there may be no delay in clearing wire trouble, it is necessary for the wire chief to at all times know the exact location of the division line repairer. Early each morning, say 7 a.m., each line repairer should file a work report giving movements for the day, stating explicitly just where he will be and on what trains he will move, if away from headquarters, advising the wire chief immediately of any change in his plans.

In case of unusual conditions prevailing, wire chiefs should be authorized to direct the movement of construction or repair gangs, as communication with the superintendent's office may be entirely cut off by wire trouble at any time. In case of a sleet storm or any unusual interruption affecting all wires, so as to cut off communication with the general office, each wire chief should immediately advise his superintendent fully of the conditions on his own district, and continue to do so at intervals until communication is again restored, using Western Union or Postal wires, if working. If all commercial wires are down the telephone toll lines should be used if available.

I have noticed a tendency on the part of some wire chiefs to

discourage operators calling for a balance, which often results in operators working for some time on a wire almost unworkable, which could be remedied by a balance, and its capacity often doubled.

The third trick chief should, in addition to testing all wires early in the morning, carefully inspect his repeaters and quadruplex apparatus, especially the points of his pole changers and transmitters, and balance his quadruplex sets, for the reason that during the early hours of the morning possibly only one or two corners have been in service, and the wires are too busy to be taken out of service for this purpose after the arrival of the first trick chief. While the use of files for cleaning points is very necessary at times, it should be borne in mind that a clean smooth point is by far more desirable than a clean rough one, or one with sharp edges or corners.

Once a week all wires should be measured for insulation and current strength of different circuits measured. Quad batteries should also be measured, compensating resistances of quadruplex sets adjusted, and a full report mailed to the superintendent of telegraph. For insulation tests a battery of approximately 100 cells should be used, all wires to be removed from this battery while being used for this purpose. The wires should be removed for the reason that otherwise the current strength will vary, being governed by the demands upon the battery, due to the opening and closing of the other wires.

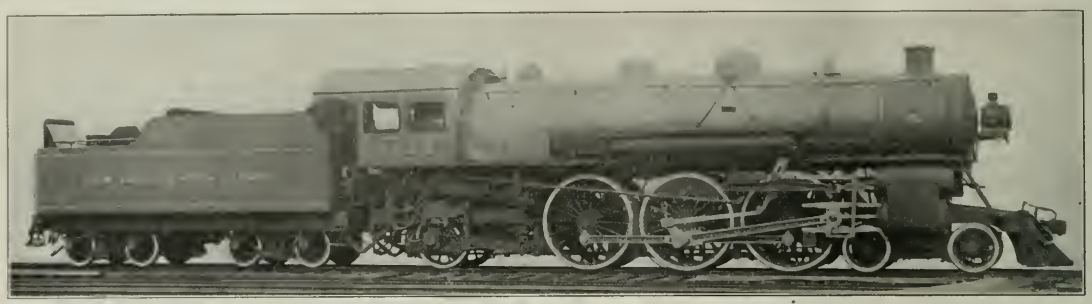
In making insulation tests we use a battery of 100 cells if available, or a current of 90 volts potential, inserting a voltmeter in the different circuits, having the distant terminal open the wire, noting and recording its deflections. If the needle shows an escape, intermediate offices are called in until the point of escape is located as nearly as possible. The lineman is then advised and instructed to report when covered. Upon receiving his report the wire is again tested and the lineman advised of the result.

The current readings are taken by inserting a milammeter in the different circuits while conditions are as nearly normal as possible. In this way we secure a report showing the actual amount of current being furnished for the operation of each wire.

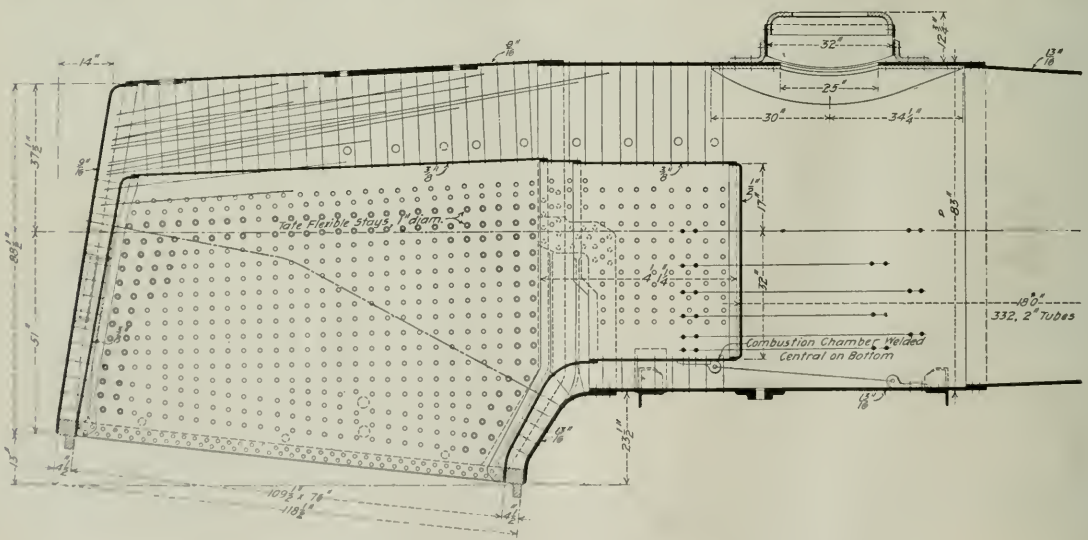
Pacific Locomotive for the Lake Shore & Michigan Southern.

In 1901 the first prairie locomotive on the Lake Shore & Michigan Southern was put in service. Since that time it has been the favorite type for heavy passenger work. Recently an order was given to the American Locomotive Company for 25 Pacific engines, one of which is illustrated here. The engine is interesting as marking the introduction of a new type on the Lake Shore and also because some of the new engines have the combustion chamber in the firebox, a feature that is being tested in a number of places. Also, these engines are the heaviest passenger engines the builders have ever made, excepting those of the same type built for the Pennsylvania.

As compared with the heavy prairie engines already alluded to, these new locomotives have about the same weight on the driving wheels and carry the same boiler pressure, but, with cylinders ½ in. larger in diameter, they have a greater tractive power. As three of the order are to be fitted with combustion chambers and as there will be but little difference in the equated firebox heating surface, this order will afford an excellent opportunity for checking the action of the boiler with and without the combustion chamber.



Pacific Locomotive with Combustion Chamber; Lake Shore & Michigan Southern.



Firebox of Boiler for Pacific Locomotive; Lake Shore & Michigan Southern.

The following table gives the ratios and some of the principal dimensions of the Pacific engines with and without the combustion chamber and the prairie engines that have been used up to the present:

	Prairie.	Pacific— Without combust'n chamber.	Pacific— With combust'n chamber.
Total weight, lbs	214,700	261,500	261,500
Weight on drivers, lbs	170,000	170,700	167,000
Tractive eff rt, lbs.	27,850	29,200	29,200
Cylinders, diameter, In.	21½	22	22
Piston stroke, In.	28	28	28
Drivers, diameter, In.	79	79	79
Total heating surface, sq. ft	3,905	4,195.0	3,409.3
Tube, heating surface, sq. ft	.....	3,960.6	3,112.5
Firebox heating surface, sq. ft.	.....	206.2	268.4
Arch tube heating surface, sq. ft	.....	28.4	28.4
Grate area, sq. ft	55	56.3	56.3

Weight on drivers / Tractive effort	5.1	5.83	5.72
Weight on drivers / Total weight	69.17	65.01	65.91
Total weight / Tractive effort	8.9	9.63	9.04
Tractive effort x diameter drivers / Heating surface	561.0	559.0	67[illegible]
Heating surface / Grate area	71.0	74.5	66.5
Firebox heating surface / Total heating surface		4.91	7.87
Weight on drivers / Total heating surface	43.6	40.6	48.9
Total weight / Total heating surface	62.7	62.4	76.7
Volume of two cylinders, cu. ft. / Total heating surface	11.76	12.61	12.61
Volume two cylinders / Grate area	308.0	340.0	276.0
Volume two cylinders / Firebox heating surface	4.68	4.46	4.16
Tube heating surface	6.17	4.92	8.62
Tube heating surface equated to firebox heating surface (Vaughan formula)		888.3	734.1
Total equated firebox heating surface	1,061.0	1,091.0	1,002.3
Ratio equated to actual heating surface	1—3.68	1—3.81	1—3.41
Tractive effort x diameter drivers / Equated heating surface	2,070.0	2,114.0	2,302.0
Total weight / Equated heating surface	230.0	239.0	260.6

It will be noticed from this table that in the Pacific engine without the combustion chamber 340 sq. ft. of heating surface has been provided for each cu. ft. of cylinder volume. This is a trifle more than was allowed in the prairie engine and considerably more than in the Pacific having a combustion chamber. But if we compare them on the basis of equated heating surface, the figures become: 98.72 sq. ft. for the prairie, 86.52 sq. ft. for the Pacific without the combustion chamber, and 79.48 sq. ft. for the one with the combustion chamber. This means that experience with the combustion chamber has shown that the boiler is slightly more efficient with it than without it, as indicated by the Vaughan formula, a variation that might well be due to an increased efficiency of combustion due to the larger volume of the firebox, as has been pointed out previously.

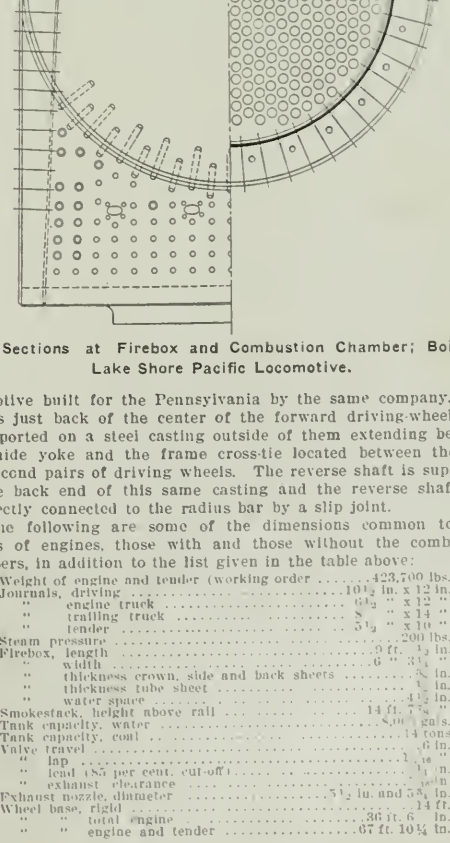
The difference in boiler ratios between the prairie and Pacific engines without the combustion chamber is insignificant, as in designing the latter, especial attention was given to provide the same satisfactory proportions that had obtained in the older engine. The boilers with the combustion chamber are radial stayed with conical connection, the outside diameter of the first or smallest course being 72 in. Those without the combustion chamber have 379 tubes, 2 in. in diameter and 20 ft. long. The boiler with the combustion chamber, shown in the accompanying illustration, is exactly like those of the other engines of the order, excepting the introduction of the combustion chamber and a reduction in the number and length of the tubes. The tube sheet has been moved ahead so that the tubes are 18 ft. long, or only 2 ft. shorter than in the engines without the combustion chamber, although the combustion chamber is 4 ft. long. The number of tubes has been reduced to 332. These changes reduce the tube heating surface 848 sq. ft., or 21.4 per cent., while the firebox heating surface is increased 62 sq. ft., or 33.4 per cent. Results from the use of the combustion chamber on the Northern Pacific have shown that the increase in firebox heating surface fully offsets the decrease in tube heating surface and the evaporative efficiency of the boiler is in no way decreased. The relative steaming qualities of the two boilers here described are best shown by a comparison of the figures for equated heating surface in the above tables. These figures are obtained from H. H. Vaughan's formula which equates the total firebox heating surface to the tube heating surface divided by the square root of the length of the tubes in feet. By such a comparison, it will be seen that although the total actual heating surface has been reduced 786 sq. ft., or 18.7 per cent., the total equated heating surface has been reduced only 89 sq. ft., or 8.1 per cent., which would indicate that the engine with combustion chamber will steam fully as well as those not so equipped.

As will be noticed in the illustration, the combustion chamber is stayed to the shell of the boiler by radial stays on the crown and sides and expansion stays on the upper section. A number of 1¼ in. rod braces between the chamber and the shell of the boiler serve to further stiffen it. The water space between the chamber and the shell of the boiler is about 5½ in. at the bottom and 7 in. where the chamber is nearest the sides, which gives ample room for good circulation.

There are two rows of flexible staybolts at the ends and top with crosters in the upper corners. The use of the bolts at the top and ends and in clusters at the corners is standard practice, but as to whether there shall be one, two or three rows seems to be a matter of personal judgment with no agreement of individual opinions. The bolts are put in where experience has shown that most stays break, and these places, of course, are those where the distance between the inner and outer sheets varies most. It would appear that the better combustion resulting from the use of the chamber would raise the temperature at the front end of the firebox and thus expand the sheets more than in a similar boiler without the combustion chamber, so that more flexible bolts should be used.

The application of the combustion chamber to these engines, as well as to two of a duplicate order of 20 for the same road, and to the six decapods recently built for the Buffalo, Rochester & Pittsburg, shows the increasing popularity of this feature as a means of reducing boiler trouble.

Another interesting feature of the design is the arrangement of the Walschaert valve gear. This is similar to that on the Pacific



Half Sections at Firebox and Combustion Chamber; Boiler of Lake Shore Pacific Locomotive.

locomotive built for the Pennsylvania by the same company. The link is just back of the center of the forward driving-wheels and is supported on a steel casting outside of them extending between the guide yoke and the frame cross-tie located between the first and second pairs of driving wheels. The reverse shaft is supported on the back end of this same casting and the reverse shaft arm is directly connected to the radius bar by a slip joint.

The following are some of the dimensions common to both classes of engines, those with and those without the combustion chambers, in addition to the list given in the table above:

Weight of engine and tender (working order)	423,700 lbs.
Journals, driving	10½ in. x 12 in.
" engine truck	6½ " x 12 "
" trailing truck	8 " x 14 "
" tender	5½ " x 10 "
Steam pressure	200 lbs.
Firebox, length	9 ft. 1½ in.
" width	6 " 3½ "
" thickness crown, side and back sheets	⅜ in.
" thickness tube sheet	½ in.
" water space	4½ in.
Smokestack, height above rail	14 ft. 7⅝ "
Tank capacity, water	8,000 gals.
Tank capacity, coal	14 tons
Valve travel	6 in.
" lap	1 1/16 "
" lead (85 per cent. cut-off)	1/4 in.
" exhaust clearance	1 3/16 in.

The Risks of the Trade.*

If a farmer sends two of his hired workmen to the woods to chop timber and one of them carelessly lets slip his hold on the ax, sinking the blade into his fellow workman's leg, it would strike the average intelligence of mankind as unjust to hold the farmer liable or accountable in damages to the injured man. It is not easy to distinguish such a case in principle from the case of a man engaged in driving rivets in a boiler shop, who carelessly lets slip his hold on the handle of the hammer and strikes out his fellow workman's eye; or from the case of a switchman working for a railroad company, who in a moment of carelessness leaves the switch open and derails an on-coming engine, injuring the engineer. Yet many of the states have enacted statutes making the employer of labor on railroads or in factories or in mines, absolutely liable to an employee injured by the personal carelessness or negligence of his own fellow workmen.

In June of last year the Congress of the United States passed a law applicable to railroads engaged in interstate commerce, more drastic in its provisions than any legislation heretofore enacted by any of the states—providing upon this particular subject, in effect, that the fact than an employee was injured or killed solely by the negligence of his own fellow workmen should constitute no defense to the railroad company. This was followed up by the President of the United States in his last annual message to Congress, in which we find, among other things, the following forcible expression:

"Among the excellent laws which the Congress passed at the last session was an employer's liability law. It was a marked step in advance to get the recognition of employers' liability on the statute books, but the law did not go far enough. . . . Compensation for accidents or deaths due in any line of industry to the actual conditions under which that industry is carried on should be paid by that portion of the community for the benefit of which the industry is carried on—that is, by those who profit by the industry. . . . It is therefore clear to my mind that the law should place this entire 'risk of a trade' upon the employer."

Before this Federal statute, so heartily approved by the President was six months old, and within 30 days from the delivery of the President's message, the law was declared by two Circuit courts of the United States to be unconstitutional. The high commendation the law had received at the hands of the President did not in any degree tend to cure its obvious and glaring illegalities, nor affect to any appreciable extent the opinion of the bench and bar upon the subject.

In the state of Pennsylvania no employee injured by the personal negligence of another employee can claim any right to compensation for his injury, from their common employer; no matter what the rank of the negligent employee may be, whether superior or inferior of the injured servant, except only, such employees as are injured by the negligence of heads of departments. A number of other states adhere to this principle with more or less consistency. The theory which has governed legislation and actuated the courts of Pennsylvania on this particular branch of the law of negligence is this: that it is better for the working man, to enforce such laws as will have a tendency to prevent accidents and casualties and the consequent maiming and death of employees, than to afford to an injured employee compensation after he has been hurt; that an ounce of prevention is worth a pound of cure.

Proceeding on this general theory, it is consistently held in Pennsylvania that when an employee knows that if he is injured by the negligent act of a fellow servant he must look alone to that fellow servant for redress, when he knows that if his own negligent act injures a fellow servant, the injured man must look alone to him for redress; thereby a powerful and effective incentive to vigilance, forethought, attention and care on his own part is ever present, constraining him to the utmost precaution for his own safety and imperatively moving him, by vigilance, to detect repeated acts of forgetfulness on the part of his fellow servants likely to injure him or others, and to promptly report them. It is the theory and the practice of the Pennsylvania law that this tends in the first instance to preserve the lives and limbs of the working men. So far indeed has the legislature and the courts of Pennsylvania carried this principle, that since 1868 there has stood upon the statute books of Pennsylvania a law which provides: "That if any man who is employed by a third person to work about the railroads, depots, cars or premises of a railroad company, shall be injured by a railroad employee, that his rights to recover against the company are only such as they would be if he were employed by the company," and of course the effect of that statute is to make the many thousands of men who are employed in mills, furnaces, yards and elsewhere about the tracks and cars of railroad companies, fellow servants of trainmen, and for their negligence injuring any of these there can be no recovery. The argument is that inasmuch as these men are subjected to precisely the same risks as railroad men, working shoulder to shoulder with them, loading cars, unloading cars, or working upon cars, that the same motive of vigilance, care and attention will have the same salutary and preventive effect, if their rights against the employer are thus limited. This statute has been viciously assailed by text writers and more than once denounced by courts of foreign jurisdiction.

An interesting case involving this statute was not long ago decided by the United States Supreme Court. A postal clerk employed by the Government, while working on a mail train running between Cleveland and Pittsburg was injured by the derailment of his train which ran into an open switch, carelessly left open by a railroad switchman. He brought suit against the railroad company in Ohio for heavy damages, and it came within the scope of my employment to defend the case for the railroad company. As the accident happened in the state of Pennsylvania, the railroad company pleaded that the law of Pennsylvania governed his rights; that he was employed by a third person, that is, the United States Government, to work upon a car of the railroad company; that under the statute of 1868, to which I have already alluded, his rights were such only as they would have been if he had been employed by the railroad company, and that such being the case, he was a fellow servant of the switchman who left the switch open, and for the negligence of that switchman the railroad company was not liable under the laws of Pennsylvania. The plaintiff in reply admitted all this, but averred that the statute of 1868 was contrary to the Constitution of the United States, in several respects; that it was an attempt of the state to regulate interstate commerce; that it deprived the plaintiff of equal protection of the law; and that it deprived him of property without due process of the law. The case was tried through all the courts of Ohio, and through the Supreme Court of that state—every court holding that this statute was not unconstitutional, but was valid, and denied a recovery against the company. The plaintiff then proceeded, doubtlessly aided in his litigation by the postal clerks' union, to the Supreme Court of the United States, where the case was argued in Washington last November. In December the case was decided, the court holding that the statute was in accordance with the Constitution of the United States, and in accordance with the amendments thereof, and was in no wise violative of any of the provisions of the Constitution, and that the plaintiff could not recover.

Turning now to the state of Ohio, we find the fellow servant law still existing, but much diluted by judicial refinement and legislative amendment. There the question of liability turns upon the rank of the negligent servant. If an employee having any authority whatever to direct another servant, inadvertently injures him, the company is liable; or if one servant who has control over another carelessly injures a servant over whom he has no control, but which servant has no control over anybody else, the railroad company is liable. The result is, to take a familiar illustration: If a train be moving through Ohio toward the Pennsylvania line and a conducter through some act of inadvertence or carelessness, no matter what, injures one of his brakemen, the company is absolutely liable in damages to the injured employee; but if before the accident happens the train has moved, even ten feet, across the line into Pennsylvania, and the employee is injured in the same way, there is no liability whatever upon the part of the company.

All over the United States the same contrariety of judicial decisions, and the same conflict of statutory laws prevails. Of course it goes almost without saying that if injury or sudden death overtakes a workman by reason of some negligence on the part of his employer to repair broken machinery, or cars or appliances, or to make the place of work reasonably safe for that purpose, the employer is absolutely liable, and justly so; or if the employee fails to observe the precautions and safeguards prescribed by Congress or by the state legislatures, such as the using of automatic couplers, or automatic air brakes, certain required hand holds upon its cars, guards or fenders over exposed cog wheels meshing into each other, or railings or shields about revolving wheels or cranks, or saws, in all these instances, injury or death arising from their absence creates liability. Yet all this is subject to one very material condition. If the employee knows that a machine is defective, or broken, or out of order, or that the safeguard has been omitted, and continues to work with it, or about it, without obtaining promise to repair the defect, and is injured by it, he is conclusively held to assume the risk of that danger and cannot recover.

Referring again to the suggestions of the President of the United States contained in his last message, we find the following recommendation: "If the entire 'trade risk' is placed on the employer, he will promptly and properly add it to the legitimate costs of production, and assess it proportionately upon the consumers of his commodities." Thus the employer of labor in the United States would be an insurer of the safety and the lives of his employees. The employer would make compensation for injury or death, whether the accident resulted solely from the negligence of the unfortunate person, or from the negligence of another workman, or from the master's negligence. This proposition is not so startling as at first blush it appears. If the President had gone further

*From a paper read before the Railway Club of Pittsburg, by James I. Wilson.

and suggested a fixed scale of indemnity reasonable in amount, and graduated according to the extent of the injury, or in case of death, determinable by the decedent's earning capacity, so that the employer thus made an insurer might know the exact extent of his liability, so that he might in all instances insure against it and tax the amount of premium he pays to the trade, he would then, in effect, have recommended the adoption in this country of that policy and practice which has for many years been adopted and enforced in many of the countries of continental Europe. In Belgium, Norway and Sweden, Switzerland, France and Germany, and of late in Great Britain, legislation is constantly tending to a universal liability of employers for injury or death to the employes, in any of the industrial arts, regardless of the manner of the accident, or whether it resulted from the negligence of the injured party, or his fellow servant, or his employer. In all of those countries, however, the amount to be paid in each specific instance, whether of injury or death, is graduated and determined by a fixed and unalterable scale, being in general a certain percentage of the previous earning capacity of the unfortunate employee, varying according to the extent of the disability, whether temporary or permanent, or in case of death, by the previous earning capacity of the deceased, and the amount of compensation exacted by law of the employer is so reasonable and moderate that, as a matter of general experience, the aggregate amount paid by the employers of labor, under the continental system, is absolutely less than the amount paid by the employers of labor in America, who pay upon the theory that only those who are deserving of compensation shall be paid.

In Norway and Sweden the government insures all workmen against accident or death. The premium is paid by the employer, but the expense of administering the insurance department is defrayed by the state. The amounts paid are based upon a percentage of the last yearly wages earned by the injured or deceased person. These benefits are paid so long as the disability, either partial or total, continues. The percentage varies in proportion to the severity of the injury. In case of death the widow gets 60 per cent. of the last annual wages for life, and each child under fifteen gets 15 per cent. until it reaches that age. The employer is not permitted to deduct the premium he pays from the employees wages, but he has, doubtless, long since anticipated the advice of President Roosevelt, added it to the cost of his product, and taxed it to the trade.

In Switzerland, while the government has not gone into the insurance business, it compels an employer of labor to take out accident insurance for his workmen, and the premium may not be deducted from their wages.

In Germany the government requires that all those manufacturers engaged in a certain line of production shall stand the entire risk of the injuries or death to employees engaged in any of the plants where those lines of manufacture is carried on. This risk must be insured against, and the insurer graduates the premium in proportion to the relative risks in the different plants. Thus all workmen are insured. For all total permanent disability two-thirds of the last annual earnings are paid for life, and proportionately less for partial temporary or partial permanent disability. In case of death 60 per cent. of the annual wages go to the widow for life, and 20 per cent. to the children during minority.

In France there is a fixed scale of price to be paid, but insurance against those risks is optional with the employer. The Government enjoins: First, the payment of all medical and funeral expenses. Second, commencing with the fifth day after the accident for temporary incapacity, one-half wages during the time of his disability. Third, for a total permanent disability, two-thirds of the annual wages for life, and proportionately less for partial, permanent or temporary disability. In case of death two-thirds of the annual wages go to the widow, and 15 per cent. to minor children during minority. Against the risks the employer in France protects himself, either by ordinary indemnifying insurance, or by mutual protective insurance associations organized among the employers, or by insurance in the Government National Accident Insurance Bank. The premiums may not be deducted from the wages, but are undoubtedly added to the price of the article, and most cases collected from American tourists, who in turn, become smugglers with more or less success.

In Great Britain, since 1897, payment [illegible] railroads, factories, mines, quarries or engineering works [illegible] case of death, not more than the last three years' annual earnings shall be paid to the widow or dependent family, and in no event shall an amount be paid exceeding three hundred pounds and proportionately less if the family be not dependent. In case of permanent partial disability, from 50 per cent. of the annual earnings down, but in no case to exceed one pound per week.

For obvious and sound reasons the application of such a system to the industrial conditions of the United States would be attended by extreme difficulty, if indeed its adoption be at all possible or desirable. In the first place, the Federal government is admittedly without authority to enact or enforce laws of that character. As we have seen, the employer's liability act of the last Congress, even though limited in its operation to railroad companies engaged in interstate commerce, met with disaster in the first United States Court which tested the authority of Congress to enact it.

The individual states alone may legislate the subject within their own territorial limits. We have already noted the vast difference, the utter contrariety of existing laws upon this subject in the various states of this Union, the diverse theories and principles which obtain in different localities. What reasonable ground for expectation have we that all the states would ever agree to fasten a general liability upon all employers of labor? A system which to some of them may appear beneficent, to others is most repugnant. If by a wild flight of fancy we can imagine that all the states would agree to such a law, who so rash as to venture to suggest the adoption by all of a uniform, limited, reasonable and moderate scale of payments and indemnities in case of injury or death, such as the nations of Europe administer with humane results, for their people? What state legislature so deaf to the unthinking clamor of the multitude, so blind to its own political fortune, as to stand against extortionate demands for high and ruinous rates of compensation?

The Southern's New Line from Jasper, Ind., to French Lick.

The St. Louis-Louisville lines of the Southern Railway have a short branch running south from Huntingburg, Ind., to the Boonville coal field, with spurs to three different points on the Ohio river, one of which is Evansville. There is also a seven-mile spur north from Huntingburg to Jasper. Practically all of the coal now produced by this field is taken north by the Southern for delivery

by its main line either at Louisville or St. Louis. To reach the Chicago market it must either go north over the Chicago, Indianapolis & Louisville (Monon) from New Albany, Ind. (opposite Louisville), or over the Evansville & Terre Haute and Chicago & Eastern Illinois from Princeton, Ind., the junction point with the Southern. It has thus been unable to compete in the Chicago market with coal fields having a direct outlet and as a result has been largely shut out from the most desirable and profitable market of the Central West. The establishment of a direct line of transportation to Chicago would mean not only the development of this particular field, with the resulting augmented tonnage to be hauled, but also it would doubtless mean stimulated output and increased tonnage from all southern Indiana coal districts served by the Southern not now directly connected with the Chicago market.
